The Islandi Shell TINU which

Map differ entire begin right requi meth The copy filmed here has been reproduced thanks to the generosity of:

University of Alberta

The images appearing here are the best quality possible considering the condition and legibility of the original copy and in keeping with the filming contract specifications.

Original copies in printed paper covers are filmed beginning with the front cover and anding on the lest page with a printed or illustrated impression, or the back cover when appropriate. All other original copies are filmed beginning on the first page with a printed or illustrated impression, and ending on the last page with a printed or illustrated impression.

The last recorded frame on each microfiche shell contain the symbol -- (meaning "CON-TINUED"), or the symbol ▼ (meening "END"), whichever applies.

Maps, pletes, charts, etc., may be filmed at different reduction ratios. Those too large to be entirely included in one exposure are filmed beginning in the upper left hand corner, left to right and top to bottom, as many frames as required. The following diagrams illustrate the method:

L'exemplaire filmé fut reproduit grâce à la générosité de:

University of Alberta

Les images suiventes ont été reproduites avec le plus grand soin, compte tenu de la condition et de la netteté de l'exemplaire filmé, et en conformité avec les conditions du contrat de

Les exemplaires originaux dont la couverture en papier est imprimée sont filmés en commencant per le premier plat et en terminant soit per le dernière page qui comporte une empreinte d'impression ou d'illustration, soit par le second plat, selon le cas. Tous les autres exemplaires originaux sont filmés en commençant par la première page qui comporte une empreinte d'impression ou d'Illustration et en terminant par la dernière page qui comporte une telle empreinte.

Un des symboles suivents apperaître sur la dernière image de chaque microfiche, selon le cas: le symbole -- signifie "A SUIVRE", le symbole ♥ signifie "FIN".

Les cartes, planches, tableaux, etc., peuvent être filmés à des taux de réduction différents. Lorsque le document est trop grand pour être reproduit en un seul cliché, il est filmé à partir de l'angle supérieur gauche, de gauche à droite, et de haut en bas, en prenent le nombre d'images nécessaire. Les diagrammes suivants illustrent la méthode.

SYNOPSIS

OF THE

FAMILIES AND GENERA

OF

NORTH AMERICAN DIPTERA,

EXCLUSIVE OF THE GENERA OF THE NEMATOCERA
AND MUSCIDÆ, .

WITH

BIBLIOGRAPHY AND NEW SPECIES, 1878-88.

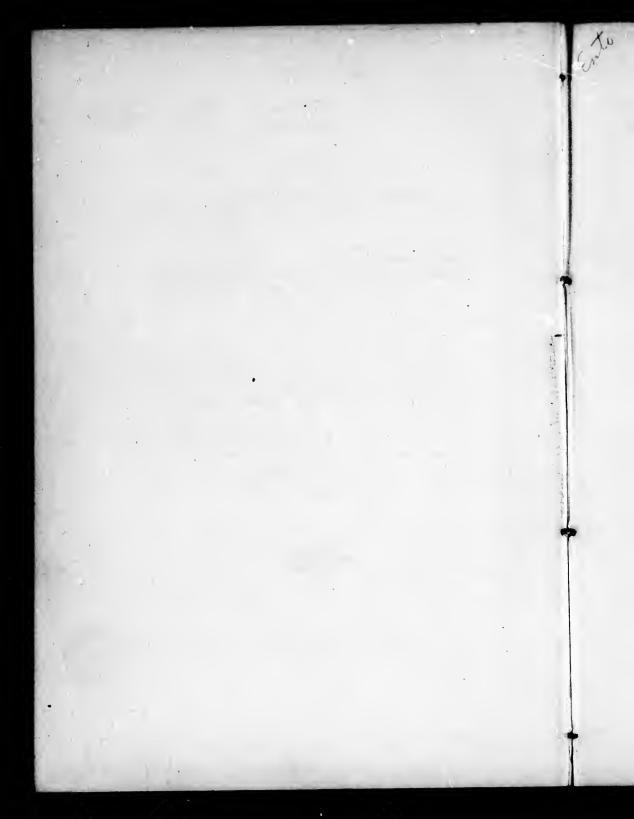

BY

SAMUEL W. WILLISTON,

Professor of Anatomy, Yale University.

NEW HAVEN: J. T. HATHAWAY, PUBLISHER. 1888.

NORTH AMERICAN DIPTERA.

INTRODUCTION.

THE writer has, during the past five years, published in different periodicals various synoptic tables of the families and genera of North American Diptera. The intention was, at first, to reprint these with revisions, that they might be more accessible to those interested in this order of insects. In order to make, it is trusted, the tables of more service, those of other families have been added, either as compiled or reproduced from standard authorities, or prepared from the examination of specimens in the author's collection. It will be understood, however, that, in not a few families, the present condition of American dipterology does not admit of the preparation of synopses free from error; the writer's acquaintance, too, with not a few families, has been less complete than with others, and it is very true that only he who has made a critical study of abundant material is competent to compile such tables with much success. For this reason, the tables of genera in the Nematocerous and Muscid families have been omitted. It may be mentioned that very nearly all the genera defined in the present work have been examined by the writer, though not all with the same degree of critical study. The faunal limits embraced are those north of Mexico; and whenever extralimital forms are introduced they will be found preceded by a o.

The student will soon learn that the characters of many flies are not so simple and apparent as a mere synoptic table would indicate them to be. He will often be puzzled at the interpretation of characters, even after he has acquired a considerable experience. Furthermore, it is often necessary to study any author a considerable time before he becomes thoroughly familiar with his peculiarities of style and modes of expression; he must become, one may say, familiar with the personal equation of each writer before he can feel confidence in the results obtained from him. It is precisely those authors who reduce that personal equation to the minimum who are most successful as describers. One, for instance, may feel confident of a determination of a species described by Macquart,

where the same description under Osten Sacken's name he would feel certain did not apply. Doubt of the right generic location of a specimen may often be surest dissipated by attempting to refer to some species. In fact the only way that the present writer was enabled to generically determine the larger part of his species in his earlier studies was by first ascertaining the species. Until the student has acquired a sort of intuitive acquaintance with the different families, the work will often be tedious, but, by perseverance, he can not fail to overcome whatever obstacles families and genera may present. He will be very much aided, at the beginning, however, by having a tolerably large collection at his command—already named by some one else if convenient—by which to make comparisons. Difficulties to the inexperienced will often disappear, with positive evidence before him, where negative characters are puzzling.

To determine his species the student will need a large series of papers, a list of which up to 1878, will be found in Osten Sacken's Catalogue, and from that time to the present in the concluding pages of this work. But, very much can be done with a much smaller and more accessible list. After he has become acquainted with the order in general, he can select any particular group and procure the papers for systematic work in that group at comparatively small expense. Much the larger part of the descriptions, it is true, will be found in foreign languages, but that need not deter him; descriptive phraseology is very simple, and it needs but a little exertion to become sufficiently acquainted with the four or five languages to read descriptions in them with ease or even to write them, if need be. A thorough knowledge of the German, however, is absolutely essential before much headway can be made. As in many other branches of biology, German literature is by far the most important and abundant-indeed it is almost a matter of doubt whether the balance between the bad and good in dipterological literature by the French, English and Italian authors is not almost equal, and this without intimating anything against the really good authors these countries have produced: Walker, Desvoidy and Lioy make a combination hard to match in any branch of science.

The following works are to be commended for the use of the beginner

✓ OSTEN SACKEN. Catalogue of Diptera, 2d edition, Smithsonian Institution, 1878.

SCHINER. Fauna Austriaca, Diptera. 2 vols. Vienna, 1862-64.
LOEW and OSTEN SACKEN. Monographs of North American Diptera. 4 vols. Smithsonian Institution, 1862-72.
WILLISTON. Synopsis of the North American Syrphids. Bull.

U. S. National Museum, No. 31, 1886.

-100 OSTEN SACKEN. Prodrome to a Monograph of the Tabanide. Boston Soc. Nat. Hist. 1875-8.

LOEW. Diptera Centuriæ, 1860-1872. (One thousand new N. A. species.)

2 50 WIEDEMANN. Ausscreuropaeische Zzeifluegelige Insekten, 1828-30. and 5 supplements, 1838-55.

MEIGEN. Systematische Beschreibung der Europalschen Zweiflue-

geligen Insekten, 1818–38. (Useful for the figures.) OSTEN SACKEN. Biologia Centrali-Americana, Diptera, 1886. cess to this work can only be obtained in large libraries.) SCHINER. Novara Expedition, Diptera, 1868.

550 .MACQUART. Histoire nat. des Dipteres, Suites a Buffon. 2 vols. 1835.

The above list has been arranged in about the order in which the works will prove the most useful.

In order to render the tables and descriptions intelligible to the student wholly unacquainted with this order of insects, for whom, indeed, the present work is more especially intended, some brief descriptions of the peculiar terminology is necessary. The terminology here used is essentially that of Loew, who gives a fuller exposition of it in the first volume of his monographs, works which, with Osten Sacken's more recent catalogue, will be of first importance to all those who would pursue the study further than that of mere separation into families and genera.

TERMINOLOGY OF DIPTERA.—The large compound eyes are present in all diptera, except some pupipara. In the majority of males they are contiguous on the upper part (HOLOPTIC), rarely so in the females. The narrow border, immediately surrounding them is the orbit, indicating often a more or less indefinite space. When the eyes are separated (DICHOPTIC), as they are in most females and many males, the space between them, limited above by the upper margin of the head, or VERTEX, and below by a line drawn across the base of the antennæ, is called the FRONT; on the lower part of the front, in most diptera cyclorrhapha, there is a crescentic space (FRONTAL LUNULE) separated by an impressed line. On the upper part of the front, near the vertex, there are usually three, rarely two, often no, simple, small eyes, called ocelli-their presence or absence is an important character. In the holoptic male, the triangle upon which these ocelli are situated, limited in front by the eyes,

behind by the vertical margin, is known as the OCELLAR, or VERTICAL, triangle; a similar triangle below, above the base of the antenne, is called the FRONTAL TRIANGLE. Below the antenne, the space, limited by the oral margin, the cheeks and the eyes, is the FACE, and characters drawn from it are of the highest value in specific classification. The space below the eyes, indefinitely limited in front by the face, and behind by the margin of the OCCIPUT (the posterior surface of the head) is the CHEEK. Of the mouth-parts, the PROBOSCIS, when not rarely absent, with its terminal, often fleshy, scraping or suctorial flaps, the LABELLA, and the one to five jointed face is sometimes spoken of as the peristoma, or hypostoma, but the more common and better term is EPISTOMA. Of the antenne, the third joint, in the brachycerous and cyclorrhaphous diptera, usually bears a bristle (ARISTA), or STYLE.

The THORAX is composed, as in other insects, of three parts, the PRO-thorax, MESO-thorax, and META-thorax, but the first and and the last are so aborted as to present but few anatomical characters. The prothorax is perhaps most readily distinguished in the nematocerous flies, forming a rounded collar, back of the NECK. The metathorax is not seen at all from above; the SCUTELLUM, a semi-oval body behind, cut off by an impressed line, really belongs to the mesothorax, the dorsum of which is often called the MESONO-TUM. Across, near the middle of the mesonotum, there is an impressed line, terminating on each side a little in front of the wings, that is known as the TRANSVERSE SUTURE. The anterior superior angles of the thorax are the BUMBRI, or humeral CALLOSITIES, and on the margin of the mesonotum, between the wings and the scuteilum, there is, on each side, an oval, obtuse process, named the Post-ALAR CALLUS. Limiting the mesonotum, running from the humerus to the wing, is the DORSO-PLEURAL SUTURE; below it, the whole side of the thorax forms the PLEURA, divided by sutures into smaller spaces called the MESO-pleura, STERNO-pleura, HYPO-pleura, and META-pleura. The under part of the thorax is the PECTUS or breast. The oval, arched portion behind, beneath the scutellum, is the META-NOTUM, and, on either side, we see a slender organ with a knob-like head, the aborted second pair of wings, and known as the balancers, poisers, or HALTERES. Above them, and back of the base of the wings, are the more or less well-developed membranous scales, the TEGULÆ.

