APRIL.—Some kinds of manure are more liable to be injured by what is called firefang than others. Horse manure, if allowed to lie in considerable quantities, is apt to undergo the process of fermentation under a high heat, when it assumes a mouldy whitish appearance and becomes very light. It suffers an immense loss, so much so that its virtue is gone, and as compared with unheated manure, it will produce scarcely any appreciable effect. The fertilizing qualities, especially ammonia, are thrown off and the mass is left inert and useless. In the management of manures, therefore, care should be taken to prevent too great a heat, by composting and forking over. Loam and muck, if mixed freely under the stables, will preserve the heap, prevent fire-fanging, and thus prove very useful. Compost the manure heap through the winter when opportunity serves.
