Technical and Bibliographic Notes/Notes techniques et bibliographiques

The Institute has attempted to obtain the best original copy available for filming. Features of this copy which may be bibliographically unique, which may alter any of the images in the reproduction, or which may significantly change the usual method of filming, are checked below.

L'Institut a microfilmé le meilleur exemplaire qu'il lui a été possible de se procurer. Les détails de cet exemplaire qui sont peut-être uniques du point de vue bibliographique, qui peuvent modifier une image reproduite, ou qui peuvent exiger une modification dans la méthode normale de filmage sont indiqués ci-dessous.

- ☐ Coloured covers/ Couverture de couleur
- ☐ Covers damaged/ Couverture endommagée
- ☐ Covers restored and/or laminated/ Couverture restaurée et/ou pelliculée
- ☐ Cover title missing/ Le titre de couverture manque
- ☐ Coloured maps/ Cartes géographiques en couleur
- ☑ Coloured ink (i.e. other than blue or black)/ Encre de couleur (i.e. autre que bleue ou noire)
- ☐ Coloured plates and/or illustrations/ Planches et/ou illustrations en couleur
- ☐ Bound with other material/ Relié avec d'autres documents
- ☑ Tight binding may cause shadows or distortion along interior margin/ La reliure serrée peut causer de l'ombre ou de la distortion le long de la marge intérieure
- ☐ Blank leaves added during restoration may appear within the text. Whenever possible, these have been omitted from filming/ Il se peut que certaines pages blanches ajoutées lors d'une restauration apparaissent dans le texte, mais, lorsque cela était possible, ces pages n'ont pas été filmées.
- ☑ Additional comments:/ Commentaires supplémentaires: Various pagings.

- ☐ Coloured pages/ Pages de couleur
- ☐ Pages damaged/ Pages endommagées
- ☐ Pages restored and/or laminated/ Pages restaurées et/ou pelliculées
- ☑ Pages discoloured, stained or foxed/ Pages décolorées, tachetées ou piquées
- ☐ Pages detached/ Pages détachées
- ☑ Showthrough/ Transparence
- ☐ Quality of print varies/ Qualité inégale de l'impression
- ☐ Includes supplementary material/ Comprend du matériel supplémentaire
- ☐ Only edition available/ Seule édition disponible
- ☐ Pages wholly or partially obscured by errata slips, tissues, etc., have been refilmed to ensure the best possible image/ Les pages totalement ou partiellement obscurcies par un feuillet d'errata, une pelure, etc., ont été filmées à nouveau de façon à obtenir la meilleure image possible.

This item is filmed at the reduction ratio checked below/
Ce document est filmé au taux de réduction indiqué ci-dessous.

The copy filmed here has been reproduced thanks to the generosity of:

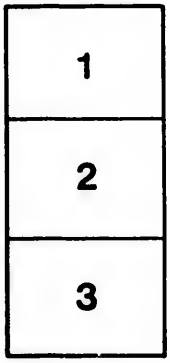
Seminary of Quebec
Library

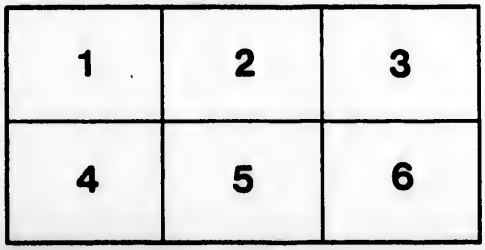
The images appearing here are the best quality possible considering the condition and legibility of the original copy and in keeping with the filming contract specifications.

Original copies in printed paper covers are filmed beginning with the front cover and ending on the last page with a printed or illustrated impression, or the back cover when appropriate. All other original copies are filmed beginning on the first page with a printed or illustrated impression, and ending on the last page with a printed or illustrated impression.

The last recorded frame on each microfiche shall contain the symbol → (meaning "CONTINUED"), or the symbol ▽ (meaning "END"), whichever applies.

Maps, plates, charts, etc., may be filmed at different reduction ratios. Those too large to be entirely included in one exposure are filmed beginning in the upper left hand corner, left to right and top to bottom, as many frames as required. The following diagrams illustrate the method:





L'exemplaire filmé fut reproduit grâce à la générosité de:

Séminaire de Québec
Bibliothèque

Les images suivantes ont été reproduites avec le plus grand soin, compte tenu de la condition et de la netteté de l'exemplaire filmé, et en conformité avec les conditions du contrat de filmage.

Les exemplaires originaux dont la couverture en papier est imprimée sont filmés en commençant par le premier plat et en terminant soit par la dernière page qui comporte une empreinte d'impression ou d'illustration, soit par le second plat, selon le cas. Tous les autres exemplaires originaux sont filmés en commençant par la première page qui comporte une empreinte d'impression ou d'illustration et en terminant par la dernière page qui comporte une telle empreinte.

Un des symboles suivants apparaîtra sur la dernière image de chaque microfiche, selon le cas: le symbole → signifie "A SUIVRE", le symbole ▽ signifie "FIN".

Les cartes, planches, tableaux, etc., peuvent être filmés à des taux de réduction différents. Lorsque le document est trop grand pour être reproduit en un seul cliché, il est filmé à partir de l'angle supérieur gauche, de gauche à droite, et de haut en bas, en prenant le nombre d'images nécessaire. Les diagrammes suivants illustrent la méthode.

INDEX.

MAGNETICAL AND METEOROLOGICAL OBSERVATIONS.

DIRECTIONS FOR PLACING THE PLATES.

INTRODUCTION.

It has been suggested to me that the time is arrived when a brief review of what the Colonial Magnetic Observatories have accomplished may be desirable, showing—primarily, how far they have successfully carried out the instructions originally drawn up for their guidance by the Committee of Physics of the Royal Society (and approved by the President and Council of that body); and, collaterally, how a similar organization may be made available for the further prosecution of the objects for which the Colonial Observatories were established.

The magnetic investigations designed to be carried into execution by the Colonial Observatories embraced a much wider scope than had been contemplated by any previous institutions, or than had been provided for by the arrangements or instrumental means of any then existing establishment, whether national or private. Not, as previously, limited to observations of a single element (the Declination),—or combining at the most one only of the components of the Magnetic Force,—the instructions of the Royal Society, and the instrumental means prepared under its direction, provided for the examination, in every branch of detail, of each of the three elements which, taken in combination, represent, not partially but completely, the whole of the magnetic affections experienced at the surface of the globe, classed under the several heads of absolute values, secular changes, and variations either periodical or occasional,—and proceeding from causes either internal or external. To meet the requirements of inductive reasoning, it was needful that the results to be obtained should comprehend all particulars under these several heads attainable by an experimental inquiry of limited duration. That no uncertainty might exist as to the objects to which, in so novel an undertaking, attention was to be directed, the Report of the Committee, approved and adopted by the President and Council of the Royal Society, conveyed in a very few sentences, remarkable alike for their comprehensiveness and conciseness, the desiderata of magnetical science. It may be convenient to reproduce these, when desiring to show the degree in which the Observatories have fulfilled their contemplated purposes:—"The observations will naturally refer

" themselves to two chief branches, into which the science of terrestrial magnetism in " its present state may be divided. The first comprehends the actual distribution of " the magnetic influence over the globe, at the present epoch, in its mean or average " state, when the effects of temporary fluctuations are either neglected, or eliminated " by extending the observations over a sufficient time to neutralize their effects. The " other comprises the history of all that is not permanent in the phenomena, whether " it appear in the form of momentary, daily, monthly, or annual change and restoration, " or in progressive changes not compensated by counter-changes, but going on conti- " nually accumulating in one direction, so as in the course of many years to alter the " mean amount of the quantities observed."—(Report of the Committee of Physics, pp. 1 and 2.)

With reference to the first of these two branches, viz. the actual distribution of the magnetic influence over the globe at the present epoch, the Report goes on to state:—" The three elements, viz. the horizontal direction, the dip, and the intensity " of the Magnetic Force, require to be precisely ascertained before the magnetic state " of any given station on the globe can be said to be fully determined . . . . . and " as all these elements are at each point now ascertained to be in a constant state " of fluctuation, and affected by transient and irregular changes, the investigation " of the laws, extent, and mutual relations of these changes is now become essential to " the successful prosecution of magnetic discovery."

With reference to the second branch, viz. " the secular and periodical variations," it is observed, that " the progressive and periodical being mixed up with the transitory " changes, it is impossible to separate them so as to obtain a correct knowledge and " analysis of the former, without taking express account of and eliminating the latter;" and with reference to the secular changes in particular, it is remarked, " These cannot " be concluded from comparatively short series of observations, without giving to those " observations extreme nicety, so as to determine with perfect precision the mean " state of the elements at the two extremes of the period embraced, which, as already " observed, presupposes a knowledge of the casual deviations."

It is clear from these extracts, that in the discussion of the observations the first point to be attended to, in the order of time, ought to be an investigation into " the " laws, extent, and mutual relations of the transient and " (as they were called at the time the Report was written) " *irregular* changes," as a preliminary step to the elimination of their influence on the observations from which a correct knowledge and analysis of the progressive and periodical changes were to be obtained. It will be

proper to show, therefore, in the first place, what the Observatories have accomplished in regard to the so-called casual or transitory variations.

Casual Variations.—All that was known regarding these phenomena at the period when the Report of the Committee of Physics was written, was, that there occurred occasionally, and, as it was supposed, irregularly, disturbances in the horizontal direction of the needle, which were known to prevail, with an accord which it was impossible to ascribe to accident, *simultaneously* over considerable spaces of the earth's surface, and were believed to be in some unknown manner connected, either as cause or effect, with the appearances of the aurora borealis. The chief feature by which the presence of a disturbance of this class could be recognized at any instant of observation,—or by which its existence might be subsequently inferred independently of concert or comparison with other Observatories,—appeared to be the deflection of the needle from its usual or normal position to an amount much exceeding what might reasonably be attributed to irregularities in the ordinary periodical fluctuations. The observations which had been made on the disturbances anterior to the institution of the Colonial Observatories had been chiefly confined to the Declination. A few of the German Observatories had recently began to note the disturbances of the Horizontal Force, but as yet no conclusions whatsoever as to their laws had been obtained;—in the words of the Committee's Report, the disturbances "apparently observe no law."—(Report, p. 10.) By the instructions cited above, the field of research was enlarged, being made to comprehend the disturbance-phenomena of the *three* elements; and the importance of their examination was urged, not alone as a means of eliminating their influence on the periodic and progressive changes, but also on the independent ground that "the "theory of the transitory changes might prove itself one of the most interesting and "important points to which the attention of magnetic inquirers can be turned, as "they are no doubt intimately connected with the general causes of terrestrial "magnetism, and will probably lead us to a much more perfect knowledge of those "causes than we now possess."

The feature which has been referred to as furnishing the principal if not the only certain characteristic of a disturbance of this class, namely, the *magnitude* of the departure from the usual or normal state at the instant of observation, has, in the discussion of the observations, been made available for the object at present under notice; it has afforded the means of recognizing and separating from the entire mass of hourly observations, taken during several years, a sufficient body of observations to furnish the necessary data for investigating at three points of the earth's surface—one in the

temperate zone of the northern hemisphere, a second in the temperate zone of the southern hemisphere, and a third in the tropics—the laws or conditions regulating or determining the occurrence of the magnetic disturbances. The method by which this separation has been effected has been explained on several recent occasions, and will be found fully described in pp. viii, ix, and x of the present volume, when treating of the disturbances of the Horizontal Force at Toronto. By processes of a similar description, the disturbances of principal magnitude in each of the three elements, the Declination, Inclination, and Total Force, have been separated from the other observations at the three Observatories of Toronto, Hobarton, and St. Helena, and submitted to an analysis, of which the full particulars as regards the Toronto observations are contained in the present volume, as those of Hobarton and St. Helena will be in volumes which have yet to appear. By the adoption of a uniform magnitude as constituting a disturbance throughout the whole period comprised by the analysis, the amount of disturbance in the several years, months, and hours is rendered intercomparable. The result of this investigation (which could not be otherwise than a very laborious operation, since the Toronto observations alone, for example, considerably exceeded 100,000 in number, each of which had to be passed through several distinct processes), has made known to us that this class of phenomena, which may with propriety and advantage receive in future the appellation of *occasional*, are, in their mean or average effects, subject to periodical laws of a very systematic character, placing them, as a first step towards an acquaintance with their physical causes, in immediate connection with the *Sun* as their primary exciting cause. They have, 1°, a *diurnal* variation which follows the order of the solar hours, and manifests, therefore, its relation to the sun's position as affected by the earth's rotation on its axis; 2°, an *annual* variation, connecting itself with the sun's position in regard to the ecliptic; and, 3°, a third variation, which seems to refer still more distinctly to the direct action of the sun, since both in period, and in epochs of maximum and minimum, it coincides with the remarkable solar period of about ten or eleven of our years, the existence of which has been recently made known to us by the phenomena of the solar spots; but which, as far as we yet know, is wholly unconnected with any thermic or physical variation of any description (except magnetic) at the surface of the earth, and equally so with any other cosmical phenomena with which we are acquainted. The discovery of a connection of this remarkable description, giving apparently to magnetism a much higher position in the scale of distinct natural forces than was previously assigned to it, may justly be claimed on the part of the Colonial Observatories, as the result of the system of observation enjoined (and so patiently and carefully maintained), and of the investigation for which it has supplied the data; since it was by means of the

disturbance-variations so determined, that the coincidence between the phenomena of the solar spots and the magnitude and frequency of magnetic disturbances was first perceived and announced.—(Phil. Trans. 1852, Art. viii.)

The extent and mutual relation of the disturbance-variations of the three elements, even at a single station (as is shown in the present volume for Toronto), supply a variety of points of approximation and of difference, which are well suited to elucidate the physical causes of these remarkable phenomena; but valuable as such aids may be when obtained for a single station, their value is greatly augmented when we are enabled to compare and combine the analogous phenomena as they present themselves at different points of the earth's surface. To give but a single example: there are certain variations produced by the mean effects of the disturbances which attain their maximum at Toronto during the hours of the night (pp. lix—lxi of this volume); the corresponding variations attain their maximum, at Hobarton, also during the hours of the night, but with a small systematic difference as to the precise hour, and with this distinguishing peculiarity, that the deflection at Hobarton is of the opposite pole of the needle (or of the same pole in the opposite direction) to the Toronto disturbance; whilst at a third station, St. Helena, which is a tropical one, the hours of principal disturbance are those, not of the night, but of the day. A very superficial examination is sufficient to show that for the generalisation of the facts,—a generalisation which is indispensable for their correct apprehension and employment in the formation of a theory,—the stations at which the phenomena are known must be increased. Those which were chosen for a first experiment were well selected to prove the importance of the investigation, and thus to lead to its extension. It is only at the Colonial Observatories that the disturbance-variations have hitherto been made out; and, guided by experience, we may infer that by adopting a similar organization and similar processes of observation at other stations, similar results may be expected, and the inquiry be further prosecuted.*

* The Colonial Observatories which were under my superintendence were originally four in number; viz. Toronto, St. Helena, Cape of Good Hope, and Hobarton. In July 1846 the detachment of the artillery at the Cape of Good Hope was withdrawn by orders from England, and the charge of the Magnetical and Meteorological Observations transferred to Mr. Maclear, the Government astronomer at that station. The Magnetical Observations made at the Cape, whilst the Magnetic Observatory was one of those which were under my superintendence, were published in 1851 in a volume similar to the present. Since the transfer to Mr. Maclear, Mr. Pierce Morton, a gentleman of considerable mathematical attainments, who has been added as an assistant to take charge, under Mr. Maclear, of that branch of the Cape Observatory, has applied himself to the investigation of the lunar magnetic influence (as derived from the Cape Observations), with a view of presenting the results to the Royal Society. For this and for other investigations into which he may desire to enter, he will have the entire series of observations, viz. those, as above stated, already published, and those which have been made since the transfer of the Observatory up to the present time.

Periodical Variations.—The anticipation expressed in the Report of the Committee of Physics, that, for the purpose of obtaining a correct knowledge of the "*regular periodical* "*variations*," it would be found necessary to eliminate the "casual perturbations," has been fully confirmed. Had the latter been strictly "casual," or accidental in a sense contra-distinguished from and opposed to periodical, a sufficiently extended continuance of observation might have occasioned their mutual compensation; but now that we have learned that the mean effects which they produce are governed by periodical laws, and that these laws and those of the regular periodical variations are dissimilar in their epochs, it is manifest that in their joint and undivided effects we have two variations, due to different causes and having distinct laws, superimposed upon each other; *to know the one correctly, we must necessarily therefore eliminate the other.* A striking illustration of the importance of such elimination is furnished by the solar-diurnal variation of the Total Force. It will readily be imagined that the question must be an important one, whether a variation which is supposed to derive its origin from the sun be a single or a double progression; whether it have two maxima and two minima in the 24 hours, or but one maximum and one minimum in that period. When no separation is made of the disturbances, the progression appears to be a double one, having two minima, one occurring in the day and the other in the night. With the removal of the disturbed observations the night-minimum disappears, and we learn that the regular solar-diurnal variation of the Total Force has but one notable inflection in the 24 hours; viz. that which takes place during the hours when the sun is above the horizon. The night-minimum is, in fact, the mean effect of the occasional disturbances (pp. xciii—xcv of this volume). It is probable that the nocturnal inflection of the solar-diurnal variation of the Declination may be ascribed to the same cause, namely, to the superposition of two distinct variations.

A careful analysis of the solar-diurnal variations of the Declination at the Colonial Observatories has brought to light the existence at all these stations of an annual inequality in the direction of the needle, concurrent with changes in the *sun's declination*, having its maxima (in opposite directions) when the sun is in or near the opposite solstices, and disappearing at or near the epochs of the equinoxes. An intercomparison of the results of the analysis at these stations has shown, that this inequality has the remarkable characteristic of having notably the same direction and amount in the southern as in the northern hemisphere, and in the tropical as in the temperate zones. An ingenious explanation of these phenomena has been suggested by Dr. Langberg of Christiania (Proceedings of the Royal Society, Vol. VII., p. 345); but whether this explanation be or be not the correct one, the

theoretical importance of the facts is considerable, inasmuch as they appear to be wholly irreconcilable with the hypothesis which would attribute the magnetic variations to thermic causation. We may ascribe to the general and almost exclusive prevalence of the thermic hypothesis, and to its influence on magnetic reasonings, that the well-known erroneous opinion was so confidently promulgated by a deservedly high magnetic authority,* that a line *must* exist surrounding the globe in which the needle would be found to have *no diurnal variation*. We have now, on the contrary, reason to be assured by the facts above referred to that there is no such line, but that everywhere in the regions of its supposed existence a diurnal variation subsists, having opposite characteristics in opposite parts of the year, as influenced by the sun's position on either side of the equator, and disappearing only at the epochs when the sun passes from south to north or from north to south declination.

Lunar Variation.—But if thermic relations have failed to supply a connecting link between the sun and those magnetic variations which are, without doubt, referable to the sun as their primary cause, the failure of that hypothesis is made still more obvious by the existence of variations governed by the *moon's* position relatively to the place of observation. We are indebted to Mr. Kreil, now holding the same position in Austria that I have filled in England, for the first suggestion of the existence of a lunar-diurnal variation of one of the elements, viz. the Declination, founded on observations at Milan and Prague; and in the present volume, pp. lxxviii—lxxxvi, will be found a complete exposition of the facts of the moon's diurnal influence on all the three magnetic elements at Toronto, viz. on the Declination, Inclination, and Total Force. In the case of this investigation also, notwithstanding the smallness of the values concerned, the instrumental means supplied to the Colonial Observatories have been found competent to determine with an approximation sufficient for present theoretical purposes, the character and amount *for each element* of the regular daily effect of the moon on the terrestrial magnetic phenomena, the existence of which does not appear to have been even suspected at the time when the Report of the Committee of Physics was drawn up. The *discovery* of the moon's influence on any of the magnetic elements is due, as already stated, to Mr. Kreil; but Toronto is the first, and as yet the only, station at which the numerical values at every lunar hour of the lunar-diurnal variations of the three elements have been published. Corresponding statements to that which has been given for Toronto will be given for St. Helena and Hobarton in the volumes of those Observatories which are now in preparation. All the results

* Arago, Annuaire, 1836, p. 284.

at the three stations present the same *general* characters. The lunar influence does not appear to partake in the decennial inequality which is found in all the variations depending upon the sun.—(Phil. Trans. 1857, Art. I.) The lunar-diurnal variation of each of the elements is a double progression in the 24 lunar hours, having epochs of maximum and minimum symmetrically disposed. In character, therefore, it differs from what might be expected to take place if the moon were possessed of inherent magnetism—*i.e.* if she were a magnet, as it is usually termed, *per se*—and accords with the phenomena which might be expected to follow if she were magnetic only by induction from the earth. On the other hand, it is believed that the *amount* of the variation, as observed at each of these stations, very far exceeds what can be imagined to proceed from the earth's inductive action reflected from the moon. In this theoretical difficulty, we are naturally thrown back to seek a more extensive knowledge of the phenomena than we have yet obtained, and to the generalisation which will follow when sufficient materials for it have been procured. In subordinate particulars a difference which is apparently systematic is perceived to exist in regard to the hours which constitute the epochs of maxima and minima at the three stations, as well as in regard to the amounts of the respective variations; these differences are no doubt intimately connected with the causes of the phenomena, and are likely to lead to their elucidation. It is therefore greatly to be desired that the number of stations furnishing complete determinations, such as the Colonial Observatories only have hitherto supplied, should be increased.

The domain of periodical variations has thus been considerably enlarged since the Report of the Committee of Physics was drawn up, and must henceforth be understood to comprise, in addition to the variations "whose amount is a function "of the hour-angle of the sun, and of his longitude," [or of his declination] (Report, p. 10)—1°, those variations of the three elements whose amount is a function of the hour-angle of the moon; 2°, those variations which were classed in the Committee's Report as "irregular," or "apparently observing no law," but which are now known to be governed by laws depending on the sun's declination and hour-angle; and 3°, those variations, both "regular" and "occasional," which have their epochs and amounts dependent apparently on a solar period of not yet perfectly ascertained duration, manifesting itself also by periodical changes in the frequency and amount of the solar spots. With the exception of the last-named class, all these variations require for their generalisation that the phenomena should be investigated at several points of the earth's surface widely distant from each other; and we have now the knowledge, grounded on experience, that a very few years are sufficient for the observations at each station,

with the instrumental means and methods recommended by the Royal Society, and when the investigation is made a primary object by those who engage in it.

Absolute Values and Secular Changes.—But interesting and valuable as is the acquisition of a fuller and more precise knowledge of the comparatively small magnetic variations, produced at the surface of the earth by the action or influence of external bodies, even greater importance seems to attach, when *terrestrial* magnetism is in question, to the purposes of that distinct branch of the duties of a Magnetic Observatory, which consists in the determination of the absolute values and secular changes of the three magnetic elements. By the *absolute values* we seek to acquire a knowledge of the actual present order and distribution of the terrestrial magnetic influence at the surface of the earth, and to provide the materials by which the constancy, or otherwise, of the earth's magnetic charge may hereafter be examined; and by determinations of the present direction and amount of the *secular changes*, we seek to become acquainted with the laws, and ultimately with the causes, of that most mysterious change, by which the magnetic condition of the globe at one epoch passes progressively and systematically into that of another. It is specially by determinations of this class, obtained with the necessary precision in different parts of the globe, that (in the words of the Committee's Report) the "patient inductive inquirer "must seek to ascend to the general laws of the earth's magnetism." At the time when the Report of the Committee of Physics was written, doubts were reasonably entertained whether the limited time during which the Colonial Observatories were likely to be maintained in action would be sufficient for the determination of the secular changes; and it was therefore very properly urged, that "these changes "cannot be concluded from comparatively short series of observations without giving "to the observations *extreme nicety*, so as to determine with perfect precision the "mean state of the elements at the two extremes of the period embraced." It is with much satisfaction, and with a well-deserved recognition of the pains which have been bestowed by the successive Directors of the Toronto Observatory, and their assistants, to this branch of their duties, that I am able to refer to the determinations of the absolute values and secular changes of the three elements contained in this volume, in evidence that the instrumental means which were devised, and the methods which have been adopted, have proved, under all the disadvantages of a first essay, sufficient to determine these data with a precision which is greatly in advance of preceding experience, and, as far as may be judged, equal to the present requirements of theoretical investigation. It should, moreover, be noticed, that Toronto is a station where the casual and periodical variations, which it was apprehended would seriously

interfere with the determination of absolute values, are unusually large. We may derive, therefore, the greatest encouragement from the results thus obtained, to persevere in a line of research which is no longer one of doubtful experiment, and to give it that further extension which the interests of science require.

Amongst the results which have recompensed the labours of the Colonial Observatories in this branch of their inquiries, perhaps there is none of more general theoretical importance than the conclusion which has been established by means of the observations of the Declination at St. Helena, that the current annual amount of secular change takes place by *equal aliquot portions in every month, and even in every fortnight, of the year.* The magnitude of the annual change of the Declination at St. Helena, 8′ (or more precisely 7′·93), in each of the eight years during which the observations were maintained, and the comparative tranquillity of the tropical regions in regard to magnetic disturbances, were circumstances which made St. Helena a particularly eligible locality for this investigation. The result has been to remove secular change conclusively and altogether from the category of atmospheric or thermic relations, with which, in the absence of a correct knowledge of the facts, it has frequently been associated, and to characterize it henceforward as a phenomenon of far more systematic order and regularity than had previously been generally apprehended.—(Proceedings of the Royal Society, vol. VII. pp. 67—75.)

It has thus been shown that in each and all of the branches of inquiry for which the institution of the Colonial Observatories was recommended they have accomplished the objects which were contemplated, and have in many respects exceeded the expectations on which the recommendation was founded. Nor has the scope of their performance been limited to a mere registry of the observations, or to their publication in a crude and undigested form. It was well remarked by an authority of the greatest weight, when addressing the British Association on the occasion of the assembly of the Magnetical and Meteorological Conference at Cambridge in 1845 (Herschel, Address, p. xxxv), that "a man may as well keep a register of his dreams as of the "weather or any other set of daily phenomena, if the spirit of grouping, combining, and "eliciting results be absent." To advance by the simple and straightforward path of inductive inquiry, in a science such as terrestrial magnetism in which a physical theory has yet to be sought, the endeavour must be made "to grapple with the palpable "phenomena, seeking means to reduce their features to measurement, the measure-"ments to laws, the laws to higher generalisations; and so step by step to advance to "causes and theories." The mere observational part is not, and ought never to be, viewed as the fulfilment of the duties of institutions such as Magnetic Observatories;

those duties ought always to be held to include (either on the part of the Directors of the Observatories themselves, or on that of persons who, as Superintendents or otherwise, have constantly watched the progress of the work) "the systematic deduction from "the registered observations of the mean values, and of the local coefficients of diurnal, "annual, and secular change," because "no other class of persons stands in anything like "so favourable a position for working out the first elementary laws of phenomena, and "referring them to their immediate points of dependence," as those who have directed or superintended the processes by which the data required for the knowledge of the phenomena have been obtained. The introductory discussions prefixed to the several volumes which contain the observations of the Colonial Observatories,—and a succession of papers presented to the Royal Society and published in the Philosophical Transactions,—bear testimony to at least unsparing labour on the part of the Superintendent, to give a completeness to the experiment of Colonial Observatories corresponding to its original conception, though this portion of the duty might well have fallen into abler hands. One great advantage in the task has undoubtedly been enjoyed; viz. the union of the detailed knowledge above alluded to with the opportunity of generalisation, and consequent insight, afforded by results admitting of strict comparison and combination, obtained from well-selected stations at such distant points of the globe, and by a uniform system of observation.

