

Miscellaneous.

BLASTING ROCK UNDER WATER.

A few days ago, in a long railway ride, I had for a companion in the same seat a very intelligent man, whose profession was that of a contractor for the removal of submarine rock in rivers, harbors and along shore; anywhere in fact.

I did not understand very clearly the process by which this work is done, and my fellow traveler very kindly explained the whole thing most satisfactorily. Many persons may like to know about it as I did.

I have done a great deal of work, said he, under General Thom. If all United States officers were like him, the government, I think, would be much better served than I hear it now is. I find as the General grows older he becomes more and more particular, and wants the work done papered off more than he did.

But I should like to know exactly how you go to work to remove living rock from the bottom of a river or harbor so as to deepen the channel.

Exceptional cases require exceptional processes, but generally, this is the way of doing it. We prepare, to begin with, a lighter or scow or two, according to our needs; sometimes a steam tug, if necessary, also. These scows we moor over the rock, or about it, according to circumstances, so as to be in the most convenient position. We have a diving suit and all the necessary apparatus for remaining under water. We have a tripod for our drill, made generally of iron, gas or water pipe, which may be made longer or shorter, according to the depth of water; the change from shorter to longer is very easily and speedily done.

The drill, of larger or smaller diameter, according to our needs, is so fixed upon this tripod, that it may be worked with equal facility at any required angle with the horizon. We have a heavy cylinder of cast iron, six inches in diameter and 24 inches high, with a hole through the center for the drill to work in. This cylinder is placed upon the rock to be operated upon, and stands on three sharp pointed iron legs.

What is the use of this piece of iron?

It is to direct the point of the drill and keep it steadily at one spot when it begins to act upon the surface of the rock. Without this, the drill could not act upon the rock, and it would have made for itself a hole so deep that the end would play all within it.

Where is the steam engine that makes the drill work?

That is upon the tripod, and is so arranged in a very simple way, that it always acts in a line with the drill, whatever the angle may be, at which this is fixed.

Is the steam generator upon a tripod also?

No, that is in the scow or lighter, and the steam is conveyed to the engine through a strong rubber tube, longer or shorter according to the necessities of the case.

Being already, how do you fix the tripod in place so as to begin operations?

We go down to the surface of the rock and explore it carefully, in every part, so as to determine at what point to commence; for a good deal depends upon this, as to making good blasts, each of which can be adjusted easily to the inequalities of the rock. Then the tripod is put in place, so that the drill shall be exactly in line with the bore in the rock block. This being done, the steam is let on and the drill begins its work with a slower or quicker motion according to the particular case.

How large are these bores which you make?

The size varies according to the circumference of each case. We employ drills of one and a half inch diameter, and of different sizes above that to three inches in the largest.

How long an operation is it, the drilling of these bores?

The depth of them varies, of course, according to the circumstances of the case, and the time required per foot here depends upon the character of the rock and the size of the drill. The smaller drill makes more rapid way than the larger. We always make the bore a foot deeper than the new surface is to be after the rock shall be removed. A three inch drill may be driven one foot in ten minutes according to circumstances.

Now the bore is completed, what is the next thing to be done?

The tripod is removed and the scows are moved away so far as to be out of danger. Our carriage case is of tin, fitting easily into the bore, and is longer or shorter, according to the need of a larger or smaller charge. The case is half filled with dynamite or whatever other explosive is employed, then a powerful explosive cap is fitted into it, and the case is filled with dynamite. Connected with this cap are two wires about a foot long, by which it is exploded.

In the top of the case is fitted a wooden cap with a hole through which thrusts a wooden rod to the bottom of the bore. This done he comes up; the electric circuit is completed and the cartridge exploded.

Is there much commotion in the water at the explosion?

Generally, not much, about as much as upon the surface of a pot that boils, but the water is disturbed upon the shallowness or depth of the water, of course, and upon the depth of the bore, and the magnitude of the charge. In shallow water we are careful to keep a very respectful distance.

Now you have loose rock below, and how do you remove it?

In our scow or scows we have a crane properly rigged, actuated by steam or not (it will work by steam or hand as we wish). We take these scows over the spot of the explosion, and the divers fix chains or grapplings, as the case may be, to the large fragments of rock, which are then raised from their

bed sufficiently to clear all obstructions; and then the scows move away and drop the rock at the nearest point that will be out of the channel we are forming. We have an iron cage also, suspended to the cranes, and into these we put the smaller fragments, which are removed in the same manner.

But sometimes rock may be broken on top by exploding dynamite on the surface.

Yes, we do that often when the quantity of rock is not great.

How do you proceed in a case of the kind?

We examine the surface of the rock carefully with reference to its form and as to its stratification and seams, if any as in the former case, and determine the point at which we will commence, which is generally upon one side or edge of the surface to be operated on.

