## Reported Discovery

OF SYNTHETIC COAL FROM

The reported discovery by a Mun-druggist, Prussky, by name, as ocess for making a high grade anacite coal from stone and chemals has aroused considerable exciteent in Germany, and incidentally in

To the new industrial Germany and iron and steel are the great-

an even the discovery of great gold deposits could be.

Germany has lost its school containes in Upper Siles to Poland.

Considered proble that the grench will keep the Sarre Valley, ind are eagerly looking for any opporunity to occupy and retain the Ruhr

fistrict, containing the most important coal mines of Continental Europe and the only rich anthracite territhry still under German control. Ger to develop the Rhine between Basel and Lauterburg, and the other oil rivers, with the exception of the Weser, have been internationalized. So it seems that Germany's very existence was placed in jeopardy, the more so as the peace treaty prevents her from entering into commercial

treaties, except on minor subjects. Nineteenth and twentieth century civilization is largely based on the use of mechanical power for the purpose of production. The mutual relations of mechanical power and civilization have never been drive home to the public at large as they have been brought to universal attention by the world wide coal shortage during the

#### Synthetic Coal Produced.

Though the Berlin Patent Office has not yet rendered a decision of Prueckner's application for a patent on his synthetic coal process the fact that Prueckner produced synthetic coal that in every respect is the equal of anthracite has been established beand any doubt by a number of offial practical tests.

One of the tests was made to ascertain the heating power of each of the two kinds of tuel. The synthetic coal burned without a smell and with an insignificant volume of smoke and produced 7995 heat units per 100 kilogrammes, 220 pounds, while anthracite coal has a heating power of from 7.000 to 8,000 heat units per 100 kilogrammes and emits many times more smoke, causing the well known odor. That means that synthetic coal, if used to produce directly heat or steam, at least signals high grade

Still more favorable was the gas est. One hundred kilogrammes of anthracite were placed in one retort and the same quantity of synthetic coal in another. Both retorts were subjected to the same heat, and their contents converted into gas and coke. The gas obtained from the synthetic coal yielded more heat units per second while it lasted and it lasted longer than the anthracite. The coke of both kinds of coal equalled in weight and heating power. That result is of special importance because Germany is consistently striving to restrict consumption of coal to factories and gas works, and has made aready much progress in that

#### Gas Germinating Plants.

The heat from burning coal is to be utilized to make steam to drive stationary engines. But thereby not more than 18 per cent. of the inherent power of coal can be utilized. Not to waste the remaining power, the fires beneath the boilers will be connected with gas generating plants the illuminating gas yielding about twice as much heat or power as the direct burning of coal.

The chief by-product of the trees is coke to be burned as board of ships and in households, which may also use either fluminating gas. or hydrogen gas for heating purposes. The hydrogen gas is produced by pouring water on live coke. Small and medium industrial establish-

ments will by and by have to install gas motors and use illuminating or hydrogen gas. The process of production of synthetic coal is simple, according to Prueckner who operates near Munich