The term abdomen is usually applied to the upper side of the third principal part of the insect, only; for the under side we use the term venter. At the terminal part of the male abdomen, are the sexual appendages, to which the name htropygium is applied.

In the female, the corresponding part is the ovirosron.

To understand the neuration of the winos, let the student select for comparison a common large horse-fly (Tabanids) and a common house or blue-bottle fly (Musclds). Observe in the former, near the middle of the wing, directed transversely, a large, oblong, five or six-sided cell, surrounded on all sides by other cells. This is the DISCAL cell, and is present in nearly all flies. Some. where on the vein (FOURTH LONGITUDINAL) that bounds this cell in front, will be seen a short connecting vein, directed anteriorly; this is the ANTERIOR OF SMALL CROSS-VEIN, and affords, in most cases, a key to the neuration, no matter how intricate. It always connects the fourth iongitudinal vein behind with the third longitudinal in front; the cell behind it is the discal, in front the SUBMARGINAL, on the outer side the FIRST POSTERIOR, on the inner side the FIRST BASAL. Lying parallel with the first basal cell, and just behind it, is the SECOND BASAL cell; just behind the second basal cell is the THIRD BASAL OF ANAL cell. In the horse-fly, the anal cell is seen to run back obliquely to near the posterior margin of the wing, where it terminates acutely, that is, the anal cell is said to be closed near the border of the wing; should the two veins that close it run separately into the wing's margin, then the cell is open. Now, counting outwardly along the posterior border to the third longitudinal vein (posterior branch), there will be seen five posterior cells, all open (except in a few species of our Tabanide the first posterior cell is closed), with their bases bordering on the discal and first and second basal cells. By following the third longitudinal vein ontwardly from the anterior cross-vein, it is seen to give off an anterior branch, which runs to terminate in the front margin or costa of the wing; the third longitudinal voin is here furcate, and two submarginal cells are present. Compare now these same structures in the house-fly, and the discal is found much more elongated, the basal and anal cells small, the third longitudinal vein simple, not furcated, and only one submarginal and three posterior cells are present. Do not confound the obliquely placed vein that nearly closes the first posterior cell with the furcation of the third vein. The house-fly will also show clearly the six longitudinal veins, the last of which runs obliquely backward from the anal cell toward the margin, the fifth bordering the discal cell behind, the first and second running into the costs. The first vein that terminates in the costs (before the middle of the wing) is the AUXILIARY. The vein that closes the discal cell outwardly is the POSTERIOR OF GREAT Cross-vein; the vein that closes the anal cell outwardly, the POSTERIOR BASAL cross vein.

By comparing the tip of the TARSI (feet) in the two above-mentioned flies, the student will immediately observe what is meant by the expression "empodia developed pulvilliform." The middle membranous appendage on the underside of the claws (unours) in the horse-fly is the pulvilliform EMPODIUM, while in the house-fly the

outer ones, the FULVILLI, alone are present. The TARSUS, composed of five joints, the proximal one of which is called the META-tarsus, the TIBLA, the FEMUR, and the COXA, attaching the leg to the thorax,

will be readily understood.

A few words only, as regards the collection and preservation of flies. Moisture of any kind spoils all specimens; for that reason they should always be pinned, and never preserved in fluids. Further, the collecting bottle should be carefully lined with blotting paper to absorb the moisture exhaled. Many flies are injured by rubbing or handling. Specimens should always be pinned, never glued to cards.

CLASSIFICATION OF THE DIPTERA.—Professor Brauer has recently published[®] a classificatory system of Diptera, based upon the immature and mature stages, which, as the most recent exposition by one recognized as an authority in the classification of insects in general, is worthy of acceptance, at least in greater part. It will be difficult to supplant some of the names already in use, such as the Muscaria calyptrats, etc., nor is such desirable; but names, here as elsewhere, are wholly of secondary importance—the facts or views to which such give expression are all that we at present care for. His system is as follows:

	Sub-order ORTHORRHAPHA.
NBMA- TOCERA.	(/Tribe EUGRPHALA. Mycetophilidæ, Bibionidæ, Chironomidæ, Culicidæ, Blepharoceridæ, Simulidæ, Psychodidæ, Ptychopteridæ, Rhyphidæ. 4Tribe OLIGONBURA. Cecidomyidæ. 4Tribe POLYNEURA. Limnobidæ, Tipulidæ.
BRACH- YCERA.	Tribe Acroptera. Homoo- DACTYLA. HETERO- DACTYLA. Tribe Orthogenya. Lonchopteridæ. Notacantha. Stratiom., Xyloph. Tanystoma. Tabanidæ, Acanthomeridæ, Leptidæ. Bombylimorpha Acroc., Nemistr. Procephala. Mydaidæ, Asilidæ, Bombylidæ. Polytoma. Therevidæ, Scenop. Empidæ, Dolichopodidæ.
A	Sub-order CYCLORRHAPHA.
ABURIEN	Tribe SYRPHIDE. Syrphide, Pipunculide. Tribe Hypochea. Phoride, Platyperide. Schizometone. Muscide calvatrates
PHORA.	Tribe EUMYIDE. Schizometopa. Muscide calyptrate: Holometopa. Muscide acalyptrate: Hippoboscide, Nycteribide.

Denkschr. d. k. Akad. d. Wissensch. XLVII, 11, 1883.

TABLE OF FAMILIES.

 Flies of a leathery or horny structure, living parasitically in the adult state upon warm-blooded vertebrates; head small, either closely united to the emarginate anterior part of the thorax, or folding back into a groove upon the dorsum; mouth-parts incomplete, the paipi wanting; legs separated by the broad sternum; abdomen indistinctly segmentated; claws well developed. 49 Flies of softer structure, never living parasitically in the adult
state upon warm-blooded vertebrates; head separated from thorax by a free neck
2. Antenns many-jointed, often longer than the thorax, the two basal joints, only, differentiated, the remaining joints usually distinct; palpi composed of from three to five joints, usually elongate; anal cell never closed or narrowed at the margin. (Nematocers.)
Antenne rarely as long as the thorax, composed primarily of three joints, the third of which may be simple or complex,
(that is, composed of more or less distinct annuli or segments,) with or without a terminal or dorsal arists or style; anal cell
closed before the border, or distinctly narrowed in the border, or, if other structure, the antenne composed of three simple joints; palpi rarely much elongate, composed of from one to three joints.
 Dorsum of thorax with a distinct V-shaped suturef; wings (wanting in Chionea) many-veined, often with a complete discal cell; ocelli wanting (present in Trichocera); often large
flies
Dorsum of thorax without a V-shaped suture, or rarely with any transverse suture (Blepharoceridæ.)

^{*} Plecla, and perhaps some others, may be exceptions.

[†] Bittacomorphs, Ptychopters, and Idioplasts will alone cause dou't here. They have the suture incompletely V-shaped and sincous. The last will be distinguished from Bhyphids chiefly by the absence of ceelli; the two former will be separated from the Culic ds by the absence of hair on the veins, their large size, and in Bittacomorphs by the peculiar clubbed tibis.

4. 1	A complete discal cell present; ocelli present; empodia developed pulvilliform, pulvilli rudimentary. RHYPHDA
1	No discal ceil
6.	Wings with only a few longitudinal veins, and no cross-veins; coxe not elongate, tibis without terminal spurs, legs not thickened; ocelli present or absent; small or minute, delicate, mostly gall-producing fles
0	Not such flies, wings usually many-veined. 6 Ocelli present. 7
0.	Freezens, Freeze
	Ocelli wanting (compare Mycetophilidæ.) . 9
7.	Wings broad, bare, characteristically marked by numerous folds between the veins, giving a netted, spiderweb-like appearance
	Wings not so marked; no entire transverse suture 8
8.	Coxe much elongated (moderately so in Sciarinæ); antennæ often elongate, the joints constricted; three or two ocelli (in the latter case situated near the eyes, and often hardly perceptible); all the tibiæ with spurs. MYCETOPHILIDÆ Coxe short, the thorax rounded, not humped, above; antennæ shorter than the thorax, thickened, the joints closely united without marked constrictions; legs strong, the front femora often thickened; empodia putvilliform, the pulvilli sometimes absent; eyes of male large. BIBIONIDÆ
9.	The costal or marginal vein does not extend beyond the tip of the wing.
	The marginal vein encompasses the entire wing 11
10.	Antennæ slender, the joints more or less constricted, and often bushy plumose; legs slender, hind tibiæ and metatarsi never dilated; body and abdomen slender; wings narrow. Chironomidæ
ď	Antennæ shorter than the thorax, the joints broadly and closely united, without marked constrictions, and never hairy or pilose; legs strong, hind pair more or less dilated; body thickset, cbdomen ovate; wings broad, bare, the anterior veins stouter, the posterior ones weak. Black-flies, buffalo-gnats.
11.	Wings distally, with ten longitudinal veins, without cross-veins, broad, pointed, veins strongly hairy; tibiæ without terminal spurs; small, lepidoptera-like flies, the wings, when at rest, folded roof-shaped. PSYCHODIDÆ

	pointed, the veins hairy and conspicuously fringed along the hind margin; wings when at rest not roof-shaped. Mosquitoes. Culicidæ
12.	Third joint of the antennæ complex; basal cells of wings long. 13 Antennæ composed of three simple joints, the third not annulated or segmentated, with or without a dorsal arista, or terminal style or arista
18.	Empodia undeveloped or bristle-like; antennæ elongate, composed of four or five joints, without differentiated style or arista; vertex and front hollowed out transversely between the eyes; eyes of male never contiguous
14.	Tegulæ rather large; third longitudinal vein furcate; five posterior cells always present; the costal vein encompasses the whole margin of the wing; proboscis of the female adapted for piercing; third joint of antennæ with from three to eight annuli, never with style or bristle. Horseflies. Tabanidæ Tegulæ small or rudimentary; mostly flower-flies. (See No tacantha.)
15.	Tibiæ wholly without terminal spurs; longitudinal veins of the wings usually crowded anteriorly, those posteriorly often weak; the costal vein does not reach beyond the tip of the wing; antennæ long or short, with or without a terminal or dorsal arista or terminal style. Strationyidæ The middle tibiæ at least, with distinct spurs; the costal vein encompasses the entire wing; third longitudinal vein always furcate, and five posterior cells always present.
16.	All the tibiæ with spurs; third joint of antennæ sometimes divided into separate divisions
17.	Fourth posterior cell of wings closed (Subula). STRATIONYIDE, pt.
18.	Fourth posterior cell open (Arthrocerine.)
	Face with two diverging furrows ARTHROCERAS

19.	Antennæ apparently single-jointed, with a long bristle; wings with several stout veins anteriorly, and other weaker ones running across the surface unconnected by cross-veins; femora flattened, the hind legs long; antennæ situated near the mouth; small, quick-running, hunchback-like flies. Phoridæ Not such flies.
20.	Empodia developed pulvilliform, that is, three nearly equal, membranous appendages on the under side of the claws. 21 Empodia wanting, rudimentary or linear, not developed like the pulvilli
-21.	Tegulæ very large, inflated; thorax and abdomen inflated; head small, eyes very large; neuration varied. ACROCKRIDA Tegulæ of moderate size or rudimentary.
22.	Middle tibiæ, at least, with spurs, no bristles on femora or tibiæ; third longitudinal vein furcate; five posterior cells present (four in Agnotomyla); anterior cross-vein always distinct; third joint of the antennæ with a bristle or slender style, usually terminal. LEPTIDÆ Not such flies.
23.	Third longitudinal vein of the wing simple, not furcate. 32 Third longitudinal vein furcate, two or more submarginal cells present. 24
24.	Arists or style of antennæ, when present, always terminal. Arists dorsal, always present.
25.	Vertex and front distinctly hollowed out transversely between the eyes; eyes of male never contiguous; basal cells large; mostly large flies
26.	Proboscis without fleshy labella at the tip, the under part forming a horny sheath; the posterior branch of the third vein terminates behind the tip of the wing; five posterior cells always present; predaceous flies. ASILIDÆ Proboscis with fleshy labella at the tip; neuration complicated, the third vein, at least, curves forward to terminate before the tip of the wing; antennæ with a terminal flattened lamella. MIDAIDÆ
27.	Five posterior cells in the wing; basal cells large 30
	Never more than four nectories calls in the wing

