The black hydrated cobalt oxide, as formed commercially by precipitation from a chloride or sulphate solution with bleach, or the brown Co₃O₅, H₃O, may be calcined at any temperature between 385° C, and 910° t°, to yield substantially the same product, but in practice it is better to calcine at a good red temperature, in order that the calcination may take place with reasonable speed.

That there is a range between 385° C, and 940° C, through which very little oxidation or reduction of the black Co₃O₄ takes place, is shown by the following figures:

Starting with Co₃O₄, heated to constant weight at 385° C, the loss in weight heating it to constant weight at 610° t 0.7% loss " " " " " " 770° C. 1.2% loss " " " " " 860° C. 2.1% loss " " " " " " " 910° C. 2.5%

Just above 910° C., however, the reduction begins to take place very rapidly, and the black t'o₃O₄ reacts to become grey CoO. Continuing the experiment for which the figures above are given, we have:

Loss in weight heating it to constant weight at 980° C Co₂O₄ shows no trace of being magnetic.

The Oxide (Co.O.)

 $\mathrm{Co}_{\delta}\mathrm{O}_{7}$ is not to be distinguished from $\mathrm{Co}_{\delta}\mathrm{O}_{4}$ either in appearance or in method of preparation; in fact, we have not succeeded in forming a pure oxide of cobalt which analysed very close to $75 \cdot 9C_{\ell}$. On the other hand, as will be noticed in many places throughout this paper, the analyses of the material obtained by calcining at a red heat are frequently something in excess of $73 \cdot 4C_{\ell}$ after making allowance for impurities. We, therefore, assume that a certain amount of $\mathrm{Co}_{\delta}\mathrm{O}_{\tau}$ accompanies the $\mathrm{Co}_{\delta}\mathrm{O}_{\delta}$.

Cobalt Monoxide (CoO)

Cobalt monoxide is the stable oxide of cobalt when calcination takes place at a high temperature, that is, in the neighbourhood of 1000° C.

It is a grey powder and may be reduced to the metal by heating with carbon monoxide gas at any temperature above 450° C., or with hydrogen gas at any temperature above 250° C.

Cobalt monoxide also exists in an allotropic form which is a yellow-green powder. Either the yellow-green or the grey cobalt monoxide exidizes to $\mathrm{Co}_3\mathrm{O}_6$ or to a mixture of $\mathrm{Co}_3\mathrm{O}_4$ and $\mathrm{Co}_4\mathrm{O}_7$ when heated to any temperature between 385° C, and 910° C. The yellow-green variety is readily formed by heating $\mathrm{Co}_3\mathrm{O}_4$ with 2 to 3° by weight of C at temperatures in the neighbourhood of 900° C.

Numerous analyses of the purified grey oxide have been made, which range around the theoretical value 78·8°. The following experiment was tried to prove that yellow-green oxide is an allotropic form of the grey CoO.

Black Co₂O₄ calcined at 640° C, to constant weight was then calcined to constant weight at 1020° C. It lost thereby 7·1° in weight, and the product was grey Cot). Yellow-green Cot), produced by the reduction of black Co₃O₄ with hydrogen at 300° C, was calcined to constant weight in air at 640° C, gaining thereby 6.5° in weight and becoming black. This experiment, like the others, indicates that the grey and the yellow-green
