PREFACE

BY COLONEL SABINE, R.A.

THE observations of Admiral Löwenorn, in 1786, at Reikiavik in Iceland, confirmed by Lottin in 1836, and those made by myself in 1823 at Fairhaven in Spitzbergen, also confirmed by the observations of the "Commission du Nord" at Magdalena Bay in Spitzbergen, in 1839, showed that, in the high magnetic latitudes of the northern hemisphere, the horary variation of the magnetic declination is subject to wide differences in respect of the turning hours, and the direction of the movement at the same hours of local time, from the phænomena which in the middle latitudes of the same hemisphere are found to prevail generally, and, with very slight The progress which, since the modifications, in all meridians. results of the magnetic observatories established in the last few years have been known and discussed, has been made towards the physical explanation of many of the magnetic phænomena, renders it desirable that facts which at first sight, and to minds accustomed to the comparative regularity of the diurnal variation elsewhere, have somewhat the aspect of anomalies, should be more extensively investigated and better understood. The differences which they present from the ordinary march of the phænomena are far too considerable and too consistent to be ascribed to accident: they are obviously specialities; and the particular laws which govern them will no doubt ultimately be found to be consistent with, and to form, in fact, a part of, the general laws by which the diurnal variation in all parts of the globe shall be comprehended.

But the parts of the globe where such observations can be made are little frequented, and are difficult of access; and the observations cannot be effectively made without considerable sacrifices of personal convenience. The Magnetic Survey of the British Possessions in North America—undertaken by Her Majesty's Government at the recommendation of the Royal Society, and

PREFACE.

executed by Captain Lefroy, of the Royal Artillery—and the expedition in search of Sir John Franklin and his companions, under the direction of Sir John Richardson, afforded opportunities which the zeal and public spirit of those gentlemen did not suffer to pass unimproved.

The instruments with which the observations were made were supplied from the establishment under my direction at Woolwich; and on the completion of the services, the observations were trans-On application to the Treasury, a sanction was mitted to me. obtained for their publication in the present form. The observations of Captain Lefroy, both magnetical and meteorological, have been arranged and discussed by himself, as have the meteorological observations of Sir John Richardson by himself; but on learning from Sir John Richardson, soon after his return, that his professional duties at Haslar would prevent him from undertaking the examination and reduction of his magnetical observations, they were placed in the hands of Captain Younghusband, of the Royal Artillery, then my assistant at Woolwich, by whom that portion of the volume has been The proof-sheets of the whole have been read and comprepared. pared with the original manuscripts by the non-commissioned officers of the Royal Artillery permitted by the Master General of the Ordnance to be employed in my office for purposes of a similar nature.

EDWARD SABINE.

MAGNETICAL AND METEOROLOGICAL OBSERVATIONS

AT

LAKE ATHABASCA AND FORT SIMPSON,

Territory of the Hudson's Bay Company.

INTRODUCTION

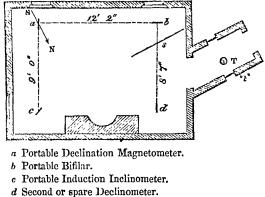

BY CAPTAIN J. H. LEFROY, Royal Artillery.

THE stations of magnetical observations established in North America in the year 1840, namely, Philadelphia, Washington, and Cambridge near Boston, in the United States; Toronto in Canada; and Sitka in Russian America; might all, with the exception of the last, be comprised in a circle of little over 200 miles radius; nor were any means at that time provided for attaining a knowledge of the absolute or relative values of the magnetical elements, or of their regular and irregular changes, in the northern parts of the British possessions; a region of peculiar interest, as comprising both the focus of maximum magnetic intensity in the northern hemisphere, and the point or pole of vertical dip. It was the principal purpose of the magnetic survey of British North America, authorized by the Government in 1841, and in part executed in the years 1843 and 1844, to supply the former deficiency; but with a view also to the latter. I was provided, in addition to other instruments, with a complete set of transportable magnetometers, of the construction of Dr. Weber, as improved by Captain Riddell; and it was arranged with the authorities of the Hudson's Bay Company, that the excursion of the first summer should terminate at Moose Factory on Hudson's Bay, where it was left optional with me to pass the whole of the ensuing winter, or to return in the course of it to Canada. The employment of these instruments in the magnetical term days, and in the observation of disturbances, was in either case the special duty of the time to be so employed. On arriving at the Red River settlement, in June 1843, I found various difficulties in the way of

INTRODUCTION.

an execution of this part of my instructions, and was led to believe that their object would be better attained by wintering at some more northern station. As Colonel Sabine, foreseeing the difficulty of precisely defining the details of a task which involved many contingencies, had kindly left me considerable discretionary latitude to be guided by circumstances, I decided on giving up the journey to Moose Factory, for that time, and selected in its place Fort Chipewyan on Lake Athabasca; not only the most northerly station which could be conveniently reached in the season, but one also whose resources would make an unexpected addition of eight persons, to the number of its occupants, a matter of no inconvenience. I reached this post with my assistant, Corporal William Henry, Royal Artillery, since Adjutant of Pensioners, on the 23d September 1843. Observations were here made every hour of the 24th from the 16th October 1843 to the 29th February following; together with very numerous extra observations on magnetic disturbances. On the 3d March 1844 I started, in company with the same assistant, and a party of four or five servants of the Company, for Fort Simpson on Mackenzie's River; we were provided with three trainaux, each drawn by three dogs, for the conveyance of the instruments and provisions; and a cariole, to which a team of four dogs was allotted, was very kindly provided by Mr. Colin Campbell for my own use, if required. The distance, which is about 350 geographical miles in a straight line, but considerably more by the course of the Slave and Mackenzie rivers, which is the route travelled, was accomplished in twenty-one days, including one day of detention at Great Slave Lake; and without other hardship or inconvenience than that occasioned by the severity of the cold, which ranged on several occasions between 30° and 40° below zero of Fahrenheit.

Fort Chipewyan is situated in latitude 58° 43' N., longitude 7^h 35' 15" W. from Greenwich, and is distant about 1,700 geographical miles from Toronto. By the exertions of Mr. Campbell,—to whose kindness, as well as to that of Mr. Lewis, the chief factor resident at Fort Simpson, and to Sir George Simpson, the Governor of the Hudson's Bay Company, I have to acknowledge the greatest obligations,—a small detached log building was erected, 18×13 feet in dimensions, especially for my use as an observatory; it was begun on the 27th September, and finished on the 13th October. No iron was used in the construction, it was furnished with an open fire place, and received light from three parchment windows, each having a small panel of glass, and so disposed as to throw light on the scales of the instruments, the arrangement of which is shown in the annexed diagram.

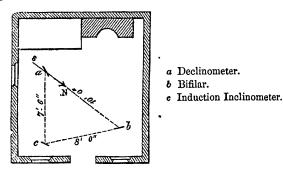

- T Portable transit instrument.
- t Thermometers.
- s Screen.

The Bifilar was screened from the direct action of the fire by a leather curtain, the Inclinometer was screened by the projection of the chimney; the whole were mounted on firm wooden pillars disconnected from the floor. The internal temperature ranged from $+61^{\circ}$ 0 on 19th October, to -1° 2 on the 22d January; we have even the mean for 24^h as high as 52°'8 on 18th October, and as low as 15°'2 on the 8th January. The extremes of cold usually occurred on Monday morning, the room not being occupied on the Sunday.

The system of relief adopted to carry out a series of hourly observations with only one assistant, was this: A observed from 8 P.M. to midnight, and on retiring aroused B, who observed from 1 to 5 A.M.; he in turn retiring, again aroused A, who resumed the observations at 6 A.M., and so on for four hours alternately. It will not be found that the omissions are numerous, the fatigue of this system, maintained for so many months, being considered. I have much pleasure here in acknowledging the assistance rendered by Mr. T. Dyke Boucher, the junior resident of the fort, upon several occasions. T have before acknowledged the zeal and spirit with which Corporal Henry devoted himself to his laborious dutics throughout the magnetic survey.

The building given up to my use at Fort Simpson as an observatory and dwelling-room, was also a detached wooden building on the north side of the principal house; which has since been removed to a point a little further back from the river. It was close to the then north-west angle of the inclosure. Care was taken to keep out of it, while occupied as a sitting-room and bed-room, all

guns, axes, and utensils of iron. The annexed diagram represents the arrangement of the instruments :---

The Declination Magnet produced an effect of -0.3 div. on the scale reading of the Bifilar, and of -1.8 div. on that of the Inclinometer. The Bifilar Magnet produced an effect of +1.7 div. on the scale reading of the Inclinometer, but no sensible effect on that of the Declinometer; the effect of the Inclinometer Magnet was +0.6 div. on the Bifilar, and of -0.5 div. on the Declinometer.

Fort Simpson is situated in latitude $61^{\circ} 51'^{\cdot}7$ N., longitude $8^{\rm h} 5' 40''$ W. from Greenwich, and is about 1,800 geographical miles distant from Toronto; its distance from the Russian Observatory at Sitka is about 460 miles, that of Fort Chipewyan from the same point being 780 miles.

I have endeavoured in the following pages to pursue the comparison of the phenomena observed, as far as the data admitted, through the registers of all the Magnetical Observatories in North America; reducing the results to a common unit, by means of the scale co-efficients given in the respective publications of the Observatories. As the observations at Toronto have been published since the completion of these reductions, it is necessary to observe that the scale co-efficient of the Bifilar at Toronto, here employed, —namely, k = `0001057 X,—was determined by an extensive series of experiments of Deflection made in 1848, in conformity with a circular of Instructions addressed at that time to Directors of Magnetical Observatories.

It has been found necessary to omit the detail of a part of the observations on Magnetical Disturbances and Term Days, for want of space.

Woolwich, July 1854

J. H. LEFROY.

ERRATA.

The reader is requested to make the following corrections :---

Page 18. Near the foot, for fourteen-inch, read fifteen-inch.

" 19. Heading of Table X., for 14-inch, read 15-inch.

, 65. Near the foot for $\frac{\Delta R}{R}$ read $\frac{\Delta \phi}{\phi}$.

- " 75. Near the top, after evident, insert that.
- " 75. Near the foot, for substracted, read subtracted.
- , 79. Line three from foot, for does, read it does.
- " 80. Heading, insert VIII., after the word Table.
- " 106. Table L., heading, for extremes of each instrument, &c., read comparison of selected days at three stations, with reference to the degree of disturbance which prevailed.
- " 140. Above the centre, after or Fort Simpson, add with two exceptions, and bracket [October 24] and [December 8].
- " 140. Below the centre, for all coinciding, read two of them coinciding, and bracket [October 19].
- " 142. Table LXV., midnight, January No. of A., for 7, read 6; at the foot, for 51, read 50; in column of total, for 23, read 22. See below, p. 169. Again, 17^h February No. of A., for 2, read 3; in column of total, for 12, read 13.
- " 148. First line, for Table LXVII., read Table LXVI.
- " 152. Before the Table, dele together with the values of those quantities.
- " 153. Near the top, for but five instances, read but four instances; and dele November 27.
- , 167. Foot-note, for -3° , read $-37^{\circ} \cdot 8$.
- " 169. At 18^d 20h, the entry of Aurora at 20^h 45^m belongs to January 17s.
- " 178. February 29^d 0^h, after the entry, add, idem 1^h.
- " 298. Second line, for second, read first.

MAGNETICAL OBSERVATIONS

AT

LAKE ATHABASCA AND FORT SIMPSON.

ADJUSTMENTS, ABSTRACTS, AND COMMENTS.

SECTION I. DECLINATION.

e ge

MAGNETICAL OBSERVATIONS.

SECTION I.

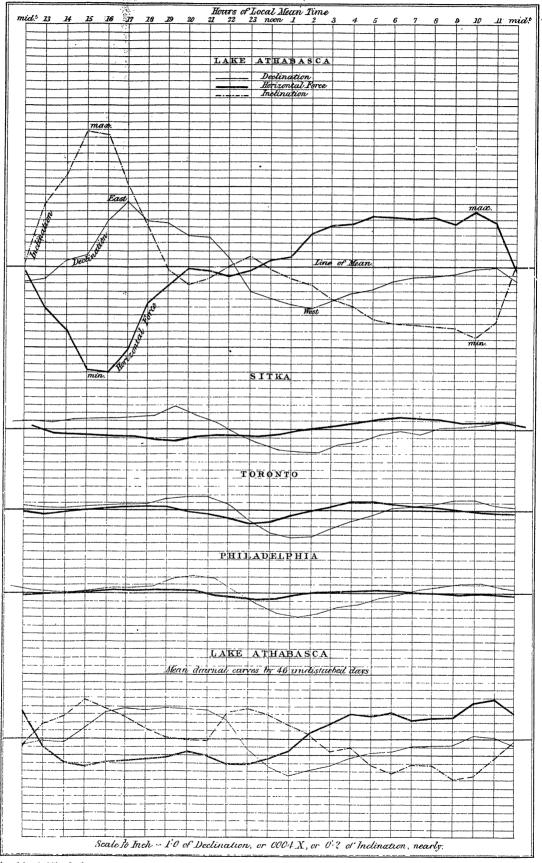

MAGNETIC DECLINATION.

Declinometer, 12th October 1843.—The adjustment of this instrument consists in levelling the base, and turning the arm which carries the Telescope in azimuth, until the central division of the scale coincides with its line of collimation. This being done, the value of the ratio $\frac{H}{F}$, for the coefficient of torsion, was found to be $\frac{1}{1452}$, whence one division of the scale = a $(1 + \frac{H}{F}) = 1'.00069$. The Magnet was 3 inches in length, and suspended by a single thread of silk. The effect of the massive copper box in which it was suspended was such, that the Magnet was generally at rest, and underwent considerable changes without vibration. Increasing numbers on the scale denote an easterly movement of the north end of the bar.

Absolute Declination.—The following observation was made with the Collimator Magnet, c. 9. October 16th 1843, to determine a zero value of the Declinometer scale. The portable Theodolite was levelled, and made to coincide approximately with the magnetic axis of the Collimator, then directed to the sun, and the transit of both limbs observed; after reading off the verniers, it was again directed to the magnetic axis of the Collimator, and a series of simultaneous readings of the scale and of the Declinometer were taken. The sun was too low at the conclusion to allow the Theodolite to be referred to it again.

B 2

The absolute values corresponding to the mean scale reading for each fortnight, will be found at p. 13, Table IX. The mean of the whole is 420'93, and the corresponding absolute Declination 28° 42''6.

Diurnal Variation of the Declination.

Before proceeding to examine the mean diurnal curves for the four and a half months of observation at Lake Athabasca, it will be useful to obtain a general idea of the magnitude of the changes to which the Declination is liable at this station and at Fort Simpson. The following Table has been drawn out with this view, showing the difference between the highest and lowest hourly readings, and between the highest and lowest readings, observed in each Göttingen day; the latter shows the actual range of the element, the former is requisite for comparison with other stations. The Table may be referred to, also, for the dates of disturbances.

Since the date of these observations, a considerable extension has been given to our knowledge of the occasional amount of irregular or disturbed movements, by the remarkable disturbances of 1847 and 1848. In those years a range exceeding 4° was three times recorded at Toronto; but from 1840 to 1847, the greatest range of Declination attained at this station in any one disturbance, was 2° 15', and if we compare the above ranges at Lake Athabasca and Fort Simpson with those of the same season at Toronto, it will be obvious that their magnitude increases in a much higher ratio than that of the inverse proportion of the Horizontal Force at these stations, which is as 7:4 nearly. There were 116 days of observation at Lake Athabasca between 16th October 1843 and 29th February 1844, having 23d December for their middle period. There were 46 days of hourly observation at Fort Simpson, between 1st April and 25th May, having 27th April for their mean period. By classifying the ranges according to magnitude, we have the following results:—

Daily Change	Lake A	thabasca.	Fort Simpson.			
of Declination.	Hourly Observations.	Hourly and extra.	Hourly Observations.	Hourly and extra.		
Less than $10' - 15' - 10' - 15' - 20' - 25' - 25' - 25' - 25' - 35' - 35' - 35' - 35' - 40' - 40' - 45' - 45' - 50' - 55' - 55' - 60' - 55' - 55' - 60' - 55' - 65' - 70' - 70' - 75' - 75' - 80' - 90' - 100' - 110' - 120' - 100' - 110' - 110' - 120' - 2^{\circ} - 3^{\circ} - 3^{\circ} - 4^{\circ} 10'$ Above 7° -	$ \begin{array}{cccccccccccccccccccccccccccccccccccc$	$ \begin{array}{c} 6\\ 17\\ 13\\ 20\\ 12\\ 6\\ 10\\ 2\\ 4\\ 2\\ 0\\ 3\\ 5\\ 2\\ 1\\ 2\\ 1\\ 4\\ 0\\ 7\\ 0\\ 0\\ 0 \end{array} $	$ \begin{array}{c} 0\\ 0\\ 1\\ 2\\ 5\\ 0\\ 6\\ 7\\ 2\\ 4\\ 3\\ 1\\ 1\\ 2\\ 2\\ 1\\ 0\\ 0\\ 4\\ 5\\ 0\\ 0\\ 0 \end{array} $	0 0 1 2 4 0 5 4 2 3 3 3 3 2 1 0 2 0 0 6 4 1		

TABLE II.

The greatest range in any one day during the winter at Lake Athabasca was $2^{\circ} 35'$, on the 16th October 1843; and the greatest during the spring at Fort Simpson was $7^{\circ} 27'$, on the 16th April 1844. Upon the last occasion, however, the actual difference of scale reading observed was $8^{\circ} 10'$, the westerly extreme falling on April $16^{d} 19^{h} 50^{m}$, and the easterly on April $17^{d} 1^{h} 24^{m}$; this is believed to be the greatest range hitherto recorded. During the same season the distribution at the three permanent Observatories in America was as follows :—

'	T.	AE	É	É	III.

	16th Oct. 184	3-29th Fe	b. 1844.	April-	April—May 1844.				
Acres 1	Philadelphia.	Toronto.	Sitka.	Philadelphia.	Toronto.	Sitka.			
Less than 10' - 10'	103 13 0 0 1 0	94 19 1 2 1 1	81 29 12 4 3 3	23 22 6 1 0 1	8 / 32 5 3 1 2	6 31 18 3 0 3			
	117	118	132	,53	51	61			

The means of all the daily ranges during the above periods by the regular hourly observations, that is to say, the square roots of the mean of their squares are:—(1.) For the winter, 7''77 at Philadelphia, 9''56 at Toronto, 11''64 at Sitka, and 33''8 at Lake Athabasca: (2.) For the spring, 12''32 at Philadelphia, 15''17 at Toronto, 18''40 at Sitka, and 75''6 at Fort Simpson. For the several months again, we have the means as follows:—

TABLE IV.

	Philadelphia.	Toronto.	Sitka.	L. Athabasca. Fort Simpson.
	,	1 .	, '	,
1843. October (the whole) ,, (16th to 31st November December 1844. January February March April May		$10.44 \\9.70 \\8.44 \\8.07 \\8.38 \\12.25 \\16.94 \\15.62 \\14.73$	$12.63 \\ 12.50 \\ 9.80 \\ 10.39 \\ 10.44 \\ 14.33 \\ 21.02 \\ 21.19 \\ 15.19 $	53 · 31 27 · 32 30 · 30 30 · 85 32 · 03
June - July -	- 12.14 - 12.85	$13.75 \\ 14.27$	$15.35 \\ 15.65$	_
August -	- 12 85 - 15.01 - 14.50	15.95	13 03 22.93 18.25	_

The observations were made at the same moment of time, at all the stations; the difference in the number of days arises from the Sunday being a day of observation at the Russian stations. There is no marked preponderance of number under any one daily range at Lake Athabasca between 13' and 29', and these two values include half the days of observation.

11

It appears, then, that during the winter under comparison, the movement of the Declination Magnet, observed hourly, exceeded 15', in the proportion of fifteen days to each hundred at Philadelphia, seventeen days to each hundred at Toronto, and exactly the same at Sitka, but on eighty days of each hundred at Lake Athabasca. During April and May they exceeded 30' in the proportion of about two to a hundred at Philadelphia, four to a hundred at Toronto, five to a hundred at Sitka, but of eighty-five to a hundred at Fort Simpson, showing an increase in the liability to disturbance at these stations, which it appears difficult to attribute to the merely negative influence of a diminished directive power in the magnet.

The next Table contains the hourly means of all the observations during the winter period, with the exception of six days which are omitted at Lake Athabasca as incomplete, namely, October 20th, November 3d and 4th, January 2d, 9th, and 27th. Each Value at this station is, therefore, the mean of 110 observations at the same hour. Since the principal novelty of these means consists in their maxima being found at a period of the $24^{\rm h}$ which is not marked by a similar inflexion at any other station, they are, in the same Table, compared with the means for the corresponding periods at the other three American stations.

TABLE V.

Mean Diurnal Curves of Declination at all the American Stations, for the Period included between the 1st or 16th October 1843 and the 29th February 1844; together with the Difference of each hourly Value from the Mean of the whole; expressed in arc.

* In every instance in which the observations at Sitka are referred to, the mean for the month of November 1843, as given in the Annuaire Magnetique, &c., has been corrected by adding 23'2 div. to each scale reading of Declination from 1^d 0^b to 14^d 10^b Gott, being the difference between the means for the 24^b before and after the last-named hour. This difference is permanent, and appears due to some accidental cause, although no explanation of it is given.

TABLE V.—continued.

The observations were taken 5^m before the hours named at Lake Athabasca, 28^m after the hours named at Sitka, 3^m after at Toronto, and 19^m after at Philadelphia.

It appears that the mean diurnal changes of Declination at Lake Athabasca follow the same law as at all the other stations, so far as relates to the principal minimum or westerly extreme of the 24^h, which occurs at 2 P.M.; from this hour the Declination continues to increase until 11 PM.; it shows a westerly tendency at midnight and 1 A.M., after which it increases again, at first slowly, but between 3^{h} and 4^{h} A.M. with rapidity, until it attains its maximum or easterly extreme between 4^{h} and 7^{h} A.M., after which it begins a westerly course, conducting to the minimum at 2 P.M. This occurrence of a strongly marked maximum at the earlier hours of the morning has not been observed at any other station.*

It has been shown by Colonel Sabine, from the observations at Toronto, that no continuance of observation will give a strictly

* A second Declinometer, having a Magnet of only two inches in length, was observed from the 16th December to the 29th February. The means by 58 complete days of observation in this period are given below:

normal curve, or one wholly free from the effects of disturbance, since the disturbing causes are not entirely irregular in their action, but have a preponderating influence in one direction. It will be shown below that this remark applies equally at the stations under consideration, consequently the foregoing mean cannot be regarded as a true representation of the normal curve at Lake Athabasca. This can only be obtained by some selection of undisturbed days, and the next Table has been formed as an approximation to it. Ŧŧ contains the mean by all those days on which no extra observations were made, assuming that circumstance to be a proof of the absence of any decided disturbance. They amount to 46, and the mean of the same 46 days at Toronto, which have been formed into a similar abstract, furnishes a direct comparison of the mean diurnal movement, uninfluenced by disturbance, or nearly so, at these two stations.

TABLE VII.

It appears that a partial rejection of the more disturbed days at Lake Athabasca has the effect of throwing back the hour of greatest westerly deviation to 1 P.M., but occasions very little change, and none of a systematic character, in the mid-day or afternoon branches of the curve. The principal effect is shown in the reduction of the daily variation between midnight and 10 A.M. The maximum at 5 A.M. disappears, and in its place we have a nearly uniform value prevailing from $5^{\rm h}$ to $9^{\rm h}$ A.M. constituting the easterly extreme of the $24^{\rm h}$, but materially less in amount than the corresponding value before the rejection, thus proving the unusual maximum at 11 P.M. is thrown back to 10 P.M., but the succeeding minimum is scarcely affected. The mean curve given by the corresponding 46 days at Toronto differs so little from that of the whole period, that when drawn on a scale of 10' to one inch they can scarcely be distinguished.

Proceeding now to the observations at Fort Simpson, we find the same peculiarity in a more marked degree, as may be expected from the greater magnitude of the daily ranges observed at this station. The incomplete days here are not omitted, as they form rather too large a proportion of the whole to be passed over. There were 46 days of observation, of which number twelve are imperfect. The omissions occur as follows, at

consequently, the two first alone can be materially affected, and at twenty of the twenty-four hours the means are strictly comparable. In one of the cases at each of the above-named hours an observation taken *late* has been employed.

* Ob of Göttingen mean time at Fort Simpson.

The observations at Fort Simpson were made 15^{m} after the hour named, the rest as before stated.

It will be seen that a remarkable difference exists in the amount of the daily movement at Fort Simpson and Lake Athabasca, although the diurnal law is nearly the same. It is difficult to attribute this altogether to change of locality, which in this case involves but a slight change of magnetical position*; we are therefore led to connect it with the advance of the season. On referring to the Table, it will be seen that the westerly extreme at 2 P.M., which is so well marked at Toronto and the lower stations, is here prolonged for nearly four hours, during which space the magnet does not sensibly deviate from it. After 7 P.M. it returns to the eastward, but so gradually as not to attain its mean, or zero value, before 2 A.M. instead of 8 P.M., as at Toronto. Then commences a sudden and rapid increase, leading to a maximum at 7 A.M., after which a steady and rapid westerly movement takes place, which attains its limit, as already stated, at or about 2 P.M., and amounts to the very large mean quantity of 32'. The sun was above the horizon 15^h 44^m on the middle date at this station, and 5^h 56^m on the middle date at Lake Athabasca, which correspond to 13^h 48^m and 8^h 44^m on the same dates at Toronto respectively. Notwithstanding this great difference in the length of the day in December and April, it will be observed that the magnet in its regular westerly movement from 7 A.M. to 2 P.M. cuts the line of mean at or near the same hour in both periods, as it does also on its return at night towards its easterly extreme. When referred to the westerly limit, or lowest mean value, as zero, instead of to the mean of the whole twenty-four hours, the diurnal changes at Lake Athabasca for the afternoon branch do not exceed, but, upon the whole, rather fall short of those at Toronto, and at Fort Simpson they are less than those at Toronto for ten hours following that epoch, namely from 3^h to 12^h inclusive. It is the nocturnal branch at both stations which occasions the great apparent excess of their diurnal changes above the changes at Toronto.