It may be useful on the present occasion, that we should recall to more distinct recollection the views and opinions entertained by those who were the principal instigators of the proceedings by which the Royal Society became the responsible advisers,—and Her Majesty's Government the chief supporters,—of measures which have placed this country in the very conspicuous position of taking that lead in the advancement of certain branches of science which other nations were willing and desirous that she should take. These views cannot be better stated than in the words of one to whom all will be willing to concede pre-eminence, as well in counselling the recommendation to Government, as in conducting the several matters connected with it to a successful issue (Herschel, in Quar. Rev., No. CXXXI.):—"Great physical "theories, with their trains of practical consequences, are pre-eminently national "objects, whether for glory or utility. In effect, such they ought to be considered "by every nation calling itself civilized; and if we look to consequences, we have "only to point to the history of science in all its branches to show, that every great "accession to theoretical knowledge has uniformly been followed by a *new practice*, "and by the abandonment of ancient methods as comparatively *inefficient* and "*uneconomical*. This consideration alone we think sufficient to justify, even on

" utilitarian grounds, a large and liberal devotion of the public means to setting on foot
" undertakings and maintaining establishments in which the investigation of physical
" laws and the determination of exact data should be the avowed and primary object,
" and practical application the secondary, incidental, and collateral one. That the
" time is now fully arrived when other great branches of physical knowledge must be
" considered as entitled to share in that public support and encouragement which has
" hitherto fallen to the lot of astronomy alone, will, we think, be granted without
" hesitation by all who duly consider the present state and prospects of science. The
" great problems which offer themselves on all hands for solution—problems which
" the wants of the age force upon us as practically interesting, and with which its
" intellect feels itself competent to deal—are far more complex in their conditions,
" and depend on data which to be of use must be accumulated in far greater masses,
" collected over an infinitely wider field, and worked upon with a greater and more
" systematised power, than has sufficed for the necessities of astronomy. The collect-
" ing, arranging, and duly combining these data are operations which, to be carried
" out to the extent of the requirements of modern science, lie utterly beyond the
" reach of all private industry, means, or enterprise. Our demands are not merely for
" a slight and casual sprinkling to refresh and invigorate an ornamental or luxurious
" product, but for a copious, steady, and well-directed stream, to call forth from a
" soil ready to yield it an ample, healthful, and remunerating harvest. There are
" secrets of nature we would fain see revealed; resources hidden in her fertile bosom
" for the well-being of man upon earth, we would fain see opened up for the use
" of the generation to which we belong. But if we would be enlightened by the
" one, or benefited by the other, we must *lay on power*, both moral and physical,
" without grudging and without stint."

If at the period when it was still doubtful what the Colonial Observatories, then just established, might be able to accomplish,—and when in effect the expectations from them were little more than the anticipations of what a voyage of discovery upon an unknown ocean might produce,—the propriety of embarking upon such investigations was thus unhesitatingly affirmed, how much more confidently may the duty of *perseverance* be insisted upon, when the results of the first experiment have already more than realized the expectations which caused it to be undertaken. They have indeed confirmed the belief that "the gigantic problem proposed to be resolved" is of a nature to yield in its full extent only to "continued and persevering inquiry," but at the same time they may be said to have narrowed the field of inquiry, by showing more distinctly than was previously apprehended, both what is desired to be known,

and how and where it is to be sought. If the history of magnetical science is to be something more than a fragment, the researches must be persevered in.

In considering the means by which the researches thus opened out may be most advantageously prosecuted, it is natural that we should look in the first instance to the adoption, at other selected stations, of arrangements similar to those which were instituted at the stations which were chosen for a first, and, as it has proved, successful, experiment; and with this view, I may be permitted to restate the opinions which I submitted to the Magnetical and Meteorological Conference at Cambridge in 1845, as all that has since taken place has served to confirm those opinions:—

"Before I close this communication, I wish to advert to the expediency of "extending the system of observation now in operation at Toronto, St. Helena, and "the Cape of Good Hope, to other of the British colonies, where the same objects "can be accomplished in an equally effective and economical manner.

"In cases where the institution of similar establishments is strongly urged by the "Governor of a colony,—where competent persons are present and disposed to "superintend the observations,—and where soldiers of the artillery are stationed, "whose services may be available, and whose employment has been shown to be "economical and effective in a high degree in the execution of a laborious and exact "routine of observation,—there is wanting only a supply of instruments, the tempo-"rary allotment of a building to contain them, extra pay such as the individuals "at the above-named Observatories receive, and an authorised connexion with a "head-quarter establishment, whence they may derive instruction and guidance.

"The cost of one of the Ordnance Observatories (including 100*l.* a year for "incidentals of all kinds) is 392*l.* a year, exclusive of publication. It may be "assumed that five years of hourly observation is a sufficient time of continuance for "obtaining in any particular colony the mean values of the magnetical and meteoro-"logical elements, and their diurnal, annual, and secular variations, as well as the "peculiarities of climate bearing on the health and industrial occupations of man. If "the observations were printed *in full detail* for the five years, they would occupy "two quarto volumes; but if it were thought sufficient hereafter that duplicate or "triplicate manuscript copies should be deposited in different public libraries, and "that publication should be confined to abstracts and an analysis, the cost of the "publication would form but a small addition.

"The colonies of Ceylon, New Brunswick, Bermuda, and Newfoundland are in the "described case; their respective Governors are recommending the establishment of "Magnetical and Meteorological Observatories in them; competent Directors are on "the spot" (this was written in 1845); "and they are all artillery stations."

To the four stations thus named may now be added Mauritius and Demerara, as from both these colonies strong and repeated applications to the same effect have been sent through their respective Governors to the Secretary of State for the Colonies. Both these colonies have offered to bear a portion of the expense of the proposed establishments, and have earnestly solicited to be placed in connexion with a head-quarter establishment, from which they might receive properly constructed instruments, with instructions and guidance in their use. Can it be said that we perform our duty as a mother country when we put such applications on the shelf?—whilst, in the interests of science, it would be difficult to estimate too highly the value of such institutions,—in forming good observers, who might subsequently extend their activity over a wider range,—in affording to travelling observers the opportunity of testing and correcting their instruments, as well as keeping up and perfecting their skill in observation,—and in contributing to arouse, to nourish, and to extend to other parts of natural knowledge that desire for the greatest possible accuracy, which was formerly met with only in astronomy and in geodetical operations of the highest class.

When it was first suggested that the officers and soldiers of the scientific corps of the army (Artillery or Engineers) stationed in the colonies might, both beneficially to themselves and advantageously to the public interests, be made available for the performance of such temporary services, the suggestion, from its novelty, might have been open to many objections. None were, indeed, made by the military authorities of the time, who, on the contrary, approved and encouraged the proposition. There may have been doubts entertained in other quarters whether persons, whose ordinary occupations were so dissimilar, would be found to possess the necessary qualifications for carrying out a scheme of exact and varied observation, in which there was no precedent to guide, and of which the performance would be sure to be extensively and closely scrutinized; but such doubts, if they existed, have probably long since subsided as the successive volumes of the Colonial Observatories have appeared; and if any should yet remain, the contents of the present volume, it is hoped, may entirely remove them.

One great and unquestionable advantage which future institutions of this nature will have over those whose duties are accomplished, will be found in the assistance they will derive from the *Physical Observatory of the British Association* at Kew, as a head-quarter Observatory, in which their instruments can be prepared and verified, the constants, &c. carefully determined, new instruments be devised as occasion may require, and be tested by experiment before they are sent out for use; and to which practical difficulties of all kinds which may present themselves to the Directors

may be referred. The omission of a provision of this kind, when the Observatories were first formed, was undoubtedly a great fault, which has been, and could only be, very imperfectly remedied by the Woolwich establishment, designed for a very different purpose, and of insufficient strength even for the duties for which it was designed.

The colonial establishments were first instituted at the instance of the Royal Society and British Association, with a more general concurrence and approval on the part of the cultivators of science in all parts of the globe than, it is believed, were ever before manifested in regard to any purely scientific undertaking; and with such a cordial and effectual co-operation of the public authorities as is well deserving of being held in remembrance. It is for those two great scientific bodies to consider whether any and what steps should now be taken to procure the continuance of the researches.

EDWARD SABINE.

Woolwich, March 1857.

ADJUSTMENTS, ABSTRACTS, AND COMMENTS.

HORIZONTAL FORCE.

Separation and Analysis of the larger Disturbances.—An important preliminary step in this investigation must be the examination in the most direct and practical manner, *i.e.*, by means of the observations themselves, of the equivalent, in divisions of the scale of the Bifilar Magnetometer, to a change of temperature of 1° Fahrenheit.

From the latter end of 1843 to the termination of the hourly series in June 1848, we have an unbroken series of Bifilar observations particularly suitable for this examination, inasmuch as that interval comprehends the principal part of the observations which it is intended to employ in the purposed investigation. Collecting into one view the mean monthly scale readings and their corresponding temperatures from the general monthly tables of the Horizontal Force in vols. II. and III. of the Toronto Observations, we have as follows :—

TABLE I.

Month and Year.	Monthly Mean in Scale Divisions.	Temperature of the Magnet.	Quarterly Mean in Scale Divisions.	Quarterly Mean Temperature.	Seasons.

	April	625·18	53·36	625·39	54·06	Spring Quarter (18).
	May	617·48	61·96			

It is obvious on the first glance that, independently of variations in the scale readings from the influence of temperature, there was a progressive increase in the scale readings (though by no means regular or even uniformly progressive) from the commencement of the series to its close. According to the mode in which the Bifilar was adjusted, an increase in the scale reading should correspond to a decrease of force either in the earth's magnetism or in the magnetism of the Bifilar Magnet. In the latter case, (that of the decrease of the magnetism of the bar,) we have no reason to expect that the decrease should be regular or uniform; viz., of equal amount in equal times. Nor in respect to secular change in the magnetism of the earth could we venture to assume, in the present state of our knowledge, that the progress of such secular change, whether it were an increase or a decrease of the force, should be uniform. If, however, we except the increase in the scale readings between the spring and summer quarters in 1844, when, from some peculiar cause, it was greater than

ordinary, the departures from a uniformly progressive increase will not appear great, particularly when we take into account the influence of magnetic disturbances, and of the regular periodical variations in the earth's horizontal force in different parts of the year, by which the different quarters may have been influenced. If, therefore, we take the mean between the scale readings, and also between the temperatures in the winter quarters of 1843-1844 and 1844-1845, Nos. (1.) and (5.), and compare these means with those of the intermediate summer quarter in 1844, No. (3.), regarding the difference in the scale divisions $\left(\frac{519\cdot96 + 577\cdot93}{2} - 510\cdot28 = 38\cdot67\right)$ as the value in scale divisions corresponding to the differences of the winter and summer temperatures $\left(\frac{41^\circ\cdot73 + 42^\circ\cdot61}{2} - 68^\circ\cdot13 = 25^\circ\cdot96,\right)$ we shall have $\frac{38\cdot67}{25\cdot96} = 1\cdot48$ as the scale equivalent to 1° Fahrenheit, a result subject only to inaccuracies which may be due to magnetic disturbances, or to irregularities in the decrease of magnetic force in the bar magnet, or to other causes which we are not able to particularize, which may have influenced the departures from uniformity in the progressive increase in the scale divisions during the period under consideration. In like manner, a combination of the spring and autumn quarters in 1844 with the intermediate summer quarter in the same year (Nos. (2.) and (4.) with No. (3.)) will yield a second result, but of comparatively less value than the first, because the differences of temperature between the summer and the mean of the spring and autumn quarters are less than between the summer and winter quarters. The eighteen quarters will thus yield fifteen results, which are as follow :—

TABLE II.

	Differences of Temperature.	Differences of Scale readings.		Equivalent of 1° Fahrenheit.
	°			Sc. Div.
(1) and (5) with (3)	25·96	38·67	=	1·48
(2) and (4) with (3)	13·25	16·08	=	1·21
(3) and (7) with (5)	27·00	46·85	=	1·73
(4) and (6) with (5)	11·83	21·33	=	1·80
(5) and (9) with (7)	28·40	44·16	=	1·57
(6) and (8) with (7)	15·76	23·52	=	1·49
(7) and (11) with (9)	29·05	51·65	=	1·78
(8) and (10) with (9)	13·70	25·15	=	1·84
(9) and (13) with (11)	30·18	52·18	=	1·74
(10) and (12) with (11)	14·59	22·22	=	1·52
(11) and (15) with (13)	29·18	51·25	=	1·78
(12) and (14) with (13)	14·17	28·40	=	2·00
(13) and (17) with (15)	26·68	39·25	=	1·47
(14) and (16) with (15)	15·20	17·53	=	1·15
(16) and (18) with (17)	11·22	17·49	=	1·56
Sums	306·17	495·73	=	1·62

Whence $\frac{495 \cdot 73}{306 \cdot 17} = 1 \cdot 62$ is the equivalent in scale divisions to 1° of temperature.

The quarters into which the year is here divided are those usually called "Meteorological Seasons," December being classed with January and February, and August with June and July. By this division of the year the differences of temperature between the seasons compared are greater than if the more ordinary division had been adopted.

The partial results obtained by the comparison of the summer and winter quarters (which have the largest differences of temperature) exhibit a very satisfactory accord. There are seven such comparisons, and their results are as follow:—

TABLE III.

	Differences.		Equivalent to 1°.
	Temperature.	Scale-readings.	
	°		Sc. Div.
(1) and (5) with (3) -	25·96	38·67	1·48
(3) and (7) with (5) -	27·00	46·85	1·73
(5) and (9) with (7) -	28·40	44·16	1·57
(7) and (11) with (9) -	29·05	51·65	1·78
(9) and (13) with (11) -	30·18	52·18	1·74
(11) and (15) with (13) -	29·13	51·25	1·78
(13) and (17) with (15) -	26·63	39·25	1·47
	196·35	324·01	1·65

Whence $\frac{324 \cdot 01}{196 \cdot 35} = 1 \cdot 65$, the equivalent to 1°. The value which has been adopted in reducing the observations to an uniform temperature during the period under consideration is $1 \cdot 63$.

According to the method prescribed in the Instructions of the Royal Society, the equivalent in scale divisions for 1° of temperature should be obtained by dividing the change corresponding to 1° of temperature found by experiment in the magnetic moment of the Bifilar Magnet, by the scale coefficient or the value of one division of the scale, both being expressed in parts of the Horizontal Force. The first of these values (viz., q, = the change in the magnetic moment of the magnet for 1° of Fahrenheit) was found, by the experiments recorded in vol. II. p. liii, to be ·000234 parts of the Horizontal Force; and that of the scale coefficient $k = ·000087$, also in parts of the force (pp. li and lii). The change in the scale-readings corresponding to 1° of temperature should have been, therefore, $\frac{q}{k} = \frac{·000234}{·000087} = 2 \cdot 69$ scale divisions. This is the value which, in conformity with the instructions under which the colonial observatories have acted, has been employed in the discussion of the Bifilar observations in the preceding Toronto volumes. It is no doubt quite possible that the values of the temperature and

of the scale-coefficients, as determined by the experiments referred to, may have been, either one or both, slightly inaccurate; but it is scarcely possible to imagine inaccuracies, in either or in both, of sufficient importance to account for the difference between 2·69 and 1·63. The existence of a similar discrepancy in the case of the Makerstoun Bifilar has been shown by Mr. Broun in his very valuable discussion of the observations made at that observatory. The experiments by which the change in the magnetic moment of the bar, corresponding to variations of temperature, is determined, are made with the magnet *dismounted*; and it may be quite possible that the suspension may in some cases (if not in all the Bifilar Magnetometers of the description employed in the colonial observatories) exercise an influence in the changes of direction of the magnet produced by changes of temperature, which was not taken into account in the prescribed Instructions. Whatever may be the cause of the difference, however, there can, I apprehend, be no hesitation in preferring the result which is derived directly from the observations themselves.

The correct amount of this very important element in the reduction of the observations was the subject of earnest and even anxious consideration with Captain Lefroy during the latter part of his stay at Toronto, and led to an endeavour, after the hourly series had terminated, to ascertain the effect of changes of temperature on the readings of the Bifilar scale by a direct experiment with the magnet suspended precisely as when employed in the hourly observations. For this purpose the magnetometer was enclosed by boards extending from the floor to the ceiling, in a space sufficiently large to include also a copper stove. The scale was read by means of an aperture, which could be closed by a slider when not required. The account of this experiment, and its result, cannot be better related than by making the following extract from Captain Lefroy's report:—"The experiments were made by kindling a fire and keeping "up the temperature for three days, then allowing it to go out, and opening the "communication with the external air for the same length of time. There were five "cold and three hot alternations, each of three days. The readings were taken every "half-hour from 6 A.M. to 11 P.M., and at each reading the *small Bifilar*, which had "been in adjustment since December 1845, was also observed. It was hoped that the "small Bifilar would not show the changes of temperature of the other instrument, but "it was not found practicable to prevent the whole body of air in the room being "affected by these changes to some extent. Instead, therefore, of having a means of "correction independent of the temperature coefficient of the second instrument, we "have to reduce the small Bifilar readings to an uniform temperature by the employment of its own coefficient: but, in the first place, the value of $\frac{q}{k}$ obtained for this "instrument in the ordinary way is more likely to be practically correct than that of "the other instrument, the suspension of the one being of silk and the other of metal; "and in the second place, the value of k given by adjustment for this instrument

" (·0003551) agrees very nearly with the value found by deflection (·0003644); " lastly, if the correction $\frac{q}{k}$ employed be somewhat in error, the result will be affected " only by the difference between the actual and the assumed value, which cannot be " important upon differences not exceeding 5°, as compared with the correction for " differences averaging 61° with the other instrument. To compute the results two " abstracts are formed, one containing the half-hourly observations on the fifteen cold " days, the other those of the twelve hot days: by these we get two diurnal curves with " both instruments, which must be exactly comparable as diurnal curves, the days being " alternate. The differences between the corrected mean scale reading of the small " Bifilar for the same hour of observation by the two diurnal curves is therefore the " change of Horizontal Force which we have to eliminate before comparing the corre- " sponding readings of the large Bifilar. Multiplying this difference by the ratio of the " scale coefficients of the two instruments, and applying it as a correction to the second " curve of the large Bifilar, the two curves of the latter instrument are reduced to the " same values of the Horizontal Force, and the difference of scale reading between them " is the residual effect of the change of temperature. We have then from the successive " half-hourly observations a like number of equations; omitting the three first half- " hours on each day, when it may be probable that the magnet may not have taken " up the temperature indicated by the thermometer (the bulb of which was, however, " close to it), we obtain, as the result of the whole, 1·74 as the equivalent in scale " divisions for 1° of Fahrenheit."

" The inner case of gilt wood was removed, and the outer one was slightly raised by " wedges to allow the air in the box to acquire the temperature of the rest of the room. " There was no reason to suppose that currents of air affected the scale readings: there " was no iron whatsoever about the stove, and it was always in the same position, " whether heated or otherwise."

That the result of these experiments should exhibit so close an approximation to the value (1·63) which has been found to represent the actual change produced in the readings of the scale by 1° of temperature in the whole body of the observations themselves, is a strong testimony to the care which must have been taken in conducting the experiments under the very difficult condition of regulating artificial temperatures in air heated by a stove.

The separation and analysis of the larger disturbances of the Horizontal Force has been conducted on the principle already described in discussing the larger disturbances of the Declination (Toronto Observations, vol. II. pp. xxii to xxxv). As the first step, the whole of the observations were reduced individually to an uniform temperature of 55°, employing the coefficient named in the preceding pages (1·63); the *mean* scale division was then computed for every hour in each of the sixty months, and the correctness of the whole work was examined by the comparison of these hourly means with the hourly

means printed in the monthly tables, the latter being reduced to the standard temperature of 55° by the application in each case of the correction due to the difference between the recorded temperature and 55°.

The hourly means thus corrected in each month presented to the eye at the different hours the diurnal variation of the Horizontal Force, cleared from the influence of temperature on the magnetism of the bar, but retaining whatever effects may have been due to disturbances. For the purpose of eliminating the disturbances of largest amount, the observations which had been individually corrected for temperature were compared each with the monthly mean, at the same hour and in the same month, and every observation which differed 14·0 scale divisions or more from that mean was provisionally marked as a disturbed observation. Fresh means for each hour in each month were then taken, omitting the observations marked as disturbed, and the means thus obtained were then used as standards of comparison for a second examination. This process was repeated until the hourly means were strictly the means of all the remaining observations, after the separation of those which differed from them respectively by 14·0 scale divisions or more.

The value of 14 scale divisions in parts of the Horizontal Force at Toronto was about ·0012. When the larger disturbances are thus separated, the diurnal variation at the same period of the year, in different years, exhibits a very satisfactory accordance; and, by the process of elimination which has been explained, it is probable that the diurnal variation has very little, if any, influence on the determination of the observations separated as disturbed.

A much greater practical difficulty has been occasioned by a circumstance already noticed in discussing the temperature-coefficient, namely, the progressive increase in the scale readings, partly from secular change and partly also from instrumental causes. Whenever the amount of increase in the course of a month was seen to be such as to interfere with the proper comparability of the observations in the earlier or later portions of the month with the means taken in the usual manner, fresh means, more suitable for the comparison, have been formed; thus, for example, for comparison with the observations in the last week of one month and the first week of the next, it has in some instances appeared preferable to form the hourly means from the whole of the observations of the two months united, instead of from each month separately, whereby the advantage is gained, that the period which furnishes the standard of comparison for the fortnight in question extends to a nearly equal distance on either side of the observations compared with it. In a few instances in which the increase was more irregular than was commonly the case, fortnightly means, and even, when absolutely required, weekly means, have been substituted for the monthly or two-monthly means. This part of the process requires in the person who conducts it an attentive preliminary consideration and study of the observations, and it is important that it should be carefully executed, because normal values, correctly obtained, form an essential basis for the

study of all the terrestrial magnetic variations. To facilitate researches of this nature in which the observations contained in these volumes may hereafter be employed, as well as to show the steps by which the conclusions now submitted have been arrived at, a table of the hourly means of the readings of the Horizontal Force Magnetometer reduced to 55° Fahrenheit, and omitting the observations in which the amount of disturbance equalled or exceeded 14 scale divisions (or ·0012 parts of the whole Horizontal Force,) is subjoined at the close of this discussion (pp. xviii to xxi), specifying in each case the interval to which the normal values correspond, as well as the interval comprehended by the observations from which they have been derived.

The period which the hourly observations included in this investigation comprise is one of five complete years, terminating on the 30th June 1848. It is not, however, an absolutely unbroken period, as in October 1843 the magnet of the *Vertical* Force Magnetometer was displaced from its mounting, and employed in experiments designed to show the change in its magnetic moment occasioned by changes of temperature. It was remounted in February 1844; consequently the five months from October 1843 to February 1844 that would have made a *continuous* suite during the five years are deficient. These have been replaced (in the similar investigation to the present, in which the observations of the Vertical Force Magnetometer have been employed) by the observations of the same months of the preceding year, viz., October 1842 to February 1843. And as it is desirable that the five years submitted to this investigation should consist of identical months in the Horizontal and in the Vertical Force, the observations of the Horizontal Force during the months from October 1843 to February 1844 have been replaced by those of October 1842 to February 1843. It will be understood, therefore, that whenever in the subjoined pages the year ending June 30th 1844 is spoken of in reference to the Horizontal and Vertical Forces, (and to their theoretical equivalents, the Inclination and Total Force,) the months which constitute that year consist of July to September 1843 inclusive, October 1842 to February 1843 inclusive, and March 1844 to June 1844 inclusive.

The course that has been followed in working out the several parts of the process by which the larger disturbances of the Horizontal Force have been separated from the other observations, and the laws of their periodical variations shown, has been as follows:—The hourly observations of the Bifilar Magnetometer during the five years terminating June 30, 1848, were received at Woolwich from Toronto precisely in the state in which they appear in the 2d and 3d Toronto volumes; namely, the readings, uncorrected for temperature, at every hour of Göttingen time, arranged in monthly tables, accompanied by corresponding tables of the temperature of the Bifilar Magnet, shown by a thermometer of which the ball was enclosed in the same case with the magnet, and which was read contemporaneously with the Bifilar scale. The monthly tables of the scale readings and of the temperature were summed before their transmission to Woolwich, both in Vertical and Horizontal columns, and means

taken of all the days in the month at the different hours, and of all the hours of the day on the different days, forming "hourly means" and "daily means." In this state the Observations were received at Woolwich and printed; they were, in fact, printed from the original manuscripts.

The first step taken at the Woolwich office was to rewrite the whole of the observations of the five years in scale divisions, corresponding to the respective readings, but reduced to an uniform temperature of 55°, taken as a convenient approximate mean temperature; for this purpose each of the observations had to receive a correction proportioned to the difference between the recorded contemporaneous reading of the thermometer and the standard temperature of 55°, and computed by a coefficient representing the change in the scale reading produced by an alteration of 1° of the thermometer. The mode and process of deriving this coefficient from the observations themselves has been stated in pp. i to vi of this volume. The formation of the monthly tables of the "Scale Readings reduced to an uniform temperature of 55°" from the tables "uncorrected for temperature" was performed under the superintendence of Mr. Magrath, the principal clerk in this office, by two non-commissioned officers, each working independently of the other, and having the correctness of the work proved by the accordance of the two independent computers; the daily and hourly means were then taken in the same manner by two independent computers, and were additionally checked by comparison with the daily and hourly uncorrected means calculated at Toronto, when these means were also reduced to the standard temperature of 55° [excepting in a very few instances in which the observations on days of *excessive* disturbance had been omitted in the sums and means of the uncorrected readings computed at Toronto, but were restored in the sums and means of the corrected tables]. The new tables thus formed, of the scale readings reduced to 55°, then passed into my hands; and having satisfied myself by a careful examination that a difference of 14 scale divisions above or below what might be taken as a normal value, (viz., the mean value at the same hour during the same month, or for several preceding and several succeeding days,) would constitute a convenient minimum limit for the disturbances of largest amount—being on the one hand a greater departure from the normal value than could reasonably be ascribed to any other cause than that of a disturbance in the earth's magnetism, whilst on the other hand the number of disturbances that would be thereby separated would form a sufficient body to permit their periodical laws (if such existed) to be investigated—I proceeded to mark provisionally with a pencil every observation which differed 14 scale divisions or more from its normal. I then recomputed the normals omitting the observations provisionally marked as disturbed, and compared afresh all the observations, including the provisionally marked ones, with the new normals, altering the markings where required, and continuing this process until the normal in every case included every observation which differed less than 14 scale divisions from itself, and excluded every

observation which differed 14 scale divisions or more from itself; the latter were then marked finally with a surrounding ring in ink. In this state the tables were returned to the office, and the correctness of the markings, and of the normals excluding the larger disturbances, was examined by a separate computer.

A table was then formed by two computers working separately, and their work compared, of the marked disturbances during the five years, arranged chronologically, showing the day, the hour, and the amount of disturbance (*i.e.* the difference from the normal) in scale divisions; and on the receipt of this table from the office I proceeded to distribute the disturbances according to the years, months, and hours of their occurrence, separating them into disturbances increasing and disturbances decreasing the force, and forming the tables contained in the following analysis; the correctness of the distribution and of the calculations in each of the tables being in every case examined by a second person.

In the course of the process of marking the disturbances it became evident, as already remarked, that there were times, occasional but by no means frequent, when the change in the mean monthly scale reading, (*i.e.* the means of all the hours and all the days in the month from one month to the next,) was so considerable as to cause the regular hourly normals of the month to be inapplicable to the earlier or later portions of the month. In such cases the difficulty was met, and more suitable normals obtained for the earlier or later portions of the month, by taking the hourly means of the last fortnight of the one month and the first fortnight of the next, or by a mean of the normals of the two months combined; or in a very few instances, in which the departure from an uniformly progressive change was greatest, by normals derived from periods of less duration than a month.

The number of the Bifilar observations in which the amount of disturbance equalled or exceeded 14·0 scale divisions in the five years was 2968, being about 1 in between 12 and 13 of the whole body of the observations.

The aggregate values of the disturbed observations of the Horizontal Force in the different *years*, each ending June 30, are as follow—

TABLE IV.

