The copy filmed here has been reproduced thanks to the generosity of:

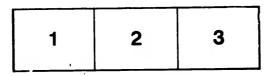

Library of Congress Photoduplication Service

The images appearing here are the best quality possible considering the condition and legibility of the original copy and in keeping with the filming contract specifications.

Original copies in printed paper covers are filmed beginning with the front cover and ending on the last page with a printed or illustrated impression, or the back cover when appropriate. All other original copies are filmed beginning on the first page with a printed or illustrated impression, and ending on the last page with a printed or illustrated impression.

The last recorded frame on each microfiche snall contain the symbol \longrightarrow (meaning "CON-TINUED"), or the symbol ∇ (meaning "END"), whichever applies.

Maps, plates, charts, etc., may be filmed at different reduction ratios. Those too large to be entirely included in one exposure are filmed beginning in the upper left hand corner, left to right and top to bettorn, as many frames as required. The following diagrams illustrate the method:

L'exemplaire filmé fut reproduit grâce à la générosité de:

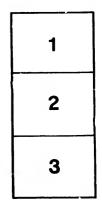

Library of Congress Photoduplication Service

Les images suivantes ont été reproduites avec le plus grand suin, compte tenu de la condition et de la netteté de l'exemplaire filmé, et en conformité avec les conditions du contrat de filmage.

Les exemplaires originaux dont la couverture en papier est imprimée sont filmés en commençant par le premier plat et en terminant soit par la dernière page qui comporte une empreinte d'impression ou d'illustration, soit par le second plat, selon le cas. Tous les autres exemplaires originaux sont filmés en commençant par la première page qui comporte une empreinte d'impression ou d'illustration et en terminant par la dernière page qui comporte une teile empreinte.

Un des symboles suivents apparaîtra sur la dernière image de chaque microfiche, selon le cas: le symbole → signifie "A SUIVRE", le symbole V signifie "FIN".

Les cartes, planches, tableaux, etc., peuvent être filmés à des taux de réduction différents. Lorsque le document est trop grand pour être reproduit en un seul cliché, il est filmé à partir de l'angle supérieur gauche, de gauche à droite, et de haut en bas, en prenant le nombre d'images nécessaire. Les diagrammes suivants Illustrent la méthode.

PREFACE.

THE present treatise on Roofs and Bridges is designed as a text-book for the use of schools. The object of this work is 'o develop the principles and explain the methods employed in finding the forces in Roofs and Bridges, and to train the student to compute the stresses, due to the dead, live, snow, and wind loads, in the different members of any of the simple roof and bridge trusses that are in common use.

The aim has been to explain the principles clearly and concisely, to develop the different methods simply and neatly, and to present the subject in accordance with the methods used in the modern practice of roof and bridge construction.

In introducing each new truss it is at first carefully described, and the method of loading it explained. A problem is then given for this truss, and solved to determine the stresses in all the members. This problem is followed by several other similar ones, which are to be solved by the student. Nearly all of these problems were prepared especially for this work, and solved to obtain the answers. The instructor can at any time easily make up problems for his pupils without the answers.

The book consists of four chapters. Chapter I. is entirely given to Roof Trusses. Chapter II. treats only of Bridge Trusses with Uniform Loads.

iii

PREFACE.

iv

Chapter III is devoted to Bridge Trusses with Unequal Distribution of the Loads. This is divided into three parts, as follows:

(1) The use of a *uniformly distributed excess load* covering one or more panels, followed by a uniform train load covering the whole span.

(2) The use of one or two concentrated excess loads, with a uniform train load covering the span.

(3) The use of the actual specified locomotive wheel loads, followed by a uniform train load.

Chapter IV treats of Miscellaneous Trusses, including the Croscent Roof Truss, the Pegram and Parabolic Bowstring Bridge Trusses, and Skew Bridges.

The stresses in this work are nearly all given in tons, the word "ton" meaning a ton of 2000 pounds. Any other unit of load and of stress might be used as well.

My best thanks are due to my friend and former pupil, Mr. George H. Blakeley, C.E., of the class of '84, now ' Chief Engineer of the Passaic Rolling Mill Company, for reading the manuscript and for valuable suggestions.

CHAPTER I.

ROOF TRUSSES.

Art. 1. Definitions. — A Framed Structure is a collection of pieces, either of wood or metal, or both combined, so joined together as to cause the structure to act as one rigid body. The points at which the pieces are joined together are usually called *joints*.

A Truss is a structure designed to transfer loads on it to the supports at each end, while each member of the truss is subject only to longitudinal stress, either tension or compression. The simplest of all trusses is a triangle; and all trusses, however complicated, containing no superfluous members, must be composed of an assemblage of triangles, since a triangle is the only polygon whose form cannot be changed without changing the lengths of its sides.

A Strut is a member which takes compression. Struts are sometimes called *post*_i, or columns.

A Tie is a member which takes tension.

A Brace is a term used to denote both struts and ties.

A Counter Brace is a member which is designed to take both compression and tension. A Counter is a member designed to take either compression or tension; that is, for one position of the load the member may be compressed, while for another position it may be elongated.

1

1

The Upper and Lower Chords are the upper and lower members of a truss, extending from one support to the other. Each half of the upper chord of a roof truss is sometimes called the "main rafter," while the lower chord is often called the "tie rod." The upper chord is always in compression and the lower chord is always in tension. The spaces between the joints of the chords are ealled *panels*.

The Web Members are those which connect the joints of the two chords. They are generally alternately struts and ties.

A Roof, in common language, is the covering over a structure, the chief object of which is to protect the building from the effects of rain and snow.

A Roof Trusses is a structure which supports a roof. Roof Trusses are of almost innumerable forms, and they differ greatly in the details of their construction.

The External Forces include all the exterior or applied forces, such as the weight of the structure, the weight of snow, the force of the wind, the reactions, etc., which act upon and tend to distort the structure. The external forces on the whole structure must balance each other, or else the whole structure will begin to move.

Strain is a change in the length or in the form of a body, which has been produced by the application of one or more external forces; and it is to be measured, not in tons, but in units of length, as inches or feet.

Stress is the name given to that internal force which is exerted by the material in resisting strain; and it is measured in pounds or tons the same as the external forces. It follows that, when every part of a strained member of a structure is in equilibrium, the internal stress exerted at any imaginary section through the member is equal and opposite to the straining force.

3

Various Kinds of Stresses. — The external forces may produce, according to circumstances, different internal forces or stresses in the various pieces of the structure. These forces or stresses and their accompanying strains may be classified as follows:

1. A direct pull or a tensile stress, producing extension or elongation.

2. A direct thrust or a compressive stress, producing compression.

3. A shearing force or a shearing stress, producing a cutting asunder.

A shearing force or shearing stress is caused by two forces acting parallel to each other, and at right angles to the axis of the piece, but in opposite directions, and in two immediately consecutive sections. The tendency is to cause two adjacent sections to slide on each other; and the term shearing force, or shearing stress, is used, because the force is similar to that in the blades of a pair of shears in the act of cutting.

Art. 2. The Dead Load. — The dead or fixed load supported by a roof truss consists of the weight of the truss itself and the weight of the roof. The weight of the truss can only be approximated. The following formula* gives approximately correct results for short spans: Let l = span in feet; b = distance between trusses in feet; and W = approximate weight of one truss in pounds. Then

$W = \frac{1}{24} bl^2$.

The roof includes the roof-covering, the sheeting, the rafters, and the purlins. Its total weight will vary from 5 to 30 lbs. per square foot of roof surface. The purlins are

a body, or more s, but in

which is is meascces. It ber of a erted at pual and

4

beams running longitudinally between the trusses, and fast ened to them at the upper joints, and often midway between them as well.

Art. 3. The Live Load.—The live or variable load consists of the snow load and the wind load.

The snow load varies, according to the locality, from 10 lbs. to 30 lbs. per square foot of horizontal projection. The weight of new snow varies from 5 lbs. to 12 lbs. per cubic foot, although snow which is saturated with water weighs much more. The snow load need not be considered when the inclination of the roof to the horizontal is 60° or more, as the snow would slide off.

The wind load is variable in direction and intensity, and often injurious in its effects; especially is this the case with large trusses placed at considerable intervals apart. The maximum wind pressure on a surface normal to its direction is variously estimated at from 30 lbs. to 56 lbs. per square foot. The calculation, therefore, of the stresses caused by the wind forces is often of considerable importance, and should never be left out of account in designing iron roofs of large span.

Art. 4. The Apex Loads and Reactions. — Both the dead and live loads are transferred, by means of the purlins, to the joints or apexes of the upper chords of the truss; and these loads at the apexes are called *the apex loads*. They are also called the *panel* loads.

The truss, roof, and snow loads, being vertical, and uniformly distributed over each panel, the apex loads are each equal to one half the sum of the adjacent panel loads. Thus, the load at h, Fig. 1, is equal to one half the panel load on hc plus one half the panel load on ah. The wind

The P. W. J. - 1 & 10

load at h is also equal to one half the wind load on hc plus one half the wind load on ah, the load on each being normal to the surface.

If the truss be symmetrieal, and the panels be of equal length, the apex loads are determined by dividing the total load by the number of panels in the upper chords. Thus in Fig. 1, the apex loads

F14. 1 at h and c are each one fourth of the total load. At the sup-

ports, a and b, the loads are only one half those at h and c. Reactions. - For dead and snow loads both reactions of the supports of the truss are vertical, and each is one half of the total load, if the truss is symmetrical. For wind load the reactions depend upon the manner of supporting the truss.

Prob. 1. A roof truss, like Fig. 1, has its span 80 feet and its rise 40 feet; the distance between trusses is 12 feet, center to center. Find (1) the weight of the truss, (2) the weight of the roof, (3) the snow load, (4) the apex loads, and (5) the reactions.

For these problems, take 20 lbs. per square foot of roof surface for weight of roof, and 20 lbs. per square foot of horizontal projection for snow load.

Here ab = 80 feet, dc = 40 feet, and ac = 56.56 feet.

Weight of truss,	$W_{l} = \frac{1}{24} bl^{2}$	= 32	00 lbs.
Weight of roof,	$W_r = 56.56 \times 20 \times 12 \times$	2 = 271	48.8 lbs.
Weight of snow,	$W_{\bullet} = 80 \times 12 \times 20$	= 192	00 lbs.
Each apex load	$=$ $\frac{1}{4} \times 49548.8$	= 123	87.2 lbs.
Each reaction,	$R = \frac{1}{4} \times 49548.8$	= 247	74.4 lbs.

Prob. 2. A roof truss, like Fig. 2, has its span 90 feet, its rise 30 feet, and distance between trusses 13 feet: find the

total apex loads and the reactions for the weights of the truss, roof, and snow.

Ans. Apex loads = 6989 and 13977 lbs.; reaction = 27954 lbs.

Prob. 3. In the roof truss of Fig. 3, the span is 100 feet, the rise is 25 feet, and the distance between trusses 12.5 feet: find the total apex loads and the reactions for the truss, roof, and snow loads.

Ans. Loads = 7270 and 14540 lbs.; reaction = 29079 lbs.

Art. 5. Relations between External Forces and -Internal Stresses .- The external forces acting upon a truss-are in equilibrium with the internal stresses in the truss are in equilibrium way. members of the truss. Let mn be a solving passed through the truss, Fig. 4, cut-

ig. 4, ent-

· · · ·

Sec.

ting the members whose stresses are desired, and let these stresses be replaced by equal external forces. Then it is

clear that the equilibrium is undisturbed. Therefore we have the principle:

The internal stresses in any section hold in equilibrium the external forces acting upon either side of that section.

If we remove either portion of the truss, as the one on the right of the section, then the external forces on the remaining part of the truss, together with the internal stresses, form a system of forces in static equilibrium. And from Anal. Mechanics, Art. 61, the conditions of equilibrium for a system of forces acting in any direction in one plane on a rigid body are:

S horizontal components	= 0						(1)
S vertical components	= 0						(2)
S moments	=0	•			•		(3)

These three equations of condition state the relations between the internal stresses in any section, and the external forces on either side of that section. If only three of these internal stresses are unknown, they can therefore be determined.

For example, in Fig. 4, let R, P_0 , P_1 be the reaction and apex loads, found as in Art. 4; let s_1 , s_2 , s_3 be the stresses in the members hc, kc, and kd, that are cut by the section mn, and let θ_1 and θ_2 be the angles made by s_1 and s_2 with

·

100

8

the vertical. Applying our three equations of equilibrium, we have:

for horizontal components, $s_1 \sin \theta_1 + s_2 \sin \theta_2 + s_3 = 0$,

for vertical components, $R - P_0 - P_1 + s_1 \cos \theta_1 + s_2 \cos \theta_2 = 0$.

In applying our third equation of condition, the center of moments may be chosen at any point, Anal. Mechanics, Art. 46. If we take it at c, the moments of s_1 and s_2 are zero, and the equation is —

$$(R - P_0) \frac{1}{2} ab - P_1 \times \frac{1}{4} ab - s_3 \times cd = 0.$$

These three equations enable us to find the unknown stresses.

NOTE 1. — In all cases, in this work, a tensile stress is denoted by the positive sign, and a compressive stress, by the negative sign.* In stating the equations, it will be convenient to represent the unknown stresses as tensile, pulling away from the section, as in Fig. 4. Then, if the numerical values of these stresses are found to be positive, it will show that they were assumed in the right direction, and are *ten*sile, but if they are negative, they were assumed in the wrong direction, and are *compressive*.

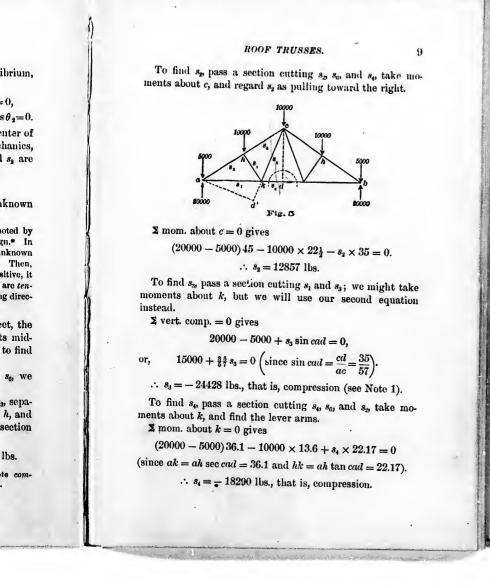

Prob. 4. In the truss of Fig. 5 the span is 90 feet, the rise is 35 feet, hk is perpendicular to the rafter at its midpoint, and the loads are as shown: let it be required to find the stresses in all the members of the truss.

Representing the stresses by s_1 , s_2 , s_3 , s_4 , s_5 , and s_6 , we proceed to apply our three equations of equilibrium.

To find the stress s_1 , pass a section cutting s_1 and s_3 , separating the portion to the left, take moments about h, and regard s_1 as pulling toward the right from the section (see Note 1). Then, Σ moments about h = 0 gives

 $(20000 - 5000) 22\frac{1}{2} - s_1 \times 17\frac{1}{2} = 0.$ $\therefore s_1 = 19287$ lbs.

* This convention is entirely arbitrary. Some writers denote compression by the positive sign, and tension by the negative sign.

: 0, $s\theta_2=0.$ inter of hanics, l s₂ are

known

gn.∗ In nknown sitive, it are tenng direc-

et, the ts mid-

h, and

lbs.

10

To find s_5 , pass the section uniting s_1 , s_5 , and s_4 , and take moments about a. Then

 $10000 \times \frac{4.5}{2} + s_5 \times \frac{5.7}{2} = 0$, $\therefore s_5 = -7895$ lbs.

To find s_{0} pass the section entring s_{2} , s_{0} and s_{4} , and take moments about a. Then,

10000 × 22.5 − s_6 × 35=0 (since the lever arm of s_6 = cd=35), ∴ s_6 = 6428 lbs.

Since the truss is symmetrical and symmetrically loaded, it is evident that the stresses in all the pieces of the right half are equal to those just found in the left.

Note 2. -- In the above solution we have called forces acting upwards and to the right, *positire*, and forces acting downwards and to the left, *negative*; also we have called noments tending to cause rotation in the direction of the hands of a clock from left to right, *positive*, and those in the opposite direction, *negative*. The opposite convention would do as well; we have only to introduce opposite forces and opposite moments with unlike signs.

Prob. 5. A roof truss like Fig. 1 has its span 40 feet, its rise 20 feet, and the apex loads 2000 lbs.: find the stresses in *ad*, *ah*, *he*, and *hd*.

Ans. ad = +1.5 tons, ah = -2.12 tons, hc = -1.41 tons, hd = -0.71 tons.

Prob. 6. A truss like Fig. 2 has its span 60 feet, its rise 20 feet, and the panel loads 4000 lbs.: find the stresses in ad, ah, hc, and hd.

Ans. ad = +4.5 tons, ah = -5.46 tons, hz = -3.64 tons, hd = -1.82 tons.

Prob. 7. A truss like Fig. 3 has its span 80 feet, its rise 20 feet, and the panel loads 10,000 lbs.: find the stresses in all the members.

Ans. ak = +15 tons, kl = +10 tons, ak = -16.75 tons, hc = -14.5 tons, hk = -4.5 tons, kc = +5 tons, cd = 00 tons.

11

Art. 6. Methods of Calculat'on. — Our three equations of equilibrium, Art. 5, furnish us with two methods of calculation: the method by resolution of forces, and the method of moments. The principle of the first method is embraced in the first two equations of equilibrium; the principle of the second method is embraced in the third equation of equilibrium.

Either of these methods may be used in the solution of any given case; but in general there will be one, the employment of which in any special case will be found casier and simpler than the other. Sometimes a combination of both methods furnishes a readier solution.

REMARK. — A section may be passed through a truss in any direction, separating it into any two portions. Thus, in Fig. 5, a section may be passed around h, entring hc, hk, and ha. Then the internal stresses s_4, s_5, s_3 , and the apex load of 10,000 lbs, at h form a system of forces in equilibrium, to which our equations are applicable.

A judicious selection of directions for the resolution of the forces often simplifies the determination of the stresses. Thus, to find s_5 in Fig. 5, if we resolve the forces hato a direction perpendicular to the rafter *ac*, we shall obtain an equation free from the forces s_3 and s_4 ; whereas if the directions are taken at random, all of the forces will enter the equation. This principle is a very useful one.

Thus, we have at once in Fig. 5, calling θ the angle between the load and the rafter,

10000 sin $\theta + s_5 = 0$, $\therefore s_5 = -10000 \cos cad = -7895$ lbs. as before.

Similarly, if a section be passed around d in Fig. 5, cutting dk, dc, and db, and the vertical components be taken, the stress in dc is found at once to be zero.

In solving by the second method, the center of moments

12

may be taken anywhere in the plane of the forces. It is often more convenient to write three moment equations for the stresses in the three members cut, taking a new center of moments each time, than it is to use the first two equations of equilibrium; and if the center of moments be taken at the intersection of two of the pieces cut, we shall have at once the moment of the stress in the other piece, balanced by the sum of the moments of the external forces, since the moments of the stresses in the other two cut pieces are zero.

Thus, in solving Proh. 4, a section was passed cutting s_2 , s_6 , s_4 . To find s_2 we took moments about c, the intersection of s_6 and s_4 , which gave us an equation of moments containing only s_2 and known terms. To find s_4 we took moments about k, the intersection of s_2 and s_6 , which gave us an equation of moments s_6 , which gave us an equation of moments containing only s_4 and known terms. Also, to find s_6 we took moments about a, the intersection of s_2 and s_4 , which gave us an equation of moments containing only s_4 and known terms.

Therefore, to find the stress in any member by the method of moments, we have the following *Rule*:

Conceive at any point of this member a section to be passed completely through the truss, cutting three members. To find the stress in this member, take the center of moments at the intersection of the other two. Then state the equation of moments between this stress and the external forces on the left of the section.

Should the section that passes completely through the truss cut more than three pieces whose stresses are unknown, if all but that piece in which the stress is required meet at a common point, the center of moments may be taken at that point.

Should the section cut but two pieces, the center of moments for either piece may be taken at any point of the other.

Prob. 8. With the dimensions and apex loads given in Prob. 5 find the stress in *cd* of Fig. 1. (See Rem.)

Ans. + 1 ton.

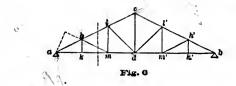

13

Prob. 9. With the dimensions and apex loads given in Prob. 6 find the stress in cd of Fig. 2. Ans. +1.2 tons.

Prob. 10. In a truss like Fig. 4 the span is 80 feet, the rise of truss is 20 feet, the rise of tie rod is 4 feet, the panel loads are each 4 tons: find the stresses in all the members.

ins. ak = +18.4 tons, kd = +10 tons, ah = -20.2 tons, hc = -18.4 tons, hk = -3.6 tons, kc = +9 tons, cd = 0 (only supports part of the tie rod).

Prob. 11. In Fig. 6 the span is 100 feet, the rise of truss

is 25 feet, the apex loads are 3 tons: find the stresses in all the members.

Ans. ah = -16.8, hl = -13.44, lc = -10.03, ak = +15, km = +15, md = +12, hk = 0 (only supports part of the tie), lm = +1.5, cd = +6, hm = -3.36, ld = -4.2.

Suc. - The stresses in the lower chords and in all the verticals except the center one are best found by the method of moments; the

stresses in the upper chords, and also in the diagonals, may be found by the method by resolution of forces, although the stresses in the diagonals are easily found by the method of moments, taking the center at a. To find the stress in cd it is best to pass a section around d and take vertical components, as in Probs. 8 and 9.

Prob. 12. A truss like Fig. 6 has 80 feet span, 20 feet rise, distance between trusses 12 feet, and weight of roof 20 lbs. per square foot of roof surface (see Prob. 1): find the dead load stresses in all the members, in tons.

Ans. ah = -11.5, hl = -9.21, lc = -6.9, ak = +10.28 = km, md = +8.22, hk = 0, lm = +1.03, cd = +4.11, hm = -2.3, id = -2.88.

Art. 7. Lever Arms — Indeterminate Cases. — In determining the stresses by the method of moments the only difficulty lies in finding the *lever arms* of the various pieces. These can always be found by the use of geometry and trigonometry. Thus, in Fig. 6, the lever arms for the lower panels are evidently the perpendiculars let fall upon these panels from each opposite upper apex. The lever arms for the upper panels are the perpendiculars drawn to these panels from each opposite lower apex. The lever arm for each brace is the perpendicular to the direction of the brace drawn from the left end a of the truss, where the rafter and tie intersect. This is evident from our rule in Art. 6.

Thus, in Fig. 6, suppose a section to cut hl, hm, and km. By our rule the center of moments for km is h, the point of intersection of the other two pieces 'l and hm. For hl the center is m, the intersection of hm and km. For hm the center is a, the intersection of hl and km.

For trusses in which the members have various inclina-

and *km*. point of or *hl* the *hm* the

inclina-

tions, all different, the computation of the lever arms is quite tedious. In such cases, it is sometimes advisable to make a careful drawing of the truss, and then measure the lever arms by scale. Indeed, this method can, in all cases, be used as a *check* upon the accuracy of the results obtained for the lever arm by computation.

If the section dividing the truss into two parts ents more than three members, the stresses in which are unknown, the problem is *indeterminate*, because there are more unknown quantities to be found than there are equations of condition between them. In such cases a fourth condition is sometimes found in the symmetry of the truss and loads.

Thus, if we pass a section through cl, cd, dl', and dm', Fig. 6, it ents more than three pieces. But the stress in dl'is equal to that in dl, by reason of the symmetry of the truss and loads. Even if this were not the ease, it could easily be found by working toward it from the right end. Then there remain only three unknown quantities, whose values can be determined by our three equations.

The section may cut any number of members, so long as it is possible to find independently the stresses in all but three. Any truss which violates this rule is improperly framed, and has *unnecessary* or *superfluous* pieces.

REMARK. — The half of each end panel load carried by the support does not affect the truss, and need not be taken into account in finding either ionds or reactions. Thus, in Fig. 5, the reaction and the half panel load acting at the support are equivalent to an upward force equal to their difference. This upward force is the reaction found by omitting the two apex loads at the supports, and is known as the *effective or working* reaction. Thus, instead of calling 20000 the reaction, and writing the equation

 $20000 \times 22^{\frac{1}{2}} - 5000 \times 22^{\frac{1}{2}} - s_1 \times 17^{\frac{1}{2}} = 0,$

as is done in the solution of Prob. 4, we call the reaction 15000 and write the equation as follows

$$15000 \times 22^{\frac{1}{2}} - s_1 \times 17^{\frac{1}{2}} = 0,$$

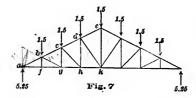

and so for all the other moment equations.

16

þ.

Prob. 13. A truss like Fig. 7 has 80 feet span, 20 feet rise, distance between trusses 12 feet, and weight of roof as

before (see Prob. 1): find the dead load stresses in all the members.

Here the dead apex load

$$=\frac{12\times80^{2}}{24\times8}+12\times20\sqrt{5^{2}+10^{2}}=3083$$
 lbs.

= 1.54 tons, say 1.5 tons.

Effective reaction $= 1.5 \times 3.5 = 5.25$ tons (see remark). To find fy = af, take moments around b.

 $5.25 \times 10 - fy \times 5 = 0$. $\therefore fg = +10.5$ tons.

To find gh take moments around c.

 $5.25 \times 20 - 1.5 \times 10 - gh \times 10 = 0$. $\therefore gh = +9$ tons.

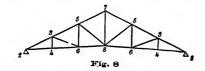

To find bg-pass section around g (see rem. of Art. 6).

$$10.5 + bg \times \frac{10}{11.18} - 9 = 0$$
. $\therefore by = -1.68$ tons; and so on

17

Ans. ab = -11.76, bc = -10.08, cd = -8.4, de = -6.72, af = +10.5, fg = +10.5, gh = +9, hk = +7.5, bf = 0 (only supports part of the tie rod), cg = +0.75, dh = +1.5, ck = +4.5, bg = -1.68, ch = -2.15, dk = -2.7.

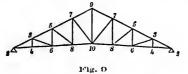

Prob. 14. In Fig. 8 the span is 60 feet, the rise of truss is 15 feet, the rise of tie rod at point \$ is 2 feet, the panel

loads are 1.5 tons, the struts 3-4, 5-6, 7-8 are vertical, dividing the rafter 2-7 into three equal parts: find the stresses in all the members.