The persistency of the magnet at its westerly extreme, in April and May, is strongly contrasted with a similar persistency at its easterly extreme, which appears to be one of the principal characteristics of the curve at Lake Athabasca in the winter. We see by Table IV. that when free from the effect of disturbances, the easterly maximum is maintained from 5^{h} to 9^{h} A.M., which suggests the inference that the effect of the advance of the season on the

^{*} The Horizontal Force is $2^{\circ}02$ at Lake Athabasca, and $1^{\circ}95$ at Fort Simpson; the inclination is $81^{\circ}37'$. 6 and $81^{\circ}52'$. 3, the total force $13^{\circ}92$ and $13^{\circ}84$, at the same stations respectively.

daily curve is analagous to that of the sun's diurnal progress, the increased power of the sun being attended by a determination of the north end of the magnet to the west, its diminished power by a determination of the same end to the east.

Comparing together the means of the four American stations for the two periods under discussion, we find that besides the different amount of the daily changes shown, they have peculiarities of a systematic character, which is apparent more particularly in those of the spring months, but not so decidedly in either group as in those of the bifilar. Referring first to the curves for April and May, it appears that the magnet attains its daily limit to the westward at nearly the same hour at Toronto and Philadelphia, namely, 2 P.M. or thereabouts, and then commences an immediate return towards its mean position; it reaches the same limit about half-past three at Sitka, and its return is more gradual. It would appear from the general character of the curve at Fort Simpson that its turning hour is there as late as 5 or 6 P.M., and the return is effected still more slowly. The hour of attaining the easterly limit does not appear to vary much. The number of hours at which the magnet is to the eastward of its mean position is, however, considerably less at the more northern than at the southern stations, which results from the easterly tendencies during the night having the effect of raising the mean scale reading, and throwing the readings in the latter hours of the afternoon and evening relatively to the westward. The numbers for the winter group are sixteen at Philadelphia, seventeen at Toronto, fourteen at Sitka, and nine at Lake Athabasca; for the spring group, sixteen, fourteen, thirteen, and nine respectively.

The mean scale readings at both stations show an increase of Easterly Declination, which was slight in the winter months, and very rapid in the spring. Taking the means for each fortnight, and referring them to absolute values, we have the following series. The approximate means for the same periods at Sitka, are inserted for comparison.

TABLE IX.—continued.

The regular character of the progression makes it difficult to attribute the easterly movement, from October 16th to the end of January, to any accidental or instrumental cause, still more so the much more rapid movement in April and May; the latter is the more difficult to account for, as the effect of Disturbances at Fort Simpson in those months appears to have been less exclusively easterly than during the previous period at Lake Athabasca. The means at Sitka, which are derived for the present comparison from the three equidistant observations of 0^h, 8^h, and 16^h, Gött., show no similar tendency from November to January, and but a slight one from February to May. We have, however, a similar result from the observations of Sir John Franklin at Great Bear Lake in 1826, which give the mean Declination in February 38° 41' 6, and in March 38° 50' 2 E. As no observations were made by Sir J. Franklin at those hours of the night which are now shown to include, in these latitudes, the extreme easterly movements, the difference in this case is probably within the truth. The effect of Disturbances being greater in March than in February, would have increased the relative easterly value of the former month.

In all the foregoing tables, the movements of a three inch-magnet at one station have been regarded as comparable with those of a fourteen-inch magnet at the other, without consideration of the difference of their size and weight. It appears, however, from a comparison of the mean diurnal curves, deduced from observations of two magnets of these dimensions respectively at Toronto, that there is a slight and apparently specific difference between them. The diurnal variation by the small bar is greatest from 8 P.M. to 5 A.M., and least from 6 AM. to 8 P.M., with an exception at 1 P.M. only; that is to say, the Declination by the larger magnet is slightly more

* The regular division is continued at Sitka; at Fort Simpson the fortnights are taken from April 1st to 14th, and so on.

easterly during the day, and less easterly during the night, than the Declination by the smaller bar, and this peculiarity presents itself in every month, but the amount is not sufficient to affect any of the foregoing conclusions. A difference of a similar nature is observable between the mean diurnal curves by two bifilar magnets of corresponding dimensions.

HORIZONTAL FORCE.

SECTION II.

BIFILAR MAGNETOMETER.

The instrument employed was a small transportable biflar, provided with a hollow 3 0-inch magnet, weighing 207 grains. The reading telescope was carried by an arm connected with the base of the instrument, so that the copper box and suspension apparatus turned with the telescope. The azimuth circle read by verniers to single minutes, the torsion circle to 5' 0. The suspension silk was about 9 inches long. The arc value of each division of the scale attached to the telescope was 2' 0.

Adjustment, 13th October 1843.—(1.) The reading telescope was brought to the magnetic meridian by attaching the magnet to an unifilar suspension and bringing the central division of the scale (210) to the wire. The azimuth circle read $302^{\circ} 55'$, declination 428, whence $302^{\circ} 45'$ corresponds to the scale reading 418 °0 found at the next step.

(2.) The magnet was next attached to a bifilar suspension of waxed silk, the north end pointing to the north, and the torsion circle turned until the same division was on the wire, showing the plane of detorsion to coincide with the meridian. At the first trial the force of torsion was too great, the interval of the threads was in consequence reduced; this, however, altered the position of the plane of detorsion, and it appears that in adjusting it afresh to the meridian, the telescope was inadvertently moved 34' to the west, the next reading of the horizontal circles being 302° 11' instead of 302° 45'. The plane of detorsion, therefore, instead of being in the meridian, was in such a position as to deflect the magnet 34' to the westward, or rather, correcting for a small change of declination, $33' \cdot 2$ to the westward. If (u) and (v) be the angles at which the magnetic force and the force of torsion act on the magnet, we have in every position of equilibrium $\frac{F}{G} = \frac{\sin v}{\sin u}$, and in the present case $\frac{F}{C^2} = 0.86$, and u = 33'.2, hence v = 28'.4, and the angle $u + v = 61''_{0}$, being the angle by which the plane of detorsion

HORIZONTAL FORCE.

differed from the meridian to the westward. The reading of the torsion circle was $58^{\circ} 50'$, whence the true position of the plane of detorsion was $58^{\circ} 50' + 1^{\circ} 1' \cdot 6 = 59^{\circ} 51' \cdot 6$, which is the datum employed. Declination 418 0 scale reading of bifilar 209 6 (for 210).

(3.) The telescope was now turned 90° in azimuth, from the assumed meridian, or 90° 33' 2 from the true one; the division of the scale at right angles to it was therefore 226'6 instead of 210, and the torsion circle being turned until the scale read 208, the magnet was carried 37' 2 beyond the position intended, namely, that at right angles with the magnetic meridian. The torsion circle read 0° 15' Declination 416'5.

In the equation $\frac{\mathbf{F}}{\mathbf{G}} = \frac{\sin v}{\sin u}$ we have therefore $u = 90^{\circ} 37'^2$ instead of 90°, which somewhat diminishes the sensibility of the adjustment, but is otherwise unimportant. $v = 59^{\circ} 51' \cdot 6 - 0^{\circ} 15' =$ $59^{\circ} 36' \cdot 6$, also $a = 2' \cdot 0$, whence the value of one division of the scale in parts of the Horizontal Force was

 $k \equiv a \cot a v \equiv 0003432.$

Increasing numbers denote increasing Horizontal Force.

It appears that the scale readings decreased regularly until January, showing the north end of the magnet to be carried from the meridian to the south of west; the readings increase again in February, and this circumstance, coupled with that of a contrary change in the inclinometer scale readings, makes it appear that in part, at least, the effect was due to a real increase of Inclination and decrease of Horizontal Force in the winter months, having respectively their maximum and minimum in the latter portion of the month of January. Mixed up with this periodical change there is probably also a loss of magnetic moment in the bifilar bar, and an increase of permanent magnetism in the soft iron bar of the The fortnightly mean scale readings of both instruinclinometer. ments are collected in the following table. Dr. Lloyd having shown that any three equi-distant observations give, very nearly, the true mean of the twenty-four hours, that principle has been applied in the present and all the similar tables, to obtain true mean scale readings for days on which one or more observations were omitted, by the simple proceeding of omitting, also, the corresponding readings of the imperfect triplet or triplets, and taking a mean of the remainder or perfect triplets.

TABLE XI.

Fortnightly Mean Scale Readings of the Bifilar and Inclinometer at Lake Athabasca.

Date.	Period.			Inclino-

The first fortnight has only half weight.

The coefficient of Temperature of the biflar magnet was ascertained after its return to Toronto, in January 1845. A series of deflections on different days gave the following results:— January 8, 1845, a = 0.0003128

ry 8,	1845, $q =$: 0'0003128
10	"	·0003009
11	,,	0001784
14	,,	·0001941
17	39	'0001818
ч .		· · · · ·

The mean of the whole is 0 0002336. The mode of proceeding was the same in each case. The temperature of the magnet was raised at once from the lowest to the highest point, being about 40° Fahr. and 90° respectively, and three sets of readings taken at each, with an interval of 5^{m} between them, the bar being previously allowed 15^m to acquire the temperature of the surrounding water; the Declination and Horizontal Force were also observed at the same time. As the two first of the above values differ materially from the rest, the experiment was repeated in 1848 under similar arrangements, except that the change of temperature at each alternation was from 40° to 60° and no higher temperature was employed, the intervals were also reduced to 4 minutes between each set, and 10 minutes between each alternation :

> March 4, q = 0.00024726 0002138 7 0002874

The mean of these is 0 0002495, not materially different from the former value. Lastly, the mean of both sets is,

q = 0.0002396

And adopting this value, we have the ratio $\frac{q}{k}$, or the change in scale divisions for a change of temperature of 1° Fahr. = 0.70. The whole of the readings in the abstracts have been reduced to the uniform temperature of 40° with an approximate coefficient $\frac{q}{k} = 0.66$, which occasions, however, an error of only 2°1 divisions at the extreme temperature recorded, a quantity so small, as compared with the extent of other changes, that it has not been thought necessary to correct the work. The more accurate coefficient has been employed below in deducing the mean diurnal curve, and in correcting the observations on term day, and disturbances.

HORIZONTAL FORCE.

In Absolute Measure. - The observations of the Absolute Horizontal Force made at Lake Athabasca and Fort Simpson have been published in detail by Colonel Sabine (Contributions to Terrestial Magnetism, No. VII.), but it may be convenient to repeat the particulars here. Six deflecting magnets, varying in length from 3.6 inches to 2 0 inches, were employed at both stations; two of these, Nos. 30 and 31, of three inches in length, were considered the standard bars, and the others employed for verification. The whole of the magnets were suspended for vibration by a silk fibre attached directly to the bar, without the addition of any stirrup; bars 30 and 31 were also vibrated in a stirrup, the weight of which was 322 grains, thus giving a second and independent value of the term $m \mathbf{X}$. The amount of inertia of each suspension was found by vibrating the magnet with and without the addition of carefully turned brass rings, according to the method recommended by Dr. Lamont. The following are the mean values :---

Bar 30. Bar 31.

Log. $\pi^{2}k$ for vibration without the stirrup 1 33408 1 33952 Log. $\pi^{2}k$ for vibration in the stirrup 1 50167 1 50521

The observation at Lake Athabasca was commenced on the 13th October, shortly after completing the adjustment of the bifilar already described; the experiments of deflection with four bars were completed on that day, and with the other two on the following day. The bars were vibrated without the stirrup on the 14th, and with it on the 20th, each experiment being connected with scale readings of the bifilar. The observation was repeated in March 1844.

HORIZONTAL FORCE.

24

The mean value by the other four bars in October was

X = 2.030

which agrees nearly with the mean deduced from the observations of Bars 30 and 31; but it has not been employed, as three of them were corrected with an assumed coefficient of temperature, and the value of the moment of inertia employed has not been so well determined as that for the standard magnets.

The value of the Absolute Horizontal Force was found to be

X = 2.040

by the standard bars in July 1844, being an increase of 0 0088X, or $\frac{1}{1+3}$ of its whole amount, over the value found in October and March, which may probably be attributed to a real increase of that element in the summer months.

Since the publication of the preceding observations by Colonel Sabine, Captain Younghusband has succeeded in obtaining a satisfactory determination of the value of the ratio $\frac{\Delta}{m}$ for Bar 30, the previous results having been obtained without any correction for the change in the induced magnetism of the bars under the different circumstances of vibration and deflection. Five experiments made at Woolwich in May 1847 gave the following results:—

$$\frac{\Delta m_{\circ}}{m_{\circ}} = 0.00042$$

$$\frac{0.00048}{0.00037}$$

$$\frac{0.00048}{0.00042}$$

$$0.00042$$

$$0.00056$$

mean of the whole, 0'00045. Assuming the magnetic moment of the bar itself at the period of these experiments to have been nearly the same as in June 1846, when the absolute intensity was determined last with it at Woolwich, we have the means of reducing this value of the correction to the value applicable at the northern station.

$$\frac{\Delta m}{m} = \frac{\Delta m_{\circ}}{m_{\circ}} \quad \frac{A_{\circ}}{A}$$

where $A_o =$ the ratio $\frac{m}{X}$ at Woolwich, and A the same at the northern station. $A_o = \frac{0.372}{3.728}$ and $A = \frac{0.419}{2.022}$ (at Lake Athabasca), whence $\frac{\Delta m}{m} = .000218$ On applying this correction to the times of vibration and the angles of deflection, by the formula given in the Supplement to Magnetical Instructions, §c., 1846, the difference in the

resulting value of X proves to be insignificant; it is less than 0 0003, and does not affect the above values, which are not carried beyond the third decimal, the effect is negative.

The foregoing value of the Horizontal Force is not referable to any one division on the bifilar scale. The readings of the instrument on the 14th and 20th October, taken in connexion with the experiments of vibration, differed considerably from the readings on the 13th, which were taken with the experiments of deflection. The mean on the 13th was 176 0 at 64° 6, on the 14th 255 5 at 57° 4, and on the 20th 254'4 at 50°'4; there is therefore a change of about 74 divisions between the 13th and 14th of October. The greatest difference between two successive daily means in the subsequent series is 27'4 div., which makes it probable that the change between the 13th and 14th October was partly instrumental, the magnet not at once taking up its position of adjustment. As the change of reading on the first day of regular observation amounted to 223'8 div., the amount of this difference did not appear at the time to be so great as to call for re-adjustment, but in calculating the observation of absolute intensity the observations on the 13th and 14th were reduced separately to the mean reading on those days respectively, and those on the 20th to the mean of the first week of regular observations, which commences on 16th October. The instrument had been dismounted before the observation of March. but the regular change evinced by the fortnightly means would have rendered the zero division of the scale in October, had it been determined, inapplicable in succeeding months.

Changes of the Horizontal Force and Inclination.—These elements, especially the last named, like the declination (p. 1.) were found to be liable to daily change far exceeding in magnitude anything commonly observed at stations in lower magnetic latitudes. The daily extremes of both are brought together in the next table. The section relating to the inclinometer may be referred to for the grounds on which the value of the scale has been assigned. The ranges of inclination here given are considered subject to an uncertainty not exceeding one tenth of their amount.

* Extra observations were taken from 5^d 21^h to 5^d 25^h.

It appears from the foregoing table, that the greatest change of Horizontal Force observed in any Göttingen day in the winter, was '0991X, on the 4th January 1844, the change of Inclination observed being 1° 6' 9, according to the approximate scale value employed. The greatest change of Horizontal Force observed in any Göttingen day of the two spring months was not less than 0 '173 X, on the 17th April, or one sixth of the whole amount of that element, and was accompanied by a change of inclination of 1° 45' 7; the movements of both instruments upon this occasion went beyond the limits of their scales, and could only be valued approximately, by holding up some object and afterwards measuring its distance from the zero of the scale. The mean inclination at Lake Athabasca was

81° 37''7, and at Fort Simpson 81° 52''0; a change of $\pm 1'$ of these elements would therefore produce a change of \mp 001996 X at the former, and of \mp '002037 X at the latter station; in round numbers $\pm 1''0$ of inclination corresponds to ∓ 002 of horizontal force at both stations; classifying the daily ranges upon this scale, we have the following results:

Range	Lake At	habasca.	Fort S	impson.	Range	Lake At	habasca.	Fort Si	mpson.

TABLE XIV.

* A day is here included which is wanting in the Inclinometer series, namely, May 2. † Two days are included which are wanting in the Bifilar series, namely, Feb. 23 and 29, 1844.

It may be remarked in reference to this table, that were the total force to undergo no changes, we should expect to find an exact coincidence between the number of days giving certain ranges of the horizontal force, and their equivalents in terms of the inclination. unless there existed an error in one of the co-efficients; the great changes of the former element being always positive, and those of the horizontal force negative, we have an indication, in the excess under the higher ranges of inclination, which is apparent above, that the tendency in disturbances is to an increase of total force.

The mean range of horizontal force during the winter months at Lake Athabasca, that is to say, the square root of the mean of the squares of the differences between the highest and lowest scale reading, included in the hourly observations of each day, is '0286 X, and that of the inclination 17' 0 (minutes). The corresponding means for the two spring months at Fort Simpson are '0421 X, and

47' 5 of inclination. The other American stations give the following values for the mean range of horizontal force found in the same way, and for the same periods. For the winter months, 16th October 1843, to 29th February 1844, Philadelphia '00149 X, Toronto '00240 X, and 3' 25 of inclination*, Sitka '00377 X. For the two spring months, April and May 1844, Philadelphia '00157 X, Toronto '00357 X, Sitka '00429 X. For the several months again, we have the mean ranges in the following table, which, like that of the declination, I have extended to include twelve months at the permanent stations.

TABLE XV.

The scale co-efficients used above were 1 division = -00040 X at Philadelphia, (magnetic and met. observations at Girard College, p. 1819), = 0001236 at Sitka for the observations of 1843, and 000128 for those of 1844, = 000105 for those at Toronto; the observations at the two former stations were not reduced to a uniform temperature, but from the irregularity in the hours of occurrence of the greatest and least values, the effects of inequalities of

* By observations with an instrument of one bar from 16th October 1843 to 10th February 1844, 1 division -0' 820.

34

temperature must be in a great measure neutralized in the final result for each month.

Diurnal Variation of the Horizontal Force.—The following Tables contain the mean of the scale readings of the Biflar as observed, and the same reduced to the uniform temperature of 40°. As the observatory was artificially warmed, the mean daily range of internal temperature is small, although the occasional fluctuations were very considerable; the uncorrected curve differs in consequence comparatively little from the corrected one.

TABLE XVI.

Monthly means of the Bifilar readings, uncorrected for temperature, and with omission of incomplete days, namely, October 20th, November 4th, January 2d and 9th, February 28th and 29th.

Mean temperature of the Bifilar magnet.

The general mean for each hour in the above Tables has been obtained by dividing the sum of all the observations by the total number, which is 110.

In the next Table, the difference from 40° of each mean temperature in Table XVII has been multiplied by the co-efficient $\frac{q}{k} = 0.702$, anp applied to the values in Table XVI.

It is remarkable, that the above means have a decided feature in common, which is not found in the corresponding ones at Toronto, or at any other American station,-they all exhibit a minimum of Horizontal Force at or near 3 A.M. By omitting all days on which extra observations for Disturbance were taken, as in Table VII., the lowest value of the 24^h is still at 3 A.M., but the amount of the daily change is most materially reduced, proving this feature to be, in great measure, due to the effect of disturbances, which has already been shown to be the case with the extreme of Declination at the same The following Table exhibits, side by side, the mean diurnal hour. curve of Horizontal Force at all the American stations, for the period included in the observations under discussion, to which is added the mean by the 46 days selected as free from disturbance.

TABLE XIX.

Comparison of the mean diurnal curve of Horizontal Force at all the American stations for the period included between October 1843 and February 1844.

The observations were taken 19^m after the hour named at Philadelphia, 3^m after at Toronto, 28^m after at Sitka, and 5^m after at Lake Athabasca.

Fort Simpson.—The Bifilar magnetometer at Fort Simpson received an accidental shock on the 10th April, which rendered it nccessary to

readjust it^{*}, this was done on the 13th, a correction being applied to the intermediate readings. We have therefore two series, the first of only eleven days, of which one is incomplete, the second of thirtyfive days, nine of which, however, want one observation or more. A separate mean for each will be found in the abstract. The whole forty-six days have also been combined in a general mean, without omission of any one, for the reasons already stated in reference to the Declination Observations, page 15.

TABLE XX.

Mean scale reading and temperature of the Bifilar Magnet at Fort Simpson in April and May 1844, to which are added the mean for the same two months at all the American stations, and the difference of each reading from the mean of the whole, in terms of the Horizontal Force. The scale readings at Philadelphia arc the complement to 1100 of the actual readings.

See remark at Table XIX, as to the difference of the actual observation from the hours given.

* The details of the adjustments will be found in a future section,

Mean diurnal curve of Horizontal Force.--The mean diurnal curve of the Horizontal Force, as given by observation, and influenced by disturbances, appears to consist at Lake Athabasca of a single progression, having its minimum at 4 A.M. and its maximum at 10 P.M., and agreeing in neither respect with the diurnal changes of this element at Toronto. The latter have at the same season two maxima, namely, at 3 P.M. and 6 A.M., and two minima, at 11 A.M. and 1 A.M. respectively!

Upon closer examination, it is evident that a second progression is superadded to the first at Lake Athabasca, which produces a subordinate maximum at 8 A.M., and a minimum at 10 A.M. Lastly. by omitting days most influenced by disturbance, and confining our attention to the mean given by 46 days, which were in a great measure free from it, we obtain evidence of the two diurnal maxima and two minima, as at Toronto, but accompanied by a third and more considerable maximum at 11 P.M., of which there is no trace at the The first of these maxima occurs at 8 A.M., and latter station. appears to correspond to that which occurs two hours earlier at Toronto; the second occurs at 4 or 5 P.M., and corresponds to the principal daily maximum at Toronto; the third is caused by the Horizontal Force retaining its high value after the hour just named at Athabasca, and even exhibiting an increase of it at 10 and 11 P.M. immediately before its great diurnal decline, whereas at Toronto it uniformly and steadily declines from 5 P.M. to 1 A.M.

Comparing together the values at the American stations as a group, from Table XIX., as laid down, plate 2, we find that the mean diurnal curve of the horizontal component at the two most southern stations, Philadelphia and Toronto, which are about 300 miles distant from each other, are similar in their hours of maxima and minima, but differ considerably in the value of their ordinates for the same hours, those at Toronto being much the larger, especially about the time of the morning minimum at 11 A.M., and of the principal maximum at 5 P.M.; they both present an increasing force at the hours at which it is decreasing to its lowest value at Lake At Sitka, which geographically is not far distant from Athabasca. the last-named station, while magnetically it belongs to the same group as the former, we have a curve of intermediate character; the great decrease of the Horizontal Force from 11 P.M. to 4 A.M., which occurs at Lake Athabasca, and is there followed by an equally rapid return towards mean values until 8 A.M., is, it is true, wanting, but we have a continuous slightly decreasing value, from 11 P.M. to 7 A.M., being the same period in which it is increasing at Toronto and Philadelphia. The curves in fact exhibit a striking progression of character, both in respect to the minimum and maximum of force;

we see the latter increasing rapidly in amount, and tending more and more towards an advanced period of the afternoon, as we proceed to the north, each culminating point falling above and in advance of that of the curve belonging to the stations to the southward from the lowest, which is that of Philadelphia, to the greatest, which belongs to Lake Athabasca. Again, we find the maximum at 6 A.M., which at Philadelphia exceeds that at 5 P.M. in amount, at Toronto is considerably less than the latter; at Sitka it cannot be distinguished with certainty upon the observations of one winter; and at Lake Athabasca we find in its place the very low values already pointed out, or if the small relative maximum of 8 A.M. be identified with it, it exists only as an inconsiderable undulation upon a much larger movement, determined probably by other causes.

At Fort Simpson the mean curve does not differ in general character from that at Athabasca, but is enormously increased in amplitude; the extreme deviations, both positive and negative, are doubled in amount, and there are other proofs of the influence of the advance of the season, the subordinate maximum just referred to being reduced to a still smaller relative amount, and shown three hours later; we find also no trace of the increase of the element preceding its great nocturnal decline, which was remarked in every one of the winter months; it declines slightly from 6 P.M. to 10 P.M., and then the great movement commences. At this station, as at Lake Athabasca, the mean curve by the induction inclinometer follows all the inflexions of that of the Horizontal Force, and gives a satisfactory confirmation of the accuracy with which they are represented.

A comparison of all the American stations for the two spring months, confirms the previous remark as to the systematic character of their differences, but shows also the curious fact that the *relative* change from winter to spring was less at Sitka than at either of the other stations, which is also apparent in the declination.

Induction Inclinemeter.—The instrument employed for measurement of the changes of Inclination was the Unifilar, with which the absolute determinations of the Horizontal Force were made. The arm opposite to the one which carried the reading telescope and scale was provided with a socket, at the distance of 5 inches from the suspended magnet, for the reception of a single soft iron bar of 12 inches in length. The length of the suspended magnet was 2°5 inches; the are value of the scale was 1'°0.