			Ratios.
Year ending June 30, 1844	8618·7 Sc. Div.		0·49
„ „ 1845	8032·4 „		0·45
„ „ 1846	9479·2 „		0·53
„ „ 1847	19700·1 „		1·11
„ „ 1848	42905·3 „		2·42
Total in the Five Years	88735·7 „		

The sum of the disturbances in the five years (88735·7 sc. div.) gives an annual mean of 17747·1 sc. div.; and calling this annual mean = 1·00, we obtain the ratios which the aggregate values in the different years bear to the average annual value. We find in this table a progressive increase in the annual value of the disturbed observations from the years ending in June 1844 and June 1845 to the year ending June 1848. The aggregate value in the year ending June 1844 exceeds by a small amount that of the year ending June 1845; but it will be remembered that the former of these two years included five months taken from the preceding year, namely, October 1842 to February 1843 inclusive, in consequence of the Vertical Force Magnetometer having been dismounted from October 1843 to February 1844 inclusive; and as we learn from the observations of the Declination at Toronto, (Vol. II. p. xxiii) that 1843 was a year of minimum disturbance in comparison with the years which preceded and followed it, it was to be expected that the aggregate value of the disturbed observations which stand in the table as corresponding to the year ending June 1844, should be swelled by the substitution of the disturbances in five months of a preceding year. It will be seen in the sequel, that when the months actually belonging to the year ending June 1844 are employed, the aggregate values, and consequently the ratio in that year, are *less* than in 1845.

Table V. exhibits the aggregate values in the different years, divided into disturbances increasing the force and disturbances diminishing the force.

TABLE V.

	Increasing.	Decreasing.	
Year ending June 1844 - -	1963·9	6654·8	sc. div.
„ „ 1845 - -	1122·5	6909·9	„
„ „ 1846 - -	1566·8	7912·4	„
„ „ 1847 - -	2385·8	17314·3	„
„ „ 1848 - -	5015·5	37889·8	„
Totals in the five years - -	12054·5	76681·2	

It appears from this table that the effect of the larger disturbances was in each year to diminish the Horizontal Force considerably more than to increase it. The ratio of the value of the disturbances decreasing the force to those which increased it was, on the average of the five years, nearly as 6·4 to 1.

The next table exhibits the aggregate values of the disturbed observations, distributed into the different *months* of their occurrence. The final column expresses the

ratio which the values in the preceding column bears to the mean monthly value or average of all the months :—

Total in the five years - - - -						88735·7	
Mean monthly value - - - $\frac{88735·7}{12}$ =						7395 = 1·00	

April and September are the months of maximum disturbance, and January and June of minimum disturbance. The progression from the maxima to the minima and from the minima to the maxima are continuous, with the exception of the month of December; an exception obviously caused by the occurrence of excessive disturbance December 1847. If the year ending June 1848 be omitted, the ratios in December and January of the other four years to the average monthly disturbance in those four years are, of December 0·58 to 1, and of January 0·56 to 1. On the whole, therefore, we may conclude that in the larger disturbances of the Horizontal Force, as in those of the Declination (Toronto Observations, Vol. II. p. xxvi), the greatest amount of disturbance takes place at or about the equinoxes, and the least at or about the solstices. The amount of disturbance at the equinoxes (April and September) is to that at the solstices (January and June) in the proportion of between 3 and 4 to 1.

The next table exhibits the aggregate values of the disturbed observations, distributed into the different *hours* of their occurrence.

	Total in the five years - - -					88735·7		
	Mean hourly value - - $\frac{88735·7}{24}$ =					3697 = 1·00		

When we examine the ratios presented in this table we at once perceive that the occurrence of the larger disturbances of the Horizontal Force at Toronto is regulated by periodical laws. The amount of disturbance is systematically greater at all the

hours from 10 P.M. to 10 A.M. inclusive, than at any hour from 11 A.M. to 9 P.M. inclusive. The ratios are equal to or above unity from 10 P.M. to 10 A.M. inclusive, and below unity from 11 A.M. to 9 P.M. inclusive. The maximum is at 2 A.M., and the minimum intermediately between 2 and 6 P.M., during which latter hours there is but little variation in the amount. There is also a secondary maximum about 7 or 8 A.M., preceded by a secondary minimum at 5 or 6 A.M. In the year ending June 1848 (but for that year only,) the secondary maximum at 7 A.M. was greater than at 2 A.M. (the usual hour of the principal maximum,) or than at any other hour in that year; this circumstance is chiefly due to the great disturbances which occurred in December 1847.

Tables VIII. and IX. exhibit the aggregate hourly values in the different years separated into disturbances increasing the force and disturbances decreasing the force; with the ratios at each hour to the respective mean hourly values.

				Total in the five years - -		76681·2		
				Mean hourly value $\frac{76681}{24}$ =		3195·0 = 1·00		

We perceive by these tables that both the disturbances which increase and those which decrease the force are governed in respect to their frequency and amount by periodical laws depending on the solar hours, and that the laws are different in the two cases. The disturbances which increase the force have a maximum at 4 P.M., and a minimum from 2 to 4 A.M. There are also secondary maxima at 11 A.M., at 2 P.M., and at 7 P.M.; and secondary minima at 1, 3, and 6 P.M., unless we may regard these secondary maxima and minima as accidents which would disappear on a longer continuance of the observations.

From 10 A.M. to 8. P.M. inclusive the ratios are with a single exception above unity and from 9 P.M to 9 A.M. inclusive without an exception below unity. It is in the hours

of the day, consequently, that the disturbances which increase the force have their greatest prevalence, whilst the hours of the night are comparatively tranquil. The converse law holds in regard to the disturbances which decrease the force; from 10 P.M. to 9 A.M. the ratios exceed unity at every hour, and from 10 A.M. to 9 P.M. they are uniformly less than unity. The maximum is at 2 A.M. and the minimum at 4 P.M. The continuous progression from the maximum to the minimum, and from the minimum to the maximum, undergoes an interruption of very marked character at 7 and 8 A.M., constituting a very decided secondary maximum in the disturbances which increase the force at those hours, which hours are not distinguished by any peculiarity in the disturbances of opposite character.

The table which follows (Table X., pp. xviii to xxi) shows the normal values finally adopted, the periods for which they have been employed, and the periods from which they have been derived. This table is the result of careful consideration; and is presented, not alone as one of the steps by which the conclusions arrived at in this volume have been obtained, but as a means of rendering the whole body of the Bifilar Observations in the five years more valuable for future enquiries than they would be without a table of this kind. Possessed of a table containing an approximate normal reading for every day and every hour, the inquirer has it in his power, by a simple comparison of the observations in the monthly tables, with the table of normals, to ascertain the state of the Horizontal Force relatively to its mean value on any particular day or hour to which his attention may be directed; he will have in such case only to correct the tabular scale reading in the monthly table to the standard temperature of 55°, by the aid of the coefficient 1·63 as the equivalent of 1° of Fahrenheit.

Table X.

Hourly Means of the Readings of the Bifilar Magnetometer, reduced to an uniform Temperature of 55° Fahrenheit; omitting disturbed Observations in which the Amount of Disturbance equalled or exceeded 14 Scale Divisions or about ·0012 parts of the whole Horizontal Force at Toronto.

TABLE X.

Hourly Means of the Readings of the Bifilar Magnetometer, reduced to an uniform Temperature of 55° Fahr. exceeded 14 *Scale Divisions, or about* ·0012 *parts of the whole.*

VERTICAL FORCE.

Separation and Analysis of the larger Disturbances.—In preparing the observations of the Vertical Force Magnetometer for the various deductions that can be made from them, the first step must be to ascertain in the most direct and practical manner, from the observations themselves, the equivalent in divisions of the Magnetometer scale to a variation of 1° of temperature. Commencing with February 1844, in the middle of which month the Magnetometer was adjusted, an unbroken series continued until the end of May in the following year, when a re-adjustment took place. From March 1844 to May 1845 inclusive, we have consequently an unbroken series of fifteen months, in which the mean monthly scale readings, with the corresponding temperatures, were as follows:—

TABLE XI.

		Sc. Divisions.	Temperature.	Sc. Divisions.	Temperature.	
			°		°	
1844.	March	121·8	46·5			
	April	99·0	56·5	102·93	54·5	Spring (1).
	May	88·0	60·5			
	June	75·1	64·8			
	July	60·2	69·7	64·60	67·6	Summer (2).
	August	58·5	68·3			
	September	61·4	65·1			
	October	83·6	53·4	80·03	55·2	Autumn (3).
	November	95·1	47·1			
	December	101·1	42·7			
1845.	January	99·5	42·7	97·97	42·77	Winter (4).
	February	93·3	42·9			
	March	82·9	48·0			
	April	72·1	53·6	71·20	53·67	Spring (5).
	May	58·6	59·4			

From the difference in the mean scale reading in the spring quarters of 1844 and 1845 (102·93 − 71·20 = 31·73) in which quarters the temperatures were nearly the same, we may infer that a considerable change took place in the scale readings during this interval from other causes than changes in the earth's magnetism; variations depending on particular periods of the year can have no place, since the seasons compared are the same, and any secular change which could be reasonably imagined must have been far less considerable. We must, therefore, attribute this decrease of 31·73 scale divisions occurring in one year principally, if not wholly, to instrumental causes.

On a comparison of the *monthly* scale readings each with the others we further find reason to believe that the decrease thus occasioned was progressive during the whole interval, though not always to an uniform amount. Under these circumstances, perhaps the best mode of combining these five quarterly results with the view of

eliminating periodical and secular variations, and, as far as may be, instrumental error, and of thereby obtaining the effect of temperature, is to mean the results in the spring and autumn of 1844 (Nos. 1 and 3), and compare their mean with the intermediate summer (No. 2); and in like manner to mean the results of the autumn of 1844 and spring of 1845 (Nos. 3 and 5), and compare their mean with the intermediate winter (No. 4); and then to take a mean of the results of these two comparisons: these are stated in the following table:

TABLE XII.

	Difference of Temperature.	Difference of Scale Readings.	Equivalent to a Variation of 1° Fah^t.
From (1) and (3) compared with (2) we have -	12°·75	26·85	2·10
From (3) and (5) compared with (4) we have -	11·65	22·40	1·92

If we could regard these comparisons as sufficient of themselves to give a final result, we should only have to take the mean between them, 2·01, in which we might consider that any subsisting periodical and secular variations were eliminated. But the shortness of the period during which the series was unbroken, together with the magnitude and irregularity of the change from instrumental causes, will not permit us to rest in this as a final result, and we are led to seek for further evidence.

In examining the *monthly tables* in which the Vertical Force Observations from March 1844 to May 1845 inclusive are contained (Toronto Observations, vol. 2, pp. 224-243, 404-413), we find several instances in which the temperature of days very near to each other differed very considerably, and when consequently the effect of a change of temperature on the indications of the magnetometer can be examined with advantage. In choosing amongst these, it is obvious that the shorter the interval between the observations compared, the less the result is likely to be affected by the instrumental change which has been adverted to; and those instances are to be preferred in which a high temperature may be found between two nearly equidistant low temperatures, or a low temperature between two nearly equidistant high ones; provided that the condition of proximity be tolerably preserved, and that care be taken to avoid times of considerable magnetic disturbance. The following table presents a selection of instances made on these principles, with the results which they give individually and collectively:—

TABLE XIII.

Dates.			Mean Temperature.	Mean Scale Readings.	Differences.		Equivalent to a Variation of 1° Fah^{t}.
					Temperature.	Readings.	
			°	Sc. Div.	°	Sc. Div.	Sc. Div.
1844.	March	12 and 13	50·77	116·13	10·67	17·72	1·66
		18 and 19	39·46	133·64			
		25 and 26	49·50	115·72			
1844.	May	20 to 22	56·63	94·47	8·84	15·53	1·79
		27 to 28	66·55	95·58			
	June	10 and 11	58·80	87·75			
1841.	September	16 to 20	71·47	48·92	15·52	29·02	1·87
		23 to 27	55·95	77·94			
1844.	October	21 and 22	50·80	87·33	9·29	16·74	1·80
		24 and 25	57·21	76·00			
		28 to 31	45·05	98·16			
1844.	October	28 to 31	45·05	98·16	8·54	14·02	1·64
	November	4 to 8	50·69	89·48			
		25 to 28	39·25	108·83			
1841.	November	25 to 28	39·25	108·83	7·41	12·68	1·70
	December	2 to 6	46·30	95·74			
		16 to 20	38·52	108·00			
1845.	January	23 to 25	47·29	89·91	14·39	25·09	1·74
	February	1 to 7	31·44	109·50			
		21 to 26	50·37	78·92			
1845.	March	11 to 13	48·54	80·36	9·50	17·68	1·86
		17 to 19	41·38	95·03			
		26 to 28	53·22	74·34			
1845.	May	7 and 8	54·10	69·53	13·27	25 55	1·93
		12 and 13	68·67	40·93			
		15 and 16	56·70	63·42			
			Collectively		97·43	171·03	1·78

From this table we have 1·78 as the equivalent in scale divisions to a variation of 1° temperature: or if we combine this with the result previously obtained from the five quarterly means (page xxiii), we have $\frac{174·03 + 49·25}{97·43 + 24·38} = \frac{223·28}{121·81} = 1·83$ sc. divisions, as the equivalent of 1°. The value adopted for the portion of the observations from March 1844 to May 1845 inclusive has been 1·80.

From June 1845 to August 1845 inclusive, and from September 1845 to March 1846, the Vertical Force Observations form two series, the break between them occurring at the end of August; each series is therefore of only a few months' duration. At the end of March 1846, the magnet was removed from the Magnetometer, remagnetised, and mounted afresh. The time of Horizontal Vibration, which had been previously 11″·50, was reduced by the stronger magnetic charge imparted to the needle to 10″·29 observed on 1st of April 1846; which was only increased to 10″·36 when again observed on February 28th, 1849. The series of observations which was commenced in April 1846 continued without interruption to the close of the hourly observations in

June 1848, forming an unbroken series of twenty-seven months; and for this period it will be necessary to examine afresh the equivalent in scale divisions to a change of 1° of temperature, inasmuch as the equivalent must be expected to be slightly modified by the increased magnetism of the needle.

The mean monthly scale readings, with the corresponding temperatures, are as follow, and are collected in quarterly values:—

TABLE XIV.

Dates.		Scale Readings.	Temperature.	Quarterly Means.		Seasons.
				Readings.	Temperature.	
1846.	April	214·0	51°·7			
	May	198·3	62·8	199·3	62°·0	Spring (1).
	June	185·7	68·6			
	July	173·7	73·6			
	August	170·8	73·7	173·5	72·3	Summer (2).
	September	175·9	69·5			
	October	197·1	56·6			
	November	200·6	52·8	202·6	50·8	Autumn (3).
	December	210·2	43·0			
1847.	January	209·0	40·3			
	February	203·4	42·3	204·4	42·4	Winter (4).
	March	200·7	41·6			
	April	188·9	51·4			
	May	171·8	60·3	174·2	58·5	Spring (5).
	June	161·9	63·9			
	July	143·1	73·0			
	August	145·4	70·4	149·8	68·6	Summer (6).
	September	160·8	62·4			
	October	172·5	56·1			
	November	179·8	51·6	180·2	51·0	Autumn (7).
	December	188·3	45·2			
1848.	January	187·2	43·4			
	February	182·5	43·9	182·5	44·3	Winter (8).
	March	177·7	46·7			
	April	165·9	53·3			
	May	148·9	61·5	149·5	61·0	Spring (9).
	June	133·7	68·2			

By comparing with each other similar seasons in different years, and thus eliminating periodical variations, whilst, at the same time, we have the temperatures approximately the same, we find that during this period, independently of changes from other causes, a progressive decrease took place in the scale readings which did not greatly differ from an uniform decrease. Without entering at present into the question of the cause of this decrease, let $x =$ its amount taken from quarter to quarter, assumed to be uniform, and counted from the middle quarter (April, May, and June, 1847), and let $y =$ the equivalent in scale readings for a change of temperature of 1°. Then each quarter will furnish an equation towards the values of x and y; and by least squares we find the most probable value of x to be 6·43, and of y 1·64, the coefficient of x being positive in the quarters antecedent to April, May, and June, 1847, and negative in the

subsequent quarters; and the coefficient of y positive when the temperature is above 56°·7 (the arithmetical mean of the temperatures of the nine quarters), and negative when it is less than 56°·7.

Comparing the summer and winter quarters, or the quarters in which the differences of temperature are greatest, we have as follows:—

		Differences.		Equivalent of 1°.
		Scale Readings.	Temperature.	
Summer and Winter	(2) and (6) with (4) -	42·75	28·05	$\frac{86·4}{53·3} = 1·62$
	(4) and (8) with (6) -	43·65	25·25	

Comparing also the spring and autumn quarters alternately with summer and with winter, we have as follows:—

		Differences.		Equivalent of 1°.
		Scale Readings.	Temperature.	
Spring and Autumn with Summer,	(1) and (3) with (2) -	27·45	15·90	$\frac{88·5}{53·7} = 1·65$
,, ,, Winter,	(3) and (5) with (4) -	16·00	12·25	
,, ,, Summer,	(5) and (7) with (6) -	27·40	13·85	
,, ,, Winter,	(7) and (9) with (8) -	17·65	11·70	

The equivalent to 1° of temperature appears, therefore, to have been somewhat less in the period from April 1846 to June 1848 than in the period from March 1844 to May 1845; between these periods the needle had been re-magnetized, and its magnetic force increased, the times of Horizontal and Vertical vibration being slightly affected thereby (Toronto, vol. II. p. lxi). The ratio of the times of Horizontal and Vertical vibration being one of the elements upon which the change in the scale readings, corresponding to changes of temperature, depends, we should be prepared to expect that the amount of the equivalent to 1° of temperature would not be exactly the same before and after the re-magnetization, but that the equivalent would be slightly diminished in amount when the magnetic charge of the needle was increased. The two values, 1·80 and 1·64, differ from each other in the direction, and very nearly to the amount which might be expected from the change effected in the times of Horizontal and Vertical vibration. The results may be considered, therefore, as being each approximately corroborative of the other.

The value of the Scale-coefficient, k, computed according to the Instructions of the Royal Society, varied in different months between March 1844 and May 1845 from ·000060 to ·000065 parts of the Vertical Force, the mean being ·0000628; and between April 1846

and June 1848 from ·000065 to ·000067, the mean being ·0000658. Thence we should have, *theoretically*, the change in the magnetic moment of the needle corresponding to 1° of Fahrenheit, ·0000628 × 1·80 = ·000113 for the first period, and ·0000658 × 1·64 = ·000108 for the second period. There were two attempts made to obtain the change in the magnetic moment by direct experiment, one at the end of 1843 and beginning of 1844, of which the particulars are related in the Toronto Observations, vol. I. pp. liii–lvii, the result being ·000112; and a second in March and April 1846, of which the particulars are given in vol. II, pp. lxii–lxiii, and of which the result was ·00007. The result of the experiments in 1843 and 1844 (·000112) is in remarkable accord with the deduction obtained by the present investigation, ·0001105 (mean of ·000113 and ·000108). The partial results in the second series, viz., in March and April 1846, accord better with each other than do those of 1843–1844; but it is possible that there may have been some accidental oversight causing an error which may have pervaded the whole. The needle itself has been since transferred, by direction of Her Majesty's Government, to the provincial authorities of Canada, and remains at Toronto in what is now a provincial observatory; it has not been possible, therefore, to repeat the direct experiments on its magnetic moment at Woolwich, which would otherwise have been done. It would have been satisfactory to have *proved* by this means, what is, however, extremely probable, that in the case of the Vertical Force needle the method of determining the temperature equivalent prescribed in the Instructions, and that which has been here adopted, of deriving it from the observations themselves, lead to an identical conclusion.

The separation and analysis of the larger disturbances of the Vertical Force has been conducted on the same principle as in the case of the larger disturbances of the Horizontal Force. As the first step, the whole of the observations were reduced individually to an uniform temperature of 55°, employing the coefficients named in the preceding pages. The *mean* scale division was then computed for every hour in each of the sixty months; and the correctness of the whole work was examined by the correspondence of two computers, and by the agreement of these hourly means with the hourly means printed in the monthly tables, when the latter were reduced to the standard temperature of 55° by the application in each case of the correction due to the difference between the recorded temperature and 55°. The hourly means thus corrected in each month presented to the eye at the different hours the diurnal variation of the Vertical Force, cleared from the influence of temperature on the magnetism of the bar, but retaining whatever effects may have been due to disturbances. For the purpose of eliminating the disturbances of largest amount, the observations which had been individually corrected for temperature were compared each with the monthly mean, at the same temperature, hour, and month, and every observation which differed 4·0 scale divisions or more from that mean was provisionally marked as a disturbed observation.

Fresh means for each hour in each month were then taken omitting the observations marked as disturbed, and the means thus obtained were then used as standards of comparison for a second examination. This process was repeated until the "hourly means" were strictly the means of all the remaining observations, after the separation of those which differed from them respectively by four scale divisions or more. (The value of four scale divisions in parts of the Vertical Force at Toronto was ·00026.)

When the larger disturbances are thus separated, the diurnal variation at the same period of the year, in different years, exhibits a very satisfactory accordance; and, by the process of elimination which has been explained, it is probable that the diurnal variation has very little, if any, influence in the determination of the observations separated as disturbed.

A much greater practical difficulty was occasioned by a circumstance already noticed in discussing the temperature coefficient; namely, the progressive decrease in the scale readings from instrumental causes, and possibly also in part from secular change. Whenever the amount of decrease in the course of a month was seen to be such as to interfere with the proper comparability of the observations in any part of the month with the means taken in the usual manner, fresh means more suitable for the comparison were formed; thus, for example, for the observations in the last week of one month, and the first week of the next, it has in some instances appeared preferable to form the hourly means for comparison from the whole of the observations of the two months united, instead of from each month separately, whereby the advantage is gained that the period which furnishes the standard of comparison for the fortnight in question extends to a nearly equal distance on either side of the observations compared with it. In a few instances in which the decrease was more irregular than was commonly the case, fortnightly means, and even, when absolutely required, weekly means, were substituted for the monthly or two-monthly means. This part of the process requires an attentive preliminary consideration and study of the observations, and it is important that it should be carefully executed, because normal values, however obtained, form an essential basis for the study of all the terrestrial magnetic variations. To facilitate researches of this nature, in which the observations contained in these volumes may hereafter be employed, as well as to show the steps by which the conclusions now submitted have been arrived at, a table of the hourly means of the readings of the Vertical Force Magnetometer reduced to 55° Fahrenheit, and omitting the observations in which the amount of disturbance equalled or exceeded four scale divisions (or ·00026 parts of the whole Vertical Force at Toronto), is subjoined, (pp. xxxviii to xli) specifying in each case the interval to which the normal values correspond, as well as the interval comprehended by the observations from which they are derived.

The period which these normal values comprise is one of five complete years, terminating on the 30th June 1848. It is not, however, an absolutely unbroken period, as in October 1843 the magnet of the Vertical Force Magnetometer was displaced from

its mounting, and employed in experiments designed to show the change in its magnetic moment occasioned by changes of temperature. It was remounted in February 1844; consequently the five months from October 1843 to February 1844 that should have formed a continuous suite are deficient. These have been replaced by the observations of the same months of the year preceding, viz., October 1842 to February 1843.

It will be understood, therefore, that, throughout the discussion of the Vertical Force disturbances, whenever the year ending June 30th 1844 is named, the months which constitute it consist of July to September 1843 inclusive, October 1842 to February 1843 inclusive, and March 1844 to June 1844 inclusive.

The number of the Vertical Force observations in which the amount of disturbance equalled or exceeded 4·0 scale divisions in the five years was 5220, being about 1 in 7 of the whole number of observations.

The aggregate values of the disturbed observations of the Vertical Force in the different years, each ending June 30th, are as follow:—

TABLE XV.

Year ending June 30, 1844	7008·5	Scale Divisions.
" " 1845	6201·1	"
" " 1846	7839·1	"
" " 1847	13055·7	"
" " 1848	19161·5	"
Total in the five years	53265·9	

Table XV. shows a progressive increase in the annual value of the disturbed observations from the years ending in June 1844 and 1845 to the year ending June 1848. The aggregate value in the year ending in June 1844 exceeds by a small amount that of the year ending June 1845; but it must be remembered that these two years do not admit of strict comparison with each other, because the first included five months taken from a preceding year, in consequence of the magnetometer being dismounted from October 1843 to February 1844 inclusive. If, as there is reason to believe, 1843 was a year of minimum disturbance (as was certainly the case in the Declination and Horizontal Force), it becomes probable that the amount of disturbance in the Vertical Force in the year ending June 1844 may have been swelled by this substitution of five months from the preceding year.

The sum of the disturbances in the five years (53265·9 scale divisions) gives an annual mean of 10653·2, and hence we obtain the ratios which the aggregate values in the different years bear to the average annual value, as shown in the following table:—

TABLE XVI.

Year ending June, 1844	0·65 to 1.
" " 1845	0·58 to 1.
" " 1846	0·73 to 1.
" " 1847	1·23 to 1.
" " 1848	1·80 to 1.

Table XVII. exhibits the aggregate values in the different years, divided into disturbances increasing the force and disturbances diminishing the force.

TABLE XVII.

	Increasing.	Decreasing.	
Year ending June, 1844 - -	3174·2 -	3834·3	Scale Divisions.
" " 1845 - -	2061·2 -	4139·9	"
" " 1846 - -	3356·1 -	4483·0	"
" " 1847 - -	4372·9 -	8682·8	"
" " 1848 - -	9298·3 -	9863·2	"
Sums in the five years -	22262·7 -	31003·2	"

It appears from this table that the average operation of the disturbances of larger amount at Toronto is to diminish the Vertical Force more than to increase it. The ratio of the disturbances diminishing the force to those which increased it, on the average of the five years, was nearly as 1·4 to 1.

The next table exhibits the aggregate values of the disturbed observations, distributed into the several *months* of their occurrence, with the ratios which the values in the preceding columns bear to the mean monthly value or average of all the months.

TABLE XVIII.

Months.	In the Year ending June 30, 1844.	1845.	1846.	1847.	1848.	Sums in the Five Years.	Ratios.	Months.

April - -	1374·4	249·5	1048·3	2034·5	1901·7	6608·4	1·49	April.
May - -	490·5	382·7	1347·2	1084·9	1683·1	4985·4	1·12	May.
June - -	182·8	116·8	857·8	420·4	657·2	2235·0	0·50	June.
Total in the five years - -						53265·9		
Mean monthly value, $\frac{53265·9}{12}$ =						4438·8	= 1·00	

April and September are the months of maximum disturbance, and January and June the months of minimum disturbance. The progression from the maxima to the minima, and *vice versâ*, is continuous with the exception of December, an exception manifestly caused by the occurrence of excessive disturbance in December 1847. If the year ending June 30, 1848, be omitted, the ratios of the disturbances in the months of December and January respectively, to the mean monthly disturbance in the remaining four years are, December 0·63 and January 0·58. On the whole, therefore, we may conclude, that in the disturbances of the Vertical Force, as in the Declination and Horizontal Force, the maxima occur at or about the equinoxes, and the minima at or about the solstices. The values of the disturbances at the equinoxes are to those at the solstices in the ratio of nearly 3 to 1.

Tables XIX. and XX. exhibit the aggregate monthly values in the different years, separated into disturbances increasing the force, and disturbances decreasing the force.

Total in the five years - -						31003·2		
Mean monthly value, $\frac{31003·2}{12}$ =						2583·6 = 1·00		

It is seen by Tables XIX. and XX. that the values of the disturbances which increase the force, and of those which decrease the force, follow, in their ratios to their respective mean monthly values, the same general law as that obtained from their conjoint consideration in the remarks on Table XVIII. The equinoxes are the epochs of maxima, and the solstices of minima.

It has been seen in page xxx. that, on the average of the whole year, the disturbances which decrease the force preponderate in value over those which increase the force in the ratio of 1·4 to 1·0. This preponderance, however, appears to be subject to a periodical variation, and to have a maximum about the time of the northern solstice, and a minimum at the opposite period of the year. This variation is of considerable amount; and though the number of years (five) over which the series of observations extends is insufficient to give its progression with great regularity, it is still quite sufficient to indicate the general fact of the existence of such a variation, and to point it out as worthy of a more extensive examination. Table XXI. exhibits the ratios in the different months of the values of the disturbances decreasing the force to those which increase it, the latter being taken throughout as the units.

TABLE XXI.

Ratios of the Values of the Disturbances decreasing the Vertical Force in the different Months to the Value of those which increase it.