28. Third antennal joint without bristle or style; three posterior cells; first posterior cell narrowed or closed, the fourth longitudinal vein terminating at or before the tip of the wing.
Third antennal joint rarely without terminal style; four or three posterior cells; the fourth vein terminates beyond the tip of the wing.
29. Anal cell narrowly open, or closed near the border. BOMBYLIDÆ Anal cell closed remote from the border EMPIDÆ
30. Neuration intricate, the small cross-vein wanting or rudimentary, owing to the coalescence of the third and fourth veins for a longer or shorter distance; tibis without terminal spurs; empodia and pulvilli membranous, but frequently minute. NEMISTRINIDAE
Neuration not intricate; the anterior cross-vein always distinct;
labella of proboscis fleshy
31. The posterior branch of the third vein terminates before the tip of the wing; male sexual organs prominent. APICCERIDE The posterior branch of the third vein terminates behind the tip of the wing; male sexual organs small. Therevide
32. Antennæ with a dorsal arista
83. Wings pointed, no cross-veins in the middle, the fourth longitudinal furcate and united with the fifth; small species. LONGROPTERIDA
Wings rounded at the tip, not lancet-like
34. Second basal cell confluent with the discal cell, not separated by a small vein; the auxiliary vein does not terminate in the costa; small, mostly brilliant-colored, predaceous flies.
DOLICHOPODIDÆ Second basal cell separated from discal cell by a small vein. 35
35. Antenne with a terminal style
36. First posterior closed (Conopide, pt., Syrphide, pt.) 41 First posterior cell open
37. Head comparatively small; the proboscis usually more or less elongated; alules of wings usually rudimentary. EMPIDÆ Head as broad as the thorax; proboscis fleshy; alules distinct. PLATYPEZIDÆ
·

88.	narrowed; tegulæ usually large. Botflies. ŒSTRIDÆ Proboscis not rudimentary; palpi present. 39
80.	Second basal cell confluent with the discal cell; not separated by a small vein; small, mostly brilliant-colored, predaceous flies; face never broad and convex. Dolichorodid. Second basal cell separated from the discal cell by a small crossvein (or, if not, not brilliant-colored, predaceous flies, and the face always broad and arched, Ephydring.) 40
40.	Posterior basal cells of wing elongate; the anal cell closed toward the margin; first posterior cell closed or much narrowed (except a metimes in Pipunculids.)
41.	Face with sub-antennal vertical grooves or depression. (Conopids, pt.). 48 Face convex transversely, or with a median ridge; never with a sub-antennal depression. 42
42 .	Between the third and fourth longitudinal veins, and sub-paral- lel with them, crossing the anterior cross-vein, a spurious longitudinal vein, or, when rarely not present, the first pos- terior cell closed a considerable distance from the border; eyes never extraordinarily large; abdomen without bristles.
	Spurious vein never present; first posterior cell never closed before the margin; eyes very large, including the largest part of the head; small species.
13.	Proboscis horny, elongate, often folding back near the middle; abdomen never with bristles; tible without terminal spurs (or, if with them, the face with a median ridge, and the proboscis folding;) first posterior cell closed or narrowed.
	Proboscis fleshy and not elongate, (or if elongate and slender, with or without a median hinge, the abdomen with distinct bristles, or the bristle of antenne plumose.)
14.	Tegulæ large; face with sub-antennal vertical grooves or depression. (Muscidæ calyptratæ.)

45.	First posterior cell widely open, not narrowed in the margin. ANTHYOMYIDA
	First posterior cell closed, or more or less narrowed 46
46.	Antennal arista wholly bare TACHINIDA Antennal arista distinctly pubescent or plumose
47.	Arista bare on the distal part; dorsum of abdomen rarely bristly before the distal part
48.	Dorsum of abdomen bristly; legs usually elongate. Abdominal segments without bristles, except sometimes somewhat near the tip.
49.	Wingless flies, parasitic upon bats; head not flattened, folding back upon the dorsum of the thorax; first joint of tarsi not abbreviated. NYCTERIBLE Winged or wingless flies, parasitic upon birds or quadrupeds; head flattened, sunk into a shallow emargination of the thorax; first joint of the four anterior, or all, tarsi abbreviated. HIPPOROGENE

44

FAMILY CHARACTERS AND SYNOPSES OF GENERA.

NOTACANTHA.

Empodia developed pulvilliform, pulvilli present. Without distinct bristles. Basal cells of wings large. Third joint of antennæ segmented or annulated. Tegulæ small or rudimentary. Proboscis not adapted for piercing. Males holoptic or dichoptic.

no	ot adapted for piercing. Males holoptic or dichoptic.
1.	Tibiæ wholly without spurs; velns usually crowded anteriorly.
	Tible more or less spurred; the costal vein encompasses the whole wing; two sub-marginal and five posterior cells always
	present
2.	All the tibiæ with spurs
	Front tibiæ without spurs
8.	Third joint of antennæ not acute at tip, or, if so, the scutellum with spines on its border XYLOPHAGIDÆ Third joint acute; palpi cylindrical; scutellum without spines. ARTHROPEAS
4.	Fourth posterior cell closed SUBULA Fourth posterior cell open. (Leptidæ.) 5
5.	Face projecting on each side into a rounded conical protuberance, thickly covered with hair
	Face with two deep, diverging furrows, running from the base of the antennæ to the oral margin. ARTHROCERAS

XYLOPHAGIDÆ.

Species of moderate or large size, more or less elongated, thinly pilose, or nearly bare. Ocelli present. Antennæ elongate, third joint annulated or segmentated, never with a differentiated style or bristle. Veins of the wings distinct, not crowded anteriorly, third longitudinal vein furcate; five posterior cells. Abdomen with seven or eight visible segments. All the tibiæ with spurs at the tip.

The flies are usually found about trees, where they feed upon the sap, or about decaying logs, and are often mistaken for ichneumonids.

- 2. Fourth posterior cell closed; third joint of antennæ much elongate, composed of numerous distinct divisions, often pectinate; eyes emarginate near the antennæ. RHACHICERUS Fourth posterior cell open; third joint of antennæ composed of eight annuli, indistinctly separated. XYLOPHAGUS

RIIACHICERUS Haliday, in Walker, List, etc. V, 103, 1854.
XYLOPHAGUS Meigen, in Illiger's Magazine, II, 266, 1803.

ARTHROPEAS LOEW. See Leptidæ.
ARTHROCERAS Williston. See Leptidæ.
GLUTOPS Burgess. See Leptidæ.

STRATIOMYIDÆ

Head large, bemispherical. Antennæ situated at or below the middle of the head in profile, short or elongate, the third joint composed of more or less distinct annuli; usually with a more or less differentiated style, or bristle. Eyes bare or pilose; ocelli present. Scutellum often with thickened spine-like points. Abdomen elongate, clavate, oval, or rounded, flattened or convex above, of five or more visible segments. Legs never very stout, often slender, tibiæ without spurs (except in some exotic genera.) Wings usually with the veins more or less crowded anteriorly, often on the outer posterior part weak and faint; third longitudinal vein usually furcate, terminating before the tip of the wing; four or five posterior cells, all open, the posterior yeins not seldom more or less rudimentary.

Species from three or four to twenty or more millimeters in length, bare or moderate pilose. They are mostly flower-flies, and are often found upon vegetation in the vicinity of damp places. Larvæ pupigerous, that is the pupæ remain within the larval skin till ready to emerge as perfect insects.

2. Three posterior veins, all discal. PACHTGASTRINE. Four posterior veins, the anterior ones sometimes rudimentary. 3
3. All the posterior veins discal, the last posterior cell contiguous at its base with the discal cell.
The last posterior vein arises from the second basal cell, the last posterior cell not contiguous at its base with the discal cell. 5
4. Third antennal joint with a long, delicately fringed, lamelliform style; usually large, more or less elongated species; males dichoptic. (Hermetlinæ.)
5. Antennæ with a slender dorsal or terminal bristle. SARGINÆ Antennæ never with a slender or long bristle. STRATIOMYINÆ
Beridinæ.
Abdomen with seven visible segments in the male, in the female with an additional ovipositor. Wings with a stigmatic spot; all the posterior veins arise from the discal cell.* Abdomen flattened.
1. Three posterior veins; occiput flat
2. Scutellum with spines; palpi rudimentary Beris Scutellum without spines (Metoponia Lw., non Macq.) ALLOGNOSTA
3. Occiput excavated; hind femora thickened at the extremity.
Occiput flat, hind femora simple; last two abdominal segments small Scoliopelta
Sarginæ.
Body usually elongate; rather small, nearly bare species. Four posterior veins, the last one arising from the basal cell, Antennes short, the third joint rounded or subquadrate, with an apical or preapical arista. Scutellum without spines on its border. [Occiput deeply excavated.]
1. Anterior ocellus more widely separated than the other two; males
holoptic or dichoptic

^{*} Variable in Beris.

MICROCHRYSA

9	Abdomen contracted toward the base, clavate, pedicellate.
۵.	Macrosangus
	Abdomen not pedicellate in the male, in the female the second segment not concave on the sides SARGUS
3.	Second antennal joint prolonged on its inner side into a projection, extending on, and closely lying upon, the third joint. Precticus
	Second joint not with such a projection
4.	Males dichoptic; eyes bare
5.	Eyes thickly pilose

STRATIONYINA.

enlarged facets above.

Rather large species, the abdomen usually ovate and more or less thickened. Five posterior cells; often, however, one or more of the three veins that arise from the discal cell is faint or rudimetary, and the cells coalescent: in such cases the discal cell will usually show angulations, indicating their origin. The last posterior vein is nearly always distinct, and arises from the second basal cell. Anterior veins often crowded toward the front. Antennæ never with a long or slender bristle.

- 2. Face projecting conically downward; small species. MYXOSARGUS
 Face not projecting downward in a cone; abdomen not elongate.

 ODONTONYIA

CLITELLARINA.

Abdomen short, usually but little longer than broad; four posterior veins, all of which arise from the discal cell. Small or moderately large species, nearly bare.

 Scutellum without spines; face produced below into a projecting cone; posterior veins of wing weak; small species.

2. Antennæ short, with a subtermina	al bristle. ,	OXYCER	A
Antennæ more or less elongate, w	vithout bristle		3

PACHYGASTRINÆ.

Small species, abdoncen oval. Three posterior veins, all arising from the discal cell. Antennæ situated near the middle of the face in profile, third joint short, with a terminal arista, scutellum without spines.

Pachyoaster

ALLOGNOSTA Osten Sacken, Berl. Ent. Zeit. XXVII, 297, 1883. BERIS Latreille: Hist. Nat. des Crust. et des Ins. XIV. 340, 1804. SCOLIOPELTA Williston, Entom. Amer. I, 119, 1885. TANYSTOMA.

Tarsi with three membranous pads at the tip (the empodia developed pulvilliform); body and legs wholly without macrochætæ; males holoptic, eyes rarely narrowly separated; two sub-marginal, five posterior cells in the wing,* fifth posterior cell not contiguous

^{*}The genus Agnotomyia with four posterior cells, is the only exception.

at its base with the discal cell; the marginal vein encompasses the whole wing; some or all the tible with spurs.

Third joint of the antennæ annulate, never with differentiated style or bristle; tegulæ rather large. . . TABARIDÆ
Third joint of antennæ simple, with a simple, or thickened styliform, bristle; tegulæ rudimentary. . . Leftidæ

TABANIDÆ.

Species never very small, often among the largest in the order; never thickly pilose; in life the eyes usually brilliantly colored and marked. Head short, broad, eyes large. Antennæ porrect, the third joint_composed of from three to eight annuli or segments. Thorax not very convex, scutellum without spines on its border. Abdomen broad, moderately elongate or short, never slender or constricted. Legs moderately stout, the front and middle tibiæ sometimes dilated, the middle tibiæ always with spurs. Veins of the wings distinct; first posterior cell (and fourth in exotic species) rarely closed.

Early stages passed in the water or earth; larvæ carnivorous, with a distinct head; pupæ free. The females are blood-sucking, usually found in the neighborhood of pastures, in sunny open parts of woods, during the hot sun-shiny days of summer. The males are much more rarely met with, and will be found usually in sweepings of meadow lands, on flowers, etc.