This instrument was one of the first of the kind that were made, and the first employed in any of the colonial observatories. I believe, also, that the present observations with it are the first that have been published at large, and as the Induction Inclinometer is less known than any other of the magnetical instruments referred to in this account, and has been less generally employed than its merits appear to deserve^{*}, it will be proper to state at some length the grounds for that degree of confidence in the results which has led to their being included in the present volume.

The principle of the instrument may be stated from the explanations of Dr. Lloyd, as follows + :- If a soft iron bar, perfectly devoid of magnetic polarity, be held in a vertical position, it immediately becomes a temporary magnet under the inducing action of the earth's magnetic force, the lower extremity becoming a north pole, and the upper a south pole; accordingly, if a freely suspended magnet, whose dimensions are small in comparison with those of the bar, be situated near, and in a plane passing through one of these poles, it will be deflected from the magnetic meridian. The deflecting force is the induced force of the bar, which is a function of the vertical component (Y) of the earth's magnetic force and of the temperature, but depends also upon the quantity and distribution of the magnetism in the bar, and its distance from the suspended magnet. In practice it may also contain a term depended upon the *permanent* magnetism of the bar, which is seldom wholly evanescent. The tendency of this force is to turn the magnet; it is resisted by the horizontal component (X) of the same force; under the opposing influence of these two forces the bar assumes a position of equilibrium at a certain angle (u) from the magnetic meridian. This position serves to determine the ratio which subsists between them, and from the changes which it undergoes, may be, in like manner, inferred the changes of this ratio, and therefore those of the magnetic inclination.

The moment of free magnetism of the suspended magnet being denoted by m, let mU be the moment of the force exerted on it by the iron bar, U being, as already stated, a function of the vertical component and of the temperature; then, since mX sin u is the

[†] Proceedings of the Royal Irish Academy, 1842 and 1850; also Letter to Colonel Sabine, dated 12th October 1848, printed and circulated for the information of the Directors of the British Colonial Observatories.

^{*} The advantages of the Instrument are these: Its construction is not attended with any of the mechanical difficulties which have led to the failure of the Balance Magnetometers. The changes of inclination being given directly, the deduction of those of the total force is much facilitated. It can be employed with increased advantage where the Balance Magnetometer, which is its only substitute, becomes nearly useless from its limited range of scale, and its unsteadiness in disturbances. It is easily adjusted, and not liable to get out of adjustment. It is observed with the same facility as a Declinometer, and its coefficient can be verified as often as we please without interrupting the series of observations; this last circumstance was not known at the period of the present observations, which was prior to the suggestion by Dr. Lamont of the method of deflection, to be referred to presently.

moment of the opposing force of the horizontal component X excited at the angle u, the equation of equilibrium is

$$\mathbf{U} = \mathbf{X} \, \sin \, u$$

now let the two components of the earth's force undergo any small changes ΔX and ΔY , and let $V\Delta Y$ be the change of U, then Δu , denoting the corresponding change of the angle u, in parts of radius $V\Delta Y = X \cos u \Delta u + \Delta X \sin u$

whence, dividing by the equation $Y = X \tan \theta$, in which θ denotes the magnetic inclination,

V
$$\tan \theta \frac{\Delta X}{X} = \cos u \Delta u + \sin u \frac{\Delta X}{X}$$

or if $p = V^{-1} \cot \theta$ we have

$$\frac{\Delta \mathbf{Y}}{\mathbf{Y}} = p \left(\cos u \Delta u + \sin u \; \frac{\Delta \mathbf{X}}{\mathbf{X}} \right)$$

assuming that the induced magnetism of the iron bar is proportional to the inducing force, the co-efficient p may be found by inverting the bar and observing the angle of deflection in the direct and inverted positions; denoting these angles by u and u', it is shown that

$$p = \frac{2}{\sin u + \sin u'}$$

whence

$$\frac{\Delta \mathbf{Y}}{\mathbf{Y}} = \frac{\cos u}{\sin \mathbf{S} \cos \mathbf{D}} \Delta u + \frac{\sin u}{\sin \mathbf{S} \cos \mathbf{D}} \quad \frac{\Delta \mathbf{X}}{\mathbf{X}}.$$

where $S = \frac{1}{2} (u + u')$ and $D = \frac{1}{2} (u - u'.)$ also since

$$\Delta \theta = \sin \theta \cos \theta \left\{ \frac{\Delta Y}{Y} - \frac{\Delta X}{X} \right\}$$

by substitution

$$\Delta \theta = \frac{\sin 2 \theta \cos u}{2 \sin S \cos D} \left\{ \Delta u + \frac{\cos S \sin D}{\cos u \sin 1'} \cdot \frac{\Delta X}{X} \right\}$$

The angle u in this formula being the deviation of the suspended magnet from the position which it would assume under the action of the earth alone, its changes Δu are the differences between the observed changes of position, measured from a fixed line, and the corresponding changes of declination. The effect of temperature upon the iron bar may be corrected by substituting ($\Delta u + a \Delta t$) for Δu , Δt being the actual change of temperature, and a the change of angle in parts of radius, corresponding to a change of 1°. Dr. Lloyd states, that the effect of an increase of temperature upon a soft iron bar, in all his experiments, has been an *increase* of its induced magnetism, being the reverse of its effect upon the permanent magnetism of an artificial magnet. The same effect was observed in the case of the present instrument, and in that of the observatory instrument with two bars at Toronto, but the amount was very small in both, as was also found by him.

Since the date of the observations under discussion, Dr. Lamont has shown that the assumption, that the induced magnetism of the bar is proportional to the inducing force, is not strictly in accordance with the fact, and has proposed a method of determining the scale co-efficient of the instrument, "which is independent of all hypothesis, and necessarily includes all the circumstances upon which the quantity sought depends." The principle of his method consists in altering the induced force artificially, by a small but known amount, and observing the change of angle produced thereby, and this is effected by placing a magnet at a considerable distance* above or below the suspended magnet, their centres being in the same vertical line, and observing the scale readings with this magnet, first vertical, in which position it exerts no direct action upon the suspended magnet, but only on the iron bar, and next horizontal, and at right angles to the suspended magnet, in which position it should exercise no action on the iron bar, but only on the suspended magnet. It will be shown below that at the distances of deflection which it is necessary to employ in practice, the assumption that in its horizontal position the magnet exercises no effect on the induced magnetism of the iron bar is not quite in accordance with the fact, but the effect produced can be eliminated very nearly, by reversals. Now if n be the angle of deflection with the magnet vertical, n' with the magnet horizontal, a the distance of the magnets from centre to centre, e the length of a line connecting the centre of the fixed magnet with the centre of the iron bar, and ϕ the angle which that line forms with the vertical, it is shown by Dr. Lloyd, that

$$\frac{n}{n'} = \frac{a^3}{c^3} (1 + \cos^2\theta) \mathbf{V}$$

By substituting the value of V thus found, in the formula above,

 $\frac{\Delta \mathbf{Y}}{\mathbf{Y}} = \mathbf{V}^{-1} \cot a \theta \left(\cos u \Delta u + \sin u \frac{\Delta \mathbf{X}}{\mathbf{X}} \right)$

a new and more accurate expression is obtained for the changes of the Vertical Force; also since

$$\Delta \theta = \sin \theta \cos \theta \left(\frac{\Delta Y}{Y} - \frac{\Delta X}{X} \right)$$

By substituting the last expression for $\frac{\Delta \mathbf{I}}{\mathbf{V}}$, we have

$$\Delta \theta = \mathbf{V}^{-1} \cos^2 \theta \cos u \Delta u + \mathbf{f} \cdot \frac{\Delta \mathbf{X}}{\mathbf{X}}$$

* Seven or eight times the length of the deflocting magnet is the distance recommended, but it does not appear to be sufficient.

where $f = V^{-1} \cos^2 \theta \sin u - \sin \theta \cos \theta^*$; or if we put $\sin \phi = V^{-1} \cos \theta \cos u$,

then $f = 2 \cos \theta \cdot \cos \frac{1}{2} (\phi + \theta) \sin \frac{1}{2} (\phi - \theta)$

The instrument made use of at Lake Athabasca has been subsequently sent to the East Indies, and I have had no opportunity of putting in practice both these methods of determining the scale co-efficient with it, for the purpose of ascertaining in what manner the value obtained by the original method must be modified, to agree with that resulting from the experiments of deflection. Both methods have been tried, however, with this view, with two different instruments at Toronto, and with other instruments elsewhere; the results appear to warrant the conclusion, that the ratio between the values thus obtained is not only constant for the same instrument, but so nearly the same for all instruments of similar construction, and furnished with iron bars of similar quality, that we may obtain a pretty good approximation to the true scale value, when, as in the present case, it cannot be directly determined, by multiplying the value given by the formula of the instructions by the mean ratio deduced from all the experiments.

The following Table contains the particulars of a series of experiments of deflection made with an Induction Inclinometer with one iron bar, at Toronto; this instrument is precisely similar to the one used in the northern observations, except that the magnet suspended is 3 °O instead of 2 °G inches in length; it was made and sent to America at the same time.

* The foregoing explanation is, in substance, derived entirely from the Papers of Dr. Lloyd referred to in a previous note, and is given as much as possible in his own words.

In the foregoing experiments, the deflecting magnet employed was the one used in the determinations of Absolute Horizontal Force, its length 3 66 inches. It will be observed that all the co-efficients obtained when the acting end of the bar was a south pole, or the bar was upwards, are greater than those given by the formula of the instructions, and all those obtained when the acting end was a north pole, or the bar downwards, with one exception, are less. It was proved, by reversing the deflecting magnet in the vertical position when the iron bar was away, that it has no effect on the suspended magnet in

* The particulars of the previous adjustments are as follows: n = number of reversals of the iron bar to obtain mean values of S and D; $\theta = 75^{\circ}$ 19'.

this position; but it would appear that the difference in question may result, in part at least, from an effect on the induced magnetism of the iron bar when the magnet is horizontal, which renders the angle n' greater in each case when the acting end is a south pole, for the same value of a, than when it is a north pole. According to the theory, the angle of deflection when the magnet is horizontal should be the same for the same distance, whatever the position of the iron bar, which is supposed not to be affected by it.

As it appeared desirable to establish this point, and it might be suggested that the effect was in consequence of not taking a sufficient distance of deflection, although in some of the foregoing experiments it was between nine and ten times the length of the magnet, a second series was made, with a deflector of 7.5 inches, which allowed a considerably greater distance to be used. The particulars are contained in the next Table.

It appears that, notwithstanding the increased distance of deflection, we have the same result as before. The ratio which the experimental scale value bears to the theoretical one evidently depends upon the nature of the acting pole, or rather upon the position of the iron bar above or below the suspended magnet at the time of the experiment; it is about one tenth greater for adjustments in the former position than for those in the latter. In both positions the value given by deflection is the greatest of the two.

* The following are the particulars of the adjustments in Table XXII. n = number of times the iron bar was reversed, to obtain the values of S and D.

			n	u	s	D	
X. XI. XII. XIII.	June 23 June 24 June 24 June 25	- - -	 7 3 5 5		$\begin{array}{c} \circ & \prime \\ 16 & 36 \cdot 0 \\ 16 & 34 \cdot 4 \\ 16 & 47 \cdot 6 \\ 16 & 47 \cdot 6 \\ 16 & 47 \cdot 6 \end{array}$	° / 1 19 1 21 1 56.6 1 56.6	Collet shifted to other end of bar,

The upper end of the iron bar being always a north pole, the effect of presenting towards it the north and south poles of the deflecting magnet alternately, during its horizontal reversal is always the same as regards its induced magnetism; when, however, the bar is *above*, or the acting end a south pole, this effect concurs with the tendency of the magnet in the same position to deflect the suspended magnet, and the angle of deflection is increased proportionably; when the iron bar is

reversed, or the upper end is the acting pole, the contrary is the case, the angle of deflection is diminished; the effect being less, however in the ratio of $\frac{e^3}{e'^3}$ to unity, (e' the value of e when greater than α or the iron bar below.)

Taking the *difference* between observed value of the angle n', in two adjustments, at which the position of the iron bar was different but the distance of deflection the same, to be the sum of the effects produced in each case by the action of the deflector in its horizontal positions upon the induced magnetism of the iron bar, it appears, in the case of the experiments numbered VIII. and IX., to have * amounted to $(46^{\circ}15-42^{\circ}66)=3^{\circ}49$ scale divisions, when the distance was 33 °0 inches; and to $(66^{\circ}26 - 60^{\circ}84) = 5^{\circ}42$ div. when it was only 29 3 inches. Let the effect in the two positions of the iron bar be η and η' , where $\eta' = \left(\frac{e}{e'}\right)^{3}\eta$, then in this case the two values of η are 2.55 and 4.05 div., therefore those of η' are 0'94 and 1'37 div.; that is to say, the double angles of deflection, when the magnet was horizontal and the iron bar above, were increased by the two former amounts, at the greater and less distances of deflection respectively, and by the two latter when the iron bar was below; in each case in consequence of the effect upon its induced The corrected values of n' are therefore 43.6 and 62.2 magnetism. divisions respectively, which slightly reduces the difference between the resulting co-efficients, but to so small an extent as to prove that it is not caused by the effect in question alone, and that we must look elsewhere for a solution of the difficulty, probably to the introduction of other terms into the expressions involving the distances e and a; but without pursuing this subject any further here, I have concluded that the only way of approximating to the true value of the ratio required is to take the mean between the values found for the same distances under two adjustments, one in which the iron bar is below, the other in which it is above.

The experiments with the 3,6 deflector supply the following couples:---

It would follow, from the whole series, that the scale co-efficient determined for this instrument in the ordinary way will be brought to accordance nearly with the true value, by augmenting it in the ratio 1 146. I have employed, however, the last series alone, the distances of deflection having been more favourable, and the general result less likely to be influenced by any terms involving that quantity beyond what are employed. We have, again, a series of experiments with another instrument, one of those provided with two iron bars. In this case one bar being always above and the other below the suspended magnet, the effect of the deflecting magnet in its horizontal position is neutralized in great measure, being of a contrary sign in the two bars respectively. The following are the particulars: —

TABLE XXV.

From the deflections at the nearer distance, we find a mean value of 1.332, and from those at the greater distance, a mean value of 1.318, for the ratio in which we must augment the value of the scale co-efficient found in the ordinary way for this instrument, to make it agree with the value deduced from experiment.

Lastly, Dr. Lloyd has found for his instrument a value of about 1'3 for the same ratio.

I conceive that whole evidence warrants the conclusion that the scale co-efficient found by the formula of the magnetical instructions is invariably less than the true value as determined by experiment; that the ratio in which it must be augmented is constant for the same instrument; and that it is nearly the same for all instruments furnished with bars of similar quality. I propose to adopt 1.22 provisionally, for the instrument used at Lake Athabasca, which I consider leaves the changes of inclination under an uncertainty of about one tenth their apparent value; a quantity which, however considerable, does not perhaps greatly exceed the uncertainty of all the observations of the changes of this element thus far; it does not affect their value for many relative purposes, and will not alter the character of any periodical law deducible from the observations.

The great amount of the daily changes of inclination indicated by the scale readings has been shown in Table XIII., in connexion with the corresponding changes of Horizontal Force. Satisfactory proof of the *reality* of these changes, and of the practical value of

the instrument, may be given by a comparison of the effect of sudden magnetical shocks, which sometimes occurred, of a very marked character upon the Inclinometer and Bifilar. The following instances have been selected with this view from the observations of Disturbances. The instruments were generally read in succession, with an interval of one minute between them. I have therefore interpolated a value of the Bifilar for the minute of observation of the Inclinometer; the last columns contain the change in scale readings and in terms of the Inclination and Horizontal Force, between each successive observation, usually a space of three minutes. It will be observed, that however great and sudden the changes of Horizontal Force shown by the Bifilar, the Induction Inclinometer never fails to exhibit a corresponding change of scale reading; indeed these changes so much exceed in general what would be inferred from the change of Horizontal Force alone, as to leave an excess sufficiently large to prove that in these cases, making full allowance for probable uncertainty of the scale value of the Inclinometer, the shocks must have been accompanied by large changes of Total Force.

TABLE XXVI.—continued.

^a Readings interpolated.

^b Readings taken simultaneously with those of the Inclinometer.

I conclude, from the foregoing examples of the action of the instrument in extreme cases, as well as from the close correspondence in the mean diurnal curves of inclination, as derived from the observations, with that of Horizontal Force, which will be pointed out below, that the testimony of the observations themselves is in favour of the opinion that the series, with some uncertainty as to the absolute values assigned, furnishes, as far as it goes, a true representation, and the only one we can at present refer to, of the regular and irregular changes of the Inclination in high magnetic latitudes.

Adjustments.

First Adjustment, 14th October 1843.—On conclusion of the experiments of deflection for determination of the absolute Horizontal Force, the instrument was placed on its pedestal, the base levelled, and the telescope adjusted to the meridian. The scale read 420°0, the corresponding reading of the Declinometer being 404°4, Bifilar 282°0, mean reading of Vernier's 199° 56′ 30″. The soft iron bar was now inserted in the socket, the upper or north pole deflecting, and was moved in the collet until the angle of deflection appeared to be a maximum; mean of Vernier's 252° 20′ 10″; when the same division of the scale was on the wire, Declination 406°6. The bar was next reversed, the lower end or south pole deflecting, and the telescope turned in azimuth until the central division was again on the wire; the Vernier's now read 158° 20′ 30″, Declination 406°8. We have then

	,	
$u = 41^{\circ} 36'$	S=46° 59′ 8	$\theta = 81^{\circ} 37''6$
$u' = 52^{\circ} 23'^{\circ} 6$	$D = 5^{\circ} 23''8$	a = 1.0007

whence the co-efficient for differences of scale reading, when corrected for changes of Declination, Temperature, and Horizontal Force, is

$$a\mathbf{P} = a \frac{\sin 2 \theta \cos u}{2 \sin S \cos D} = 0^{\prime \cdot} 148$$

according to the formula then in use. This value I have augmented in the ratio 1 22, for the reasons already stated in the actual reductions.

Increasing numbers indicated a return of the north end of the magnet towards the north, or a decrease of Inclination; the actual readings have therefore been inverted in the abstracts, by taking the complement of each to 500; and increasing numbers represent increase of Inclination throughout.

It would appear, from the difference between the angles u and u'above, that the iron bar must have possessed a considerable degree of permanent magnetism, or else that the suspended magnet was not on a level with the centre of the collet; it is possible, as there is no record to the contrary, and attention was not directed to this circumstance in the instructions then in use, that there may have been a difference on this account in the position of the acting pole, and, consequently, the amount of its action in the two positions of the iron bar, which would partly account for the difference in question; but the existence of permanent magnetism was afterwards shown by experiments at Fort Simpson. The bar was there employed as a deflector in the horizontal position, its centre at 15.7 inches from that of the suspended magnet, and it was found that there was a regular difference of 29''8 in the reading, according as one end or the other was presented; this difference gives an angle of deflection of 14'.9, one end acting as a north, the other as a south pole. The angle of deflection produced by a three-inch magnet, the centre at very nearly the same distance, was 612''0; the relative forces, being expressed nearly by the tangents of these angles, were as 1 to 41.5. I was not aware at that time of the facility with which an iron bar can be deprived of its permanent magnetism, by dipping it, according to Dr. Lamont's suggestion, several times alternately into hot and cold water; but to ascertain whether this circumstance is likely to have had any sensible influence on the results, the experiments of deflection Nos. X. to XIII., at Toronto, above, were purposely made when the bar had contracted a still greater amount of permanent magnetism by being inadvertently placed too near a magnet, but they do not show any difference from those in which the bar was almost entirely free from it, except a slight increase in the value of given changes, which may be due to ciner causes.

It became necessary to raise the suspended magnet on the 19th October, owing to the difficulty of reading the scale; the effect of

thus altering its position with reference to the acting pole of the iron bar was shown by a decrease in the scale readings, indicating an increase in the angle u of about 1° 53′. As the instrument was not otherwise disturbed, and the position of the bar was not altered, this quantity has been added to the angle u in the above formula until the end of the month, making the scale co-efficient

$a P = 0' \cdot 1747$

Second adjustment, 31st October 1843.—The soft iron bar being removed, the telescope was adjusted to the meridian, Vernier's reading 198° 28′ 20″, Declination reading 414 °O. The bar was then inserted in its socket, reversed, the telescope being turned in azimuth until the same division of the scale was on the wire, Vernier reading 248° 50′ 30″, Declination 413°O. The bar was lastly inserted, and the telescope again turned in azimuth until the same scale reading was obtained. Vernier reading 150° 0′ 5″, Declination 410°O. We have now

 $\begin{array}{cccccccc} u = 44^{\circ} & 28' \cdot 2 & S = 47^{\circ} & 25' \cdot 2 & \theta = 81^{\circ} & 37' \cdot 6 \\ u' = 50^{\circ} & 22' \cdot 2 & D = 2^{\circ} 57' \cdot 0 & a = 1 \cdot 0007 \end{array}$

whence

$$a \mathbf{P} = a \frac{\sin 2\theta \cos u}{\sin S \cos \mathbf{D}} = 0^{\prime \cdot} 140$$

And this quantity multiplied by the ratio 1'22 as before, gives for the approximate value of the scale, the co-efficient

· 1′ 1705

The situation of the instrument made it convenient to have the iron bar in both adjustments in the position in which the permanent magnetism and the induced magnetism were opposed.

CORRECTIONS.

Declination Changes.—Each reading has been reduced to the zero of 400 on the Declination scale, by subtracting from it the difference of the corresponding Declination reading from that number. In term days and magnetic disturbances, and whenever observations were made at short intervals, the correction applied was the mean between the Declination reading immediately preceding and following the Inclinometer observation; this was rendered absolutely necessary in many cases, by the rapidity of the changes of the Declination, which not infrequently caused the correction to vary more than a degree from one reading to the next, where the interval between them was only three minutes.

Bifilar Correction.—The correction due to the observed changes in the Inclinometer scale reading, for variations of the horizontal component of the earth force, involves the same quantity (V), of which the determination is the object of the experiments of deflection, and cannot be accurately assigned in the present case; being, however,

always very small, compared with the changes of the Inclination itself, the error involved by the application of the original formula can seldom be sensible. That formula is

$$B = \frac{\cos S \sin D}{\cos u \sin 1'} \frac{k}{a}$$

where h is the co-efficient of the Bifilar, a the value of one division of the scale of the Inclinometer in terms of radius, and the correction to each observed reading is B.n, n being the difference in scale divisions between the corresponding Bifilar reading and the standard reading, for the first adjustment B=0.100, and for the second B=0.057. These corrections have been applied to all the readings; the standard division adopted was the mean of the Bifilar readings for the same day in the month of October, and in the other months the mean of all the observations of each month respectively, to the nearest convenient unit, namely, the division 200 in November, 170 in December, 140 in January, and 160 in February.

The following Table contains the correction in scale divisions of the inclinometer for each value of n from 1 to 100 divisions of the Bifilar, under the adjustment of October 31; also the value of $\frac{\Delta X}{X}$ for the same values of n, for convenience in comparisons of the

 \mathbf{X}^{-} for the same values of n, for convenience in comparisons of the Bifilar readings.

Temperature Correction.—Experiments were made at Toronto in December 1844, after the return of the instrument from the northwest, to determine the effect of changes of temperature upon the induced magnetism of the soft iron bar. A copper vessel was fixed upon the arm of the instrument itself, surrounding the bar, and provided with a stop-cock for changing the water, a regular adjustment was completed, and the experiments were then made by filling the vessel with water at different temperatures, while the bar was in place. The temperature was carried at once from the lowest to the highest point, the average extremes being 50° and 95° respectively, and the bar allowed 15 minutes to take up the change. Eacn value of the corresponding scale readings employed in the calculation was the mean by three independent observations, with five minutes interval between them. The value of q is found by the formula

$$q = \frac{\Delta u}{\Delta t^{\circ}} \frac{\cos u}{\sin S \cos D}$$

These values and the other particulars of the experiment are given in the following Table.

TABLE XXVIII.

Experiments to determine the Effect of Changes of Temperature upon the induced Magnetism of the soft iron Bar.

The observation on the 27th has been rejected.

The correction to the scale readings of the Inclinometer for given changes of temperature is found by the formula—

$$\mathbf{R} = \frac{\sin S \cos D}{\cos u} \cdot \frac{q}{a}$$

The values found are R=0.368 for the first adjustment, and R=0.390 for the second. This correction has not been applied to the individual readings. The following table contains the value of $R \Delta t^{\circ}$ for each value of $\Delta^{\circ} t$ from 1° to 39°, to be subtracted from

INDUCTION INCLINOMETER.

the scale readings (as inverted) when the observed temperature is higher than the standard temperature, and the contrary when it is lower.

Corrections to reduce the Inclinometer scale readings under the Second Adjustment to a standard temperature.

The adjustment last described remained undisturbed until December $21^d 2^h$ Göttingen, when the arm of the instrument was accidentally struck and moved, occasioning a change of 123 scale divisions in the reading; such a movement does not sensibly affect the adjustment, and that quantity has been subtracted from all subsequent readings to correct the series.

Changes of the Inclination.—The approximate amount of the daily range of this element, indicated by the difference between the highest and lowest scale readings, has been already given in Table X111. in connexion with that of the Horizontal Force.

Diurnal variation of the Inclination.—The following Table contains the mean scale readings of the Inclinometer for each month, corrected for changes of the Declination and Horizontal Force, in the manner described above.

TABLE XXX.Monthly Means of corrected Inclinometer readings, omitting October 20,November 4, January 2-9, which are incomplete.

