

increase in the accumulation on this side. Consequently the situation will appear statistically less favorable at the end of April than it did a month previous.

While we are optimistic in a broad way, especially with respect to increasing consumption, it must be recognized that for the moment the prospects for the copper market is inauspicious. Although the world's visible supply is proportionately less than some previous accumulations, the existence of a large stock has created a pessimistic popular impression which apparently cannot be dispelled. Although manufacturers may recognize that copper ought to fetch upwards of 13c, they evidently are not interested in laying in supplies under such conditions. The outcome will probably be such concession in price by leading producers as will interest speculators in taking over large blocks of the accumulation with a view to carrying the metal for a long pull. After the market may be in a position for speculators will be interested remains to be seen.

Prevention of Ankylostomiasis

The ankylostoma, or miner's worm, has been for two years the subject of a campaign at the college of medicine, Newcastle, England, by Sir Thomas Oliver and Hermann Belger. The chief object of the campaign is to prevent infection of wet and ill-ventilated mines. On January 21, 1910, Sir Oliver read a paper before the Society of Tropical Medicine. According to the statements in this paper, of the 41 disinfectants, only 10 were found to be suitable for use in the mines. This cost \$12 a ton. A 10 per cent. solution of it would cover 100 square yards of floor 1 cm. deep. It would prevent the development of any eggs that might be present, and be effective as a disinfectant. Old cladding is better than fresh, because richer in iron. Fresh cladding is more likely to be found in the grooves at the side of main entries. These grooves should be sprinkled with the disinfectant. Salt above and below ground. Salt is a third possible disinfectant. It is a larvicide within an hour. Crocote oil kills larvae quickly. Hence when air is moist and there is no danger from fire, the lower end of about half yard, ankylostoma larvae are found clinging and wooden props are some reservoirs of them. Managers of collieries and brickfields in cold climates are apt to think that their winter fires are the cause of the ankylostomiasis. Oliver and Belger found that larvae in warm boots, although these had been in the mud in which the larvae were working. This suggests that the larvae may migrate in boots from one mine to another. The interval between the infection of a man (through mouth or skin) and the appearance of his feces, is 30 to 35 days.