- Third joint of the antennæ composed of eight annuli, the first of which is only a little longer than the following ones.
 Third joint composed of five or fewer segments, the first of which is much longer than the following; occili present.
- 4. Second joint of the antennæ about half as long as the first; wings hyaline or with small spots; eyes in life with numerous small dots.

 SILVIUS

Second joint as long, or but little shorter than the first; wings with a dark picture; eyes in life with fewer, larger spots.

CHRYSOPS

- 5. Front of the female as broad as long; callus transverse; front tibis a little dilated; base of third antennal joint not dilated.

 Hæmatofota
 - Front of female narrow. 6

LEPTIDÆ.

Rather small to rather large species; thinly pilose, with short thorax, elongate abdomen and large wings. Head short, eyes of male contiguous or approximate; ocelli present. Antennæ mostly short, never elongate, the third joint with a terminal or dorsal bristle, or terminal slender style. Face small, excavated. Proboscis short; palpi slender, porrect, often bushy pilose. Abdomen elongate, broadest toward the base, composed of seven segments; the female ovipositor pointed. Legs slender, the hind pair somewhat elongate; some or all the tibiæ spurred. Posterior cells of wings usually all open.

Larvæ carnivorous, living in earth, decaying wood, dry sand, in moss or in water. The flies are usually found about meadow and

AGNOTOMYIA

low woodlands, on	bushes, etc., and prey upon other insects.	Some
western species of	Symphoromyia suck blood, as do the	horse-
flies.		

1. Front tible with terminal	spurs.				2
Front tibiæ without spurs.					3

2.	Front tibie with two spurs;	five posterior cells in	the wing.
			TRIPTOTRICHA

ASILIDÆ.

Species of moderate to large size; bristly; predaceous. Head flattened, the eyes prominent. Front concave between the eyes, the eyes not contiguous in either sex. Ocelli present. Antennæ porrect, with or without a terminal bristle or style; when with a terminal style, the antennæ apparently four or five-jointed. Proboscis pro-

jecting, never elongate, without terminal fleshy labella, adapted for piercing. Abdomen with eight segments, the hypopygium or oviduct usually prominent. Legs strong, moderately long; empodia bristly, not pulvilliform, the pulvilli sometimes rudimentary. Basal cells of the wing long; five posterior cells, two or three submarginal cells; anal cell open or closed in the margin.

The flies are usually observed in sunny open paths, or upon leaves of underbrush, on the alert for other insects, which they seize upon the wing and pierce with their stout proboscis.

1.	Marginal cell of the wing open. (Dasypogoninæ.) 2 Marginal cell closed
2.	Front tibiæ with a terminal claw-like spur
3.	Pulvilli rudimentary or wanting
4.	Face very narrow; abdomen very long, slender, narrow on proximal part; hind legs elongate, slender. Leptogaster Face moderately narrow; abdomen not unusually long, broader at base; hind legs not elongate Ablautatus
5.	Head narrow, about as high as broad; face narrow above, broader and swollen below, in large part covered with hair. Large, elongate species
в.	Head very obviously broader than high 8 Antennæ with a terminal style
7.	First posterior cell open, not closed before the border of the wing. Stenorogon First and fourth posterior cells closed before the border of the wing; third joint of antennæ shorter, style longer. SCLEROPOGON
8.	Fourth posterior cell closed before the border 9 Fourth posterior cell wide open, rarely nearly closed
9.	Antennæ elongate, of five joints (Myelaphus) 14 Antennæ not elongate, of three joints, and a terminal style. 10
10.	Face bare, except on oral margin; abdomen elongate, cylindroidal; anterior intercalary vein continuous, or nearly so, with

	the fourth vein, the last section of fourth vein oblique, sinuous, closing or much narrowing the broad first posterior cell. Large, or very large species
11.	Abdomen cylindrical, not narrow at the tip, elongate; near the base of second and third segments with white pollinose emarginate cross-bands; wings dark DIZONIAS Abdomen less elongate, with five or six white pollinose cross-bands
12.	First posterior cell open, scarcely narrowed, face broad.
	First posterior cell much narrowed or closed TRICLIS
13.	Antennæ elongate, composed of five joints; nearly bare species. 14 Antennæ less elongate or short, of three joints, with or without a short or slender style
14.	First and second joints of antennæ of nearly equal length, third elongate, fourth short, fifth elongate and densely pubescent; third and fourth not lobed at tip
15.	Style of antennæ short, thick, obtuse, not easily distinguishable from the third joint, or, if so, forming apparent joints; antennæ more or less elongate
16.	Nearly bare species; face flattened, bare except below. Small, or rather small, species, shining or metallic black, with narrow or cylindrical abdomen and large wings. 17 Thickly pilose species, the bristles few and hair-like; antennæ situated upon a convexity, thence receding to the facial tubercle, which is situated upon the lower part of the face; abdomen short; head narrow. DICOLONUS
17.	All the tibiæ and the hind femora with short, strong setæ.
	Hind femora without such setæ Dioctria

18.	Face distinctly convex in profile, swollen or gibbose.* 19 Face flattened or gently convex
19.	Thickly pilose species; the gibbosity of the face reaches to the base of the antennæ; anal cell usually open.* Cyrtopogon Thinly pilose, more pollinose species, the convexity of the face on the lower part, anal cell usually closed. DAULOPOGON
20.	Abdomen elongate; front broad anteriorly, narrow behind.
	Plesiomma
	Front not narrowed behind
21.	Hind tibiæ toward the tip, and their metatarsi, much thickened. 22 Hind tibiæ not, or but slightly, thickened toward the tip; metatarsi not thickened
22.	Head much broader than high, transverse, "goggle"-like; abdomen short, wings large Holcocephala Head only moderately broader than high, not at all spectacle-like in appearance Holopogon
23.	Abdomen with thick recumbent pile above; thickly pilose species; antennæ slender
24.	Slender, nearly bare species; face perpendicular, straight or gently concave, narrowed above, bare, except on oral margin. 25 Face gently rounded, not prominent below, in large part hairy, not or but slightly narrowed above. 20
25.	Thickly whitish pollinose; abdomen flattened, usually reflected upward, third joint of antennæ and style both slender. STICHOPOGON
	Less thickly pollinose; abdomen cylindrical, a little broader at base; third joint of antennæ short, broad, style minute. See Habropogon bilineatus Will.
26	Large, elongate species, style of antennæ short . Callinicus Moderately large, not much elongate
27.	Abdomen broader at the base, depressed; thorax much convex above, antennæ slender, style long and slender (compare species of Cyrtopogon) Anisopogon

^{*}Several species are placed provisionally under Cyrtopogon in which the facial gibbosity is small, and the body thinly pilose. They may be distinguished by the abdomen not being broad, and having white pollinose cross-bands; in some the wings have small but distinct clouds on the crossveins.

	Abdomen short, cylindrical. Black, with bright golden opaque pollinose markings on thorax and abdomen. See "Laparus" pictitarsis Bigot.
28.	Large species; face bare with bristles on the oral margin, in profile straight or concave, the oral margin projecting. 29 Smaller species, face convex on lower portion, not projecting. 30
20.	Elongate; fourth posterior cell closed, usually a considerable distance before the margin Deronyia Less elongate; fourth cell open or closed in the margin, rarely a little petiolate Saropoon
30	Head broad and flat, face not gibbose, third joint of antennæ slender, elongate
31.	Abdomen finely punctulate, of nearly equal width; hind tibiæ at the tip and their tarsi only a little thickened; wings hyaline. TARACTICUS Abdomen smooth; hind tibiæ at the tip and their tarsi thickened (compare here Nicocles? scitula); antennal style
32.	slender, acuminate; wings variegated
99	Antennæ without a terminal bristle (Laphrinæ) 34
• >>).	Antennæ with a terminal bristle (Asilinæ)
34.	The veins at the distal ends of the discal and fourth posterior cells in the same straight line, continuous, or nearly so. 35 The veins, etc., not in the same straight line, the vein closing the fourth posterior cell more or less remote and oblique. 36
35.	First joint of antennæ elongate, slender; second posterior cell narrowed toward the margin of the wing CEROTAINIA First joint of the antennæ much shorter than the third; first posterior cell narrowed or closed, the second wide open. Atomosia

36. First posterior cell narrowed or closed
First posterior cell wide open
37. Three submarginal cells, i. e. the upper branch of the third vein is connected with the second by a short vein. Pogonosom Two submarginal cells.
38. Hind femora of nearly equal thickness throughout; antenno with a distinct terminal style; very large, robust, thickly pilose species
39. Thorax and abdomen nearly or quite bare; hind femora with spinous tubercles below. Thorax and abdomen pilose, larger species.
40. Densely pilose species; the abdomen short, broad, usually broade beyond the middle, in the male sometimes more elongate proboscis thick. Less pilose, more elongate species; proboscis more elongate and slender. Laphri
41. Bristle of antennæ plumose Ommatiu Bristle not plumose
Bristle not plumose

^{*}The remainder of this table is a translation from Loew, Diptf. Sud. Afrikas, p. 143.

48 Face without gibbosity. Face with gibbosity; if restricted to the lower part, and hence not conspicuous, face neither carinate nor unusually narrowed. 52
48. Face narrow throughout, not at all carinate, the mystax composed of few long hairs
49. The closed fourth posterior cell much widened at the expense of the discal cell which is narrowed in its middle. Synolous Fourth posterior cell not unusually broader towards its base. 50
50. Mystax moderately thick, bristly, not wall-like. ODYSCLYTUS Mystax fine-haired, long and thick, wall-like 51
51. Second posterior cell widened near the base in front at the expense of the first posterior cell • Lophonotus Second posterior cell not widened in front at the base. • TRICHONOTUS
52. Dorsum of thorax with bristles reaching to the front part, or at least thickly hairy along the middle
53. Facial gibbosity slight, reaching nearly to the antennæ. • DASOPHRYS Facial gibbosity very distinctly prominent, reaching much less high
54. Third joint of the antennæ slender, linear. PROTOFRANES Third joint of the usual elongate elliptical shape. DYSMACHUS
55. End lamellæ of the oviduct (Q) egg-shaped and wedged in. EUTOLMUS
End lamellæ wholly free, nearly style-like
57. Legs prevailing shining yellow NEOMOCHTHERUS Legs prevailing black, or light and opaque colored 58
58. Abdomen shining black above and below. STILPNOGASTER Abdomen not shining on both sides
59. General color yellowish-gray or ash-gray, the legs with reddish yellow stripes or bands; opaque ° EPITRIPTUS

	General color more or less black-gray, the legs prevailing black, the tibiæ often red
60.	The male genitalia very thickly club-like, or at least the sixth and seventh abdominal segments help form the female oviduct. NEOITAMUS Male genitalia not club-like, the sixth and seventh segments take no part in the formation of the oviduct. 61
61.	Male genitalia, when seen from above, more or less acute on the end; facial gibbosity rather large
62.	Abdomen without bristles before the incisures 63 Abdomen with bristles before the incisures 68
63.	Facial gibbosity extraordinarily large, the extremely sharp tip of the proboscis bent somewhat upwards. O PROAGONISTES Facial gibbosity of usual size, the proboscis wholly straight, and not sharper than usual
64.	Mystax bristly as usual
65.	Abdomen fine-haired, depressed
66.	Bright colored, large species 67 Small, ash-gray species
67.	Feet of usual length and structure ASILUS Feet unusually elongated
68.	First joint of the four anterior tarsi remarkably short.
	First joint, etc., not remarkably shortened 69
89	Oviduct (Q) club-shaped, thickly pilose below. Antipalus
100.	Oviduct conical, beset with short spines at the end. PHILODICUS

APIOCERIDÆ.

Moderate to rather large, elongate, bristly, thinly pilose, predaceous flies. Head somewhat flattened, narrower than the thorax; front not excavated between the eyes, the eyes not contiguous in the male. Ocelli present. Antennæ porrect, not short, the third joint with a short terminal style. Face very short. Proboscis porrect, moderately elongate, with flattened, more or less fleshy labella. Abdomen elongate; hypopygium disengaged; more or less enlarged; oviduct with a terminal circlet of spines. Legs bristly; empodia not pulvilliform. Basal cells of wings elongate; third longitudinal vein furcate or simple (genus novum, Australia); five posterior cells; the third and fourth longitudinal veins both curve forward to terminate before the tip of the wing.

