

## HOW A 42-CENTIMETER SHELL WORKS.

This illustration, from the Graphic, shows the progress of a big shell at work. The shell is discharged from the gun by nitro-cellulose, in which cotton is the main ingredient. The shell flies through the air and strikes a piece of concrete work. When it strikes the soft nose of the shell bends in and explodes the fulminating mercury. This explodes the picric acid and it in turn explodes the trinitrotoloul or trinitrotoluene, as the English term it.

## Why Canada Cannot Make More Shells And Incidentally Why Canada Would Last Two Weeks in a "Great War" By CHEMIST

UCH abuse is being handed out to the Brit-W UCH abuse is being handed out to the Brit-ish Government, to the Canadian Govern-ment, to General Bertram's Shell Commit-tee, and to the ubiquitous D. A. Thomas because Canada did not get more of the shell oracrs placed on this continent by the Allies. It is inter-esting to note that these charges are answered by arguments which reveal not only our limited ability to help in this crisis, but our previous unprepared ness in case of a war in which we might have to fight alone. alone.

alone. The truth is simple and clear that Canada would have had more orders for shells if this country had been further advanced in chemistry. There was a shortage of picric acid and toloul. There was no demand for these substances in Canada and natur-ally no manufacturers had erected a two million dollar factory to make them. Yet these substances were absolutely essential to the making of shells, as whall now be explained

were absolutely essential to the making of shells, as shall now be explained. Before picric acid was adapted in 1886, all ex-plosives for military purposes were gun cotton and nitro-glycerine. In 1901 the aromatic nitro-com-pounds were discovered. Gun cotton was discarded as a shell filler becausc of premature explosions. It is still used in "under water" explosives because, unlike gunpowder, dyna-mite and picric acid, it will explode even when wet. Nitro-glycerine cannot be transported pure, and even when mixed with infusorial earth, is affected by frost.

Pieric acid is made from phenol or carbolic acid. Phenol is treated with sulphuric acid and later with nitric acid. This gives pieric acid or trinitiphenol. Pieric acid attacks metals, and the projectile into which it is introduced must be varnished inside. It is soluble in water, and, therefore, cannot be used in mines or torpedos. It can be used only in small shells. In large guns the pressure at firing is so great that the nieric acid evided acid acid. shells. In large guns the pressure at firing is so great that the picric acid explodes prematurely. Con-sequently a new explosive had to be found for big

This was discovered in the hydro-carbon toloul. It

This was discovered in the hydro-carbon toloul. It is treated as phenol was, with nitric acid, and trinitrotoloul results. Toloul is made from coal, a ton of coal giving up a gallon of toloul. One hundred pounds of trinitrotoloul is used in every 750-lb. shell. Phenol + nitric acid = trinitiphenol or picric acid. Toloul + nitric acid = trinitrotoloul. Trinitrotoloul is neutral and corrodes no metal and it is insoluble in water. These are the two char-acteristics which gave it popularity. It is less sensi-tive to shock and friction than picric acid, and may be used in the largest shells. The Germans use it for the 42-centimetre shells. Trinitrotoloul, being less sensitive to shock, ře-quires more fulminating mercury in the caps of the shell. In the shell, as described in the accompany-ing illustration, the toloul or toulene is used as the explosive, and both picric acid and fulminating mercury as detonators. This is done to delay the final explosion and allow the shell to penetrate

farther before doing its final work. Ammonal used by the Austrians is a combination of gunpowder and modern nitrates. It consists of an intricate mixture of ammonium nitrate, charcoal, trinitrotoloul and aluminum. It is not waterproof, but neither is it sensitive to shock or friction. A shell charged with ammonal and fired at armourplate will not explode until after it has pierced the plate. All disruptives in shells are ignited by an explosive fuse consisting of fulminating mercury and 15 per cent. of potassium chlorate. This brief description of shell explosives shows what the ammunition worker is "up against." He must get pieric acid or trinitrotoloul in addition to fulminating mercury to complete his shell. When war broke out, these substances were not made in Canada except in insignificant quantities. The Brit is Government could not get them, either. A char-coal manufacturer in a neighbouring State is said to be building a plant for the pritish Government for the making of pieric acid. This plant will cost about two million dollars and will supply a considerable guantity. No doubt there are other sources being created which the Governments concerned are not divulging. Great Britain's failure to get shells was as much

created which the Governments concerned are not divulging. Great Britain's failure to get shells was as much due to a shortage of picric acid and trinutrotoloul as to anything else. Canada's inability to get shell orders was largely due to the same cause. We could not supply the completed shell. How serious this situation was and is may be realized if we consider the possibility of an unthink-able attack from the United states. At the present moment Canada could not make a thousand complete artillery shells a week. This is our state of unpre-paredness. Of course, it doesn't matter, because Britannia still rules the waves. But without Brit-ain's help, we would last as a nation at war approxi-mately a fortnight.

## Why Russia Retreated

BY A MILITARY CORRESPONDENT.

BY A MILITARY CORRESPONDENT. WERY "man in the street" is asking why the Russians have retreated and allowed the Germans to over-run their country. Imagine the Dominion of Canada, abandoning To-ronto and Montreal and Winnipeg to the enemy, after removing the money from the banks, the goods from the big warehouses, the machinery from the factories and the locomotives and cars from the railways. What a tremendous national sacrifice? What a sad blow to our national pride? What a terrific waste and disturbance? And yet Russia has done this very thing. Warsaw, Lodz, Grodno, Kovno, Bielostok are gone, with hur-divangorod and Neo Georgievsk. Why did they do it? Why did they not stand and fight it out to the bitter end as the Canadians did at St. Julien? Of

course,

## "He who fights and runs away Will live to fight another day."

But surely this does not apply when you are de-fending your home and your hearth and the sacred soil of a nation! That they should abandon Galicia was understandable, that they should elect not to defend Poland west of the Vistula was thinkable, but that the Russians should give up so much of "White that the Russians should give up so much of "White Russia" without a decisive battle is not what we expected expected.

L ET us go back. When the war broke out, Russia was unprepared. Germany and Austria has been working, as we know, for three years on the accumulation of arms, guns and shells, but even Germany and Austria understimated that Germany and Austria underestimated their needs for this war. After it began, they came to a standstill because their supplies began to give out, and it was necessary to wait until their machinery was speeded up. Britain underestimated what was needed and is only now beginning to draw even with her enemies. France speeded up early and has made the best show France speeded up early and has made the best show-ing. Italy took a year to gather supplies before she was ready. Russia was not only short of supplies, but Russia was short of the machinery to make supplies. supplies.

Where would France be without her machine shops? Where would Britain be without her machine shops? Where even would Germany be without her machine shops which she got in captured Belgium and Northern France? Why, then, marvel that Rus-sia fell down? Russia to-day is buying rifles and guns, ammunition and shells from all the neutral world that makes them. Russia needs tremendous quantities of supplies, and they are slow in coming. It will be the spring of 1916, before Russia is in a position to drive the enemy from within her borders. Where would France be without her machin It will be the spring of 1916, before Russia is in a position to drive the enemy from within her borders. Knowing the unfortunate position of Russia, the Germans decided to seek a decision in the East, while holding the French and British in the West. They had planned to crush the Western Allies first, but that plan failed at the Battle of the Marne. Now, nearly a year later, they resolved to try the plan again, to crush one enemy at a time, and they chose Russia because of her lack of big guns, large ammuagain, to crush one enemy at a time, and they choose Russia because of her lack of big guns, large ammu-nition and swift transport. On April 30th, with the four beautiful months ahead of them, they began their drive through conquered Galicia. During May,