Ans. Stress in 2-3 = -9.75, in 3-5 = -7.8, in 5-7 = -5.85, in 2-4 = +8.73, in 4-6 = +8.73, in 6-8 = +7, in 3-4 = 0 (only supports part of tie rod), in 5-6 = +0.75, in 7-8 = +3.7, in 3-6 = -1.85, in 5-8 = -2.24.

Prob. 15. In Fig. 9 the span is 90 feet, the rise of truss is 22.5 feet, the rise of tie rod is 3 feet, the struts, 3-4, 5-6,

7-8, and 9-10 are vertical, dividing the rafter into four equal parts; the apex loads are 2 tons: find the stresses in all the members.

n 15000 and

0 feet rise, of roof as

Ans. Stress in 2-3 = -20.34, 3-5 = -19.44, 5-7 = -18.54, 7-9 = -17.64, 2-4 = +18.3, 4-6 = +15.66, 6-10 = +9.3, 3-4 = -1.78, 5-6 = -3.56, 7-8 = -1.78, 4-5 = +2.64, 5-8 = +2.64, 6-8 = +6.84, 8-9 = +9.48, 9-10 = 0 (not necessary to stability of truss).

Art. 8. Snow Load Stresses. — The snow load is estimated per square foot of horizontal projection (Art. 3). If the main rafters of the truss are straight — as in all of our previous publems — the snow load is uniformly distributed over the whole roof, and the apex snow loads are all equal (see Art. 4); therefore the dead load and snow load stresses are proportional to the corresponding apex loads.

Thus, in Prob. 13, the dead panel load was 3083 lbs. and the snow panel load $= 10 \times 20 \times 12 = 2400$ lbs. Therefore if we multiply each dead load stross by $\frac{2400}{3000}$ (=.778), we shall have the corresponding snow load stress.

But if the main rafters are not straight, the snow load is not uni'ormly distributed over the whole roof, and the apex snow loads are not all equal; in such case, the snow load stresses have to be determined independently.

Thus, with the dimensions given in Fig. 12, for 9 feet between trusses, we have the apex snow load at b and at b'each equal to one half the panel load on ab plus one half the panel load on bc

 $= 6 \times 20 \times 9 = 1080$ lbs. = 0.54 ton.

20

The apex snow load at c equals one half the panel load on cb plus one half the panel load on cb'

$= 8 \times 20 \times 9 = 1440$ lbs. = 0.72 ton.

The stresses due to these apex snow loads may now be found in the same way as the dead load stresses were found in the preceding problems.

It is possible for one side only of a roof to be loaded with snow. This possibility is recognized in designing roofs of very large span, such as the roof of the Jersey City train shed of the Pennsylvania R.R. In special forms of trusses such a distribution of snow load may produce a maximum stress in some members.

Problem. With the dimensions and apex snow loads above given, find the snow load stresses in all the members of Fig. 12.

Ans. ab = -1.44, bc = -1.3, ad = +0.85, bd = +0.58, dh = +1.3, dc = +0.06.

Art. 9. Wind Loads. — One of the most important questions to be dealt with in the construction of roof-trusses is the pressure of the wind; for it is evident that the stability of such a structure depends upon its power of carrying not only the weight of the truss, roof, snow, etc., but also the pressure caused by the wind. In the case of large trusses, it will often be found that, notwithstanding the great weight of the structure, the stresses produced in some of the members by a gale of wind are almost or quite

panel load

ROOF TRUSSES.

· • .

21

• •

as great as those produced in the same pieces by the dead load. It appears, therefore, that in designing roofs, especially iron roofs of large span, a correct estimate of the wind loads is quite as important as a correct estimate of the dead loads.

And yet, the subject of wind forces is not well understood. It is hardly possible to define, with any precision, what degree of violence can be taken to represent the greatest wind storm that has to be provided against. In estimating the wind pressure and the resulting stresses in the members of a truss, the practice of engineers has varied greatly. Until recently, it has been considered in England sufficient to provide for a wind force of 30 to 40 lbs. per 'square foot of surface normal to its direction; while in this country the figures have been taken at 30 to 50 lbs. per square foot.

Taking the maximum wind pressure against a surface normal to its direction as 50 lbs. per square foot, we shall probably be on the side of safety.

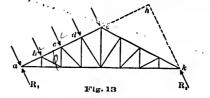

The following table gives the normal wind pressure per square foot in pounds for different inclinations of the roof equivalent to a horizontal wind pressure of 50 lbs. per square foot, calculated by Hutton's formula:

INCLIN.	Non. PRES.	INCLIN.	NOR. PRES.
10°	12.1 /	33° 30' (1	span) 36.6
15°	18.0	35°	37.8
20°	22.6	40°	41.6
21° 48/	(1 span) 25.2	45°	43.0
25°	28.8	50°	47.6
26° 34'	(1 span) 30.2	55°	49.5
30°	33.0	60°	50.0

For inclinations greater than 60° the normal pressure per square foot is 50 lbs. For intermediate inclinations we can find the pressures by interpolation.

 $\mathbf{22}$

Art. 10. Wind Apex Loads and Reactions. Let Fig. 13 represent a roof truss, its span being 100 fect, and its rise 25 feet; let the distance between trusses be 12 feet, and suppose the wind to be on the left side. Then the inclination of the rafter *ae* to the horizon = $\tan^{-1}\frac{1}{2}=26^{\circ}34^{\circ}$. Hence, from our table, the normal wind pressure per square

foot = 30.2 lbs. The total normal wind pressure on the side of the roof ae is therefore

 $= 30.2 \times 12 \times \sqrt{50^2 + 25^2} = 30.2 \times 12 \times 55.9 = 20258$ lbs.,

one fourth of which, or 5064.5 lbs., is the pressure on each panel. Hence the normal wind load at each apex b, c, d, is 5064.5 lbs., or say, in round numbers, 5000 lbs., or 2.5 tons, and at each apex a, and e, it is 2500 lbs., or 1.25 tons (Art. 4).

The Reactions caused by the wind pressure are inclined; the horizontal component of the wind tends to slide the entire truss off its supports. The weight of the truss and the roof are usually sufficient to eause friction enough to hold it in place. But if it is necessary, the truss should be fastened at its ends to the wall. Roof trusses of short span, and especially wooden trusses, have generally both ends fixed to the supporting walls. But large iron trusses have only one end fixed, while the other end is free, and resting upon friction rollers, so that it may move horizontally, tions. Let 00 feet, and a be 12 feet, Then the $a^{-1}\underline{1} = 26^{\circ} 34'$. a per square

ROOF TRUSSES.

23

under changes of temperature. We have then two cases: the first, when both ends are fixed; the second, when one end only is fixed, and the other end is free to move upon rollers.

CASE I. When both ends are fixed. — Let Fig. 13 represent a roof truss with both ends fixed, its span being 100 feet, its rise 25 feet, and the wind apex loads 1.25, 2.5, 2.5, 2.5, and 1.25 tons, as found above. In this case, the two reactions R_1 and R_2 are parallel to the normal wind loads, and may easily be found, as follows:

Let θ be the angle between the rafter and the lower ehord ak, and take moments about the left end a. We have then

 $R_{a} \times ah - (2.5 \times ab + 2.5 \times ac + 2.5 \times ad + 1.25 \times ae) = 0,$

or, we may take the resultant of all the loads, or 10 tons, acting at c,

 $\therefore R_2 \times 100 \cos \theta - 10 \times 27.95 = 0,$ $\therefore R_2 = 3.13 \text{ tons (since } \cos \theta = \frac{50}{56}).$

The reaction R_1 may be found by subtracting R_2 from the total wind load, giving us $R_1 = 6.87$ tons. Or, we may find R_1 by taking moments about the right end k. Thus,

 $R_1 \times ah - 10 \left(ah - ac \right) = 0,$

from which we get $R_1 = 6.87$ tons, as before.

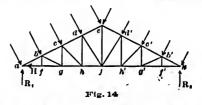

CASE II. When one end is fixed and the other is free. — (1) Suppose the right end of the truss to be free, and the wind blowing on the fixed side, as in Fig. 14. The right end of the truss is supposed to rest upon rollers, the support at a taking all the horizontal thrust due to the wind. This being the case, the reaction R_2 at the free end will be vertical, and the reaction at the fixed end will be inclined.

24

gives

To find R_2 take moments about a_3 ; let the dimensions and wind loads be the same as in Fig. 13. Thus,

Resolve the left reaction into its horizontal and vertical components, H and R_1 , thus,

$$\Sigma \text{ hor. comp.} = 0$$

10 sin $\theta - H = 0$. $\therefore H = 4.46$.

$$\Sigma$$
 ver. comp. = 0

gives $R_1 + 2.8 - 10 \cos \theta = 0$. $\therefore R_1 = 6.13$.

Or, we might find R_1 by taking moments about the right support; thus,

 $R_1 \times 100 - 10 (100 \cos \theta - 28) = 0$. $\therefore R_1 = 6.13$, as before.

(2) Suppose the wind to blow on the free side ek of the truss, Fig. 14. The reaction R_2 is vertical, as before, and the reaction at the fixed end a may be resolved into its horizontal and vertical components, in the same way as above. Thus, we find,

$H = 4...6, R_1 = 2.8, R_2 = 6.13;$

that is, when the wind changes from one side of a roof to the other, the horizontal component H has the same value as before, but acts in the opposite direction, and the reactions R_1 and R_2 interchange their values. nsions and

Prob. 18. A truss like Fig. 14 has its span 40 feet, rise 10 feet, and the total normal wind load on the fixed side 3.2 tons: find the wind load reactions.

Ans. $R_1 = 1.96$, $R_2 = 0.90$, H = 1.43 tons.

Prob. 19. A truss like Fig. 3 has its span 50 feet, its rise 12.5 feet, and the distance between the trusses 8 feet: find the reactions when both ends are fixed.

Ans. $R_1 = 2.32$, $R_2 = 1.06$ tons.

Prob. 20. A truss like Fig. 4, with one end free, has its s_{1} and 80 feet, its rise 20 feet, and the total normal wind load on the fixed side 5 tons: find the wind load reactions.

Ans. $R_1 = 3.07$, $R_2 = 1.4$, H = 2.23 tons.

Prob. 21. A truss like Fig. 4, with one end free, has its span 60 feet, rise of truss 12 feet, rise of tie rod 2 feet, and the total normal wind load on the fixed side 4.5 tons: find the wind load reactions.

Ans. $R_1 = 2.97$, $R_2 = 1.21$, H = 1.67 tons.

Prob. 22. A truss like Fig. 6, with one end free, has its span 90 feet, its rise 18 feet, and the total normal wind load on the fixed side 6 tons: find the wind load reactions.

Ans. $R_1 = 3.94$, $R_2 = 1.62$, H = 2.25 tons.

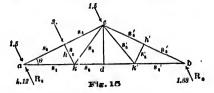

Art. 11. Wind Stresses. — (1) If the truss have both ends fixed, we must consider the wind blowing normally to the principal rafters on one side only (either side indifferently); and as the wind load is unsymmetrical to the roof, the wind stresses in the members on one side of the truss are different ...om those in the corresponding members on the other side, and hence they must be computed for every member in the truss.

(2) In trusses with one end fixed and the other free, we

26

must consider the wind blowing first on one side of the truss, and the γ on the other; and the stresses produced in the two cases will have to be computed.

Prob. 23. A truss like Fig. 15, with both ends fixed, has its span 50 feet, its rise 12.5 feet, and the wind loads and reactions as shown: find all the wind stresses.

We find ac = 27.95 feet, or, in round numbers, 28 feet; ak = 15.68 feet = kc; hk = 7 feet.

Representing the stresses by s_1 , s_2 , s_3 , s_4 , s_5 , and s_6 , and applying the principles of Arts. 5 and 6, we have for the left half of the truss:

$2.62 \times 14 - s_i \times 6.25 = 0,$	$\therefore s_i = +5.87$ tons.
$2.62 \times 28 - 3 \times 14 - s_2 \times 12.5 = 0,$	$\therefore s_2 = +2.51$ tons.
$2.62 \times 14 + s_3 \times 7 \qquad = 0,$	$\therefore s_3 = -5.24 \text{ tons} = s_4.$
$3+s_5 = 0,$	$\therefore s_s = -3.00$ tons.
$-3 \times 14 + s_6 \times 12.5 = 0,$	$\therefore s_6 = +3.36$ tons.

For the right half it is better to resolve the right hand reaction 1.88 into its horizontal and vertical components, thus,

$H = 1.88 \sin \theta = 0.84$, and $V = 1.88 \cos \theta = 1.68 \text{ tons}$,

and to state the equation of each piece including the external forces on the right of the section rather than on the left. Thus, le of the oduced in

 $\begin{array}{ll} 1.68 \times 12.5 - .84 \times 6.25 - s_1' \times 6.25 = 0, & \therefore s_1' = +2.52 \text{ tons.} \\ 1.68 \times 25 - .84 \times 12.5 - s_2' \times 12.5 = 0, & \therefore s_2' = +2.52 \text{ tons.} \\ 1.68 \times 15.68 + s_3' \times 7 = 0, & \therefore s_2' = -3.76 \text{ tons} = s_4', \\ s_3' = 0, & s_6' = 0. \end{array}$

Prob. 24. A truss like Fig. 15, with one end free, has its span 40 feet, its rise 10 feet, and the total normal wind load on the fixed side 3.2 tons: find all the wind stresses.

We must first find the reactions and horizontal component, as in Case II. Thus,

$R_1 = 1.96, R_2 = 0.9, H = 1.43.$

Ans. $s_1 = +3.6$, $s_2 = +1.8$, $s_3 = -2.8$, $s_4 = -2.8$, $s_5 = -1.6$, $s_6 = +1.8$, $s_1' = +1.8$, $s_3' = -2$, $s_4' = -2$, $s_5' = 0$, $s_6' = 0$.

Suc. — It will often be best to state the equation, using the external forces on the *right* of the section. Thus, to full the stress in s_2 . If we use the forces on the right of the section, the equation is

 $.9 \times 20 - s_2 \times 10 = 0$, $\therefore s_2 = 1.8$.

But if we use the forces on the left of the section, the equation is

 $1.00 \times 20 + 1.43 \times 10 - 32 \times 11.18 - s_2 \times 10 = 0$, $\therefore s_2 = 1.8$. Of course, to find the stresses in members near the left end, not so much is gained by using the forces on the right of the section.

Prob. 25. A truss like Fig. 4, with one end free, has its span 30 feet, its rise 15 feet, rise of tie rod 3 feet, and the total normal wind load on the fixed side 5 tow : find the wind stresses in all the members.

Ans. Stress in ak = +8.7, kd = +3.5, ah = -7.78, hc = -7.78, hk = -2.5, kc = +5.45, bk' = +4.36, bh' = -4.8, h'c = -4.8, h'k' = 0, ck' = +1.0, cd = 0 (not necessary to stability of structure).

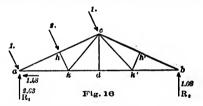

Prob. 26. A truss like Fig. 14, with one end free, has its span 80 feet, its rise 20 feet, and the total normal wind load

 $\overline{28}$

on the fixed side 8 tons: find the wind stresses in all the members.

Ans. Stress in af = +11.16 = fy, gh = +8.92, hj = +6.68, bg = -2.5, ch = -3.16, dj = -4.02, cg = +1.12, dh = +2.24, ej = +3.35, ab = -9, bc = -7.5, cd = -6.0, de = -4.5, kf' = f'g' = g'h' = h'j = +4.47, b'g' = c'h' = d'j = 0, b'f' = c'g'= d'h' = 0, kb' = b'c' = c'c' = d'e = -5.0 tons.

Prob. 27. A truss like Fig. 16, with one end free, has its span 60 feet, its rise 12 feet, the struts hk and h'k' normal

to the rafters at their middle points, and the total normal wind load on the fixed side ac 4 tous: find the wind stresses in all the members.

Ans. Stress in ak = +5.4, kd = +2.7, ah = -4.6 = hc, hk = -2, ck = +2.7, bk' = +2.7 = dk', bh' = -2.91 = ch', h'k' = 0 = ck'.

Prob. 28. In the same truss Fig. 16, with the same dimensions as given in Prob. 27, let the same normal wind load of 4 tons blow on the free side bc: find the wind stresses in all the members.

In this problem the values of the reactions are the same as those in Prob. 27, but interchanged, and the horizontal component has the same value, but act: in the opposite direction. See Case II. of Art. 10; therefore, here $R_1 = 1.08$. $R_2 = 2.63$, H = 1.48.

Art. 12. Complete Calculation of a Roof Truss. — By comparison of the values of the stresses in Prob. 27 with those in Prob. 28, we see that the stresses are quite different, and generally greater when the wind blows on the fixed side of the roof than when it blows on the free side. When the wind blows on the fixed side it tends to "flatten" the truss; and when it blows on the free side it tends to "shut up" the truss, or "double it up."

In the complete calculation of a roof truss, we must find the stresses due to the greatest dead load, and combine them with the greatest stresses due to the live load, so as to get the greatest possible tension and compression in each member. If the dead load and live load stresses in any piece are of the same character, both compressive or both tensile, we must add them to obtain the greatest scress in the piece. But if these stresses are of opposite characters, one compression and the other tension, their difference will be the resulting stress due to the combination of live and dead loads, and if the live load stress is less in amount than the dead load stress, it will only tend, when the wind blows, to relieve the stress due to the dead load by that amount, and the dead load stress is the maximum stress in the member. But if the live load stress is greater than the dead load stress and of an opposite character, it will cause a reversal of stress and this piece will then need to be counterbraced.

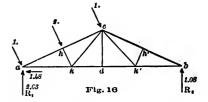

It is the customary American practice to determine the greatest stresses in each member of the fixed side of the roof truss which could be caused by the wind force acting

 $\overline{28}$

on the fixed side 8 tons: find the wind stresses in all the members.

Ans. Stress in af = +11.16 = fy, gh = +8.92, hj = +6.68, bg = -2.5, ch = -3.16, dj = -4.02, cg = +1.12, dh = +2.24, ej = +3.35, ab = -9, bc = -7.5, cd = -6.0, de = -4.5, kf' = f'g' = g'h' = h'j = +4.47, b'g' = c'h' = d'j = 0, b'f' = c'g'= d'h' = 0, kb' = b'c' = c'c' = d'e = -5.0 tons.

Prob. 27. A truss like Fig. 16, with one end free, has its span 60 feet, its rise 12 feet, the struts hk and h'k' normal

to the rafters at their middle points, and the total normal wind load on the fixed side ac 4 tons: find the wind stresses in all the members.

Ans. Stress in ak = +5.4, kd = +2.7, ah = -4.6 = hc, hk = -2, ck = +2.7, bk' = +2.7 = dk', bh' = -2.91 = ch', h'k' = 0 = ck'.

Prob. 28. In the same truss Fig. 16, with the same dimensions as given in Prob. 27, let the same normal wind load of 4 tons blow on the free side bc: find the wind stresses in all the members.

In this problem the values of the reactions are the same as those in Prob. 27, but interchanged, and the horizontal component has the same value, but acts in the opposite direction. See Case II. of Art. 10; therefore, here $R_1 = 1.08$, $R_2 = 2.63$, H = 1.48. ROOF TRUSSES.

those in has the Art. 10;

normally to the truss on the fixed side only, and then to build the members of the two sides of the truss of the same size. Since the stresses caused by the wind blowing on the fixed side of the roof are at least as great as those caused by the wind blowing on the free side, this arrangemengives the maximum stresses, and is on the safe side; and for reasons of economical manufacture both sides of the truss are constructed alike.

Prob. 29. A truss like here 14, with one end free, has its span 80 feet, its rise 16 deet, distance apart of trusses 16 feet, rafter divided into four equal parts, struts vertical, dead load of roof 20 lbs. per square foot of roof surface, snow load 20 lbs. per square foot of horizontal projection, normal wind load on fixed side by table of Art. 9: find the dead load, snow load, wind load, and maximum stresses in all the members.

From the given rise and span we have the length of one half of roof $ae = \sqrt{40^2 + 16^2} = 8\sqrt{29} = 43.08$ fect.

Weight of truss $=\frac{1}{24}bl^2$ (Art. 2) $=\frac{16 \times (80)^2}{24} = 4266$ lbs. Dead panel load $=\frac{4266}{8} + \frac{43.08 \times 16 \times 20}{4} = 3977$ lbs.

 $\frac{8}{4} = 1.9885 \text{ tons, Cr say, 2 tons.}$

Snow load per panel = $10 \times 16 > 200$ lbs.=1.6 tons. Inclin. of roof = $\tan^{-1} \cdot 4 = 21^{\circ} 48'$.

Nor. pressure of wind per sq. foot (table of Art. 9)=25.2 lbs.

Nor. wind load per panel = $25.2 \times \frac{43.08}{4} \times 16$

= 4342 lbs. = 2.171 tons, or say, 2.2 tons.

From these data the dead load, snow load, and wind load stresses (wind on the fixed side only) may be computed,

v, 2.2 tons. wind load computed,

dead load, snow load, and wind load stresses, giving the greatest total tension and the greatest total compression. Of course, the wind stresses in the members of the other half of the truss will be less than those above given for the members of the half on the windward side, and therefore, the maximum stresses in these members will be less than those in the above table, since the dead and snow load stresses in the corresponding members of the fixed and free sides of the truss are the same.

If there is no wind blowing, the maximum stresses are found by adding together the dead load and snow load stresses. If there is neither wind nor snow the dead load stresses are also the maximum stresses. If the wind blows on the free side of the truss, the maximum stresses cannot exceed those found above.

Prob. 30. A truss like Fig. 9, with one end free, has its span 90 feet, rise of truss 18 feet, rise of tie rod 3 feet, rafter divided into four equal parts, struts vertical, dead load per panel 2 tons, snow load per panel 1.5 tons, normal wind load per panel, wind on fixed side, 2.25 tons: find the dead load, snow load, wind load, and maximum stresses in all the members of the half of the truss on the windward side,

Here the effective reaction for dead load

ROOF TRUSSES.

87

When the members of a truss have many different inclinations, as, for example, in the Crescent Truss and Arch Truss, the calculation of the stresses by the method of moments and the method by resolution of forces (Art. 6), becomes very tedions, owing to the difficulty in finding the lever arms, or the sines and cosines. In practice the graphic method is often used for determining the stresses in such trusses; but if the analytic method is preferred to the graphic, the truss should be drawn to a large scale, and all the lever arms and sines and cosines be scaled from the diagram.

The present chapter is but a brief treatise on roof trusses. The student who desires to continue the subject further is referred to more extended works, such as "Strains in Framed Structures," by Du Bois, and "Theory and Practice of Modern Framed Structures," by Johnson, Bryan, and Turneaure.

CHAPTER H.

BRIDGE TRUSSES WITH UNIFORM LOADS.

Art. 13. Definitions. — A Bridge is a structure for earrying, moving loads over a body of water, or over a depression in the earth. For railroad and highway accommodations, it connects two roads so as to form a continuous road. A framed bridge, or trassed bridge is composed of two or more trusses, which lie in vertical planes, para.'el to the line of the road. A bridge truss, like a roof truss, consists of the upper and lower chords and the web members. The upper chord of a simple* bridge truss is in compression, and the lower is in tension, while the web members are some in compression and some in tension. The trusses are united by lateral bracing, attached to the panel points of either the upper or lower chords, or both. The object of this lateral bracing is to support the trusses sideways, and stiffen the structure against the action of the wind.

The Floor, or Floor System, of a bridge consists of the *floor beams, stringers,* and *flooring.* The *floor beams* run at right angles with the chords, and are connected to them at the panel points. The *stringers* frame into or rest upon the floor beams, and are parallel to the chords, and support the flooring of a highway bridge, or the cross ties and rails of a railroad bridge.

• This is true only for simple trusses, and not for cantilever trusses, continuous trusses, or trusses of draw spans.

38

BRIDGE TRUSSES.

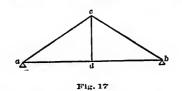

89

A Through Bridge is one in which the roadway is supported by the bottom chords, with lateral bracing overhead between the top chords.

A Deck-bridge is one in which the roadway is supported by the top chords; the trusses are usually placed nearer to each other than on through bridges, the roadway extending over them.

When a through bridge is not of sufficient height to allow of the upper lateral bracing, the trusses are called *Pony Trusses*. Such trusses are necessarily short; they are "stayed" by bracing connected with the floor system.

Art. 14. Different Forms of Trusses. — The Kingpost Truss is a term applied to a truss in which there is a central vertical tie and two braces resting against it, as in Fig. 17. It was formerly built for country highway bridges

of short span. The term "king- ρ ost" is an old one, and came into use when the central piece was made of wood, and resembled a *post*, although its office was that of a *tie*; this tie is now usually a wrought iron rod. The load at the center *d* is carried by the tie up to the apex *c*, and then by the two inclined braces *ca* and *cb* down to the abutments, *a* and *b*.

The Queen-post Truss is a truss in which there are two vertical *ties* against which rest two braces, as in Fig. 18.

)ADS.

e consists of or beams run ected to them or rest upon and support ties and rails

ntilever trusses,

40

This is also an old term and has become familiar with long use. It is sometimes called a *trapezoidal truss*. The panel

loads at h and k are carried up the ties to c and d, and then by the two inclined struts ca and db down to the abutments, a and b.

The Howe Truss, Fig. 19, has its vertical members in tension and the inclined ones in compression; the diagonal counter struts are in by ken lines. The chords and diagonal

Flg. 10

web members are of wood, and the vertical ties of iron. This truss was patented in the United States in 1840 by William Howe. It has proved the most useful style of bridge truss ever devised for use in a new and timbered country. It is still very largely used where timber is cheap, for both highway and railway bridges.

The Pratt Truss, Fig. 20, has its vertical members in compression and the inclined ones in tension. All the

Fig. 20

members of this truss are of iron or steel; though it was formerly built all of wood, except the diagonal ties, which with long The panel

es of iron. n 1840 by il style of l timbered timber is

embers in All the

ugh it was ies, which

BRIDGE TRUSSES.

41

were of wrought iron. The Pratt truss is a favorite type, and is used more than any other kind. Figure 20 shows a *deck*-bridge. The deck or through Pratt truss is the standard form of truss for both highway and railway bridges of moderate spans, though it is not generally used for railway bridges in which the span is much less than 100 feet.

The Warren Truss, or Warren Girder, has all its web members inclined at equal angles, some of them being in tension and some in compression. This truss is an example of the pure triangular type. Its web members consist always of *equilateral triangles*. When the triangles are not equilateral, the truss is simply a "triangular truss."