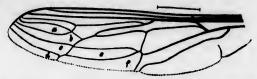

APIOCERA Westwood, London and Edinburgh Phil. Magaz. 1835; Pomacera Macquart; Anypenus Philippi.

NEMISTRINIDÆ.

Species of moderate size, thinly or thickly pilose. Neuration complicated; the basal cells elongate. Antennæ small, short; third joint simple, with a terminal, slender, jointed style. Ovipositor of the female elongate, often slender. Tibiæ without spurs; empodia developed pulvilliform, but, with the pulvilli, often minute.

But four species of this small family are known from the United States, and they will be readily recognized by the accompanying cut of the wing of Rhynchocephalus volaticus Will. The habits of the larvæ of this family are known in but one species,

Hirmoneura obscura of Europe, where they are parasitic upon beetles.

Wing of Rhynchocephalus volations Will.—a, second submarginal, b, c, d, e, f, first—fifth posterior cells.

Proboscis long, directed backwards. Antennæ broadly separated.

Eyes bare. Ovipositor of the female composed of two slender diverging lamellæ. Three submarginal cells.

RHYNCHOCEPHALUS

HIRMONEURA Meigen, Syst. Beschr. II, 182, 1820. RHYNCHOCEPHALUS Fischer, Mem de la Soc. imp. d. natur. de Moscou, I, 217, 1806.

MIDASIDÆ.

Rather larger to very large, thinly clothed or bare, elongate flies. Neuration complicated; the basal cells long; the fourth longitudinal vein always terminating at or before the tip of the wing. Antennæ elongate, the third joint flattened, and composed of several distinct segments. Ocelli wanting. Proboscis with fleshy labella. Empodia very little developed, not pulvilliform.

Larvæ found in decaying wood, etc., probably carnivorous.

- A small cross-vein runs into the hind margin of the wing between the anal cell and the tip; hind tibiæ of female with spurs.

No such small cross-vein; hind tibiæ (?) without spurs.

LEPTOMIDAS

"Generis Ectyphi proximum, differt: antennis elongatis, segmento penultimo cylindrico, ultimo, \$\delta\$, circiter duplo longiore." compresso, basi parum dilatato, apice obtuse acuminate \$\mathbb{Q}\$, duplo breviore, obtusiore, abdominis segmento ultimo inermi, cyathiforuntrinque, parum dilatato. (Long. 20mm. undique niger, abdomine nitente, alis violaceo micantibus, extremo apice albidis.—P. phyllocerus, Rocky Mts.)

MIDAS Fabricius, Entom. Syst. IV, 252, 1794.
LEPTOMIDAS Gerstæcker, Stett. Ent. Z. 1868, 81.
ECTYPHUS Gerstæcker, Stett. Ent. Z. 1868, 92.
Phyllomidas Bigot, Bullet. Soc. Ent. Fr. 1879, 62.

BOMBYLIDÆ.*

Medium to small-sized flies; often with abundant, long, delicate pile. Antennæ usually short, composed of three joints, the third simple, with or without a terminal style. Ocelli present; eyes in the male separated or contiguous. Proboscis usually projecting from the oral cavity and slender; sometimes short, with broad labella. Legs moderately long, weak, with short bristles or spines; empodia rudimentary; pulvilli sometimes rudimentary. Wings often with dark markings; two or more submarginal, three or four posterior, cells present; anal cell closed in or near the border, or narrowly open.

Flower flies, found in the bright sunshine hovering over blossoms, or resting on sunny paths, sticks or stones, rarely on leaves. Larvæ, so far as known, parasitic upon hymenoptera and orthoptera; pupæ free.

The bifurcation of the second and third veins takes place opposite, or nearly opposite, the small cross-vein; the second vein forms a knee at its origin from the præfurca; the third vein in a straight line with the præfurca.
 3
 The bifurcation of the second and third veins takes place some distance before the small cross-vein, at an acute angle; the second vein does not form a knee at its origin from the præfurca.
 10
 Three or more submarginal cells.
 3
 Two submarginal cells.
 6

^{*} Table reproduced from Osten Sacken, Biologia Centrali-Americana, Diptera, p. 75, 1886.

3.	Four, sometimes five, submarginal cells. HYPERALONIA Three submarginal cells. 4
4.	Third joint of the antennæ elongate-conical 5 Third joint of the antennæ short, onion-shaped, with a very long style, not bisected by a suture 6
5	The conical third joint bears a more or less long style, separated by a distinct suture
6.	Proboscis long, projecting far beyond the oral margin. Stonyx Proboscis withdrawn within the oral cavity; rudimentary pulvilli
7.	The style of the third antennal joint distinctly bisected by a suture, and bearing a pencil of hairs at the tip. ARGYRAMORBA
	The antennal style not bisected, and with a microscopic bristle, but no pencil of hairs, at the tip
8.	Eyes of the male contiguous on the vertex; anal cell closed.
	• ASTROPHANES Eyes of the male not contiguous on vertex; anal cell open. 9
9.	The contact of the discal cell with the third posterior not much longer than its contact with the fourth posterior cell; proboscis long, projecting far beyond the oral margin; sides of the abdomen with a fringe of scales, and not of hairs only. LEPIDANTHRAX
	The contact of the discal cell with the third posterior at least twice as long as its contact with the fourth posterior cell, the latter contact often merely punctiform. Anthrax
10.	Body Anthrax-like; frontal triangle in the male large; frontal space in the female of a corresponding size
11.	Antenné approximate at the base; third antennal joint gradually attenuate
12.	Pulvilli distinct APHŒBANTUS Pulvilli none

13.	Body (antenne, thorax, abdomen) clothed with more scales than hairs, gibbose, the abdomen hanging down; antenne long,
	first joint unusually long
	Body clothed with hairs, or else nearly glabrous 15
14.	Four posterior cells LEPIDOPHORA Three posterior cells
10.	Four posterior cells
16.	First posterior cell closed
17.	Two submarginal cells
	First basal cell longer than the second
19.	Head comparatively small; the emargination of the occipital orbit almost imperceptible; contact between the second submarginal cell and the first posterior more than punctiform: BOMBY LUS
	Head comparatively large; the emargination of the occipital orbit distinct; contact between the second submarginal cell and the first posterior cell often only punctiform. Comastes
	Underside of the head moderately pilose, and hence its different parts (including the base of the antennæ, the oratedge, etc.) easily perceptible
21.	Two submarginal cells
•	Three submarginal cells
22.	Three submarginal cells
23.	Third antennal joint not truncate at the tip. ECLIMUS, EPIBATES Third antennal joint flattened, truncate at the tip
	Proboscis short PARACOSMUS
27.	Proboscis very long
	The rather narrow marginal cell very much expanded at the end.
	LORDOTUS
	The marginal cell only moderately expanded Ploas

"Q Gen. Geronis (auctor.) vel Dasypalpi (Macq. Dipt. Exot.) satis vicinum, præcipue differt antennarum palporumque conformatione.

"Corpore augustato, dorso thoracis gibboso, breviter et parce viliosulo; capite fere spherico, thorace angustiore; antennis basi anguste approximatis, fronte lata, parum prominula, genis, suborbita, angustissimis; proboscide rigido; porrecto, labris invisis antennas longitudine superante; palpis haustello subæque longis, gracilibus, porrectis, rigidis, fere cylindricis, segmento ultimo, viilosulo; antennarum, capite longiorum, segmentis duo basalibus abbreviatis, gracilibus, æquilongis, 3°, præcedentibus, simul sumptis, duplo longiore, oblongo, basi leniter dilatato, compresso, apice obtuso, superne villosulo, ad apicem leniter suiciolato, chæto inviso; alis, abdomine multo longioribus, cellulis posticis tribus, tribusque submarginalibus munitis, cunctis late apertis, anali ante marginem clausa, basali externa interna parum longiore, vena quarta longitudinali (Rondani) bifurcata, vena transversali externa, ante medium cellelæ discoidalis satis elongata, locata."

Rhadopselaphus

"Antennæ porrect, third joint when viewed from the side scarcely longer than wide, somewhat oval in outline, but tapering to the tip, which is blunt and bears a very short style, tipped with a short bristle; first joint longer than the second, but not one half so long as the third; first two joints of nearly an equal width, not more than one half as wide as the third at its base. Face retreating below, bare except on oral margin. Head a little thicker than long, wider than the thorax, and fully three-fourths as large. Thorax with bristles in front of wings and on hind angles. Scutellum rounded behind. Wings with two submarginal and four posterior cells, all of the latter open, as is also the third basal; small cross-vein near middle of discal cell; furcation of second and third veins occurs before proximal end of discal cell. All of the tibiæ provided with bristles; pulvilli pad-like."

THEREVIDÆ.

Rather small, elongate, bristly, predaceous flies. Eyes of the male contiguous; front in the female not excavated. Antenna composed of three joints, the third simple, with a terminal style, sometimes wanting. Proboscis moderately projecting, the labella broad. Ocelli present. Abdomen elongate; genitalia (3, 2) moderately or but little prominent. Legs slender, bristly; empodia wanting. Third longitudinal vein of the wings furcate, the posterior

branch terminating beyond the tip; five posterior cells; basal cells long, the third (anal) closed in the border.

Predaceous files, concealing themselves among the leaves of low bushes where they lie in wait for other insects. Larvæ long, snakelike, apparently composed of nineteen segments; those of the known species found in fungi or decaying wood; pupæ free.

Antennæ situated upon a frontal projection, the first joint elongate and more or less thickened, longer than the head.

XESTOMYZA

Front not projecting; first joint of the antennæ usually slender, when thickened, never longer than the head. . . . 2

XESTOMYZA Wiedemann, Nova Dipt. Gener 1820. THEREVA Latreille, Precis, etc. 1796. PSILOCEPHALA Zetterstedt, Ins. Lapp. 525, 1840.

SCENOPINIDÆ.

Small, slender, bare flies. Males usually holoptic; the front in neither sex excavated. Ocelli present. Antennæ composed of three simple joints, without style or bristle, the third joint elongate. Proboscis short, concealed. Legs rather short; empodia wanting. Third longitudinal vein furcate; three posterior cells, the first narrowed or closed in the margin; basal cells elongate, the first much longer than the second, anal cell closed before the margin.

Scenopinus Latreille, Hist. Nat. d. Ins. et Crust. XIV, 392, 1803.

ACROCERIDÆ.

Small to large, never elongate, pilose or bare species. Head small, or very small; thorax large, spherical; scutellum large; abdomen closely united to thorax, large and inflated. Antennæ two or three jointed, with or without a terminal bristle or style, inserted high up or low down. Eyes very large, contiguous in both sexes. Two, three, or no ocelli present. Proboscis rudimentary or very long. Legs rather stout; empodia developed pulvilliform. Tegulæ very

large, inflated.	Neuration variable, th	e veins sometim	es indistinct.
The flies belo	nging here will be read	ily recognized b	y the hunch-
back-like shape	e, very small head and	l large tegulæ.	. They are
not very commo	on, found in sweepings, o	ete. Larvæ, so i	ar as known,
parasitic upon s	piders or their cocoons.		

1.	Antennæ with a terminal bristle	
2.	. Antennæ inserted near the vertex	3
	Antennæ inserted near the mouth	4
3.	. Wings with a stout costal spur near the tip of aux	dilary vein.
		PTERODONTIA
	Wings without such spur; anal cell absent.	ACROCERA
4.	. Venation complete; eyes pilose	. Opsebius
	Veins more or less obsolete; eyes bare.	. Ocnæa
5.	Proboscis rudimentary	. Oncodes
	Proboseis elongate	6
6.	. Ocelli wanting; large flies	
	Ocelli present; smaller files

ONCODES Latreille, Precis, etc. 154, 1796.

LONCHOPTERIDÆ.

Small (2-4 mm.) slender, brownish or yellowish flies. Antennæ short, porrect, third joint simple, circular, with a terminal bristle. Ocelli present. Scutellum with two bristles. Legs long, short bristly; pulvilli very small; empodia wanting. Wings lancet-like, pointed; three basal cells of moderate size, of nearly equal length; fourth longitudinal vein furcate, and united with the fifth near the base.

