SCIENTIFIC—SANITARY ENGINEERING.

Lectures by Professor H. T. Bovey, of McGill College.

ANSWERS TO QUESTIONS IN LECTURE No. VIII.

1. A long sewer of circular section has a uniform slope; show that if the water is to attain the greatest velocity the stream must only partially fill the channel; and if A be the supplement of the angle subtended at the centre of the section has a the section by the unwetted portion of the circumference, then $= + A = \tan A$.

Ans.—The angle subtended at the centre is 180° - Λ° . The sectional area of the water-way is therefore $\frac{R^2}{2}$ ($\tau + A + \sin A$), and the wetted perimeter is R (π + A), where R is the radius.

Then the mean hydraulic depth H is equal to $\frac{R^2}{2}(\pi + A + \sin A)$

Now, the velocity varies directly as the mean hydraulic depth, and therefore will be a maximum when H is a maximum.

Putting the differential co-efficient of H with respect to A equal to zero, we obtain finally $\frac{2 R (1 + \cos A) (\pi + A) - 2 R (\pi + A + \sin A)}{2 R (\pi + A + \sin A)} = 0$, which $4(\pi + A)^2$

reduces to $\pi + A = \tan A$. "Hence, too, we see that the velocity of the stream is greatest when the JOHN S. O'DWYER, (3rd year). sewer is not quite full."

2. A low-level sewer of circular section recently constructed in Torquay is seven feet in diameter, and is capable of discharging 8,000 cubic feet per minute; will it be a sewer of deposit?

Find the fall, and also the "head," which would be sufficient to maintain the velocity of discharge, the length of the sewer being about 2,000 feet.

If the sewer were constructed of brickwork, what should be its thickness?

Ans.—The velocity of discharge in feet per minute is equal to

 $\frac{0.000}{\text{sectional area of sewer}} = 208 \text{ nearly.}$

Therefore the sewer will not be one of deposit, as the velocity is quite

Again, the fall in feet per mile is given by the equation V = 55 (2 F D)%, or 208 = 55 (2 F 134)½, whence F, the fall in feet per mile, is 4.1 nearly. Hence the fall for a length of 2,000 feet is 1.86 feet, nearly,

To find the head of water personnel to maintain the discharge of 2,000 To find the head of water necessary to maintain the discharge of 8,000

cubic feet per minute, we have the equation $Q = 2356 \left(\frac{h}{l} d^5\right)^{1/3}$, where Q denotes the state of t notes the discharge, h the head, l the length, and d the diameter, all in feet.

The depth of excavation being twenty feet, the thickness of the sewer is Hence h = 1.4 ft. nearly. given by $t = \frac{d.r}{100} = \frac{20 \cdot (1 + 3\frac{1}{2})}{100}$. Hence $t = 10\frac{1}{2}$ inches; so that the sewer will require to be three rings thick of 4-inch bricks.

T. DRUMMOND (2nd year).

LECTURE IX.

MATERIALS.

Portland Cement is composed of chalk and clay burned at a high temperature, and ground to a very fine powder. The heavier it is, the stronger it ture, and ground to a very fine powder. The heavier it is, the stronger it becomes and the longer it takes to set; it must therefore be protected from running water. It does not deteriorate from age, if kept dry. The amount of cernent required is not less than the interstice space of the sand used. cement required is not less than the interstice space of the sand used.

SPECIFICATION.—It is to be of the best quality, ground extremely fine, and weighing not less than 112 lbs. to the Imperial striked bushel. It is to be brought upon the works in a state fit for use, but it is not to be used therein until it shall have been upon the works, at state fit for use, but it is not to be used therein until it shall have been upon the works, at state fit for use, but it is not to be used therein until it shall have been upon the works, at state fit for use, but it is not to be used after in a fit for use, and shall be tested as the engineer may direct. It shall be mixed in the immersion in water, and shall be tested as the engineer may direct. It shall be mixed in the proportion of one of cement to one of sand, and shall not be used after it has begun to set.

Raman Canada is manufactured from "Sentaria" and is cheaper than

Roman Cement is manufactured from "Septaria," and is cheaper than Portland Cement, but not so strong. It sets quickly, and is therefore useful as an incident the strong of the stro an inside rendering. Its tensile strength does not exceed 100 to 125 lbs. per an inside rendering. Its tensile strength does not exceed 100 to 125 lbs. per square inch after seven days immersion. It should not weigh more than 75 lbs. to the stall and should be used in the proportion of one of lbs. to the stall and should be used in the proportion of one of lbs. to the striked bushel, and should be used in the proportion of one of

Medina Cement is also manufactured from "Septaria," and sets very cement to one of sand. quickly, but has less strength than either Portland or Roman Cement.

Blue Lias and Hydraulic Limes may be used, but they must be of the best Possible quality, and should "invariably" be carefully tested. They are to be ground sufficiently fine to pass through a sieve with 1,600 meshes to the square inch.

SPECIFICATION.—The lime (say blue lias) shall be obtained from the lowest and hardest beds of the blue lias formation, and shall be brought in lumps fresh from the kiln and ground upon the works in mills under edge runners.