Fig. 21

Figure 21 shows a Warren truss as a *deck* truss. The Warren truss is generally built all of iron or steel, and is used for comparatively short spans; it is of more frequent occurrence in England than in this country.

The Double Triangular, or Double Warren Truss (or Girder), Fig. 22, has each panel braced with two diagonals intersecting each other, and forming a single lattice.

F1g. 22

Other forms of trusses will be explained as we proceed. All these forms of trusses, and bridge trusses generally, may be arranged so as to be used either for deck-bridges or through bridges.

42

Art. 15. The Dead Load, or permanent load, consists of the entire weight of the bridge. It includes the weight of the trusses, the lateral bracing, and the floor system. In highway bridges, the floor system consists of the floor beams, which are supported by the chords at the panel points, the stringers, which are supported by the floor beams, and the planks, which are supported by the stringers. In railway bridges the stringers support the cross ties, rails, guardrails, spikes, etc. The dead load depends upon the length of the bridge, its width, its style, and upon the live loads it is intended to carry. For highway bridges with plank floors the total dead load per foot may be found approximately by the following formula:

w = 150 + cbl + 4 bt,

where w = weight in pounds per linear foot of bridge.

l =length of bridge in feet,

- b = width of roadway in feet,
- t = thickness of planking in inches,

 $c = \frac{1}{2}$ for heavy city bridges,

- = $\frac{1}{k}$ for ordinary city or suburban bridges,
- = $\frac{1}{2}$ for light country bridges.

For single track railroad bridges the dead load per linear foot is given very closely by the following formulæ (taken from "Modern Framed Structures," by Johnson, Bryan, and Turneaure, p. 44).

For deck-plate girders,

w = 9l + 520.	•	•	•	•	•	•	(1)
For lattice girders,

dge.

,es

per linear ılæ (taken on, Bryan,

(1)

(2)

" ... DGE TRUSSES. For through pin-connected bridges, w = 5l + 750 (3)

For Howe trusses, w = 6.5l + 675 (4) where *l* is the span in feet, and *w* the dead load in pounds

43

per linear foot. These four formulæ give dead loads of iron railway bridges, including an allowance of 400 lbs. per foot for the weight of track material, for bridges designed to carry 100-ton locomotives. For lighter locomotives the dead load would be less, and for heavier locomotives it would be more. For double track bridges add 90 per cent to the above values;* for the load on each truss take one half the above values.

Prob. 34. What is the weight of a Warren truss bridge 105 feet long?

Here we may find the dead load from formula (2), as follows:

Dead load per linear foot

= w = 7 l + 600 = 1335 lbs.

 \therefore weight of bridge = $1335 \times 105 = 140,175$ lbs. and weight of bridge to be carried by one truss

= 70087.5 lbs.

Prob. 35. What is the weight of a through pin-connected bridge of 100 feet span?

Ans. 125,000 lbs.

Prob. 36. What is the weight of a Howe truss bridge of 144 feet span?

Ans. 231,984 lbs.; or 115,992 lbs. per truss.

*For double track bridges the weight of the metal work is about 90% greater than for a single track; but the weight of the track material is just double that for a single track bridge.

44

Art. 16. The Live Load, or moving load, is that which moves over the bridge, and consists of wagons and foot passengers on highway bridges, and trains on railway bridges.

For highway bridges, the live load is usually taken as a uniform load of from 50 to 100 lbs. per square foot of roadway, or the heaviest concentrated load, due to a road-roller, which is likely to come upon the bridge. The trusses of highway bridges are usually found to receive the greatest stresses from a densely packed crowd of people, while the floor system usually receives the greatest stresses from the concentrated load. The following are the live loads specified by Waldell, per square foot of floor:

Span of liridge.	City and Subarban Bridges.	Country Bridges.				
0 to 50 feet.	100 lbs.	90 lbs.				
50 to 150 feet.	90 lbs.	80 lbs.				
150 to 200 feet.	80 lbs	70 lbs.				
200 to 300 feet.	70 lbs.	60 lbs.				
300 to 400 feet.	60 lbs.	50 lbs.				

The live load per panel of a highway bridge may then be found by nultiplying the width of roadway including the sidewalks by the product of the load per square foot with the panel length.

For railway bridges the live load is o. en specified as the weight of two of the heaviest locomotives which we think will ever pass over the bridge, and followed by a uniform load due to the heaviest possible train.

In English, and sometimes in American practice, it is considered sufficiently accurate to use the corresponding *uniformly distributed* load which causes the same stresses in the chords as those which result from the above concentrated locomotive loads. BRIDGE TRUSSES.

45

The following equivalent uniformly distributed live loads per linear foot of track, produce approximately the same stresses as the above concentrated loads.

Span, 10, 20, 30, 40, 50, 100, 200, 300 feet.

Load, 10,000, 6600, 5500, 4900, 4600, 4000, 3700, 3500 lbs.

This loading is very nearly that used by the Pennsylvania Railroad. The Erie Railroad uses a live load one fifth greater; and the Lehigh Valley Railroad a live load one third greater.

The live load is taken greater for short spans than for long ones, because if the span is short one or two locomotives may eover the whole bridge, while if the span is long, the whole bridge would not often be loaded with more than a train drawn by one or two locomotives. 'The calculations of the stresses are made in precisely the same way for railway as for highway bridges, so long as the live load is uniform.

In the use of equivalent uniform loads, the following precautions are to be observed: In obtaining the stresses in the chords and the main web members, the equivalent load corresponding to the length of the *truss* is to be used. But in such members as receive a maximum stress from a single panel load, another equivalent load must be used. Thus, in the "hip verticals" of a Pratt truss, Fig. 30, or in the "vertical suspenders" of a Warren truss, Fig. 35, the maximum stress is obtained by using the equivalent load corresponding to a span of two panel lengths.

Prob. 37. A bridge for a city has its roadway 20 feet wide in the clear, and also two sidewalks, each 6 feet wide in the clear. The span is 200 feet and there are 10 panels. Find the live panel load per truss.

Ans. 5.4 tons.

Art. 17. Shear — Shearing Stress. — Let Fig. 23 represent a beam fixed horizontally at one end and sustaining a

load P at the other end. Imagine the beam divided into vertical slices or transverse sections of small thickness. The weight P tends to separate or shear the section or slice on which it immediately rests from the adjoining one. The lateral connection of the sections prevents this

separation, and the second section or slice is drawn by a vertical force equal to the weight P which tends to slide or shear it from the third section, and so on. Thus, a vertical force equal to the weight P is transmitted from section to section throughout the length of the beam to the point of support. This vertical force is called the "shearing force," or "shear"; and the equal and opposite internal force or stress in the section that balances it is called the "shearing stress."

The shear then at any section is that force which tends to make that section slide upon the one immediately following.

The vertical shear at any section is the total vertical force at that section, and it is equal to the sum of the vertical components of all $l \in$ external forces acting upon the beam on either side of the section.

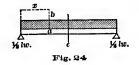

Thus, let Fig. 24 represent a beam l feet long, resting horizontally on supports at its extremities; and let the

46

BRIDGE TRUSSEL.

47

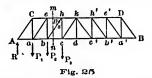

beam have a uniform load of w lbs. per foot. Consider a section ab at any distance x from the left end. Then, the reaction at each support is $\frac{1}{4}wl$; the shear in the section ab is the weight that is between that section and the center

of the beam, or $(\frac{1}{2}l - x)w$, since this is the total vertical force at ab, which is the shear by definition; but this is the same as the algebraic sum of the vertical components on the left side of ab.

For the algebraic sum of the vertical components on the left of the section $ab = \frac{1}{2} lw - xw$, or $(\frac{1}{2}l - x)w$.

Art. 18. Web Stresses due to Dead Loads – Horizontal Chords. – Let *ABCD* be a truss with horizontal

chords* AB, CD, and let a section mn be drawn in any panel bc cutting the diagonal bh and the two chords, and let θ be the angle which the diagonal makes with the vertical. Then (Art. 5) the stresses in these three members must be in equilibrium with the external forces on the left of the section; and therefore the algebraic sum of the

h tends to owing. tical force tical combeam ou

g, resting d let the

vertical components of these forces equals zero. Hence, ealling S the stress in the diagonal bh, we have

$$R - P_1 - P_2 + S\cos\theta = 0. (1)$$

But $R - P_1 - P_2$ is the vertical shear for the given section mu (Art. 17).

Hence (1) becomes

48

Shear +
$$S\cos\theta = 0$$
;

 $\therefore S = - \text{ shear sec } \theta. \quad . \quad . \quad . \quad (2)$

Therefore, for horizontal chords and vortical loads, the stress in any web member is equal to the vertical shear multiplied by the secant of the angle which the member makes with the vertical.

Since the shear in the section cutting hc is the same as that in the section mn, no load being at h, therefore the stress in Ch is equal to the shear in ch, that is, equal to the shear in the panel bc. Since there are no loads between the joints b and c, the shear is constant throughout the panel bc; and we usually speak of it as the shear in the panel bc.

It will be observed from (2) that, for the diagonal bh, the stress is negative, or compressive, provided that the shear is positive; but for the dead load the shear is always positive in sections left of the middle of the truss. Hence the stress in b^{-} is compressive, and so for all the other diagonals in th. left half of the truss, since they are all inclined in the same direction, that is, downwards toward the left. Conversely, for members inclining downwards toward the right, in the left half of the truss, the stresses are positive or tensile.

Prob. 39. A through Howe truss, like Fig. 25, has 8 panels, each 15 feet long, and 20 feet deep: find all the

BRIDGE TRUSSES.

49

web stresses due to a dead load of 450 lbs. per linear foot per truss.

Panel load
$$=\frac{450 \times 15}{2000} = \frac{27}{8} = 3.38$$
 tons.
Reaction $=\frac{27}{8} \times \frac{7}{2} = \frac{189}{16} = 11.8$ tons,

which is also the shear in panel Aa. The shear in each of the other panels is found by subtracting from the reaction the loads on the left of the panel.

see
$$\theta = \frac{\sqrt{15^2 + 20^2}}{20} = \frac{5}{4} = 1.25$$

The secant for the verticals = 1. We have then the following stresses for the *diagonals*:

Stress in $AC = -11.8 \times 1.25 = -14.8$ tons. Stress in ae = -(11.8 - 3.38)1.25 = -10.5 tons. Stress in bh = -(11.8 - 6.76)1.25 = -6.3 tons. Stress in ck = -(11.8 - 10.14)1.25 = -2.1 tons.

For the verticals:-

Stress in aC = +11.8 tons. Stress in be = +8.4 tons. Stress in ch = +5.1 tons. Stress in dk = +3.4 tons.

This last value is found by passing a section around d cutting dc, dk, dc' (see Rem. of Art. 5), and taking vertical components.

Prob. 40. A deck Pratt truss, like Fig. 20, has 12 panels, each 6 feet long, and 6 feet deep: find all the web stresses due to a dead load of 500 lbs. per linear foot per truss.

Ans. Stresses in verticals

= -8.25, -6.75, -5.25, -3.75, -2.25, -1.50 tons. Stresses in diagonals

Prob. 41. A through Warren truss, Fig. 26, has 10 panels, each 10 feet long, its web members all forming equilateral

triangles (Art. 14): find the stresses in all the web members due to a dead load of 400 lbs. per linear foot per truss.

Ans. Stresses in 1-2, 3-4, 5-6, 7-8, 9-10 are -10.38, -8.08, -5.76, -3.46, -1.14 tons.

Stresses in 1-4, 3-6, 5-8, 7-10, 9-12, are +10.38, +8.08, +5.76, +3.46, +1.14 tons; that is, the signs alternate in the web members.

Art. 19. Chord Stresses due to D₂ad Loads --Horizontal Flanges.

(1) To find the chord stresses by the method of moments.

Pass a section cutting the chord member whose stress is required, a web member, and the other chord, and take the center of moments at the intersection of the web member and the other chord. Then, supposing the right part of the truss removed, state the equation of moments between the unknown stress and the exterior forces on the left of the section. For stresses in the upper chord members the centers of moments are at the lower panel points; and for stresses in the lower chord members the centers are at the upper chord points.

Thus, in Prob. 41, each panel load is 2 tons, and each reaction is therefore 9 tons; the depth of the truss is $10 \sin 60^\circ = 8.66$ feet. Hence for the lower chord stresses, we have:

ıs 10 panels, 5 equilateral

 $9 \times 5 - \text{stress}$ in $2 - 4 \times 8.66 = 0$; :. Stress in 2-4 = +5.20 tons. $9 \times 15 - 2 \times 5 - \text{stress in } 4 - 6 \times 8.66 = 0;$ \therefore Stress in 4-6 = + 14.43 tons. $9 \times 25 - 2(15 + 5) - \text{stress in } 6 - 8 \times 8.66 = 0;$:. Stress in 6-8 = +21.36 tons. $9 \times 35 - 2 \times 45 - \text{stress in } 8-10 \times 8.66 = 0;$ \therefore Stress in 8-10 = + 25.98 tons. $9\times45-2\times80-$ stress in 10–12 $\times8.66=0$; :. Stress in 10-12 = +28.28 tons; and for the upper chord stresses, we have: $9 \times 10 - \text{stress in } 1 - 3 \times 8.66 = 0;$ \therefore Stress in 1-3 = -10.38 tons. $9 \times 20 - 2 \times 10 - \text{stress in } 3-5 \times 8.66 = 0;$ \therefore Stress in 3-5 = -18.48 tons. $9 \times 30 - 2(20 + 10) - \text{stress in } 5-7 \times 8.66 = 0;$:. Stress in 5-7 = -24.24 tons. $9 \times 40 - 2 \times 60$ - stress in 7-9 × 8.66 = 0; \therefore Stress in 7-9 = - 27.70 tons. $9 \times 50 - 2 \times 100 - \text{stress in } 9 - 9 \times 8.66 = 0;$

 \therefore Stress in 9-9 = - 28.86 tons.

(2) By the method of chord increments.

Let it be required to find the stress in the chord member 6-8, Fig. 26. Denote the vertical shears in the web members 2-1, 1-4, 4-3, etc., by v_1 , v_2 , v_3 , etc., and the angles these members make with the vertical by θ_1 , θ_2 , θ_3 , etc. Now pass a curved section enting the chord member 6-8 and all the web members on the left. Then from the first

condition of equilibrium the sum of the horizontal components is zero. But the horizontal component of the stress in any web member is equal to the vertical shear in that member multiplied by the tangent of its angle with the vertical. Hence we have:

Stress in 6-8

52

$= \sum_{i=1}^{n} \tan \theta_1 + v_2 \tan \theta_2 + v_3 \tan \theta_2 + v_4 \tan \theta_4 + v_5 \tan \theta_3.$

Therefore, to find the stress in any chord member, pass a curved section enting the member and all the web members on the left, multiply the vertical shear in each web member by the tangent of its angle with the vertical, and take the sum of the products.

From an inspection of Fig. 26 it is seen that the stress in any chord member, as 4-6 for example, is greater than the stress in the immediately preceding chord member, 2-4, by the sum of the horizontal components of the stresses in the web members, 1-4 and 4-3, intersecting at the panel point between these two members; That is, the increment of chord stress at any panel point is equal to the sum of the horizontal components of the web stresses intersecting at that point; or, equal to the sum of the products of the vertical shears of these web members by the tangents of their respective angles with the vertical.

It is well to test the stress found by this method by the method of moments, as the results obtained by the two methods should agree; and this affords a check on the work.

The method by chord increments applies only to *kori*zontal chords, while the method by moments applies to trusses of any form, that is, when the chords are not horizontal as well as when they are.

Prob. 42. Let it be required to find the chord stresses in Prob. 41 by the method of chord increments. izontal comment of the ical shear in s angle with

ord stresses in

BRIDGE TRUSSES.

53

Here each panel load is 2 tons, and all the web members are inclined at an angle of 30°;

 $\therefore \tan \theta_1 = \tan \theta_2 = \text{etc.} = \tan 30^\circ = .5773.$

Hence for the lower chord stresses we have:

Stress in $2-4 = 9 \times .5773 = + 5.20$. Stress in $4-6 = (9 + 9 + 7) \times .5773 = + 14.43$. Stress in $6-8 = (9+9+7+7+5) \times .5773 = + 21.36$. Stress in $8-10 = (32+5+5+3) \times .5773 = + 25.98$. Stress in $10-12 = (42+3+3+1) \times .5773 = + 28.29$;

and for the upper chord stresses we have:

Stress in $1-3 = -(9+9) \times .5773 = -10.39$. Stress in $3-5 = -(18+2\times7) \times .5773 = -18.47$. Stress in $5-7 = -(32+2\times5) \times .5773 = -24.25$. Stress in $7-9 = -(42+2\times3) \times .5773 = -27.71$. Stress in $9-9 = -(48+2\times1) \times .5773 = -23.86$.

Prob. 43. Find all the chord stresses in the deck Pratt truss of Prob. 40.

Ans. Stresses in lower chords

= + 8.25, +15.0, +20.25, +24.0, +26.25 tons. Stresses in upper chords

= -8.25, -15, -20.75, -24, -26.25, -27.0 tons.

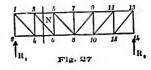

Prob. 44. A through Howe truss, like Fig. 25, has 12 panels, each 10 feet long, and 10 feet deep: find the stresses in all the members due to a dead load of 400 lbs. per linear foot per truss.

Ans. Lower ehords = 11.0, 20.0, 27.0, 32.0, 35.0, 36.0 tons. Verticals = 11.0, 9.0, 7.0, 5.0, 3.0, 2.0 tons. Diagonals = 15.5, 12.68, 9.86, 7.04, 4.22, 1.4 tons.

Of course the upper chord stresses can be written directly from those of the lower chord by (1) of Art. 5.

54

Art. 20. Position of Uniform Live Load Causing Maximum Chord Stresses.— Let Fig. 27 be a truss sup-

ported at the ends. Then to find the stress in any chord member, we pass a section cutting that member, a web member, and the other chord, and take the center of moments at the intersection of the web member and the other chord; and since the lever arm for the chord is constant, the stress in any chord member will be greatest when the live load is so arranged as to give the greatest bending moment.

Now suppose we have a uniformly distributed moving load coming on the truss from the right, till it produces the left abutment reaction R_1 ; then any increase in the load on the right of the section N will affect the forces on the left only by increasing the reaction R_{i} , and consequently the bending moment. Hence, as R_1 increases with every load added to the right of N, the bending moment increases, and therefore the chord stress also increases. Also, suppose we have a uniformly distributed moving load covering the truss on the left of the section producing the right abutment reaction R_2 ; then any increase in the load on the left of the section N will affect the forces on the right only by increasing the reaction \mathcal{A}_{2} , and consequently the bending moment. Hence every load, whether on the right or left of the section, increases the bending moment, and therefore the chord stress.

a truss sup-

in any chord nber, a web 10 center of 10 and the chord is congreatest when itest bending

nted moving produces the a the load on s on the left sequently the th every load acceases, and o, suppose we ring the truss flat abutment the left of the ly by increasling moment. ft of the secfore the chord

BRIDGE TRUSSES.

55

Therefore, for a uniform load, the maximum bending moment at any point, and consequently the maximum chord stress in any member, occurs when the live load covers the whole length of the truss.

To determine the chord stresses then due to a uniform live load, we have only to suppose the live load to cover the whole truss, just as the dead load does, and compute the chord stresses in exactly the same way as we compute the dead load stresses.

Prob. 45. A through Warren truss, like Fig. 26, has 8 panels, each 8 feet long: find the stresses in all the chord members due to a live load of 1000 lbs. per linear foot per truss.

Ans. Upper chord stresses=16.16, 27.72, 34.64, 36.96 tons. Lower chord stresses= 8.08, 21.92, 31.20, 35.80 tons.

Prob. 46. A deck Pratt truss has 11 panels, each 11 feet long, and 11 feet deep: find all the chord stresses due to a live load of 800 lbs. per linear foot per truss.

Ans. Upper chord stresses

= 22.0, 39.6, 52.8, 61.6, 66.0, 66.0 tons.

Art. 21. Maximum Stresses in the Chords.—According to the principles of the preceding Article the stresses in the chords will be greatest when both dead and live loads cover the whole truss. We have then only to determine the stress in each chord member due to the dead and live loads, as in Arts. 19 and 20, and take their sum; or, we may add together at first the dead and live panel loads, and determine the maximum stress in each chord member directly. This method is the simplest and shortest; but it is not the one which in practice is generally employed.

All modern specifications require a separation of dead and live load stresses. One type of specification permits twice the allowable stress per square inch of metal for dead load that it permits for live load; thus 10,000 lbs, per square inch for live load stresses and 20,000 lbs, per square inch for dead load stresses. So that if a tension member has a live load stress of 100,000 lbs, and a dead load stress of 50,000 lbs., the sectional area is determined as follows:

$$\frac{100000}{10000} = 10 \text{ sq. n.} \qquad \frac{50000}{20000} = 2\frac{1}{2} \text{ sq. in.}$$

That is, $12\frac{1}{2}$ square inches are required for the sectional area of the member.

Another type of specification requires the sectional area to be determined by a consideration of the minimum and maximum stresses. Thus, for tension members, the allowable stress is

$$10000 \left(1 + \frac{\min. \text{ stress}}{\max. \text{ stress}}\right)$$
 lbs. per square inch.

In the above case the allowable stress would be

$$10000\left(1 + \frac{50000}{150000}\right) = 13333$$
 lbs. per square inch.

Prob. 47. A deck Howe truss, for a railroad bridge, Fig. 28, has 12 panels, each 12 feet long, and 12 feet deep; the

dead load is given by formula (4), Art. 15, the live load is 1500 lbs. per linear foot per truss: find the maximum chord stresses.

Here we have the dead panel load per truss from fornula (4)

 $=\frac{(6.5 \times 144 + 675)12}{2} = 9666 \text{ lbs.} = 4.833 \text{ tons, say 5 tons.}$ Live panel load per truss $=\frac{1500 \times 12}{2000} = 9 \text{ tons.}$

57

We have then at each upper apex a load of 5+9=14 tons, from which the maximum chord stresses may be computed directly.

Ans. Maximum stresses in lower chord

= 77, 140, 189, 224, 245, 252 tons.

The upper chord stresses can be written from the lower by (1) of Art. 5.

Prob. 48. A deck Howe truss has 11 panels, each 11 feet long, and 11 fect deep; the dead load is 400 lbs. per foot per truss, and the live load is 1200 lbs. per foot per truss: find the maximum chord stresses.

Ans. Lower chord stresses

= 44.0, 79.2, 105.6, 123.2, 132, 132 tons.

The upper chord stresses for the Howe and Pratt trusses equal the lower chord stresses with contrary signs, (1) of Art. 5; also, all the chord stresses in the Howe and Pratt are the same, no matter on which chord the loads may be placed.

Art. 22. Position of Uniform Live Load Causing Maximum Shears. — (1) For a uniform live load the maximum positive shear at any point N, Fig. 27, occurs when every possible load is added to the right and when there is no load on the left; for the shear at this point N is then equal to the left reaction R_1 , and adding a load to the right increases the left reaction R_1 and therefore the positive shear, while adding a load to the left decreases the positive shear. Hence the maximum positive shear at any point occurs when the live load extends from that point to the remote abutment.

(2) Let a uniform live load be placed on the left of N, producing the left reaction R_1 . Now this reaction R_1 is

and and live he allowable mits for live stresses and t if a tension load stress of

l area of the

l area to be num stresses.

live load is imum chord

ss from for-

, say 5 tons.

marine 1

tons.

only a part of the weight of the live load, while the shear is this reaction minus the whole weight of the load, and is therefore *negative*; and every load added to the left of this point increases numerically this negative shear. Hence the maximum negative shear at any point occurs when the live load extends from that point to the nearest abutment.

Prob. 49. Find the greatest positive and negative shears for each panel of Fig. 27 when the apex live load is 9 tons.

By the principle just proved, the greatest positive live load shear in any panel occurs when all joints on the right are loaded, the joints on the left being unloaded. Hence, for greatest positive shear in 1-3 the truss is fully loaded. We have then

Positive shear in $1-3 = 9 \times 2\frac{1}{2} = 22.5$ tons.

There is no negative shear in 1-3.

For greatest shear in 3-5 all joints except 3 are loaded. Taking moments about right end, we have

Positive shear in
Negative shear in $3-5 = R_1 = 9(\frac{1}{6} + \frac{2}{6} + \frac{4}{5} + \frac{4}{5}) = 15$ tons. $3-5 = R_1 - 9 = 9 \times \frac{5}{6} - 9 = 7.5 - 9$ = -1.5 tons,

or, negative shear in $3-5 = -9 \times \frac{1}{6} = -1.5$ tons, as before. Likewise,

 Positive shear in
 $5-7 = \frac{9}{6}(1+2+3) = 9$ tons.

 Negative shear in
 $5-7 = -\frac{9}{6}(1+2) = -4.5$ tons.

 Positive shear in
 $7-9 = \frac{9}{6}(1+2) = 4.5$ tons.

 Negative shear in
 $7-9 = -\frac{9}{6}(1+2+3) = -9.0$ tons.

 Positive shear in
 $9-11 = \frac{9}{6} \times 1 = 1.5$ tons.

 Negative shear in
 $9-11 = -\frac{9}{6}(1+2+3+4) = -15$ tons.

 Negative shear in
 $11-13 = -\frac{9}{6}(1+2+3+4) = -15$ tons.

= -22.5 tons.

 $\mathbf{58}$

59

There is no positive shear in 11-13.

The greatest positive shears are equal and symmetrical to the greatest negative shears. Thus, the positive shear in 1-3 is equal numerically to the negative shear in 11-13; the positive shear in 3-5 is equal numerically to the negative shear in 9-11; and so on.

Prob. 50. Find the greatest positive and negative shears for each panel of Fig. 25 when the apex live load is 6 tons.

Ans. Positive shears = 21.0, 15.75, 11.25, 7.5, 4.5, 2.25, 0.75, 0.0 tons.

Negative shears = 0.0, 0.75, 2.25, 4.5, 7.5, 11.25, 15.75, 21.0 tons.

Prob. 51. Find the maximum positive and negative shears for each panel of Fig. 28 when the apex dead and live loads are 5 and 9 tons, respectively, as in Prob. 47.

4	n	5	۱.		

