mortar and cement stone trimmings. It has southern pine columns, beams and plank floors. Each floor is crowned in the middle so as to give a slight fall each way toward the side walls. The wearing floors are hard maple, laid in the direction of the fall, on top of thick waterproof

floor felt, which is placed between the plank flooring and the wearing floor. Along each side wall a shallow gutter

is formed, lined with galvanized iron and connected to scuppers carried through the walls, so that in case of fire water thrown on any one of the upper floors would run off outside of the building without descending to the floors below.

The elevator will have automatic gates The and fire doors. stairs are isolated inside brick walls, cut off from the rest of the building on all fire doors. The partitions are all solid mill construction and

nothing has been omitted to make this building a firstclass example of the best type of mill construction. The windows and skylights are of wired glass and fireproof

frames on exposed sides. The boiler rooms and coal bunks are of fireproof construction entirely. This building is designed and a permit obtained for five stories and basement, and the footings, foundations and walls, plers, and so forth, are being built for that height of building, with floors throughout to sustain very heavy loads, though it is intended for the present to stop at the third storey. The location is very central, within half a minute of Yonge street, and it is not unlikely that in the near future the two upper stories will be carried up.

The building is owned and the first three floors will be occupied by the E. B. Shuttleworth Chemical Co., Limited. It will be steam-heated and will have most up-to-date sanitary plumbing appliances throughout. Messrs. R. J. Edwards & Saunders, Toronto, are the architects.

The structure as a whole is a fair example of the best that can be done in the matter of fireproofing a mill-constructed building, and is reproduced here only for this reason and not because we consider its type of construction best adapted to warehouse building, for, as we have repeatedly stated, there is no reason for the use of wooden columns, beams and joists in the

modern warehouse.

Suggestions to Architects on Concrete Construction

N view of the extent to which concrete is at present being employed in connection with all forms of building construction, the following suggestions to architects by E. P. Goodrich, consulting engineer of New York City, and published in the last issue of The Concrete Review, cannot fail to find interest among a large class of readers. At the very outset the author refers to the field of usefulness of the material in question, as follows:

Concrete has a unique and proper field. It cannot and should not be forced to compete with steel, timber or masonry under all conditions. Do not think it necessary or try to make concrete imitate other materials, either as to finish or as to structural design.

The value of concrete in the construction of warehouses and factory buildings of moderate height is un-

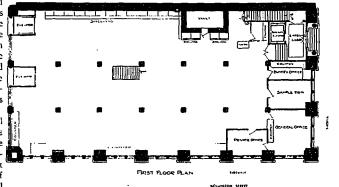

questioned. When fire prevention is important it finds its greatest usefulness.

Where bold simple exterior treatment is appropriate, concrete can be employed to advantage.

As regards styles of architecture and surface finish, use the mission style of architecture OΓ other simple massive type, rather than the claborate classic orders.

Don't try to imitate brick or stone by devices of centreing. Let the architectural details show that the material is concrete

and let it stand for itself. Secure contrasts by means of shadows, by using deep reveals at apertures and heavy (but not heavily overhanging) cornices and belt courses.

floors by self-closing Fig. 12-first floor plan, ogilvie building, toronto, showing ar-RANGEMENT AND LOCATION OF THE STEEL COLUMNS, FIREPROOFED WITH CONCRETE.