Months.	Ratios.	Months.	Ratios.
July	2·33	January	0·89
August	2·41	February	1·29
September	1·56	March	1·13
October	1·49	April	1·43
November	1·18	May	1·72
December	0·61	June	1·37

In December and January the preponderance of the decreasing values ceases, and increasing values preponderate. If we combine in one view the north-solstitial months of May, June, and July, the mean ratio is 1·8 to 1·0. In the opposite part of the year (combining November, December, and January in one view,) the preponderance is reversed, the mean ratio being as 0·83 to 1·0. In the comparison of the values of the easterly and westerly disturbances of the Declination at Toronto (Toronto Observations, vol. II. p. xxvii), we have the evidence of an analogous periodical variation existing in that element. In the north-solstitial months, easterly disturbances preponderate, and in the south-solstitial months westerly predominate. In the analogy thus traced the predominance of easterly disturbances of the Declination ranges itself with the predominance of disturbances which decrease the Vertical Force, and the predominance of westerly disturbances of the Declination with that of disturbances which increase the Vertical Force.

On comparing with each other the periodical affections of the Vertical Force in the different months which have been thus brought into notice, we find that in the sums of the values of the *whole* disturbances (when those which decrease are combined with those which increase the force) the equinoctial months are the epochs of maximum disturbance, and the solstitial months epochs of minimum disturbance; whilst in the periodical variation of the ratios of the disturbances of opposite character to each other (viz., those which decrease and those which increase the force,) the extreme dissimilarity takes place at or near the solstitial epochs, whilst the equinoctial epochs hold a middle place. In both these respects the analogy holds in respect to the disturbances of the Declination.

Table XXII. exhibits the aggregate values of the disturbed observations, distributed into the several *hours* of their occurrence, together with the ratios of the values at the different hours to the mean hourly value or average of all the hours.

Total in the five years - -						53265·9		
Mean hourly value - $\frac{53265·9}{24}$ =						2219·4 = 1·00		

When we examine the values presented in this table, we at once perceive that the occurrence of the larger disturbances of the Vertical Force at Toronto is governed by periodical laws depending on the hours of solar time. The aggregate value of the disturbances in the five years is a maximum at 3 P.M. and a minimum at 11 A.M.; there is also a secondary maximum at 5 P.M. and a secondary minimum at 9 P.M. There is, therefore, a double progression, and between the successive maxima and minima the progression is everywhere continuous. During the hours of the day, *i. e.* from 8 A.M. to 11 P.M., the ratios are less than unity, except from 4 to 7 P.M. inclusive, when the secondary maximum takes place. From midnight to 7 A.M. the ratios at every hour exceed unity.

Tables XXII. and XXIII. exhibit the aggregate values at the different hours, separated into disturbances increasing the force and disturbances decreasing the force, and the ratios of the values at each hour of both kinds of disturbance to their respective mean hourly values.

17	366·9	415·2	352·0	650·7	1040·9	2825·7	2·19	5 a.m.
	Total in the five years - -					31003·2		
	Mean hourly value - $\frac{31003·2}{24}$ =					1291·8 = 1·00		

When we examine the ratios presented in these tables, it is at once seen that both the disturbances which increase the force and those which decrease it are regulated by periodical laws. In the disturbances increasing the force, the values are highest from noon to 10 P.M. inclusive; they exceed the mean hourly value from 1 to 9 P.M., and exceed twice that value from 4 to 7 P.M. The hours of maximum and minimum are approximately, the maximum about 5 P.M., and the minimum about 5 A.M., though (in the latter case particularly) the precise hour is not very distinctly marked. In the disturbances decreasing the force, the values are least from 10 A.M. to 9 P.M. inclusive; they are less than the mean hourly value from 9 A M. to 10 P.M. inclusive, and greater from 11 P.M. to 8 A.M. inclusive: from midnight to 5 A.M. the values exceed at each hour twice the mean hourly value. The maximum is well marked at 3 A.M.; the minimum less distinctly marked takes place during the hours of the afternoon. When the ratios are highest in the disturbances increasing the force they are *generally* lowest in those decreasing the force, and *vice versâ;* but the periodical laws in the two cases are not strictly the converse of each other.

The account given in pp. viii to x of the operations by which the successive steps were accomplished in the investigation of which the disturbances of the Horizontal Force were the subject, applies equally to the present investigation into the periodical laws of the disturbances of the Vertical Force; and in Table XXV. will be found the successive normal values which have been employed of the Vertical Force at the standard temperature of 55° at the different hours, corresponding to Table X in the case of the Horizontal Force.

INCLINATION AND TOTAL FORCE.

Analysis of the larger Disturbances.—The disturbances of the Inclination which equalled or exceeded 1′·0, and of the total force which equalled or exceeded ·0004 of the whole force, both measured from the respective normals at the same hour and in the same month, were obtained from the observed disturbances of the Horizontal and Vertical Forces in the following manner: Tables were formed, in the first column of which were placed in chronological order the larger disturbances of the Vertical Force, separated as already described, and in the second column those of the Horizontal Force, each expressed in terms of the respective forces, by the conversion of the scale divisions in which the disturbances were observed into parts of the respective forces by means of the scale coefficient.

At a large proportion of the hours of contemporaneous observation, when one of the two components of the force exhibited a disturbance which by its amount was brought into the category of the larger disturbances, the other component was also disturbed. In such cases there were contemporaneous entries in both columns; but when one of the components only was so affected, the entry in the corresponding column of the other component was blank. These blanks were all filled up by inserting for the component which did not exhibit a disturbance of sufficiently large amount to have been classed as a large disturbance and separated accordingly, the difference, whatever that might be, between the observation at that hour and its proper normal. These two columns then exhibited all the larger disturbances of both the horizontal and vertical components whenever either component was disturbed, with the contemporaneous difference of the other component from its mean or normal value in the cases when one only of the two components exhibited a large disturbance. The entries in the two columns had each their proper signs prefixed, + if the disturbance or difference from the normal were in augmentation of the force, and − if in diminution of the force. These two columns then expressed the values of $\frac{\Delta Y}{Y}$ for the Vertical Force, and $\frac{\Delta X}{X}$ for the Horizontal Force, for every hour at which either $\frac{\Delta Y}{Y}$ equalled or exceeded ·00026 parts of the Vertical Force, or $\frac{\Delta X}{X}$ equalled or exceeded ·0012 parts of the Horizontal Force. A third and fourth column were then filled in, the third expressing the values of $\Delta\theta$, or the disturbances of the Inclination, and the fourth the values of $\frac{\Delta \mathfrak{F}}{\mathfrak{F}}$, or the disturbances of the Total Force (in parts of $\mathfrak{F}$, the total force at Toronto), corresponding to the entries in the first and second columns, and computed by the formulæ—

$$\Delta\theta = \sin\theta \cos\theta \left(\frac{\Delta Y}{Y} - \frac{\Delta X}{X}\right);$$

$$\frac{\Delta \mathfrak{F}}{\mathfrak{F}} = \cos^2\theta \frac{\Delta X}{X} + \sin^2\theta \frac{\Delta Y}{Y}$$

From the third and fourth columns all the disturbances of the Inclination ($\Delta\theta$) which equalled or exceeded 1'·0 in amount, and all the disturbances of the total force $\left(\frac{\Delta\Phi}{\Phi}\right)$ equalling or exceeding ·0004 in amount, were taken, as forming respectively a sufficient body of the larger disturbances of each element to permit their periodical laws to be investigated and shown. These disturbances were then dealt with, in regard to classification and tabular arrangement, in the same manner that has been already explained in treating of the disturbances of the horizontal and vertical components of the force.

In deriving the disturbances of the Inclination and Total Force from those of the Horizontal and Vertical Forces, all the calculations and arrangement in tables have been prepared, under the superintendence of Mr. Magrath, by the Non-Commissioned Officers of the Royal Artillery employed in the Woolwich Office; every part of the process having had the advantage of two independent computers.

Inclination.—The aggregate values of the disturbed observations of the Inclination in the different years, each ending June 30th, are as follows:—

TABLE XXVI.

Year ending June 30th 1844*	684'3
" " 1845	613'9
" " 1846	753'7
" " 1847	1399'0
" " 1848	3139'8
Total in the five years	6590'7

Mean annual value $\frac{6590'7}{5} = 1318'1.$

The ratios in each year to the mean annual value are as follows:—

TABLE XXVII.

Year ending June 30th 1844	0'52
" " 1845	0'47
" " 1846	0'57
" " 1847	1'06
" " 1848	2'40

Table XXVIII. exhibits the aggregate values in the different years divided into disturbances increasing the Inclination and disturbances decreasing the Inclination.

* Having five months of the preceding year (October 1842 to February 1843) substituted for five of its own months (*see* page xi).

TABLE XXVIII.

	Increasing.	Decreasing.
Year ending June 30th 1844 - -	498'8	185'5
" " 1845 - -	510'5	103'1
" " 1846 - -	612'7	111'0
" " 1847 - -	1165'8	233'2
" " 1848 - -	2809'8	330'1
Total in the five years -	5597'5	993'2

The effect of the larger disturbances is, therefore, to increase the Inclination considerably more than to decrease it. The ratios of the values of the disturbances increasing the Inclination to those which decrease it, on the average of the five years is 5·6 to 1. In the several years the ratios are as follows:—

TABLE XXIX.

Year ending June 30th 1844: As 2·7 to 1.
" " 1845: As 5·0 to 1.
" " 1846: As 4·3 to 1.
" " 1847: As 5·0 to 1.
" " 1848: As 8·5 to 1.

The augmentation of the ratio in the year ending June 30th, 1848, was occasioned by the excessive amount of disturbance in December 1847, which in the case of the Inclination was chiefly in disturbances increasing its value.

Table XXX. exhibits the aggregate values of the disturbances, distributed into the different *months* of their occurrence, and the ratios which the values in the different months bear to the mean monthly value or average of all the months.

TABLE XXX.

Months.	In the Year ending June 30th, 1844.	1845.	1846.	1847.	1848.	Sums in the Five Years.	Ratios.	Months.
July - -	69'7	16'1	38'4	95'2	89'5	308'9	0·56	July.
August - -	53'5	62'5	45'4	100'5	143'4	405'3	0·74	August.

April - -	83'8	49'8	111'2	236'6	288'2	772'6	1·41	April.
May - -	30'5	33'1	99'9	162'1	140'9	466'5	0·85	May.
June - -	8'2	10'8	85'9	60'8	48'9	214'6	0·39	June.
Total in the five years - -						6590'7		
Mean monthly values - $\frac{6590'7}{12} =$						549·2 = 1·00		

December is the only exception to a periodical variation, having its maxima at the epochs of the equinoxes, and its minima at those of the solstices. This apparent anomaly was occasioned by the excessive and unusual disturbances in December 1847. The ratio for the month of December taken from a comparison of the disturbances in that month in the first four years, with the mean monthly value in the same years, is 0·77.

Table XXXI. exhibits the aggregate values of the disturbances of the Inclination distributed into the different *hours* of their occurrence, together with the ratios of the values at each hour to the mean hourly value or average of all the hours.

	Total in the five years - - - -					6590·7		
	Mean hourly value - - $\frac{6590·7}{24}$ =					274·6 = 1·00		

The hourly disturbances of the Inclination arrange themselves in four groups, exhibiting a double progression. From 7 A.M. to noon, and again from 7 P.M. to 2 A.M. inclusive, the values equal or exceed the mean hourly value; and from 1 P.M.

to 6 P.M. inclusive, and again from 3 A.M. to 6 A.M. inclusive, they fall short of the mean hourly value.

Table XXXII. shows, in columns 2 and 3, the values at the different hours separated into disturbances which increase the Inclination and disturbances which decrease it.

The disturbances which increase the Inclination have two epochs of maxima, and two of minima; the principal maximum is at 1 A.M., and the secondary maximum at 7 A.M.; the principal minimum at 4 P.M., and the secondary at 5 A.M. The progression from the afternoon minimum to the maximum twelve hours later, may be regarded as continuous, with slight and possibly accidental interruptions at 8 P.M. and midnight; from the maximum at 1 A.M. to the minimum at 5 A.M., and thence to the secondary maximum at 7 A.M., the progressions are continuous and uninterrupted; and from the maximum at 7 A.M. to the afternoon minimum it is also continuous, with slight and possibly accidental interruptions at noon and 3 P.M.

The disturbances which decrease the Inclination are comparatively small at all the hours: they exhibit, however, a systematic tendency to be greater during the hours of the day than during those of the night; their actual maximum is at 2 P.M., and their minimum at 2 A.M.

The disturbances which increase the Inclination preponderate greatly at all the hours. In the Declination, there are certain hours in which the easterly deflections preponderate, and others in which the westerly deflections preponderate; and in the total force there are certain hours in which the general effect of the disturbances is to increase the force, and other hours in which their general effect is to decrease it. The Inclination differs in this respect from either of the other two magnetic elements; inasmuch as its disturbances have a uniform character in increasing the Inclination at all the hours. The greater or less degree in which this effect is produced is shown in column 4, which contains the *differences* between the two preceding columns (or their sums when the signs prefixed are regarded). This column therefore exhibits at the different hours the accumulated *effect* in five years of the disturbances of 1′·0, and upwards. The least amount of disturbance occurs at 2, 3, and 4 in the afternoon; at 6 P.M. it becomes considerable, and continues so till 3 A.M. inclusive, showing a decided maximum at 1 and 2 A.M. There is a second increase in the amount of disturbance at 7, 8, and 9 A.M., with a secondary maximum at 7 A.M., not much inferior in amount to the principal maximum at 2 A.M. In column 5 is shown the average *daily* effect of the disturbances of 1′·0 and upwards, at the different hours of the 24; this is obtained by dividing the accumulated effect at the different hours in five years by 1550, being the number of days in the five years on which the observations were made.

Total Force.—The aggregate values of the disturbed observations of the Total Force in the different years, each ending June 30th, are as follows:—

TABLE XXXIII.

Year ending June 30th 1844*	- -	·4491 parts of the total force.
" " 1845	- -	·2775 " "
" " 1846	- -	·3809 " "
" " 1847	- -	·7293 " "
" " 1848	- -	1·0747 " "
Total in the five years	- -	2·9115
Mean annual value -	$\frac{2·9115}{5} = ·5823 = 1·00$	

* Having five months of the preceding year (October 1842 to February 1843) substituted for five of its own months (*see* page xxix).

The ratios in each year to the mean annual value are as follows:—

TABLE XXXIV.

Year ending June 30th,	1844*	- - -	0·77
„ „	1845	- - -	0·48
„ „	1846	- - -	0·65
„ „	1847	- - -	1·25
„ „	1848	- - -	1·84

Table XXXV. exhibits the aggregate values in the different years divided into Disturbances increasing the force, and Disturbances decreasing the force.

TABLE XXXV.

			Increasing.	Decreasing.	
Year ending June 30th,	1844	- -	·2044	·2480	parts of the Total Force.
„ „	1845	- -	·0616	·2159	„ „
„ „	1846	- -	·1363	·2446	„ „
„ „	1847	- -	·1839	·5454	„ „
„ „	1848	- -	·4067	·6680	„ „
Total in the five years		- -	·9896	1·9219	

The general effect of the larger disturbances of the Total Force is to decrease the total magnetic force more than to increase it.

The ratio of the values of the disturbances decreasing the Total Force to those which increase it, on the average of the five years, is 1·94 to 1. The ratios in the several years are as follows:—

TABLE XXXVI.

Year ending June 30th,	1844	- - - -	as 1·23 to 1
„ „	1845	- - - -	as 3·51 to 1
„ „	1846	- - - -	as 1·79 to 1
„ „	1847	- - - -	as 2·96 to 1
„ „	1848	- - - -	as 1·64 to 1

* Including five months (October to February) substituted from the preceding year (see page xxix).

Table XXXVII. exhibits the aggregate values of the disturbances distributed into the different *months* of their occurrence; with the ratios which the values in the different months bear to the mean monthly value or average of all the months.

June - -	·0012	·0056	·0404	·0176	·0300	·0948	0·39	June.
Total in the five years - -						2·9115 parts of the Total Force.		
Mean monthly value $\frac{2\cdot9115}{12} = \cdot2426 = 1\cdot00$								

The anomaly in the month of December, which is the only exception to a periodical variation having its maxima at the epochs of the equinoxes and its minima at those of the solstices, was occasioned by the excessive and unusual disturbances in December 1847. If the ratio for December be taken from the value of the disturbances in that month in the four years ending respectively June 30th, 1844, 1845, 1846, and 1847, compared with the mean monthly value in the same years, it is found to be 0·66, which would place it in its natural order in the progression. We may, therefore, regard the general progression of the annual variation of the Total Force depending on the larger disturbances to be from a maximum at each of the equinoxes to a minimum at each of the solstices, and *vice versâ*; and the month of December 1847 as forming an accidental exception, presenting a decided anomaly in that particular year, but which might possibly disappear if the month were comprehended in observations continued through a longer series of years than are here combined.

Tables XXXVIII. and XXXIX. exhibit the aggregate monthly values in the different years separated into disturbances increasing and disturbances decreasing the force.

Total in the five years - -							1·9219 parts of the Total Force.	
Mean monthly value $\frac{1·9219}{12}$ = ·1602 = 1·00								

Both the disturbances which increase the Total Force and those which decrease it show the same periodical law of monthly variation which has been pointed out in the remarks on Table XXXVII., in which they were exhibited conjointly. In both, the equinoxes are epochs of maxima and the solstices of minima. In the disturbances decreasing the force, the progression from the minima to the maxima and from the maxima to the minima is continuous and uninterrupted. In those increasing the force, December is the only interruption, and ceases to be so if the ratio be taken from the four years ending June 30th, 1844, 1845, 1846, and 1847; omitting the year ending June 30th, 1848. The excessive disturbances in December 1847 are seen by Tables XXXVIII. and XXXIX. to have been chiefly disturbances increasing the Total Force.

Table XL. exhibits the aggregate values of the disturbances distributed into the different *hours* of their occurrence; together with the ratios of the values at the different hours to the mean hourly value or average of all the hours.

				Total in the five years - -		2·9115 parts of the Total Force.		
				Mean hourly value		$\frac{2·9115}{24} = ·1213 = 1·00$		

The law which regulates the occurrence in the *diurnal* period of the disturbances of larger amount of the Total Force is here in its principal features sufficiently distinct and obvious. From 8 A.M. to 11 P.M. inclusive the disturbance at every hour is less than at any hour from midnight to 7 A.M. inclusive. It is a minimum at 11 A.M., and a maximum at 3 A.M., the disturbance at the hour of maximum being about eleven times greater than at the minimum hour. From the maximum at 3 A.M. to the minimum at 11 A.M. the progression is continuous and uninterrupted: from the minimum at 11 A.M. to the maximum at 3 A.M. the progression is interrupted in the afternoon by secondary small maxima at 5 and 7 P.M., with corresponding secondary minima at 6 P.M. and 9 P.M., but from the secondary minimum at 9 P.M. to the principal maximum at 3 A.M. the progression is continuous and uninterrupted.

Tables XLI. and XLII. show the aggregate hourly values in the different years, separated into disturbances increasing and disturbances decreasing the force; with the ratio of the values at each hour to the respective mean hourly values.

When Tables XLI. and XLII. are examined, it is seen that the disturbances increasing the force and those decreasing it, may be generally viewed as parts of one and the same phenomenon, subject to one and the same law, expressed by ratios which in the two cases are approximately the complement of each other, viz., at the hours when the one augments in value, the other diminishes, and *vice versâ;* and that the two classes of disturbances, distinguished from each other by the opposite effects which each produces on the mean or normal state of the magnetic force, do in fact constitute when viewed together a diurnal variation of very striking order and regularity, having a maximum of increased force at a certain hour, and a maximum of diminished force at another hour distant nearly twelve hours from the preceding, and forming a regular progression from the hour of the greatest increased force to that of greatest diminished force, and *vice versâ.* To see this in its just light, and to obtain the true

proportions in which the magnetic force is increased or diminished at the different hours by the effects of the disturbances, it is necessary to combine the values in Tables XLI. and XLII. somewhat differently from what is done in Table XL., by taking the *differences* instead of the *sums* of the increasing and decreasing values. When we take the sums we investigate the proportion which the *whole amount* of disturbance, whether its effect be to increase or to decrease the force, bears at each hour to the mean hourly value or average of all the hours: the ratios in this case are shown in Table XL. When, on the other hand, we take the differences, we exhibit the amount by which the magnetic force of the earth is either increased or decreased at the several hours by the influence of the disturbances of ·0004 and upwards during five years. This is shown in column 4 of Table XLIII.; the values are in parts of the Total Force at Toronto.

15; or 3 A.M.	+ ·0122	− ·2264	− ·2142	− ·000138
16; or 4 A.M.	+ ·0073	− ·1986	− ·1913	− ·000123
17; or 5 A.M.	+ ·0120	− ·1806	− ·1686	− ·000109

We learn from this table that the law of the diurnal variation due to the disturbances of the Total Force at Toronto is as follows:—From 11 A.M. to 9 P.M. inclusive they augment the force; from 10 P.M. to 10 A.M. inclusive they diminish it. The hour of greatest augmentation is 5 P.M.; of greatest diminution 3 A.M. The decreasing effect changes to an increasing effect about midway between 10 and 11 A.M.; the increasing

to a decreasing between 9 and 10 P.M., nearer to 9 than to 10. The greatest diminution is nearly twice as great as the greatest augmentation. The hours of most rapid change are from 7 to 8 A.M., and from 11 P.M. to midnight. From the greatest diminution at 3 A.M. to the greatest increase at 5 P.M. the progression is continuous and uninterrupted, and from the greatest increase at 5 P.M. to the greatest decrease at 3 A.M. it is also continuous, except in a small and apparently accidental interruption at 7 P.M. As the values in column 4 of Table XLIII. are the accumulated values in five years, and as each year comprised about 310 days of observation (or 1,550 days in the five years) we may take an approximate view of the *mean* diurnal variation due to the disturbances equalling or exceeding ·0001 in amount. An increase of force at 5 P.M. of ·1125 divided by 1,550 days = ·000073; and a decrease of force at 3 A.M. of ·2142 divided by 1550 = ·000138; making together an average diurnal range of ·000211 parts of the force, changing progressively from + ·000073 at 5 P.M. to − ·000138 at 3 A.M.

As it is not probable, on the one hand, that the disturbances of ·0001 and upwards comprehend all the disturbances of the class to which they belong, we may regard the preceding range as expressing the minimum limit of the true average daily range of variation due to the disturbances of occasional occurrence; whilst, on the other hand, it appears extremely improbable that the minor effects of the causes which produce the larger disturbances should equal in aggregate value those which exceed ·0001. We have, then, the same degree of improbability that the range of the diurnal variation due to all the disturbances of this class should amount to twice the value which has been obtained by this analysis, or to ·000211 × 2 = ·000422. The diurnal range may be regarded as something between ·000211 and ·000422, but probably nearer to the first than to the last. The final column of Table XLIII. (column 5) shows the average daily effect of the disturbances of ·0004 and upwards at every hour of the day and night.

DECLINATION.

Analysis of the larger Disturbances.—To complete the view of the magnetic disturbances at Toronto in the five years ending June 30th 1848, a second and a more perfect analysis has been made of the disturbances of the Declination during that period than that which is contained in the second volume of the Toronto Observations (pp. xxvii—l), which was deemed sufficient for a first approximation when other duties pressed heavily on the time at command.

The disturbances which were then subjected to analysis, were those which differed five scale divisions (3′·6 in arc) or upwards from the mean or normal positions of the magnet in the same month and at the same hour, the normal positions being derived from the whole body of the observations, excluding only some very extreme disturbances. The more perfect mode of proceeding is that which has been stated in describing the process adopted in the cases of the Horizontal and Vertical Forces; viz. the subsequent correction of the normal positions by a recalculation in which the *whole* of the disturbances are excluded, and a revision of the disturbances in conformity with the new normals; both processes being repeated until the normals finally adopted are derived from a body of observations including all which differ less, and excluding all which differ more, than a certain fixed value from themselves. At the same time this fixed value has itself been altered by raising the standard considered to constitute a disturbed observation from five scale divisions to seven (*i.e.* from 3′·6 to 5′·0 of arc), the experience gained in the former investigation having led to the belief that the higher value would constitute in some respects a preferable standard. The number of observations thus separated amounted to 2,172 in the five years of hourly observations ending June 30th 1848, averaging about 1 in 17 of the whole body.

The aggregate values of the disturbed observations in the different years are shown in the following table:—

TABLE XLIV.

Year ending June 30th 1844	2053′·2	minutes of arc.
„ „ 1845	2521′·8	„
„ „ 1846	3246′·6	„
„ „ 1847	5478′·7	„
„ „ 1848	6122′·0	„
Total in the five years	19722′·3	
Mean annual value $\frac{19722'\cdot3}{5}$	= 3944′·5	

The ratios in each year to the mean annual value are as follow:—

TABLE XLV.

Year ending June 30th	1844	0·52
" "	1845	0·64
" "	1846	0·82
" "	1847	1·39
" "	1848	1·63

The observations of the Declination were not interrupted in the months from October 1843 to February 1844; consequently the years ending June 30th 1844, 1845, 1846, 1847, and 1848 are here strictly what they profess to be, and the ratios show a continuous progression from a minimum in the first year to a maximum in the last.

Table XLVI. shows the aggregate values in the different years, divided into easterly and westerly disturbances.

TABLE XLVI.

		Easterly.	Westerly.
Year ending June 30th	1844	1235·8	817·4
" "	1845	1325·4	1196·4
" "	1846	1973·3	1273·3
" "	1847	2958·9	2519·8
" "	1848	3573·5	2848·5
Total in the five years		11066·9	8655·4

The general effect of the larger disturbances is therefore to decrease the westerly Declination at Toronto. The easterly values preponderate in the ratio of 1·28 to 1.

Table XLVII. exhibits the aggregate values of the disturbances distributed into the different *months* of their occurrence, with the ratios which the values in each of the months bear to the mean monthly value or average of all the months.

TABLE XLVII.

Months.	Years ending June 30, 1844.	1845.	1846.	1847.	1848.	Sums in the Five Years.	Ratios.	Months.
July	327·9	160·8	159·3	565·1	329·5	1542·6	0·94	July.

November - -	556·6	0·60	725·4	1·06	0·77	November.
December - -	527·4	0·57	717·4	0·99	0·74	December.
January - -	527·0	0·57	409·0	0·57	1·29	January.
February - -	772·9	0·84	610·9	0·84	1·27	February.
March - -	1062·9	1·15	761·8	1·06	1·40	March.
April - -	1187·5	1·29	1141·5	1·59	1·04	April.
May - -	901·3	0·98	699·5	0·98	1·29	May.
June - -	691·1	0·75	181·3	0·25	3·82	June.
Total in the five years,	11066·9	- -	8655·3			
Mean monthly values -	922·2 = 1·00	-	721·3 = 1·00			

The same general law is seen to prevail in both easterly and westerly disturbances when separately viewed as when they are viewed conjointly; the equinoxes are the epochs of maximum and the solstices of minimum.

The ratios which indicate the proportion in which the easterly disturbances preponderate over the westerly exhibit, on the other hand, a tendency towards a maximum at the June solstice and a minimum at the December solstice. The mean ratio in the months of November, December, and January is 0·93, and in the months of May, June, and July 2·17.

The next table exhibits the aggregate values of the disturbed observations distributed into the different *hours* of their occurrence, with the ratios which the values at each hour bear to the mean hourly value or average of all the hours.

					Total in the five years	- -	19722'3	
					Mean hourly value, $\frac{19722'3}{24}$	=	821'8 = 1'00	

From 10 A.M. to 7 P.M. inclusive the ratios are invariably below unity, and from 8 P.M. to 9 A.M. inclusive as invariably above unity. The hour of least disturbance is 1 P.M., and of greatest 9 P.M., both being well-marked features. The progression during the hours of the day from 8 A.M. to 9 P.M. is uninterrupted to and from the minimum at 1 P.M., but is much less regular during the hours of the night.

Table L. exhibits the aggregate values separated into their easterly and westerly constituents, with the ratios at each hour to the mean hourly value or average of all the hours.