MEMBERS.	2-4	4-6	6-8	8-10	10-12	12-14
Dend tong oncone	+27.50	+22.50	+17.50	+12.50	+ 7.50	+ 2.50
	+49.50	+41.25	+83.75	+27.00	+21.00	+15.75
	0.00	- 0.75	- 2.25	- 4.50	- 7.50	-11.25

	+27.50	+21.75	+15.25	+ 8,00	0,00	- 8.75

The maximum shear is always positive in the left half of the truss, but the minimum may be either positive or negative. In this problem we see that a negative shear can occur in panel 12-14, and that there is no shear in panel 10-12, while the shears in all the other panels are positive. Members to the left of 10, and of course in the four right hand panels also, are therefore subjected to but one kind of stress, while in the four middle panels they may be sub-

the shear ad, and is eft of this Hence *the he live load*

jected to either kind of stress, and hence must be counterbraced. Though there is no negative shear in panel 10-12, it would be counterbraced for safety.

Art. 23. The Warren Truss. — The chord stresses in the Warren Truss may be computed by the method of chord increments, (2) of Art. 19, and the web stresses by the method of Arts. 18 and 22. The dead and live load stresses may be found separately and their sum taken for the maximum and minimum stresses; or the maximum and minimum stresses of any member may be determined directly, from a single equation, by placing the dead and live loads in proper position. In the following solution of the deck Warren truss the dead and live load stresses are found separately.

Prob. 52. A deck Warren truss, as a deck railroad bridge, Fig. 29, has 10 panels, each 12 feet long, its web members

all forming equilateral triangles (Art. 14); the dead load is given by formula (2), Art. 15, the live load is 1500 lbs. per foot per truss: find the maximum and minimum stresses in all the members.

The dead panel load per truss from formula (2)

 $=\frac{(7 \times 120 + 600)12}{2} = 8640 \text{ lbs.} = 4.32 \text{ tons}$

= say, 4 tons, for convenience in computation.

Live panel load per truss $=\frac{1500 \times 12}{2000} = 9$ tons.

61

Since the loads are distributed uniformly along the joints of the upper chord, 3 and 3' will receive three fourths of a panel load each. The dead and live load stresses will be found separately. $\tan \theta = .577$; sec $\theta = 1.1547$.

DEAD LOAD STRESSES.

Left reaction = $4.75 \times 4 = 19$ tons. This is also the shear in panel 1-3. The dead load shear in each of the other panels is found by subtracting the loads on the left of the panel from the abutment reaction. We have then the following chord stresses by chord increments:

UPPER CHORD STRESSES.

Stress in	$3-5 = (19 + 16) \times .577$		- 20.20 tons.
Stress in	$5-7 = (19 + 2 \times 16 + 12) \times .57$		
Stress in	$7-9 = (19 + 2 \times 16 + 2 \times 12 + 12)$	8) ×	.577
		= -	- 47.90 tons.
Stress in	$9-11 = (75 + 2 \times 8 + 4) \times .577$		- 54.82 tons.
Stress in	$11-11' = (91 + 2 \times 4) \times .577$	=-	- 57.12 tons.
Stress in	13		00.00 tons.

LOWER CHORD STRESSES.

. .

Stress in	$2-4 = 19 \times .577$	= 10.96 tons.
Stress in	$4-6 = (19 + 2 \times 16) \times .57$	
Stress in	$6-8 = (51 + 2 \times 12) \times .57$	7 = 43.28 tons.
Stress in	$8-10 = (75 + 2 \times 8) \times .577$	= 52.51 tons.
	$10-12 = (91 + 2 \times 4) \times .577$

 Stress in
 $9-10=4 \times 1.154 = +4.61$ tons

 = -stress in 10-11.

 Stress in
 1-2=4 of a panel load = 1 ton.

LIVE LOAD STRESSES.

The maximum live load chord stresses occur when the live load covers the whole length of the truss (Art. 20); - hence they are found in precisely the same way as the dead load chord stresses above; or we may find them by multiplying the above dead load chord stresses by the ratio of live to dead panel load, which = $2\frac{1}{4}$ here, giving us the following chord stresses:

UPPER CHORD STRESSES.	LOWER CHORD STRESSES.
1-3 = 00.00 tous.	2-4 = 24.66 tons.
3-5 = -45.45 tons.	4-6 = 66.19 tons.
5-7 = -81.81 tons.	6-8 = 97.38 tons.
7-9 = -107.77 tons.	8-10 = 118.15 tons.
9-11 = -123.34 tons.	10-12 = 128.52 tons.
11-11' = -128.52 tons.	

63

WER STRESSES.

The stress in any web member is equal to the shear in the section which cuts that member and two horizontal chord members, multiplied by the secant of the angle which the web member makes with the vertical (Art. 18); the stress is therefore a maximum when the shear is a maximum. The maximum positive live load shear in any panel occurs when all joints on the right are loaded and the joints on the left are unloaded (Art. 22).

The maximum positive live load shear for 2-3 will occur when the truss is fully loaded. We have then

Stress in $2-3 = 9 \times 4.75 \times 1.154 = -49.30$ tons.

The maximum positive shear for 3-4 and 4-5 will occur when all joints except 3 are loaded (Art. 22). Taking moments about the right end, and multiplying by sec θ , we have

Stress in 3-4

 $= \frac{9}{20} \left(\frac{3}{4} + 3 + 5 + 7 + 9 + 11 + 13 + 15 + 17 \right) \times 1.1547$ = $\frac{9}{20} \times \frac{323}{4} \times 1.1547 = 41.96$ tons = - stress in 4-5. Stress in 5-6

 $= \frac{6}{20} \left(\frac{8}{4} + 3 + 5 + 7 + 9 + 11 + 13 + 15 \right) \times 1.1547$ = 33.13 tons = - stress in 6-7.

Stress in $7-8 = \frac{9}{20} \left(\frac{3}{4} + 3 + 5 + 7 + 9 + 11 + 13\right) \times 1.1547$ = 25.33 tons = - stress in 8-9.

Stress in $9-10 = \frac{9}{20} \left(\frac{4}{3} + 3 + 5 + 7 + 9 + 11\right) \times 1.1547$ = 18.58 tons = - stress in 10-11.

Stress in $11-12 = \frac{9}{20}(\frac{3}{4}+3+5+7+9) \times 1.1547$ = 12.87 tons = - stress in 12-11'.

We see from this table of web stresses that, (1) when the live load comes on from the right, all the web members in the left half of the truss are subjected to but one kind of stress, that is, the members 2-3, 4-5, 6-7, 8-9, 10-11 are subjected to compressive stresses, and the members 3-4, 5-6, 7-8, 9-10, 11-12 are subjected to tensile stresses; (2) when the live load comes on from the left, all the web members to the left of 9-10 are subjected to but one kind of stress, but the members 9-10, 10-11, 11-12 have their stresses changed, that is, the stresses in 9-10 and 11-12 are changed from tensile to compressive, while that in 10-11 is changed from compressive to tensile.

Hence, the members 2-3, 4-5, 6-7, 8-9, should be struts to carry compression only, and the members 3-4, 5-6, 7-8,

-9′.

66

should be ties to earry tension only, while 9-10, 10-11, 11-12 should be members expable of resisting both compression and tension, and should therefore be *counter braces* (Art. 1): and the same is true for the right half of the truss.

In this solution for web stresses the live load was brought on from the *right*, and the maximum *positive* shear was found in each panel of the *right* half of the truss, and then the resulting stress; if preferred, the live load may be brought on from the *left*, and the maximum *negative* shear be found in each panel of the *left* half of the truss (Art. 22), and then the resulting stress. Thus, the maximum positive shear in any panel in the right half of the truss as 6'-8' has the same numerical value as the maximum negative shear in the corresponding member 6-8 in the left half; and the resulting stress in any member 7'-8' has the same value as that in the corresponding member 7-8.

The maximum and minimum stresses may be determined directly from a single equation by placing the dead and live loads in proper position.

Thus, for the maximum stress in 8-9, we pass a section eutting it, place the live load on the right, and have

Max. stress in $8-9 = -[2 \times 4 + \frac{9}{20}(\frac{3}{4} + 3 + 5 + 7 + 9 + 11 + 13)] \times 1.1547 = -34.57$ tons, as before.

For the minimum stress the live load is reversed and covers the truss on the left of the section. Thus

Min. stress in $8-9 = -[2 \times 4 - \frac{9}{20}(\frac{3}{4}+3+5)] \times 1.1547$ = -4.69 tons, as before.

Prob. 53. A deck Warren truss, like Fig. 29, has 10 panels, each 10 feet long, its web members all forming equilateral triangles; the dead load is 800 lbs. per foot per truss, and the live load is 1600 lbs. per foot per truss; the

Art. 24. Mains and Counters. — In the Pratt truss, Fig. 30, all the verticals, except 1-4 and 1'-4', are to take compression only, and all the inclined members, except 1-2,

1'-2' are to take tension only. The two inclined members, 1-2 and 1'-2', are usually called the "*inclined end posts*." The verticals 1-4 and 1'-4' do not form any part of the truss proper, since they serve only to carry the loads at 4 and 4' up to the hip joints 1 and 1'; they are called *hip* verticals.

The members 1-C, 3-8, 3'-8', and 1'-6' are mains, or main ties. They are the only inclined ties that are put under stress by the action of the dead load, or by a uniform dead and live load extending over the whole truss. The members 5-6, 5-8', 5'-8, and 5'-6', in dotted lines, are counters,

71

or *counter ties.* In the Pratt truss there are no counter braces (Art. 1). These four counters are called into play only when the live load covers a part of the truss.

Thus, if a load be placed at the joint 6', it is carried by the truss to the abutments at 2 and 2'. The part of this load which goes to 2 may be conceived as being carried up to 5', down to 8', up to 5, down to 8, up to 3, down to 6, up to 1, down to the abutment at 2. The other part of this load, which goes to the right, passes up to 1', then down to 2'. For this loading, the counters 5'-6', 5-8', and the mains 3-8. 1-6, and 1'-6' are put under stress, while the counters 5'-8, 5-6, and the main tie 3'-8' are idle, and might be removed without endangering the truss. If the two middle joints, 8 and 8', are loaded equally, the part of the load at 8' going to 2' is just balanced by the part of the load at 8 going to 2, and hence there is no stress in the intermediate web members 5-8', 5'-8, 5-8, and 5'-8', nor in the counters 5-6 and 5'-6'. If the live load going from 6' to the left abutment is greater than the dead load going from 8' to the right abutment, the counter 5'-6' must be inserted. If this counter 5'-6' were not inserted, the panel 6'-8' would be distorted. The load at 6' would bring the opposite corners 3' and 8' nearer together, and the opposite corners 5' and 6' farther apart, because the main tie 3'-8' cannot take compression. Whenever the live load would tend to cause compression in any main tie, a counter must be inserted uniting the other corners of the panel. Both diagonals in any panel cannot have compression or tension at the same time.

If the action of the dead and live loads tend to subject a member to stresses of opposite kinds, the resultant stress in the member will be equal to the numerical difference of the opposite stresses, and will be of the same kind as the greater. Thus, if the dead load, going from 8 to the left

.49, + 13.56,

1.01, - 4.05,

Pratt truss, are to take , except 1-2,

ed members, *l end posts.*" part of the e loads at 4 re called *hip*

uins, or main e put under niform dead The memare counters,

 $\mathbf{72}$

abutment, should subject the main tie 3-8 to a tension of 8 tons, and if the live load, going from 6 to the right abutment, should tend to subject the same tie to a compression of 5 tons, there would be a resulting tension of 3 tons in the member 3-8; and the counter 5-6 would not be needed for this loading. But, if the dead load should subject the tie 3-8 to a tension of only 2 tons, while the the live load should tend to subject the same piece to a compression of 5 tons, there would be a resulting force of 3 tons, tending to bring the joints 3 and 8 nearer together, or to separate the joints 5 and 6 from each other. In order to provide for this compression or tension, either a brace would be needed alongside the main tie 3-8, to take the compression of 3 tons, or the counter tie 5-6 would be needed to take the tension of 3 tons.

In the Howe truss, Fig. 31, the verticals are to take tension only, and the inclined members are to take compression

only. The mains, or main braces, are represented by the full lines; the dotted lines denote counters, or counter braces. Under the action of the dead load, or of a uniform dead and live load covering the whole truss, the main braces are the only diagonals that are put under stress. The counter braces are called into play only when the live load covers a part of the truss, as in the ease of the Pritt truss.

Thus, if a load be placed at the joint 6, the part of it which goes to the right abutment 2' may be conceived as

tension of 8 a right abutcompression of 3 tons in of the needed 4 subject the the live load mpression of tons, tending r to separate a provide for ld be needed ion of 3 tons, a the tension

to take tencompression

ented by the of a uniform ss, the main under stress. when the live of the Pritt

he part of it conceived as being carried up to 3, down to 8, up to 5, down to 8', up to 5', down to 6', up to 3', down to 4', up to 1', down to 2'. If the live load going from 6 to the right abutment is greater than the dead load going from 8 to the left abutment, the counter brace 3-8 must be inserted. If this counter 3-8 were not inserted, the panel 6-8 would be distorted. The load at 6 would bring the opposite corners 3 and 8 nearer together, and the opposite corners 5 and 6 farther apart, because the main brace 5-6 cannot take tension. But if the live load going from 6 to the right abutment, the counter brace 3-8 will not be needed for this loading. The main and counter 'n any panel cannot both take stress at the same time by any system of loading.

We may determine where the counters are to begin, as follows: Consider the left half of the truss, and let the live load come on from the left; then the dead and live load shears, or stresses, are of opposite kinds. It results from this at once that counters — counter ties in the Pratt, and counter braces in the Howe — must begin in that panel in which the stress or shear caused by the live load is greater than that of the opposite kind caused by the dead load.

Thus, in Fig. 30, let the dead pauel load be 3 tons and the live pauel load 14 tons. Then we have the following maximum negative shears:

Shear	in	2-4	=+	9 —	0	= + 9.	
Shear	in	4-6	=+	6 —	↓ × 14	= + 4.	
Shear	in	6-8	=+	3 —	$14(\frac{1}{7}+\frac{2}{7})$	= -3.	

Hence the counters must begin in the third panel, and therefore the third, fourth, and fifth panels must have counter ties for this loading.

74

Prob. 58. In the Howe truss of Fig. 28, with 12 panels, the dead panel load being 4 tons and the live 9 tons, find the number of panels to be counterbraced.

Ans. The 5th, 6th, 7th, and 8th panels must have counter braces.

Art. 25. The Howe Truss. - The maximum and minimum stresses, both in the chords and the web members of the Howe truss, may now be computed by the principles of Arts. 18, 19, 22, and 24. The dead and live load stresses may be found separately, and their sum taken for the maximum and minimum stresses; or, the maximum and minimum stresses of any member may be determined directly, from a single equation, by placing the dead and live loads : proper position. In the following solution of the through Howe truss, this method is the one employed:

Prob. 59. A through Howe truss, as a through railroad bridge, Fig. 32, has 10 panels, each 12 feet long and 12 feet

deep; the dead load is given by formula (4), Art. 15, the live load is 1500 lbs. per foot per truss: find the maximum and minimum stresses in all the members.

From tormula (4), Art. 15, we find the dead panel load per truss

$= \frac{(6.5 \times 120 + 675) 12}{2} = 8730 \text{ lbs.} = 4.365 \text{ tons}$ = say, 4 tons, for convenience of computation.

Live panel load per truss $=\frac{1500 \times 12}{2000} = 9$ tons.

 $\tan \theta = 1$, see $\theta = 1.41$.

75

The maximum and minimum *chord stresses* may be written out at once (Arts. 19 and 21). They are as follows:

Max. stresses in lower chord = 58.5, 104.0, 136.5, 156.0, 162.5 tons.

Min.stresses in lower chord = 18.0, 32.0, 42.0, 48.0, 50.0 tons. The upper chord stresses may be written from the lower at once. Thus, stress in 3-5 = - stress in 2-4; and

WEB STRESSES.

The maximum stress in any web member is equal to the maximum shear in the section which cuts that member and two horizontal chord members, multiplied by the secant of the angle which the web member makes with the vertical (Art. 18). The maximum positive live load shear in any panel in the left half of the truss occurs when all joints on the right are loaded and the joints on the left are unloaded (Art. 22). For the maximum stress in 2–3, we pass a section cutting it, place the live load on the right, in this case covering the whole truss, and have

Max. stress in 2-3

so on.

 $= - \left[4 \times 4.5 + \frac{9}{15} \left(1 + 2 + 3 + 4 + 5 + 6 + 7 + 8 + 9\right)\right] 1.41$ = - 82.48 tons.

For the max. stress in 4-5 all the joints on the right of 4 are loaded. Hence,

Max. stress in 4–5

 $= - [4 \times 3.5 + \frac{9}{10}(1 + 2 + 3 + 4 + \dots + 8)] 1.41 = -65.42 \text{ tons.}$ Max. stress in 6-7

 $= -[4 \times 2.5 + \frac{9}{10}(1 + 2 + 3 + \dots + 7)] 1.41 = -49.63 \text{ tors.}$ Max. stress in 8-9

 $= -[4 \times 1.5 + \frac{6}{10}(1 + 2 + 3 + \dots + 6)] 1.41 = -35.10 \text{ tons.}$ Max. stress in 10-11

 $= - [4 \times 0.5 + \frac{9}{10}(1 + 2 + \dots + 5)] 1.41 = -21.85$ tons.

ith 12 panels, re 9 tons, find

ough railroad 1g and 12 feet

), Art. 15, the the maximum

ıd panel load

365 tons

itation.

ons.

For the minimum stress in any member in the left half of the truss, the live load is reversed and eovers the truss on the left of the section (Art. 22). Hence,

Min. stress in $2-3 = -[4 \times 4.5 - 0]1.41 = -25.38$ tons.

Min. stress in $4-5 = -[4 \times 3.5 - \frac{9}{10} \times 1]1.41 = -18.47$ tons. Min. stress in 6-7

 $= -[4 \times 2.5 - \frac{9}{10}(1+2)]1.41 = -10.29$ tons.

Min. stress in 8–9

76

 $= - \left[4 \times 1.5 - \frac{9}{1^{9}} (1 + 2 + 3)\right] 1.41 = -0.85 \text{ tons.}$

Min. stress in 10-11 = $-[4 \times 0.5 - \frac{9}{10}(1 + 2 + 3 + 4)]$ 1.41 = +9.87 tons.

That is, the minimum stress in 10-11 is a tension of 9.87 tons. But as the diagonals in the Howe truss are to be subjeeted only to compression, the brace 10-11 cannot take tension, the counter brace 9-12 must therefore be inserted to take this 9.87 tons, which is the excess of that part of the live load going from 8 to the right abutment over that part of the dead load going from 10 to the left abutment. If a tie were placed alongside the main brace 10-11, it would take this tension of 9.87 tons, and the counter brace 9-12 would not be needed; or, if the diagonal 10-11 were built so as to take either tension or compression, the counter 9-12 would not be needed. In this latter case the member 10-11 would have a range of stress from -21.85 tons to + 9.87 tons, the former when the live load covered all the joints on the right of it, the latter when it eovered all the joints on the left. But as the diagonals are to be subjected only to compression in this truss, the minimum stress in 10-11 is zero, and the tension of 9.87 tons in 10-11 becomes the maximum compression in the counter brace 9-12. The three diagonals, 4-5, 6-7, 8-9, are always in compression.

77

Hence, theoretically, there is only one counter brace needed in the left half of this truss; but, practically, a counter brace would be put in the fourth panel also, so that the truss would have counter braces in its four middle panels.

The maximum stress in any vertical, except the middle one, is equal to the maximum positive shear in the section eutting it and two chord members, or it is equal to the maximum positive shear in the panel *toward* the abutment from the vertical. Thus,

$$\begin{split} & \text{M}_{0} \text{ x. stress in } 3\text{-}4 = 13 \times 4.5 = 58.5 \text{ tons.} \\ & \text{Max. stress in } 5\text{-}6 \\ & = [4 \times 3.5 + .9 \, (1 + 2 + \dots + 8)] = 46.4 \text{ tons.} \\ & \text{Max. stress in } 7\text{-}8 \\ & = [4 \times 2.5 + .9 \, (1 + 2 + \dots + 7)] = 35.2 \text{ tons.} \\ & \text{Max. stress in } 9\text{-}10 \\ & = [4 \times 1.5 + .9 (1 + 2 + \dots + 6)] = 24.9 \text{ tons.} \end{split}$$

The maximum stress in the middle vertical 11-12 is equal, either to the maximum positive shear in panel 10-12, or to a full panel dead and live load, whichever is the greater. For, if this maximum positive shear is greater than a panel load, then the shear in the next right hand panel under the same loading is also positive, and the counter brace in that panel will be in action, thus making the shear in panel 10-12 the same as that in the vertical 11-12; but, when the counters are not in action, the stress in 11-12 is always equal to the load at 12.

Max. positive shear in 10-12

 $= 4 \times 0.5 + \frac{9}{10}(1 + 2 + \dots + 5) = 15.5$ tons.

Full panel load = 4 + 9 = 13 tons.

 \therefore Max. stress in 11-12 = 15.5 tons.

the left half ers the truss

tons.

).85 tons.

+ 9.87 tons.

ension of 9.87 are to be subnot take tenbe inserted to t part of the ver that part utment. If a -11, it would er brace 9–12 11 were built , the counter e the member 21.85 tons to vered all the overed all the be subjected num stress in 0-11 becomes ee 9–12. The compression.

78

The minimum stress in any vertical is equal to the maximum negative shear in the section cutting it and two chord members, or it is equal to the maximum negative shear in the panel toward the abutment from the vertical, or to a dead panel load, whichever is the greater. Thus,

Min. stress in 3-4 = 4 × 4.5 - 0 = 18.0 tons. Min. stress in 5-6 = 4 × 3.5 - $\frac{9}{16}$ × 1 = 13.1 tons. Min. stress in 7-8 = 4 × 2.5 - $\frac{9}{16}$ (1 + 2) = 7.3 tons. Min. stress in 9-10 = 4 × 1.5 - $\frac{9}{16}$ (1 + 2 + 3) = 0.6 tons.

But the stress in a vertical of this truss cannot be less than the weight of a dead panel load; therefore

Min. stress in 9-10 = 4 tons.

Min. stress in 11-12 = 4 tons.

We may now collect these web stresses in a table as follows:

WEB STRESSES.

MEMBERS.	2-3	4-5	6-7	89	10-11	9-12

80

= 4.5, 41.0, 33.0, 25.5, 18.5, 12.0, 7.5 tons.

The maximum stress in any vertical of the deek Howe truss except the middle one, is equal to the maximum positive shear in the section cutting it and two chord members, or it is equal to the maximum positive shear in the panel *away* from the abutment from the vertical. The stresses in the verticals need to be very carefully tested.

Prob. 62. A deck Howe truss has 10 panels, each 14 feet long and 14 feet deep; the dead load is 714 lbs. and the live load is 2000 ibs. per foot per truss: find the maximum and minimum stresses in all the members.

Ans. Max. stresses in lower chord = 85.5, 152.0, 199.5, 228.0, 237.5 tons.

Max. in main braces

= -120.55, -95.74, -72.89, -52.02, -33.37 tons.

Min. in main braces

=-31.73, -22.70, -11.70, 0.0, 0.0 tons.

Max. in verticals

= 9.5, 67.9, 51.7, 36.9, 23.5, 14.0 tons.

Max. in counters = -1.27, -16.22 tons.

Prob. 63. A through Howe truss has 8 panels, each 18 feet long and 24 feet deep; the dead load is 806 lbs., and the live load is 1500 lbs. per foot per truss: find the maximum and minimum stresses in all the members.

81

Art. 26. The Pratt Truss. — All parts of the Pratt truss are of iron or steel, the verticals being compression members, except the hip verticals, and the diagonals tension members. The maximum and minimum stresses of any member may be determined directly from a single equation, as in the case of the Howe truss (Art. 25).

Prob. 64. A through Pratt truss, as a through railroad bridge, Fig. 33, has 10 panels, each 14 feet long and 14 feet

deep; the dead load from formula (1), Art. 15, the live load is 1800 lbs. per foot per truss: find the maximum and minimum stresses in all the members.

From formula (1), Art. 15, the dead panel load per truss

$$=\frac{(9 \times 140 + 520)14}{2} = 12,460$$
 lbs. = 6.23 tons = say, 6 tons.

Live panel load per truss = 16.2 tons = say, 16 tons.

 $\tan \theta = 1$, $\sec \theta = 1.414$.

The max. and min. chord stresses may be written out at once (Arts. 19 and 21). They are the following:

Max. stresses in lower chord

-

= 99.0, 99.0, 176.0, 231.0, 264.0 tons.

Min. stresses in lower chord

= 27.0, 27.0, 48.0, 63.0, 72.0 tons.

ROOFS AND BRIDGES.

WEB STRESSES.

The web stresses may be found exactly as in Prob. 60. The following are the equations for a few of the members:

Max. stress in 2-3 = - [4.5 × 22]1.41 = - 139.5 tons.

Max. stress in 3-6

$$= [3.5 \times 6 + 1.6(1 + 2 + \dots + 8)]1.41 = 110.8$$
 tens.

Max. stress in 5-8

 $= [2.5 \times 6 + 1.6(1 + 2 + \dots + 7)]1.41 = 84.3 \text{ tons.}$

Max. stress in 7-8

 $= -[1.5 \times 6 + 1.6(1 + 2 + \dots + 6)] = -42.6$ tons.

Max. stress in 11–12

 $= -[-0.5 \times 6 + 1.6(1 + 2 + \dots + 4)] = -13.0$ tons.

Min. stress in 5–8

 $= [2\frac{1}{2} \times 6 - 1.6(1+2)]1.41 = 14.4$ tons.

Max. stress in 10–11

 $= \left[-\frac{1}{2} \times 6 + 1.6(1 + 2 + \dots + 4) \right] 1.41 = 18.5$ tons.

Thus we find the stresses in the following table:

WEB STRESSES.

Mumbers.	2-3	8-6	5-8	7-10	9-12	8-9	10-11
Max, stresses Min, stresses	-139.5 -38.1	+110.8 + 27.4	+81.3 +14.4	+60.0 0.0			

Max. stresses in the verticals = +22.0, -59.8, -42.6, -27.0, -18.5 tons.

83

Prob. 65. A through Pratt truss has 11 panels, each 10 feet long and 10 feet deep; the dead load is 1200 lbs., and the live load is 2000 lbs. per foot per truss: find the stresses in all the members.

