

The Canadian Engineer

Vol. V.—No. 4.

TORONTO AND MONTREAL, AUGUST, 1897.

PRICE, 10 CENTS
\$1.00 PER YEAR.

The Canadian Engineer.

ISSUED MONTHLY IN THE INTERESTS OF THE

CIVIL, MECHANICAL, ELECTRICAL, LOCOMOTIVE, STATIONARY
MARINE AND SANITARY ENGINEER; THE MANUFACTURER,
THE CONTRACTOR AND THE MERCHANT IN THE
METAL TRADES.

SUBSCRIPTION—Canada and the United States, \$1.00 per year; Great Britain
and foreign, 6s. Advertising rates on application.

OFFICES—62 Church Street, Toronto; and Fraser Building, Montreal.

BIGGAR, SAMUEL & CO., Publishers,

E. B. BIGGAR Address—Fraser Building,
R. R. SAMUEL MONTREAL, QUE.
Toronto Telephone, 1392. Montreal Telephone, 2589.

All business correspondence should be addressed to our Montreal
office. Editorial matter, cuts, electrots and drawings should be
addressed to the Toronto Office, and should be sent whenever
possible, by mail, not by express. The publishers do not undertake to
pay duty on cuts from abroad. Changes of advertisements should
be in our hands not later than the 1st of each month to ensure
insertion.

For THE CANADIAN ENGINEER.

RAILWAY ENGINEERING.*

BY CECIL B. SMITH, MA. E., MEM. CAN. SOC. C. E., ASSISTANT
PROF. OF CIVIL ENGINEERING IN M'GILL UNIVERSITY.

CHAPTER II.

TRAIN RESISTANCES AND THEIR COST.

ART. 6.—TRAIN RESISTANCES.—(Continued).

(C.) CURVE RESISTANCES.

In America a curve is designated by the number of
degrees which a hundred foot chord subtends at the centre
of the circle, thus a 1° curve subtends 1°, etc. The radius
of a 1° curve=5730 feet, and the radius of a

D° curve is (approx.) = $\frac{5730}{D}$ feet.

The centrifugal force of a train passing around a curve
at v feet per second = $C = \frac{Wv^2}{gr}$ (6)

If we change v into V (miles per hour) and r into D (degree
of curve) we will get $C = \frac{W}{32.2} \times \frac{V^2(1.467)^2}{1} \times \frac{D}{5730} = \frac{WV^2D}{85666}$
..... (7)

Now, in order to counterbalance this force, the outer rails,
on curves, are elevated sufficiently above the inner ones
(super-elevation) to make the resultant of gravity and cen-
trifugal force to pass midway between the rails and at

*This series of papers will be issued in book form as soon as they have
appeared in THE CANADIAN ENGINEER.

right angles to the track, and the floor of the car will then
be parallel to the track (see Fig. 3). It is evident from the
figure that by similar triangles

$$\frac{\text{Super-elevation}}{\text{Gauge}} = \frac{\text{Centrifugal Force}}{\text{Weight}} \text{ or}$$

$$\text{Elevation} = E = G \times \frac{C}{W} = \frac{59V^2D}{85666} \left\{ \text{from (7)} \right\} \dots \dots \dots (8)$$

by which it will be seen that the required elevation varies
directly with the degree of curve and with the square of
the velocity.

$$\text{For a } 1^\circ \text{ curve, } E = \frac{59}{85666} V^2 = .00069 V^2 \dots \dots \dots (9)$$

TABLE VII.

TABLE OF SUPER-ELEVATION OF OUTER RAIL, PER DEGREE, FOR DIF-
FERENT VELOCITIES.

V (miles per hour) ...	5	10	15	20	25	30	35	40	45	50	60	70	80	90	100
E (inches).....	.02	.07	.15	.28	.43	.62	.81	1.10	1.40	1.72	2.48	3.36	4.40	5.60	6.90

It is evident, however, that only at that particular
speed for which the outer rail is elevated will the car body
be normal to the track. At slower speeds, the inner
springs will compress and outer ones extend somewhat,
while for higher speeds the reverse will be the case. The
custom, on general traffic roads, is to elevate for medium
passenger speeds of say 30 miles per hour, which is
slightly over one-half inch per degree, while on high
speed passenger tracks of roads having only light curves,
particularly, elevations of as much as one inch per degree
are common.

It may be assumed that a safe maximum riding speed
will exist when the car body becomes level. Wellington's
assumption is that the weight of a passenger-car will
compress its springs six inches, and that the distance of
the centre of gravity of the car body above the springs is
equal to the distance of the springs apart giving equal
turning couples. The total centrifugal force necessary for
this action will be approximated.

$$C = \frac{WV_1^2D}{85666} = \left(\frac{E}{6} \times \frac{W}{2} \right) + \left(\frac{WV^2D}{85666} \right) = \frac{59V^2DW}{12 \times 85666} + \frac{WV^2D}{85666}$$

$$\text{or, eliminating, } V_1^2 = \left(\frac{59}{12} + 1 \right) V^2 = \frac{71}{12} V^2$$

$$\therefore V_1 = 2.43V \dots \dots \dots (10).$$

(where V_1 = speed to bring car body level.)

(V = speed for which track is elevated.)

This speed is, evidently, independent of the curvature.

The speed at which trains, running on tracks properly
elevated, will overturn, is very high, and not of sufficient
interest to calculate, and will depend on the amount of
compression possible in the springs before the car body
comes down on the buffers, and upon the amount of
elevation per degree of curve given to the track:

Those roads which have sharp curves will always run
at moderate speeds around them; the sharper the curve
the less the speed. This fact and practical ballasting diffi-
culties have limited the total super-elevation to about six
or eight inches, which corresponds to a curve of 8° to 12°,
depending on the speeds expected, on curves of greater
sharpness the lessened speeds will require less elevation
per degree.

The position which a short rigid truck assumes in
passing around a curve is as in Fig. 4; the front outer
wheel flange against the rail head, and the rear wheels
radial to the curve and midway between the rails, unless