Total in the five years.	11066·9	8655·4			
Mean hourly values.	461·1	360·6			

The easterly disturbances are below the average during the hours of the day, or from 5 A.M. to 5 P.M. inclusive, and above the average during the hours of the night, or from 6 P.M. to 4 A.M. inclusive; the westerly disturbances are below the average from noon to midnight inclusive, and above the average, with a single exception at 3 A.M., from 1 A.M. to 11 A.M. inclusive. The easterly have a maximum and the westerly a minimum, both decided features, at 9 P.M.; the westerly have a well-marked maximum at 8 A.M., and the easterly have minima scarcely differing from each other at 9 A.M. and at 1, 2, and 3 P.M. From noon to 5 P.M. both easterly and westerly disturbances are below their respective averages, consequently these are the hours of least general disturbance. From 6 P.M. to 11 P.M. the easterly are so much above their average that they more than compensate for the deficiency of the westerly; from midnight to 5 A.M. both easterly and westerly are above their respective averages (with the slight and apparently accidental exception already noticed at 3 A.M.), and from 6 A.M. to 10 A.M. the high values of the westerly more than compensate for the low values of the easterly disturbances. Excepting at the hours from noon to 5 P.M. inclusive,

when both easterly and westerly disturbances are small, and from 1 A.M. to 5 A.M., when they are both large, there is a systematic tendency to a diminution of easterly disturbance at the hours when large westerly disturbance prevails, and to a diminution of westerly disturbance when large easterly disturbance prevails.

In the following table is shown for each hour (in column 2) the excess of easterly disturbance over westerly, or of westerly over easterly, in the aggregate values of the five years; and in column 3 the mean effect at each hour, or a *daily* average, obtained by dividing the accumulated excess in five years shown in column 2 by 1,552, the number of days of observation in the five years. Column 3, therefore, exhibits the *mean diurnal* variation produced on a general average by the disturbances amounting to or exceeding 5′·0 of arc, and which, as a general and systematic effect, is superimposed upon the more regularly occurring diurnal variation derivable from the great body of the observations after the disturbed observations have been individually abstracted.

TABLE LI.

It is seen by this table that when a daily average is derived from all the disturbances of larger amount (5′·0 and upwards) occurring in five years at Toronto they are found to produce a maximum easterly deflection of the Declination magnet of 0′·87 at 9 P.M., and a maximum westerly deflection of 0′·52 at 8 A.M., the intermediate progression either way being continuous, and only interrupted by a few slight irregularities occurring in the hours of the afternoon when the disturbances are fewest and of least amount. The range is 0·87 + 0·52 = 1′·39, which might possibly be increased to 2′·0 if the disturbances of the same class which are less than 5′·0 could be separated and included in the analysis.

Table LII. contains the hourly normals of the Declination for each month from July 1843 to June 1848 inclusive, omitting disturbed observations in which the amount of disturbance equalled or exceeded 7·0 scale divisions or 5′·0 of arc.

GENERAL CONCLUSIONS.

In a communication made to the Royal Society on the 18th of March 1852, it was shown that the larger disturbances of the Declination, both at Toronto and at Hobarton, indicated, by the variation in their numbers and aggregate values in different years, the existence of a *periodical inequality*, of which the extreme and opposite phases were five years distant from each other, and the years 1843 and 1848 were respectively the epochs of minimum and maximum. The examination which had led to this conclusion comprehended the years from 1841 to 1848 inclusive, and was definite in respect to 1843 as the year of minimum; inasmuch as 1841, 1842, and 1843 showed a progressive *decrease* in the number and aggregate value of the larger disturbances in each year, whilst from 1843 to 1848 there was a progressive *increase* of both in successive years.

It was noticed in the same communication that the regular *diurnal* variations of each of the three magnetic observation-elements at Toronto and Hobarton, the Declination, the Horizontal Force, and the Vertical Force, and of each of the two derived elements, the Inclination and the Total Force, exhibited evidences of a corresponding periodical inequality in the amplitude or extent of the diurnal variation, the years 1843 and 1848 being also epochs respectively of minimum and maximum. The observation of one of the elements, the Declination, extending uninterruptedly at both stations over eleven entire years, or from 1841 to 1851 inclusive, distinctly marked 1848 as the year of maximum, as well as 1843 as the year of minimum.

This discovery of the existence of a periodical inequality, common to the magnetic disturbances of larger amount and to those more regular diurnal magnetic variations of which the sun has been long recognised as the primary cause, (inasmuch as they conform systematically to laws depending on solar time,) was regarded as affording presumptive evidence of the subsistence of a causal connection common to those two classes of phenomena; which presumption was corroborated by facts adduced in the same communication, proving that the disturbances are themselves subject, on the average, to a well-marked diurnal period regulated also by solar time.

The periodical inequality thus manifested, having its opposite phases of maximum and minimum separated by an interval of five years, and of which the cycle might therefore be conceived to include about ten of our solar years, did not appear to connect itself with any of those divisions of time with which we are conversant, as depending upon the relative circumstances of the sun, and the earth and her satellite. The cycle might or might not be one of regular and unfailing recurrence. The observational evidence to which we are indebted for a knowledge of its existence, though sufficiently decisive as far as the period of observation extended, could only be viewed, in reference to a permanently cyclical character of the phenomenon, as fragmentary, and as the commencement of an investigation which would require to be pursued in one or more of the permanent magnetic observatories established in our own and other countries.

Had no other circumstance presented itself to give additional interest to an investigation which held out at least a fair promise of making known laws of definite order and sequence in phenomena which have excited so much attention of late years, but of which so little has hitherto been ascertained,—had, for example, the decennial period, which appeared to prevail with precisely corresponding features in two distinct classes of the magnetic variations, connected itself with no other periodical variation either of a terrestrial or cosmical nature with which we are acquainted,—there might have been, indeed, little reason to apprehend, in these days of physical curiosity and inductive application, that the investigation would have been suffered to drop; but the interest and importance of the inquiry have doubtless been greatly enhanced by the remarkable coincidence, which it was the object of the paper communicated to the Royal Society in March 1852 to announce, between the above-described periodical inequality by which the magnetic variations referable to solar influence are affected, and the periodical inequality which has been discovered by M. Schwabe to exist in the frequency and magnitude of the solar spots. The coincidence, as far as we are yet able to discover, is absolute; the duration of the period is the same, and the epochs of maximum and minimum fall in both cases on the same years. The regularity with which the alternations of increase and decrease have been traced by M. Schwabe in his observations of the solar spots (which have been now continued for about thirty years), must be regarded as conferring a very high degree of probability on the systematic character of causes which as yet are known to us only by the visible appearances which they produce on the sun's disk, and by the disturbances which they occasion in the magnetic direction and force at the surface of our globe. As a discovery which promises to raise terrestrial magnetism to the dignity of a cosmical science, we may feel confident that, although the colonial observatories have been brought to a close, the investigations, which they have thus successfully commenced, will be pursued to their proper accomplishment in those national establishments which have a permanency suitable for such undertakings.

The conclusions which have been hitherto drawn, both in the Philosophical Transactions and in the introductory discussions in the Toronto and Hobarton volumes, regarding the periodical laws of the disturbances at those stations, have been confined exclusively to the disturbances of a single element, viz. the Declination. It was fully recognised that each of the other two observational elements, viz. the Horizontal and the Vertical Force, might be expected to furnish concurrent, but strictly independent, evidence of the periodical affections to which the magnetic disturbances are subject; but the work to be accomplished for the elaboration of that evidence was considerably greater than in the case of the Declination, from the necessity of eliminating the influence of changes of temperature on the magnets employed in measuring the variations of the Horizontal and Vertical Forces, before these disturbances could be separated for analysis. The labour required in the different processes of reduction has now been gone through, and statements of the results in full detail are contained in the

preceding pages of this volume: it now remains to bring together in one view the evidence which the three observational and the two derived elements furnish of the periodical laws—decennial, annual, and diurnal—which regulate the occurrence of the larger disturbances.

Decennial Period.—In respect to the decennial period, it must be regarded as a fortunate circumstance that the five years of hourly observation, which were commenced before the existence of any inequality of longer duration than a year was suspected, began with 1843, the year of minimum, and closed with 1848, the year of maximum disturbance, so that the variation has been followed through a complete phase. This has been strictly the case in the Declination and Horizontal Forces, and with a single exception in the Vertical Force also, the exception being caused by the interruption of the observations of that element, (for purposes explained elsewhere,) during the months of October, November, and December 1843, January and February 1844. These months have been supplied, in the year ending June 1844, from hourly observations made with the same apparatus in the preceding year, viz. in the months of October, November, and December 1842, January and February 1843, thus rendering the five years of the Vertical Force complete for the investigation of the *annual* and *diurnal* variations; but, of course, in regard to the *decennial* period the months taken from a different year, even though it be the adjacent one, are an imperfect substitute. The effect of this substitution has been in fact, as shown in p. xxix, to swell the aggregate value of the disturbances of the Vertical Force in the year nominally ending June 30, 1844, but really comprising five months taken from a preceding year, so as to make them slightly exceed the aggregate value in the year ending June 30, 1845. A similar slight excess in the aggregate value of the disturbances of the Horizontal Force in the year ending June 1844, over the aggregate value in the year ending June 1845, is shown (p. ix) when the same five months of the preceding year are substituted for its own months; but when, in the case of the Horizontal Force (the observations of which were not suspended, as were those of the Vertical Force), the actual observations throughout the year ending June 1844 are taken, the true progression is restored, and the apparent anomaly disappears.*

* When the disturbances are taken from the observations of the months actually belonging to the year ending June 1844, the aggregate values of the disturbed observations of the Horizontal Force in the different years are as follow:—

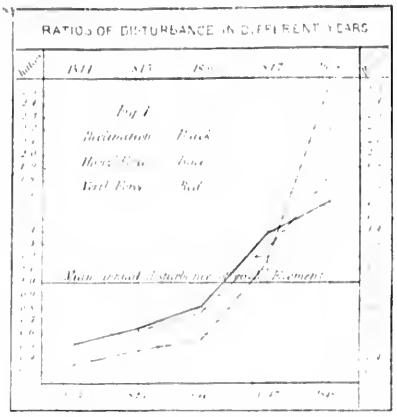
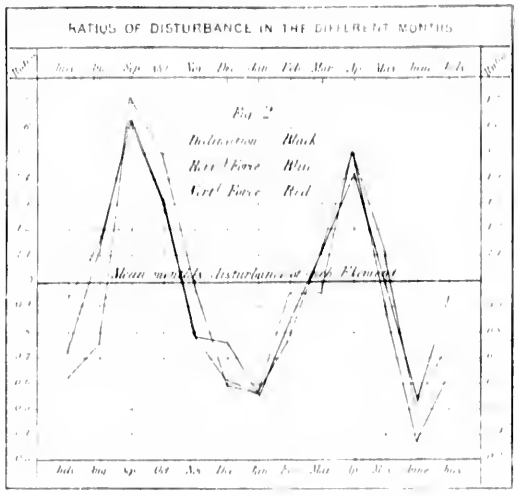
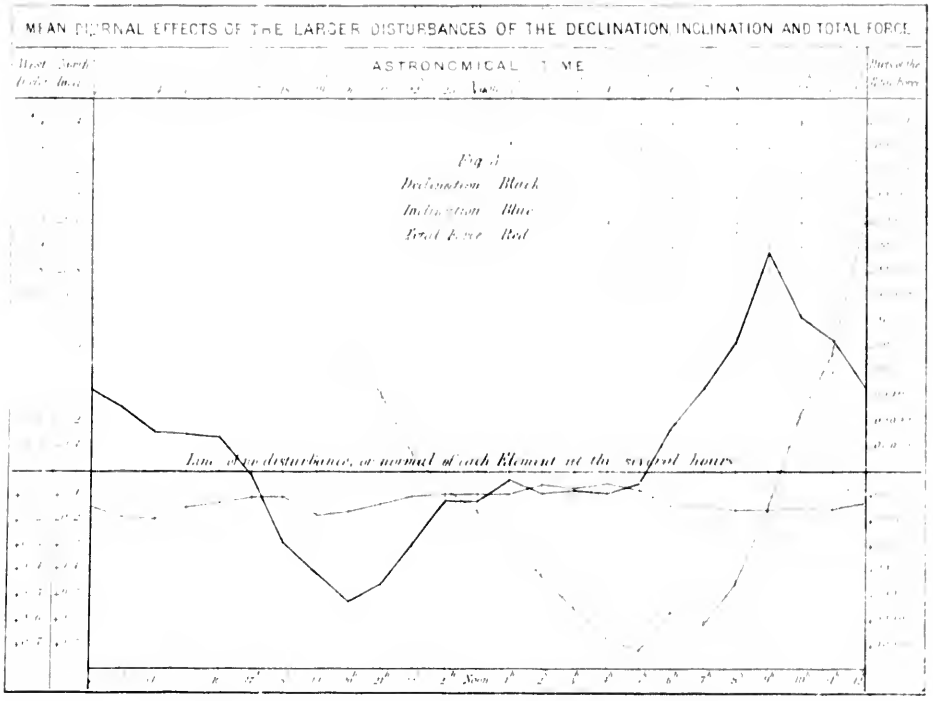
ILLUSTRATIONS OF THE MEAN EFFECTS OF THE LARGER DISTURBANCES







The variations of the three magnetic elements being measured by instruments wholly distinct and unconnected with each other, each element affords an independent evidence of the progressive increase in the aggregate values of the larger disturbances during the period under examination. The sum of the aggregate values of each element in the five years, divided by 5, gives the *mean* annual value of that element, which we may take in each case as equal to 1·00, for the purpose of comparison with the *actual* aggregate values in the different years. We have then the ratios of the disturbances of the different elements in the different years as follows:—

TABLE LIII.

	Declination.	Horizontal Force.	Vertical Force.	Mean.
Year ending June 30, 1844	0·52	0·35	0·65*	0·41
„ „ 1845	0·61	0·47	0·58	0·57
„ „ 1846	0·82	0·55	0·73	0·70
„ „ 1847	1·39	1·14	1·23	1·25
„ „ 1848	1·63	2·49	1·80	1·97

The final column has been added [illegible]ow the mean ratio of disturbance in each year as derived from the three elements, measured by the aggregate value in each year of all the disturbances which exceeded a certain definite magnitude in each element, the same magnitude being taken throughout the five years.

It is seen by this table that in the year ending June 1847 the ratio of disturbance is above twice as great, and in the year ending June 1848 nearly four times as great, as in either of the years ending June 1844 or June 1845. In the year ending June 1848, which is the year of maximum, the proportion is nearly five times as great as in the year ending June 1844, which is the year of minimum. The evidence of the existence of a decennial period borne by the disturbances of the Declination receives the fullest confirmation from the variations in different years of the disturbances of the Horizontal and Vertical Forces.

Fig. 1. pl. 1. has been drawn in illustration of the progressive increase of disturbance in each of the three elements between the year ending June 1844 and the year ending June 1848. The dotted horizontal line represents the *mean* or *average* annual disturbance in each element, and is the zero line, or unit, with which the *actual* aggregate values of the disturbance of each element in each year are compared: the Declination is represented by a black line, the Horizontal Force by a blue line, and the Vertical Force by a red line. The rate of increase of disturbance is seen to be much slower in the first half than in the second half of the five years.

Annual Period.—The sum of the aggregate values of the disturbances of each element in the five years, divided by 12, gives the average *monthly* disturbance-value

* In the deduction of this number, five months of the preceding year have been substituted for five months of the year ending June 1844; it has not been included, therefore, in the final column which shows the *mean* ratios in each year.

The evidence afforded by each of the three observational elements in regard to annual variation is to one and the same effect. January and June are the months of minimum disturbance, September and April the months of maximum disturbance. The aggregate value of the disturbances in the equinoctial months is about three times as great as in the solstitial months. Of the two equinoctial months the value is somewhat higher in each element in September than in April; and of the two solstitial months December is higher than June, also in each of the three elements.

Fig. 2. pl. 1. has been drawn in illustration of the annual variation which has been thus described. The dotted horizontal line is the *mean* monthly disturbance of each element (*i.e.* the sum of the disturbance in the twelve months, divided by 12). The black line for the Declination, the blue line for the Horizontal Force, and the red line for the Vertical Force, show in each case the variation in the proportion which the actual disturbances in each month bear to the *mean* monthly disturbance in the same element. The correspondence of the three elements could scarcely be more perfect.

The annual variation which has been thus deduced has reference exclusively to the variable amount in the different months of the sums of the aggregate values of the disturbances of each element, without distinguishing apart or separating the disturbances which cause easterly deflections and those which cause westerly deflections; or those which increase and those which decrease the Horizontal and Vertical Forces. When this separation is made, we continue to find that each of the two portions into which the disturbances of each element are divided, exhibits distinctly and notably the same general features which have been derived from their conjoint consideration. The equinoxes are in all cases the epochs of maxima and the solstices of minima. But when we study more carefully the relative prevalence of disturbances of particular

character at different periods of the year,—which we may do by forming tables of the relative proportion which the aggregate values in the different months of the easterly disturbances bear to the aggregate values in the same months of the westerly disturbances, and the disturbances which decrease the force bear to those which increase it,—we find that indications present themselves of an annual variation of a different kind from that which has been hitherto described, namely, an annual variation in the *character* of the disturbances of two at least of the elements which have been observed; and although a greater length of time and a greater amount or continuance of observation may be required for the satisfactory establishment of such a periodical variation, its present indications ought not to be overlooked, since the range of the variation is of considerable magnitude, and its systematic character as distinctly marked as could well be expected in an *annual* variation derived from not more than *five* years of repetition. The elements in which these phenomena are most distinctly noticeable are the Declination and the Vertical Force, and the correspondence between the indications of these two elements is in many respects very remarkable. In both elements, when the relative proportions are taken,—in the Declination, of the aggregate values in the different months of easterly and of westerly disturbances; and in the Vertical Force, of disturbances which decrease and disturbances which increase the force,—we find that in both cases the proportions vary from a minimum at the southern solstice to a maximum at the northern solstice, the equinoxes being intermediate. At the northern solstice easterly disturbances are in considerable excess, as are disturbances which decrease the Vertical Force; at the southern solstice, the excess is on the other side; westerly disturbances then predominate, as do the disturbances which increase the Vertical Force. The relative proportion of the aggregate values of easterly to westerly disturbances of the Declination, and of disturbances which decrease the Vertical Force to those which increase it, varies from the one solstice to the other, approximately, as three to one, and in both elements nearly alike.

In the Horizontal Force the disproportion between the values of the disturbances which increase the force and those which decrease it is so great (decreasing disturbances *greatly* preponderating at all periods of the year) that a variation corresponding to that of the two other elements is not so simply arrived at; but it may be stated generally that the proportion of decreasing disturbances is greater at the epoch of the southern solstice than at that of the northern solstice.

Diurnal Variation.—Before we proceed to examine the diurnal variation of the Declination, Inclination, and Total Force which it is the average effect of the larger disturbances to produce, it may be desirable to show the proportions in which the disturbances of the three *observed* elements occur at the different hours. This is expressed in the following table by the ratio which the aggregate values in the five years of the disturbances at each particular hour bear to the mean or average disturbance at all the hours in the same five years taken as the unit.

17	1·05	1·02	1·41	5 a.m.

From the systematic increase and decrease of the ratios at the different hours, it is obvious that the disturbances of each element, when viewed on the average of a sufficient body of observations, are regulated by laws which have a diurnal period. The diurnal variation thus presented is far, however, from being identical in each of the three elements. The maximum disturbance takes place, indeed, in all the elements during the hours of the night, and the minimum disturbance during the hours of the day; but the particular hours of maximum and minimum are different in the three cases. The hour of maximum in the Declination, for example, is 9 P.M., when the disturbances of the Horizontal and Vertical Forces are both even *less than the hourly average:* and the Horizontal and Vertical Forces do not reach their hours of maximum until, respectively, 2 and 3 A.M., when the disturbances of the Declination have notably declined. So in respect to the hour of minimum: that of the Declination, 1 P.M., is nearly midway between that of the Vertical Force at 11 A.M. and that of the Horizontal Force at 4 P.M., the disturbance of the Horizontal Force being still high when that of the Vertical is a minimum, and the disturbance of the Vertical Force being still high when that of the Horizontal Force is a minimum. Speaking generally, the disturbances of the three elements are above the average in the hours of the night and early morning, and below the average during the hours of the day; to the latter, however, there is an exception in the Vertical Force, which is above the average from 4 to 7 P.M. In the Declination the aggregate value of the disturbances at the hour of

maximum is about six times as great as at the hour of minimum; in the Horizontal Force, about 2·7 as great; and in the Vertical Force, about five times as great.

In the ratios of the Declination-disturbances at the different hours shown in the preceding table we have the joint effects of two classes of disturbances, those which produce easterly and those which produce westerly deflections; and in the ratios of the disturbances of the Horizontal and Vertical Forces at the different hours, we have the further complication that the variations of the Horizontal and Vertical Forces do not bear a simple relation to those of the theoretical equivalents to which they are due,—viz. the Inclination and the Total Force,—but involve quantities dependent on the resolution of forces, which, when the Inclination is great, as it is at Toronto, have a tendency to mask the simplicity of the variations of the Inclination and of the Total Force, as they would appear if they were the subjects of direct observation. In the following table, therefore, are placed the proportions at the different hours in which the six classes of phenomena respectively vary, viz. the disturbances which produce easterly and those which produce westerly deflections, those which increase and those which decrease the Inclination, and those which increase and those which decrease the Total Force.

17	0·91	1·23	0·76	0·55	0·22	2·24	5 a.m.

We learn from this table that the laws which regulate the occurrence of easterly and westerly disturbances of the Declination are not on the one hand similar, nor on the other hand are they always complementary to each other. Thus from 1 P.M. to 5 P.M. both classes are considerably below the average, and from 1 A.M. to 5 A.M. both classes, with a slight exception, are above the average; whilst from 6 P.M. to 11 P.M. easterly disturbances greatly exceed, and westerly fall greatly short, of the average; and from 6 A.M. to 11 A.M. westerly exceed and easterly fall short of the average. In the Inclination and Total Force the complementary character of the opposite affections of each element is somewhat more extensively manifested: thus, the disturbances which increase the Inclination are below the average from about noon and the early hours after noon, when those which decrease it are above the average; and are below the average from about midnight and the early hours after midnight, when those which increase the same element are above the average. In the Total Force, from 1 A.M. to 8 A.M. the disturbances which increase the force are greatly above, as those which decrease the force are greatly below, the average,—a contrast which is reversed from 1 A.M. to 8 A.M., the disturbances which decrease the force being then greatly above, whilst those which increase it are greatly below, the average. In neither of the two elements, however, does the complementary character exclusively prevail. It may be remarked, that in all the instances which have been thus brought into view, treating successively the diurnal variations of the disturbances of each of the three elements, the parallel cases which have been cited, whether of identity or of contrast, fall, without exception, on homonymous hours—a circumstance which affords additional evidence of the systematic character of the affections of which we are treating.

There does not appear to be any uniform cotemporaneous connection between the prevalence of either easterly or westerly Declination-disturbance, and that of disturbances which either increase or decrease the Inclination or the Total Force. Thus, for example, the hours at which the disturbances which increase the Total Force are most notably above the average occur from 1 P.M. to 9 P.M.; whilst we find that for half that period, or from 1 P.M. to 5 P.M., the Declination-disturbances are characterised by a very low proportion of easterly disturbances, and for the other half of the period, or from 6 P.M. to 9 P.M., by a very high proportion of easterly disturbances; and, without multiplying instances of dissimilarity, it may be remarked generally, that the more the six classes of disturbance are examined and compared with each other, the less reason does there appear to conclude that there is any uniform interaccompaniment of the variations of different elements.

As the instrument by which the variations of the Declination are observed is more simple in construction than those required for the variations of the Inclination and Total Force, and the disturbances of the Declination are therefore more easily observed and more generally known, a somewhat disproportionate consideration has been frequently given to them in the discussion of these phenomena, which it may be

desirable briefly to remark upon. Thus the knowledge of the magnetic disturbances having been chiefly drawn hitherto from those of the Declination, it has been very generally and very naturally imagined that the early hours of the night, or from 8 P.M. to 11 P.M., are those at which magnetic disturbances principally take place; that about 11 P.M., or a little after, they begin to subside, disappearing almost wholly in the daytime, and reappearing again possibly the following evening, at the same hour as on the preceding evening, in supposed analogy with certain peculiar atmospheric disturbances, which manifest a tendency to recur at the same hours on successive days. It is in this supposed analogy that the term of magnetic *storms* appears to have originated. An examination of the observations of the three elements at but a single station, as Toronto for example, teaches us that this view requires to be considerably modified. The disturbances of the Declination, which reach a maximum at 9 P.M., have indeed already subsided considerably at 11 P.M., but those of the Inclination show no abatement until about 2 A.M., whilst those of the Total Force, which are *much below* their average at 9 P.M., increase progressively to their maximum, which is only reached at 3 A.M., or nearly six hours after the maximum of the Declination disturbances has taken place. In like manner the hours of the afternoon, in which the Declination is but little disturbed, and which have been supposed in consequence to be hours in which an intermission of disturbance takes place, are seen by the table to be precisely those hours at which the disturbances which increase the Total Force have their principal development, being then in the proportion of nearly ten to one when compared with the homonymous hours after midnight. When these remarkable phenomena are more fully studied, the aspect they present is that of a disturbance continued frequently through several successive days, changing from one element to another, and affecting each at different hours and in different modes, in conformity with laws the average operation of which it has been the object of this investigation to ascertain; and wearing the appearance consequently, when only a single element is regarded, of a limitation to those hours when that element in particular is affected, but which appearance ceases when the phenomena are more generally apprehended.

It was the supposed analogy between magnetical and atmospherical disturbances which led, in the commencement of the British colonial observatories, to the *simultaneous* observation and record of these two great and, as we have now reason to believe, distinct branches of natural phenomena; and as the inquiry advances we are continually becoming acquainted with additional circumstances to strengthen the persuasion, that the causes of these occasional and previously supposed "irregular" manifestations of disturbing magnetical influence are to be sought in more distant sources than in variations of the meteorological phenomena.

There is another misapprehension in regard to the nature of the occasional disturbances, which has followed very naturally from the limitation of the view to the disturbances of a single element. An inference has sometimes been drawn in favour of a *local origin* of a particular disturbance (in contradistinction to the general fact of

their simultaneous occurrence at extremely distant parts of the globe), from the circumstance that though the disturbance was manifested by the Declination at one station, no indication of it was shown by the cotemporaneous observations of the Declination at another and a distant station. Now, simultaneity at stations separated by considerable intervals of longitude implies a difference in the *solar* time; and the observations at Toronto show that a difference in the solar time may determine the question whether a disturbance, which may nevertheless be common to both stations, may or may not be traceable by simultaneous observations of a single element only. Towards the attainment of a just conclusion, therefore, in regard to a possible local origin, it is indispensable that a more extensive generalization should be made, and that cotemporaneous affections of the *three* elements should be brought into the comparison. Nor can this condition of the inquiry be dispensed with even in comparing the phenomena at stations under the same meridian, but separated by large intervals of latitude, unless it be first shown that the same law of solar hours prevails at both stations in regard to the occurrence of the disturbances of each particular element. It need scarcely be said that the general simultaneity of the disturbances has a very important bearing upon their theory, inasmuch as it militates decidedly against the supposition of their originating in atmospherical peculiarities, and tends to assign them, with far greater probability, to a cosmical source. That some disturbances may have a local origin is undoubtedly *possible*, but no such case has yet, I believe, been established on adequate evidence.