Ans. Max. stresses in lower chord

Prob. 67. A deck Pratt truss has 9 panels, each 18 feet long and 24 feet deep; the dead load is 500 lbs., and the live load is 1000 lbs. per foot per truss: find the stresses in all the members.

Ans. Max. stresses in lower chords = 0.0, 40.5, 709.91, 91.1, 101.3 tons.

Max. stresses in main ties

= 67.5, 51.9, 37.5, 24.4, 12.5 tons.

Min. stresses in main ties

84

= 22.5, 15.6, 7.5, 0.0, 0.0 tons.

Max. stresses in counters = 1.9, 12.5 tons.

Max. stresses in verticals

=-60.8, -54.0, -41.5, -30.0, -19.5 tons.

The chord stresses are the same in the Howe trusses, and also in the Pratt trusses, whether the load be placed on the top or the bottom chord.

Art. 27. The Warren Truss with Vertical Suspenders.— The left half of this truss is represented in Fig. 35, in which the web bracing consists of equilateral or

isosceles triangles and vertical ties or suspenders. In a through truss, each of the verticals 3, 5, 7, 9, simply earries a panel load from the lower chord to the upper, while the verticals 4, 6, 8, 10, are only to support and stiffen the upper chord. If the truss is a deck, the last named verticals become posts.

85

Prob. 68. A through Warren truss with vertical ties, one half of which is shown in Fig. 35, has 16 panels, each 8 feet long, its braces all forming equilateral triangles; the dead load is given by formula (2) of Art. 15, the live load is 1500 lbs. per foot per truss: find the maximum and minimum stresses in all the members.

The dead panel load per truss

 $= \left(\frac{7 \times 128 + 600}{2}\right) 8 = 5984 \text{ lbs.} = 3 \text{ tons.}$ Live panel load per truss $= \frac{1500 \times 8}{2000} = 6 \text{ tons.}$ $\tan \theta = .577 \text{ ; sec } \theta = 1.1547.$

The chord stresses may be written out at once by chord increments.

For the verticals the maximum stress is evidently the dead and live panel load, or 9 tons; the minimum stress is the dead panel load, or 3 tons.

The following are the equations for determining the stresses in a few of the members:

Max. stress in 2-4 = 7.50 × 9 × .577 = 38.9 tons. Max. stress in 4-6 =[7.50 + 6.50 + 5.50]9 × .577 = 101.3 tons. Max. stress in 3-5 = -[7.50 + 6.50] × 9 × .577 = -72.7 tons. Max. stress in 2-3 = -[7.50 × 9 × 1.154] = -77.9 tons. Max. stress in 5-6 = [4.5 × 3 + $\frac{6}{16}$ (1 + 2 + 3 + ... + 12)] 1.154 = 42.75 × 1.154 = + 49.3 tons. Min. stress in 7-8 = [2.5 × 3 - $\frac{6}{16}$ (1 + 2 + 3 + ... + 5)] 1.154 = + 2.2 tons. In this way all the stresses may be found.

Prob. **70.** A through Warren truss with vertical ties, like Fig. 35, has 10 panels, each 12 feet long and 12 feet deep, its braces all forming isosceles triangles; the dead and live loads are 1000 lbs., and 2000 lbs. per foot per truss: find the maximum and minimum stresses in all the members.

Art. 23. The Double Wairen Truss, or Double Triangular Truss, or Girder. — This truss, shown in Fig. 36, has two systems of triangular bracing, the one system represented in full lines and the other in dotted lines, the

chords being common to both systems. The roadway may be carried either upon the upper or the lower chord.

In all the trusses hitherto considered, a vertical section taken at any point of the truss will cut only three members; but in the double Warren truss this is not the case, since a vertical section will in general cut *four* members, causing the problem at first to seem to be *indeterminate* (Art. 7). This is obviated, however, by the fourth condition that: the truss is equivalent to the two trusses, shown in full and in dotted lines, welded into one. Thus, the loads at 6, 10, 10', 6' are carried to the abutments by the diagonals drawn in full, while the loads at 4, 8, 12, 8', 4' are carried by the dotted diagonals. The chord and web stresses are readily found as in a simple triangular truss, assuming each system as independent. This truss is used both as a riveted, and as a pin-connected bridge.

s, and it truss."* it it has liagonals

BRIDGE TRUSSES.

91

This truss was at one time more common than any other in American bridge practice. It is still used though very rarely for highway bridges; for railway bridges it is as a rule avoided by the best practice.

It is assumed that this truss is equivalent to the two trusses shown in full and in dotted lines, and that each system acts independently and earries only its own loads to the abutments; but in the case of the web members, this is not strictly true. If, however, the truss is built with an even number of panels, the error in the web stresses obtained on the assumption of independent systems is probably very small. With the chord stresses there is no ambiguity; the chord stresses are a maximum for a full load, and may be found as usual by chord increments, or by moments. The vertical shear will be the same whether the load is applied at the top or at the bottom chord.

Prob. 75. A through Whipple truss, Fig. 37, has 12 panels, each 10 feet long and 20 feet deep; the dead load is 750 lbs., and the live load is 1200 lbs. per foot per truss: find the stresses in all the members.

The dead panel load per truss = 3.75 tons.

The live panel load per truss = 6.0 tons.

 $\tan \theta = 1$: $\sec \theta = 1.414$: $\tan \theta' = 0.5$: $\sec \theta' = 1.118$.

The following are the equations for finding the stresses in a few of the members:

Max. stress in $4-6 = 3 \times 9.75 \times 0.5 = 14.6$ tons. Max. stress in $6-8 = 14.6 + 2\frac{1}{2} \times 9.75 \times 1 = 39.0$ tons = - stress in 1-3. Max. stress in 9-11

 $= - [39.0 + (2 + 1\frac{1}{2} + 1 + \frac{1}{2})9.75] = -87.8 \text{ tons}$ = stress in 11-13,

^{*} since for a uniform load the diagonals meeting the upper chord between 9 and 9' are not in action.

Max. stress in $1-4 = 3 \times 9.75 \times 1.118 = 32.7$ tons.

Max. stress in 1-6

92

 $= [2\frac{1}{2} \times 3.75 + \frac{4}{12} (2 + 4 + 6 + 8 + 10)] \times 1.414$ = 24.375 × 1.414 = 34.5 tons.

Max. stress in 1-2 = - 29.25 - 24.375 = - 53.6 tons.

Thus the following stresses are determined.

CHORD STRESSES.

Prob. 77. A deck Whipple truss, like Fig. 38, has 16 panels, each 12 feet long and 24 feet deep; the dead load is 750 lbs. per foot per truss, and the live load is 2000 lbs. per foot per truss: find the stresses in all the members.

Art. 30. The Lattice Truss, or Quadruple Warren Truss.^{*} — This truss, Fig. 39, contains four web systems

welded into one. It is built only as a short-span riveted structure.

In determining the stresses in the different members of this trass, an ambiguity arises from two causes: (1) the web members being riveted together at each intersection, the different systems cannot act independently; and (2) two of the systems are not symmetrically placed in reference to the center of the truss. Thus, if equal loads be placed at each joint, the abutment at 2 will carry more than half of the load on the system 4, 12, 20, 16', 8', and less than half of the load on the system 8, 13, 20', 12', 4'. But it simplifies the solution to assume that each system acts independently, and is symmetrical in reference to the center of the truss. The chord and web stresses are then readily found, as in a simple triangular truss.

 * All double systems, such as this and the Whipple, owing to the indoterminate character of the strains, are now usually avoided by the best practice.

95

Prob. 78. A through lattice truss containing four web systems, as shown in Fig. 30, has 20 panels, each 10 feet long, the depth of the truss is 20 feet; the dead load is given by formula (2) Art. 15, the live load is 2000 lbs. per foot per truss: find the stresses in all the members.

Dead panel load per truss = 5 tons.

Live panel load per truss = 10 tons.

$\tan \theta = 1$, see $\theta = 1.414$.

Nore. — In finding the shear for a web member due to the dead load or to the live load covering the whole truss, a slight difficulty arises, owing to the two ..nsymmetrical systems above referred to. This shear may be found, either by taking the algebraic sum of the greatest positive and the greatest negative shears (Art. 22), or by simple inspection of the truss.

Thus, the dead load shear in 5-10 is the weight of the two panel loads at the joints 10 and 18, because the system to which 5-10 belongs is symmetrical with reference t the center of the truss; but the shear in 7-12 is not the weight of the two panel loads at the joints 12 and 20, because this system is not symmetrical in reference to the center. If the joint 20 were at the center 22, the shear for 7-12 would be $1\frac{1}{2}$ panel loads; but if it were at the joint 18, the shear would be 2 panel loads. Being midway between the joints 18 and 22, the shear for 7-12 is the mean of $1\frac{1}{2}$ and 2 panel loads, or 1.75 panel loads; and so for the shear in any other web member.

By chord increments, we have

Max. stress in 2-4 = 2 × 15 × 1 = 30 tons. Max. stress in 4-6 = $(2 + 1.75 + 2.75) \times 15 = 97.5$ tons. Max. stress in 6-8 = $97.5 + (1.5 + 2.5) \times 15 = 157.5$ tons. Max. stress in 1-3 = $2.5 \times 15 = 37.5$ tons. Max. stress in 3-5 = $(2.5 + 2 \times 2.25) \times 15 = 105.0$ tons.

MAXIMUM WEB STRESSES.

The maximum stress in 3-8 will be when the dead and live loads cover the whole system to which 3-8 belongs. Likewise for the member 5-10. The maximum live load stress in 7-12 will be when the live panel loads are at the joints 12, 20, 16', 8', since these are the only loads which act in the system to which 7-12 belongs, on the right of 7-12. For the dead load stress, see Note.

Max. stress in 3-8
$= 2.25 \times 15 \times 1.414 = 47.7$ tons $= -$ stress in A-3.
Max. stress in 5-10
$= 2 \times 15 \times 1.414 = 42.4$ tons = $-$ stress in 2-5.
Max. stress in 7–12
$= [1.75 \times 5 + \frac{10}{26}(3 + 7 + 11 + 15)] 1.414 = 37.8 \text{ tons}$
=- stress in 4-7.
Max. stress in 9–14
$= [1.5 \times 5 + \frac{1}{2}(2 + 6 + 10 + 14)]1.414 = 33.2 \text{ tons}$
=- stress in 6-9.

Thus the following stresses are determined:

MENBERS, 1-8	8-3	5-7	7-9	9-11

four web ; long, the loads are ie stresses

shown in 11ar truss s, and all

shown in 55 is that eally, are inclined by one half of a panel length, and the ties by one and one half panel lengths. All the panels of both chords are of equal length, except the two end panels of the lower chord, which are each one half a panel in length.

There are ambiguities in the character of the stresses in this truss, as there are in all double systems of bracing. It is impossible to separate the two systems as they are connected at the center. But if we assume that, under a full load, the members 7-10' and 7'-10 are not acting, if it is a deck truss, or that the members 7-10', 7'-10, 9-10, and 9-10' are not acting, if it is a through truss, then the chord stresses are readily found. Also, if we assume that the systems 2, 1, 6, 5, 10, 7', 8', 5', 4', 1', 2', and 2, 1, 4, 3, 8, 7, 10', 5', 6', 1', 2' are independent, the web stresses may be readily found.

Prob. 81. A deek Post truss, Fig. 40, has 8 panels in the upper chord, each 10 feet long, and 20 feet deep; the dead and live loads are 400 lbs., and 1600 lbs. per foot per truss: find the stresses in all the members.

Dead panel load per truss = 2 tons. Live panel load per truss = 8 tons. tan θ = 0.25, and see θ = 1.0308 for the posts. tan θ = 0.75, and see θ = 1.25 for the ties. Max. stress in 1-3=[2 × $\frac{1}{4}$ + 1 $\frac{1}{2}$ × $\frac{3}{4}$]10 = 16.3 tons. Max. stress in 4-6=[2 × $\frac{1}{4}$ + 2 × $\frac{1}{4}$]10 = 10.0 tons. Max. stress in 5-6 =[1 $\frac{1}{2}$ ×2+(2+4+6)]×1.03=15.5 tons. Max. stress in 3-8 =[2 + (1 + 3 + 5)]×1.25 = 13.8 tons. Min. stress in 3-8=[2 - 8 × $\frac{1}{8}$] × 1.25 = 1.3 tons.

109

s, shown in uilt in the d king post ry the load hord. The in compres-The short BRIDGE TRUSSES.

101

ties shown in dotted lines in each panel serve to stiffen the structure.

Bollman trusses were largely used in the Baltimore and Ohio Railroad from 1840 to 1850; but they were abandoned long ago.

Prob. 83. A deck Bollman truss, Fig. 41, has 6 panels, each 12 feet long, and 16 feet deep; the dead and live loads are 1000 lbs., and 2000 lbs. per foot per truss: find the stresses in all the members.

Art. 33. The Fink Trass. — This trass, shown in Fig. 42, was first built about 1851, and was regarded as an improvement on the Bollman truss. It consists of a com-

bination of inverted king post trusses with equally inclined ties, as the primary system AdA', the secondary systems AbE and A'b'E, and the tertiary systems AaC, CcE, etc. The vertical pieces are struts, the upper chord is in compression, and there is no stress in the lower chord; all the diagonals are ties.

The load may be earried either upon the upper or the lower chord, though it has been used more often for deck

than for through bridges. These trusses were built from 1851 down to about 1876; but they are not now generally regarded with favor by bridge builders.

Prob. 84. A deek Fink truss, Fig. 42, has 8 panels, each 12 feet long, and 16 feet deep; the dead and live loads are 500 lbs., and 2000 lbs. per foot per truss: find the stresses in all the members.

The dead panel load per truss = 3 tons.

The live panel load per truss = 12 tons.

We see at once, from Fig. 42, that the maximum stresses in all the members occur when there is a full panel load at every apex. Hence the maximum stresses will be when 15 tons are placed at every apex, and the minimum stresses will be one fifth of the maximum. The maximum stress in each of the posts Ba, Dc is -15 tons. The maximum stress in the post Cb is the panel load of 15 tons at C, plus one half the panel load of 15 tons at D, plus one half the panel load of 15 tons at $B_{2} = -30$ tons. Similarly the stress in Ed = -60 tons.

Also,

102

Stress in $Aa = \frac{1}{2} \times 15 \sec \theta = 9.4 \ \text{tons} = Ca = Cc = Ec.$ Stress in $Ab = \frac{1}{2} \times 30 \sec^{-a}_1 = 27.0 \ \text{tons} = Eb.$ Stress in $Ad = \frac{1}{2} \times 60 \sec \theta_2 = 95.0 \ \text{tons}.$ Stress in $AA' = -[\frac{1}{2} \times 15 \times \frac{3}{4} + \frac{1}{2} \times 30 \times \frac{9}{4} + \frac{1}{2} \times 60 \times \frac{12}{4}]$ $= -118.1 \ \text{tons}.$

Prob. 85. A deek Fink truss has 8 panels, each 10 feet long and 15 feet deep; the de ul and live loads are 400 lbs. and 2000 lbs. per foot per truss: find the stresses in all the members.

BRIDGE TRUSSES WITH INCLINED CHORDS.

Art. 34. The Parabolic Bowstring Truss. — In this truss, Fig. 43, the lower chord is horizontal, and the upper

ehord joints lie on the arc of a parabola; the verticals may be in compression and the diagonals in tension, or the verticals may be in tension and the diagonals in compression.

Let l = the length of the span AB, d = the height of the are OC at the center of the span, and w = the uniform load in lbs. per foot of truss; let (x, y) be any joint P of the upper chord referred to the axes AB and AY, and S the stress in the lower chord panel opposite P. Then we have

$$S = \frac{(lx - x^2)w}{2y} \quad . \quad . \quad . \quad . \quad (1)$$

108

The equation of the parabola referred to its vertex O as origin is

$$(\frac{1}{2}l - x)^2 = 2p(d - y) \quad . \quad . \quad . \quad . \quad (2)$$

and for the point A this becomes $\frac{l^2}{4} = 2 pd$; $\therefore 2p = \frac{l^2}{4d}$. Substituting this in (2) and solving for y, we get

$$y = \frac{4d}{l^2}(lx - x^2)$$
 (3)

which in (1) gives

Hence, for a uniform load on a parabolic truss the stress in the lower chord is the same in every panel.

104

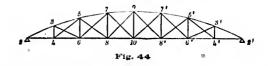

Since the horizontal component of the stress in any diagonal, as PD for example, is equal to the difference of the chord stresses in the adjacent panels, ED and DC.

Therefore, for a uniform load there is no stress in any diagonal.

It follows at once that, for a uniform load the horizontal component of the stress in the upper chord is the same in every panel, and is expressed by equation (4).

Therefore, for a uniform loud the stress in any inclined panel of the upper chord is equal to the stress in a panel of the lower chord multiplied by the secant of the inclination.

Prob. 86. A parabolic howstring, Fig. 44, as a through bridge, has 8 panels, each 10 feet long, and 10 feet center

depth, the verticals take either tension or compression, the diagonals are ties; the dead and live loads are 400 lbs., and 800 lbs. per foot per truss: find the stresses in all the members.

The max. stress in any panel of the lower chord, by (4),

$$=\frac{1200 \times \overline{80^2}}{80 \times 2000} = 48 \text{ tons.}$$

 \therefore Min. stress = $\frac{1}{3} \times 48 = 16$ tons.

Dead panel load = 2 tons. Live panel load = 4 tons.

105

By (3) we have lengths of 3-4, 5-6, and 7-8 = 4.375, 7.5, and 9.375 feet.

Max. stress in
$$2-3 = \frac{48 \times \sqrt{(10)^2 + (4.375)^2}}{10} = 52.4$$
 tons.

Since the dead load produces no stresses in the diagonals, the max. stress in any diagonal is found by putting only the live load on the bridge in the position to give the max. shear in that member (Art. 22).

Thus, for the maximum stress in 5-8 the live load is placed on the right, the center of moments is on the lower ehord at 20 feet to the left of the point 2. The lever arm of 5-8 is 30 feet.

The reaction for this loading

=
$$\frac{4}{6}(1+2+3+4+5) = 7.5$$
 tons.
 \therefore Stress in 5-8 = $\frac{7.5 \times 20}{30} = 5$ tons.

For live load on the left, the stress in 5-8=0, and the counter 6-7 comes into action. The lever arm of 6-7 is 27.4 feet; the reaction for this loading = 6.5 tons. Therefore the stress S for 6-7 is found from the equation

$$6.5 \times 20 - 4 (30 + 40) + S \times 27.4 = 0.$$

$$\therefore S = \text{stress in } 6-7 = 55 \text{ tons.}$$

If we cut a vertical as 5-6 by a section, place the live load on the right, and take the center of moments at the intersection of 3-5 and 4-6, which is 4 feet to the left of the point 2, we shall obtain the maximum *compression* in it caused by the live load. Thus,

The reaction for this loading = 7.5 tons. \therefore Max. stress in 5-6 due to live load

Max. stress in 5-6 due to five load
$$7.5 \le 4$$

$$=-\frac{6.5 \times 4}{24} = -1.25$$
 tons.

Min. stress in 5-6 = 2.0 - 1.25 = 0.75 tons.

s in any ferènce of *DC*.

through et center

20

sion, the lbs., and all the

by (4),

The maximum stress in each vertical is one of tension, and will occur when the live load covers the bridge, and is a dead and live panel load, or 6 tons.

If there be no live load on the truss, the stress in any vertical is a dead panel load, or a *tension* of 2 tons. Now let the live load come on from the right, a part of it which goes to the left support will cause *compression* in each vertical, or will diminish the tension in that vertical due to the dead load. Thus, when the live load reaches the joint S', it will cause in the vertical 9–10 a compression of 2.2 tons, which will neutralize the dead load tension of 2 tons, and leave as the result a compression of 0.2 tons. Also, when it reaches the apex 8, it will cause in the vertical 5–6 a compression of 1.25 tons, as we saw above, which will neutralize that much of the dead load tension of 2 tons, and leave as the result a tension of 0.75 tons.

The following stresses are found in a manner similar to the above:

Min. stress in 4-5 = -2.2, in 5-6 = -1.3, in 6-7 = -3.6, in 7-8 = -3.1 tons.

This problem is taken, with slight changes, from Burr's Stresses in Bridge and Roof Trusses.

Prob. 91. A through circular bowstring truss has 8 panels, each 15 feet long, the center depth is 19.74 feet; the joints of the upper chord lie on the are of a circle of 100 feet radius, each joint being directly over the center of the panel below; the dead and live loads are 1000 lbs., and 2000 lbs. per foot per truss: find the stresses in all the members.

Art. 36. Snow Load Stresses. — For railway bridges the snow load is not taken into account, since the floor is open, so that but little is retained. For highway bridges the snow load is taken from 0 to 15 lbs. per square foot of floor surface, depending upon the climate where the bridge is sitnated.* The snow load is taken lower than for roofs, since the full live load is not likely to come upon the bridge while it is heavily loaded with snow. Since the snow load is uniform, the stresses due to it are computed in the same way as the dead load stresses; or the snow load and dead load stresses are proportional to the corresponding apex loads (Art. 8).

⁴ In building highway bridges in England and France the snow load is not generally considered.

Art 37. Stresses due to Wind Pressure. — In bridges of large span, it is often found that the stresses produced in some of the members by a gale of wind are almost as great as those eaused by both the dead and live loads. In the principal members of the Forth bridge, Scotland, Sir Benjamin Baker estimated that the maximum stresses due to these three separate forces were as follows:

> Stress due to dead load = 2282 tons. Stress due to live load = 1022 tons. Stress due to wind load = 2920 tons.

In estimating the wind pressure, and the resulting stresses in the members of a bridge, the practice of engineers varies greatly. Different railroads have their own specifications for wind pressure. The standard wind pressure per square foot ranges in this country from 30 to 50 lbs. It is assumed by many engineers that there will be no train on the bridge

111

10 panels, f roadway feet; the the snow

tons.

unels, cach ulway, in-15 lbs. per in all the

In bridges coduced in st as great . In the , Sir Benses due to

ng stresses ers varies cifications er square s assumed the bridge when the wind blows with greater pressure than 30 lbs. per square foot. A wind pressure of 30 lbs. per square foot will overturn an empty freight ear. In such a gale it would be hardly possible for a train to reach the bridge. It might, however, be caught there by a sudden squall; and this is just what appears to have happened in the ease of the Tay bridge, which was destroyed by a wind storm in 1879. A maximum pressure of 50 lbs. per square foot is taken as applying to the bridge alone.

The surface exposed to the wind action is commonly taken as double the side elevation of one truss, for the reason that the windward truss eannot afford much shelter to the leeward truss, whatever may be the direction of the wind. In a heavy gale of wind there is not much shelter to be found under the lee of a lamp-post at a distance of 20 feet from it, even if the post be directly to windward. Experiments show that the wind pressure against the two trusses of a bridge is more than 1.8 times that on the exposed surface of one truss.

For Highway Bridges the wind pressure is frequently taken at about 30 lbs. per square foot of exposed surface of both trusses. It is assumed that there will be no live load upon the bridge when the wind is blowing at this maximum pressure of 30 lbs. per square foot.

For Railroad Eridges the wind pressure is taken at about 30 lbs. per square foot of exposed su: face of both trusses, and about 300 lbs. per linear foot due to the train surface. The train surface is about 10 square feet for each linear foot of the bridge. The 30 lbs. per square foot of the trusses is treated usually as a dead load, and the 300 lbs. per linear foot due to the train surface as a live load. This regards each truss as fully exposed even when the train is on, though it partially shelters one taxes.

112

To estimate the 30 lbs. pressure per square foot of exposed surface of both trusses, when this surface is not known, it is enstomary now to use the following rule: *Take* 150 *lbs. per linear foot per truss, or* 75 *lbs. per linear foot for cach chord.*

The wind load on the trusses is assumed to be divided equally between the upper and lower lateral trusses, while the wind load on the train is all taken by the lateral truss belonging to the loaded chord. The lateral trusses are the horizontal trusses placed between the chords of the vertical trusses. The chords of the vertical trusses are also the chords of the lateral trusses. The lateral trusses of a bridge are either of the Pratt, Howe, or Warren type, corresponding generally with the type of the main trusses.

REM. — In finding wind stresses the loads on the lateral system of the unloade l chord are considered as applied equally upon the two sides, windward and leeward, while the loads on the lateral system of the loaded chord are considered as applied wholly on the windward side. The stresses are then readily found by methods already familiar for finding dead load and live load stresses.

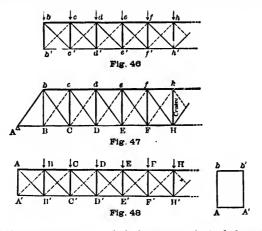

The lower lateral system in a through bridge and the upper lateral system in a deck bridge are calculated for a dead load of 30 lbs, per square foot of exposed surface of both trusses, and a live load of 300 lbs, per linear foot of train; while the other lateral system is calculated only for a dead load of 30 lbs, per square foot of exposed surface of both trusses.

The resulting chord stresses should be combined with those due to the dead load, or with those due to the dead and live loads if the live load acts with the wind load. The lower chord is always in tension under the action of the dead and live loads. When the wind acts the bridge is bent laterally, and the windward lower chord has its maximum tension diminished by the compression due to the wind,

113

while the lower leeward chord has its tension increased by the tension due to the wind. The compression in the windward chord due to the wind may exceed the tension due to the dead load, or to the dead and live loads combined. The lower chord on each side then should not only be able to sustain the total maximum of dead, live, and wind loads, but to act as a strut to resist compression.

Prob. 94. A through Pratt truss railway bridge 16 feet wide, half of which is shown in Fig. 47, has 12 panels, each 16 feet long; the upper and lower lateral systems, Figs. 46

and 48, are Pratt trusses: find the stresses in both lateral systems due to a wind pressure of 30 lbs. per square foot of exposed surface of both trusses and 300 lbs. per linear foot of train surface.

(1) UPPER LATERAL SYSTEM (10 PANELS).

Panel load for one chord (see rule) = $\frac{75 \times 16}{2000}$ = 0.6 tons.

This load acts as a dead load at each apex of the windward and leeward chords in the direction of the arrows, shown in Fig. 46; hence there is no stress in the dotted diagonals.

$$\tan \theta = 1$$
; $\sec \theta = 1.414$.

Stress in hh' = -0.6 tons. Stress in $ff' = -0.6 \times 2 = -1.2$ tons. Stress in $ee' = -0.6 \times 4 = -2.4$ tons. Stress in $be = -0.6 \times 9 \times 1 = -5.4$ ton Stress in $cd = -[5.4 + 4.2] \times 1 = -9.6$ tons. Stress in $fh' = +0.6 \times 1.414 = +0.8$ tons. Stress in $ef' = +3 \times 0.6 \times 1.414 = +2.5$ tons.

