

be listed as follows: 1) electrical power, 3) stage lights.

of a building that large. At least that's the way to say that we can be fact that a building of this size can have good

acoustics in a structure. Right from the concept of the rink surface does the essential shape of the adjustments of length, determine the nature of the acoustical environment. At the architects went to the Council (NRC) with the aid of NRC acoustic experts and data into the computer design was reasonable. A factor in the acoustics of the building is a consideration of the materials present within the building. They will effect various sound qualities, especially when the building was under construction. Measurements were taken of the sound within the building on the basis of these calculations. Measurements were made as sound absorbing units required to bring the sound to acceptable values. When Professor Garland, and others, and purposes, the building was designed a company which installed devices, which are used. These devices are architectural objects hanging from the ceiling of the building and cost \$10,000 of them.

the building has the characteristics of a low ceiling, and flat response. The sound doesn't sound like a problem with the boards causing a problem on the rink level, but with good sound system

considerations of electrical power can be said that AUC is that is put in there is a difficulty. The dressing rooms are for the dual purposes of concert dressing rooms which I will mention

For the spectator of an event, the entrances and exits are more than adequate and convenient. These exist are a problem in moving people on and off the floor for a stage event or dinner - but when proper signs are placed and the main stair towers are used as was intended, this problem will be minimized.

I have discussed many of the very positive aspects of the building. Good acoustics, good layout, good sound system, good athletic facilities and most importantly, the fact that nothing was done which prohibits the addition of left-out features like a stage lighting system. There must be some negative features in all of that, and there are indeed. However, they are few in number and do not constitute major blunders.

The ones that stand out in my mind are: 1) the scoreclock is far too small and inadequate. Unless you have 20-20 vision, it is not possible to see the scoreclock beyond about 50 feet. Since this information is available in several good textbooks, one can only assume that the clock was chosen without reference to those books. As a solution, more small ones could be added in various locations, or a bigger one could be purchased.

2) The ice-making plant is PROBABLY not adequate for maintaining the ice during the summer months. Eventually, as a solution, one of the two ice-making machines could be increased in size. (one is smaller than the other)

3) The boards are not very strong. It is conceivable that they would fail at a hockey game, and it is likely that they will be strengthened in some way relatively soon.

4) The dressing rooms have a perimeter of asphalt-like boards on the floor to protect skates from the concrete floor. Skaters will notice that if a player is sitting on the wall bench, they will have to walk on to the floor with their skates to get around that player, defeating the whole purpose of these tiles. Current best practice in rinks of that size is to carpet the dressing rooms with a special single loop pile carpet which will not cut. This is not only cheaper, but the dressing rooms are much more pleasant, and certainly makes them more attractive for use as concert dressing rooms.

5) The "Rink-Tex" covering is very sensitive to staining and burning. There is no doubt in my mind that pubs and even concerts should not occur with such a

covering on the ice, yet there is no other choice. "Rink-Tex" is not intended for non-athletic uses, but there will be no choice but to use it. It seems likely that on the long term, it will have to be supplemented with another covering.

So even the problems are relatively minor, and the positive aspects far out-weigh the negative.

The Aitken Centre has turned out very well. It is, I think noteworthy that it has received more student input than any other building on campus. Even more noteworthy - that input has been listened to and acted upon. There is no doubt in my mind that neither would this be so nor that the building would have turned out so well if it had not been for the determination of the president of UNB, Dr. Anderson to make it the best building possible. It's one thing to ask for help; it's quite another to have student input listened to.

The greatest effort on constructing and getting the building in shape has come from Professor Eric Garland. Were it not for him, we would have ended up with a rink that would be as poor as the rest.

The students owe a great debt of thanks to these two. I also should mention three other people who had a great deal to do with the success of the design. Firstly, from the athletic side of things, Dr. John Meagher has put much effort, and with good success into the design of the facility concerned with sports and sports teaching. Secondly, Mr. Doug Beirsto has put countless hours into the design of the sound system and intercom. Lastly, but by no means least, is the firm of Murray & Murray & Partners, who designed the building.

Next week:  
Concerts, hockey  
games, and  
economics