For the purpose of viewing in its simplest form, and expressed in numerical value, the influence which, on a daily average, the larger disturbances exercise on the Declination, Inclination, and Total Force, we must revert to the aggregate values in the five years which supplied the ratios of disturbance at the different hours in each of the six classes of phenomena contained in Table LVI. From these values we obtain readily and immediately for each hour the excess in the aggregate amount of easterly over westerly, or of westerly over easterly, deflection, and of disturbances which increase or decrease the Inclination or the Total Force over those which respectively decrease or increase those elements. Hence we can easily form a table containing, for each of the elements at every hour, the numerical *excess* in the aggregate values of whichever kind of disturbance predominates at that hour; and dividing the excess by 1550, which is the number of days of observation in the five years, we have the mean effect corresponding to the larger disturbances of each of the elements at the different hours, or the average diurnal variation of each element due to the larger disturbances. This is shown in the following table, illustrated by Fig. 3. pl. 1., in which the diurnal variations of Declination and Inclination are expressed in decimals of a minute of arc, and that of the Total Force in parts of the Total Force at Toronto, which in absolute value and employing British units may be taken with sufficient approximation at 1·39.

TABLE LVII.

Toronto Astronomical Time.	Mean Diurnal Variation occasioned by the larger Disturbances.			Toronto Civil Time.
	Declination.	Inclination.	Total Force.	
H.	′	′	Parts of the Total Force.	
18	0′·29 W.	+0′·10	−·000092	6 a.m.
19	0′·41 W.	+0′·18	−·000092	7 a.m.
20	0′·52 W.	+0′·16	−·000047	8 a.m.
21	0′·46 W.	+0′·13	−·000032	9 a.m.
22	0′·30 W.	+0′·10	−·000008	10 a.m.
23	0′·11 W.	+0′·09	+·000007	11 a.m.
0	0′·11 W.	+0′·09	+·000015	Noon.
1	0′·03 W.	+0′·09	+·000027	1 p.m.
2	0′·09 W.	+0′·05	+·000042	2 p.m.
3	0′·08 W.	+0′·07	+·000054	3 p.m.
4	0′·09 W.	+0′·05	+·000068	4 p.m.
5	0′·04 W.	+0′·08	+·000073	5 p.m.
6	0′·18 E.	+0′·14	+·000058	6 p.m.
7	0′·34 E.	+0′·14	+·000062	7 p.m.
8	0′·52 E.	+0′·16	+·000047	8 p.m.
9	0′·87 E.	+0′·16	+·000016	9 p.m.
10	0′·61 E.	+0′·15	−·000022	10 p.m.
11	0′·53 E.	+0′·16	−·000047	11 p.m.
12	0′·33 E.	+0′·14	−·000098	Midnight.
13	0′·26 E.	+0′·18	−·000125	1 a.m.
14	0′·17 E.	+0′·19	−·000132	2 a.m.
15	0′·16 E.	+0′·14	−·000138	3 a.m.
16	0′·15 E.	+0′·12	−·000123	4 a.m.
17	0′·02 W.	+0′·10	−·000109	5 a.m.

From this table we find that the range of the diurnal variation of the Declination representing the influence of the larger disturbances is from 0′·52 W. at 8 A.M. to 0′·87 E. at 9 P.M. (or the whole range has an extent of 1′·39); that of the Inclination, from a minimum increase of 0′·05 at 2 P.M. to a maximum increase of 0′·19 at 2 A.M. (or a total extent of 0′·14); and that of the Total Force, from a maximum decrease of ·000138 at 3 A.M. to a maximum increase of ·000073 at 5 P.M. (or a total extent of range of ·000211 parts of the Total Force at Toronto).

As the larger disturbances of each element which have been separated by the processes and subjected to the analysis described in this communication, can by no means be supposed to include the whole of the disturbances of the class to which they belong, we can only regard the extent of the diurnal variation as stated above to be in each case a minimum limit, which would be certainly somewhat exceeded if by any mode of proceeding we could succeed in separating the minor effects of the same causes; but we have no reason to suppose that the epochs of maxima and minima or the laws of intermediate progression would sustain any material alteration thereby.

As the aggregate values of the disturbances are taken from the five years which include a complete quinquennial or semi-decennial period, the *mean* diurnal variation

deduced from them must be considered as also subject to a small decennial variation, analogous to that which has been found to exist in the ordinary solar-diurnal variation. And as the sums of the variation-values at the different hours, taken with their proper signs, in no case equal zero, but have a sensible magnitude in each element, the absolute values of the three elements must also be affected with a very small cyclical variation due to the disturbances, of which the period will also be decennial.

LUNAR-DIURNAL VARIATION.

The observations employed in the investigation on which we now enter are the six years of hourly observations of the Declination from July 1st, 1842, to June 30th, 1848, and the five years of hourly observations of the Horizontal and Vertical Forces commencing July 1st, 1843, and ending June 30th, 1848, but having in the first year of the Horizontal and Vertical Forces the months of October, November, December 1842, January and February 1843, substituted for the same months in the subsequent year, during which the observations of the Vertical Force were suspended.

The larger disturbances of each element having been marked for omission, and the hourly normals (excluding the observations so marked) computed as already described, the retained observations were then characterised in reference to their lunar relation by small figures signifying the lunar hour to which each observation most nearly corresponded. For this purpose the time of the moon's meridian passage at Greenwich was taken from the Nautical Almanac, and corrected for the difference of longitude, so as to give the time of the moon's passage of the astronomical meridian at Toronto in the mean solar time of the station. The difference of time corresponding to the difference between the meridians of Toronto and Göttingen was then applied, so as to give the mean *Göttingen* time of the moon's passage of the astronomical meridian at Toronto. The observation at the Göttingen hour nearest to the time thus computed was then marked with 0^{m}, signifying that it was the nearest observation to the moon's upper culmination, and from which its distance could not exceed half an hour. The time of the moon's inferior passage was then computed in a similar manner, and the observation at the Göttingen hour nearest to it was marked 12^{m}. The intermediate hours received corresponding markings, except that when thirteen solar hours, and consequently thirteen observations, were comprised within twelve lunar hours, that observation was omitted which fell most nearly equidistant between the epochs of two exact lunar hours. The monthly tables were thus marked for the lunar hours before they were returned from myself to the office, and were considered to be prepared for re-arrangement in tables conforming to lunar time; but instead of the observations themselves, the *differences* at each hour between the scale readings observed and the normals at the same hour (Tables X., XXV., and

LII.) were entered in the lunar tables, by which process the diurnal and other variations depending on the period of the year and the hour of the solar day were, in great part at least, eliminated. The differences were marked with a + or − sign according as the scale reading at the time of observation was greater or less than the normal, the entries having a + sign implying in the case of the Declination a westerly deflection of the north end of the magnet, and those having a − sign implying the converse.

The means were then taken in every month, at every lunar hour, the signs being regarded; the monthly means were then collected into yearly means; and finally, the means at each lunar hour in the six years of observation were collected as shown in the subjoined table, in which the entries are expressed in scale divisions, one scale division equalling 0″·721 of arc.

Representing the mean of the six years by the usual formula of sines and cosines, we have the coefficients of the several terms as follows, expressed in seconds of arc, a being counted in hours (multiplied by 15°) from the time of the moon's upper culmination.

TABLE LIX.

Arguments.	Constant.	cos a.	sin a.	cos 2 a.	sin 2 a.	cos 3 a.	sin 3 a.	cos 4 a.	sin 4 a.	cos 5 a.	sin 5 a.	cos 6 a.
Coefficients.	$A_0 =$	$A_1 =$	$B_1 =$	$A_2 =$	$B_2 =$	$A_3 =$	$B_3 =$	$A_4 =$	$B_4 =$	$A_5 =$	$B_5 =$	$A_6 =$
	$0''{\cdot}0$	$+0''{\cdot}20$	$-1''{\cdot}03$	$-19''{\cdot}18$	$+0''{\cdot}45$	$+1''{\cdot}84$	$-0''{\cdot}32$	$+1''{\cdot}21$	$+0''{\cdot}59$	$+0''{\cdot}61$	$-0''{\cdot}48$	$-0''{\cdot}22$
Arguments.	**sin 6 a.**	**cos 7 a.**	**sin 7 a.**	**cos 8 a.**	**sin 8 a.**	**cos 9 a.**	**sin 9 a.**	**cos 10 a.**	**sin 10 a.**	**cos 11 a.**	**sin 11 a.**	**sin 12 a.**
Coefficients.	$B_6 =$	$A_7 =$	$B_7 =$	$A_8 =$	$B_8 =$	$A_9 =$	$B_9 =$	$A_{10} =$	$B_{10} =$	$A_{11} =$	$B_{11} =$	$A_{12} =$
	$+0''{\cdot}57$	$-0''{\cdot}56$	$+0''{\cdot}08$	$+0''{\cdot}16$	$-0''{\cdot}03$	$-0''{\cdot}91$	$-0''{\cdot}39$	$-0''{\cdot}50$	$-0''{\cdot}42$	$+0''{\cdot}49$	$+0''{\cdot}28$	$-0''{\cdot}29$

The coefficient of principal magnitude is $A_2 = -19''{\cdot}18$, whose argument is cos 2 a. The same coefficient calculated for the different years is as follows:—

TABLE LX.

	$''$
Year ending June 30th, 1843	$-19''{\cdot}35$
" " 1844	$-17''{\cdot}61$
" " 1845	$-21''{\cdot}05$
" " 1846	$-20''{\cdot}22$
" " 1847	$-19''{\cdot}04$
" " 1848	$-18''{\cdot}53$
And from the mean of the six years	$-19''{\cdot}18$

Whence we obtain the probable error of $-19''{\cdot}18$ (the value of A_2 from the mean of the six years) $= \pm 0''{\cdot}34$.

With the two first terms of this formula, viz.—

$$\Delta_x = 0''{\cdot}0 + 0''{\cdot}20 \cos a - 1''{\cdot}03 \sin a - 19''{\cdot}18 \cos 2a + 0''{\cdot}45 \sin 2a$$

or its more convenient equivalent,

$$\Delta_x = 0''{\cdot}0 - 1''{\cdot}05 \sin (a + 348^\circ\, 52') + 19''{\cdot}186 \sin (2a + 271^\circ\, 21')$$

we obtain the deflections of the north end of the magnet at the several lunar hours as follows:—

5 a.	cos 6 a.
=	Λ_6 =
48	$-0''.22$
1 a.	sin 12 a.
=	Λ_{12} =
28	$-0''.29$

TABLE LXI.

Lunar Hours.	Deflections.	Lunar Hours.	Deflections.	Lunar Hours.	Deflections.	Lunar Hours.	Deflections.
	″		″		″		″
22	9·29 to the East.	4	9·19 to the West.	10	10·67 to the East.	16	10·77 to the West.
23	15·92 „	5	15·89 „	11	17·30 „	17	17·78 „
0	18·95 „	6	18·14 „	12	19·38 „	18	20·21 „
1	16·46 „	7	15·34 „	13	16·31 „	19	17·43 „
2	9·54 „	8	8·20 „	14	8·86 „	20	10·19 „
3	0·14 „	9	0·42 to the East.	15	1·04 to the West.	21	0·42 „

Comparing these values with the actual deflections, we find the probable error at each observation hour ± 1″·37.

In Plate II., Fig. 1., the darker line represents the deflections in Table LXI. constituting the lunar-diurnal variation, the dotted line showing the mean or normal position of the magnet. The variation thus represented is that derived from the mean of the six years; and for the purpose of showing the accordance of the results when the whole period of six years is divided into three portions, each consisting of two years, —viz., July 1842 to June 1844, July 1844 to June 1846, and July 1846 to June 1848, —the corresponding curves have been computed by the subjoined formulæ, obtained as already described, and are represented by the fainter lines. The formulæ are—

July 1842 to June 1844, $\Delta_x = +0''{\cdot}41 - 2''{\cdot}09 \sin(a+291°) - 18''{\cdot}1 \sin(2a+87°{\cdot}7)$
July 1844 to June 1846, $\Delta_x = +0''{\cdot}30 + 3''{\cdot}04 \sin(a+78°7') + 20''{\cdot}6 \sin(2a+270°{\cdot}1)$
July 1846 to June 1848, $\Delta_x = -0''{\cdot}58 - 5''{\cdot}23 \sin(a+53°5') + 18''{\cdot}9 \sin(2a+276°{\cdot}1)$

The number of hourly observations of the Declination made in the six years amounted to 42,888; of these, 2,345 were disturbed to an amount which equalled or exceeded 5′·0 of arc from the normal at the same hour, and were consequently excluded; leaving 40,543 as the number of observations from which the results of the lunar-diurnal variation have been derived.

Horizontal Force.—Table LXII. exhibits, in columns 2 to 6, the mean hourly variation of the Horizontal Force at the different lunar hours in each of the five years ending June 30, and in column 7 the mean of the five years. The lunar influence at the several lunar hours is shown in decimals of a scale division, one such division being approximately ·000087 parts of the whole Horizontal Force at Toronto. The sign + implies that the force is increased, and − that it is decreased, by the lunar influence.

We may represent the values in column 7 of Table LXII. (or the variation of the Horizontal Force at the several lunar hours on the average of the five years of observation) by the first terms of the usual formulæ for periodical functions; viz.,

$$\Delta_x = A_0 + A_1 \cos a + B_1 \sin a + A_2 \cos 2a + B_2 \sin 2a;$$

and by substituting in this formula the numerical values of the coefficients obtained from the numbers in column 7, it becomes

$$\Delta_x = + \cdot 05 - \cdot 024 \cos a + \cdot 214 \sin a + \cdot 0775 \cos 2a + \cdot 323 \sin 2a,$$

or its more convenient equivalent,

$$\Delta_x = + \cdot 05 + \cdot 215 \sin (a + 353^\circ \cdot 6) + \cdot 3324 \sin (2a + 13^\circ \cdot 5),$$

the coefficients being decimals of a scale division, and a reckoned in hours (multiplied by 15°) from the time of the moon's superior culmination. By this formula we obtain the curve which is shown by the stronger line in Plate II., Fig. 2.; and for the purpose of showing the degree of confidence to which this curve is entitled as an approximate representation of the variation produced in the Horizontal Force by the moon in the course of a lunar day, the variation in the different years in columns 2 to 6 of Table LXII. have been so combined as to form two separate means, one representing the columns headed 1844, 1845, and 1846, and a second representing

the columns headed 1846, 1847, and 1848,—the years 1844 and 1845 having double weight assigned to them in the first mean, and those in the columns headed 1847 and 1848 double weight in the second mean. The formulæ representing these separate means are—

For 1844 to 1846, $\Delta_x = +\cdot088 + \cdot243 \sin(a + 347°\cdot6) + \cdot277 \sin(2a + 4°\cdot6)$

For 1846 to 1848, $\Delta_x = +\cdot013 + \cdot192 \sin(a + 355°\cdot0) + \cdot395 \sin(2a + 19°\cdot2)$

The curves respectively computed by these formulæ are shown by the fainter lines in Fig. 2., in which the stronger line has been already noticed as being derived from the mean of the five years.

The number of hourly observations of the Bifilar Magnetometer employed in this investigation is 34,303.

Vertical Force.—Table LXIII. exhibits, in columns 2 to 6, the mean hourly variation of the Vertical Force at the different lunar hours in each of the five years ending June 30, and in column 7 the mean variation in the five years. The lunar influence at the several lunar hours is expressed in decimals of a scale division, one scale division being approximately ·000065 parts of the whole Vertical Force at Toronto. The sign + implies an increase, and − a decrease, of the force from the lunar influence.

22	+0·08	+0·04	−0·21	−0·07	+0·07	−0·02	22
23	+0·11	+0·04	−0·18	−0·13	−0·03	−0·06	23

The curves obtained from the values comprised in this table are represented to the eye in Plate II., Fig. 3., the fainter lines corresponding to the variations in the separate periods, 1844 to 1846, and 1846 to 1848, and the stronger line to the mean of the whole period of five years. The formulæ by which these curves have been computed are as follow:—

1844 to 1846, $\Delta_x = +\cdot006 - \cdot092 \sin(a + 0°\cdot5) + \cdot036 \sin(2a + 345°\cdot1)$
1846 to 1848, $\Delta_x = -\cdot014 - \cdot028 \sin(a + 355°\cdot5) + \cdot058 \sin(2a + 316°\cdot7)$
1844 to 1848, $\Delta_x = +\cdot005 - \cdot058 \sin(a + +2°\cdot0) + \cdot048 \sin(2a + 330°\cdot0)$

The coefficients are decimals of a scale division, and a is reckoned in hours (multiplied by 15°) from the time of the moon's superior culmination. The number of hourly observations of the Vertical Force Magnetometer employed in this investigation is 31,773.

Inclination and Total Force.—The variations of the Inclination and Total Force in a lunar day are derived from those of the horizontal and vertical components of the force by the formulæ—

$$\Delta\delta = \sin\delta\cos\delta\left(\frac{\Delta Y}{Y} - \frac{\Delta X}{X}\right);$$

$$\frac{\Delta\mathfrak{F}}{\mathfrak{F}} = \cos^2\delta\frac{\Delta X}{X} + \sin^2\delta\frac{\Delta Y}{Y};$$

in which δ is the inclination, $\mathfrak{F}$ the total force, X its horizontal, and Y its vertical component. They are shown for the whole period of the five years in Table LXIV., computed from the values of the Horizontal and Vertical Forces in columns 7 of Tables LXII. and LXIII. The variation of the Inclination is expressed in seconds of arc, the sign + signifying an increase of the dip of the north end of the magnet; and that of the Total Force in parts of the Total Force at Toronto, of which the approximate *absolute value* is 13·9 in British units.

TABLE LXIV.

These variations are represented to the eye by the stronger lines in Figs. 4. and 5. of Plate II.; in which also the fainter lines show the variations derived respectively from the half periods constituted as previously described. In Fig. 6., of Plate II. are collected in one view the lunar-diurnal variations of the Declination, Inclination, and Total Force, as they are separately represented in other figures of the same plate.

General Conclusions.—The three magnetic elements concur in showing that the moon exercises a sensible magnetic influence at the surface of the earth, producing in every lunar day a variation in each of the three elements, which is distinctly appreciable by the instruments employed in the observatories established to carry out the system of observation recommended by the Royal Society, when due care has been taken in conducting the observations, and suitable methods are adopted for elaborating the results.

The lunar-diurnal variation consists in a double progression in each lunar day in each of the three elements: the Declination has two easterly and two westerly maxima, and the Inclination and Total Force each two maxima and two minima in each interval between two successive passages of the moon over the astronomical meridian; the variation passing in every case four times through zero in the course of the lunar day. The easterly maxima of the horizontal deflection of the north end of the magnet synchronise with the moon's superior and inferior passages of the meridian, the westerly maxima with the lunar hours of 6 and 18. The maxima of the increased magnetic force due to the moon's action occur about the lunar hours of 3 and 16, and the minima about the hours of 9 and 20. The maxima of the Inclination, *i.e.* of the dip of the north end of the magnet, occur about the lunar hours of 3 and 14, and the minima about 9 and 20. The extent of the variation in the lunar day, or the range between the extremes that are widest apart, is in the Declination 38″·33, in the Inclination 4″·4, and in the Total Force ·000012 parts of the whole terrestrial magnetic force at Toronto. These are the values derived from the whole period of observation, *i. e.* from six years of the Declination, and from five years of the Inclination and Total Force. When the whole period is subdivided into two half-periods, the hours of maxima and minima and the extent of the range accord with the results of the whole period in each of the three elements, with slight and wholly insignificant exceptions. The reality of the variations is thus attested no less by the accordance of the results when the whole period during which the phenomena were observed is subdivided into separate and independent portions, than by the systematic character which the variation is seen to possess, when the strictly independent results at the several lunar hours are brought together and exhibited continuously.

As it happens that in the Declination the variation resulting from the moon's action is greater, relatively to the instrumental means for measuring it, than either in the Inclination or in the Total Force, it is reasonable to conclude that we have a better

opportunity of judging of the particular nature and character of the moon's magnetic influence by studying the effects produced on the Declination than by studying those produced on either of the other elements.

Referring to Table LIX., p. lxxx, which exhibits the coefficients of all the twelve terms in the formula of sines and cosines by which the results of observation are strictly represented, we perceive that the coefficient of the cosine of twice the hour angle is not only the one of greatest amount, but is, in fact, the only one which we can with confidence regard as possessing a substantial value. All the other coefficients are, without exception, not only extremely small in comparison with the one above noticed, but are so small that they may well be supposed to represent the small deviations from a natural law ascribable to errors which cannot wholly be extinguished in averages derived from not more than six years of observation. On the other hand, the coefficient in the second term has a value far beyond any explanation resting on the supposition of errors of observation. The probable error of any single hour is 1″·37, whilst the range of the variation is not less than 38″. Whilst, therefore, the general result of this investigation is to establish conclusively the existence of a lunar-magnetic influence sensible at the surface of the earth, the lunar-diurnal variation which is thus manifested appears to be consistent with the hypothesis that the moon's magnetism may be, in great part at least, if not wholly, derived by induction from the magnetism of the earth.

It is further observable, that in the lunar-diurnal variation there is no appearance of the *decennial* period which constitutes so marked a feature in the solar-diurnal variations.

SOLAR-DIURNAL VARIATION.

Declination.—In the first volume of the Toronto Observations, published in 1845, an inference was drawn from the examination of the observations in 1841 and 1842 printed in that volume, that the *double progression* which showed itself in the diurnal variation, (produced by a small westerly retrogression of the north end of the magnet occurring between the hours of 10 and 14), might be an effect of the superposition of two distinct diurnal variations, each proceeding from a distinct class of phenomena; one class being the regular solar-diurnal variation corresponding to the sun's daily (apparent) revolution round the earth; and the other class produced by causes, not indeed of daily, but of *occasional* occurrence, the diurnal variation being in the latter case the representative of the *mean* effect of the occasional causes: and it was suggested, that if by any process the whole effect of the occasional disturbances could be eliminated, it might be very possible that the residual variation, or that portion which might be regarded as more strictly deserving the name of "diurnal variation," might prove to be "a single progression with but one maximum and one minimum in the 24 hours." It was at the same time further suggested, that though it might be

difficult, and perhaps impossible, to eliminate from the observations the whole effect of the disturbances referred to, it might be very possible, by a partial separation of those of largest amount, to examine whether their influence on the diurnal variation was or was not of a systematic character, and such as might produce the supposed effects.

The Toronto observations from 1843 to 1848 have since been received and printed, and have been treated according to the suggestion above noticed. The result has been to establish the fact, that the occasional and previously called "irregular" disturbances are phenomena subject to periodical laws; and that amongst these there is one which regulates their occurrence in the diurnal period, causing them to constitute in their *mean* effect a diurnal variation wholly distinct from the regular *daily* solar-diurnal variation, and having different hours of maxima and minima. (*Phil. Trans.* 1851, Art. V.; 1852, Art. VIII.; 1856, Art. XV.; and pp. lxxvi and lxxvii of this volume.)

The disturbed observations which have been separated from the great body of the observations for the purpose of this investigation are all those which differ from the normal position of the magnet, at the same hour and in the same month, by a quantity equalling or exceeding 5′·0 of arc. These have sufficed to establish the systematic characters and distinctive features of the diurnal variation which the disturbances occasion, but we are sure that they do not give its *full numerical amount;* for it cannot be doubted that there must be minor disturbances of the same class,—minor effects proceeding from the same causes,—which remain in the body of the observations when those of 5′·0 and upwards have been removed; and which must still continue to exercise an influence similar in kind, and possibly (as being more numerous) not less in degree, on the residual diurnal curve, modifying the pure result which would be obtained if the whole influence of the disturbances could by any process be separated. The question, then, which now remains to be considered is, whether, and with what degree of probability, we may infer, by means of a comparison of the diurnal variation with and without the disturbances of 5′·0 and upwards, that if their whole influence were eliminated the residual diurnal variation would show itself as a single instead of a double progression.

This question is of some theoretical importance; for since the publication of the first volume of this work, in 1845, the physical explanation of the diurnal variation has occupied the attention of eminent physicists, two of whom in particular, Faraday and Secchi, have propounded physical theories, which, however dissimilar they may be in other respects, concur in regarding the diurnal variation derived from the whole of the observations including the disturbances, as phenomena of one and the same class, and the double progression as an integral part of the same, and a necessary consequence of the physical theory adopted for their explanation. An additional importance is therefore given to the inquiry whether, after the deduction of that portion of the diurnal variation which has now been ascertained to proceed from a distinct class of

phenomena, not of daily but of occasional occurrence, the residual variation, or that due to the regular daily course of the sun round the earth, may not be regarded with greater probability as a "single progression with but one maximum and one minimum," rather than as a "double progression with two maxima and two minima."

In column 2 of the subjoined table (Table LXV.) is shown the mean diurnal variation derived from the whole of the observations, including the disturbances; in column 3 the mean diurnal variation derived from the disturbances which equal or exceed 5′·0 (from Table LI., p. lxi); in column 4 we have the residual diurnal variation when the values in column 3 are deducted from those in column 2; and in column 5 we have the diurnal variation such as it would be found if we permitted ourselves to suppose that by abstracting the disturbances equalling or exceeding 5′·0 we had eliminated *half* the influence of the disturbances of the class to which they belong.

From this table we perceive, 1st, that when the diurnal variation is derived from the whole body of the observations including the disturbances as in column 2, the march of the north end of the magnet towards the east, which is otherwise continuous from

the extreme westerly direction between 1 and 2 P.M. to the extreme easterly direction between 7 and 8 the following morning, is interrupted by a small westerly retrogression between 9 P.M. and 4 A.M.; 2d, that when the *larger* disturbances, or those which equal or exceed 5′·0 in amount, and produce as their *mean* effect the diurnal variation in column 3, are eliminated, the westerly retrogression previously noticed is reduced very considerably both in amount and continuance, as is seen in column 4; and 3d, that if we assume that, by abstracting the disturbances equalling or exceeding 5′·0, we may have eliminated *half* of the whole influence of the causes to which the larger disturbances are due (which is certainly no unreasonable supposition), we have the residual diurnal variation as in column 5, in which the westerly retrogression is almost wholly obliterated, and the variation has become virtually a single progression, with but one maximum and one minimum.

Viewing, then, the residual variation after the elimination of the influence of the disturbances as the best approximation we can obtain towards a representation of the phenomena of the regular solar-diurnal variation, and regarding this representation as corresponding to a *mean* state of the phenomena, or to that which would belong to all the days in the year if the sun's path were always in the plane of the equator, we find the mean solar-diurnal variation at Toronto to be approximately as follows:—The chief variation takes place during the hours when the sun is above the horizon; the motion of the north end of the magnet towards the east, which during the hours of the night is extremely slow, quickens between 4 and 5 A.M., and continues at a nearly uniform rate, exceeding 1′ an hour, from 5 A.M. to a few minutes before 8 A.M., when the easterly extreme is reached. The north end then returns rapidly towards the west, attaining the westerly extreme of its daily progress about 20 minutes past 1 P.M. This interval is the time of most rapid motion, the whole amplitude or extent of the diurnal variation, amounting to about 10′ of arc, being passed through in about 5½ hours. The motion is most rapid between 10 and 11 A.M., when the change of direction in one hour is very nearly 4′·0. After reaching the westerly extreme, at or about 1h. 20m., the north end returns again towards the east, at a nearly uniform rate a little exceeding 1′·0 per hour, until near 6 P.M., at which time the night phase of the variation may be said to commence. This, apart from the disturbances, is a continuation of the easterly motion, but at a comparatively very slow rate, which, on the average of the 10 hours from 6 P.M. to 4 A.M., scarcely exceeds 0′·16 per hour.

Table LXVI. exhibits the solar-diurnal variation of the Declination in the different months of the year after the separation and omission of the larger disturbances. This table is similar in form to Table VII. in vol. II. (p. xv), but differs from it inasmuch as the latter is derived from *all* the observations, including the disturbances, and in this the disturbances are excluded. The sign + implies that the north end of the magnet is to the east, and — to the west, of the mean position in the month.

In the case of the Total Force, the diurnal variation due to the mean effect of the larger disturbances bears so large a proportion to the regular solar-diurnal variation, that when one is superimposed upon the other, and they are viewed in combination, —as is the case when the diurnal variation is obtained from the whole of the observations *including the disturbances*,—the true character of the regular ordinary solar-variation is altogether masked, and we are in danger of drawing erroneous conclusions in regard to it. Thus, in Vol. I. of the Toronto Observations, pp. lxx, lxxi, the

diurnal variation being there derived from *the whole* of the observations, the principal features appeared to be, and were stated as follows :—

A principal maximum at 5 hours.
A principal minimum at 15 hours.
A secondary maximum at 18 to 20 hours.
A secondary minimum at 22 or 23 hours.