(2) LOWER LATERAL SYSTEM (12 PANELS).

Panel load for both chords

 $=\frac{150\times 16}{2000}+\frac{300\times 16}{2000}=1.2\ {\rm tons}+2.4\ {\rm tons}.$

The former we treat as a dead load, the latter as a live load, both acting at each apex of the windward chord in the direction of the arrows, shown in Fig. 48. (See Remark.)

Stress in $AB = -5.5 \times 3.6 = -19.3$ tons. Stress in CC'

$$= -\left[4.5 \times 1.2 + \frac{2.4}{12}(1 + 2 + 3 + \dots + 10)\right] = -16.4 \text{ tons}$$

Stress in DE'

114

$$= [2.5 \times 1.2 + 0.2(1 + 2 + 3 + \dots + 8)] 1.414 = 14.4 \text{ tons}$$

r as a live hord in the Remark.)

16.4 tons.

4.4 tons.

BRIDGE TRUSSES.

115

Thus the following stresses are computed:

UPPER LATERAL SYSTEM.

Stresses in chords = -5.4, -9.6, -12.6, -14.4, -15.0 tons. Stresses in struts = -5.7, -4.8, -3.6, -2.4, -1.2, -0.6 tons. Stresses in diagonals = +7.6, +5.9, +4.2, +2.5, +0.8 tons.

LOWER LATERAL SYSTEM.

Stresses in chords = 19.8, 36.0, 48.6, 57.6, 63.0, 64.8 tons. Stresses in struts

= -21.6, -19.8, -16.4, -13.2, -10.2, -7.4, -5.4 tons. Stresses in diagonals = 27.9, 23.1, 18.6, 14.4, 10.4, 6.8 tons.

The chord *bedh* is in compression under the action of the dead and live loads; this compression is increased by that due to the wind pressure, as just found.

The chord A'B'C'H' is in tension under the action of the dead and live loads; this tension is increased by that due to the wind pressure, as just found.

When the wind blows on the opposite side of the bridge the diagonal and chord stresses are to be interchanged, while the strut tresses remain the same. Thus there will be the same stresses in b'c', c'd', etc., as in bc, cd, etc., and the same in A'B', B'C', etc., as in AB, BC, etc., and the dotted system of braces will act in each lateral.

The wind loads on the left half of the upper lateral are transferred to the abutment at A by means of the *portal* bracing AA'b'b in the transverse plane of Ab.

116

Prob. **95.** A through Howe truss railway bridge 20 feet wide has 12 panels, each 20 feet long; the upper and lover lateral systems are Howe trusses: find the stresses in both lateral systems due to the same wind pressure as in the previous problem.

By taking the dotted diagonals, Figs. 47, 46, and 48 will represent the left half of the Howe truss and the upper and lower lateral systems. Then by *rule*:

Panel load for one chord of npper lateral = 0.75 tons, to be taken as a dead load.

Panel load for both chords of lower lateral

= 1.5 tons + 3.0 tons;

the former to be taken as a dead load, the latter as a live load, all acting in the direction of the arrows.

Stress in $b'c = -9 \times .75 \times 1.414 = -9.5$ tons.

Stress in C'D= $-[3.5 \times 1.5 + \frac{3}{12}(1 + 2 + \dots + 9)]$ 1.414 = -23.3 tons. Stress in $B'C' = 10 \times 4.5 \times 1 = 45$ tons.

UPPER LATERAL SYSTEM.

Stresses in chords = 6.8, 12.0, 15.8, 18.0, 18.8 tons. Stresses in struts = 0.4, 6.0, 4.5, 3.0, 1.5, 0.8 tons. Stresses in diagonals

= -9.5, -7.4, -5.3, -3.2, -1.1 tons.

LOWER LATERAL SYSTEM.

Stresses in chords = 24.8, 45.0, 60.8, 72.0, 78.8, 81.0 tons. Stresses in struts = 2.3, 20.5, 16.5, 12.8, 9.2, 6.0, 3.8 tons. Stresses in diagonals

= -34.9, -28.9, -23.3, -18.0, -13.0, -8.5 tons.

117

Prob. 96. A deck Pratt truss railroad bridge 20 feet wide has 10 panels, each 20 feet long; the upper and lower lateral systems are Pratt trusses: find the stresses in both lateral systems due to a wind pressure of 40 lbs. per square foot of exposed surface of both trusses and 300 lbs. per linear foot of train surface.

By taking only the full diagonals, Fig. 46 will represent the left half of the deck Pratt truss and also the upper and lower lateral systems.

Since this is a deck bridge, the upper laterals are on the loaded, and the lower laterals are on the unloaded chord. Hence by the *rule*:

Panel load for one chord on lower lateral system

$$=\frac{100 \times 20}{2000}=1$$
 ton,

to be taken as a dead load at each apex of the windward and leeward chords (Rem.).

Panel load for both chords on upper lateral system

$$=\frac{200 \times 20}{2000} + \frac{300 \times 20}{2000} = 2 \tan 3 \tan 3$$

the former to be taken as a dead load, the latter as a live load, both acting at each apex of the windward chord (Rem.), and all acting in the direction of the acrows in Fig. 46.

UPPER LATERAL SYSTEM.

Stresses in chords = -22.5, -40.0, -52.5, -60.0, -62.5 tons. Stresses in struts = -25.0, -22.5, -17.8, -13.4, -9.3, -5.0 tons. Stresses in diagonals = +31.7, +25.1, +18.9, +13.1, +7.7 tons.

= -9.5, -8.0, -6.0, -4.0, -2.0, -1.0 tons.

Stresses in diagonals

= +12.7, +9.9, +7.1, +4.2, +1.4 tons.

Prob. 97. A through Pratt truss railroad bridge 164 feet wide has 9 panels, each 17 feet long; the upper and lower lateral systems are Pratt trusses: find the stresses in both lateral systems due to the same wind pressures as in Prob. 94.

Art. 38. The Factor of Safety for a body is the ratio of its breaking to its working stress; or it is the ratio of the load which will just crush the body to the assumed load, or load which it is intended to carry. Thus, if the tearing unit-stress of an iron plate be 20 tons and the working unit-stress be 4 tons, the factor of safety will be 5.

The value of the factor of safety is generally assumed by the engineer; different engineers assume different factors of safety, depending somewhat upon the manner of applying the loads, the character of the structure, and the nature and quality of the material. Thus, for steady loads and slowly varying stresses, the factor of safety may be low; but when the load is applied with shocks and sudden stresses, the factor ought to be large. In a building the stresses on the walls are steady, and hence the factor of safety may be low. In a bridge the stresses on the different members are more or less varying, and hence the factor of safety must be higher.

119

Also, it has been seen (Art. 16) that the live load for a short span is much more than that for a long span. For this reason the variation of stress in passing from a loaded to an unloaded state is much greater in the members of a short span than in those of a long one. Consequently, the material in a short span will suffer what is termed *futigue* more than in a long one. And although the fatigue of metals is a subject not yet well understood, yet it is clearly entablished that these sudden changes of stress in short spans demand a larger factor of safety than those in long spans.

In American practice the values of the factor of safety, for steady and for varying stresses, are: from 3 to 7 for wrought iron, from 5 to 15 for cast iron, from 4 to 8 for steel, from 8 to 12 for timber, and from 12 to 30 for stone or brick.

At times it may be necessary to employ a much larger factor of safety than either of these, owing to local circumstances. If the risk attending failure (such as loss of life or property) is small, the factor of safety may be small. But if the risk is large, the factor of safety must be large in proportion. With a bridge in perfect condition, a very small factor would be sufficient. But no bridge is in perfect condition; all rough places, such as rail joints, more or less open, produce shocks which cause sudden stresses. These stresses cannot be measured. A very large allowance has to be made for these uncertaincies and for the imperfect state of our knowledge; and therefore there must be a large factor of safety to cover all uncertainties.

CHAPTER III.

BRIDGE TRUSSES WITH UNEQUAL DISTRIBUTION OF THE LOADS.

Art. 39. Preliminary Statement. — The preceding chapter has treated of stresses produced by dead loads and uniformly distributed live loads. While this is the general method of treatment for *kighway* bridges, and in English practice for *railway* bridges, it has become the general practice of American engineers to calculate these stresses for railway bridges by one of the following three methods:

(1) The use of a *uniformly distributed excess load* covering one or more panels followed by a uniform train load covering the whole span.

(2) The use of one or two concentrated excess loads with a uniform train load covering the span.

(3) The use of the actual specified locomotive wheel loads followed by a uniform train load.

It is proposed in this chapter to show how to find the maximum stress in each member of a truss by each of these three methods.

Art. 40. Method of Calculating Stresses when the Uniform Train Load is preceded by one or more Heavy Excess Panel Loads.— This method of finding maximum stresses is sometimes used to avoid the laborious practice of finding the stresses due to the actual locomotive wheel loads to be described later.

120

Prob. 98. A through double Warren truss, Fig. 49, has 10 panels, each 12 feet long and 12 feet deep; the dead load is 1000 lbs. per foot per truss, and the train load is

2000 lbs. per foot per truss, preceded by one decomotive panel load of 30 tons per truss: find the stresses in all the members.

We may first find the stresses caused by the uniform dead and train loads, and then the stresses caused by the excess locomotive load, and add the results; or, we may determine the maximum stress in each member directly by one equation, as we have generally done; and this is the simplest method.

Dead panel load per truss = 6 tons. Train panel load per truss = 12 tons. Lecomotive panel load per truss = 30 tons. Locomotive excess panel load per truss = 18 tons.

 $\tan \theta = 1$; $\sec \theta = 1.414$.

For the maximum chord stresses (except 2-4) the locomotive must stand at 4, and the train panel loads at all the other joints; for the maximum stress in 2-4 the locomotive must be put at 6, as can easily be seen.* Then,

Max. stress in 2-4

 $= 2 \times 6 + \frac{8}{10} \times 30 + \frac{12}{10}(2+4+6) = 50.4$ tons. Max. stress in 4-6

 $= 2 \times 18 + 4 \times 18 + (\frac{9}{10} - \frac{1}{10})18 = 122.4$ tons.

* This method does not give strictly the maximum stresses in all the chord members. While the error near the ends of the truss 's quite small, it increases towards the middle.

BUTION

preceding loads and the general in English he general se stresses methods: ad covering

oad cover-

loads with

vheel loads

o find the h of these

es when one or method of avoid the

the actual

The minimum ehord stresses are due to dead load alone. For the maximum stress in any diagonal the live load is placed on the right of a section entting that diagonal, as by the usual method. Thus,

Max. stress in 5-8

122

= $[1\frac{1}{2} \times 6 + 30 \times \frac{7}{16} + 1.2(1 + 3 + 5)]1.414 = 57.7$ tons. Min. stress in 7-10

 $= [1 \times 6 - 30 \times {}_{1^{\circ}6}] 1.414 = 0.0.$

That is, the dead load passing through 7-10 to the left abutment is neutralized by the part of the locomotive load passing through 7-10 to the right abutment.

The following stresses are found in a manner similar to the above:

per foot per truss, and the train load is 1600 lbs. per foot per truss preceded by two locomotive panel loads of 30 tons each per truss: find the stresses in all the members.

Consider three fifths of the dead load as applied at the upper chord, and two fifths at the lower chord.*

Dead panel load per truss = 5 tons. Train panel load per truss = 10 tons. Excess panel load per truss = 20 tons.

For maximum chord stresses put locomotive panel loads at joints 3 and 5, and the train panel loads at all the other joints. Thus,

Max. stress in 1-3

 $= 4\frac{1}{2} \times 15 + 20(\frac{9}{10} + \frac{8}{10}) = 101.5 \text{ tons} = \text{stress in } 4-6.$ Max. stress in 3-5

$$= 8 \times 15 + 20 \left(\frac{9}{10} + \frac{8}{10} + \frac{8-1}{10} \right) = 168.0$$
 tons.

Max. stress in 5-7

 $=10\frac{1}{2} \times 15 + \frac{20}{10}(17 + 7 - 3) = 199.5$ tons.

For maximum stress in any diagonal the live load is placed on the right, by the usual method.

* In railroad bridges It is enstomary to take two thirds of the dead load as applied at the loaded chord; that is, the chord which carries the live load, and one third at the unloaded chord.

Prob. 103. A through Whipple truss, Fig. 38, has 16 panels, each 10 feet long and 20 feet deep; the dead and train loads are 1000 lbs. and 3000 lbs. per foot per truss, the train being preceded by one locomotive panel. all of 30 tons per truss: find the stresses in all the members.

Art. 41. Method of Calculating Stresses when one Concentrated Excess Load accompanies a Uniform Train Load. — This method is sometimes used, like the one in Art. 40, to avoid the practice of finding the stresses due to the locomotive wheel loads. But we have seen that the method in Art. 40 does not give strictly the maximum stresses in all the chord members.

Let Fig. 51 be a truss supporting a uniform train load covering the span, and a concentrated excess load P. We suppose the excess load P to be the difference between the locomotive panel load and the uniform train panel load as in Art. 40. Then the stress in any chord member, as bd, cansed by the concentrated load P, is equal to the bending moment at c, the center of moments for bd, divided by the lever arm for the chord; and hence the chord stress will be

128

a maximum when the concentrated load P is so placed as to make the bending moment a maximum. Now, for a single concentrated load, the maximum bending moment at any

point occurs when the load is at that point, for, if the load be moved to either side of the point, the reaction of the opposite abutment will be diminished, and hence the moment will be diminished.

Therefore, for a concentrated excess load and a uniform train load, the maximum bending moment at any point, and consequently the maximum chord stress in any member, occurs when the concentrated load is at the center of moments for that member, or at the vertical section through the center of moments, and the uniform train load covers the whole span (Art. 22).

Thus, for the maximum stress in bd, the concentrated load P is at c, the center of moments for bd; and so for any other panel in the lower chord, or unloaded chord generally. For any panel in the upper, or loaded chord generally. For any panel in the upper, or loaded chord, as bc, of a like the Warren, the concentrated load P acts at c, or at that end of the panel which is to the right of the vertical section through b, the center of moments for hc, while the uniform train load covers the whole span (Art. 22). For any panel in the loaded chord of a truss like the Pratt or Honce, where the apexes of the upper chord are vertically above those of the lower chord, the concentrated load P is at the apex directly over or under the center of moments for that member.

concentrated ind so for any ord generally. d, as *hc*, of a *P* acts at c, ht of the vers for *hc*, while Art. 22). For e the *Pratt* or are vertically entrated load center of moFor a single concentrated load, the maximum positive shear at any section will occur when the load is just to the right of the section; for the left reaction is then a maximum.

Therefore, for a concentrated excess load and a uniform train load, the maximum stress in any brace occurs when the concentrated load is at the panel point immediately on the right of the section, and the uniform train load covers the span from the right abutment to this sume panel point.

Thus, the greatest positive shear, and therefore the maximum stress, in bc or in bh, occurs when the concentrated load is at the apex c and the uniform train load extends from this apex to the right abutment. The greatest negative shear for bc or for bh would occur when the concentrated load is at the apex h and the uniform train load reaches from this apex to the left abutment. For maximum chord stresses, cars both precede and follow the locomotive. This does not often happen. For maximum stresses in the braces the locomotive precedes the cars. It follows therefore, that maximum ehord stresses, which occur for every passage of the train.

Prob. 104. A through Howe truss, Fig. 32, has 10 panels, each 12 feet long and 12 feet deep; the dead and train loads are 1000 lbs. and 2000 lbs. per foot per truss, and the locomotive panel load is 30 tons per truss: find the stresses in all the members.

Consider one third of the dead load as applied at the upper chord.

Dead panel load = 6 tons. Train panel load = 12 tons. Excess panel load = 18 tons.

For the maximum stress in any chord member, as 6-8, the excess load is placed at the joint 8 and the train load covers the whole span. Then, (2) of Art. 19,

Max. stress in

130

 $6-8 = 10.5 \times 18 + \frac{7}{10} \times 18 \times 3 = 226.8$ tons.

Otherwise by moments, (1) of Art. 19, thus:

Left reaction = $4\frac{1}{2} \times 18 + \frac{7}{10} \times 18 = 93.6$ tons.

The equation of moments about the point 7 is

 $93.6 \times 36 - 18(12 + 24) - \text{stress in } 6-8 \times 12 = 0.$ \therefore max. stress in

 $6-8 = 93.6 \times 3 - 18 \times 3 = 226.8$ tons, as before.

For the maximum stress in any diagonal, as 4-5, the excess load is placed at 6, and the train loads cover the span from this point to the right abutunent. Then,

Max. stress in

 $\begin{array}{l} 4-5 = - \left[3\frac{1}{2} \times 6 + 1.2(1+2+\dots+8) + .8 \times 18 \right] 1.414 \\ = - 111.1 \ {\rm tons}. \end{array}$

Min. stress in

$$6-7 = -[2\frac{1}{2} \times 6 - \frac{12}{10} \times 3 - \frac{2}{10} \times 18]1.414 = -11$$
 tons.

+23.2-23.2 BRIDGE TRUSSES.

Prob. 107. A deck Pratt truss, Fig. 50, has 10 panels, each 15 feet long and 15 feet deep; the dead and train loads are 800 lbs. and 2000 lbs. per foot per truss, and the excess load is 20 tons per truss: find the stresses in all the members.

Art. 42. Method of Calculating Stresses when two equal Concentrated Excess Loads, placed about 50 feet apart, accompany a Uniform Train Load. — This method is often used, like the two in Arts. 40 and 41, to avoid the practice of finding the stresses due to the locomotive wheel loads, and is a nearer approximation to the actual loads than either of the other two.

Let Fig. 52 be a truss supporting a uniform train load covering the span, and two equal concentrated excess loads,

 P_1 and P_2 . As in Arts. 40 and 41, we suppose each excess load to be the difference between the locomotive panel load and the uniform train panel load. Then the stress in any chord member, as *bd*, caused by the concentrated loads P_i and P_2 is equal to the bending moment at *c*, the center of moments for *bd*, divided by the lever arm of *bd*; and hence the chord stress will be a maximum when the two concentrated loads are so placed as to make the bending moment a maximum.

Now, for two equal loads, a fixed distance apart, the maximum moment at any point occurs when one load is at

133

184

the point and the other is on the longer segment of the truss. This may be shown as follows:

Let l = length of span in Fig. 52, d = distance between the two equal loads P_1 and P_2 , and a = distance from left abutment to center of moments c_j then supposing the load P_1 to be at a distance x to the left of c_j and calling M the moment at the point c_j due to the two loads, P_1 and P_2 , and denoting each load by P_j since they are equal, we have

$$M = P \frac{a(2l - 2a - d) - (l - 2)x}{l}$$
$$= P \frac{a(l)}{l} \frac{a - d}{l}, \text{ a maximum, when } x = 0.$$

Similarly, if the load P_1 be placed at a distance x to the right of c, the moment at the point c will be a maximum when x = 0.

Therefore, for two equal concentrated excess louds, and a uniform train load, the maximum bending moment at any point, and consequently the maximum chord stress in any member, occurs when one of the equal concentrated loads is at the center of moments for that member, and the other concentrated load is on the longer segment of the trass, while the uniform train load covers the whole span.

Thus, for the maximum stress in *bil*, the concentrated load P_1 is at *c*, and the other load P_2 is to the right; and so for any other panel in the lower, or unloaded, ehord of the left half of the truss. For any panel in the upper, or *loaded*, chord of the left half, as *hc*, of a truss like the *Warren*, where all the members are inclined, the load P_1 acts at *c*, or at that end of the panel which is to the right of the BRIDGE TRUSSES.

135

ment of the

ance between nice from left using the load calling M the r_1 and P_2 , and we have

when x = 0.

anee x to the a maximum

loads, and a oment at any stress in any ted loads is at the other conrass, while the

concentrated right; and so , ehord of the the upper, or russ like the ne load P_1 acts e right of the vertical section through b_i , the center of moments for hc_i and the other load P_2 is to the right.

For any panel in the *loaded chord* of a truss like the *Pratt* or *Honce*, where the upper apexes are vertically above the corresponding lower ones, the concentrated load P_1 is at the apex directly over or nuder the center of moments for that member.

For two equal concentrated loads P_1 and P_2 , the maximum positive shear at any section occurs when both loads are on the right of the section and P_1 is as near to it as possible; for the left reaction is then a maximum.

Therefore, for two equal concentrated excess loads and a uniform train load, the maximum stress in any brace occurs when both loads are on the right of the section and one of them is at the panel point immediately on the right of the section, and the uniform train load covers the span from this point to the right abutment.

The second excess load P_2 should be placed at a panel point at an interval of *about* 50 feet to the right of P_1 , to simplify the computation. Thus, should the panel length be 12, 15, or 18 feet, the distance between the loads would be 48, 45, or 54 feet.

Prob. 108. A through Warren truss, Fig. 53, has 8 panels, each 10 feet long and 10 feet deep, its web members all

10 Fig. 53

forming isosceles triangles; the dead and train loads are 1000 lbs. and 2000 lbs. oer foot per truss, and there are two

136

ROOFS AND BRIDGES.

excess loads 50 feet apart, each of 33 tons: find the stresses in all the members.

Dead panel load = 5 tons. Train panel load = 10 tons. Each excess load = 33 tons. $\tan \theta = \frac{1}{2}$; see $\theta = 1.117$.

For the maximum stress in any chord member, as 4-6, one excess load is placed at 6 and the other one at 4', or 50 feet to the right of the first, and the dead and train loads cover the whole span. Then (2) of Art. 19,

Max. stress in $4-6 = [9\frac{1}{2} \times 15 + \frac{33}{8}(1+6)3] \times .5$ = 114.6 tons.

Otherwise by moments, (1) of Art. 19, as follows:

Left reaction = $3\frac{1}{2} \times 15 + 33(\frac{1}{8} + \frac{6}{8}) = 81.375$ tons.

The equation of moments about the point 3 is

 $81.375 \times 15 - 15 \times 5 - \text{stress in } 4-6 \times 10 = 0.$

 \therefore max. stress in 4-6 = 114.6 tons, as before.

For the maximum stress in any diagonal, as 2-3, one excess load is placed at 6 and the other 50 feet to the right of it at 4', and the train loads cover the span from 6 to the right abutment. Then,

Max. stress in $3-6 = [2\frac{1}{2} \times 5 + \frac{3.0}{8} (1 + 2 + \dots + 6)]$

 $+\frac{33}{8}(6+1)$] 1.117 = 75.5 tons = - stress in 3-4.

Min. stress in $5-6 = -[1\frac{1}{2} \times 5 - \frac{3}{6} \times 10 - \frac{2}{6} \times 33]1.117.$ = 5.0 tons.

Max Min							

Prob. 111. A through parabolic bowstring truss, Fig. 44, has 8 panels, each 10 feet long, and 10 feet center depth; the verticals are ties, and the diagonals are struts; the dead and train loads are 1000 lbs. and 3000 lbs. per foot per truss, and there are two excess loads 50 feet apart, each of 30 tons: find the stresses in all the members.

Dead panel load = 5 tons. Train panel load = 15 tons. Each excess load = 30 tons.

Length of 3-4 = 4.375 feet; length of 5-6 = 7.5 feet. Length of 7-8 = 9.375 feet; length of 9-10 = 10.0 feet.

Then, for the maximum chord stresses, a full dead and train panel load must be at each lower apex. For any member of the lower chord, as 2-4, one excess load of 30 tons is placed at 4 and the other at 6', or 50 feet to the right of the first, and the dead and train loads cover the whole span, as just stated. Here we cannot use the "method of chord increments," since the chords are not parallel, but must use the "method of moments," (1) of Λ rt. 19.

140

٠.

Reaction at the left end = $3\frac{1}{2} \times 20 + 30 \left(\frac{7}{8} + \frac{2}{8}\right) = 103.75$ tons.

Max, stress in
$$2-4 = \frac{103.75 \times 10}{4.375} = 237.1$$
 tons.

This tensile stress in 2–4 is equal to the horizontal component of the compressive stress in 2–3, by (1) of Art. 5. Therefore the stress in 2–3 is equal to the stress in 2–4 multiplied by the secant of the angle between 2–3 and 2–4. Thus,

Max. stress in $2-3 = -237.1 \times 1.092 = -258.9$ tons.

For the maximum stress in 3-5, one excess load is put at 6 and the other at 4', while the dead and train loads cover the whole span; then take center of moments at intersection of 4-5 and 4-6 or at 4. And so on for the stresses in 5-7 and 7-9.

The diagonal stresses are found by putting only the train and excess loads on the truss in the proper position for each member, since the dead load produces no stress in the diagonals (Art. 34). Thus, to find the maximum stress in 4-5, one excess load is placed at 6 and the other 50 feet to the right of it at 4', and the train loads cover the span from 6 to the right abutment.

Now cut 3-5, 4-5, and 4-6, and take center of moments at the intersection of 3-5 and 4-6, which is 4 feet to the left of 2; the diagonal 3-6 is not in action for this loading.

Lever arm of $4-5 = 14 \sin \theta = 14 \times \frac{7.5}{12.5} = 8.4$ feet. Left reaction for this loading

$$=\frac{15}{8}(1+2+\dots+6)+\frac{30}{8}(6+1)=65.625 \text{ tons.}$$

max. stress in $4-5=-\frac{65.625\times4}{8.4}=-31.25 \text{ tons.}$

truss, Fig. 54, generally for panel lengths. ones by insert-

truts and subthrough truss. *ai, bj, ck,* etc., they directly support; the dotted diagonals 4k, 6l, 6'm, 4'n are counters, not being in action for full load.

Prob. 114. A deek Baltimore truss, Fig. 54, has 16 panels, each 10 feet long and 20 feet deep; all the verticals are posts, and all the inclined pieces are ties; the dead and train loads are 800 lbs. and 1600 lbs. per foot per truss, and there are two excess loads 50 feet apart, each of 30 tons: find the stresses in all the members.

Dead panel load = 4 tons. Train panel load = 8 tons. Each excess load = 30 tons.

The maximum chord stresses ocenr when the dead and train loads act at every upper apex (Art. 20), and the excess loads act at the proper apexes (Art. 42). Thus for 3b, we have 30 tons at b and at 9, 50 feet to the right of b. The center of moments is at 4, the intersection of 3-4 and 2-4. Hence, the left reaction for dead and live loads is,

 $R = 7\frac{1}{2} \times 12 + \frac{30}{16}(13 + 8) = 129.375$ tons.