The general mean is taken, as in the other Tables, by dividing the sum of all the observations under each hour by the total number, which is 112; and the co-efficient for this curve, which includes observations under the separate adjustment of October, with those of the subsequent months, is

 $a P = 0.1405 \times 1.22 = 0.1714$

A mean having been taken however for the complete days from November to February inclusive, prior to the application of the Bifilar correction, I subjoin it at the foot of the page*; but as the

*	TABLE	XXXI.

Mean by 98 complete days under the Second Adjustment uncorrected for changes of Horizontal Force.

INDUCTION INCLINOMETER.

month of October was marked by considerable disturbances, which have probably affected the mean curve of Horizontal Force, it is here included with the other months. In the next Table the small correction necessary to reduce the means to a uniform temperature of 40° has been applied to the general mean; and under each corrected value is given its difference from the mean of the whole in scale divisions of the instrument, together with the approximate value of this difference in terms of the inclination.

Corrected Mean Diurnal Curve of the Inclination by 112 days of observation at Lake Athabasca.

We see by the foregoing Table that the hour of 3 A.M. is that at which the Inclination deviates most from its mean value, a result precisely similar to what we have found for the other elements; and there is the same reason for attributing the magnitude of the deviation to the effect of disturbance at that hour. If we select the same undisturbed days as before, and take their mean, the result is a signal diminution in the amount of the diurnal change at that period of the 24^{h} .

60

TABLE XXXIII.

Mean Diurnal Curve of Inclination by 45 Days * selected as free from Disturbance, corrected for Variation of Horizontal Force, and reduced to a uniform Temperature; together with the Differencc of each mean from the mean of the whole in Scale Divisions and in terms of the Inclination.

For comparison of the mean diurnal curve of Inclination at Lake Athabasca with that of the same element at Toronto, the only other American station at which it was observed directly, in 1843-4, I subjoin a Table, containing, first, the mean scale readings of a one-bar Inclinometer, observed from the 15th October 1843 to the 10th February 1844; and, secondly, the mean for the same five months, October to February inclusive, of the scale readings of a two-bar Inclinometer for the years 1845, 1846, 1847.

The scale co-efficient given by adjustment for the one-bar instrument was (a P)=0'723, which it appears by the experiments contained in Tables XXII.-XXIV., must be augmented in the ratio 1'166 to agree with the value given by experiments of deflection, the instrument there used being the same, giving for the approximate co-efficient 0'820. The other mean is related to various adjustments,

~

^{*} One day less than for the other elements, the 14th February being excluded on account of the omission of an observation.

[†] I take the experiments with 7.5 inch deflector alone as the best series.

INDUCTION INCLINOMETER.

and proportioning the co-efficient according to the number of days under each, the value applicable to it is (a P) = 0'. 3686. This must be augmented in the ratio 1.32, according to the experiments contained in Table XXV., to give the true scale value for this instrument, which is also the one to which those results refer, giving aP = 0'.486.

TABLE XXXIV.

Mean Diurnal Curve of Inclination at Toronto for 101 days, October to February 1843, by a one-bar Inclinometer; also, Mean Curve for the same period for three years, by a two-bar Inclinometer.

It will be remarked, that while the above means give similar diurnal curves, there is a difference of a large proportional amount between the values of the ordinates for the corresponding hours under them; a similar difference being observable between the corresponding mean curves of Horizontal Force, it would appear that the range of both elements was really less for the winter under discussion than its average amount. Taking the difference between the highest and lowest mean scale reading of the Bifilar, and the mean of the whole for each month in the above periods respectively,

62

it appears that the mean of the former, from October 1843 to February 1844, at Toronto, was +5.77 scale divisions, and of the latter -6.12 scale divisions; the corresponding quantities for the period included in the second part of the table are +7.78 and -10.52 scale divisions respectively. The adjustment of this instrument was the same for both periods, but the difference shown is not nearly enough to account for the whole effect. The adjustment of the one-bar Inclinometer was made with every care. I am nevertheless disposed to believe that the co-efficient deduced is too small. I present the result, however, because the instrument was similar to the one used in the north, and the *diurnal law* deduced is independent of the absolute amount of the change.

The mean diurnal curve of Inclination at Lake Athabasca presents two principal maxima and two minima; the first of these occurs at 3 A.M., and corresponds to the minimum of Horizontal Force; the second maximum occurs at 11 A.M., and corresponds to the small relative minimum of the latter element, which has been pointed out as having the effect of creating an undulation in the ascending branch of its daily curve. The principal minimum occurs at 10 P.M., and agrees nearly with the daily maximum of Horizontal Force; the smaller minimum, which is at 8 A.M., agrees in like manner with a subordinate maximum of this element at the same hour. Proceeding in the same way as before, to eliminate, partially, the effect of disturbances, by assembling all those days on which no extra observations were taken, we find that the mid-day maximum becomes more prominent, and the maximum at 3 A.M. considerably less so. The hours of maximum and minimum are but little altered, but a slight increase of inclination is shown at 8 P.M., immediately preceding the lowest value of the day, and answering to a contrary inflexion in the mean curve of Horizontal Force at the same hour. It appears, therefore, that in the minor as well as in the more prominent features of the curves, each maximum of the Horizontal Force corresponds to a minimum of Inclination, and each minimum of the former to a maximum of the latter; and we have, from the independent changes of these two elements, observed, by methods which have nothing in common, a strong mutual support and confirmation.

The mean diurnal curve of Inclination at Toronto, for the period under discussion, consists principally of a single progression, having its maximum at 11 A.M., about one hour after the daily minimum of Horizontal Force. This characteristic is the same, whether we take the mean by 101 days, corresponding to the period of observation at the northern station, or the general mean for the same months. There are indications of a second maximum at 10 P.M. The principal minimum occurs at 5 A.M. There is not the slightest trace of an inflexion corresponding to the daily maximum at 3 A.M., which constitutes the principal feature of the northern curve.

Fort Simpson.—The details of the adjustment of the Inclinometer at Fort Simpson will be given in a future section. The observations at this station are divided into two series; the first of 26 days, five of which are rendered imperfect by the omission of one or more observations; the second of 19 days, three of which are in the same condition. The omissions only affect the means at 0h. and 1h., and the whole 45 days have been combined for a general mean, without excluding the imperfect days, for the reasons assigned in reference to the Declinometer at the same station (p. 11.)

TABLE XXXV.

Mean scale reading of Inclinometer at Fort Simpson, corrected for changes of Declination and Horizontal Force, for the months of April and May 1844. To which is added the Mean for the same two months at Toronto, by observations of four years, 1845– 1848.

Scale co-efficients :---

The mean diurnal curve of inclination at Fort Simpson deducible from the observations of April and May presents only one wellmarked maximum and one minimum, the former at 4 A.M., the latter at 7 P.M.; there is an indication of a very slight maximum at 1 P.M., which coincides with a contrary inflexion in the mean curve of Horizontal Force, but both curves approach more nearly to a single progression than in the winter months. Viewed generally, the mean diurnal curve of inclination at this station, as at Lake Athabasca, is the exact converse of that of the Horizontal Force; the morning maximum of the latter element shown in the winter months is here reduced in amount, proportionably, as much as the mid-day maximum of the former, both features have nearly disappeared. There is no corresponding difference shown at Toronto in the mean curves of the same elements for the same periods respectively; and without grounding too much on observations embracing so short a period, I regard the corroboration afforded by the two elements to one another as giving good grounds for the conclusion that in high latitudes the advance of the season, and the rapid increase in the length of the day, produces changes in the character of the daily course of the magnetic elements which is not experienced in lower ones.

As the Inclinometer was not observed at Toronto in April and May 1844, I have taken the mean for these two months for four years, as a normal curve for that station. It does not differ in any characteristic from that of the five months previously described. It consists of a dcuble progression, having two minima of nearly equal amount, at 6 A.M. and 5 P.M. respectively, and two maxima, of which the first, at 11 A.M., is so strongly marked as to be the great feature of the whole curve, and the second, at 9 P.M., is so small in amount, as to fall on the negative side of the mean line. The curves of this element, therefore, at the two stations have scarcely anything in common.

Total Force.—Owing to the uncertainty in the precise values of the scale co-efficient of the Inclinometer, the inferences we can derive from the observations as to the changes of the Total Force, which depend very much upon those of the inclination, are necessarily somewhat vague; having found, however, by trial, that the *law* of the diurnal changes deducible is not altered by any moderate change in the scale value of the Inclinometer or of the Bifilar readings, but only the *amount*, I think it worth while to present the result.

The changes of Total Force are found by the formula

$$\frac{\Delta R}{R} = \frac{\Delta X}{X} + \tan \theta \Delta \theta$$

in which the quantities $\frac{\Delta X}{X}$ and $\Delta \theta$, are taken from Tables XX., XXXIII., and XXXIV.

The prevalence of positive and negative signs alternately, in both the mean curves contained in this Table, indicates clearly that the total Magnetic Force at Lake Athabasca in the winter months has two maxima and two minima daily; and on laying down the above quantities upon a sufficiently large scale, the hours of the latter are seen to be 8 A.M. and 8 P.M. nearly, while of the former, one maximum falls by both curves at or near 2 P.M., and the other at or near 3 A.M. if we include the disturbed days, and at or near midnight if we exclude them. There is very little difference in character or amount between the curves given by the whole period and by the selected days respectively in any other than the particular just alluded to. By both curves the Total Force is greater at the maximum in the night than at the one in the day, and less at the minimum, which occurs four hours before noon, than at the one eight or nine hours after noon. The difference between the highest and lowest mean value, or the mean diurnal range of total force, appears to be about '002. R by both curves. To examine the influence of an error in the co-efficients upon this curve it was assumed that the value of

TOTAL FORCE.

the scale divisions of either instrument might be one tenth greater or the same quantity less than the value actually employed; this supposition allows of eight combinations, and, having computed and laid down the values upon every one of them, it appears that in each case we have the two daily maxima and minima at nearly the same hours; the differences are chiefly in the amount of the changes and the relative prominence of the two maxima.

TABLE XXXVII.

Approximate Mean Diurnal Curve of total Magnetic Force at Fort Simpson from 46 days of observation in April and May 1844.

The above curve presents but one maximum and one minimum, the former at 4^{h} A.M., the latter at 7^{h} or 8^{h} P.M.; the mid-day maximum has disappeared, but the amount of the daily fluctuation is increased fourfold. This change of character in the mean diurnal fluctuation of the total force does not appear to attend the progress of the seasons at Toronto, but would necessarily be inferred from the altered character of the mean curves of all the elements at Fort Simpson; it is evident that the causes preceding the minor fluctuations at Lake Athabasca are here overruled by the more powerful influences to which the principal fluctuation is due, and we see in the case of each of the three elements observed an approach to one great diurnal movement, owing its character almost entirely to the

TOTAL FORCE.

extraordinary constancy and regularity which appears, in these regions, to belong to a class of influences elsewhere denominated *irregular*.

In this Table the observed mean diurnal values of the Horizontal Force for the seasons compared have been combined with the normal curves of inclination given by the observations of three years. They agree in showing that the mean diurnal curve of Total Force at Toronto has one principal maximum, which in the winter seems to occur about 2 P.M. and in the spring about mid-day; the lowest value occurs in the forenoon in the winter at 9 A.M., and in the spring two or three hours earlier. The indications of a secondary maximum and minimum are undecided; in neither case is there any appearance of a maximum of Total Force answering to the nocturnal one in the north. The curve computed from the changes of inclination shown by the one-bar instrument gives also a single maximum at noon, but of a small amount.

68

ABSOLUTE DETERMINATIONS AND

ADJUSTMENTS OF THE MAGNETICAL INSTRUMENTS

AT FORT SIMPSON.

Declination.-The Declinometer was adjusted on the 30th March The Magnet was suspended by a single fibre of silk, of which 1844. the force of torsion was quite insignificant; the mean change of scale, reading produced by turning the torsion circle 90° was 4'1 div. whence $\frac{\bar{H}}{\bar{F}} = \frac{1}{1769}$. The base was levelled, and the fixed wire of the telescope made to cut the central division of the scale, when the instrument was ready for observation. It became evident, however, after a time, that the length of the scale, which was between 12° and 13° of a circle, was insufficient to allow the full range required in some of the great disturbances at this station, if it was to be bisected in the mean position of the Magnet; advantage was therefore taken of a state of entire quiescence of the Magnet, on the 21st April, to move the arm and telescope 1° 40' to the westward, adding 100 divisions to the range of the scale on the east side of Zero, and diminishing the readings to the same amount; 100 has been subtracted from all readings prior to that date, in order to connect them with the subsequent series.

Absolute Declination.—An observation was made on the 30th March with the azimuth compass. Two sets of azimuths of the sun were observed A.M. and two sets P.M., giving the following values, which are reduced to the mean for $24^{\rm h}$ by a correction from Table VIII.

At 7^{h} 58^m 1 A.M. var. east 37° 35''7 at 9^{h} 12^m 7 A.M. , 38° 32''8 at 3^{h} 46^m 2 P.M. , 37° 39''0 at 4^{h} 55^m 8 P.M. , 38° 12''7 37° 55''8 38° 0''0

The following observation with a Collimator Magnet was made on the 8th May 1844.

The Theodolite was levelled and directed to the Collimator, mean scale reading 77 84, Declination 416 0, mean of verniers $359^{\circ} 59' 30''$, deviation from the magnetic axis 3'43 div. = 8' 30'' to the west. It was then directed to the sun, and the transit of both

(69)

limbs observed, mean reading of Vernier's 86° 17' 30" for the sun's centre, at 9^{h} 0^{m} 17^s apparent time. We have, then, the sun's apparent

Magnetic azimuth -	-		-	-	86°	18'	0″
Deviation of telescope		-		-	0°	8′	30″
1						_	
Sun's magnetic azimuth	-		-	-	86°	9′	30″

Absolute Declination - $37^{\circ} 56' 58''$ east, corresponding to 416 0 on the Declination scale. The mean scale reading on the 8th was 399 9, corresponding, therefore, to $37^{\circ} 40'' 9$ east Declination. There is a regular and progressive increase of Declination shown by the scale readings in April and May, as already remarked *ante* p. 17, Table IX. The following means were there given :—

Differences.

April, from 1st to 14th, Mean Declination 358'14

		154h 40 074h		285.00 27.78
••	"	15th to 27th,	99 1	³⁸⁵ 92 ⁻ } 14.41
"	,,	28th to 11th May	"	$ \begin{array}{c} 385 \cdot 92 \\ 385 \cdot 92 \\ 400 \cdot 33 \\ 418 \cdot 21 \end{array} $ $ \begin{array}{c} 27 \cdot 78 \\ 14 \cdot 41 \\ 17 \cdot 88 \\ 17 \cdot 88 \end{array} $
May,	,,	12th to 24th	"	418.21

The mean for April will be $374^{\circ}59 = 37^{\circ} 16'^{\circ}6$ east, and the mean for May $410^{\circ}01 = 37^{\circ} 53'^{\circ}0$ east. The mean of the whole, which corresponds to April $27^{\circ}5$, will be $390^{\circ}76 = 37^{\circ} 31'^{\circ}7$.

The results of the Declination observations have been discussed in connexion with the corresponding series at Lake Athabasca, *ante* p. 15, et seq.

BIFILAR.

First Adjustment, 30th March 1844.

1. The telescope was placed in the meridian, by suspending the magnet with unifilar suspension; reading of the azimuth circle 118° 12'.

2. The telescope was next suspended by the same double suspension as was used at Athabasca, and the interval of the threads adjusted by trial to give an angle of about 60°. Scale reading 210.

3. To bring the plane of detorsion of the double suspension into the meridian, the magnet was suspended, and the torsion circle turned until a position was found by trials, in which the scale readings were nearly the same, whether the magnet hung with its marked end to the north, or, by turning the arm 180°, it was reversed and hung with the marked end to the south. The final readings were

70

AT FORT SIMPSON.

	Telescope :	Torsion Circle :	Scale :	Bar:
	$118^\circ 12'$	265° 30'	278.0	N. end to N.
5	298° 12′	265° 30'	300.0	N. end to S.

265° 30' was therefore taken as the position of the index of the torsion circle which made the plane of detorsion in the meridian.

4. The arm was then turned 90° to 208° 12', and the torsion circle turned until the scale read 277 ° 0, torsion circle 326° 50'.

We have then $v = (326^{\circ} 50' - 265^{\circ} 30' =) 61^{\circ} 20'$ when K = a cotan v = -000318. Increasing numbers denote increase of Horizontal Force.*

The Bifilar received an accidental shock after the observation of April $10^d 3^h$, which produced a change of reading of + 80 div.; this quantity has been added to the readings from that hour down to the re-adjustment of the instrument on the 13th.

Second Adjustment, 13th April.

1. The telescope was placed in the meridian by suspending the magnet with unifilar suspension, reading on the torsion circle $119^{\circ} 45'$, scale 210, Declination 264 0.

2. The double suspension being applied as before, a number of trials were made to bring the plane of detorsion into the meridian. The final readings were as follows:

Telescope :	Torsion	Circle :349°	50'	Scale :207 5
299° 50′		349°	50′	202'0
Bar : N. end	to N.	Declination	ı :— 46	5.0
N. end	to S.		46	0.0

349° 50′ was therefore taken as the position of the index, which made the plane of detorsion in the meridian. The arm was turned 90° to 209° 50′, and the torsion circle turned until the scale read 204°0, when the reading of the torsion circle was 53° 50′, Declination 464°0, whence $a \cot n v = -000283$. Increasing numbers denote increase of force, as before.

The length of the scale of the Bifilar was found insufficient at this station, and a continuation on card was attached to it, on the side of decreasing force; but even this was insufficient on some occasions, when the observed range exceeded both the natural scale and its continuation.

HORIZONTAL FORCE.

In absolute measure.—The determination at Fort Simpson was similar in all respects to that at Lake Athabasca, except that three distances of deflection were employed instead of two. The details were as follows:—

* Decrease of Horizontal Force as actually observed, but the numbers having been inverted, Increase of Force in the register.

In addition to the foregoing values by the standard bars, we have those given by the magnets employed for verification; namely,

By bar 17, May 2, 1844, 1'959 | Bar 20, June 2d, 1844, 1'972. bar 17, June 12, 1'956. | bar 23, June 2, 1'947. Including in the present instance the results by bar 17, the general mean is

which is the value employed.

Variations of the Horizontal Force.-See Tables XXIII, &c.

INDUCTION INCLINOMETER.

First Adjustment, March 30, 1844.

1. The base was levelled, and the meridian reading of the verniers found to be $297^{\circ} 30' 0''$.

2. The iron bar was inserted in its collar reversed, the lower or north end deflecting, and the telescope was turned in azimuth until the central division of the scale appeared on the wire, verniers $249^{\circ} 34' 10''$, hence $u = 47^{\circ} 55' 50''$.

3. The bar was inverted, the upper or south end deflecting, and the telescope turned as before.

Verniers, $351^{\circ} 29' 0''$, whence $u = 53^{\circ} 59' 0''$, also $S = 50^{\circ} 57' 25''$, $D = 3^{\circ} 1' 35''$, and $\theta = 81^{\circ} 52'$.

Then
$$a\mathbf{P}_{,=} a \frac{\sin 2\theta \cos u}{2 \sin S \cos \mathbf{D}} = 0^{'} \cdot 106$$

which value being multiplied as before by the co-efficient 1 22, gives for the approximate scale value under the first adjustment 0 1293.

$$B = \frac{\sin D \cos S}{\sin 1' \cos u} \cdot \frac{K}{a} = 0.0618 \text{ when } K = .000318.$$

= 0.0551 when K = .000285.
$$R = \frac{\sin S \cos D}{\cos u} \cdot \frac{q}{a} = 0.488$$

The series was broken by an accidental shock to the instrument 2d May, by which the arm carrying the telescope was moved about 5°; advantage was taken of this opportunity to make the series of observations of the Absolute Horizontal Force given at page 72, after which the instrument was re-adjusted.

Second Adjustment, May 2, 1844.

1. The meridian reading of the verniers was 181° 57' 10", Declination 400.

2. The iron bar was inserted in its collar reversed, the lower

73

end deflecting, verniers 135° 59' 45", Declination 387.0, whence $u_{,}=45^{\circ}$ 57' 25 - 13' 0 = 45° 44' 25".

Then $aP_{\mu} = 0' \cdot 127 \times 1' \cdot 22 = 0' \cdot 1549$

B=0.023R=0.388

which continue applicable to the end of the series. There are 26 days in the first adjustment and 19 days in the second, giving

$$aP = 0' \cdot 115 \times 1 \cdot 22 = 0' \cdot 1402$$

for the value applicable to the diurnal curve obtained by uniting the whole.

Increasing numbers in every case denote increase of Vertical Force or Dip.

The means of the Inclinometer scale readings at this station will be found in Table XXXV.

IRREGULAR FLUCTUATIONS OF THE MAGNETIC ELEMENTS.

It has been shown in the preceding sections, by an arbitrary selection of days regarded as free from magnetic disturbance, that the portion of the mean diurnal curve of each of the elements, which owes its peculiar character most to the influence of what are usually called the *irregular* movements, is comprised between midnight and 7^{h} or 8^{h} A.M., and their effect, as far as can be inferred from the proportionate reduction in the deviation of the magnet from its mean position, made by rejecting them, is much the greatest during that part of the night. As regards the Declination, at least, this result is unexpected, being different from the conclusion to which Colonel Sabine and Dr. Lloyd have been led by their examination of the observations of Toronto and Dublin respectively, and is of so much importance that it will be necessary to investigate it more fully.

If we take the difference between the scale reading (ψ_{λ}) at each hour of observation, and the monthly mean at the same hour $(\overline{\psi_{\lambda}})$, the square root of the mean of the squares of these differences $\sqrt{\frac{\Sigma}{n}(\psi_{h}-\overline{\psi_{h}})^{2}}$ is a quantity regarded by Colonel Sabine* as the mean effect of the *irregular disturbing force* at the hour, and is called by Dr. Lloyd the mean disturbance[†], being analogous to the mean error of an observation at that hour; similarly $\sqrt{\frac{\Sigma'}{N}(\psi_{h}-\overline{\psi_{h}})^{2}}$ gives the value for a whole month, or longer period, N being the total number of observations, and Σ' the sum of all the squares. These quantities have been calculated for each of the elements at

† Transactions of Royal Irish Academy. Vol. XXII. part 1.

^{*} Preface to Observations during Magnetic Disturbances. Part 1. p. ix. 1842.

both the northern stations, and for some of them at Toronto, Philadelphia, and Sitka, with the view of giving stronger prominence to the peculiarity of the others. The work was first done, employing the observations as they stand in the abstracts, but it was evident, while the law is thus deducible, and the quantities for the several hours are relatively correct, their absolute values, when the scale readings of the instrument have undergone any considerable regular change, whether of a periodic or instrumental character, are very much exaggerated, and altogether deceptive. In these cases the scale readings at the beginning and end of the month differ from its mean $(\overline{\psi})$ by a quantity which includes, with the irregular fluctuation, the amount of the regular change in half the month. The differences between the successive fortnightly mean values in Table XI., show how considerable this change was in the Horizontal Force and Inclination at Lake Athabasca; it was equally large in the Declination at Fort Simpson; all these differences $(\psi_b - \overline{\psi_b})$ therefore were exaggerated to an amount proportioned to their interval in time from the middle period. It was thought worth while, in the case of the elements just named, to endeavour to eliminate this change, which was done by assuming that all the daily means of each month would, but for this cause, have been equal, and that the difference of each from the mean of the whole was a measure of the amount of the progressive change to be eliminated in the interval elapsed between that day and the middle day. Each daily mean therefore furnishes the equation $ne - (\psi_n - \overline{\psi}) = 0$, where e the value of the daily change required, and n the interval in days; by summing these equations in the usual manner, a mean value of the quantity e was obtained for each month, and this again, being multiplied by n, was added to, or substracted, as the case might be, from all the scale readings of each day, and the differences taken anew from the readings thus corrected. The values of e actually employed, or the approximate change of mean scale reading from day to day, were as follows :-Bifilar at Lake Athabasca, for the month of November 2'47 divisions, for the month of February 2'16 divisions; Incunometer, November 1'29 divisions, December 0'91 divisions, January 0'75; for the other months the change did not appear large enough to call for the correction. Again, for the Declination at Fort Simpson, from the 1st to the 27th April 1 537 divisions, from the 28th April to the 24th May 1 268 divisions. In the following tables the quantities given are those derived from the readings thus corrected.

TABLE XL.

Value of the Mean Disturbance of the Declination, taken without regard to sign, at the several observation hours at Lake Athabasca, to which are added the corresponding quantities for the same period at Toronto and Sitka, the whole expressed in Arc.

a Irregularity produced by a single unusual observation. See remark below.

It appears that the mean disturbance of the Declination at Lake Athabasca, or the mean disturbing force, if that term is preferred, is nearly constant, and at its lowest amount from 9 A.M. to 7 P.M.; it is greatest at 5 A.M., but an inferior maximum is presented at 10 P.M., which is the hour at which the greatest value prevails at Toronto and at Dublin. We have consequently an indication of the existence of at least two classes of irregular movements, the one due to causes which apparently act universally, the other due to some cause which only comes into operation in high magnetic latitudes. The characteristics of the curve for the five months in question at Toronto, are a nearly uniform value from 8 A.M. to P.M., when it begins to diminish; it is least at 7 P.M., and then increases regularly until 10 P.M., when it is greatest; it diminishes again until midnight, but appears to vary little during the night. There are indications in each of the three curves of a small increase in the mean disturbance about noon. Referring next to the mean for the Russian station at Sitka, the nearest geographically to Lake Athabasca, we find a manifest approximation to the law which prevails at the latter station; the greatest mean disturbance is shown at midnight, but high values The lowest value is here also prevail from 10 P.M. to 2 A.M. at 5 P.M.