We place a cartridge upon the rock and explode it. This will shatter the rock to the depth of about six inches under the cartridge, and after the loose rock is removed we repeat the explosion upon the same point until our depth is sufficient. We have now a wall or shoulder of rock upon the side where the rock is to be removed, and we place our charges by the side of this and on the new surface we have made.

The explosion of these charges shatters this surface as before, and at the same time knocks away great quantities from the wall or shoulder, and we follow up until we have knocked off the entire surface of the rock to be removed and to the required depth.

Where do you find your divers?

I do that work myself. I used to hire divers at \$15 a day, but I found my jobs prolonged indefinitely. These men instead of putting the cartridges into boxes prepared for them at a great cost of time and machinery, sometimes placed them on the surface of the rock, so as to spin out their job at fifteen dollars a day. By doing the work myself I make an enormous saving in many ways.

Then there are unfaithful servants in your business, as well as unfaithful administrators of trust funds?

Yes, everywhere, some such are to be found, I'm sorry to say—everywhere; but there are also very many honest ones.

The power of these explosives is enormous, immeasurable in fact, and the danger in dealing with them is great, especially with nitro-glycerine. I went to San Francisco some time ago, being employed by the Government to remove a formidable obstruction from the waters of the Golden Gate. On examination I found this obstruction to be an enormous rock, rising somewhat like a sugar-loaf from the bottom of the bay, and which was about twenty feet above its surface. The operation upon this rock was not easy, because it was exposed to the Pacific ocean, on which there was a steady swell, and I could not work except in smooth water.

I had everything ready, after forming my plan, and after many days of smooth water. In a steam-tug I went to the rock and put around its top, like a necklace, an iron chain. To this I suspended a strong iron cable, which was fastened to eight hundred pounds of nitro-glycerine. The cable was sunk twenty-two feet below the surface, hanging along the rock. The charge was exploded with great concussion and a report as of the simultaneous discharge of a park of artillery. The waters flowed smoothly over the spot; there was no rock there.

I did not trouble myself to see what had become of it—nobody knows.

A DEAD SEA RAILWAY.

It is reported that French capitalists have secured a grant for a railway line from Acre to the interior of Palestine, which will open up the Jordan valley and the whole region north of the Suez Canal. In certain contingencies this road might become of great utility, but it appears further that the productive resources of this country are considerable, and what is more surprising, that the Dead Sea itself is being turned to commercial account. Chief of these at present are the stores of natural combustibles for which that region is noted. Hitherto the main object to the development of steam traffic in the Levant has been the total absence of combustible material. Not only Egypt, but the shores of Syria and the Red Sea are completely stripped of wood, and the coal imported from the West commands a price ranging from \$10 to \$24 a ton. Now the masses of asphalt continually thrown up by the Dead Sea attest the presence of vast subterranean layers of fossil vegetable matter, and these long were not overlooked by the enterprising men attracted to Suez by the opening of the canal and the movement of commerce to that direction. Recently numerous soundings have been made between Java and the Dead Sea, which, so far, have not disclosed any deposits of coal proper, but, on the other hand, have laid bare inexhaustible beds of lignite. Of itself this store of lignite is likely to prove an inestimable gain to the industries and commerce of the Levant, but we should add that the juxtaposition of asphalt in great quantities furnishes the elements of a mixture of lignite and asphaltum in the form of bricks, which is equal in heating capacity to the richest bituminous coal, while its cost on the ground is only \$2.50 a ton. It is known that similar bricks, made up of coal dust and bituminous earth from gas works, are much sought after by French railways since, besides their heating power, they greatly facilitate stowage, owing to their regular shape. Of course the bitumen of lower Palestine has been known from immemorial times, and was used to impart solidity to the structures of unburnt clay in Assyria and Egypt; but it may be said that the discovery of the subterranean combustible has lifted once for all the curse which has so long rested upon Sodom and Gomorrah, and will transform the waste shores of the Dead Sea into a focus of industry and a magazine of wealth.—Scientific American.

The Assembly Chamber of the new Capitol is now under way. The site is a shallow water we are careful to keep a very respectful distance.

Now you have loose rock below, and how do you remove it?

In our scow or scows we have a crane properly rigged, actuated by steam or not (it will work by steam or hand as we wish). We take these scows over the spot of the explosion, and the divers fix chains or grapplings, as the case may be, to the large fragments of rock, which are then raised from their

OTAWA, May 1st, 1877. NO Discount on American Invoices until further notice.

J. JOHNSON, Commissioner of Customs.

Something New Under the Sun!

M. R. HARDING, DODGE & COMPANY, Annapolis, Md. respectfully announce to the public in general that he is about opening a shop where he will be prepared to manufacture Buggies, Farm Wagons, Panel Doors, Window Frames, Sashes, Shutters, &c. Parties wishing work in his line will do well to call upon him as he has had a number of years' experience in the United States in building all kinds of wheels, and is prepared to warrant his work. New hubs inserted in old wheels, spokes inserted without removing the tyres.
