FALL PLOWING ENSURES THE LARGEST SUPPLY OF MOISTURE FOR THE CROPS NEXT YEAR
Summer rainfall does not furnish one-half the moisture necessary to properly supply a growing crop. The moisture that ensures against crop failure is the moisture stored in the soil during autumn, winter and early spring. It is wise, therefore, to make every provision to enable the soil to store a maximum amount of water. To fall plow is to make such provision and, furthermore, it exposes the soil to the beneficial action of the weather and saves time and allows the crops to be gotten in earlier the next spring. A gang plow and four-horse team such as here shown in use by Mr. John Salkeld, Huron Co., Ont., enables one to get the work done well and with dispatch before the frost seals the ground for winter.