The flies are met, often in abundance, in the grass or on the stones near the margins of shady brooks. The larve are but little known.

LONCHOPTERA Meigen, Illiger's Magaz. II, 272, 1803.

EMPIDÆ.

Rather small to very small, elongate, usually nearly bare, predaceous flies. Head small, usually round, attached by a free neck. Antennæ porrect; first two joints often very small; third joint variable in shape, simple, not annulate, with or without a terminal arists or style, or dorsal arista. Front not excavated. Eyes of male usually contiguous. Ocelli present. Proboscis short or elongate, adapted for piercing; porrect, vertical, or directed backward. Tegulæ small. Abdomen in the female pointed, in the male with more or less prominent genitalia. Legs very variable in structure, the coxæ and femora often in part thickened, elongate, or with various structural peculiarities, usually sexual; empodia not developed pulvilliform. Wings variable in neuration; the discal cell often wanting, as also the anal cell; one to three submarginal cells present.

The flics in their habits are very much like the Asilidæ; they are often observed in swarms about brooks. The larvæ live in decaying vegetable matter. Pupæ free.

DOLICHOPODIDÆ.*

Usually metallic green or blue flies of small size; active, predaccous, found on vegetation or in damp situations. Head hemispherical, eyes large, rarely contiguous in the male. Front with bristles on the vortex only; ocelli present. Antennæ porrect; third joint

^{*}The family characters and table are reproduced from Loew's Monograph of the family (Smithsonian Institution, 1863), to which the reader is referred for further information.

simple with a terminal or dorsal arista. Proboscis short and stout. Hypopygium of male usually inflected under the abdomen, and composed of two consecutive parts, bearing at the end eight paired and two single appendages. The auxiliary vein terminates in the first longitudinal vein; third longitudinal vein not furcate; second basal cell united with the diseal cell; anal cell small; three posterior cells. Legs more or less bristly, in the male usually with structural differences; empodia not developed pulvilliform.

Larvæ found in the ground, or in decaying vegetable matter.

ľ	upæ tree.

sm lat of his	"First antennal joint bristly above, second sall, with an extraordinarily elongated dorsal hed shovel-shaped at the end. Face descending the eyes. Hind femora in front with only oned metatarsi unarmed. Hypopygium free; the nelliform. Last section of the fourth longitu	rudimentary, third oristle, which is di- g below the angle opreapical bristle; exterior processes

SYRPHIDÆ.

convergent toward the third, so that the terminations of the two veins are close together. M. (Tachytrechus) mæchus Loew."

Rather large to rather small, thickly or thinly pilose, often brightly colored flies. Ocelli present; males holoptic or dichoptic. Third joint of antennæ simple; with a dorsal bristle, or rarely a terminal style. Abdomen very variable in shape. Legs often with structural sexual peculiarities; empodia not developed. Three basal cells of wing large; first posterior cell closed near or at some distance before the margin of the wing; between the third and the fourth longitud-

inal veins, and subparallel with them, crossing the anterior cross-vein, a false or spurious vein, nearly always present, and characteristic; face without subantennal grooves.

Flower-flies, usually only to be found in bright sunshiny weather. Larvæ found in decomposing organic matter, under bark, in soft mud, etc.; pupæ enclosed in the larval skin, the fly escaping through a circular anterior orifice (Diptera cyclorrhapha).

a ci	rcular anterior orifice (Diptera cyclorrhapha).
1.	Antennæ with a terminal style
2.	Antennæ cylindrical, first two joints elongate Ceria First two joints short, third compressed Pelecocera
3.	Marginal cell of the wing closed and petiolate
4.	Anterior cross-vein of the wing distinctly before the middle of the discal cell, usually rectangular
5.	Antennæ elongate , ,
6.	Dorsum of thorax without yellow lateral stripes 7 Dorsum of thorax with yellow lateral stripes; large species. Chrysotoxum
7.	Face rounded, pilose, not tuberculate, oral margin not projecting
8.	Large species; scutellum flattened, usually with spines or tubercles; a stump of vein in the first posterior cell from the third longitudinal vein
9.	Body clothed with sparse tomentum; all the femora thickened and with a row of short spines below (see, also, Myiolepta strigilata)
10.	Face tuberculate below, partly or wholly yellow; epistoma receding; face and front not wrinkled. PARAGUS Epistoma projecting; front and face black

Abdomen oval or slender, not spatulate or club-shaped.

NORTH AMERICAN DIPTERA.

49

22. Hind femora slender; abdomen elongate, usually slender toward the base; front of female long, narrowed above. Вассна
Hind femora thickened
23. Epistoma produced anteriorly, in profile deeply concave from antennæ to oral margin; third joint of antennæ rounded. Sphegina
Epistoma produced more downward, in profile gently concave; third joint of antennæ not rounded NEGASCIA
24. Abdomen with definite yellow cross-bands, interrupted or entire
25. Hind femora extraordinarily thickened SYRITTA Hind femora slender
26. Sixth abdominal segment in the male as long as the two preceding together, cylindrical; fifth segment in the female one-half as long as the preceding. Sixth segment not peculiar; the fifth segment in the female one-
third or one-fourth as long as the preceding 27
27. Front very convex; eyes of male with an area of enlarged facets above
Front not remarkably convex
28. Third longitudinal vein with a distinct curvature into the first posterior cell; third joint of antennæ elongate oval. DIDEA Third longitudinal vein straight or gently curved; epistoma not produced (if produced in a long porrected snout, Rhingia.) Syrphus
29. Dorsum of thorax with a median cinereous line. MESOGRAPTA Dorsum without such line
30. Eyes of male with an area of enlarged facets above; fourth segment of abdomen with two median yellow stripes and an oblique side spot
81. Face projecting below; slender species Sphærophoria
Face receding; abdomen oval, at least not slender.
Xanthogramma
32. Abdomen oval, black, basal portion light-colored; thickly pilose
species Leucozona
Thinly pilose species, not so marked

	NORTH AMERICAN DIPTERA. 51
33 .	Hind femora thickened
34.	Species wholly or chiefly reddish or lutescent
	Scutellum unusually large, nearly square in outline; males dichoptic
36.	Face carinate; abdomen oval BRACHYOPA Face produced, obtusely tuberculate. HAMMERSCHMIDTIA
37.	Epistoma produced into a long porrected snout RHINGIA Epistoma not at all produced
38.	Third longitudinal vein bent deeply into the first posterior cell
39.	Arista feathery plumose Volucella Arista very densely plumose, appearing like a solid mass. COPESTYLUM
40.	Hind femora with sharp tooth-like projection below near the outer end; large species
41.	Frontal triangle of male strongly protuberant. Dollosyrphus Frontal triangle not protuberant
42.	Thorax with distinct yellow markings; femora thickened; hypopygium large
43.	Arista plumose
44.	Thinly pilose, abdomen with yellow bands Sericomyia Thickly pilose, abdomen without yellow ARCTOPHILA
45.	Third longitudinal vein bent deeply into the first posterior cell; hind femora thickened
46.	Face with a sharp longitudinal ridge in the middle; hind femora with an angular protuberance below near outer end. TROPIDIA

	Face tuberculate or arched, not carinate 47
47.	Thorax and scutellum very densely pollinose above.
	PTERALLASTES
	Scutellum not densely pollinose above
48.	Third joint of antennæ broad, thorax not vittate
49.	Thickly pilose
50 .	Hind tibiæ of male with an internal median spur.
	Hind tibiæ of male not with an internal median spur. POLYDONTA
51 .	Hind femora thickened, with a bifld spur below on outer end. STENOGASTER
	Hind femora not with a bifid spur below
52.	Slender species, abdomen narrowed on basal portion. BACCHA Abdomen in no wise club-shaped or narrowed basally 53
53.	Thorax with distinct yellow markings other than on the humeri
54.	Face transversely arched or carinate, not produced, not tuber- culate; abdomen more or less elongate and nearly bare. 55 More or less thickly pilose species, often large. 57
55.	Hind femora extraordinarily thickened; anterior cross-vein rectangular
56.	Face sharply carinate TROPIDIA Face transversely arched XYLOTA
57.	Scutellum, margin of the thorax, and the pleuræ with bristly hairs
58.	Face short, not produced, concave from antennæ to tip, not tuberculate; hind femora thickened
50	Abdomen elongate
00.	Abdomen very broad, thorax densely pilose, very large species. Pocota

 Face produced forward, pointed, concave from antennæ to tip, not tuberculate, sub-carinate; hind femora thickened.

CRIOPROBA

Face not evenly concave, tuberculate or convex. . .

- 61. Third joint of antennse produced above into a conical process, terminating in the thickened arista.

 MERAPIOIDES
 Third joint of antennse obliquely oval; hind femora rarely thickened.

 CRIORRHINA
- 63. Antennæ inserted low down, near the middle of the head in profile; face not longer than the front. . Temnostoma Antennæ situated high up, on a conical process, front short, face much produced downward; antennæ long or short.

SPHECOMYIA

LEPIDOSTOLA Mik, Wien. Ent. Zeit. V. 278, 1886. (Lepidomyia Loew, Lepromyia Will.)

HAMMERSCHMIDTIA Schummel, Oken's Isis, 1834, p. 740. (Exochila Rond., Eugeniamyia Will.)

(For descriptions of genera and species, see Williston, Synopsis, etc. Bull. U. S. National Museum No. 31, 1886[7].)

CONOPIDÆ.

Thinly pilose or nearly bare, more or less clongated species. Head broad; front broad in both sexes; occili present or absent. Anteunæ porrect, composed of three simple joints, the third with a dorsal arista or terminal style Oral opening large; proboscis slender. Abdomen more or less clongated, often constricted toward the base. Basal cells of wing usually large, the third (anal) closed; three posterior cells, the first closed or much narrowed; no spurious vein. Flower flies. Larvæ parasitic upon hymenoptera and orthoptera.

Pupe enclosed in larval skin (cyclorrhapha).

Antennæ with a terminal style; proboscis directed forward, without medium hinge; abdomen constricted toward the base.

^{*} If thinly pilose, with the abdomen nearly bare, and the hind femora thickened, see Xylota tuberans.

Antennæ with a dorsal or subdorsal arista 4
2. Face with a median ridge, without X-shaped grooves.
O'TROPIDOMYIA WILL.
Face with a well-marked A-shaped groove
3. Femora and tibiæ not thickened or dilated, or, if so, the thickening regular; small cross-vein of the wings nearly opposite the tip of the auxiliary vein, and near the middle of the discal cell
Femora irregularly thickened toward the base, the tible with irregular outlines; small cross-vein of wings near the outer third of discal cell
4. Proboscis directed forward, not bent near the middle. Zodion Proboscis bent near the middle, the distal part folding back. 5
5. Vertex with bristles; tiblæ spurred; face carinate, not grooved; ovipositor of female very long Stylogaster Vertex and tiblæ without bristles; face with x-shaped groove. 6
6. Anal cell short; ovipositor elongate and folded beneath the abdomen
7. Cheeks not as broad as the vertical diameter of the eye.
ONCOMYIA
Cheeks as broad or broader than the vertical diameter of the eye.

PIPUNCULIDÆ.

[For description of species, see Williston, Trans. Connecticut Acad. VI, 377.]

Small, thinly pilose or nearly bare species. Head nearly spherical, broader than the thorax, composed chiefly of the very large eyes. Eyes in the male contiguous, front in the female narrow.

Antennæ small, short, three-jointed, the third joint oval or reniform, with a dorsal arista. Face small, narrow. Proboscis small. Hypopygium thickened, clubbed; ovipositor usually elongate and folded under the abdomen. Basal cells of wing well developed, the third elongate; one submarginal, three posterior cells present; first posterior cell narrowed in the margin.

The flies are met with on flowers or in sweepings, and are readily distinguished by their large spherical head. Larvæ parasitic; pupæ obtected.

PLATYPEZIDÆ.