Calling S the stress in 3 b, we have

 $129.375 \times 40 - 12(30 + 20) + S \times 20 = 0;$

 $\therefore S = \text{stress in } 3 b = -228.8 \text{ tons} = \text{stress in } b 5.$

The stresses in 1a and a3, 3b and b5, 5c and c7, 7d and d9, etc., must always be the same, since the posts ai, bj, ck, etc., are perpendicular to the chords, and cannot therefore eause any stresses in them.

For 5c and c7, we must put the excess loads at c and 7', and take the center of moments at 6, the intersection of 5k and 4-6; and so on.

For any lower chord member, as 4-6, we have 30 tons at 5 and at e, 50 feet to the right of 5. The center of moments is at 5. Thus,

 $R = 7\frac{1}{2} \times 12 + \frac{30}{16}(12 + 7) = 125.625$ tons.

 $\therefore 125.625 \times 40 - 12(30 + 20 + 10) - S \times 20 = 0.$

 \therefore S = stress in 4-6 = 215.3 tons.

144

It is evident that the maximum stress in each subvertical, ai, bj, ck, dl, etc., is equal to a full panel load, 4 + 8 + 30= 42 tons compression.

It is also evident that half of the load on ai, bj, ck, etc., is transmitted to 3, 5, 7, etc., through the half ties i3, j5, k7, etc.

Therefore the maximum tension in each of the half ties i3, j5, k7, etc., $=\frac{4+8+30}{2}\sec\theta=21\times1.414=29.7$ tons.¹ The maximum stress in the upper part of any main tie,

The maximum stress in the upper part of any main tie, as 5k, occurs when the excess loads act at c and at 7', 50 feet to the right of c, and the train loads are at all the apexes on the right of 5k. The shear in 5k for this loading is,

 $3\frac{1}{2} \times 4 + \frac{39}{16}(11+6) + \frac{8}{16}(11+10+\dots+1) = 78.875.$

 \therefore max. stress in $5k = 78.875 \times 1.414 = 111.5$ tons.

The maximum stress in any main vertical, as 5-4, is equal to the greatest shear in 5-4; and this greatest shear

¹ At the center of the truss these ties must act as counters. Thus, take the tie l-9, put the excess loads at 3 and d, and the train loads at all the apexes from the left abutment to d inclusive. Then the greatest shear in the section eutring d-9, l-9, and l-8 is -28.875 tons. As l-8 is not in action for this loading, this is the vertical component of the stress in l-9.

 \therefore max. stress in $l-9 = 28.875 \times 1.414 = +40.8$ tons.

nters. Thus, take in loads at all the the greatest shear . As l-8 is not in t of the stress in

tons.

in 5-4 occurs when the excess loads act at 5 and at e, 50 feet to the right of 5, and the train loads are at all the apexes from the right abutment to 5 inclusive. Then the greatest shear in 5-4 is that which is due to this loading, together with the four dead loads at 5, e, 7, and d, half of the dead load at 9, and half of the dead load at b, which is transmitted to 5 through the half tie j5. Hence,

Max. stress in 5-4 =

$$-[5 \times 4 + \frac{3}{16}(12 + 7) + \frac{8}{16}(12 + \dots + 1)]$$

= -94.6 tons.

The maximum stress in the lower part of any main tie, as j4, is equal to the maximum stress in 4-5 multiplied by the secant of the angle which the tie makes with the vertical. Hence,

Max. stress in $j4 = 94.6 \times 1.414 = 133.8$ tons.

The maximum stress in 6-l occurs when the excess loads are at a and 7, and the train loads are at all the joints from the left abutment to 7 inclusive. Then the shear in the section cutting d-9, l-9, and l-8 is -21.625 tons, which is the vertical component of the stress in l-9, since l-8 is not in action. The load at d produces in l-9 a negative shear of 2 tons, so that the difference, or 19.625, must come from the member 6-l.

 \therefore max. stress in $6-l = +19.625 \times 1.414 = +27.7$ tons.

Otherwise as follows: The live loads going to the right abutment through the panel 6-8 = 23.63 tons. The dead loads crossing this at the section cutting d-9, l-9, and l-8 are $\frac{1}{2}$ of load at $9 + \frac{1}{2}$ of load at d = 4 tons. The difference is 19.63 tons, for which the panel 6-8 must be counterbraced. Thus are found the following maximum stresses :

146

Note. — In the above determination of the maximum stresses in the long verticals and in the lower ends of the long diagonals, as, for example, in 5-4 and j-4, it was assumed that the largest possible shear in 5-4 or in j-4 occurs when the excess loads act at 5 and at e, and the train loads are at all the apexes from the right abutuent to the joint 5 inclusive. It is evident, however, from a little inspection of Fig. 54, that, if a train panel load be placed at the joint b, one half of this train load at b will be transmitted to the joint b, through the half the j_j just as one half of the dead load at b is trusmitted to 5 through the half the j₅, and that this half train load transmitted to 5, minus

147

51.00 12

the part that is transmitted to the right abutment, which is ${}_{15}^{3}$ of the train load at b, will form part of the shear in 5-4 or in j-4; that is, the shear will be increased by ${}_{\frac{1}{2}} \times 8 - {}_{15}^{3} \times 8 = {}_{15}^{5} \times 8 = 2.5$. Hence,

Max. stress in 5-4 = $-[5 \times 4 + \frac{1}{2}(12 + 7) + \frac{1}{2}(12 + \dots + 1) + 2.5]$ = -97.1 tons,

Max. stress in $j-4 = 97.1 \times 1.414 = 137.3$ tons.

Similarly,

Max. stress in $2-3 = -[7 \times 12 + \frac{30}{16}(14 + 9)] = -127.1$ tons.

Max. stress in $i-2 = 127.1 \times 1.411 = 179.7$ tons,

and so on for 6-7 and k-6, 8-9, and t-8.

Thus, stress in 6-7 = -68.6, in k-6 = 97.0, in 8-9 = -48.1, in l-8 = 61 tons.

It is evident that by putting a train panel load on the apex just to the left of the section considered, the shear in that section is increased the most when near the left end of the truss; and that it decreases on approaching the middle of the truss without becoming zero.

= 8 tons.

BRIDGE TRUSSES.

149

The maximum chord stresses occur when the dead and train loads act at every lower apex (Art. 20), and the excess loads act at the proper apexes (Art. 42). Thus for b6, we have 30 tons at 4 and at c, 48 feet to the right of 6. The center of moments is at 3, the intersection of 3–5 and 3–6. Hence the left reaction for dead and live loads is,

 $R = 7\frac{1}{2} \times 20 + \frac{30}{16}(14 + 11) = 196.875$ tons.

Calling s the max. stress in b6, we have,

 $196.875 \times 32 - 20 \times 16 + 20 \times 16 - s \times 32 = 0.$

 \therefore $s = \max$, stress in b6 = 196.9 tons = max. stress in 4b.

For any upper chord member, as 5-7, we have 30 tons at 8 and at e, 48 feet to the right of 8. The center of moments is at 8. Thus,

 $R = 7\frac{1}{2} \times 20 + \frac{30}{14} (10 + 7) = 181.875$ tons.

 $\therefore 181.875 \times 6 \times 16 - 20(16 + 32 + 48 + 64 + 80) + s \times 32 = 0.$

 \therefore s = max. stress in 5-7 = - 395.6 tons.

Similarly, the other chord stresses are found.

It is evident that the maximum stress in each subvertical, ai, bk, cl, dm, etc., is equal to a full panel load 8 + 12 + 30= 50 tons tension.

It is also evident that half of the load on ai, bk, cl, dm, etc., is transmitted to 4, 4, 6, 8, etc., through the half struts i4, k4, i6, m8, etc.

Therefore the maximum compression in each of the half struts i4, k4, l6, m8, etc.

$$=\frac{8+12+30}{2} \sec \theta = 25 \times 1.414 = 35.4 \text{ tons.}$$

The maximum stress in the lower part of any main tie, as l8, occurs when the excess loads act at 8 and at e, 48 feet to the right of 8, and the train loads are at all the apexes

from the right abutment to 8 inclusive. The shear in 18 for this loading is,

$$2\frac{1}{2} \times 8 + \frac{3}{2}(10+7) + \frac{1}{2}(10+\dots+1) = 93.125.$$

 \therefore max. stress in $l8 = 93.125 \times 1.414 = 131.7$ tons.

The maximum stress in the upper part of any main tie, as 3k, occurs when the excess loads act at 6 and at d, 48 feet to the right of 6, and the train loads are at all the apexes from the right abutinent to b inclusive: for half of the train load at b is transmitted to the joint 6 through the half strut k 6, and $\frac{3}{16}$ of the train load at b is transmitted to the right abutinent; therefore the difference of these, or $\frac{5}{16}$ of the train load at b, goes to the left abutinent and forms part of the shear in 3k; that is, the train panel load at bwill increase the shear in 3k by $\frac{5}{16} \times 12 = 3\frac{3}{4}$ tons. It is evident also that half of the dead load at b, which is transmitted to 6 through the half strut k 6, goes to the left abutment and forms part of the shear in 3k. Similarly for 5land 7m. Hence,

Max. stress in 3k

150

 $= [5 \times 8 + \frac{3}{16}(12+9) + \frac{1}{16}(12+\cdots+1) + 3.75] 1.414$ = 200.3 tons.

The maximum stress in 3-4 is equal to the full panel load at 4 plus half the sum of the panel loads at a and b

$$= 30 + 12 + 8 + \frac{1}{2}(24 + 16) = 70$$
 tons

The maximum stress in either of the other long verticals, as 7-8, is equal to the shear in 7 m plus whatever load is applied to the upper apex 7. Hence,

Max. stress 7-8

 $= - \left[8 + \frac{39}{16} (8+5) + \frac{12}{16} (8+\dots+1) + \frac{1}{16} \times 12 \right]$ = - 60.1 tons.

ong verticals, atever load is

 $\frac{1}{16} \times 12$]

BRIDGE TRUSSES.

151

The maximum stress in 3i occurs when the excess loads act at 4 and at c, and the train loads cover the whole tr esc: it is easily seen that half of the dead train loads at c, which are transmitted to 4, form part of the shear ecc. Hence,

Max. stress in $3i = -[7 \times 20 + \frac{30}{16}(14 + 11)]$ 1.414 = -264.2 tons.

The following stresses are found in a manner similar to the above:

MAXIMUM CHORD STRESSES.

8-5	5-7	7-9	2-4	4-6	6-8	8–10

MAXIMUM STRESSES IN THE VERTICALS.

8-4	5-6	7-8	9-10	ai, bk, cl, dm.
+ 70.0	-99.4	- 60.1	- 23.9	+ 50.0

152

The stress in 9-m = 9-n occurs when the excess loads act at e and 6', and the train loads act at all the joints from the right abutment to e. Then the shear in the section cutting 9-7', 9-n, and $10-n = 101.625 - 8 \times 8 = +37.625$ tons; and as 10-n cannot take compression, this is the vertical component of stress in 9-n.

 \therefore max. stress in $9-n = +37.625 \times 1.414 = +53.2$ tons.

If 10-n were constructed to take compression, this would be greatly modified. In this case the excess loads would act at 8' and g, and the train loads at all the joints from the right abutment to 8'. Then the left reaction = 92.625 tons and the shear in the section cutting 9-7', 9-n, and 10-n =92.625 - 64 = + 28.625 tons. The member 10-n takes a positive shear of 4 tons, so that the vertical component of stress in 9-n = + 28.625 - 4 = + 24.625 tons.

 \therefore max. stress in $9-n = +24.625 \times 1.414 = +34.8$ tons.

The stress in 7'-0 occurs when the excess loads act at f and 4', and the train loads at all the joints from the right abutment to f. Then the left reaction = + $^{3}4.375$ tons and the shear in the section cutting 7'-5', 7'-0, and $8'-0 = 84.375 - 8 \times 10 = + 4.375$ tons. As 8'-0 does not act in compression, this shear must be resisted by 7'-0 alone.

 \therefore max. stress in 7'-0 = + 4.375 × 1.414 = + 6.2 tons.*

Prob. 117. A deck Baltimore truss, Fig. 54, has 16 panels, each 10 feet long and 20 feet deep, the verticals being posts and the diagonals ties; the dead and train loads are 1000 lbs. and 2000 lbs. per foot per truss, and there are two excess loads 50 feet apart, each of 33 tons: find the stresses in all the members.

• It should be noted that the members m-8 and n-8' are also tension members for counter stresses.

This problem is taken from "Strains in Framed Structures" by A. J. Du Bois. It will be seen that the answers above given for the maximum stresses in the lower part of the main ties and in the long verticals differ somewhat from those given by Prof. Du Bois.

154

Art. 44. True Maximum Shears for Uniform Live Load.— Thus far, it has been assumed that the live panel loads were all concentrated at the panel points, and in order to find the maximum stress in any diagonal due to a uniform live load per linear foot, the maximum live load shear in that diagonal has been found by putting a live panel load on every joint on the right of the section cutting the diagonal (Art. 22).

For example, it has been assumed that the first apex on the right of the section in Fig. 57 has a full live panel load and the first one on the left has no live load. Now the joint n on the right of the section receives the half panel load

between the joints n and n-1, but only a small part of the load on the left of n; the other part of the load on the left of n is received by the joint n+1. When the uniform load extends from the right abutment to the joint n+1, the joint n receives a full panel load; but then the joint n+1 receives a half panel load. Let us therefore ascertain at what distance x to the left of the joint n the load must extend to produce the greatest shear in the n + 1th panel.

Let N = the number of panels in the truss, p = the panel length, w = the uniform live load per linear foot, n = the number of whole panels covered by the load, R = the reaction at the left or unloaded end. Then,

 $\frac{wx^2}{2p}$ = the part of the load wx which is carried by the joint n+1; and $wx - \frac{wx^2}{2p}$ = the part of the load wx which is carried by the joint n.

Iniform Live

the live panel as, and in order ne to a uniform load shear in ive panel load ng the diagonal

e first apex on live panel load Now the joint alf panel load

hall part of the oad on the left a uniform load n + 1, the joint at n + 1 receives in at what disnust extend to el.

s, p = the panel r foot, n = the l, R = the reac-

ied by the joint ad wa which is BRIDGE TRUSSES.

We have then for the reaction

155

Hence the shear in the n + 1th panel is

$$V = \frac{wx^{n}}{N} + \frac{wx^{2}}{2pN} + \frac{wn^{2}p}{2N} - \frac{wx^{2}}{2p} + \cdots$$
 (2)

Equating the derivative of V to zero, we have,

$$\frac{wu}{N} + \frac{wx}{pN} - \frac{wx}{p} = 0;$$

$$\therefore x = \frac{n}{N-1}p,$$

which is the distance to the left of the joint n that the live load must extend in order to produce the maximum shear in the n + 1th panel from the right end.

Thus, let the truss have 8 panels; then for the true maximum shear in the sixth panel from the right end $x = \frac{4}{7}p$, for the seventh panel $x = \frac{4}{7}p$, and for the eighth or last panel $x = \frac{4}{7}p = p$, or the whole truss is covered.

The total live load on the truss

$$= nwp + \frac{nwp}{N-1} = \frac{Nnwp}{N-1}$$

= N times the load on the n + 1th panel.

Therefore, the live load on the n + 1th panel is $\frac{1}{N}$ th of the total live load on the truss.

Substituting the above value of x in (2) and reducing, we have Maximum shear $-\frac{wpn^2}{2}$.

aximum shear =
$$\frac{1}{2(N-1)}$$

156

These values of x and the maximum shear are independent of the form of the truss, whether the webbing be inclined, as in the Warren, or inclined and vertical, as in the Pratt and Howe.

Prob. 118. A truss, Fig. 57, has 7 panels, each 16 feet long, the live load is 2 tons per foot: find (1) the true maximum live load shears in every panel and (2) the maximum live load shears by the usual method (Art. 22).

Here
$$N = 7$$
, $p = 16$ feet, and $w = 2$ tons.

For the maximum shear in the 1st panel from the left n = 6.

$$\therefore x = p = 16$$
 feet, and shear $= \frac{2 \times 16 \times 6^2}{2 \times 6} = 96$ tons,

which is half of the effective load, or the effective reaction. For max, shear in the 4th panel from left, n = 3.

 $\therefore x = \frac{5}{6} \times 16 = 8$ feet, or the load reaches to the middle of the 4th panel.

Shear
$$=\frac{2 \times 16 \times 3^2}{2 \times 6} = 24.0$$
 tons.

By the usual way of taking a full panel load as concentrated at the third apex from the right n - 1, and none at the 4th apex n, we have

Shear =
$$\frac{32}{1+2+3} = 27.4$$
 tons,

which is greater than that obtained by the strictly correct method.

Thus the following live load shears are computed (1) by the Strictly Correct Method and (2) by the Method in Common Practice:

True Method. 96.0, 66.7, 42.7, 24.0, 10.7, 2.7, 0.0 tons. Common Method. 96.0, 68.6, 45.7, 27.4, 13.7, 4.6, 0.0 tons. re independent og be inclined, s in the Pratt

157

It is seen that the shears obtained by the usual method, that is, by supposing the panel loads to be concentrated at the panel points, are larger than those obtained by the *true method*. For the reason that the shears obtained by the usual method always err on the safe side, and that the error is always small, it is the common practice to suppose all the load from middle to middle of panel to be concentrated at the panel point, as in Art. 4.

Art. 45. Locomotive Wheel Loads. — In computing the stresses in railway bridges in America, the live load which is now generally taken, consists of two of the heaviest engines in use on the line, at the head of the heaviest known train load. The weights of the engines and tenders are assumed to be concentrated at the wheel-bearings, giving definite loads at these points, while the train load is taken as a uniform load of about 3000 pounds per linear foot of single track.

(b.) (40 feet = 1 inc Fig. 58.

The first diagram of Fig. 58 represents two 88-ton passenger locomotives, as specified by the Pennsylvania Railroad.

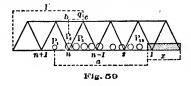

The second diagram shows two 112-ton decapod engines, used on the Atlantic Coast Line.

158

The numbers above the wheels show their weights in tons for both rails of a single track. The numbers between the wheels show their distances apart in feet.

Art. 46. Position of Wheel Loads for Maximum Shear.— Let Fig. 59 represent a truss with a decaped engine and train upon it.

Let N = the number of panels in the truss, p = the panel length, $P = P_1 + P_2 + \cdots + P_{10} =$ the sum of the wheel loads, w = the uniform train load per linear foot, W = the total live load on the truss, d = the distance of the center of

gravity of *P* from the front of the train, x = the distance of the front of the train from the right abutment, a = the distance of P_1 from the front of the train, y = its distance at the left of the *n*th panel point, and R = the reaction at the left end. Then $P_1 \frac{y}{p} =$ the part of the load P_1 that is carried by the n + 1th panel point.

We have then for the reaction

$$R = \frac{P(x+d)}{Np} + \frac{wx^2}{2Np} \cdot \cdot \cdot \cdot \cdot \cdot (1)$$

Hence the shear in the n + 1th panel is

$$V = \frac{P(x+d)}{Np} + \frac{wx^2}{2Np} - P_1 \frac{y}{p} \cdot \cdot \cdot \cdot \cdot (2)$$

eights in tons s between the

Maximum th a decapod

p = the panel f the wheel foot, W = the ' the center of

The distance of t, α = the dists distance at eaction at the that is carried

 $\cdot \cdot \cdot (1)$

. (2)

BRIDGE TRUSSES.

159

But from the figure, x + a = np + y; $\therefore y = a + x - np$, which in (2) gives

$$V = \frac{P(x+d)}{Np} + \frac{wx^2}{2Np} - \frac{P_1}{p}(a+x-np).$$

Equating the first derivative of V to zero, we have,

$$\frac{P+wx}{N} - P_1 = 0$$

or, since P + wx = W, we have,

$$P_1 = \frac{1}{N} W.$$

Hence, the shear in any panel is a maximum when the load on the panel is $\frac{1}{N}$ th of the entire live load on the truss.

In practice it is convenient to put one of the loads at the uth panel point, so that the above condition cannot, in general, be exactly satisfied. We must have in general,

$$P_1 = \text{or} < \frac{1}{N} W.$$

Hence, in general, the shear in the n + 1th panel is a maximum when one of the loads is at the nth panel point, and the load on the n + 1th panel is equal to or just less than $\frac{1}{N}$ th of the entire load on the truss.¹

Prob. 119. A through Warren truss has 10 panels, each 12 feet long: find the maximum shears in each panel eaused by a single decapod engine and tender.

Here each driver in Fig. 59 weighs 12.8 tons, each tender wheel weighs 10 tons, and the pilot wheel weighs 8 tons; the total load W is 112 tons.

¹ This holds good in all cases for shear.

Let it be required to find the maximum shear in the 2d panel from the left. Here n = 8; N = 10.

By the above rule for the maximum shear in this panel, the first driver must be put at the joint *u*, since $8 < \frac{112}{10}$, and $8 + 12.8 > \frac{116}{10}$.

In this position of the loads, the left reaction is

$$R = \frac{8}{120} \times 104 + \frac{12.8}{120} (96.0 + 91.75 + 87.5 + 83.25 + 79.0) + \frac{10}{120} (71.5 + 66.83 + 61.23 + 56.56) = 74.9 \text{ tons.}$$

: max. shear = $74.9 - \frac{8 \times 8}{12} = 69.6$ tons.

160

Let it be required to find the maximum shear in the 8th panel from the left. Here n = 2.

To find the position of the wheels for maximum shear in this panel, try the first driver at the joint n, as before.

For this position the total live load on the truss

$= 8 + 5 \times 12.8 = 72$ tons,

since the tender wheels are off the truss. By the rule, therefore, this is not the correct position, since $8 > \frac{1}{10} \times 72$. If we put the pilot wheel at *n*, the load on the truss

 $= 8 + 4 \times 12.8 = 59.2$ tons,

since the last driver is off the truss. Hence for maximum shear in this panel this is the correct loading.

With the live load in this position, the left reaction is

$$R = \frac{8}{120} \times 24 + \frac{12.8}{120} (16 + 11.75 + 7.50 + 3.25) = 5.7 \text{ tons},$$

which is also the maximum shear, since in this case there is no load to be subtracted.

Thus the following shears are determined :

Max. shears = 80.8, 69.6, 58.4, 47.2, 36.0, 24.8, 13.9, 5.7.

BRIDGE TRUESES.

161

Prob. 120. A deck Pratt truss, Fig. 50, has 10 panels, each 20 feet long and 24 feet deep: find the maximum web stresses in each panel caused by a single passenger locomotive and tender, as shown in (a) of Fig. 58.

We first find the maximum shear in the left panel. By the rule the second pilot wheel must be put at the joint 4, since $8 < \frac{3}{16}$, and $8 + 8 > \frac{3}{16}$.

With the live load in this position, the left reaction is

$$R = \frac{8}{200} (185.5 + 180 + 153.5 + 148.5 + 143 + 138) + \frac{20}{200} (171 + 163) = 71.34 \text{ tons};$$

and the max. shear = $71.34 - 8 \times \frac{5.5}{20} = 69.14$.

 \therefore stress in 1-4 = 69.14 sec $\theta = 69.14 \times 1.302 = 90.0$ tons.

For 3-4 we have the same loading as for 1-4; and the maximum compression in 3-4 is equal to the shear just found for 1-4.

 \therefore stress in 3-4 = -69.1 tons.

The maximum compression for the end vertical 1-2 is found by placing the wheels so as to bring the greatest load to the joint 1, and is found to be 71.9 tons.

Thus we find the following maximum stresses:

Diagonals = +90.0, +78.6, +67.1, +55.6, +44.2, +32.7, +21.2, +9.8 tons.

Posts = -71.9, -69.1, -60.3, -51.5, -42.7, -33.9 tons.

If the second driver be placed at the middle panel point 11, the stress in 11-12 will be found to be -39.6 tons.

Prob. 121. A deck Pratt truss, Fig. 50, has 10 panels, each 12 feet long and 12 feet deep; the dead load is 1000

lbs. per linear foot of track, the live load is a passenger locomotive and tender, as shown in (a) of Fig. 58: find the maximum web stresses in each panel.

The dead and live load stresses may be computed separately.

stresses in each panel due to a passenger locomotive and tender, as shown in (a) of Fig. 58, followed by a uniform train load of 3000 lbs. per linear foot.

(1) To find the maximum stress in 2-3.

Try the first driver at the panel point 4. In this position the total live load on the truss

$= 88 + 90 \times 1.5 = 223$ tons.

Since $8 + 8 < \frac{223}{8}$, and $8 + 8 + 20 > \frac{223}{8}$, this is the correct position for the maximum shear in the panel 2-4. The reaction is

$$R = \frac{8}{144}(135 + 140.5 + 108.5 + 103.5 + 9^{\circ} + 93) + \frac{20}{144}(126 + 118) + \frac{1}{2} \times \frac{1.5 \times 90^{\circ}}{144} = 113.77 \text{ tons.}$$

$$\therefore \text{ max. shear} = 113.77 - \frac{8}{18}(9 + 14.5) = 103.33.$$

 \therefore stress in 2-3 = -103.33 × 1.25 = -129.2 tons.

(2) To find the maximum stress in 9-8'.

l

Try the first driver at the joint 8'. In this position the total live load on the truss

$= 88 + 18 \times 1.5 = 115$ tons.

But $8+8 > \frac{115}{8}$; hence this is not the correct position for the maximum shear in the panel 10-8'.

We therefore try the second pilot wheel at 8'. We then have, for the total live load on the truss,

 $W = 88 + 9 \times 1.5 = 101.5$ tons.

Since $8 < \frac{101.5}{8}$, this is the correct position for the maximum shear in the panel 10-8'.

The reaction is

161

$$R = \frac{1540 + 1640 + 13.5 \times 4.5}{144} = 22.51 \text{ tons.}$$

$$\therefore \text{ max. shear} = 22.51 - \frac{8 \times 5.5}{18} = 20.1 \text{ tons.}$$

$$= - \text{ stress in } 9-10.$$

 \therefore stress in 9-8' = 20.1 × 1.25 = 25.1 tons.

The max, tension in the hip vertical 3-4 is found by putting the wheels so as to bring the greatest load at 4.

Thus the following maximum stresses are found: Diagonals

= -129.2, +96.4, +67.9, +43.6, +25.1, +11.3 tons. Verticals = +36.9, -54.3, -34.9, -20.1 tons.

