

APPENDIX

The body of the mature caterpillar (*Nymphula Icciusalis*) was fusiform, subcylindrical, slightly depressed, and broadest at the middle. The surface was subopaque, of a pale grayish-yellow color, and seemed to be laid in folds, regularly placed, in which were rows of indentations or pits. As the larva moved the depth of the pits varied. A few stiff setæ extended along the sides of the body, and there were four pairs on the anal shield. The head was rather small, brownish or dull yellow, with two small porrect setæ on its vertex, the Y-mark edged with dark; labrum emarginate; mandibles sharply toothed, and dark; first antennal joint truncate—conic; second, slender, tipped with a seta and three minute articles; ocelli five; hairs and setæ on the head, and the first and second segments as shown in the illustration. The true legs were stout, with dark tips, while the short prolegs had on their lower surface a narrow oval of small dark hooks.