There are two observations included in the series at Lake Athabasca taken during disturbance, which differ so much from the means for the same hours, as to produce a considerable effect upon the final result. These occurred on January 25^{d} 1^h, and February 2^d 7^h, Göttingen; by omitting them and taking fresh means for those hours, the mean disturbance for 5 A.M. becomes 10' 63, and that for 11 A.M. becomes 5''28, which are in accordance with the values before and after them. The quantities for the individual months in these cases are then 14''56 and 6''37 respectively.

The preceding results are independent of the *direction* of the disturbance. The next Tables are formed by taking the sum of the squares of the easterly and westerly deviations separately, and dividing them by their proper number. It sometimes happens that the scale reading at an individual observation is exactly equal to the mean; in this case the difference being \pm 0, the observation is not included in the number with either divisor, but being included for the disturbance without regard to sign, Table XL., occasions that value to be apparently less than, from the values for the same hours under the special signs, it should be; but such is not really the case.

TABLE XLI.

Value of the Mean Easterly Disturbance of Declination at the same stations and for the same period.

Value of the mean westerly Disturbance of Declination at the same stations, and for the same period.

b The extreme readings of Jan. 25 and Feb. 2 have been omitted here. The mean disturbance W. is 7'.77 at 5 A.M., and 8'.40 at 11 A.M., if they are retained, the monthly values being 9'.6 and 16'.2 respectively.

In the column headed "Excess" the difference between the mean values E. and W. is shown in connexion with the one which is greatest. Thus, at midnight, Table XLII., the mean westerly disturbance of Declination is 0' 78 greater than the mean easterly.

It appears by the foregoing analysis, that the westerly deviations at Lake Athabasca are, to a small extent, greater than the easterly, from 11 A.M. to 5 P.M., and also at midnight and 1 A.M. During the

IRREGULAR FLUCTUATIONS.

remainder of the night, and from 6 to 11 P.M., the easterly deviations are the greatest. Individual months present irregularities, as must be expected, but the general law is apparent in each of them; namely, a slight excess of westerly deviation during the day, and a much greater excess of easterly deviation during the night, but with a temporary preponderance of westerly tendencies at midnight; the latter particular agrees with Dr. Lloyd's deductions from the observations at Dublin. There is a considerable difference in the value of easterly and westerly tendencies at 10 P.M., a feature which these observations have in common with those at Dublin and Toronto; but the greatest difference is not as at the last-named stations at that hour, but much later in the night; it is shown from 4 to 7 A.M., and thus proves that the maximum value of the mean disturbance, included at those hours, is chiefly occasioned by easterly movements. There is no evidence in the means for five months at Sitka of that westerly tendency about midnight which is, with reference to the physical cause of the phenomena, perhaps, an important feature in the curves at the other stations; in other respects the same general law prevails; and it is interesting to observe, that although this station is in a high latitude, and nearer in point of distance by more than one half to Lake Athabasca than it is to Toronto, yet, being on nearly the same lines of equal magnetic inclination and intensity as the latter station, does not partake to a very much greater extent than Toronto in the great magnetic disturbances shown to prevail so commonly at Lake Athabasca.

79

80

readings for the progressive change alluded to above, together with the values of the same quantity for Toronto and Sitka. A Mean of the corrected readings at Fort Simpson, excluding incomplete days, is added; those days having been TABLE XLIII.-Mean Disturbance of the Declination at Fort Simpson in April and May 1844, after correcting the scale included in the Mean given Table.

IRREGULAR FLUCTUATIONS.

The diurnal law of mean disturbance of Declination indicated by the observations of April and May at Fort Simpson, appears to differ but little from that of the winter months at Lake Athabasca, as long as we disregard the sign of the movements. There is a maximum of total disturbance at 9 p.m., and another at 5 A.M., or about that hour, the latter being very far the most considerable; on referring, however, to the movements under the respective signs, it appears that the earlier of these two maxima is here caused by _ westerly and not by easterly movements, the great length of the day at this season having apparently the effect of protracting until a late hour of the night, and of increasing in relative importance the westerly tendency, which was also shown to be characteristic of the hours of the afternoon in the winter months. The very great increase in the amount of the mean disturbance is also apparently a result of the advance of the season, being participated in to a certain degree by all the stations. The apparent anomaly of an excess of westerly movements at Sitka, distant less than 500 miles from Fort Simpson, at two hours (3 and 4 A.M.) when the contrary tendency prevails at the latter station, is most remarkable; but this is not the place to follow out the inquiry it demands.

TABLE XLIV.

Mean Disturbance of the Horizontal Force and Inclination at Lake Athabasca, after applying the corrections specified above (page 75), for the changes of mean scale reading; final means for the whole period expressed in scale divisions.

* This high value appears to be chiefly produced by the observation of February 2d 6h. Gött.

81° °

It appears by the above table that the mean disturbance of both the Horizontal Force and Inclination, taken without regard to sign, is greatest at 3 A.M., being two hours earlier than the epoch of greatest disturbance of the Declination, and the subordinate maximum, which is shown by the latter element at 9 or 10 P.M., is wanting in these. The tendency to disturbance is very nearly constant, and at its lowest value, by both elements from 11 A.M. to 8 P.M.; it then begins to increase, but not very rapidly, until 11 P.M.; between this hour and midnight there is a large increase, after which very high values are maintained until 5 A.M. Referring again to the relative values, under the positive and negative signs, we find that there is a very great preponderance of negative movements of force and increasing inclination from midnight to 5 A.M.; but for some hours before midnight the contrary tendency prevails, namely, to increase of Horizontal Force and decrease of Inclination; and this latter appears to be more or less the case throughout the day, but the mean disturbance being comparatively small and the opposite tendencies nearly balanced, the latter conclusion is less certain.

All three elements then agree in supporting the conclusion drawn from the daily mean curves in the preceding part of the volume, that at Lake Athabasca a different periodical law governs the irregular fluctuations from the one established for stations in lower magnetic latitudes, or that the *reaction* succeeding the direct influences preponderating during the day, has its maximum influence at a much later hour. It also appears from the observations, that so regular in their operations in these regions are the so called *irregular* influences, that the denomination might with propriety be reversed, the observations of four or five months being sufficient to show that the mean diurnal curves of all the elements derive their chief characteristics from them. We have also seen that a similar result as far as regards the Declination is deducible from the observations of only 46 days at Fort Simpson. As the other instruments were twice adjusted in this short period, it would be scarcely worth while under ordinary circumstances to refer to them. For the purpose, however, of adding all the confirmation possible to the periodical law in question, I have calculated the mean disturbance of the Horizontal Force and Inclination at this station also; the results are contained in the next table, and are in complete accordance with the deductions from the longer period of observation.

Mean Disturbance of the Horizontal Force and Inclination, as shown by 46 days of observation at Fort Simpson, in April and May 1844, expressed in scale divisions of the instruments.

The co-efficients are added above for convenience, but the values given are probably somewhat exaggerated by the causes before mentioned. They represent the *relative* amount of the disturbing force affecting the Horizontal Force and Inclination, at the different hours of the day and night; and it must be remarked, that the values themselves are so great, that a reduction, of even a fourth part, would still leave them considerable enough to prove, that the force and activity of the causes producing irregular magnetic fluctuations, in the region to which they belong, must be a matter of not less interesting inquiry than the peculiarity of their epoch. For example, the means of total disturbance of the three first hours of the last table, when reduced by one fourth, represent '011 X and 12''4 of Inclination respectively.

The next Table is added for the purpose of completing the comparison attempted in this Report, by bringing into one view the results at all the chain of American stations; and it is of particular interest, as showing a manifest progression, inclining towards the characteristics presented at the northern stations. This is not a proper place to pursue at length the details of such a comparison, or to enter upon the very interesting subject of the annual variations of the mean curves which represent the tendency to disturbance at each hour; but it is desirable to give all the confirmation which can be derived from observations in lower magnetic latitudes, of the special

G 2

IRREGULAR FLUCTUATIONS.

form in which these phenomena present themselves in higher ones, the calculation has been extended to include a full year of observations at the three permanent observatories.

The observations at Philadelphia were made 19^m, and those at Sitka 28^m after the hour named.

It appears by this Table that the characteristic of a maximum value of the mean disturbance of Declination, extending from 8 to 10 P.M., belongs alike to all the stations, and does not materially differ in relative prominence at any of them; when, however, we compare the course of the mean values during the later hours of the night, a well marked difference presents itself. At each station the maximum just referred to is due entirely to easterly movements, and at each station it is succeeded, in the course of the night, by two other maxima, the first of easterly and the second of westerly movements: it is in the relative prominence of these maxima that the results at the three stations exhibit the difference referred to. At Philadelphia they are too inconsiderable to produce any marked result in the mean taken irrespective of direction; at Toronto they are much more decided, and a comparatively high value of the latter prevails in consequence from 1 to 7 A.M.; lastly, at Sitka they are sufficiently prominent to bear comparison with the maximum at 9 P.M., and so to prepare us for the result of observations in yet

:84

higher latitudes, by which, as we have seen above, they are shown to outweigh the latter maximum so much, as to reduce it to comparative insignificance, and to make those hours of the night in which the forces producing these movements predominate, the most important of the twenty-four, as regards their influence on the character of the mean diurnal curves of each of the magnetic elements.

There is a test of a very simple nature which the numerous observations of disturbances enable us to apply, for the purpose of ascertaining whether there is a determinate direction in the movements of the Declination magnet upon these occasions, which is different at different hours of the day. This consists in reckoning the numbers of individual readings taken during disturbances, at which the magnet was east and west of its normal mean position for that day. The latter value is found by making each day of disturbance the centre of a group of five or seven complete days, and finding the mean scale reading of the whole.

TABLE XLVII.

Showing the total number of Readings during Disturbances at which the Declination magnet was east and west of its mean position.

The observations entered at 16^{h} mean time at Fort Simpson were taken at 16^{h} 15^{m} and so on. It appears from the above Table that, from 3 to 7 A.M. the magnet at Lake Athabasca comparatively rarely passes to the westward of its mean position, and from 10 A M. to noon (and doubtless to 5 or 6 P.M.) comparatively rarely to the eastward of it. Westerly excursions have a preponderance which is not shown by the curve of mean disturbance from 9 P.M. to 1 A.M.

during the remaining hours (8 and 9 A.M. and 7 and 8 P.M.) easterly excursions preponderate. The tendency to westerly movements appears by this test also to be rather greater at Fort Simpson in April and May than at Lake Athabasca in the winter, as has been remarked in connection with Table XLIII. With regard to the apparent difference between the tendencies at 9 P.M. and the succeeding hours to 1 A.M. inferred from this Table and from the curve of mean disturbance (Table X.), it must be remarked, first, that no reference is here made to the relative magnitude of the movements to east and west, which is the subject of the other Table; secondly, that the present Table is derived from disturbances connected, it is probable, in almost every instance with the development of Aurora Borealis, that phenomenon having been visible during some part of every disturbance, on which the state of the sky permitted it to be seen with one exception. And it does appear from a careful comparison of the scale readings during disturbances visibly attended by Aurora, that the preliminary tendency in such instances is to a westerly range, the subsequent tendency to an easterly one. As the Aurora was most frequent at midnight and 1 A.M., the consequence of this distinction, if true, will be a comparative preponderance of westerly movements in the early hours of the night, but unless we admit that the same cause which produces the Aurora Borealis produces the ordinary reactionary or irregular movements, it does not appear to follow that the same law should be manifested by the entire body of observations embracing a great majority of hours on which no Aurora was present.

Shocks.—The following Table contains the total number of readings of the Declinometer which may be denominated shocks, according to the usual definition; that is c_{-} say, which differ from the mean scale reading for the same hour by a quantity equal to, or exceeding, twice the amount of the monthly mcan irregular fluctuation of the element as defined by Colonel Sabine. (Introduction to Toronto Observations, vol. 1. p. xv.) The dates and particulars of these readings will be given in a future section, when we consider the degree of correspondence between the movements at Toronto and the northern stations.

Showing the total number of Shocks or Disturbances of Declination, according to the definition of Colonel Sabine just referred to.

a For 0h Gött. Athabasca, and 1h Gött. Fort Simpson.

The total numbers are in the proportion of 1 to every 32 observations at Athabasca, and 1 to every 34 at Fort Simpson. In the five months at Toronto, October to February, we find 116 shocks, being in the proportion of 1 to every 27 observations, and in the two months April and May, we find 50 shocks, being in the proportion of 1 to every 25 observations; thus it appears that the high value of the monthly mean irregular fluctuation, caused by the prevalence of a state of disturbance at the northern stations, occasions a smaller proportion of readings to come under the definition of a shock as here applied, than the low value deduced from a comparatively undisturbed series.

It is to be observed that the proportion of easterly shocks is much greater at the northern stations than at Toronto. We have at the latter station in

1841, 70 easterly to 60 westerly.

1842, 77 easterly to 63 westerly.

In eight months, 1843-1844, 99 easterly to 89 westerly.

In all 246 easterly to 212 westerly; whereas we have seen that at the northern stations the easterly deflections are more than double the westerly in number, showing that whatever may be the cause which determines the north end of the magnet to the west, it decreases in activity in the winter season as we proceed to the northward in the American continent.

. <u>1</u>1-

ON THE CONNEXION BETWEEN THE CHANGES OF THE MAG-NETICAL ELEMENTS OBSERVED AT THE NORTHERN STATIONS AND THOSE OBSERVED AT TORONTO AND ELSEWHERE.

The circumstance that frequent and very considerable magnetical disturbances were observed at Lake Athabasca and Fort Simpson. during the winter of 1843-4 and the following spring, although the same seasons were remarkable for absence of disturbance at most of the other stations of observation which have been examined. would seem to afford a presumption that some of these disturbances were of a local character, or that their influence, when it extended to Toronto or the European stations, was too slight to attract attention. To this we may add the fact, that the hours of the day most affected by them are apparently not the same in high and in medium latitudes, as has been shown in the previous discussion of the irregular changes; lastly, it has been shown by Colonel Sabine from the Toronto observations of 1841 and 1842 (p. xx.) that the tendency of disturbances at that station is to produce westerly deviations of the declination magnet in the morning hours; and the eight months observations of 1843-4 which are here discussed. (Table XLIX.) lead to the same conclusion; indeed an inspection of any of the more important disturbances will show that the greatest movements of the declination magnet at Toronto are to the westward, whereas at Lake Athabasca and Fort Simpson they are almost invariably to the eastward, particularly in the same morning hours. In the case of this element, therefore, we have an opposite tendency in respect to direction, in addition to the difference of epoch in the Notwithstanding all these circumstances, however, two localities. a careful comparison with other published observations has led to the conclusion, that a state of magnetical disturbance prevailed at one or more other stations upon so many of the occasions upon which it was observed at Lake Athabasca and Fort Simpson, as to leave it doubtful whether, without more positive evidence, any of the disturbances, considered generally, can be considered to have been merely local. It is to be hoped, that the extension of automatic registration by means of photography will soon throw more light upon the question, whether any and what magnetic changes may be regarded as local, and how far we may consider movements which have few or no features of resemblance, to be due to a common cause, because they occur simultaneously in distant localities; meanwhile it would be to neglect a principal purpose of the observations under discussion, to omit to pursue the inquiry as far as they permit.

Extra observations at short intervals were taken at the two northern stations, on sixty-six occasions, exclusive of term days, in a period of about one hundred and sixty days of observation. Upon examination of all the records of magnetical observations for the years 1843-4 which have been published hitherto, namely, those of the four British colonial observations, those of the Russian stations, of Greenwich, Makerstoun, and Philadelphia, there are to be found only twenty-nine instances of corresponding observations elsewhere, and in this number are included five on which the correspondence consists only in one or two extra readings interpolated in the usual series at Greenwich or Makerstoun. This, however, is sufficient to show that in the view of the observers some disturbance existed. The dates to which this remark applies are October 26¹, December 8^d and 26^d 1843, April 30^d, May 3^d 1844. Of the remaining thirty-seven northern disturbances, about ten were of the first order as regards magnitude and duration, namely, those of October 15^d, 16^J, October 17^d commencing 17^h, October 25^d, 26^d, October 30^d, 31^d, December 5^d, 6^d, December 19^d, 20^d, December 29^d 1843, April 9^d, 10^d, April 14^d, 15^d, April 22¹1844; but on the whole, the coincidences of observation occur generally at the more considerable of the northern disturbances. December 28^d, February 8^d, and February 29^d, being the principal exceptions.

Proceeding next to examine the simultaneous changes of the several elements in detail, we find considerable diversity. Sometimes the movements of one or more elements correspond in epoch and in direction; sometimes in epoch when they are reversed in direction; sometimes the principal movement at one station is represented by the principal movement at the others, and as often by one of secondary prominence; sometimes there is marked agreement during part of a disturbance, no agreement during the remainder; lastly, there are several instances when movements remarkably similar in character occur at remote stations, but separated by a considerable interval of time.

All this may be shown without the aid of diagrams, by selecting the principal features of each disturbance alone for comparison, for which purpose the following brief notes are subjoined. The references are all to Göttingen time.

1843, October 17^d, 1^h to 3^h.—A great reduction of the Horizontal Force at Lake Athabasca between 0^h and 3^h, lowest value - '064 X*

* The values here given are the differences of the actual readings from the mean for the same hour and month; + or - signs before the change of declination indicate increase or decrease of the absolute value of that element, not simply easterly or westerly movements, as the absolute declination is east at Lake Athabasca, Fort Simpson, and Sitka, but west at Toronto, Philadelphia, Greenwich, Makerstoun, and St. Petersburg; the + sign indicates an easterly movement at the former and a westerly movement at the latter stations. It will be seen that the general tendency in disturbances is to an increase of absolute declination at all these stations, which reduces the difference of direction remarked above to a common principle. In selecting as the characteristic of each principal movement referred to, that one reading which happens to differ most from the mean, it is

at 1^h 46^m, but - 048 X at 2^h 1^m. Easterly extreme of Declination, +52' 7 at 1^h 35^m. At Makerstoun observations commenced at 2^h, apparently on account of a low range of Horizontal Force, - 0019 X, and the same at St. Helena, where they were also commenced at 2^h with a value of - 0012 X; there is no other obvious correspondence.

October 18-19, Term-day.-The principal movement of the Declination, which occurred between 15^h and 17^h, corresponds in general character at Lake Athabasca, Sitka, Toronto, and Philadelphia, a movement in the contrary direction being presented at the same hour at all the European stations. In the first part of the movement in question the direction is the same at all the American stations; during the latter part it is reversed, and we then have a westerly extreme -44''5 at Lake Athabasca corresponding to an easterly one $+10^{\prime}$ 8 at Sitka, with which the other stations agree. The changes of Horizontal Force between 15^h and 17^h have a general resemblance at Toronto and Lake Athabasca, save that where the element rises to a high value + '0172 X at the former station, at 17^h 6^m, it hardly passes its mean value at the latter, and they are very precisely reversed at the European stations at a later period 29^d 4^h to 6^h. The close resemblance of the changes at all the stations in America and Europe is very striking, and they here agree in direction.

October $26^d \ 20^h$ to $27^d \ 2^h$.—The principal movement at Lake Athabasca was between 0^h and 2^h , the extreme of Horizontal Force — '0624 X at $0^h \ 56^m$, and of Declination (easterly) +41' 7 at $1^h \ 5^m$. a single extra reading at $1^h \ 10^m$ at Makerstoun is the only proof that this disturbance, as such, was observed elsewhere; it shows a low value of the Horizontal Force — '0017 at $1^h \ 12^m$, and an easterly range of Declination —4'' 4 at $1^h \ 10^m$.

November 13^{i} 4^h to 7^h, and 20^h to 23^h.—A low value of the horizontal force prevails at Lake Athabasca from 4^h to 6^h, lowest -0347 X at 4^h 6^m. Declination not particularly affected, but an easterly extreme +17' 6 at 4^h 0^m. At Philadelphia the minimum of horizontal force, -0018 X, occurs at 4^h 11^m, and a low value is also maintained until 6^h. Declination, an easterly extreme -6' 2 at 4^h 0^m. This was a considerable disturbance at the last-named station, and observations were continued without intermission until 14^{d} 2^h. They were discontinued from 7^h to 20^h at Lake Athabasca, and then resumed on account of an unusual westerly range of Declination, giving a minimum -1° 6' at 22^h 16^m. At Philadelphia we

necessary to remember that from various causes, some of them perhaps instrumental, there may be an apparent difference of many minutes between the epoch of movements at two stations, which, nevertheless, viewed generally are coincident, and this is considered to be the case in all the cases cited unless otherwise stated. have a small but well marked easterly movement at the same hour, the extreme being only -1' 9 at 22^{m} .

November 24^{a} 1^h to 2^h. —A minimum of the Horizontal Force —: 0240 at Lake Athabasca at 1^h 1^m; no great change of Declination. At Hobarton extra observations also from 1^h to 2^h, the Declination chiefly affected; extreme -8'. 3 at 1^h 2^m; the Horizontal Force above the mean + 0008 X at 1^h 7^m.

December 1^d 21^h to 2^d 5^h.—Unusually large westerly movement of magnet at 22^h 15^m, -1° 37', and westerly movements prevailing until 23^h 30^m; afterwards easterly extreme +59' 2 at 3^h 27^m. Lowest value of Horizontal Force - 0443 X at 2^h 34^m, but a very low value about 22^h 45^m, and again from 2^h 0^m to 3^h 30^m. At Hobarton a low value of the Horizontal Force prevailed from 2^h 52^m, when extra observations commence, to 5^h, the lowest being - 0015 X at 3^h 47^m; Declination most affected about 3^h, extreme $-7' \cdot 0$ at 3^h 5^m.

December 8^d 18^h to 20^h .—Observations commenced at Lake Athabasca for an easterly range of Declination, maximum +44' 5 at 18^h 0^m ; disturbance of Horizontal Force not particularly marked, a minimum - '0087 X at 18^h 1^m , a maximum + '0085 at 19^h 10^m . A few readings were taken at Makerstoun, commencing at 18^h , apparently in consequence of a westerly range of the Declination of no great extent, extreme +3' 5 at 18^h 0^m ; the Horizontal Force a maximum + '0016 X at 18^h 2^m .

December $26^d 21^h$ to $27^i 2^h$.—A low value of the Horizontal Force from 22^h to nearly 0^h , minimum - 0354 X at $23^h 28^m$. Declination not particularly affected, maximum +30' 4 at $23^d 30^h$. At Makerstoun there is one extra observation only, at $23^h 35^m$. Declination +2' 8. Horizontal Force + 0001 X.

December $28^d 3^h$ to 4^h .—A great easterly movement of Declination at Lake Athabasca from 2^h to 3^h , extreme $+52' \cdot 3$ at $2^h \cdot 0^m$; the Horizontal Force not particularly affected, a minimum -0188 X at $3^h \cdot 1^m$, a maximum $+ \cdot 0105 X$ at $5^h \cdot 1^m$. At Makerstoun this disturbance attracted attention two hours earlier, a westerly extreme of Declination $+9' \cdot 7$ occurs at $1^h \cdot 52^m$, but the minimum of Horizontal Force occurs at $1^h \cdot 57^m$, $- \cdot 0018 X$, when this element differed very little from its mean value at Lake Athabasca. At Hobarton observation appears to have been commenced at 2^h , on account of an easterly range of Declination, extreme $+9' \cdot 2$ at $2^h \cdot 22^m$; the minimum of Horizontal Force coincides with that of Lake Athabasca, being $- \cdot 0013 X$ at $3^h \cdot 2^m$.

1844. January 4^d 16^h to 5^d 9^h .—Observations commenced at Lake Athabasca on account of the high range of Horizontal Force, which continued from 16^h to 20^h , maximum + '0287 X at 19^h 10^m .

IRREGULAR FLUCTUATIONS.

This is succeeded by very low values, giving two marked minima, the first and most important - '0635 at 23^h 4^m, the second - '0342 at 0^h 43^m; the Declination is also much disturbed, the extremes being -40' 7 at 21^h 0^m and $+1^{\circ}$ 6' at 0^h 57^m, but with many other great inflexions. A state of disturbance was very generally observed on this day. At Makerstoun extra observations were taken with various intermissions through the 4th, 5th, and 6th of January, and we find a maximum of Horizontal Force + 0012 X at 19^{h} 12^{m} , and the minimum at 23^{h} 17^{m} , -0021 X; also the maximum of Declination +8' 8 at 5^d 0^h 50ⁿ; in the other features no particular coincidence is to be remarked, and the great easterly movement of Declination at Makerstoun between 7^h and 8^h, giving a minimum -21' 0 at 7^h 35^m, is entirely wanting at Lake Athabasca. when the observations were resumed at that hour on account of a decrease of Horizontal Force of no great amount, which on the other hand does not appear at Makerstoun. The mean irregular fluctuation of the Declination and Horizontal Force at Toronto, on the 4th January, was the highest value of the month; the extra observations embrace but the earlier part of the disturbance, and the minimum of Horizontal Force coincides nearly with the maximum at Lake Athabasca, being -0019 X at $19^{\text{h}} 2^{\text{m}}$; the value at the regular observation of 4^d 23^h 2^m, which coincides very nearly with the principal minimum at Lake Athabasca, although also a low one - 0005 X, is not nearly so low as the reading at the epoch of greatest force at the northern station. The Declination appears to have been the most affected at Hobarton, but the minimum of Horizontal Force, - '0004 at 23^h 12^m, although very small in amount, coincides nearly with the principal one at Lake Athabasca.