The first thing we learn by the separation of the disturbances is, that the "principal minimum" so stated as occurring "at 15 hours" is either wholly or in very great part an effect of the disturbances which have their maximum influence in diminution of the force at that hour; and that the true curve of the solar-diurnal variation of the Total Force (like that of the Declination, p. lxxxix) has but one notable inflection in the 24 hours, viz. that which takes place during the hours when the sun is above the horizon. Referring to Table LVII., p. lxxii of the present volume, it will be seen that the diminution of the Total Force at 15 hours occasioned by the larger disturbances averages ·000138 parts of the Total Force in every day of the year; whilst from Table LXX., p. xcii, we learn that the diminution of the force at the same hour from the solar-diurnal variation obtained from the observations remaining after the separation and omission of the larger disturbances amounts to not more than ·000045 parts of the force. The combination of these two effects, referable as they are to different causes, produced therefore at 15 hours the apparent minimum of the force, amounting to (·000138 + ·000045 =) ·000183 parts of the force. Now of the two components which form the combined amount, it is obvious that the one depending on the disturbances would be increased, and the other component diminished, in amount, if the values assumed to constitute large disturbances of the Horizontal and Vertical Forces had been taken somewhat smaller than they have been assumed in the preceding pages: and as the remark in p. lxxvii regarding the declination-disturbances is equally true in reference to those of the Total Force, viz. that inasmuch as the larger disturbances separated by the processes described can by no means be supposed to include *the whole* of the disturbances of the class to which they belong, we must regard the mean diurnal variation obtained from them simply as a "minimum limit," which would certainly be exceeded if we could succeed in separating the minor effects of the same causes;—we may likewise reasonably infer in the case of the Total Force, that were the process of separation of the disturbances carried a little further than it has been in these pages, the small portion of the diminution of the force at 15 hours (·000045) which remains referable to the solar-variation would be progressively reduced, whilst that of the other component would be increased.

The general conclusion, therefore, to which we may be justified in arriving, is, that although we are unable to separate the effects of the two causes so completely as to assign the exact values of each of the components, we are enabled, by the processes

which have been adopted, to separate them so far, as to have no difficulty in assigning (approximately at least) the general character which each of the components would have if we could make a perfect separation between them. In such case the character of the solar-diurnal variation of the Total Force would appear to be nearly as follows: From about 18 or 19 hours (6 or 7 A.M.) the force begins to diminish sensibly, and continues to do so until nearly 23 hours (11 A.M.), when it reaches its minimum in the 24 hours; it then increases, and continues to do so until about 5 or 6 hours (5 or 6 P.M.); after which it remains without any notable inflection during the hours of the night and until after sunrise. The minimum which occurs between 10 and 11 A.M. (nearer 11 than 10) may be taken at between ·000140 and ·000150 parts of the force below the average in the 24 hours. In Plate IV., Fig. 3., p. xcvi, the *dotted* line shows the diurnal variation derived from the whole of the observations, disturbances included; in this curve, consequently, the mean disturbance-variation is combined with the regular solar-diurnal variation. The *continuous* line presents the diurnal variation derived from the observations when the *larger* disturbances have been separated and withdrawn. This line consequently *approximates* to the form which the curve of the solar-diurnal variation would present if the whole influence of the disturbances could be eliminated. The third or *broken* line further represents this curve on the supposition that the *larger* disturbances constitute about *two-thirds* of the whole disturbing influence.

ANNUAL INEQUALITY OF THE SOLAR-DIURNAL VARIATION.

The solar-diurnal variation obtained from the mean of the twelve months (entitled "Annual Means," in the tables pp. xc to xciii) represents the variation which it may be presumed would take place in every day of the year if the sun's path were always in the plane of the equator. But this is only the case at the equinoxes; and we have now to inquire into the *inequality* to which the diurnal variation is subject in different parts of the year in consequence of changes in the sun's declination. For this purpose the diurnal variations in the different months may be divided into two groups,—one composed of the six months when the sun has northern declination, and the other of the six months when he has southern declination. The means of each of the two semi-annual groups are shown, for the Declination in Table LXVI., p. xc, and for the Inclination and Total Force in Table LXIX., p. xciii. These means represent, respectively, the diurnal variation at the particular epochs when the sun is half way between the equator and either tropic, and show consequently the character and about half the amount of the range of the inequality which the diurnal variation undergoes in the different parts of the year. The phenomena now under consideration will perhaps be best apprehended by a reference to Plate III., in which (Fig. 1.) the black

curve exhibits (in arc-value) the mean diurnal variation of the Declination in the twelve months, or that which corresponds strictly with the equinoctial epochs; the red curve shows the mean of the six months (April to September) when the sun is between the equator and the northern tropic; and the blue curve the mean of the six months (October to March) when the sun is between the equator and the southern tropic. In Fig. 2. the same phenomena are represented in a different form: the "annual mean," or the diurnal variation at the equinoxes, which is the black curve in Fig. 1., is here drawn as a straight horizontal line, and the red and blue curves are projected at their respective distances from it at the several hours, and for greater distinctness on a scale of twice the magnitude of that in Fig. 1. The annual and semi-annual curves of the diurnal variation of the Inclination are represented in a similar manner in Figs. 3. and 4. of the same plate; and those of the Total Force in Figs. 1. and 2. of Plate IV. The red and blue curves have a like signification in regard to season in all the six figures; viz. the red curves correspond to the variation when the sun is north of the equator, and the blue curves to the variation when he is south of the equator.

The annual inequality which is thus manifested has been made, in the case of one of the elements, viz. the Declination, the subject of a particular discussion in papers presented respectively to the British Association and to the Royal Society.—("Reports of the British Association," 1854, pp. 355—368; and "Proceedings of the Royal Society," May 18th, 1854, pp. 67—82.) The object of these communications was to call the early notice of magneticians to the fact that the annual inequality of the diurnal variation of the Declination, as severally derived from the observations at Toronto, St. Helena, and Hobarton, presented so remarkable an accord in character and amount as to give reason to believe that they are general phenomena. The discussion was confined to the one element because the corresponding phenomena of the Inclination and of the Total Force had not then been made out. These are now given for Toronto, and will be so for St. Helena and Hobarton in the volumes now preparing, which will contain the suite of the observations at those Observatories, when the discussion will be resumed.

SECULAR CHANGE OF THE VERTICAL FORCE.

For this investigation we have the hourly observations of the Vertical Force Magnetometer from February 1844 to June 1848 inclusive. In the following table the monthly means of those observations are collected, having been reduced to a uniform temperature by employing the equivalents for 1° of Fahrenheit obtained in pp. xxii—xxvi.

Omitting June, July, and August 1845, on account of breaks in the continuity, we have in this table three continuous series, each comprising several months, during which the Magnetometer was undisturbed; viz. February 1844 to May 1845 inclusive, 16 months; September 1845 to March 1846 inclusive, 7 months; and April 1846 to June 1848 inclusive, 27 months. In each of these periods the mean monthly scale readings, when reduced to a uniform temperature, decreased, indicating (on the supposition of the magnetism of the needle having been constant) a diminution in the amount of the terrestrial Vertical Force. The mean value of a scale division in the two first series was ·000063 parts of the Vertical Force, and in the third series ·000066 parts of the force. The first series will then furnish 16 equations for the value of x, the mean monthly decrease in scale divisions; the second series 7 equations, and the third series 27 equations for the same. From these we have the values of x respectively as follows:—

For the first period of 16 months, $x = 2{\cdot}64$ scale divisions.
For the second period of 7 months, $x = 1{\cdot}47$ „ „
For the third period of 27 months, $x = 2{\cdot}06$ „ „

The mean of the 23 months composing the first and second periods, allowing weight proportioned to the number of months in each, is 2·28 scale divisions per month, = ·000143 parts of the force. The mean of the 27 months composing the third period is 2·06 scale divisions, = ·0001365 parts of the force. Hence, on the aforesaid supposition that the magnetism of the needle was constant, we may take the mean between two results which differ so little from each other, viz. ·00014, as the approximate monthly diminution of the Vertical Force from February 1844 to June 1848 inclusive, corresponding to an *annual* decrease of ·0017 parts of the force.

The degree of regularity with which the Vertical Force Magnetometer indicated this decrease may be estimated by the probable error of the monthly decrease in the mean scale readings during the third and longest period, which was of 27 months' duration. The monthly decrease was 2·06 scale divisions; the probable error of 2·06 is ± 0·44, which includes the irregularities occasioned by the disturbances. Judging from the very satisfactory performance of the Toronto instrument which is here indicated, it would appear that the capabilities of the Vertical Force Magnetometer, when used with due precaution and care, have been generally very much underrated.

It may be desirable to show how little the question, so important in many other investigations, of the omission or retention of the larger disturbances of the Vertical Force, affects the indication of the amount of the secular change of that element, derived from an unbroken series of observations of the Vertical Force of many months' continuance. The monthly means reduced to 55° Fahrenheit, from April 1846 to June 1848, in page xcvii, were taken from the whole of the observations of that period, and consequently included the disturbances; but when the larger disturbances, or all those which exceed 4·0 scale divisions from the respective normals, are withdrawn, the monthly means for the same period, also at 55° Fahrenheit, become as follows:—

TABLE LXXI.

Months.	Scale Divisions.	Months.	Scale Divisions.	Months.	Scale Divisions.
1846:		1847:		1847:	
				October - -	173·9
April - -	215·0	January - -	184·6	November - -	173·8
May - - -	211·1	February - -	182·6	December - -	171·5
June - - -	208·4	March - -	183·6	1848:	
July - - -	205·2	April - - -	183·1	January - -	168·3
August - -	203·4	May - - -	180·5	February - -	165·4
September - -	200·8	June - - -	176·5	March - -	164·2
October - -	200·6	July - - -	172·8	April - - -	163·3
November - -	197·2	August - - -	171·1	May - - -	159·9
December - -	190·4	September - -	172·2	June - - -	155·6

From these we obtain by least squares, as the most probable value of the monthly decrease, 2·08 scale divisions, with a probable error of ± 0·44, both being almost identical with the results stated in p. xcviii as obtained from the monthly means of the observations when the disturbances were retained.

We are naturally led by the satisfactory performance of the Vertical Force Magnetometer between the years 1844 and 1848 to examine the observations made with it at an earlier period, which did not receive perhaps their due consideration at the time, from the belief, which appears to have been pretty general, that this instrument was "unavailable for the determination of changes of long period;" and from the circumstance that the Bifilar Magnetometer, from which so much more was expected, did not yield at Toronto results from which any satisfactory conclusion whatever could be arrived at in regard to the secular change of the other component of the Total Force, viz. the Horizontal Force; for which a distinct instrument, the Unifilar, was in consequence supplied. Reverting to Vol. I. of the Toronto Observations, pp. liii to lvii, we find the following to be the history of the early observations of the Vertical Force Magnetometer:—During the first year, viz. September 1840 to September 1841, the magnet was occasionally (six times in the twelve months) dismounted, for the purpose of having its time of vibration in the *horizontal* plane ascertained. On each of these occasions, consequently, the readings were disconnected, and the continuity of the series interrupted. From October 1841 to October 1843, (at which latter date the magnet was again dismounted to examine the effect of changes of temperature on its magnetic moment,) the magnet was undisturbed, except by its being made to vibrate from time to time in small arcs, in order to ascertain its time of vibration in the *vertical* plane. For this purpose it was not necessary to touch the magnet, as it was put in vibration by another magnet, and was brought back by the V's to its proper position on the supports. The frequency with which this examination was made and the times of vibration severally deduced therefrom, are shown in Vol. I., Table XXXVIII., pp. liv and lv, and in Vol. II., Table XXXV., p. lxi. We have here, therefore, another period of 25 months (October 1841 to October 1843 inclusive) in which, assuming, as before, the constancy of the magnetism of the Vertical Force needle, we know of no cause (excepting variations of temperature) to interfere with the indications of the instrument as a true measure of the variations of the Vertical force. The monthly means of the observations, and of the corresponding temperatures, are contained in the following table. They were taken two-hourly from October 1841 to June 1842, and hourly from July 1842 to October 1843.

TABLE LXXII.

Months.	Scale Divisions.	Temperature.	Months.	Scale Divisions.	Temperature.	Months.	Scale Divisions.	Temperature.

Putting Y′ for the most probable monthly mean-reading in October 1842, x for the monthly change, y the equivalent in scale divisions for 1° of temperature, and a and b coefficients respectively of x and y, a being reckoned in months from the mean epoch, − if earlier and + if later, and b reckoned in degrees of Fahrenheit from a standard temperature of 55°, − if lower and + if higher, we have 25 equations, from which by least squares we obtain $Y' = 70{\cdot}6$ scale divisions, $x = -2{\cdot}19$ scale divisions, and $y = -1{\cdot}32$ scale divisions.

From the contents of Table XXXVIII., Vol. I. pp. liv and lv, we find the scale coefficient (k) during this period to have averaged, with slight and apparently accidental variations, ·0000935; the magnetic force of the needle having been stronger than in the subsequent period from February 1844 to May 1845, the experiments between October and February 1844 to ascertain the temperature correction having had the effect, as is frequently the case, of sensibly weakening the magnet. The value just found for y ($-1{\cdot}32$), multiplied by k, gives ·000123 as the variation, in parts of the force, of the magnetic moment of the needle by a change of 1° of Fahrenheit. This is a somewhat higher value than ·000110, found by subjecting the later observations to a similar process (see *ante*, p. xxvii), but the difference is small, and quite unimportant in the present investigation. The mean monthly decrease of the Vertical Force is $2{\cdot}19 \times {\cdot}0000935 = {\cdot}00020$; or the annual decrease = ·0024. This is also a somewhat larger annual decrease than was found by the later observations, but for this there may be an assignable reason. A secular change of the Vertical Force may proceed from either of two sources (or from both conjointly); viz. a secular change in the Earth's *Total* Force, or a secular change of the Inclination. Whilst whatever secular change may exist in either or both these elements preserves

a uniform rate, the secular change of the Vertical Force will be uniform also: but if the secular change of either varies, that of the Vertical Force will vary also. Now we have reason to know from the monthly observations of the Inclination between January 1841 and December 1855, discussed in the sequel of this volume, that about the beginning of 1844 the secular change of the Inclination altered from a previously existing annual decrease, to an annual increase. Assuming, therefore, the secular change of the Earth's Total Force, whatever it may have been, to have had the same value in 1841—1843 as in 1844—1848, then, in consequence of the alteration in the secular change of the Inclination, the Vertical Force if losing must have lost more (or if gaining must have gained less) in 1841—1843 than in 1844—1848. The observations of the Inclination would therefore lead us to expect what we have found, viz. that the apparent loss of the Vertical Force, as it may be inferred from the Magnetometer observations in 1841—1843 (assuming the constancy of the magnetism of the needle), should be greater than in 1844—1848.

Thus far in the discussion it has been assumed that the magnetism of the Vertical Force needle was constant; we have now to examine, as far as the materials which have been furnished for the purpose will permit, how far this was the case. The data which we possess are the times of vibration in the horizontal or in the vertical planes observed at particular epochs in the course of the Magnetometer observations. We will commence with the times of horizontal vibration, as being those best suited at Toronto to give a satisfactory result. Now, to ascertain whether a change may have taken place in the magnetic moment of a needle during a certain period from the times of horizontal vibration at its commencement and close, and what that change may have been, it is necessary to know by some independent mode the alteration which may have taken place in the interval in the terrestrial Horizontal Force itself. When the Observatories were first instituted, it was hoped that the secular changes of the Horizontal Force might have been derived from the observations made with the Bifilar magnet; but the experience of the two or three first years led to the substitution for that purpose of a distinct apparatus and a special course of observation. It was not until January 1845 that the series of determinations of the absolute Horizontal Force were commenced with the Unifilar Magnetometer, which had been sent from Woolwich to Toronto for the purpose of supplying this failure in the Bifilar. The observations with the Unifilar, discussed in the sequel of this volume, show that from January 1845 to December 1852 inclusive the mean annual decrease of the terrestrial Horizontal Force was ·00371 in absolute measure; or $\frac{\Delta X}{X} = -\frac{\cdot 00371}{3\cdot 53} = -\cdot 00105$; and as it further appears by the monthly determinations of the Inclination, also discussed in the sequel of this volume, that we may assume the annual increase of the Inclination from the commencement of 1844 to the

end of 1855 to have been approximately uniform, and to have averaged 0''·8, we may perhaps venture to extend the estimate of the annual decrease of the Horizontal Force $\left(\frac{\Delta X}{X} = - \cdot 00105$ from January 1845 to December 1852$\right)$ to one year beyond those limits—namely, 1844; whereby we may obtain a standard of comparison for the times of horizontal vibration of the Vertical Force needle observed between February 1844 and June 1848, applicable to the whole of the Magnetometer observations in Table LXX.

(It will be seen by the observations of the Inclination that we should not be justified in extending the same annual increase of the Inclination to the years preceding 1844; and since the annual change of the Horizontal Force is in part dependent on that of the Inclination, we are not possessed of sufficient data to permit a satisfactory deduction of the rate of change of the magnetism of the needle to be derived from its horizontal vibrations from an earlier date than February 1844.)

In November 1843, and to the beginning of February 1844, the Vertical Force needle was dismounted for the purpose of having experiments made on its temperature correction. By these experiments the magnetism of the needle was considerably weakened: its time of *vertical* vibration, which had been 10''·31 in October 1843, was found in February 1844, 12''·79 (Vol. II., Table XXXV., p. lxi). It happened accidentally that at the time when the second Toronto volume was published, it was not known at Woolwich that any observations had been made on the time of horizontal vibration between September 30, 1841, and March 26, 1846 (as stated in Vol. II., p. lxi). It was obvious, however, from the difference in the times of vertical vibration referred to above, that the needle had sustained a considerable loss of force during the temperature experiments (October 1843 to February 1844), and that this must have been known to Captain Younghusband, who was then Director of the Observatory. Believing, from the usual careful habits of that officer, that it was very unlikely that he should have remounted the needle for a fresh series of Magnetometer observations without previously observing its time of horizontal vibration, I had the "Miscellaneous Register Book" examined, in which a record of the observations, if made, would probably be found, and which book had been sent home to Woolwich when the Observatory was transferred to the provincial authorities. I have thus ascertained that the time of horizontal vibration was observed, as I had expected, on the 5th and 6th of February 1844, before the needle was remounted, and again in the beginning of June 1845, when the first of the continuous series in Table LXX. was completed. The time of horizontal vibration was again observed on the 26th of March 1846, when the second continuous series terminated. The needle was then remagnetized; its time of horizontal vibration observed before it was remounted, in the

beginning of April 1846, for the third series; and again observed on the 28th of February 1849. The times of vibration at these several dates were as follow:—

1844, February 5th and 6th	-	Three observations	- 11^{s}·460.
1845, June - -	-	„	- 11·490.
1846, March 26th -	-	„	- 11·4965.
1846, April 1st -	-	„	- 10·2879.
1849, February 28th	-	Two observations	- 10·3649.

For the change in the magnetic moment of the needle in the first of the three continuous series in Table LXX. (viz. of 16 months, from February 1844 to May 1845 inclusive) we have consequently an increase in the time of the needle's horizontal vibration of (11^{s}·490 − 11^{s}·460 =) 0^{s}·030 in 16 months, or ·0223 in a year, corresponding to a proportionate decrease of ·00389 in parts of the force. But the Horizontal Force itself decreased during the same period at the average rate of ·00105 in a year (p. ci). We find, therefore, the proportionate loss of force of the needle between February 1844 and June 1845 to have been at the mean annual rate of (·00389 − ·00105 =) ·00284. Now it has been shown (p. xcviii) that in the same period the monthly scale-readings of the Vertical Force Magnetometer diminished at the average rate of 2·64 scale divisions in a month, or 31·68 in a year, corresponding to (31·68 × ·0000628 =) ·00199 parts of the force; therefore the true secular change of the Vertical Force in those 16 months, allowing for the change in the magnetism of the needle, was an *increase* at the mean rate of (·00284 − ·00199 =) ·00085 in a year.

For a similar deduction during the second continuous series in Table LXX. (seven months, from September 1845 to March 1846) we have an increase in the time of horizontal vibration of (11^{s}·4695 − 11^{s}·460 =) 0^{s}·0095 in seven months, or ·0163 in a year, corresponding to a proportionate decrease of ·00284 in parts of the force; we have, therefore, a proportionate loss of force of the needle between September 1845 and March 1846 of (·00284 − ·00105 =) ·00179. The mean monthly decrease in the scale-readings of the Magnetometer (p. xcviii) was 1·47 scale divisions, or 17·64 in a year, corresponding to (17·64 × ·0000628 =) ·00111 parts of the force. Therefore the secular change of the Vertical Force in these seven months was an increase at the mean rate of (·00179 − ·00111 =) ·00068 in a year.

For the third and longest series in Table LXX. (27 months, April 1846 to June 1848 inclusive) we have a mean rate of increase in the time of the needle's horizontal vibration, derived from the observations of the 1st of April 1846 and the 28th of February 1849, of (10^{s}·3649 − 10^{s}·2879 =) 0^{s}·077 in 35 months, or ·0264 in a year, corresponding to a proportionate decrease of ·00513 in parts of the force; and therefore an annual diminution of the magnetic moment of the needle of (·00513 − ·00105 =) ·00408 in a year. The mean monthly decrease in the scale-readings of the Mag.

netometer between April 1, 1846, and June 30, 1848, was 2·08, or 24·96 in a year; and the corresponding decrease in parts of the force (24·96 × ·0000662 =) ·00165; therefore the secular change of the Vertical Force in this period, allowing for the change in the magnetism of the needle, was an increase at the mean annual rate of (·00408 − ·00165 =) ·00243 parts of the force.

Between February 1844 and June 1848 we have, therefore, three continuous series with the Vertical Force Magnetometer, by each of which we find the secular change of the Vertical Force at Toronto to have been an increase. The results collected are as follow:—

February 1844 to May 1845 inclusive,	16	months;	rate of annual increase	·00085
September 1845 to March 1846 „	7	„	„	·00068
April 1846 to June 1848 inclusive	27	„	„	·00243

Giving each of these results weight proportioned to the time it represents, we have a mean annual increase of the Vertical Force derived from 50 months of Magnetometer observations of ·00168 parts of the force.

Secular Change of the Total Force.—We have thus the mean annual secular change of the Vertical Force between February 1844 and June 1848, $\frac{\Delta Y}{Y} = +\cdot00168$; and from the monthly determinations of the absolute Horizontal Force, discussed in the sequel of this volume, $\frac{\Delta X}{X}$ at the same period $= -\cdot00105$; and as $\frac{\Delta\phi}{\phi} = \cos^2\phi \cdot \frac{\Delta X}{X} + \sin^2\phi \cdot \frac{\Delta Y}{Y}$, and ϕ at the mean epoch $= 75^\circ\ 16'$, we have—

$$-\cdot00105 \cdot \cos^2 75^\circ\ 16' + \cdot00168 \cdot \sin^2 75^\circ\ 16' = +\cdot0015 = \frac{\Delta\phi}{\phi}$$

or $\Delta\phi = +\cdot0015 \times 13\cdot9 = +\cdot0208$, the annual increase of the Total Force in absolute measure.

The conclusions to be drawn from the times of *vertical* vibration, in regard to the loss of magnetic force which the needle sustained during the Magnetometer observations (and, correlatively, to the increase of the Earth's Vertical Force during the same period), must necessarily be less satisfactory than those derived from the times of horizontal vibration, because we have no independent measure, by a distinct apparatus (as we have in the case of the Horizontal Force), of the change which the Vertical Force underwent in the interval during which the vertical vibrations measured the constant or varying product of the Earth's Vertical Force into the force of the needle. In referring to Vol. II., Table XXXV., p. lxi, it will be seen that the monthly series of observations of

the times of vertical vibration between February 1844 and June 1848 may be divided into two distinct portions; the first comprising from February 1844 to March 1846 (the needle having been remagnetized on the 28th of March 1846), and the second portion comprising from April 1846 to June 1848. In the first interval the small decrease which will be seen to have taken place in the times of vibration indicates an increase,—and on the other hand the small increase in the times of vibration in the second interval indicates a decrease,—in the product of the magnetic force of the needle into the Earth's Vertical Force. The increase in the one interval and the decrease in the other are both extremely small, and, when the two intervals are taken together, in great measure counterbalance each other. We may therefore regard the times of vertical vibration as indicating a very near approach to constancy in the conjoint forces of the earth and of the needle. But the combined evidence of the Magnetometer observations and of the times of *horizontal* vibration has shown, that throughout this whole period the needle was losing force, and therefore the earth must have gained the force which the needle lost, – or the times of vertical vibration would not have approached so nearly to constancy. The times of vertical vibration are therefore in accordance with those of horizontal vibration, in manifesting that the Vertical Force of the earth was increasing from 1844 to 1848; though, for many reasons, they are less suited than the times of horizontal vibration to give, by their combination with the Magnetometer observations, a satisfactory result in regard to the *rate* of increase.

It is much to be desired that the subject which has been here considered should receive a further elucidation by the continuance of observations of the same kind at the Toronto Observatory, which has now passed into the hands of a provincial administration, and retains the instruments with which the valuable observations which have now been discussed were made. To these the method since devised by Dr. Lloyd for the absolute determination of the Vertical Force and of its variations from time to time,—and of the Total Force and its variations,—by *direct* observation, would be an important auxiliary. It is a research which might also well repay the Directors of the Harvard College Observatory in Cambridge, in the United States, should they think fit to resume their magnetical observations, which commenced with such good promise, but were too soon abandoned.

It has been conceived that the progressive approach of the minor maximum of the force, now in the eastern part of Siberia and moving towards America, should augment the force at the American maximum, and that consequently the force at the American maximum ought at the present epoch to be increasing. If this supposition be correct, the observed increase of the total force at Toronto may be a consequence of the general increase of the total force in the vicinity of the American maximum, from the nearer approach of the two points of maxima to each other; or it may be a consequence of a systematic movement of translation of the isodynamic lines in the same vicinity;

or it may be due in part to each of these causes. The solution of such questions, which are of the first importance in relation to the secular change which the general magnetic condition of the earth is undergoing, seems imperatively to require the employment of cotemporaneous or nearly cotemporaneous observations at more than one locality in the region surrounding the maximum. In this respect Toronto is at present unaided: there is, indeed, a Magnetic Observatory at Sitka, on the north-west side of the American continent; but, unfortunately, we are not supplied by it with corresponding observations to those which have been here discussed, as the central Observatory at St. Petersburg did not succeed in constructing a Vertical Force Magnetometer. Amongst the British possessions in that quarter of the globe, perhaps Newfoundland presents practically the most eligible site for a Magnetic Observatory to be maintained in action for at least five or six years.

HORIZONTAL FORCE IN ABSOLUTE MEASURE.

The second volume of the Toronto Observations contains, in pp. 595—633, a detailed statement of the monthly observations made with the Unifilar Magnetometer to determine the value of the Horizontal Force in absolute measure, and its annual and secular variations. In the reference made to those observations in the early part of the same volume, pp. lxxxix and xc, it is stated that "as *absolute* determinations the "results can only yet be considered as provisional, as the exact values of the distances "between the centres of the suspended and deflecting magnets, and of the constants of "inertia and of induction, will have to be finally determined with the new standard "scale and weights on the return of the Unifilar to England."

Since the publication of that volume, the Unifilar has been brought back to Woolwich, and the graduation of its scale has been compared by Mr. Welsh, of the Kew Observatory of the British Association, with a certified copy of the British standard scale belonging to that observatory. The weight and dimensions of the two rings, employed at Toronto to determine the moment of inertia of the deflecting magnet and the stirrup in which it was suspended during the vibration-observations, have also been examined by Mr. Welsh, and their values assigned in terms of authenticated copies of the British standards of weight and measure.

Mr. Welsh's memorandum of the result of his measurements is as follows:—

Measurement of the Distance-arms of the Unifilar of the Toronto Observatory, and of the Half-length of the Magnet.

Distance of the point, 1 foot, on the one arm, to the point, 1 foot, on the other arm, = 23·960 inches at 62°.