Head hemispherical or spherical, as broad or broader than the thorax. Face usually broad and short. Antennæ porrect, three-jointed, the third somewhat elongate, circular, pear-shaped or conical, with a terminal arista. Proboscis short, but little prominent. Eyes bare, contiguous in the male; ocelli present. Abdomen comparatively short; genitalia projecting in Callomyia. Legs short and strong; hind legs often thickened, especially the tarsi; pulvilli present. Basal cells of wing small, the anal usually reaching to the margin; third longitudinal vein simple, the fourth sometimes furcate; discal cell sometimes wanting. Small flies.

1.	Discal cell present.	•				•		2
•	Discal cell wanting.	•		•				3
2.	Fourth longitudinal Fourth vein furcate.		-					
3.	Fourth vein simple. Fourth vein furcate.							

CALLOMYIA Meigen, Klassif. 1804.

PLATYPEZA Meigen, Illiger's Mag. 1803.

PLATYCNEMA Zetterstedt, Dipt. Scand. I, 1842.

ŒSTRIDÆ.

Moderately large to large, plump, thickly or thinly pilose flies. Head large; face and front broad. Antennæ small, three-jointed, more or less concealed in a subantennal cavity or grooves; first two

joints very short, the third round or oval, with a dorsal arista. Mouth opening small, the mouth parts small or rudimentary. Eyes comparatively small, bare. Occili present. Abdomen never elongate; hypopygium concealed; ovipositor often projecting. Legs moderately strong, the hind pair sometimes elongate. Tegulæ usually large, concealing the halteres; sometimes small, and long ciliate. Wings usually with fine transverse wrinkles; third vein simple; first posterior cell fully or narrowly open, or closed and petiolate; basal cells small; discal cell sometimes wanting; the posterior part of the wings broadly unsupported by veins.

Bot flies, parasitic in the larval stage in the skin, stomach, frontal or pharyngeal cavities of perrisodactyls, artiodactyls, rodents, elephant, monkeys, etc. Each species is parasitic in the same way, and, as a rule, on the same species of mammal; and allied species usually have similar habits, on allied animals. The occurrence of bot-flies on other than mammals needs verification. Pupal stage

passed in the ground.

1.	First posterior cell wide open, the fourth vein running straight to the border of the wing. (Horses.) Gastrophilus First posterior cell narrowed or closed, the fourth vein distinctly bent forward.
2.	First posterior cell closed and petiolate. (Sheep.). OESTRUS First posterior cell narrowly open
3.	Arista plumose on the upper side. (Rodents.) . CUTEREBRA Arista bare; pilose species
	Subantennal grooves separated by a median ridge, terminating in a shield-shape surface below, limited on each side by a slender groove running to the oral margin. Subantennal grooves continuous to the oral margin, feebly separated from each other. (Deer.) CEPHENOMYIA
5.	Palpi present. (Reindeer.) OEDEMAGENA Palpi wanting. (Oxen. etc.)

Gastrophilus Leach, 1817. Hypoderma Clark, Essay on Bots, 1815. Oedemagena Latreille, Fam. Nat. 1825. Oestrus Linne, Fauna Succica, 1761. Cephenomyia Latreille, Fam. Nat. 1825. Cuterebra Clark, Essay on Bots, 1815.

MUSCIDÆ.

The very large family of Muscidæ has been divided into numerous subdivisions, which by some entomologists are accredited with family rank. The number and limits of these sub-families, are more or less the subjects of diverse opinion by dipterologists. The following characters will apply to the family in its entirety: Antennæ three jointed, the third joint simple, usually round or oval, with dorsal arista. Proboscis always present, usually short, with dilated labella, sometimes elongate and adapted for piercing. Auxiliary vein sometimes entirely wanting, sometimes coalescent with the first longitudinal vein; one submarginal, three posterior cells present; basal cells small, the second sometimes coalescent with the diseal, the latter sometimes absent; pulvilli present; empodia never developed pulvilliform.

The flies are often small, or minute, usually more or less bristly, and not often much pilose. The larvæ are very variable in their habits; pupæ always enclosed in the larval skin.

Two ehief divisions are recognized, based upon the size of the tegulæ, the Muscidæ calyptratæ and acalyptratæ. In the former they are well developed, in the latter small or rudimentary. All the families of the former (except the Anthomyidæ) have the first posterior cell either closed or narrowly open, a character rarely found in the second division.

The differential characters of the calyptrate have already been given. The flies have hitherto received but little study in this country and it is at present impossible to give a table of the genera that would be of much value.

For the Muscids acalyptrate I am prepared to give only a translation, with some modifications, of Schiner's table of subfamilies (Fauna Austriaca), with a reproduction of the characters given by Loew in his Monographs.

MUSCIDÆ ACALYPTRATÆ.

- 1. Auxiliary vein present, distinctly separated from the first longitudinal vein, terminating separately in the costa; the first longitudinal vein usually terminates at or beyond the middle of the wing.
 - Auxiliary vein absent, rudimentary or incomplete; the first longitudinal vein usually terminates before the middle of the wing.

~	2.	Anterior border of the mouth with vibrissæ
	3.	The distance between the anterior and posterior cross-veins (on the fourth vein) four or five times less than that between the posterior cross-vein and the posterior margin of the wing. HETERONEURID.E
		The distance between these veins but little less or greater than that to the hind margin
	4.	Abdomen elongate, usually cylindrical, narrowed at the base, behind somewhat decurved; male genitalia usually clubbed, projecting from the abdomen
	5.	Front on the sides, and the vertex, with long bristles.
		CORDYLURIDE C Vertex, only, with long bristles; body always shining black. SEPRIDE Not M. A. Skill
.!	8.	Proboscis horny, shining; labella usually pointed; third antennal joint elongate; males often woolly pilose. Cordylurida O Proboscis not horny or shining; third antennal joint short or round; males never woolly pilose.
	7.	Antennæ much elongate, and porrect; second joint as long or
		Antennæ not elongate, or, if so, decumbent; second joint always shorter than the third.
	8.	Two posterior basal cells very small and indistinct.
		Lonchæidæ, Sapromyzidæ
-		Posterior basal cells large and very distinct 9
1	9.	Hind tibiæ with a preapical bristle
1	0.	Front with bristles on the sides; the auxiliary vein terminates steeply in the costa
-1	1.	Legs elongate, often very long; abdomen slender and long, nearly cylindrical, often narrowed, or pedicellate at base. 12 Legs not elongate; abdomen never narrowed at base. Ortalidate

12.	First posterior cell much narrowed in the margin. MICROPEZIDE First posterior cell but little or not at all narrowed in the margin. SEPRIDE
13.	Hind metatarsi shorter than the following joint and much thickened. BORBORIDE O Hind metatarsi longer than the following joint and not more thickened.
14.	Second basal cell united with the discal cell; posterior crossvein present
15.	Legs long and slender; abdomen elongate and narrow. MICROPEZIDÆ Legs moderately long and usually rather strong; abdomen ovate, or elongate elliptical
16.	Front without bristles, or, at most, bristly at the top; third joint of antennæ rounded, or, if elongate, the head triangular in profile. OSCINIDÆ Front bristly at least as far as the middle; third antennal joint elongate, oval, or rounded; head not triangular in profile. 17
17.	Face large; mouth opening large; anal cell wanting. EPHYDRIDÆ Face not large and arched; anal cell present. Drosophilidæ
18.	Oral vibrissæ present
19.	Front bristly at the vertex only, or not at all Sarsing Prophelicles Front bristly at least as far as the middle 20
20.	Posterior cross-vein before the middle of the wing, approximated to the anterior cross-vein
21.	Arista long plumose or pectinated. ASTEIDÆ, DROSOPHILIDÆ Arista shortly and thickly plumose, or pubescent, or bare,
22.	Anal cell of considerable size and distinct
23.	Front bristly

Not M. A. She

0

8

E B E

e E y

2

23. Silvery white or whitish gray species with unspotted wings; . . PHYTOMYZIDÆ)\d) posterior cross-vein wanting. Reddish yellow or brownish red species, often with spotted

CORDYLURIDÆ.

Neuration of the wings complete; both posterior basal cells of considerable size; auxiliary vein well separated from the first longitudinal vein; first longitudinal vein bare. Whole lateral border of the front bristly; anterior border of the mouth with strong, usually numerous vibrissæ. Tibiæ with spurs.

HELOMYZIDÆ.

Neuration of the wings complete; costa bristly; first longitudinal vein not abbreviated, but bare; the auxiliary vein is often rather approximated to it. Front bristly on its upper half only; a stout bristle at each side of the anterior border of the mouth. All the tibiæ with spurs and outwards before their tips with a more or less developed erect bristle.

SCIOMYZIDÆ.

Neuration of the wings complete; two posterior basal cells of rather considerable size; auxiliary vein well separated from the first longitudinal vein. On the lateral border of the front before the vertical bristles there are two bristles, one behind the other; face proportionately long without distinct furrows for the antennæ; border of the mouth sharp, without vibrissæ. Middle tibiæ with a greater number of bristles at the tip; all the tible on the outside before the tip with a small erect bristle

PSILIDÆ.

Body elongated, with short hairs and almost without bristles. Neuration of the wings complete; the auxiliary vein lies close by the first longitudinal vein, but diverges from it at its end and runs towards the border of the wing; by a transverse fold most characteristic in this family running from the tip of the auxiliary vein as far as the base of the third posterior cell, the outward end of the auxiliary vein is obliterated; the posterior basal cells are very large. Front with only a few bristles in the neighborhood of the crown; face receding; opening of the mouth small and with no bristles at its border. Only the middle tibiæ have spurs, and all the tibiæ are without erect bristle on the outside.

MICROPEZIDÆ.

Body slender, elongated, with very short hairs and very scarce bristles. Legs proportionately short; only the middle tibiæ have spurs, these being generally very small and weak; no small erect bristle on the exterior side of the tibiæ. Neuration of the wings

complete; first longitudinal vein bare; the auxiliary vein is very close by it and diverges from it towards its end only; the two posterior basal cells are very large. From with some bristles in the neighborhood of the crown only; bordering of the mouth without vibrisse. Last segment of the abdomen of the female prolonged into a blunt, cylindrical tube.

ORTALIDÆ.

Neuration of the wings complete; auxiliary vein separated from the first longitudinal vein and running to the border of the wing in the usual way, under an acute angle and remaining perfectly distinct in its whole length; third longitudinal vein generally with coarse hairs; two posterior basal cells large, and the outward one frequently prolonged in an acute angle. Front with bristles on the upper part only; no vibrisses at the border of the mouth; clypeus commonly very much developed, and proboscis often very much thickened. Middle tibiæ alone with spurs; no tibiæ with an erect bristle on the exterior side before the tip. Ovipositor of the female rather flattened and horny, consisting of three elongated segments, forming three drawers like those of a telescope, and ending in a simple point.

TRYPETIDÆ.

Neuration complete; the end of the auxiliary vein runs steeply to the border of the wing and becomes obsolete; first longitudinal vein aways with bristles, the third frequently, the fifth sometimes; two posterior basal cells rather large, the hindmost is often prolonged to a point. Front on each side with two rows of bristles, one of which is more above and interiorly, the other below and exteriorly. Border of the mouth with no vibrisse. Clypeus none or rudimentary. Proboscis never incrassated. Only the middle tibise with spurs; all tibize without erect bristle on the outer side before the tip. Ovipositor horny, consisting of three elongated retractile segments like the drawers of a telescope, the last of which ends in a simple point.

LONCHÆIDÆ.

Neuration complete; the auxiliary vein runs to the border of the wing in the usual way, under an acute angle and without becoming obsolete, and is verv near to the first longitudinal vein; this vein is bare; the two posterior basal cells are small. Front at each side with a single row of bristles; border of the mouth without vibrissæ; clypeus rudimentary. Middle tibiæ with spure; all tibiæ without creet bristle on the exterior side before the tip. The ovipositor of the female consists of three joints and is rather horny, quite flattened, and ends in a simple point.

SAPROMYZIDÆ.

Neuration complete; auxiliary vein of the usual structure, frequently very much approximated to the first longitudinal vein; costa of the wings without bristles or marginal spine; longitudinal veins without peculiar hairs; posterior basal cells small. Front with a

No,

single row of bristles on each side; no vibrisse on the border of the mouth; clypeus rather rudimentary. Only the middle tible have terminal spurs; all tible with a small erect bristle on the exterior side before the end. Ovipositor of the female not horny.