, **t**

January $5^{1}23^{h}$ to $6^{1}3^{h}$.—An extreme depression of the Horizontal Force prevailed at Lake Athabasca from 23^{h} to almost $1^{h}30^{m}$, lowest — '0627 X at $23^{h}1^{m}$; at the same hour occurs the lowest value of this element at Makerstoun, — '0021 X. Again a westerly extreme of Declination, —19''4, occurs at Lake Athabasca at $23^{h}0^{m}$; a minor westerly extreme, +3''0, at Makerstoun at the same time, but the principal one, +4''5 at $1^{h}25^{m}$, coincides with a considerable easterly inflexion at the former station, +24''9 at $1^{h}33^{m}$.

February 1^d 0^h to 4^h.—Great depression of the Horizontal Force from 0^h to nearly 3^h, lowest — '0465 X at 0^h 27^m. At Makerstoun this element was not particularly affected at this time; and extra observations were not commenced until 3^h, when they show a westerly extreme of Declination +7'. 6, corresponding nearly to an easterly extreme, +29'. 5, at Lake Athabasca.

Again, from 1^d 19^h to 21^h an unusual westerly range of Decli-

nation prevailed at Lake Athabasca, extreme $-1^{\circ} 22'$ at $19^{h} 27^{m}$. Extra observations were taken at Makerstoun from 18^{h} to 19^{h} , but only one between 19^{h} and 20^{h} , which one does not indicate a correspondence of this element, but shows a minimum of Horizontal Force -0011 X, coinciding with the one at Lake Athabasca, which is -0239 X, also at $19^{h} 40^{m}$.

Februarv 2^d 6^h to 8^h.-An unusual westerly range of Declination at Lake Athabasca, extreme -48''2 at 7^h 0^m. There is also a minimum of Horizontal Force - '0258 at 6^h 10^m. Coincident observations were made at Makerstoun and St. Petersburg; at the former also occurs a minimum of Horizontal Force - 0036 X at 6^{h} 12^m, and an easterly extreme of Declination - 11''3 at 6^{h} 30^m, being half an hour before the - extreme at Lake Athabasca. At St. Petersburg an easterly extreme of Declination, +18''0, occurs at 6^h 10^m, and a maximum of Horizontal Force at 6^{h} 30^m, + 0022 X. Again, 2^d 17^h to 21^h, we have a marked prevalence of westerly Declination, and a high value of the Horizontal Force, at Lake Athabasca; the extremes -37' at 17^h 42^m, and + 0264 X at 18^h 53^m. At Toronto extra observations were commenced at the same time as at the northern station, a westerly extreme of Declination, +18' 1, occurs at 17^{h} 2^{m} , and another of small extent, +2'.6, at 17^h 42^m; a minimum of Horizontal Force accompanies the former, -0.0034 at 17^{h} 7^m; the lowest of this element value at the northern station is also at 17^h 1^m, but it is still above the mean, + 0015 X.

February 5^d 0^h to 6^h.—An excessive reduction of the Horizontal Force occurs at Lake Athabasca between 23^h and 0^h, extreme – '0678 at 0^h 4^m; great changes of Declination accompanied this shock, the extreme values being $+1^{\circ}$ 4' at 0^h 21^m, and -1° 23' at 0^h 30ⁿ. At Makerstoun but a single extra observation is given between 0^h and 1^h, namely, at 0^h 20ⁿ, which shows a considerable reduction of the Horizontal Force also, – '0029 X, but no particular disturbance of Declination. At Hobarton extra observations were commenced at 1^h, and the lowest value of Horizontal Force is at 1^h 12^m, – '0017 X, being an hour later than that at Lake Athabasca, a westerly extreme of Declination, -9''0, accompanies it.

Disturbance observations were resumed at 5^{d} 16^h with a high value of the Horizontal Force, giving a maximum + '0238 at 16^h 58^m; extra observations were taken at the same time at Makerstoun, showing low values of this element, minimum - '0034 X at 16^h 32^m. We have for the Declination the easterly extreme + 42' 1 at 16^h 21^m at Lake Athabasca, and the easterly extreme -0' 5 at 16^h 10^m at Makerstoun; again, the westerly extreme -20' 1 at 17^{h} 0^m a) the former station, and +6' 5 at 17^{h} 15^m at the latter.

February 8¹ 0^h to 1^h and 5^h to 6^h.—Two sudden changes of the Horizontal Force, but of no great extent; the lowest value was that at the regular reading at 5^h 1^m, -0235 X. Extra observations were made at Makerstoun from 4^h to 6^h, and at Hobarton from 5^{h} to 6^h; at the former station we find a minimum of Horizontal Force -0038 X at 4^h 52^m, at the latter a relative maximum of the same element -0004 at 5^h 2^m. Again we have, of the Declination, an easterly extreme +19' 7 at 5^h 9^m at Lake Athabasea, an easterly extreme -6' 3 at 4^h 55^m at Makerstoun, and a westerly extreme -7' 3 at 5^h 7^m at Hobarton.

February 29^d 0^h to 1^h.-The Bifilar was not in adjustment at Lake Athabasca during this disturbance, which was one of those most generally observed. We find, however, a relative maximum of the Inclination + 3' 1 at 16^b at that station, the value being below the mean at 15^h, 17^h, 18^h, 19^h, and 20^h; the maximum of the same element + 3''8 being at 16^h 12^m at Toronto, and apparently a little earlier at Philadelphia; on the other hand, the observations at these two stations do not show the minimum which follows at Lake Athabasea at 17^{h} , -10''2; they also show a very considerable easterly movement of Declination at 16^h, +25' 1 at Toronto, +22' 2 at Philadelphia, when that element was little disturbed at the other station. Extra observations were discontinued at Toronto at 28^d 19^h; they were continued at Philadelphia until 29d 3h, and we find a minimum of the Horizontal Force at 23^h, at which time a maximum of Inclination indicates the same thing at Lake Athabasca. At Makerstoun we find an unusually large easterly movement of Declination between 16^{h} and 17^{h} , extreme -21' 3 at 16^{h} 35^{m} , half an hour later than at Toronto and Philadelphia, and an equally great reduction of the Horizontal Force, extreme - '0051 X at 16^h 27^m. agreeing, probably, nearly with the maximum of this element at the American stations.

April 2^d 22^h to 0^h.—A very great and sudden shock at Fort Simpson, affecting first the Inclination and Horizontal Force, the former gives $+ 1^{\circ} 5' \cdot 6$ at 22^h 22^m, when the latter was less than the lowest scale reading of the Biflar (< $-0^{\circ}048 \text{ X}$)* a secondary minimum of the latter element - 0028 X is shown at Makerstoun at 22^h 17^m, but the lowest value - 0042 X is there at 21^h 22^m, when there does not appear to have been any corresponding movement at Fort Simpson. We find the minimum of this element - 0013 X at 22^h 35^m at Hobarton. The regular observations at

* The readings at Fort Simpson are referred to the mean for the 24ⁿ.

Toronto at 21^h and 22^h indicate a great reduction of the same element. The westerly extreme of Declination $+9'^2$ occurs at $22^{\text{h}} 25^{\text{m}}$ at Makerstoun, and at 22^h 27^m at Fort Simpson -43''O, at the same time is the westerly extreme -14' 3 at Hobarton. Of the great easterly range which followed at Fort Simpson, there is no very obvious sign at either of the other stations. Again, the extra observations were resumed at 3th 4th, on account of a great easterly range of Declination, with its usual accompaniments, increase of Inclination and Total Force, decrease of Horizontal Force, giving the extremes of each element at or near 4^{h} 30^m, namely + 2° 5' of Declination - '0505 $X + 45'' \theta$. Extra observations were resumed at Makerstoun at 5^h, but the extreme movements do not occur until near 6^{h} , when they are decidedly past at Fort Simpson. We have at the former station the unusual values of -20^{\prime} 3 Declination at 5^h 55^m, and + '0051 X at 5^h 57^m, a time when no very marked change is shown at Fort Simpson. This second disturbance was not observed at Hobarton, but a few extra observations were made about 6^h at Greenwich, and agree with those at Makerstoun.

April 16-17, 1844.-This great disturbance was recorded at nearly every station of observation, and furnishes at many, probably at all of them, the greatest amount of change of all the elements which had been recorded up to that date. There are, however, several remarkable differences in the character of the changes at different stations: first, as regards the Declination, we have an extraordinary easterly movement at Fort Simpson between 1^h and 2^h on April 17, the extreme range being no less than $+6^{\circ} 40'$ at 1^h 24^m; at this hour no marked feature is presented at Philadelphia or Toronto, whereas at stations in Europe and at Hobarton we find a resemblance. At Makerstoun the westerly extreme observed is +17' 9 at 1^h 0^m; at Greenwich the westerly extreme is +16' 9 at 1^h 9^m; at St. Petersburgh the easterly extreme is -14' 6 at 1^h 25^m. but followed at 1^{h} 35^{m} by the westerly extreme + 15' 2; at Hobarton the westerly extreme is +31' 7 at 0^h 57^m; at St. Helena there is no marked feature at this hour; at the Cape the extra observations were discontinued at 1^h. On the other hand, we have at Toronto and Philadelphia a great easterly movement between 16^d 20^h and 21^h, which answers to a shock of short duration at Fort Simpson; the extreme readings are at Toronto +39' 3 at $20^{\text{h}} 45^{\text{m}}$; at Philadelphia +26' 9 at 20^{h} 50^m; and at Fort Simpson $+2^{\circ}0'$ 4 at 20^h 50^m. A similar correspondence appears at 21^h 50^m. Referring next to the Horizontal Force, the greatest reduction of this element at Fort Simpson commenced very suddenly at 17^d 0^h 55^m; the extreme observed was -0'128 X at 1h 28m, this is, however, but an approximation, the range having passed the limit of the scale :

here are also great negative extremes at or near 173th, 19th, and 231, but none of them approached the one just cited; this is also the epoch of greatest reduction of this element at Hobarton, the extreme being - '0069 at 17^h 27^m, and we find it a little later at St. Helena; at Toronto we have at the same hour a considerable negative movement also, giving a minimum - '0106 X at 0^h 17ⁿ, but at this station and at Philadelphia the lowest value of the day is nearly an hour earlier, and answers to a movement of secondary. importance at Fort Simpson; the values are - '0148 X at 23^h 32^m at Toronto, - '0080 X at 23^h 27^m at Philadelphia, and - '0694 at 23^h 19^m at Fort Simpson; about the same time is the lowest value at Sitka and at Greenwich, while at Makerstoun it occurs between It deserves remark that the Horizontal Force begins 21^h and 22^h. to return to its normal value at Toronto and Philadelphia at 17^d 3^h, at Fort Simpson not until 17^d 5^h, in both cases by a regular change which is perfectly similar in other respects.

April $24^d 25^d$ Term day.—An easterly movement of Declination of very marked character and great extent prevails at Fort Simpson between $25^d 2^h$ and 4^h , the extreme being $+3^\circ 7'$ at $2^h 55^m$; we have a corresponding shock at Sitka, but reduced in amount to $+19' \cdot 0$, this extreme reading being at $3^h 0^m$. A sustained westerly movement of comparatively small extent, but very obviously coinciding in epoch, occurs at Toronto and Philadelphia, giving at the former an extreme westerly reading of $+10' \cdot 9$ at $2^h 32^m$, at the latter a westerly extreme $+10' \cdot 1$ at $2^h 48^m$. The European stations do not exhibit any particular movement at this hour.

Referring to the Horizontal Force, we find a very low value of this element at Fort Simpson from 2ⁱ 17^m to 3^h 7^m, the extreme being - '0585 X at 2^h 57^m; the lowest value at Sitka - '0101 X occurs at the same reading; the movement generally is well marked at that station. There is a well marked minimum at Toronto about 2^d 17^h being half an hour carlier than the one in question, but the lowest value at this station is -'0009 X at 7^h 32ⁿ. Viewed generally, there is a marked resemblance in the successive changes of the element at these two stations, but the epochs of maxima and minima do not coincide; they would be made to do so pretty nearly if the whole northern curve were advanced about two hours of time: for example, the first important minimum at Fort Simpson occurs at 0^h, at Toronto at 2^h 10^m, the following maximum, Fort Simpson at 1^h 40ⁿ, Toronto 3^h 10^m. The next minimum Fort Simpson 2^h 57^m, Toronto 5^h 30^m, the next maximum Fort Simpson 4^h 30^m, Toronto 6^h 30^m. An unusually high value of the element prevailed at both stations on the 24th and 25th April.

Extra observations were resumed at Fort Simpson at 20^h on the

25^h April, and continued until 26^d 2^h; they were resumed at 26^d 0^h simultaneously at Philadelphia, Makerstoun, and Hobarton. Referring them to this part only of the disturbance, we find a very great reduction of Horizontal Force at Fort Simpson between 23^h and 0^h, the extreme being — '0845 X at 0^h 7^m; we find a similar movement at Philadelphia, the extreme being — '0016 X at 0^h 2ⁿ, followed by an immediate return to high values, giving a maximum + '0010 X at 0^h 58^m. At Fort Simpson the succeeding maximum is less marked, and not attained until 1^h 30^m; at Makerstoun we find a minimum at 0^h 12^m — '0033 X, but the lowest value occurs at 0^h 47^m, and there is no maximum before 2^h. At Hobarton the Declination is the element chiefly affected, but we have a maximum of Horizontal Force at 0^h 7^m + '0008, and the minimum — '0019 at 1^h 22^m.

April 26^d 18^h.—A great westerly range of Declination prevailed at Fort Simpson from 18^h to 19^h 20^m, extreme —1° 24' ⁴ at 18^h 0^m. At Philadelphia extra observations were commenced at 15^h; we have an easterly extreme —8' ⁸ at 17^h 54^m, but the principal is at 19^h 20^m, —11' ¹, and a westerly movement intervenes, corresponding to an easterly one, or a return towards normal values, at Fort Simpson. Philadelphia at 18^h 14^m, +1' ⁹, Fort Simpson at 18^h 30^m, —23' ⁸. Again, the Horizontal Force at Philadelphia presents two minima, the greater at 18^h — ¹0013 X, the next from 18^h 55^m to 19^h 20^m. At the same periods we have minima at Fort Simpson, but the latter

in this case the greater, the extreme being -0300 X at $19^{\text{h}} 31^{\text{m}}$. At Makerstoun observations occur from 13^{h} to 18^{h} , and indicate, at the latter hour, values of both elements differing very little from their mean.

April $28^d 21^h$ to $29^d 5^h$.—The corresponding readings are confined to a couple at Makerstoun, between 2^h and 3^h . Referring to this period only, we find a great easterly movement of Declination at Fort Simpson, the extreme $+2^\circ 5'$ at $2^h 3^m$, accompanied by a very low value of the Horizontal Force, the extreme — 0379 Xat $1^h 52^m$, but with no great change for about 20^m before and after that hour. The observations at Makerstoun indicate a minimum of this element between $2^h 0^m$ and $2^h 45^m$, the lowest value of those recorded being — 0015 X at the $2^h 32^m$, but the Declination differs very little from its mean value.

April 30th.—Extra observations were taken at Fort Simpson every 15^m from 14^h to 16^h, in consequence of an unusually high value of the Horizontal Force, but no marked changes occurred; as usual under similar circumstances, the Declination is westward of its mean. Afterwards, at 21^h, a considerable disturbance commences. At Makerstoun a few extra readings were taken from 14^h to 18^h, showing a

small westerly extreme $-7^{\prime \cdot 9}$ at $14^{h} 5^{m}$ accompanied by a minimum $-^{\circ}0014 \times 06$ Horizontal Force; the subsequent disturbance was not observed.

May 2^d 19^h.—The commencement of extra observations at Fort Simpson coincides with the conclusion of them at Makerstoun.

May 3.—A sudden and great reduction of the Horizontal Force occurs from 3^{h} to 4^{h} at Fort Simpson, giving a minimum — '0619 X at 4^{h} 7^{m} . At the same time is a considerable easterly movement of Declination, the extreme being $+1^{\circ}$ 57' at 4^{h} 21^{m} ; at Makerstoun extra observations were also commenced at 4^{h} 35^{m} . Apparently in consequence of the easterly movement of the declinometer, since 4^{h} 0^{m} the readings were $+5' \cdot 0$ at 4^{h} 0^{m} , and $-4' \cdot 2$ at 4^{h} 35^{m} ; a maximum of the Horizontal Force + 0019 X appears at 4^{h} 42^{m} , but the disturbance was apparently not considered to call for more than occasional readings.

May $8^d \ 13^h$ to 19^h .—An unusual westerly range of Declination prevailed at Fort Simpson, but of no great extent, and without much change. Extra observations were taken at intervals at Makerstoun from 10^h to 20^h on this day, but present no particular features of correspondence or the reverse.

May 13^d, 18^h to 21^h.—Again a westerly range of Declination, attended, as in the last instance, with high value of the Horizontal Force and diminished Inclination. Extra observations were commenced at Makerstoun at 20^h for a small easterly extreme of Declination, but present no marked features.

May 22¹, 1^h to 4^h.-Extra observations were commenced simultaneously at Fort Simpson and at Hobarton. At the former we find an easterly range of Declination prevailing the whole time, extreme $+2^{\circ}$ 11' at 1^h 33^m, accompanied as usual with increased Inclination and a low value of the Horizontal Force, extreme - 0442 X at 1^h 43^m. At Hobarton the disturbances commences with a marked westerly range of Declination, the extreme -11' 9 at 1^h 5^m; the Horizontal Force is also below the mean until the observations ceased at 3^h, extreme - '0009 X at 1^h 32^m. At 5^h extra observations were began at Makerstoun; they were again resumed simultaneously at Fort Simpson and Hobarton at 12^h, and on this occasion, as well as on the 17th April, already described, nearly every stoatin appears to have experienced the disturbance. We find extra observations at Toronto from 13^h to 20^h, Philadelphia 10^h to 20^h, Makerstoun 9^h to 20^h, the Cape of Good Hope 17^h to 22^h, St. Helena 20^h to 0^h, and Hobarton 10^h to 0^h; nevertheless, this disturbance does not appear to have been among the most considerable in point of amount. Referring first to the Declination: the

observations commence at Philadelphia at 10^h with an unusual westerly range, extreme $+8'^{5}$ at 10^{h} 12^{m} ; the regular observation at 10^h 0^m at Fort Simpson shows no corresponding feature. We have again an easterly inflexion at Fort Simpson at 13^h 6^m, but the general range being westerly, it only reaches +3' 1 as referred to the mean, although a change of nearly 56' as referred to the preceding westerly extreme at 12^h 24^m; small as it is in amount it answers to an easterly extreme -9''9 at 13^h 7^m at Toronto, or -3''9 at 13^h 0^m at Philadelphia. Again, we have a westerly extreme -50' 1 at 13^{h} 33^{m} at Fort Simpson, and corresponding to it a westerly extreme +1''8 at $13^{h} 32^{m}$ at Toronto, or of +0' 8 at $13^{h} 24^{m}$ at Philadelphia. The easterly extreme of the day, +12' 4, occurs at Hobarton at 13^{h} 22^{m} . We have then another easterly extreme. $+10^{\prime}$ 4 at 14^{h} 52^{m} at Toronto, and +7''0 at $14^{h} 44^{m}$ at Philadelphia, to which there is no corresponding feature at Fort Simpson; then a westerly extreme at both those stations -0' 5 at $15^{\rm h}$ $52^{\rm m}$ at Toronto, to which a return toward mean values at Fort Simpson appears to answer, it gives -12' 5 at 16^h 0^m, being still to the westward. So far, therefore. this element has shown several movements apparently common to Fort Simpson and Toronto or Philadelphia, but at the northern station the readings have been chiefly westerly, or of the kind which marks the beginning of a disturbance. At 22^d 23^h we have the more active disturbance, marked by a range of about 2° to the eastward, the extreme is $+2^{\circ}$ 96' at 23^h 6^m; disturbance observations had been discontinued at all the stations, except St. Helena, before this hour, but the regular observations at Toronto and Philadelphia give no proof whatever that this shock, or a similar one at 23^d 2^h, extended to them.

Referring next to the Horizontal Force ; we find at Fort Simpson a high value prevailing about 12^h, extreme + '0285 X at 12^h 31^m; a similar feature is presented at Toronto and at Philadelphia. The regular reading at 12^h 2^m at Toronto gives + 0010 X, and at Philadelphia we have + 0012 X at 11^h 58^m, which is, however, somewhat less than a value observed an hour earlier. We have next. at the same stations, a minimum between 1^h and 2^h, the whole range being as yet high at Fort Simpson; the minimum in question is only - '0056 X at 13^h 7^m at Toronto, the lowest value is - '0030 at 13^h 42^m, and at Philadelphia - '0018 X at 13^h 18^m; the correspondence ceases with the minimum. At Fort Simpson the element returns very rapidly to its high value, and gives +0.0242 X⁻ at At Toronto and Philadelphia there is no corresponding 13^h 46^m. feature; it returns to its mean value gradually, not attaining a maximum until 15^h. We have next a maximum at Toronto between 16^h and 17^h, and again between 17^h and 18^h, to which there

are answering features at Fort Simpson; the lowest value at Toronto is -0040 at 18^{h} 17^{m} ; at this hour the values are very slightly below the mean at the northern station, where, on the other hand, we have a very great decrease of this element between 23^{h} and 0^{h} , which is indicated by the regular observations at Toronto. The lowest value at Fort Simpson is -0609 at 23^{h} 25^{m} .

The foregoing disturbance completes the list of actual coincidences of observation. In the following cases the observations, although not coincident, correspond so nearly in point of time as to make it probable that the disturbances observed were magnetically the same.

1843, October 25, 26.—Lake Athabasca, 25^d 19^h to 26^d 3^h; Makerstoun, 26^d 4^h to 11^h; Greenwich, 26^d 7^h to 12^h.

October 30, 31.—Lake Athabasca, 30^{1} 21^{h} to 31^{d} 4^{h} ; Makerstoun, 31^{d} 6^{h} to 10^{h} .

December 27.—Lake Athabasca, 27^d 18^h to 20^h; Makerstoun, 27^d 22^h to 23^h.

1844, January 8.—Lake Athabasca, $8^d 15^h$ to 16^h and 20^h to 22^h ; Makerstoun, $8^d 6^h$ to 13^h and 19^h to 21^h .

February 16.—Lake Athabasca, 16^d 21^h to 22^h; Makerstoun, 16^d 18^h to 19^h.

May 2.-Fort Simpson, 2^d 19^h to 24^h; Makerstoun, 2^d 11^h to 19^h.

Lastly, we have several instances in which magnetical disturbances were observed at other stations when they were not observed at Lake Athabasca or Fort Simpson, although the attention paid to the instruments was so close as to make it improbable that any considerable disturbance could escape notice. I select those only at which the observations were made at more than one other station, and a few of the more decided disturbances at single stations.

1843, December 8.—Extra observations for disturbance at Makerstoun 6^{h} to 10^{h} , at St. Petersburg 7^{h} to 10^{h} .

December 10.—Extra observations, Hobarton 5^{h} to 7^{h} , St. Petersburg 5^{h} to 8^{h} , Makerstoun 13^{h} to 14^{h} .

December 11.—Extra observations, Makerstoun 6^{h} to 12^{h} , also 18^{h} to 20^{h} , Greenwich 8^{h} to 9^{h} .

December 12.—Extra observations, Makerstoun 2^h to 11^h , St. Petersburg 3^h to 4^h , and 11^h to 12^h .

1844, January 2.-Extra observations, Makerstoun 7^h to 14^h, St. Petersburg 7^h to 9^h.

January 9.—A state of disturbance appears to have prevailed more or less all day at Makerstoun.

January 10.—The same remark applies, the station the same.

January 23. — Extra observations, Makerstoun 6^{h} to 8^{h} , Philadelphia 12^{h} to 24^{h} .

February 7.—Extra observations, 6^{h} to 7^{h} St. Petersburg, 6^{h} to 15^{h} Makerstoun, 9^{h} to 11^{h} Greenwich.

February 22.—Extra observations, 7^h to 9^h Makerstoun, faint Aurora being visible.

April 1.—A state of disturbance appears to have prevailed at Makerstoun more or less all day.

April 5.—Extra observations at Makerstoun 12^{h} to 19^{h} , at the Cape of Good Hope 13^{h} to 23^{h} . Aurora visible at the former station.

May 14.—Extra observations, 14^{h} to 17^{h} Makerstoun, 15^{h} to 17^{h} Toronto.

The following Table contains the value of the daily mean irregular fluctuation of both elements at Toronto and the northern stations, to which is added that of the Declination for the same days at Sitka, the whole calculated according to the method of Colonel Sabine (Observations on days of unusual Magnetical Disturbance, Part I. ix.), which is as follows:—The difference is first taken between the scale reading at each observation (reduced to an invariable temperature in the case of the Bifilar Magnetometer), and the mean of the month for the same hour; these differences are regarded as the effect of the irregular disturbing force at the time of observation, and are represented, by Colonel Sabine, by the symbol $\nabla \psi_n$, *n* being the number of the Göttingen hour of observation. The *fluctuation* of the element, due to the irregular action between two consecutive hourly observations, is $\nabla \psi_n - \psi_{n-1}$, which is expressed by $F\psi_n$, and the mean irregular fluctuation for a whole day will be $F\psi =$

 $\sqrt{\frac{1}{24}} \Sigma(F\psi_n)$, if the number of observation hours have been 24, as was the case in the present series. Similarly the mean irregular fluctuation for a month or longer period may be found, by dividing the sum of all the squares of $(F\psi)$ by the total number. The scale values employed to convert the mean fluctuation in scale divisions of the Bifilar into parts of the Horizontal Force, were the following: at Toronto k = 0001056, at Lake Athabasca k = 000341, and at Fort Simpson, from 15th April to 25th May 1844, k = 000283.