The two arms are not in this instrument of one continuous piece of metal; it is therefore necessary in this case to consider the error of the distance as a constant error at all distances. It appears, therefore, that all the observed distances should be corrected by — 0·001666 foot.

The half-length of the magnet I. 18 = 0·1526 of a foot, with a probable error arising from irregularity of figure of ± ·0001 foot.

Dimensions of the Inertia Rings employed at the Toronto Observatory.

Ring No. 1.

Weight, 288·900 grains; external diameter, 2·9886 inches at 62°; internal diameter, 2·6097 inches at 62°.

Ring No. 3.

Weight, 358·462 grains; external diameter, 3·6472 inches at 62°; internal diameter, 3·2626 inches at 62°.

Kew Observatory, May 1856. J. Welsh.

1. In respect to the deflection distances. In different experiments the near end of the deflecting magnet was placed at 1·0 ft., 1·1 ft., 1·2 ft., and occasionally at 1·3 ft. from the centre of the suspended magnet, as measured on the graduated arms of the Unifilar; corresponding by Mr. Welsh's memorandum to 0·9983 ft., 1·0983ft., 1·1983 ft., and 1·2983 ft. of British measure at 62° Fahrenheit. To these must be added in each case half the length of the deflecting magnet, making the deflection distances in the different experiments respectively 1·1509 ft., 1·2509 ft., 1·3509 ft., and 1·4509 ft. On reference to Vol. II. p. 634, it will be seen that these differ only ·0001 in each case from the distances as measured by Captain Lefroy at Toronto in 1851, and employed by Captain Younghusband in computing the values of $\frac{m}{X}$ in pp. 593–633, except that the temperature of the scale on which the measurements were made by Captain Lefroy at Toronto was 50° Fahrenheit, and in Mr. Welsh's measurements 62° Fahrenheit. These differences are so minute, that it has not been considered expedient to make any alterations in the values of $\frac{m}{X}$ as computed by Captain Younghusband.

2. The weight and dimensions of the inertia rings as determined by Mr. Welsh, do not harmonize quite so well with the memorandum which accompanied the rings when sent to Toronto by their maker, Mr. William Jones, of Rupert Street; and it has therefore been necessary to recompute the moment of inertia of the deflecting magnet with the stirrup in which it was placed for the experiments of vibration. Employing Mr. Welsh's measurements, K′, the moment of inertia of the ring, = 3·94785 for ring 1, and 7·45135 for ring 3. Substituting these values for 3·93024 and 7·43213, derived from previous measures, and employed by Captain Younghusband in calculating the log. value of $\pi^2 = 1{\cdot}6558266$ as given in the memorandum in Vol. II. p. 634, we obtain the corrected log. values, viz. 1·65724 by ring 1, and 1·65748 by ring 3; and by the mean of the two rings, 1·65736. The values of T^2 and T^1 (the times of vibration of the magnet with and without the rings) employed by Captain Younghusband were obtained by three experiments of vibration with the large ring, three with the small ring, and three with the magnet alone, made in the autumn of 1845.

The results of the whole series, thus finally computed, are given in the following table:—

TABLE LXXIII.

Abstract of the Monthly Determinations of the Horizontal Force in absolute Measure.—The "Times of Vibration" are corrected for the Torsion of the Suspension Thread and the Rate of the Chronometer, and are reduced to an uniform Temperature of 50°, and to the Mean Bifilar Reading on the Day of Observation. The Values of $\frac{m}{X}$ are obtained from the Distances and from the Angles of Deflection stated in detail in Vol. II. pp. 596—632. *The Angles of Deflection are reduced to the same uniform Temperature as the Times of Vibration, and to the Mean Bifilar Reading on the Day of Observation.*

Date.	Time of Vibration.	No. of Experiments of Vibration.	Logarithmic Values.		Horizontal Force in absolute Measure (British Units).

There is still another correction to be applied to these results, which could not be determined until the return of the Unifilar, at the close of the series, to Woolwich, where in the meantime an apparatus had been prepared for the purpose of ascertaining its amount. The necessity for this correction was first pointed out by Dr. Lamont in Dove's Repertorium, Band 7 (1846). In the experiments for measuring the absolute values of the Horizontal Force two operations are required; viz., experiments of vibration, and experiments of deflection: in the experiments of vibration the magnet is in the magnetic meridian; in those of deflection it forms with that meridian an angle which is in all cases considerable. But as it has been found that the earth elicits a sensible degree of magnetism by induction in hardened and magnetized iron or steel, it follows that when placed in the magnetic meridian a magnet is stronger than when it is perpendicular to or forms an angle with the meridian. In the usual mode of computing the results deducible from the combination of the vibration and deflection experiments, the strength of the magnet which is vibrated in the one case and used as a deflector in the other, is assumed to be the same, which, however, is not strictly true, for the reason which has been assigned; hence the necessity of the correction to which has been given, not inappropriately, the name of the induction-correction. As its value depends on the capacity of the individual magnet to receive a greater or less inductive charge, it requires, like the temperature-correction, to be determined for the particular magnet which has been employed, which in this case was I. 18 throughout the whole series. The apparatus made for this purpose at Woolwich was similar in principle to Dr. Lamont's, described in Dove's Repertorium, Band 7, and was adapted to one of the ordinary portable Unifilars: it has now been transferred to the Kew Observatory, where it will in future be employed to determine this amongst the other constants of the magnetic instruments supplied through that observatory. I am indebted to Mr. Welsh for the following memorandum of the correction to be applied to the Toronto results, which he has determined by using I. 18 in this apparatus.

Determination of the Induction Coefficient for the Deflecting Magnet I. 18 *employed at the Toronto Observatory*, 1845—1852.

The experiments have been made with the Woolwich induction apparatus by the method of Dr. Lamont.

Let μ = the magnetic moment induced in the bar by the action of a magnetic force equal to unity of the English measure.

M_r = moment of permanent magnetism of the bar at the time of making the experiments for the induction coefficient.

X_r = horizontal component of the earth's magnetic force at the time and place of the experiments.

i = magnetic dip at the same time and place.

z = angle of deflection produced upon the freely suspended needle, the deflecting bar being placed vertical with the north end *downwards*.

z' = angle of deflection, north end *upwards*.

Then—

$$\frac{\mu}{M_r} = \frac{\tan \frac{1}{2}(z - z')}{X_r \tan i \tan \frac{1}{2}(z + z')}; \text{ or, } \mu = \frac{M_r}{X_r} \cdot \frac{\tan \frac{1}{2}(z - z')}{\tan i \tan \frac{1}{2}(z + z')}$$

The effect (in parts of the whole magnetic moment of the bar) of the inducing action of the Horizontal Force at any time and place is obtained from the equation,

$$\frac{\Delta m}{m} = \mu \cdot \frac{X}{m}$$

The following are the results of experiments made at the Kew Observatory, January 17 and 19, 1857:—

	January 17.	January 19.
	° ′ ″	° ′ ″
$\frac{1}{2}(z - z') =$	0 24 38·5	0 31 8·5
$\frac{1}{2}(z + z') =$	46 50 6·0	52 39 2·0
$i =$	68 25 0·0	68 25 0·0
$\text{Log } \frac{M_r}{X} =$	8·99790	8·99790
$\mu =$	0·0002617	0·0002722

Mean value of $\mu = 0{\cdot}0002685$

Hence we have for the different values of $\frac{m}{X}$ in Table LXXIII., values of $\frac{\Delta m}{m}$ ranging from 0·00173 to 0·00223; and taking the mean angle of deflection in the Table of the Toronto Observations, Vol. II. pp. 596—633, at 7°·5, the induction-correction applicable to X varies from −·0035 in the experiments of 1845 to −·0044 in those of 1852.

Kew Observatory, January 20, 1857. J. Welsh.

We obtain, therefore, from Table LXXIII. the following finally corrected values of the absolute Horizontal Force in the several years from 1845 to 1852:—

TABLE LXXIV.

Years.	Annual Means from Table LXXIII.	Annual Means corrected for Induction.	Years.	Annual Means from Table LXXIII.	Annual Means corrected for Induction.
1845	3·5378	3·5413	1849	3·5368	3·5328
1846	3·5419	3·5384	1850	3·5322	3·5280
1847	3·5381	3·5342	1851	3·5299	3·5255
1848	3·5339	3·5299	1852	3·5153	3·5110

From the annual means corrected for induction we obtain 3·5305 as the absolute Horizontal Force corresponding to the mean epoch of the table, January 1st 1849; and −·00371 ±·00091 as the mean annual secular change between 1845 and 1852 inclusive. The probable error of a single annual mean is ±·0026; a large proportion of which is due to the observations of 1852, which I have not felt at liberty wholly to omit, as no accidental cause has been stated to be known for their apparent irregularity.

MAGNETIC INCLINATION.

The first volume of the Toronto Observations contained, in pp. 328—332, a detailed statement of the observations of the Inclination made monthly from January 1841 to December 1842 inclusive; the second volume contained, in pp. 559—594, a similar record of the continuation of the series from January 1843 to December 1852 inclusive. The second volume contained also, in pp. lxxxv—lxxxix, a discussion of the results obtained during those years. I have since been favoured by Mr. Kingston, Director of the Toronto Observatory since it has become a provincial establishment, with a continuation of the series during the years 1853, 1854, and 1855, conducted upon the previous model, of which the following is an abstract:—

Table LXXV.

Observations of Inclination continued from Vol. II., page 594. Needle employed, Gambey, No. 1.

The annual means are 75° 22′·17, 75° 23′·0, and 75° 23′·55. Collecting the several annual means into one view, we have the following table :—

TABLE LXXVI.

Years.	Observed Inclination.	Years.	Observed Inclination.	Years.	Observed Inclination.
	° ′		° ′		° ′
1841	75 16·6	1846	75 15·1	1851	75 20·4
1842	75 16·4	1847	75 15·3	1852	75 20·5
1843	75 14·7	1848	75 18·3	1853	75 22·2
1844	75 14·8	1849	75 18·8	1854	75 23·0
1845	75 15·5	1850	75 20·0	1855	75 23·6

* Previous to the observations of November 1853 a new stone pillar was substituted for the original wooden one.

From these observations the Inclination appears to have reached an epoch of minimum between the years 1843 and 1844, or about the commencement of 1844; and from 1844 to 1855 to have increased at an average rate of $\frac{75^\circ\ 23'\cdot6 - 75^\circ\ 14'\cdot8}{11} = 0'\cdot8$. On this supposition we have the computed Inclination in each of the twelve years, with the deviations from the observed values, as follows:—

TABLE LXXVII.

Years.	Computed Inclination.	Computed—observed.	Years.	Computed Inclination.	Computed—observed.
1844	75° 14'·8	0'·0	1850	75° 19'·6	−0'·4
1845	75 15·6	+0·1	1851	75 20·4	−0·0
1846	75 16·4	+1·3	1852	75 21·2	+0·7
1847	75 17·2	+1·9	1853	75 22·0	−0·2
1848	75 18·0	−0·3	1854	75 22·8	−0·2
1849	75 18·8	−0·0	1855	75 23·6	−0·0

The probable error of a single annual determination computed from these twelve years is ± 0'·5.

If we further suppose the epoch of minimum to have synchronized with the commencement of 1844, and that the same rate of secular change, but with an opposite sign, existed previously, we shall have the annual means for the three preceding years, with their deviations from the observed values, as follows:—

1841 - -	75° 16'·3	Computed—observed	− 0'·3
1842 - -	75 15·5	„ „	− 0·9
1843 - -	75 14·7	„ „	0·0

This last supposition must of course be viewed as merely approximate in regard to the *rate* of the secular change before 1843; but on any other supposition than that of an epoch of minimum having occurred somewhere about the years 1843 and 1844, the probable error would greatly exceed that which is stated above. The value of the Inclination at the epoch of its supposed minimum is about 75° 14'·4. In the years immediately following the minimum, the annual increase was probably less, and in the latter portion of the twelve years greater, than the average rate of 0'·8 derived as above.

The Gambey's Inclinometer which has been used at Toronto since 1853 is rather a remarkable instrument, on account of the services it has rendered. It

is the property of Admiral Robert FitzRoy, who, when about to be employed on a voyage of survey and circumnavigation in H.M.S. "Beagle," purchased it from the maker. During that voyage, *i.e.* from 1831 to 1836 inclusive, it served for the determination of the Inclination at above 30 stations in different parts of the globe, the results of which were published in Vol. I. of the "Voyage of the 'Adventure' and 'Beagle,'" pp. 495—499. In 1837 it was lent by Captain FitzRoy to the writer of these pages, to be employed in determining the position and direction of the isoclinal lines in the magnetic survey of Great Britain, the report of which survey is published in the Transactions of the British Association for 1839. In 1842 it was again lent by Captain FitzRoy to Lieutenant (since Lieutenant-Colonel) Lefroy of the Royal Artillery, to be used in the magnetic survey of the British Possessions in North America, and served to determine the Inclination at above 100 stations between Canada and the Polar Sea. Since the completion of the North American Survey the Inclinometer has remained, with Captain FitzRoy's permission, at the Toronto Observatory, and was occasionally used, in conjunction with Robinson's Inclinometer belonging to the Observatory, in the observations previous to 1853; since 1853 it has been used uninterruptedly. It had originally two needles made by Gambey, and has since had two others, made by the late Mr. Robinson, whose dipping needles were scarcely, if at all, inferior to Gambey's. It has thus been, with few intermissions, in constant work for above a quarter of a century, during which time it has been exposed to travelling of all descriptions, and to climates of the most opposite character; and of its four needles one only is known to have suffered a slight deterioration. This speaks well both for the original instrument and for the care with which it has been treated. The observations in 1853, 1854, and 1855, of which the results only are given in Table LXXV., were all made on the same systematic plan as those of the preceding years, detailed in Vol. II., pp. 560—594, and may be referred to as a fair example of the precision which is attainable in such observations.

Solar-diurnal Variation.—In the early stage of the observations, and before experience had been obtained of the reliance to be placed on the conclusions from the combined Horizontal and Vertical Force observations, it was thought that some light might be thrown upon the solar-diurnal variation of the Inclination by dividing the *direct* observations of this element into two portions, one to be made in the forenoon and the other in the afternoon. We have since become aware that the solar-diurnal variation of the Inclination is deducible by the Horizontal Force and Vertical Force Magnetometer with much greater precision than it can be by direct observation with the Inclinometer, and that the variation is thereby obtained not merely for two epochs in the 24 hours, such as the forenoon and afternoon, but for every hour of the 24. (See *ante*, p. xciii.) Still, as direct observations were made in the forenoons and

afternoons, agreeably to the directions issued, and were continued from the commencement of 1841 to the end of 1852, it may be proper to show the comparative results which were thus obtained in each year. They are as follow :—

TABLE LXXVIII.

Years.	A.M.	P.M.	Years.	A.M.	P.M.
	° ′	° ′		° ′	° ′
1841	75 16·68	75 17·20	1847	75 15·43	75 15·27
1842	75 16·94	75 15·69	1848	75 18·23	75 18·44
1843	75 15·15	75 14·35	1849	75 19·14	75 18·70
1844	75 15·33	75 14·31	1850	75 19·90	75 20·09
1845	75 15·31	75 15·76	1851	75 20·27	75 20·44
1846	75 15·21	75 15·09	1852	75 20·56	75 20·47

The mean of the A.M. results is 75° 17′·35, and of the P.M. results 75° 17′·15. On the average of the 12 years the A.M. results exceed the P.M. by 0′·2. This is in the same direction as, but somewhat less in amount than, the difference more satisfactorily shown by the combination of the Horizontal and Vertical Force observations. If we suppose 9 A.M. and 3 P.M. to be about the mean times corresponding to the A.M. and P.M. direct observations, the difference between them should have been nearer 0′·5 than 0′·2; but a discrepancy of this small amount is within the limits of the errors of observation by the direct method.

Annual Variation.—Table L. in Vol. II., p. lxxxvii, contains the several monthly values of the Inclination from 1841 to 1852 inclusive, arranged according to the respective months. The following Table (LXXIX.) contains the continuation of the aforesaid Table in Vol. II., for the subsequent years 1853, 1854, and 1855: the final column exhibits for each month a value which is the arithmetical mean of the results in that month in the 15 years.

TABLE LXXIX.

Monthly Means of the Observations of the Inclination from January 1841 *to December* 1855 *inclusive, continued from* TABLE L., Vol. II., p. lxxxvii.

Months.	1853.	1854.	1855.	Means for each Month, 1841 to 1855 inclusive.
	75° +	75° +	75° +	
January	22′·1	21′·4	24′·0	75° 18′·78
February	22′·6	23′·4	23′·8	75 18′·43
March	22′·6*	23′·1	23′·8	75 18′·17
April	22′·6	23′·0	23′·0	75 18′·33
May	22′·5*	23′·0	23′·5	75 18′·08
June	22′·5	22′·9	22′·9	75 17′·38
July	21′·5	24′·3	23′·1	75 17′·13
August	20′·3	23′·2	23′·8	75 17′·33
September	21′·7	23′·4	24′·5	75 19′·09
October	22′·5	22′·0	23′·5	75 19′·09
November	23′·0	22′·2	23′·3	75 19′·53
December	22′·3	23′·9	23′·3	75 19′·15
Means for each year	75 22′·2	75 23′·0	75 23′·6	75 18′·38

* The months of March and May of 1853 are interpolated values, as no observations were made in those months. For March, a mean has been taken between the results in February and April of the same year; and for May, a mean between the results in April and June.

On examining the final column, the existence of annual variation is very perceptible: the Inclination is considerably less in the middle months of the year than at its beginning or ending. But these results involve the effects of the secular change which takes place during the year, as well as those of annual variation. To eliminate the influence of secular change, perhaps the least exceptionable process is to take the arithmetical means, respectively, of January and December, February and November, March and October, April and September, May and August, June and July, of all which couples, or bi-monthly means, the 1st of July is the common mean epoch; if, therefore, there were no annual variation, these six means should be all alike. They are as follow:—

January and December	75° 18′·96
February and November	75 18′·98
March and October	75 18′·63
April and September	75 18′·71
May and August	75 17′·70
June and July	75 17′·25

It appears therefore, as the result of fifteen years of careful observations, made throughout at the same spot, and according to the same systematic method, and comprising no less than 1,920 distinct absolute determinations, nearly equally distributed, and averaging, therefore, 128 for each of the twelve months,—and after the elimination of secular change,—that the Inclination is lower at Toronto in June and July than in the previous January and the succeeding December, by an amount which may be taken approximately at 1′·71.

Annual Variation, Absolute Value, and Secular Change of the Total Force.—The mean values of the absolute Horizontal Force in the different months obtained in the eight years (1845 to 1852 inclusive, pp. cvi—cxv) are as follow:—

January 3·5326;	December 3·5291;	Mean, January and December 3·5309.
February 3·5310;	November 3·5287;	Mean, February and November 3·5299.
March - 3·5329;	October - 3·5278;	Mean, March and October - 3·5303.
April - 3·5296;	September 3·5276;	Mean, April and September - 3·5286.
May - 3·5324;	August - 3·5298;	Mean, May and August - - 3·5311.
June - 3·5323;	July - 3·5318;	Mean, June and July - - 3·5321.

Combining these with the mean values of the Inclination in the different months in the preceding page, we have the values of the Total Force as follow:—

January and December	3·5309 × sec 75° 18′·96 = 13·9133	13·9194
February and November	3·5299 × sec 75 18·98 = 13·9254	
March and October -	3·5303 × sec 75 18·63 = 13·9218	13·9191
April and September -	3·5286 × sec 75 18·71 = 13·9164	
May and August -	3·5311 × sec 75 17·70 = 13·9106	13·9091
June and July -	3·5321 × sec 75 17·25 = 13·9076	

It appears therefore, as the result of 96 monthly determinations of the absolute Horizontal Force, and 180 monthly determinations of the Inclination, that the Total Magnetic Force is less at Toronto on the average of the months of June, July, August, and September, than on the average of the months of November, December, January, and February, by 0·01 in absolute measure, or about $\frac{1}{1400}$ of its whole amount.

The mean of the eight years of observation of the absolute Horizontal Force (p. cxvii) is 3·53045, corresponding to the mean epoch of January 1, 1849; the contemporaneous value of the Inclination is 75° 18′·4; whence we have 13·9188 as the absolute value of the Total Force at the same mean epoch. Or if, as some may deem preferable, we omit the observations of the Horizontal Force in 1852, which, from some unexplained cause, differ from the results of the preceding seven years by an amount which greatly exceeds the probable error of a single year as derived from those results, we have, at the mean epoch July 1, 1848,—for the absolute Horizontal Force 3·5332; for the Inclination (the mean of the same seven years) 75° 17′·63; and for the Total Force 13·9178. With the data furnished by the observations of those seven years, we have

the annual secular decrease of the Horizontal Force ·0026 ± ·0006; and the secular increase of the Inclination 1′·0 ± 0′·19; the probable error of a single annual determination of the absolute Horizontal Force ± ·0015, and of the Inclination 0′·51; and with the same data we obtain the absolute values of the Total Force, corresponding to July 1, 1845, 13·9023, and corresponding to July 1, 1851, 13·9334; showing intermediately an increase of 0·0311 in six years, or ·0052 in one year. Both combinations, therefore, *i.e.* the Horizontal and Vertical Forces examined in pp. ciii—civ, and the Horizontal Force and Inclination examined here, concur in showing an annual increase as the secular change of the Total Force; and we may view the two combinations as being in effect very nearly equivalent to two independent determinations; because, although it is true that the secular change of the Horizontal Force enters into both, yet in its combination with that of the Vertical Force, no variation in its amount which can be regarded as of any degree probable could be otherwise than insignificant in the deduction of the resulting secular change of the Total Force.

SECULAR CHANGE OF THE MAGNETIC DECLINATION.

Volume II. of the Toronto Observations contains, in pp. 635—639, the particulars of the monthly observations, made from 1845 to 1851 inclusive, to determine the absolute values of the Declination by means of a Declinometer placed in a detached building appropriated to that object only. An abstract of these observations, with a statement of their results, is given in Table I. at the commencement of the same volume (pp. iii, iv); and the conclusion from the results in p. vi. The value of the Declination at the mean epoch July 1, 1848, is stated to have been 1° 34′·91 West; and the mean annual increase of West Declination between 1845 and 1851, 1′·952.

I have since received, through the kindness of Mr. Kingston, the present Director of the Toronto Observatory, a continuation of the series made at intervals in the years 1853 and 1854, with the same instrument in the same locality; and the commencement of a new series in 1855, with the Declinometer placed in a new building. The results are contained in the following table.

TABLE LXXX.

Dates.	Mean Observed Declination.	Mean Reading of the Observatory Declinometer.	Mean Monthly Reading of the Observatory Declinometer.	Differences. $\alpha-\beta$.		Observed Declination reduced to the Mean Monthly Reading of the Observatory Declinometer.	
				Sc. Div.	Arc.		
	° ′	α Sc. Div.	β Sc. Div.		′	° ′	
1853:							
July 28, 29, and 30 -	1 48·6	349·1	355·7	−6 .	−4·7	1 43·8 W.	
August 24, 25, and 26 -	1 51·1	350·0	355·3	−5·3	−3·8	1 47·3	
1854:							
January 24 to 27 - -	1 52·0	350·4	351·9	−1·5	−1·1	1 50·9	1 47·9 W.
February 23 to 28 -	1 46·6	348·9	351·1	−2·1	−1·5	1 45·0	
March 24 to 30 - -	1 51·7	345·9	350·2	−4·3	−3·1	1 48·6	
April 25 to 27 - -	1 52·4	342·8	350·1	−7·2	−5·2	1 47·3	
June 22 to 24 - -	1 51·5	344·6	350·2	−5·6	−4·0	1 47·5	
New Series commenced after rebuilding the Observatory.							
1855:							
August 24 - -	1 56·7	369·2	376·7	−7·6	−5·4	1 51·3	1 53·3 W.
September 20 - -	1 54·2	373·5	377·5	−4·0	−2·9	1 51·3	
October 16 and 17 -	1 55·5	372·8	375·8	−3·0	−2·1	1 53·4	
November 16 - -	1 58·8	370·6	375·6	−5·0	−3·6	1 55·2	
December 17 and 18 -	1 56·6	373·6	375·4	−1·8	−1·3	1 55·3	

The annual secular change from 1845 to 1851 inclusive is an increase of 1′·95 West Declination; from July 1851 to April 1854 (two years nine months), an increase of 2′·54; and, assuming the circumstances of the new series to be strictly comparable with those of the old series, the increase from April 1854 to October 1855 is at the mean annual rate of 3′·4. It seems probable, therefore, that the rate of the secular increase of West Declination at Toronto is augmenting.

Captain Younghusband, R.A., who had been Director of the Toronto Observatory from 1841 to 1844 inclusive, and who had subsequently held the appointment of my Assistant at Woolwich, was recalled in January 1854 to regimental duty, from which he had been detached for more than twelve years. Since that date I have had no other assistance than that which I have received from Mr. Magrath, Principal Clerk, and

four non-commissioned officers of the Royal Artillery, acting as Assistant Clerks, who are changed occasionally as military convenience requires.

The long experience which Mr. Magrath has had in the office in which he has served since its commencement in 1840, and his unwearied assiduity and devotion, together with the uniform good conduct of the non-commissioned officers, have enabled me to carry on the duties since December 1853 without requiring the assistance of an officer.

EDWARD SABINE,
Major-General.

Woolwich, March 1857.

TORONTO, 1846 to 1848.

MAGNETICAL OBSERVATIONS.

DECLINATION.

Angular Value of one Scale Division of the Declinometer = 0′·721. Increasing Numbers denote decreasing Westerly Declination.

DECLINATION.

Angular Value of one Scale Division of the Declinometer = 0′·721. Increasing Numbers denote decreasing Westerly Declination.

Mean Göttingen Time.		0h.	1h.	2h.	3h.	4h.	5h.	6h.	7h.	8h.	9h.	10h.	11h.

[a] Christmas Day.

DECLINATION.

Angular Value of one Scale Division of the Declinometer = 0′·721. Increasing Numbers denote decreasing Westerly Declination.

[a] Omitted in the Means, on account of the great influence of a disturbance on that day.

[b] Seven minutes late.

[c] Ten minutes late.

[d] Eight minutes late.

DECLINATION.

Angular Value of one Scale Division of the Declinometer = 0″·721. Increasing Numbers denote decreasing Westerly Declination.

[a] Omitted in the Means, in consequence of the influence of disturbance on those days.

[b] Seven minutes late.

DECLINATION.

Angular Value of one Scale Division of the Declinometer = 0′·721. Increasing Numbers denote decreasing Westerly Declination.

[a] The Observations omitted, the Magnet having been affected considerably by the vertical iron shafts of Robinson's Anemometer.

DECLINATION.

Angular Value of one Scale Division of the Declinometer = 0′·721. Increasing Numbers denote decreasing Westerly Declination.

DECLINATION.

Angular Value of one Scale Division of the Declinometer = 0'·721. Increasing Numbers denote decreasing Westerly Declination.

[a] Good Friday.

DECLINATION.

Angular Value of one Scale Division of the Declinometer = 0'·721. Increasing Numbers denote decreasing Westerly Declination.

DECLINATION.

Angular Value of one Scale Division of the Declinometer = 0′·721. Increasing Numbers denote decreasing Westerly Declination.

[a] The observations on the 1st and 2d days are omitted from the Means, the readings having been affected to an uncertain amount (up to four hours on the 2d) by the induced magnetism of the vertical iron shafts of Robinson's anemometer.

[b] Eight minutes late.

[a] The observations on the 30th and 31st days are omitted from the Means, the readings having been affected to an uncertain amount by the induced magnetism of the vertical iron shafts of Robinson's anemometer.

VERTICAL FORCE.

One Scale Division = ·000066 parts of the V. F. Increase, in Scale Divisions, corresponding to 1° decrease of Temperature, 1·64.

[a] The observations on the 1st and 2nd days are omitted from the Means, the readings having been affected to an uncertain amount (up to 4h on the 2nd) by the induced magnetism of the vertical iron shafts of Robinson's anemometer.

[b] Eight minutes late.