Art. 47. Position of Wheel Loads for Maximum Moment at Joint in Loaded Chord. — In addition to the notation of Art. 46, let P' = the load on the left of the panel point n, Fig. 59, x' = the distance of its center of gravity from the point n, and n' = the number of panels between the left abutment and the point n. Then for the moment at the panel point n, Fig. 59, we have

$$M = Rn'p - P'x' \\ = \left[\frac{P(x+d)}{Np} + \frac{wx^2}{2Np}\right]n'p - P'x', \text{ [by (1) of Art. 46]}.$$

Equating the first derivative of M to zero, we have, since

$$dx' = cx, \ \frac{(P+wx)n'}{N} - P' = 0;$$

or since P + wx = W (Art. 46), we have

 $P' = \frac{n'}{N}W.$

BRIDGE TRUSSES.

165

Hence the moment at any panel point in the loaded chord is a maximum when the load on the left of the point is $\frac{n'}{N}$ ths of the entire live load on the truss.

In practice it is convenient to put one of the loads at the *n*th panel point, so that the above condition can very seldom be exactly satisfied. We must have in general

$$P' = \text{or} < \frac{n'}{N}W$$

Hence, in general, the moment at any panel point of the loaded chord is a maximum when the load on the left of the point has to the entire load on the truss a ratio which is equal to or just less than the ratio which the number of panels on the left of the point bears to the entire number of panels in the truss.

By this rule the maximum chord stress in any member of the unloaded chord may be determined, since we have only to divide the maximum moment at the panel point opposite the chord member by the depth of truss.

Prob. 123. A deck Pratt truss, like Fig. 50, has 8 panels, each 18 feet long and 24 feet deep: find the maximum chord stresses due to a single passenger locomotive and tender.

Let it be required to find the maximum stress in the second panel 3-5. Here u' = 2, N = 8, W = 88; therefore, by the rule, I'' must be equal to or less than $\frac{2}{8} \times 88$, or 22 tons. Hence, the first driver must be put at 5 since

8 + 8 < 22, and 8 + 8 + 20 > 22.

With the live load in this position, the left reaction is

$$R = \frac{8}{144} (122.5 + 117 + 90.5 + 85.5 + 80 + 75) + \frac{20}{144} (108 + 100) = 60.58 \text{ tons.}$$

1 tons.

ROOFS AND BRIDGES.

 \therefore stress in $3-5 = -\frac{[60.58 \times 36 - 8(9 + 14.5)]}{24} = -83$ tons

= - stress in 6-8.

Thus are found the following stresses:

Max. stress in 1-3 = -47.7, in 3-5 = -83, in 5-7 = -103.8, in 7-9 = -110.5 tons.

Prob. 124. A deck Pratt truss, Fig. 50, has 10 panels, each 20 feet long and 24 feet deep: find the maximum chord stresses in each panel due to a passenger locomotive and tender.

Ans. Max. stresses in upper chord = -57.6, -103.0, -136.4, -155.2, -161.9 tons.

Prob. 125. A through Warren truss has 10 panels, each 12 feet long and 12 feet deep: find the maximum stresses in the upper chord due to a decapod engine and tender.

Aus. Max. stresses = -80.8, -145.0, -190.9, -217.3, -225.2 tons.

Art. 48. Position of Wheel Loads for Maximum Moment at Joint in Unloaded Chord. — By the rule deduced in Art. 47, the maximum chord stresses may be determined in the unloaded chord of any simple truss, and also in the loaded chord of such trusses as the Pratt and Howe, where the web members are vertical and inclined so that the panel points of the upper chord are directly over those of the lower chord. For trusses like the Warren and lattice, where all the web members are inclined, it applies only to the unloaded chord. For the loaded chord of such trusses a modification of the formula or rule is necessary, which may be deduced as follows:

Let it be required to find the maximum moment at the panel point c of the unloaded chord, Fig. 59. $2]_{=-83 \text{ tons}}$

15-7 = -103.8,

moment at the

BRIDGE TRUSSES.

167

Let W = the total live load on the truss, Q = the load on the (n-1)th panel, and F = the load on the left of the (n-1)th panel.

Let l' = the distance of c from the left support, q = the distance bc, p = the panel length, and l = the length of the span.

Let x = the distance from the center of gravity of W to the right support, $x_1 =$ the distance from the center of gravity of P' to the panel point n, and $x_2 =$ the distance from Q to the panel point n - 1.

The part of Q that is earried by the *n*th panel point is Qx_2 .

p

Hence the moment at c is

$$M = \frac{Wx}{l}l' - P'(x_1+q) - \frac{Qx_2}{p}q.$$

Equating the first derivative of M to zero, we have, since $dx = dx_1 = dx_2$,

$$\frac{Wl'}{l} - P' - \frac{Qq}{p} = 0. \quad \therefore \quad P' + \frac{q}{p} Q = \frac{l'}{l} W. \quad . \quad . \quad (1)$$

If the braces are equally inclined, that is, if the center of moments c is directly over or under the center of the opposite member, as is usually the case, we have $\frac{q}{p} = \frac{1}{2}$, and (1) becomes

 $P' + \frac{1}{2} Q = \frac{l'}{l} W.$ (2)

For the Pratt and Howe trusses q = 0, and (1) becomes

$$P' = \frac{l'}{l} W,$$

which is the same as the formula that was found in Art. 47.

168

ROOFS AND BRIDGES.

It is convenient in practice to put one of the loads at the n-1th panel point, so that, *in general*, we must have

$$l^{p} + \frac{1}{2}Q = \text{or } < \frac{l'}{l}W.$$
 (3)

Prob. 126. A through Warren truss has 10 panels, each 12 feet long and 12 feet deep: find the maximum stresses in the lower chord due to a decapod engine and tender.

To find the maximum stress in the first panel 2-4. Here $l' = \frac{1}{4}$, l = 10, and W = 112. Therefore by formula (3), $P' + \frac{1}{2}Q$ must be equal to or less than $\frac{1}{2}_0 \times 112$ or 5.6 tons. Hence the 1st driver must be put at 4, since

$$\frac{1}{2} \times 8 < 5.6$$
, and $8 + \frac{1}{2} \times 12.8 > 5.6$.

The left reaction then = 86.14 tons. The moment at the point 1 is

 $M = 86.14 \times 6 - 8 \times \frac{8}{12} \times 6 = 484.84.$

: stress in
$$2-4 = \frac{484.84}{12} = 40.4$$
 tons.

Similarly the maximum stresses in the other lower chord members are found.

Max. stresses = 484.8, 111.9, 167.1, 203.4, 220.7 tons.

Sug. To find stress in 4-6, put 2d driver at 6; in 6-8; put 3d driver at 8; in 8-10, put 4th driver at 10; in 10-12, put 5th driver at 12.

Art. 49. Tabulation of Moments of Wheel Loads. —A diagram such as is shown in Fig 51, diminishes considerahly the work of computing stresses due to actual wheel loads. The first diagram is for an 88-ton passenger locomotive and its tender; the second is for a 112-ton decapod engine and its tender. Any locomotive can be diagramed e loads at the st have

minishes cono actual wheel assenger loco-2-ton decapod be diagramed BRIDGE TRUSSES.

169

(20 feet = 1 inch scale.)

Each diagram shows the weights and distances apart of the wheels. Below each wheel, on the *korizontal* line, is shown the weight of that wheel together with that of all the preceding ones, and its distance from the front wheel.

170

Below each wheel on the vertical line is given the moment of all the preceding wheels, with reference to that wheel. Thus, for the third driver of the decapod engine, we have 46.4 tons for the weight of it and the three preceding wheels, 16.5 feet for its distance from the front wheel, and 295.2 foot-tons for the moment of the preceding wheels with reference to the third driver. At the beginning of the uniform load we have 112 tons for the weight of all the preceding loads, 49.68 feet for the distance of this point from the front wheel, and 2910 foot-tons for the moment of all the preceding loads with reference to this point. Each diagram shows also that, the moment at any wheel is equal to the moment at the next preceding wheel on the left, plus the sum of all the preceding wheel louds multiplied by the distance from the next left preceding wheel to the wheel in question. Thus, in (a) the moment of the first three wheels about the third is 188, and about the fourth it is 476. But 476 is equal to 188 plus 36 multiplied by 8; and similarly for the moment with reference to any other point. (See Du Bois's Strains in Framed Structures.)

This diagram may be used for finding reactions, shears, and moments. Thus

Let l = the length of the truss, and the other notation as in Art. 46. Then, from (1) of Art. 46, the left reaction is

$$R = \frac{1}{l} (Pd + Px + \frac{1}{2} wx^2),$$

which for the passenger locomotive is

$$R = \frac{1}{l} \left(2388 + 88x + \frac{1}{2}wx^2 \right) \quad . \quad . \quad (1)$$

and for the decapod engine is

$$R = \frac{1}{l} \left(2910 + 112 x + \frac{1}{2} w x^2 \right) \dots \dots \dots (2)$$

BRIDGE TRUSSES.

171

Ì

Suppose, for example, that the third tender wheel of the decapod engine is 2 feet to the left of the right abutment. We take out the numbers 2181.8 and 102 from the diagram, and the reaction is

 $R = \frac{1}{i}(2181.8 + 102 + 2).$

In practice it is convenient to draw a skeleton outline of the truss to the same scale as the diagram, to be placed directly above it in the proper position for the maximum stress in each member.

Prob. 127. If the span be 120 feet, find the reactions for the passenger locomotive, (1) when the last tender wheel is 5 feet to the left of the right abutment, (2) when the first driver is 50 feet to the right of the left abutment, and (3) when the second pilot wheel is 40 feet to the left of the right abutment.

Ans. (1) 21.4 tons; (2) 52.1 tons; (3) 16.4 tons.

Prob. 128. If the span be 100 feet, find the moments for the decapod engine, (1) at an apex 30 feet to the left of the right abutment when the second driver is at that apex, and (2) at the center of the span when the first driver is there.

Ans. (1) 1341.4 foot-tons; (2) 1883 foot-tons.

Prob. 129. A through Pratt truss, Fig. 60, has 8 panels, each 18 feet long and 24 feet deep: find the maximum chord stresses due to a passenger locomotive and tender followed by a uniform train load of 3000 lbs. per linear foot.

To find the position for the maximum moment in 2-4 caused by the live load, we try the first driver at the panel point 4. Then for the uniform train load we have $x = 7 \times 18 - 36 = 90$ feet. In this position, the total live load on the truss

 $= 88 + 1.5 \times 90 = 223$ tons.

n the moment to that wheel. gine, we have ree preceding nt wheel, and g wheels with inning of the ght of all the of this point he moment of point. Each heel is equal to e left, plus the by the distance el in question. eels about the ut 476 is equal ilarly for the (See Du Bois's

actions, shears,

ner notation as ft reaction is

(1)

(2)

Since $8 + 8 < \frac{1}{8} \times 223$, and $8 + 8 + 20 > \frac{1}{8} \times 223$, this is the correct position for maximum moment in 2–4. For this load the reaction, by formula (1), is

$$R = \frac{1}{144} \left(2388 + 88 \times 90 + .75 \times \overline{90^2} \right) = 113.8 \text{ tons};$$

and the moment at 3 is

172

$$M = 113.8 \times 18 - 188 = 1860.4.$$

$$\therefore$$
 max. stress in $2-4 = \frac{1860.4}{24} = 77.5$ tons = stress in 4-6.

Similarly, the maximum stresses in the other three chord members are found to be the following:

Max. stress in 3-5 = -128.3, in 5-7 = -157.0,

in 7-9 = -165.8 tons.

Note, — To determine the maximum stress in 7-9 put 10 feet of the train to the left of the point 10; that is, put the third tender wheel at 8. Then

$$W = 88 + 1.5 \times 82 = 211$$
 tons.

But $88 + 10 \times 1.5 < \frac{1}{2} \times 211$; therefore this is about the correct loading.

$$\begin{aligned} &\mathcal{R} = {}_{1\frac{1}{2}4} (2388 + 88 \times 82 + .75 \times \overline{82}^2) = 101.7 \text{ tons.} \\ &\mathcal{M} = 101.7 \times 79 - (2388 + 88 \times 10 + .75 \times 10^2) \\ &= 3979.4 \text{ foot-tons.} \\ &\therefore \text{ max. stress in } 7-9 = -\frac{3979.4}{24} = -165.8 \text{ tons.} \end{aligned}$$

Prob. 130. A through Pratt truss, Fig. 60, has 8 panels, each 20 feet long and 24 feet deep: $\lim_{n \to \infty} (1)$ the maximum chord stresses, and (2) the maximum web stresses, in each panel, due to a decapod engine and tender followed by a uniform train load of 3000 lbs. per linear foot.

BRIDGE TRUSSES. 173

(1) To find the position for maximum stress in 2-4 we try the 2d driver at 4; then x = 102.6 feet; and

 $W = 112 + 1.5 \times 102.6 = 266$ tons.

Since $\frac{1}{8} \times 266 = 33\frac{1}{4} > 8 + 12.8$, and < 8 + 12.8 + 12.8, this is the correct position for maximum stress in 2–4, although if the *third* driver should be put at 4 we would get about the same stress, as 8 + 12.8 + 12.8 would be just less than $\frac{1}{8}$ of the load on the truss.* The reaction is

 $R = \frac{1}{160} (2909.9 + 112 \times 102.6 + .75 \times \overline{102.6^2}) = 139.3 \text{ tons.}$ $\therefore \text{ max. stress in } 2-4 = \frac{139.3 \times 20 - 152.4}{24} = 109.7 \text{ tons}$ = stress in 4-6.

Similarly, the maximum stresses in the other three chord members are found to be -181.5, -218.9, and -226.4 tons. (2) To find the position for maximum shear in 2-3 put the 3d driver at 4; then x = 106.8 feet, and

 $W = 112 + 1.5 \times 106.8 = 272.2$ tons.

Since $8 + 12.8 + 12.1 < \frac{1}{8} \times 272.2$, this is the correct position for maximum shear in 2-3. The reaction is

$$R = \frac{1}{160} \left(2009.9 + 112 \times 106.8 + .75 \times 106.8^2 \right) = 146.4 \text{ tons};$$

and shear in

$$2-4 = 146.4 - \frac{12.8}{20} (4.25 + 8.5) - \frac{8}{20} \times 16.5 = 131.64 \text{ tons.}$$

 \therefore max. stress in 2-3 = -131.64 × 1.302 = -171.4 tons.

* The conditions of Arts. 47 and 48 may sometimes be satisfied by different positions of the load.

CHAPTER IV.

MISCELLANEOUS TRUSSES.

ROOF TRUSSES.

Art. 50. The King and Queen Truss — The Fink Truss. — The types of roof trusses most commonly used for spans from 30 feet to 100 feet, and even to 130 feet, are shown in Chapter I. The King and Queen truss, Fig. 7, is a common form for *wooden trusses*, or for trusses that are all of wood except the verticals, which are iron or steel tie-rods. This type of truss is sometimes used also when it is entirely made of steel.

The Belqian, or Fink roof-truss, Fig. 10, is a very common and economical type of truss for spans up to 130 feet. The struts, 3-4, 5-6, 7-8, are normal to the rafter, dividing it into equal parts, and, with the upper chord, are made either of wood or iron. The other members are ties, and are made of iron or steel. This type of truss is often entirely of steel, and is commonly used for iron or steel roofs over mills, shops, warehouses, train-sheds, etc. Some of the largest trusses of this type are those in the car-stops of the Pennsylvania railroad at Altoona, Pa., having a span of 132 feet.

The slope of the rafter is usually determined by the kind of roof eovering used. Slate should not be used on a roof when the slope is less than 1 vertical to 3 horizontal, and preferably 1 vertical to 2 horizontal. Gravel should not be used on a slope greater than 1 vertical to 4 horizontal. Tin 177

178

may be used on any slope, or on a flat roof. Corrugated iron should not be used on a slope less than 1 to 3; for flatter roofs than 1 to 3, of corrugated iron, are liable to leak under a driving rain as the usual joints are not tight. When possible the slope should not be less than 1 to 2.

The following table gives the approximate weight per square foot of roof coverings, exclusive of steel construction.

APPROXIMATE WEIGHT PER SQUARE FOOT OF ROOF COVERINGS.

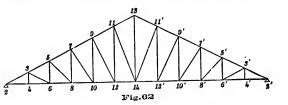

Corrugated iron, unboarded,	N	0. 2	6 t	0	No.	18	•		•		1 to 3 lbs.
Felt and asphalt, without she	at	hin	g								2 lbs.
Felt and gravel, without shea	ath	ing									8 to 10 lbs.
Slate, without sheathing, 18	t to	5 ¥	,								7 to 9 lbs.
Copper, without sheathing											1 to 11 lbs.
Tin, without sheathing .											1 to 11 lbs.
Shingles, with lath		Ż									21 lbs.

White pine sheathing, 1" thi	ck										3 lbs.
Yellow pine sheathing, 1" th	iel		:				Ż	÷			4 lbs.
Spruce sheathing, 1" thick			•	•				÷			2 lbs.
Spruce sheatning, 1" thick	•	•	•	•	·	•	•	÷	Ċ	÷	8 to 10 lbs.
Lath and rlaster ceiling .	·	•	•	•	•	•	•	•	•	•	
Tile, flat	•	•	•	•	•	•	•	•	•	•	8 to 10 lbs.
Tile, corrugated	·	•	•	•	•	•	•	•	•	•	30 to 35 lbs.
Tile, on 3" fireproof blocks	•	•	٠	•	•	•	•	•	•	•	00 00 00 105.

The weight of the steel roof construction must be added to the above. For ordinary light roofs without ceilings, the weight of the steel construction may be taken at 5-lbs. per square foot for spans up to 50 feet, and 1 lb. additional for each 10 feet increase of span. (Manual of useful information and tables appertaining to the use of Structural Steel, as manufactured by the Passaic Rolling Mill Co., Paterson, N.J. By George H. Blakeley, C.E.)

per panel, the wind being supposed to act vertically on the fixed side only:¹ find all the stresses in all the members of the half of the truss on the windward side.

The computation of the stresses is effected by the application of the principles of Chapter I.

> The radius of the upper chord = 116 feet. The radius of the lower chord = 170 feet. The lengths of 2-3, 3-5, etc. = 22.04 feet. The lengths of 2-4, 4-6, etc. = 20.81 feet.

The horizontal distance of each apex from the left abutment 2, and its vertical distance above the line 2-2', are as follows:

	(3)	(5)	(7)	(9)	
Hor. distance from 2,	17.33,	36.94,	58.06,	80 feet.	
Height above line 2-2',	13.61,	23.70,	29.91,	32 feet.	
	(4)	(6)	(8)	(10)	
Hor. distance from 2,	18.93,	38.76,	59.22,	80 feet.	
Height above line 2-2',	8.65,	14.92,	18.72,	20 feet.	

¹ If the normal wind pressure were taken, it would have a different value for each panel, owing to the curved surface of the rafters, which would increase the difficulty of the computation.

The dead load reaction = 10.5 tons.

184

and

The stresses in the chords are best found by moments; for the other members the method of resolution of forces may be used.

Thus, to compute the dead load stress in 2-3, we find the lever arm of 2-3 to be 4.89 feet.

:. dead load stress in
$$2-3 = -\frac{10.5 \times 18.93}{4.89} = -40.7$$
 tons.
Similarly, the stress in $2-4 = \frac{10.5 \times 17.33}{5.18} = 35.1$ tons.

To find the stresses in 3-4 and 3-5 pass a section cutting 2-4, 3-4, and 3-5. Then, denoting the stresses in 3-4 and 3-5 by s_1 and s_2 , we have, for horizontal and vertical components respectively,

$$35.1 \times .9095 + \frac{1.6}{\sqrt{1.6^2 + 4.96^2}} s_1 + .889 s_2 = 0,$$

and $35.1 \times .4156 - \frac{4.96}{5.21}s_1 + .4579s_2 + 7.5 = 0.$

 $\therefore s_1 = + 5.0 \text{ tons} = \text{stress in } 3-4;$

 $s_{\rm s} = -37.7$ tons = stress in 3-5.

The wind load reaction = 5.1 tons.

... wind load stress in $2-3 = -\frac{5.1 \times 18.93}{4.89} = -19.7$ tons. In this way all the stresses may be found.

BRIDGE TRUSSES.

Art. 52. The Pegram Truss — The Parabolic Bowstring Truss. — The Pegram truss, Fig. 65, consists of the same number of panels in each chord. All the panels of

each chord are of equal length, the upper chord panels being shorter than the lower. The apexes of the upper chord lie on an arc of a circle, the chord of which, 3-3', is about one and one half panel lengths shorter than the span. The rise of the upper chord is such as to make the posts,

4-5, 6-7, 8-9, nearly equal in length, or it may be so taken that the posts will decrease in length toward the ends. In a deck bridge the upper chord is made straight and the lower chord curved.

Prob. 140. A through Pegram truss, Fig. 65, has a span of 200 feet, divided into 7 panels, each 28.57 feet long; the upper apexes lie on an arc of a circle, the center height being 15 feet above the chord 3-3', which is 160 feet long; the upper panels are all of equal length, the members 2-3, 4-5, 6-7, 8-9 are stru's, all the remaining web-members are ties, the dead and live loads are 10 tons and 18 tons per panel per truss: find the stresses in all the members.

Here the radius of the upper chord = 220.83 feet.

The lengths of the upper panels 3-5, 5-7, etc.=23.37 feet. The horizontal distance of each upper apex from the left abutment 2, and its vertical height above the lower chord 2-2', are the following:

	(3)	(5)	(7)	(9)
Hor. distance from 2,	20.00,	42.20,	65.95,	88.05.
Height above lower chord,	24.00	31.29,	36.23,	38.65.

The dead load reaction = 30 tons.

Then, dead load stress in

$$4-6 = \frac{30 \times 42.20 - 10 \times 13.63}{31.29} = 36.1 \text{ tons.}$$

Also, dead load stress in 9-9'

$$= \frac{-\frac{30 \times 4 \times 28.57 - 60 \times 28.57}{38.05}}{= -44.3 \text{ tons.}}$$

Similarly, dead load stress in 3-5

$$-\frac{30 \times 28.57}{25.47} = -33.6$$
 tons.

MISCELLANEOUS TRUSSES.

189

To find the dead load stress in any web member, as 5-6, pass a section cutting 5-7, 5-6, and 4-6, and take moments around the intersection of 5-7 and 4-6, which is 102.53 feet to the 'eft of 2.

.: dead load stress in 5-6

$$=\frac{30\times102.53-10\times131.1}{144.1}=12.2$$
 tons.

The stresses in the other web members are found in like manner.

The live load stresses in the chords and in 2-3 and 3-4 are a maximum for a full load, and may therefore be t und by multiplying the corresponding dead load stresses by 1.8.

For a maximum in 5-6 and 4-5 the live load covers all the joints from the right to 6. The reaction for this loading is

$$R = \frac{18}{7} (1 + 2 + 3 + 4 + 5) = \frac{18 \times 15}{7} \text{ tons.}$$

$$18 \times 15 = 102.53 \text{ or } 102.53$$

: live load stress in $5-6 = \frac{10 \times 10}{7} \times \frac{102.03}{144.1} = 27.4$ tons.

For a maximum in 9-8' the joints 4', 6', and 8' are loaded. The reaction for this loading is

 $R = \frac{18}{4} (1 + 2 + 3) = \frac{198}{4} \text{ tons},$

which is also the maximum shear in this panel. Since the upper and lower chord members of this panel are horizontal, the stress in 9-8' is found by Art. 18.

$$\therefore$$
 max. stress in $9-8' = \frac{108}{7} \times \frac{43.41}{38.65} = 18.5$ tons.

Art. 53. Skew Bridges are those in which the end supports of one truss are not directly opposite to those of the other. The trusses of a skew bridge are usually placed so that the intermediate panel points are directly opposite in the two trusses, and the floor beams are at right angles to the trusses. When the skew is the same at each end the trusses are symmetrical; otherwise they are unsymmetrical. In the analysis of unsymmetrieal trusses, each truss must be treated separately; and the stresses are to be computed for all the members of the truss.

Prob. 142. Fig. 68 is a plan and Fig. 67 is the elevation of one of the two trusses of an unsymmetrical through

193

Pratt bridge; the span 2-18 is 120 feet, the depth is 20 feet, the panels 3-5 and 2-4 are each 18 feet, the panels 13-15 and 16-18 are each 12 feet, the other panels are each 15 feet, the inclination of the end posts 2-3 and 15-18 is the same as that of the diagonals 5-8, 7-10, 10-11, 12-13, etc., and the inclination of the two hip verticals 3-4 and 15-16 is the same; the dead and live loads are 1000 lbs. and 2000 lbs. per foot per truss: find all the stresses in all the members.

We first find the chord stresses due to the dead load as follows:

Dead panel load at $4 = \frac{1}{2}(9 + 7.5) = 8.25$ tons. Dead panel load at $16 = \frac{1}{2}(6 + 7.5) = 6.75$ tons. Dead panel load at 6, 8, 10, 12, 14 = 7.50 tons. Dead load reaction at 2 = 25.5 tons. Dead load reaction at 18 = 27.0 tons.

 $\tan \angle 3-2$ with vertical = .75 = $\tan \angle 15-18$ with vertical. $\tan \angle 3-4$ with vertical = .15 = $\tan \angle 15-16$ with vertical. $\tan \angle 3-6$ with vertical = .9. $\tan \angle 14-15$ with vertical = .6.

Hence by (2) of Art. 19 we have the following dead load stresses:

 Dead load stress in 2-4
 $= 25.5 \times .75$ = 19.1 tons.

 Dead load stress in 4-6
 $= 19.1 + 8.25 \times .15 = 20.3 \text{ tons.}$

 Dead load stress in 16-18
 $= 27.0 \times .75$ = 20.3 tons.

 Dead load stress in 14-16
 $= 20.3 - 6.75 \times .15 = 19.3 \text{ tons.}$

 etc.
 etc.
 etc.

194

* **-** -

.

ROOFS AND BRIDGES.

Also the following greatest live load stresses:

Stress in $3-6 = \frac{1}{120} [13.5 \times 12 + 15 \times 285] 1.345$ = + 49.7 tons.

Stress in $5-6 = -\frac{1}{120} [162 + 15 \times 198] = -26.1$ tons. Stress in $12-13 = \frac{1}{120} [297 + 15 \times 222] 1.166 = +35.2$ tons.