It appears by the foregoing Table that, with a few exceptions, the days of the larger mean irregular fluctuation of the Declination and Horizontal Force in each month coincide at all the stations, and that very low values, indicating a freedom from disturbance, are also generally the same; the exceptions may arise from an actual difference in the relative condition of the elements as regards this characteristic, but may also, in part, be caused by extreme movements concurring with the periods of regular observation at one station and not at another. It is due to this accidental circumstance that the mean fluctuation of both elements has a lower value on the 16th and 17th of April than on the 25th and 26th, although the amount of disturbance was considerably greater in reality on the former than on In the following Table a few instances of this the latter occasion. correspondence are selected, the number against each date being the relative place of that day among the other days of the same month at the same station, as regards the magnitude of the mean irregular fluctuation of the elements referred to.

November 14, December 12, January 8, and May 14, are inserted to show that occasionally a high relative value of the mean irregular fluctuation of one or both elements prevailed at Toronto, with a low one at the northern station; but the general conclusion from this comparison must be, that such a state of things is exceptional, a state of disturbance being more commonly prevalent at the same time over the whole area embraced, which is not an inconsiderable fraction of It has already been shown that there is not in that of the globe. general a correspondence in detail in the movements during disturbances at Lake Athabasca or Fort Simpson and the other stations in America or Europe, although it sometimes exists to a limited The first of these stations is rather less distant, and the extent. latter rather more distant from Toronto, geographically, than Barnaoul in Siberia from St. Petersburg. On referring to the curves of magnetic term days given in the Annuaire Magnetique et Meteorologique. &c. for these two stations, it will be seen that distance has apparently less to do with this want of correspondence than difference of magnetical position, for while there are numerous and interesting examples of great movements at St. Petersburg, not shown in the curve for Barnaoul, or only to be identified in some minor inflexion by the aid of the curves given for intermediate stations, yet these cases appear to be rather the exceptions, and in general a correspondence is at once perceptible, notwithstanding the distance, which is about 1,750 geographical miles, and exists both in the character and the precise epoch of the greater movements. For the purpose of showing more fully that this is not the case in the stations we are here comparing, a selection has been made of all the observations at Toronto, Sitka, and the northern stations, which differ from the mean for the month by a quantity exceeding twice the amount of the mean irregular fluctuation of the element for the same month. The values of the latter quantity will be found in the preceding Table. The dates of these observations are given in the next Table, together with the amount of the difference in each case from the mean, both at the station at which such difference reaches the given limit or amounts to a shock, and at the remaining stations. To distinguish the latter or corresponding readings from the shocks, they are printed in Italics.

TABLE LI.

A List of Shochs of the Declination at Lake Athabasca, or Fort Simpson, Toronto, and Sitka, with the differences of the scale readings at all these Stations from their means respectively at each date. Differences which fall short of $2\sqrt{\frac{\sum}{n}\overline{F\psi^2}}$, and therefore

do not come up to the definition of a Shoch, are printed in Italics. A movement of the north end of the magnet to the east is marked with the + sign at all the stations, the contrary movement with the - sign.

* Observation wanting. S. Sunday, Good Friday, or Christmas Day at the station. d Disturbance observed.

TABLE LL.—continued.

It will be seen by the foregoing Table that instances in which the Declination is simultaneously affected, to the extent which is defined as a shock, at Lake Athabasca or Fort Simpson, and Toronto, are comparatively rare; still more so those in which it is so affected at the

same observation at Sitka also. Of the latter class we find but eleven instances in a list embracing 623 dates of observation, of which number 473 were common to the three stations. It is to be observed, however, as a defect of this mode of comparison, that the number of shocks is generally least where the prevalence of disturbance is greatest, for this circumstance occasions a high value of the mean irregular fluctuation, and the proportion of instances in which the deviation exceeds double that amount is not equally augmented ; thus the number of so-called shocks is much greater at Sitka than at Lake Athabasca or Fort Simpson, the value of the mean irregular fluctuation being so low at the former station that a temporary prevalence of easterly or westerly ranges without sensible disturbance, and due probably to a different cause than the movements we are particularly investigating, is sufficient to bring nearly all the readings of certain days into the list; of this we have several examples in November and The proportion of shocks to the whole number of observa-January. tions is 1 in 34 '4 at the two northern stations taken together, 1 in 26 '6 at Toronto, and 1 in 13 3 at Sitka. Referring again to the individual stations, it appears that out of a total number of 83 shocks at Lake Athabasca, 36 coincided with shocks at Sitka; out of 31 shocks at Fort Simpson, 14 coincided with shocks at Sitka; these numbers are in the proportion of 43 and 45 per cent. respectively, whereas the number of dates coincident with shocks at Toronto are only 17 in the former and 7 in the latter number, being in the proportion of 20 and 22 per cent. This difference in the degree of correspondence is further to be seen, on paying regard to the signs of the differences of the coincidences in date at Toronto and the northern stations, 16 have the contrary and 8 the same sign; of those at Sitka and the same stations, 14 have the contrary and 36 the same sign. The evidences of agreement in the movements at Toronto and at Sitka are somewhat greater, but not materially so, than those we have found at the latter station and the temporary ones. In an aggregate of 187 shocks at Toronto, only 61 are coincident with shocks at Sitka, being 32 per cent., and of this number those with like and unlike signs are nearly balanced, the numbers being 29 and 32 respectively. The limit assigned to shocks being arbitrary, we may consider the above list without reference to it, and solely as a selection of simultaneous deviations of the Declination Magnet, from its normal value at the three stations, under circumstances of apparent disturbance at one or more of them. Thus compared, it appears that the magnet was similarly affected, or deviated from its normal position for the same hour, in the same direction at all three stations, in 138 out of 473 instances, or 27 per cent. of the whole; the proportion is the same if we have regard to the sign of the absolute Declination, which

is easterly at the three northern stations, westerly at Toronto, and is not greater for movements under one sign than under the other, whether referred to absolute or relative value. The absolute Declination appears to have been increased or decreased simultaneously at all three stations in 140 instances out of the same number. The proportion of instances in which the movements were similar at any two of the stations was as follows:—

Toronto and Sitka, 288 out of 555 selected observations, or 52 per cent.

Toronto and Lake Athabasca, 217 out of 372 selected observations, or 58 per cent.

Toronto and Fort Simpson, 42 out of 109 selected observations, or 38 per cent.

Sitka and Lake Athabasca, 231 out of 370 selected observations, or 62 per cent.

Sitka and Fort Simpson, 75 out of 110 selected observations, or 68 per cent.

As the observations here selected as most favourable for this comparison form somewhat less than one eighth of the whole number at Toronto, and about the same at Athabasca and Fort Simpson, the inference must be that under ordinary circumstances the deviations of the Declination Magnet from its mean position for the hour of observation, at stations so distant as those compared, are not referable to any common cause, and that where apparent resemblance exists, it is entirely casual.

In extending this mode of comparison to the changes of Horizontal Force, it was found that in consequence of the low value of the mean irregular fluctuation of the element at Toronto during the months examined, the proportion of readings which differed from their mean by double that quantity was too large to furnish a real criterion of the state of disturbance prevailing.

The numbers were as follows :-

In October 1843, number of observations 432, shocks -77-🔆 "In November 1843, 🖞 624. 211,, " ,, In December 1843. 600, 181 ,, . 99 وو In January 1844, 647, 293 ~,, **"** •• In February 1844, (` · 600. 200 وو`` 99 In March 1844. . 624. 135 وو ` •• • • In April 1844, -600. · 98 ,, " · In May 1844. 646. 152وو وو ÷., ,,

To render the view complete, however, as regards the northern stations, a list of the shocks of the Horizontal Force at Lake Athabasca and Fort Simpson is subjoined. The differences are taken in the same manner as those given in disturbances, that is to say, each

115

observation is first referred to the normal mean for that day, and the difference corrected for the mean diurnal change proper to the hour. The latter step has not been taken for the observations of April and May.

TABLE LII.

A List of Shochs of the Horizontal Force at Lake Athabasca and Fort Simpson, with the difference on each occasion from the mean for the hour, expressed in parts of the Horizontal Force, and the corresponding differences of Inclination; to which are added the differences of the former element from its mean, at Toronto and Sitha, at the same hours. The scale readings at Sitha have been reduced to the temperature of the mean of the month by means of the co-efficient $\frac{q}{h} = 7.0$, as stated in the "Annuaire Magnetique," §c. 1843, a value which makes q = 00038 in the English notation.

TABLE LII.—continued.

§ The values at Fort Simpson in April and May are referred to the da'ly and not the hourly mean.

-

••

It does not appear by the foregoing Table that the great and sudden changes to which the Inclination at Lake Athabasca and Fort Simpson was liable, extended in general even to Sitka, the nearest station. These changes were always accompanied by a proportionate change of the horizontal component, and, being generally positive, occasioned those great reductions of the last-named element which are contained in the list of shocks, and form the most conspicuous feature of almost every disturbance. We find that in 105out of the 170 observations here given, the value of the element had opposite signs at one or more of the stations at the same hour; of these, 74 are observations at Sitka. Of the instances in which the element appears to have been similarly affected. April 16th and 17th are the most decided, and the great reduction appears to have occurred earlier at Sitka on this occasion than at Fort Simpson. There are 106 of these dates at which the deviation of the Declination. from its mean, at one or more of the stations, amounted to a shock, and 64 at which the Horizontal Force alone exhibits the effect.

TERM DAYS AND MAGNETIC DISTURBANCES.

3

. Introduction.-The regular magnetical Term Days were observed at Lake Athabasca and Fort Simpson, and, in addition, extra observations were taken whenever the irregularity of the scale readings seemed to call for it, as well as upon some occasions when, from the presence of aurora or from some other cause, it was deemed advisable to commence them in anticipation of magnetic disturbance. During October, and for the first half of November 1843, the customary intervals of five minutes were adhered to; the Declinometer was read at 0^m, 5^m, 10^m, &c. Gött. time, the Bifilar at 2^m, 7^m, 12^m, &c., and the Inclinometer at 3^m, 8^m, 13^m, &c., after the hour; the great rapidity of the changes led afterwards to a general practice of reading the instruments one after the other in recurring succession, with an interval of only one minute between them; thus each element was observed every third minute. Upon Term Days, and a few other occasions, the five minute intervals were retained. The minute entered is, in every case, that of the Declinometer reading.

In computing the simultaneous variations of the three elements of Declination, Inclination, and Total Force, which are given for each observation, as well as those of the horizontal component, the mean diurnal curves given by the whole period of observation were employed, in preference to those of the individual months, for eliminating the regular changes, the latter curves being more or less irregular from the effects of disturbances. These curves correspond

in epoch to the middle of the period, or about the 23d December; but since the scale readings of each of the instruments show some progressive change, and those of the Bifilar and Inclinometer a considerable one; the numerical values of the hourly means, by these curves, are not correct for the observations at the beginning or end of the series, and are only correct approximately near the middle of it. In order, then, to deduce true differences, each day of extra observation has been taken as the centre of a group of five, six, or seven days, according to circumstances, and the means of all the readings of that group taken as the simultaneous or co-ordinate means of the three elements for the disturbance observations on the day in question. The difference between each scale reading and the mean thus found, for the same element is the whole deviation of the element from its normal value; to this being applied, with the contrary sign, the value of the ordinate of the mean curve for the same hour and minute, the sum is the measure of the irregular fluctuation shown by the observation, which, in the case of the Bifilar and Inclinometer, is expressed in terms of the Horizontal Force and Inclination, by means of the co-efficients given in preceding sections, and stated at the foot of each page. The scale divisions of the Declinometer, being minutes of arc. need no conversion.

The actual mode of proceeding was this; a table was formed for each element and for each month, containing twelve columns and twenty-four lines; in the first column were written the hourly means by the whole number of observations \pm the difference between their mean and the mean scale reading for the month; in the succeeding columns the hourly means were repeated + a proportional part of the change of the element from one hour to the next. By taking the difference between the actual readings and the appropriate mean thus found, we have the variation of the element from its normal value, affected by whatever difference there may be between the mean for the month and the true mean for the day of observation. which was sometimes considerable, owing to the progressive changes of scale reading before alluded to. To climinate this effect a constant correction was next applied to all the readings at each disturbance, being the difference between the mean of the month and the normal mean found as above related.

It must be remarked that the curves, which we have taken as types from 110 days of observation, are still sensibly affected by the irregular observations contained in that period, and consequently can be regarded only as approximations to that character; the degree to which they are affected may perhaps be judged of in some measure by comparing them with the curves given by 46 days selected as free from sensible disturbance, and is shown by the following Table:

TERM DAYS AND MAGNETIC DISTURBANCES.

TABLE LIII.

[Difference (x, -x) between the hourly ordinates (x) given by the whole period of observation at Lake Athabasca, and the ordinates (x), given by the curves of 46 days selected as free from disturbance.]

TABLE LIII. - continued.

The differences of the Declination are in some instances referable to the mean for the same month, and not the mean for the same day; the correction applicable on this account is stated where such is the case, but rarely amounts to 1'.

It appears that at the hours most influenced by disturbances, namely, from about 9^{h} in the evening to 5^{h} in the morning, the simultaneous fluctuations of the three elements are generally less than they would be if referred to diurnal means uninfluenced by disturbances; but since the means actually employed are derived from corresponding observations, the error thus introduced enters proportionably into all of them, and leaves the values actually presented true relatively to one another.

The simultaneous fluctuations at Fort Simpson are measured from the true mean of each element for the day of observation, and include the regular diurnal changes, the period of observation having been so short, and attended by such constant magnetic disturbances that the mean curves deduced can scarcely be regarded as a true representation of the action of those forces which it is the object of the other mode of treatment to eliminate. It was found convenient also to refer the observations in October to the mean for the day, in consequence of the disconnexion of the Inclinometer readings from those of succeeding months.

TERM DAYS AND MAGNETIC DISTURBANCES.

The approximate changes of Total Force $\frac{\Delta \phi}{\phi}$, have been computed by the formula $\frac{\Delta \phi}{\phi} = \frac{\Delta X}{X} + \tan \theta \Delta \theta$: their accuracy necessarily depends upon that of the scale coefficients of the Bifilar and Induction Inclinometer; the former of these may be considered as sufficiently well determined at Fort Simpson to entitle the values assigned to the changes of the horizontal component to considerable confidence; at Lake Athabasca, where a less delicate method of adjustment was employed, the scale coefficient of the Bifilar may possibly be itself in error in the fifth decimal. The scale coefficient of the Induction Inclinometer at both stations is liable to whatever uncertainty attaches to the correction we have applied in a previous section for the defect of the method formerly employed of determining the coefficient p, in the formula $\frac{\Delta Y}{\overline{Y}} = p \left(\cos u \Delta u + \sin u \frac{\Delta X}{\overline{X}} \right)$ 13 by simply inverting the iron bar, and observing the angles of deflection in the direct and inverted position, when it was assumed مر⊮ شيو ا This method, as was there stated, appears that $p = \frac{2}{\sin u + \sin u'}$. to give a value invariably too low, to the deduced scale coefficient, and from a number of experiments the ratio 1'22 was adopted in which to augment it under all adjustments, and has been applied. It is evident, therefore, that in the face of these admissions, great precision cannot be claimed for the values assigned for the changes of Total Force; but, having carefully considered the subject and examined the results themselves, it appeared to me that, with due explanation, they were entitled to be included in this report. Very little appears to have been determined hitherto with respect to the irregular variations of the Total Force in any quarter; the present observations show at the least that this element does nevertheless undergo in high latitudes very considerable changes; and believing their value also to be here assigned with sufficient accuracy for many purposes, I offer them, as approximations only, but approximations deriving peculiar interest from the remote locality and high magnetic latitude in which the observations were made.

The following Table contains the values of $\tan \theta \Delta \theta$ for each 1''0 of $\Delta \theta$, at Lake Athabasca, and Fort Simpson.

i.

. At 124 METEOROLOGICAL OBSERVATIONS. THE meteorological observations at Lake Athabasca and Fort Simpson are confined to a register of the temperature of the air, and of the wind and weather; particular attention being paid to the frequent displays of the aurora borealis. Two portable barometers and two thermometers for hygrometric purposes, had formed part of the equipment of the expedition, but were unfortunately rendered unserviceable in the course of the previous journey.

The instrument referred to from the outset as the standard thermometer, was a spirit thermometer by Newman, one of several which had been sent into the Hudson's Bay territory sometime previously by the Royal Geographical Society, and was recommended by that circumstance, as well as by the character of its maker. The tube, however, was so far from being of uniform capacity, that its graduation proved to be many degrees in error at very low temperatures; fortunately, there was on the spot, in the possession of Mr. Colin Campbell, another spirit thermometer, by Dolland, an old instrument, and supposed to be the same which was registered by Mr. Keith in 1825-6*; this proved much the more accurate of the two, and was registered in addition to the other, from the 7th January to the 29th February 1844. These instruments stood as follows in melting snow:-

N (Newman) $33^{\circ}5$ correction $-1^{\circ}5$ D (Dollond) 31° 0 correction $+1^{\circ}$ 0

It was soon observed that the difference here shown between them increased regularly in descending the scale, and much uncertainty was felt as to which was the preferable authority, until an opportunity occurred of testing the thermometer Newman in freezing mercury, which was done as follows :-- On the 23d January a portion of mercury was exposed in the open air until it became solid, at the same time another portion was allowed to acquire a temperature very little removed from the freezing point, the solid mass being then added to the fluid, the bulb and about two inches of the stem of the instrument to be tested were immersed in the mixture. The experiment was made in a room having a temperature of 35° Fahrenheit, and the spirit of the thermometer remained steadily at -31° 0 on the scale as long as any of the frozen mercury remained solid. Assuming, then, the solidifying point of mercury to be $-40^{\circ}9$ + Fahrenheit, we have the very large correction of $+9^{\circ}$ 9, applicable

^{*} Franklin's second Journey to the Shores of the Polar Sea, Appendix II. † In adopting this datum instead of the more usual value -39° '5, I am guided by verbal-information from M. Regneault, that he has found by accurate experiments with the air thermometer, that the true freezing point of pure mercury is between -40° and -41° centigrade; the mean of these two values is equivalent to -40° '9 Fahrenheit. The mercury employed in the experiments at Lake Athabasca had been purified with nitric acid some time previously, but was dull from exposure and shaking in the constant tree it had been put to in the artificial horizon. use it had been put to in the artificial horizon.

to the scale reading, $\pm 31^{\circ}$ 0 on the thermometer N. It appears by the following comparisons that the thermometer D. read -37° 8 when N. read -31° 0, consequently the error of this instrument at the freezing point of mercury was $+3^{\circ}$ 1, or the correction at the scale reading -37° 8 was -3° 1.

Comparisons of Dollond's and Newman's thermometers at low temperatures:

	Number of	Mo	ean.		
Newman Reading.	Observation s.	Newman.	Dollond.	Difference.	
0 0		0	0	0	
	18	- 30' 40	-37.02	-6.621	
-31 to -32	12	-31.13	-37'89	-6.67 -6.81	
-32 to -33	7	-32.11	-39.14	-7.03	
-35 to -34	11	- 33 34	-40.23	-7.21	
-34 to -35	4	-34.15	-41.27	-7'65	
-35 to -36	9	-35.33	-43.10	-7.77	
-36 to -37	6	-36.50	-44.25	-8.05	
-37 to -38	2	-37.20	-44'70	-7.20	
-38 to -39	1	-38.60	-46.10	-7.20	

These results are confirmed by a number of entries in the meteorological register on the 22d, 23d, and 24th January 1844. A small quantity of mercury being at this time exposed beside the thermometers, it was found frozen at all readings below -32° 9 of Newman and $-39^{\circ}5$ of Dollond, with one exception as regards the latter instrument, namely, on January 23^d 6^h Göttingen, when it is noted that the mercury was thawing, N. reading - 32° 4, D. - 39° 6. There are nineteen hours of observation on the above days at which the fact of the mercury being solid was noted, but it appears from the register that the reading was below -31° by Newman, and therefore the temperature below the freezing point of mercury at forty-six hours of observation in that month; it did not reach it in December or February. Newman's thermometer is entered in the abstracts corrected by subtracting 1° 5 from each scale reading above 33° 5, and $1^{\circ}5+0$ 130 Δt° for each reading below 33° 5, where $\Delta t^{\circ} = (33^{\circ} 5 - \text{observed temperature})$. The coefficient 0.130 is the increase of the correction, which appeared to be uniform for each degree in descending the scale, as shown by the foregoing data. The mean temperature for each day subsequent to January 7th by hourly observations of Dollond has also been corrected independently by subtracting 1°°0 at each reading above 33°°0, and 1°°0- $0.0596 \Delta t^{\circ}$ at each reading below 33°. The non-agreement of the corrected means of the two thermometers, excepting near the two fixed points on the scale, probably shows that the supposition of a uniform rate of increase of the correction is not in accordance with the fact, for there was nothing in the position of the two instruments to account for one standing permanently about one degree higher

METEOROLOGICAL OBSERVATIONS.

than the other, but as neither thermometer was compared with any absolute standard, we appear to have no better resource than to take the mean where both were observed, which has accordingly been done in Table VI.

The position of the thermometer was on the north side of an external porch made to contain the transit instrument; they were attached to a bracket projecting a few inches from the wall, their bulbs about four feet above the soil; the readings were taken through the transit openings.

TABLE LV.

Mean Temperature of the Air at Lake Athabasca by Newman's thermometer corrected, also mean temperature for the winter quarter, comprising the months of December 1843, January and February 1844.

ĸ

Mr. C. Campbell, the resident officer of the Hudson's Bay Company, having kindly continued to record the temperature by Dollond's thermometer four times a day after my departure, until he left the station himself, we are enabled to add four months to the foregoing table :

TABLE LVI.

Month.	Sunrise.	9 A.M	3 р.м.	9 г.м.	Approx. Mean.	Corrected Mean.
1844 : March * - April May June Spring Quarter -	° - 2'42 27'82 39'14 47'20	o 1·13 † 35·48 46·74 57·17 28·91	9'13 42'50 50'31 58'83 35'03	o 2. 16 33 · 96 42 · 07 50 · 86 27 · 06	° 1.64 34.72 44.40 53.52 26.90	2·4 35·1 44·8 53·9

Mean Temperature at Lake Athabasca—continued.

* The first four days of March are wanting.

† 1° 02 by the 31 days, which are complete for this hour only.

The thermometer recorded by Mr. Campbell has been corrected for temperatures above 32°, by the uniform addition of 1°, and for lower temperatures by the scale already given. The approximate mean is that of the observations at 9 A.M. and 9 P.M., which in each of the other months at this station and at Fort Simpson is below the true mean; probably the correction $+0^{\circ}$ 8, derived from December, January, and February, will be nearly correct for March, and $+0^{\circ}$ 4, derived from April and May at Fort Simpson, nearly correct for April, May, and June at Lake Athabasca, giving the quantities in the last column.

Mean Temperature of the Air at Fort Simpson, M'Kenzie's River, for April and May 1844.

* From 1st to 25th May.

+ Corrected to the mean of the complete month, at the same average daily increment of mean temperature (0° 30) the mean for May will be 45° 5.

The observations at Fort Simpson were taken 20^m after the hours named.

In the observations of Mr. Keith at Lake Athabasca in 1825-6, referred to above, the mean temperature is derived from the mean of the daily extremes; for the sake of comparison, a similar value has been formed for each month in the foregoing tables, and is subjoined, together with other approximations to mean values.

Various approximations to the Mean Temperature.

It appears, by the foregoing Table, that the best approximation to a true mean, from October to February, is obtained by three equidistant observations, beginning with 6^{n} or 7^{h} A.M.; the mean by the daily extremes, that is to say, the highest and lowest hourly observations, is also a good approximation in October, November, and December, but considerably too low in the subsequent months; the mean by the homonymous hours from 6^{h} to 9^{h} inclusive, is decidedly too low, that of the succeeding homonymous hours 10^{h} and 11^{h} is, however, somewhat better. The same remark applies to the months of April and May; the differences from the true mean apparent in the latter are, however, considerably longer than those shown in the previous months, the mean diurnal curves of temperature having themselves a marked difference arising from the change of season.

The mean diurnal curve of temperature for the winter quarter at Lake Athabasca differs but little from that of the corresponding season at Toronto. The mean range is $5^{\circ} \cdot 92$ at the former, and $5^{\circ} \cdot 95$ at the latter station; the coldest hour is the same, $7^{\rm h}$ A.M., and the curve cuts the line of mean temperature in its morning ascent at pretty nearly the same time. By simple interpolation this epoch will be $9^{\rm h} \cdot 53^{\rm m}$ at Toronto, and $10^{\rm h} \cdot 21^{\rm m}$ at Lake Athabasca. There is a slight difference in the descending branch, which is prolonged above the mean to the latest hour at the more northern station, giving a temperature above the mean at eleven observation hours at Lake Athabasca, and at ten only at Toronto. The more rapid relative increase in the power of the sun with the advance of spring at the more northern station, is evinced by the large amount of the mean daily range at Fort Simpson in April and May, namely,

19°'71, while for the corresponding months at Toronto it is but 15° '76.

TABLE LIX.

Mean Temperature for December 1843, January and February 1844, at Toronto, also for April and May 1844, for comparison of diurnal curves with those given.

TABLE LX.—continued.

* Mean of both thermometers, corrected, from 7th January to 29th February.

