contour and size at once strikes the eye. Riley's cut represents an insect 20 lines in expanse of wings. I venture to say that no Fall Webworm Moth ever attained such a size. But latitude was necessary to take in such moths as *congrua* and *cunca*. Then as regards the series of wings given on page 246. These we may conclude, from the whole tenor of the article, include representations of *cunca*, *punctata*, *punctatissima*, etc. They are on the scale of 18 lines for expanse of wings. There is not one of them but can be exactly matched from insects I raised, or that were taken with the mother insect in the Gomin.

Let us now consider the larvæ :

and the second of the

r,

A comparison of the Rev. Dr. Hulst's account of the larvæ of S. congrua (Ent. Amer., II., 162), and of Professor Saunders's description of the larva of S. cunea, in its last stage, with the following life-history, written with care by myself, will, I think, show that the three descriptions relate to one and the same species.

Life-history of Spilosoma congrua, Walker :

 $E_{ggs.}$ —Waxen, globular, laid dispersedly and unattached on the 10th of July, very small for the size of the insect—one-thirtieth of an inch in diameter. Hatched July 16th.

Newly-hatched larva.—One-tenth of an inch long, of a pale greenish tint, with a row of .2ddish-brown tubercles along the middle of each segment above. Every tubercle has two or three rather long, black hairs. Head dark brown. The larva feeds with avidity upon Chenopodium album, also upon Taraxacum and Plantago. It shows no disposition to spin. Moulted July 23rd.

Larva after first moult.—Length, three-tenths of an inch. Body reddish-brown, with black warts, from which proceed spreading tufts of long, black hairs with short spinous branches. Head bilobed, black. Feet black. Moulted July 29th.

Larva after second moult.—Length, half an inch. Body dark brown, with dark brown warts thickly set with tufts of black hair. A side line of red warts with a black tuft above and another below each wart. Larva exceedingly active— scuffles about in true Arctian fashion. Moulted August 8th.

Larva after third moult.—Length, one inch and one-tenth. Head shining black, bilobed. Body black, warty, densely clothed with jet black hairs. A side line of red warts as before, but hardly seen under the pile that overlaps it.
