

Fourth Panel

The load on the fourth panel, l_4 , is similar to that on the second and third panels. Let these loads be P_4 and P_4' . Then

$$M_4 = \frac{1}{8}P_4l_4 + 0.128P_4'l_4 \dots\dots\dots (19)$$

in which

$$P_4 = \frac{1}{12} \times 0.434h_3l_4p$$

and

$$P_4' = \frac{1}{2}[(0.434h_3/12) + (0.434h_4/12)]l_4p$$

in which $h_4 = h_3 + l_4 \cos \alpha = 228 + l_4 \cos \alpha$.

Substituting the values of h_3 and h_4 , we get

$$P_4 = \frac{1}{12} \times 0.434 \times 228l_4p = 8.23l_4p \dots\dots\dots (20)$$

$$P_4' = \frac{1}{2}[(\frac{1}{12} \times 0.434 \times 228) + (\frac{1}{12} \times 0.434)(228 + l_4 \cos \alpha)]l_4p$$

$$= \frac{1}{2}[8.23 + 0.0362(228 + l_4 \cos \alpha)]l_4p \dots\dots\dots (21)$$

The resisting moment, as before, is

$$M_4 = 4,170bd^2 \dots\dots\dots (22)$$

Substituting values of (20) and (21) in equation (19), we get

$$M_4 = (\frac{1}{8} \times 8.23l_4^2p) + (\frac{1}{2} \times 0.128l_4^2p)(8.23 + 8.23 + 0.0314l_4)$$

Reducing and substituting for p , we get

$$M_4 = 1.29l_4^3 + 1.317l_4^3 + 0.00252l_4^3$$

$$= 2.607l_4^3 + 0.00252l_4^3 \dots\dots\dots (23)$$

Equating (22) and (23), we get

$$2.607l_4^3 + 0.00252l_4^3 = 4,170bd^2 = 6,660.$$

Solving for l_4 by trial, we get

$$l_4 = 49 \text{ ins.}$$

and

$$h_4 = h_3 + l_4 \cos \alpha$$

$$= 228 + (49 \times 0.866) = 270.5 \text{ ins.}$$

In this way the length of panels between supports can be determined for any spacing of bars and any size bar. The accompanying Table No. 1, gives these lengths for bars $\frac{1}{4}$ in. by 2 ins. to $\frac{1}{4}$ in. by 4 ins. and spacing of $\frac{1}{4}$ ins. to 3 ins. inclusive.

If it be desired to use a bar thicker than $\frac{1}{4}$ in., the length of first panel can be obtained from the table as follows:—

Cube the length, l , corresponding to a bar of the same height, d , and spacing p , and multiply by the width of bar to be used. Then divide by the width of bar in table ($\frac{1}{4}$ in.). Extract the cube root of this result, and this will be the desired length, l_1 . See equation (8).

By examining equation (13a), it will be seen that the second term of the left hand member is of small value, and the first term is the controlling factor, and we can therefore say that the length varies as the square root and not as the cube root, with no appreciable error. We can therefore say that the length of all panels after the first vary as the square root of the resisting moment of the bar. As this moment is directly proportional to the thickness of the bar, the values of l_2, l_3 , etc., can likewise be taken from the table by squaring the length given in table for a bar of the same height and spacing, and multiplying this result by the desired thickness, and dividing by the thickness used in the table ($\frac{1}{4}$ in.), then extracting the square root and using the values of l_2, l_3 , etc., so obtained.

For example, say it is desired to use a bar $\frac{3}{8}$ in. by $3\frac{1}{2}$ ins. instead of $\frac{1}{4}$ in. by $3\frac{1}{2}$ ins., and a spacing of 2 ins. Then l_1 from table = 147 ins. Let l_1' = the desired length for $\frac{3}{8}$ in. by $3\frac{1}{2}$ ins. bar. Then

$$l_1' = (l_1^2 \times 0.375/0.25)^{1/2}$$

$$= l_1(0.375/0.25)^{1/2}$$

$$= 147 \times 1.145 = 168 \text{ ins.}$$

Let l_2' = second panel length. From table, $l_2 = 69$ ins. Therefore

$$l_2' = (l_2^2 \times 0.375/0.25)^{1/2}$$

$$= l_2(0.375/0.25)^{1/2}$$

$$= 69 \times 1.225 = 84.5 \text{ ins.}$$

Let l_3' = third panel length. From table, $l_3 = 57.5$ ins. Therefore

$$l_3' = (l_3^2 \times 0.375/0.25)^{1/2}$$

$$= l_3(0.375/0.25)^{1/2}$$

$$= 57.5 \times 1.225 = 70 \text{ ins.}$$

Let l_4' = fourth panel length. From table, $l_4 = 51.5$ ins. Therefore

$$l_4' = (l_4^2 \times 0.375/0.25)^{1/2}$$

$$= l_4(0.375/0.25)^{1/2}$$

$$= 51.5 \times 1.225 = 63 \text{ ins.}$$

Of course this is only true when the angle of the rack bar is 30 degs. from the perpendicular. For any other angle, the panel lengths should be determined from the foregoing equations by substituting the proper value for $\cos \alpha$.

The values here given in Table 1 will be safe for the worst conditions imaginable, because the stress used is inside the elastic limit of steel. If the designer wishes to use a different stress, he need only multiply l_1 from the

TABLE 1

$$*M = \frac{1}{6} \times bd^2 \times 25,000.$$

table, by the cube root of the quotient, stress (S) divided by 25,000; that is, multiply l_1 from the table, by $(S/25,000)^{1/3}$ for the first panel length, and by $(S/25,000)^{1/2}$ for l_2, l_3 , etc.

Construction of Panels

The bars are usually held together by through bolts, with sections of wrought-iron pipe of proper length strung between the bars, as shown in Fig. 3. The through bolt is placed back of the centre line of the bar so that the cleaning rake will not catch so readily.

The nuts on the bolts should not project outside the panel but should be guarded by a bar which is riveted at both ends. If this is done, the rack panels can be easily withdrawn and replaced.

The lower end of the rack bars can rest in an angle iron embedded in the concrete, and the upper end should be anchored by means of a hook engaging the spacing bars.

Supporting Structure

There are various methods for supporting the bars, depending on the construction of the adjacent building. If dividing walls can be placed at frequent intervals so as not to make too great a spacing, then I-beams can be embedded in these to support the racks. Such an arrangement is