PHYCODROMIDA.

Thorax, scutellum and abdomen flat; pleurs excised above the coxs. Front bristly; border of the mouth hairy, with no distinct vibrissse. Legs stout, tibis with spurs and each with an erect hair or small bristle on the outside before the tip; the first joint of the posterior tarsi not abbreviated; last joint of all tarsi enlarged, with stout claws and long pulvilli. Neuration of the wings complete; auxiliary vein distinct in its whole length; costa without bristles; bassi cells not small.

HETERONEURIDÆ.

Neuration of the wings complete, but the first longitudinal vein rather short, and the auxiliary vein very much approximated to it; costa without bristles; basal cells smail. Front with long bristles; border of the mouth with a vibrissa at each side; clypeus not developed; palpi broad and proportionately large. Legs, and especially the tarsi, slender; middle and posterior tarsi with spurs; all the tibize without erect bristle on the exterior side before the tip; claws and pulvilli very small.

OPOMYZIDÆ.

Front with stout bristles above; clypeus rudimentary; border of the mouth either pubescent or with long hairs, the foremost of which sometimes forms a distinct vibrissa. Proboscis short; palpi rather smail. Middle tiblæ with a distinct, posterior tibiæ with a very short spur; the exterior side of the tiblæ without erect small bristle before the tip; claws and pulvilli small. Wings elongated and narrow, with no bristles on the costa; the axillary incision and alulæ are either wanting or very diminutive. First longitudinal vein much abbreviated; the auxiliary vein becomes obsolete before reaching completely the first longitudinal vein; the latter emits, shortly before its end, towards the costa, a branch, which may be considered as the end of the auxiliary vein; basal cells small.

SEPSIDE.

Head rounded; front bristly; border of the mouth more or less hairy, the foremost hair often imitating a vibrissa; clypeus rudimentary; proboscis short; palpi evceedingly small or wanting. Abdomen tapering towards the base. Middle tibiæ with distinct spurs; claws and pulvilli small. Neuration of the wings complete; the auxiliary vein distinctly separated from the first longitudinal vein; the two posterior basal cells rather large.

DIOPSIDÆ.

Neuration of the wings incomplete from the absence of the foremost of the two small basal cells; the auxiliary vein very much approximated to the first longitudinal vein. Head prolonged in two lateral apophyses bearing the eyes; front bristly only on the upper part; border of the mouth with no vibrisses. Anterior femora increassated.

PIOPHILIDÆ.

The auxiliary vein, on its whole length, is coalescent with the first longitudinal vein; with this exception the neuration of the wings is complete. Front with some small bristles above only; border of the mouth with a vibrissa on each side; clypeus rudimentary; legs rather stout, almost of the structure of those of the Sciomyzide; middle tible with spurs; all the tible without erect bristle on the exterior side before the tip.

EPHYDRIDA.

Face convex, with no distinct furrows for the reception of the antennæ and without vibrissæ, though frequently beset with hairs or bristles; clypeus very much developed; opening of the mouth large; proboscis incrassated with a swollen chin. Neuration of the wings incomplete; the auxiliary vein distinct only at its base; the foremost of the two small basal cells reunited with the discal cell. Middle tibiæ with spurs.

GEOMYZIDÆ.

Front with stout bristles above; border of the mouth with vibrisse. Clypeus rudimentary. Middle tibiæ with spurs; all the tibiæ with a small erect hair on the exterior side before the tip. Wings with bristles on the costa; first longitudinal vein exceedingly abbreviated, and the auxiliary vein so approximated to it that it is distinctly separated from it only towards the base; the two posterior basal cells very small.

DROSOPHILIDÆ.

Front with bristles above; face with distinct sub-antennal furrows; at the border of the mouth there is a feeble, frequently rather indistinct small vibrissa. Middle tibiæ with very feeble spurs; on the exterior side of the tibiæ there is either a very small or no erect bristle before the tip. Wings without bristles on the costa; the first longitudinal vein is exceedingly abbreviated; of the auxiliary vein there is only a rudiment; the discal cell is usually, but not in all genera, united with the foremost of the two small basal cells. Claws and pulvilli very small.

OSCINIDE.

Front without bristles, the crown having only a few short ones; border of the mouth without vibrissæ, which, however, are represented sometimes by a small hair on each side. Middle tibiæ with small spurs; all the tibiæ without erect bristle on the exterior side before the tip. Costa of the wings without bristles. The auxiliary vein is completely wanting; the anterior of the two small basal cells is united with the discal cell, the posterior one is totally wanting.

AGROMYZIDÆ.

Front with strong bristles; border of the mouth with a vibrissa on each side. Middle tibiæ with a terminal spur; all the tibiæ on the exterior side without erect bristle before the tip. Wings without bristles on the costa; first longitudinal vein very short, and the auxiliary vein connected with it at the tip; basal cells existing, but small; posterior transverse vein generally far distant from the border of the wing.

PHYTOMYZIDÆ.

Front bristly; border of the mouth with vibrisse on each side. Middle tible with spurs; all the tible without erect bristle on the exterior side. Wings without bristles on the costa; first longitudinal vein very short; auxiliary vein connected with it at the tip; basal cells existing, but small; posterior transverse vein wanting.

ASTEIDA.

Front bristly above; border of the mouth with a vibrissa at each side. Middle tibiæ with spurs; all the tibiæ without erect bristle on the exterior side. Wings without bristles on the costa; first longitudinal vein exceedingly short; auxiliary vein connected with it only at the tip; second longitudinal vein very short; two posterior basal cells as well as the posterior transverse vein wanting.

BORBORIDÆ.

Thorax, scutellum, and abdomen flat; front bristly; face excavated, with a vibrissa on each side of the border of the mouth; clypeus developed; first joint of the posterior tarsi abbreviated. Neuration of the wing incomplete, only a commencement of the auxiliary vein being at best visible; the hindmost two basal cells are not complete in all genera.

PHORIDÆ.

Small, hunchback-like, nearly bare species. Head small, flattened; face very short, oral opening large. Front broad in both sexes; ocelli present. Antennæ apparently one or two-jointed, the terminal joint round, with a dorsal of apical bristle. Abdomen rather short, narrowed posteriorly; genitalia of male often prominent, in the female projecting. Coxæ elongate, the femora more or less, the hind pair often extraordinarily, widened and flattened. Wings large; on the anterior part with two strong veins, not reaching beyond the middle, from which from three to five weak veins apparently arise and run across the wing.

The larvæ feed upon living or dead snails, beetles, hymenoptera and lepidoptera, or on fungi, decaying vegetables, etc. The flies have a peculiar hunchback appearance, rapidly running hither and thither.

1.	Front entirely without brist	tles			GYM	orn	ORA
	Front with long bristles.			•			2

HIPPOBOSCIDÆ.

Head depressed, flattened, closely attached to the emarginate thorax. Antennæ inserted in depression near the oral margin, apparently one-jointed, with a terminal bristle or style. Face short. Eyes small; ocelli present or absent. Thorax depressed, flattened, leathery, with a well-marked transverse suture. Scutellum broad and short. Abdomen oval, flattened, horny above. Legs short and strong, broadly separated by the sternum, the femora dilated; tarsi short and broad, the first joint of the four anterior, or of all, abbreviated; claws strong and well developed, often toothed below. Wings sometimes absent; when present, with variable neuration, the veins on the front part usually strong, and those posteriorly weak.

The flies are parasitic in their adult stage upon mammals and birds; the immature stages are completed within the body of the female, the large puparium being extruded only a little before the time for the mature fly to emerge.

1.	Wings wholly wanting MELOPHAGUS
	Wings present, functional, or rudimentary 2
2.	Claws below with three teeth; ocelli present. ORNITHOMYIA
	Claws with two teeth; ocelli usually wanting 3
8.	Wings rudimentary, or, if present, with weak and indistinct veins LIPOPTENA Wings large, the veins in front strong
4.	The furcation of the second and third veins at or beyond the middle of the wing. The furcation of the second and third veins takes place near the base of the wing. OLFERSIA

OLFERSIA Wiedemann, Auss. Zweifl. Ins. II, 1830.

· NYCTERIBIDÆ.

Wingless, pupiparous flies, parasitic upon bats in the adult stage. Head small, eyeless, folding bace into a groove on the dorsum of the thorax. Legs long, spider-like; claws well developed.

· NYCTERIBIA.

NYCTERIBIA Latreille, Hist. Nat. des Crust. etc., XIV, 1804.

Writers on systematic dipterology of the present time, whose works should be consulted:

MEADE, VERRALL, England; BRAUER, MIK, Austria: BERGROTH. GIRSCHNER, HANDLIRSCH, KARSCH, OSTEN SACKEN, ROEDER, GELDANY; KOWARZ, HUNGARY; DZIEDZICKI, SCHNAHL, POLAND; VAN DER WULP, Holland; PORTSCHINSKY, Russia; BIGOT, GOBERT, FRANCE; COQUILLETT, WILLISTON, North America; Enrique and Felix Lynch Arrihalzaga, South America.

Writers on economic entomology, whose works contain important references to American diptera:

COMSTOCK, New York; COOK, Michigan; FORBES, Illinois; LINTNER, New York; RILEY, U. S. Agricultural Department.

ADDENDA AND CORRIGENDA.

EXOPTATA Coquillett, Can. Entom. XIX, 13, 1887.—Bombylidæ. "Third antennal joint furnished with a distinct terminal style; second vein issues from the third opposite or nearly opposite the small cross-vein; anterior branch of the third vein connected by a cross-vein with the second, forming three submarginal cells; first posterior cell divided into two cells by a cross-vein placed some distance before tip of diseal cell; anterior branch of third vein and veins 2, 3, and 4 terminate in margin of wings; no pulvilli." Differs from Exoprosopa in having two first posterior cells.

ENOPLEMPIS Bigot, Bull. Soc. Ent. Fr. 1880, 62.—Empidæ.

"Generis Empidis proximum, maxime differt: Femoribus posticis robustis, subtus, apice, profunde mucronatis et unidentatis, tibiis intus, basi similiter mucronatis et unidentatis, dentibus villosulis,

crassis. E. mira.—Testaceo fulvo; antennarum apice, haustello, femoribus posticis superne, thoracis lineis quinque, lateralibus interruptis, fuscanis; alis flavidis. Calif."

MEGACYTARUS, Blgot, l. c.-Empidæ.

"Quanquam abest ab antennis. Generis Ocydromyise vicinum, differt: Cellulis basalibus abbreviatis, et, discoidali longissima, lata, subtrigona, vena transversali, fortissime sinuosa et alarum marginis posticis proxima, clausa. M. argenteus.—5mm. Cinereus, vittis quatour thoracis, haustello, pedibus totis, abdominis extremo apice, alarum macula stigmaticali minuta, nigris; abdomine argenteo, alis hyalinis. Colorado."

Hypocharassus Mik, Verh. Zool. Bot. Gesellsch. 1878, 627.—Dolichouodidæ.

"& Hypostoma latum, sub oculos descendens absque tænia transversali elata, in parte inferiore convexum. Palpi exserti latiusculi, obtusi, proboscidi crassæ, obesæ incumbentes. Antennæ elongatæ: articulo primo superne setoso, secundo transverso, tertio lanceolato, subtus exciso: seta apicali crassa, styliformi, biarticulata, articulo primo brevi, secundo longiore ante apicem subincrassato. Frons latissima, hypostomate brevior. Oculi velutini. Thoracis dorsum setulis dense obsitum, setis dorsalibus interioribus nullis, ante scutellum non impressum. Scutellum seti quatuor marginalibus validioribus. Abdomen segmentis sex, subdepressum, postice obtusum; ante incisuras setis nullis. Hypopygium inclusum, appendicibus lamellatis, prominulis. Pedes validi: femoribus posticis setis præapicalibus nullis, metatarsis posticis setis nullis, elongatis; pulvillis anticis reliquis paullulum majoribus. Coxæ posticæ seta porrecta nulla. Alarum costa usque ad apicem nervi longitudinalis quarti ducta; nervus longitudinalis tertius et quartus arcuati, apicem versus convergentes; nervus longitudinalis sextus abbreviatus; nervus transversalis porterior segmento ultimo nervi longitudinalis quinti longior."