SPECIFICATION.—The mortar shall be mixed in the proportion of one of lime to two sand; it shall be well tempered, and ground in similar mills for 30 minutes at least, of sand; it shall be well tempered, and ground in similar mills for 30 minutes at least, of sand; it shall be well tempered, and ground in similar mills for 30 minutes at least, of sand; Darian Placeter of Paris & Name of Paris & Darian Placeter of Paris & Name o

Many other cements are in use (e.g., Keene's Parian, Plaster of Paris, &c.) but are only suited for the interior fittings of public and private buildings.

Sand should be of a pure silicious character, free from nitrogenous and a saline matters and of various degrees of fineness. It dilutes the cement some saline matters, and of various degrees of fineness. It dilutes the cement,

SPECIFICATION.—The sand shall be very clean, sharp, washed river sand. so to speak.

Water.—Fresh or sea water may be used for mixing with Portland cement, and according to Grant's experiments the sea water rather augments the strength of the cement. Only sufficient water should be used to bring the mortar into a thick pasts. mortar into a thick paste.

Concrete (or Beton) is a mixture of mortar, usually hydraulic, with some coarse material, as broken stone, brick, shells or gravel. The material used should be perfectly clean, and of irregular sizes. The proportion of cement should be such as to form good mortar with the sand alone; and the mortar thus made should be somewhat in excess of the interstices to be filled, so that the coarse material may be quite surrounded. The material must be thoroughly No more than is to be quickly used should be mixed saturated with water.

Specification.—(1) Lime concrete shall be composed of clean ballast or stone chippings of sizes, and ground hydraulic line, fiesh burned, mixed in the proportion of six by measure of the former to one by measure of the latter.

(2.) The Portland cement concrete for the sewers and shafts shall be composed of four measures of hard clean limestone, broken into angular pieces so as to pass in any direction through a ring 2 inches in diameter, two measures of sharp clean sand, and one equal measure of cement. The concrete shall be turned over once dry, twice wet, and thoroughly mixed up on a clean floor, placed in the work, and rammed where directed.

Timber, for permanent work, should be free from injurious shakes, large and loose knots, and sap wood. The best kinds are alder, beech, elm, larch, oak and teak. Processes for preservation are sometimes resorted to.

SPECIFICATION.—The castings shall be clean and sound, free from porous places, sand and air-holes, and they, as well as the wrought iron work, shall be free from hammer marks of and all other imperfections. The whole shall be delivered on the works free from paint or other coatings. All iron sent with plugging or stopping in any part will be rejected, and must at once be removed. Patterns of all castings are to be approved by the Engineer before being run.

TESTS.

-(1.) Soak a sample brick in water, and expose it to frost.

(2.) Weigh the brick, then leave it immersed for a week in a strong solution of sulphuric acid, and weigh it again when dry.

(3.) The brick should also be subjected to a crushing test.

Earthenware and Stoneware. - For Impermeability .- (1.) Dry the pipe till it ceases to lose weight, submerge it in water for 24 hours, then wipe it dry

and re-weigh.
(2.) Tie a bladder over the end, reverse and fill with water, and carefully observe the tendency to sweat.

Cement.—Mechanical.—(1.) Mould the material into blocks of a suitable form, allow them to remain under water for seven days, and then subject them

to crushing and tensile strains.

Chemical.—(2.) Subject a portion of it to a standard solution of nitric acid,

distilled water with 10 per cent. of the acid.

Portland Cement.—(3.) In an emergency, make two parts, and keep one in the water and the other dry. If clay preponderates, the part in the water will assume a buff color. If the cement is over-chalked or over-burned to the point of danger, little cracks will be perceptible all round the edge of the wet cake, and if the latter of these indications are found the cement must be laid

Test equally applicable to brick, stone, mortar, &c.—Prepare a cold saturated solution of sulphate of soda, then bring it to the boiling point, and suspend by a string for 30 minutes the sample under trial; then pour the liquid, free of sediment, into a flat vessel, and suspend the stone over it in a cellar, free of sediment, into a flat vessel, and suspend the stone over it in a cellar. When efflorescences appear on the specimen, it must be dipped in the solution two or three times a day for, say, a week; the quantity of earthy sediment the vessel collected on a filter and weighed will indicate the sediment. from frost on the same sample.

Questions.

Explain the method of jointing stoneware pipes. What are the objections to the use of clay as a jointing material?

2. A line of sewer is constructed as follows:—From A to B, a distance of 367 ft., it is 1 ft. 6 in. in diameter; from B to C, 1,720 ft., 2 ft. 3 in. in diameter; from C to D, 2,200 ft., 4 ft. 6 in. in diameter; and from D to outlet, 11,387 ft., 7 ft. in diameter. At B its direction turns through a right angle, with a radius of 200 feet, and at C through an angle of 135°, with the same radius. Find the requisite falls to be given to each length, so that the line from A to D may be appoint full and the main sewer half full and discharging at the rate of a consider full and the main sewer half full and discharging at the rate of a consider full and the main sewer half full and discharging at the rate of a consider full and the main sewer half full and discharging at the rate of a consider full and the main sewer half full and discharging at the rate of a consider full and the main sewer half full and discharging at the rate of a consider full and the main sewer half full and discharging at the rate of a considered full and the full requisite falls to be given to each length, so that the rate of 3,000 running full, and the main sewer half full and discharging at the rate of 3,000 feet per minute.