135

The foregoing Tables show a remarkable prevalence of cold in January 1844 at Lake Athabasca; the mean temperature for that month differs by no less than 23° from that of December, the one being probably above, the other below, the normal mean temperature, and the mean-for the hours of 1^h, 2^h, and 3^h P.M. is 31° lower than that for the corresponding hours of February. A similar state of things prevailed at Toronto, where we have the mean temperature for December 1843, 30°'8, and for January 1844, 20°'7, difference 10°'1, the means for those months by the observations of twelve years being respectively 27° 0 and 24° 5, difference only 2° 5. We have also in the same month the extraordinary difference of 62°'3 of temperature in the course of four days, the thermometer having indicated -47°'7 Fahrenheit at 7 A.M. on the 25th, and +14° 6 at 2 A.M. on the 30th January; but this is not the whole range in the month, and is indeed exceeded by a change of 64°'9 between 3 P.M. on 22d March and sunrise on the 25th, when the temperatures observed were 42° 0 and -22° 9 respectively. For the purpose of comparing exactly the fluctuations of temperature at these northern stations with those of Toronto, the situation of which, on a peninsula formed by three of the great lakes, gives its climate somewhat of insular characteristics, I have taken the differences between the highest and lowest observation of each day, and found the mean value of the daily range thus shown, precisely as was done for the corresponding ranges of the magnetical elements, Tables I., IV., and XV. These values, and some other particulars in aid of this comparison, are contained in the next Table.

Comparison of Range of Temperature.

WINDS.

THE Direction of the Wind was entered by estimation at each hourly observation, and its force expressed in words. The number of winds from each half quadrant are given in the next Table, where the column North includes N. by W., N.N. by E., and N.N.E., and so on round the circle. The azimuths actually entered were magnetic. This arrangement was adopted to take advantage of the convenient guide furnished by the arrangement of the buildings in Fort Chipewyan, which all ran within half a point of north and south or east and west by compass. They have been converted into true directions, by subtracting two points from each, being the value of the magnetic declination less 5°, the amount of the deviation of the lines to the west of magnetic north. In similar circumstances it will be found preferable to establish a permanent guide of some simple nature to the true directions.

On comparing the results contained in the foregoing Tables with those of the corresponding period at Toronto, it is observable that the proportion of winds from the north-east is much greater at Lake Athabasca than at the more southern stations; at the former the great preponderance, whether we regard number or total pressure, is from that quarter; at Toronto, on the contrary, it is from the north-west. Resolving the total pressures in the four cardinal directions, and obtaining a general resultant, it appears that the following are the equivalents of all the winds at the two stations for the period under comparison:

TABLE LXIV.

	L	ake Athab	asca.		Toronto.

Thus it appears that the prevalent winds at Toronto and Lake Athabasca belong to different and nearly opposite systems; a northwesterly current preponderates in the lower latitudes $(43^{\circ} 49')$, a north-easterly current, inclined to the former at an angle of about 117° , prevails in the higher one $(58^{\circ} 43'.)$ The general fact of a prevalence of N.E. winds is stated in the Meterological Register by Mr. Keith for 1825–1826, which has been before referred to.

The Mean Force appears to be considerably higher at Lake Athabasca than at Toronto.

There is but little correspondence between the winds observed at Fort Simpson in April and May and those recorded at Fort Chinewyan at the same time; at the former station half of the total number of winds was from the east and south-east, at the latter the same proportion was from the north and north-east, but the period of comparison is too short for any conclusion to be drawn from the observations. A local phenomenon of interest was observed several times at Fort Simpson, in the rapid rise of the temperature of the air when the wind changed to the south-west from an easterly direction. It appeared as if the warmer air of the Pacific Ocean were transferred across the neighbouring ridges of the Rocky Mountains, with little loss of its temperature. Thus we have April 3^d 10^h, wind S.E., temperature 34° 5; 3d 11h, wind S.W., temperature 39° 5. Again, April 25d 5h, wind S.E., temperature 43° 5; 25d 6h, wind S.W., temperature 58° 0. Again, April 29d 5h, calm, temperature 39° 5; 29d 6h, wind S.W., temperature 48° 5. Lastly, May 8^d 8^h, wind S.E., temperature 53° 7; 8^d 9^h, wind S.W., temperature, 56°'7.

AURORA BOREALIS, WEATHER, &c.

· · ·

Owing to the unavoidable circumstance that only one observer could be on duty at a time during the night, whose attention was required by the magnetic disturbances, which accompanied most of the more active displays of the aurora borealis, the notices of that phenomenon are less full than could be wished, notwithstanding the great desire that was felt to do justice to so favourable an opportunity of studying it. The three magnetometers were commonly observed on these occasions in succession, with an interval of one minute between them; it was considered an object in general to miss a reading as seldom as possible; consequently, although the observation was usually an instantaneous act, as the magnets being suspended in heavy copper boxes were seldom in vibration, there was, notwithstanding, barely time for the observer to step out of doors after one of them, take a survey of the sky, and return to his place before the next, repeating the process if necessary, until the particulars required were collected. The same circumstance led to an abbreviated mode of description, which is to be regretted, but it

should be stated that the actual notes taken at the time have been carefully adhered to in the descriptions at the end of this chapter, with no other alteration or expansion than appeared absolutely necessary to make them intelligible. It must be added, that less stress was laid upon particular features and changes of aspect, or position, than would have been suggested by a better acquaintance, on my part, with what had been recommended in observations of the kind. Having been previously employed in the tropics, and passed but one winter in Canada, my attention had not been much given to the subject, nor was I provided with any such invaluable textbook for this class of observations as the report of M.M. Lottin, Bravais, and Martins, of the Commission du Nord, 1839, has since supplied to Arctic observers. A definite sense was attached from the first to each descriptive term employed, and I took pains that they should be used as much as possible alike by myself and assistant (Serjeant Henry.) Certain convenient signs or symbols were also fixed on to denote, without verbal description, particular forms of aurora, very much as those of Mr. Howard are used to denote forms of cloud. These were always used in the column of the register appropriated to remarks on the weather, but a place was also provided for more detailed descriptions. Some of the terms and distinctions, such as striated, serpentine, although suggested quite independently by the forms of aurora which presented themselves, I have since found more or less used by others, a satisfactory confirmation of their applicability.

In the descriptions which follow, then, the term streamer is confined to lines of light in rapid motion, appearing and reappearing suddenly and in any part of the heavens, but directed towards the zenith; they were frequently unconnected with any large body of stationary light. The term striæ, striated, refers to a peculiar appearance, sometimes seen in arches and even in detached masses and the larger streamers, an arrangement of the whole body of light in fine parallel lines, directed towards the zenith, and presenting the appearance of wool or cotton combed out: this was considered at the time to indicate a more active state of the electric forces than existed when it was wanting, - to be, in other words, a higher form of The terms beams, streaks, bands, were used to indidevelopment. cate long narrow portions of light, not sensibly in motion, the last being confined to those which crossed the magnetic meridian nearly at right angles. The term serpentine motion was employed to denote changes of outline different in character from the direct rectilineal motion of streamers, but resembling the changes of the folds of a curtain. Plates A. and B. of the admirably faithful Atlas of Auroras, published in connexion with the report above referred to, exhibit precisely the features described by the terms striated and serpentine ;

save that the vertical divisions are considerably more strongly marked than the writer is conscious of having seen them. The term *cirrous aurora* indicates light detached patches, scarcely distinguishable in form from cirrous clouds. Lastly, *auroral* haze denotes a luminous appearance, usually in the northern quarter, without definite form or boundary, and sometimes also the vanishing light of other descriptions of aurora. The reference (a) is given to this appearance in the abstracts as well as to the more definite forms.

The relative brilliancy is generally indicated by figures. Thus, 0.5 represents the faintest description of aurora; 1, faint aurora; 2, moderately bright aurora, and what in low latitudes would be considered bright; 3, decidedly bright; 4, the brightest and most perfect displays. Very few exhibitions were considered to come up to the last class; of these, the principal one was not observed at Lake Athabasca, but at the Painted-stone Portage near Lake Winnipeg, on the 7th August 1843. Much of the comparative brilliancy of the displays however depends on the absence of moonlight, a circumstance which was not sufficiently taken into account at the time. The dates of the changes of the moon are given in the register for reference. The elevation of arches was observed with a wooden quadrant and plummet. The directions given are magnetical, the declination being 28° E. More or less aurora was seen on 49 out of 116 nights of observation at Lake Athabasca. There was no night, properly speaking, at Fort Simpson after the 16th April, the latest date at which the sun sinks in that latitude as far as 18° below the horizon; nevertheless, the aurora was seen on twenty-four out of thirty nights of observation between the 1st April and the 6th May. After the last-named date, as the brightness of the twilight made it very difficult to distinguish between light cirrous clouds and patches of aurora, it did not receive much attention, and was not again seen up to the close of the observations on the 25th May; it is, however, quite possible that close attention would distinguish aurora occasionally, by its motion, to a much later date, as it has been seen in early evening and morning twilight in lower latitudes, and was undoubtedly seen at Toronto in full daylight, on the 29th September and 2d October 1851. It appears to have passed the zenith, when last described, on the 6th May, at about 13^h 15^m of local mean time, when the sun's centre was 9° 47' below the horizon, consequently, if its distance from the earth upon that occasion exceeded fifty geographical miles, it must have been within the sphere of the sun's rays. For want of corresponding observations elsewhere, there are no data for computing the height of any of the displays, but I avail myself of this opportunity of stating, that the impression conveyed to the senses upon many occasions was altogether opposed to the idea of the seat of the display being so distant as it seems to be in

lower latitudes. Those who have travelled in mountainous countries must have frequently observed the passage of clouds at a short distance above their heads, and remarked, that without the aid furnished by neighbouring peaks and rocks, there is the most convincing proof of the nearness of the cloud afforded by the manner of its motion, the sensible unfolding of masses of vapour, by the distinctness with which every detail of its form is seen. Precisely of the same nature is the evidence frequently given to the senses in high northern latitudes of the nearness of an aurora, and the universal belief of the fact among those who witness it perpetually, must be allowed to weigh somewhat in the same scale. This inference also is not irreconcileable with the results of actual measurement in Europe and the United States, if we suppose that the circumstances which favour this phenomenon occur nearer the earth in high than in moderate latitudes.

It is important to observe that every night on which aurora was recorded at Christiana in Norway, during the periods of observation under discussion, by M. Hansteen (Mem. de l'Acad. Royale de Bruxelles, tom. xx.) coincides with one of the dates of observation at Lake Athabasca or Fort Simpson; there are, however, but eight of the former and one of the latter, namely, October 24th, October 26th, December 8th, 1843, January 8th, January 16th, January 22d, February 17th, and April 17th, 1844. It would appear by the descriptions of M. Hansteen, that the phenomenon was generally more perfectly developed at the American than at the European station, although the latter is about 1° more to the north. There are no observations of aurora recorded at any of the Russian stations or Siberian stations, and but five at Sitka, all, except the last, noted as fuible ; the dates of these are October 15th, October 19th, 1843, and April 16th, 1844, all coinciding with northern observations, and March 7th and 28th, when no observations were made. Of the observations at Makerstour in the same periods, seven coincide with observations at our two stations, namely, October 16th, October 26th, November 2d, November 13th, April 5th, April 10th, April 17th. Of the remaining Makerstoun dates, twelve in number, observation was impossible from clouds on nine ; at two the brightness of the twilight equally prevented it; there is but one (when traces of aurora alone are recorded at Makerstoun,) upon which observation seems to have been possible, and no aurora occurred at Lake Athabasca; this date is January 5th. Such a result is the more remarkable, as the displays of the aurora at Lake Athabasca were probably of considerably less than average frequency and brilliancy. The winter of 1843-4, in the opinion of residents in that part of America, was remarkable for the absence of this phenomenon, as it was in lower latitudes.

				Number of Nights observed.	Aurora seen.	Observations impossible.
1850, November " December " January " February " March " April	-	-	-	24 31 31 28 31 30 175	11 19 20 21 19 19 109	11 9 7 7 11 10 55

The following list of Observations, made in 1850-1 by Mr. J. Anderson, C.F., at the same station, supports such an opinion.

Comparing similar periods, November to February; it appears in this case to have been seen on 89 per cent. of the nights when observation was possible. In the season of 1843-4, the proportion was 71 per cent.

The number of observations at Toronto from the 16th October 1843 to 28th February 1844 was also unusually small. It is only recorded at four hours of observation in that interval, namely, October 19^d 17^h, December 11^d 14^h, and January 24^d 17^h, and 18^h Göttingen. To these may be added October 20th, October 21st, and February 4th, from the reports of the Regents of the University of New York, and December 12th from the record of Mr. Herrick of Newhaven. The latter indefatigable observer, however, recorded suspicions of aurora on November 25th, 26th, 27th, December 10th, January 8th, 13th, and April 24th. The whole number of positive observations, however, in this period amounts to seven only, a number considerably below the average, which for Toronto alone, from 1840 to 1850 inclusive, is between eleven and twelve.

There are only four instances of aurora recorded at Lake Athabasca so soon after sunset or so shortly before sunrise as to come within the period of evening or morning twilight. On the 16th October it was visible at 6 A.M. in the east, very faint, and a portion almost imperceptible in the zenith; at this hour the sun was only 6° 44' below the horizon, and if the elevation of the aurora in the zenith exceeded twenty-four geographical miles it must have been within the sphere of the sun's rays. It was seen at the same hour on the 23d November as a faint light in the north-west, but at this time the sun was 16° 9' below the horizon. It was again observed at 6 A.M. on the 29th, the sun being at the time 17° 20' below the horizon. Lastly, it was seen at 6 P.M. on February 6th as a faint arch, the elevation of which is not recorded, and probably did not exceed 4° or 5°; the sun was at this time 11° 25' below the horizon.

There are also a few instances of its being seen very soon after twilight ended, or immediately before its commencement. The relative frequency of the phenomenon at different hours of the night is shown by the next Table.

						-						_		_		

All the hours contained in the foregoing Table may be considered. as hours of darkness, except 6 A.M. and 6 P.M. for a short period at the beginning and end of the series, and this will be compensated by the longer absence of daylight in mid-winter. The sun rose at Lake Athabasca on the 16th October at 6^h 43^m A.M., and set at 4^h 49^m; morning twilight began at 4^h 6^m, and evening twilight ended at 7^h 22^m; all of mean time. On the 28th February the sun rose at 7^h 6^m, and set at 5^h 19^m; morning twilight began at 4^h 31^m, and evening twilight ended at 7^h 54^m. Hence, if the development of auroral light have no relation to the hour of the night, in other words, no diurnal law, we should expect to find the observations nearly equally distributed throughout that period. It is at once. apparent that such is not the case; the number under the several hours increases from 6 P.M. to midnight; there is a great excess at midnight and 1 A.M., after which the numbers diminish down to 6 л.м. The result is the same, if instead of counting the number, we allow weight according to the relative brilliancy of the displays. using the scale already explained; but as the necessary observations were not made on the spot to determine, with any precision, the integral value of the auroral light developed from hour to hour, any estimate founded upon that scale is necessarily vague. However, taking the numbers as they stand, and supplying them by estimation from the descriptions, where they are wanting, they sufficiently confirm the present conclusion. The totals for each hour are added in the last column of the Table for Lake Athabasca.

There is a great difference in the total number of observations recorded in the different months, indicating a less average duration, as well as a minimum of frequency, at the winter solstice. Allowing that the aurora might have been seen upon half the occasions when it is entered as partly clouded, the proportion of observation hours in which it was actually seen, bears the per-centage shown in the following Table, to the number of favourable hours:

		Total Number of Nights.	Aurora seen.		Observations impossible.		Per-centage of Hours of Observations to favourable Hours.		
1843–4. In October November December January February April - May 1 to 6		16 26 25 26 25 25 25 6	9 10 5 15 10 21 3	" "	7 1 13 12 10 11 7 1	Nights. "' " " " "	0 · 52 · 0 · 24 0 · 08 0 · 30 0 · 24 0 · 29	0'266	

Thus it appears that aurora was visible, in the winter of 1843-4, at Lake Athabasca, at about one fourth of all the hours of observation when it was possible to see it. On April 18, at Fort Simpson, which is the mean date of auroral observations, the sun rises at 4^{h} 34^{m} A.M., and sets at 7^{h} 26^{m} P.M., App. T.; and from 8 P.M. to 4 A.M. inclusive, have been taken as the limits of darkness for the whole period.

It may deserve remark that the month of December, when it was least frequent, was a remarkably mild one, and January an unusually cold one.

If the region in which the auroral development takes place be entirely beyond the limits of the atmosphere, as is commonly supposed, it is difficult to conceive any direct connexion between the aurora and the state of that medium, but this question may perhaps be regarded as not finally settled, and it may be worth while to examine the accompanying meteorological features. The first which will be noticed on referring to the meteorological register, is the apparent connexion between the occurrences of aurora and a state of calm. It appears by Table LXII., that the proportion of hours . entered as calms, to those of sensible winds, is 1,340 to 1,420 or 94 per cent., whereas the entries accompanying aurora are as follows:

Hourly Observations of Aurora.	Lake Athabasca.	Fort Simpson.	Total.
With High Winds	21	5	26
With Light Winds	38	10	48
With Calm	97	36	133

Showing a great preponderance under calm. In order to ascertain whether this could be due to a greater average freedom from cloud under such circumstances, separate abstracts have been formed of the proportion of clear sky accompanying entries of calm and wind. The result is, that the sky was on the average clearer in calm weather than during winds, but in a materially less proportion than is required to account fully for the excess of aurora under calms. The average of clear sky for the thirteen hours included in Table LXV. is—

> Under winds, 0'354 Under calms, 0'459

With respect to prevailing winds, it will be noticed, in the same way, that a much larger proportion of the accompanying winds contain easting than westing, and if we admit that the state of the atmosphere may have something to do with the phenomenon, it would follow that the conditions favourable to it, at Lake Athabasca, are derived rather from the side of the Atlantic, or from Hudson's Bay, than from the warmer side of the Pacific.

TABLE LXVIL --- continued.

It is to be regretted that the observations are deficient as regards the azimuth of arches, and other displays, or their relation to the magnetic meridian; this particular is always too vaguely expressed, and frequently not noted at all. Careful observations of the point of convergence of streamers in the few instances in which they formed a corona, was also overlooked, which however arose chiefly from an exaggerated expectation of something better defined and more regular than ever presented itself.

The most frequent form of the auroral development was the simple arch ;* these arches in many instances underwent changes and assumed other forms, but probably in almost every instance the first definite form assumed was of this class. If we classify the entries at

^{*} Mr. Roderick Campbell, an officer in the service of the Hudson's Bay Company, kept, at my request, a meteorological register at Frances Lake, on the west side of the Rocky Mountains, situated about latitude 61° 30', longitude 129° W., from November 1844 to April 1846. This register comprises 13 months of observations of Aurora Borealis, exclusive of the Midsummer half year, when it could not be distinguished. It was seen on 66 evenings of that period, and is described as an arch in 41 of the entries; it possibly, also, had the same form on some of the nine occasions on which it is not described. There are only five dates on this list coinciding with observations at Toronto, and six more on which coincident observations are found in the Regent's Reports.

the several hours without regard to the subsequent changes, it appears that the numbers are as follow:

Nature of Display.	Before Midnight,	At Midnight.	After Midnight.	Total.
Undefined light, usually in the north A simple arch - Arch striated Arch combined with streamers Arch co-existing with transverse bands, which in most cases are probably the	3 34 2 4	3 7 2	19 26 2 3	25 67 4 9
remains of earlier arches, advanced to near the zenith Streamers alone, or principally Detached patches alone, or principally Transverse bands alone, or principally	2 3 1 2 51	4 6 1 23	8 8 12 6 79	5 15 19 9

TABLE LXVIII.

This classification rests on rather an arbitrary division, the descriptions not being sufficiently full to enable it to be made satisfactorily, but may serve as an approximation. On comparing it with the register at Toronto, it appears that the more definite forms of aurora occur in much the greater proportional number at the Northern station; a proof, if the more northern region is the nearer to the seat of the display, that the same object cannot be seen at both stations. Thus, we have at Toronto in $8\frac{1}{2}$ years of two-hourly and one hourly observations (January 1840 to June 1848 inclusive), the following number of entries:

TABLE	LXIX.

Nature of Display.	Before Midnight.	At Midnight.	After Midnight.	Total.
Undefined auroral light An arch Arch combined with streamers Other combinations, forming the finer displays	147 35 64 37	61 11 11 13	116 27 22 32	324 73 97 82
	283	96	197	576

The arches at Lake Athabasca form rather the largest proportion at the early hours of the night; the less definable forms, on the contrary, and those which the phenomenon assumes when the display approaches its conclusion, are more numerous in the latter part o. the night, all tending to show, as already inferred from the numbers in Table LXV., that the luminous display essentially belongs to the night, and that the presence of daylight is not the only reason why it is so very rarely seen when the sun is above the horizon.

A peculiarity may be noticed in the references to the state of the sky accompanying Table LXV., that there are comparatively a small number of entries under the head of "Partially clouded." It may be added, that there are comparatively few observations in the notices which follow, of the definite forms of clouds, the most usual state was a light uniform cloud or haze, covering the entire sky; this prevailed particularly for two or three hours about sunrise and sunset. The sum total of clear sky is considerably less from 6 to 9 AM., and again from 2 to 5 P.M., than at any other hours. It does not appear, however, that this was the case to a greater extent on the mornings following or the afternoons preceding aurora than on other days, but the reverse. Thus, we have the mean proportion of clouded sky for four hours (6 to 9 A.M.) on mornings following aurora, 0'52, and on the remaining mornings, 0'78. Again, for four hours (2 to 5 P.M.) on afternoons preceding aurora, it is 0.61, and on the remaining afternoon's 0'76. The aurora, therefore, would not appear from these observations, either to result from or to tend to produce, circumstances akin to those which produce common cloud, a view which has been sometimes taken. The sums total of clear. sky at the different hours are as follows :---

Midnight	51.2	Noon	41.1
1 А.М.	48.1	1 р.м.	41.2
2 "	48.1	2. "	34.5

11 ,,	42.9	11 ,,	46.9

With regard to the much disputed question of sound, neither the writer nor his assistant Serjeant Henry, were ever positive of hearing any, but the latter thought he did so upon one or two occasions. The result of inquiries upon the subject was, that opinions were nearly equally divided among the educated residents in the country; a small majority of those the writer consulted, agreed that a sound sometimes accompanied the phenomenon, but among the uneducated and native inhabitants, whose acuteness of sense is probably much supe-

rior to that of the other class, a belief in the sound is almost universal, and many individuals assured the writer they had heard it. Similar testimony has been borne very positively by the assistants at the observatory at Toronto, upon one or two occasions of great display.

CONNEXION OF AURORA WITH MAGNETIC DISTURBANCES.

A LITTLE experience in North America, whether in Canada or in the more northern regions, suffices to correct the impression that every display of aurora, however inconsiderable or distant, is attended by sensible magnetic disturbance. So far as the magnetometers, observed at short intervals, can be taken as a criterion, that is far from being the case, nor does it appear to be so by the more perfect test of photographic registration, as far as it has been applied at To this it may be added that the hours at which aurora Toronto. is most prevalent are midnight and 1 A.M. at Lake Athabasca and Fort Simpson (Table LXV.), whereas the period of greatest mean disturbance at both stations is 3 to 5 A.M.; it is also midnight at Toronto, where the period of greatest mean disturbance is 9 or 10 P.M.; if, therefore, the development of aurora has any immediate relation to the disturbance of the magnetic elements, the latter must precede the former in one region, and follow it in the other, a law which does not appear probable. On the other hand it is unquestionable that the more brilliant displays are almost always attended by magnetic disturbances, as are many of the more moderate ones; exceptions in the first class are very rare, but the writer believes that some can be established; the general conclusion must, however, be that an intimate relation exists between these distinct phenomena, although not that of cause and effect. The general practice of the observers was to read the instruments at intervals of a few minutes, during every aurora; if either of the magnets differed decidedly from its usual position, or was observed to be in vibration, readings were taken as on term days, or more usually they were read in succession, with an interval of one minute only between the observations, each being read, therefore, every third minute. If no sign of disturbance was observed, the remark "no disturbance" was made in the register, but the actual positions at the moments of observation were not thought important, and were not recorded ; this omission is to be regretted, since it reduces the amount of proof of the absence of disturbance, which has to be established.

The following are the dates of these entries of "no disturbance;" the character of the aurora on each occasion will be seen by consulting the descriptions appended:

,'	D.	н.	́н. ́	· •	•	D.	H.		D.	H.

										N

The following list contains the dates of the more brilliant and the longest displays of aurora, the number of hours at which they were recorded, and the order or relative place of each day among the other days of the same month, in respect to its "mean irregular fluctuation" of two elements (p. 74), together with the values of those quantities:

	No.	Order.		Days		No.	Or	Days

TABLE LXX.

By conforming to Göttingen time, the night is divided at 4 A.M. at Lake Athabasca, but as four-fiths of the observations of aurora fall before that hour, its influence on the daily mean irregular fluctuation should be strongly marked in the dates given. It appears that among these days there are several which take a low place in the order of relative disturbance, so far as the quantity referred to is a criterion. Upon the whole, the mean irregular fluctuation of Declination for fifty Göttingen days on which aurora is recorded, is 6'.65, and for the remaining sixty-five days is 7'.10; it is 13.28 scale divisions of the Bifilar, upon forty-nine days of observation with that instrument, when aurora was seen, and 13.38 div. on the remaining sixty-five days, thus being actually less with both instruments on the first than on the second class. The means for the month of January, on which the proportion of auroras to hours of observation (p. 145) was 0'30, are Declination 3''90, Bifilar 18'66 div.; and in December, when the former quantity is only 0'08, the latter are 7''32 of Declination and 11'99 div. of the Bifilar, the Bifilar here exhibiting a diminished disturbance, but on the

other hand the Declination, as in the other comparison, a greater degree of it.

Although, however, it can be shown that there are instances of aurora, to all appearance unattended by magnetic disturbance, it is remarkable that magnetic disturbances unattended by aurora are very rare; there is but one decided example of it under circumstances of the sky which would have allowed the latter phenomenon to be observed, if it existed; there are also one or two instances in which the disturbance was not observed to commence until some time later than the appearance of aurora, but in every other instance either the sky was clouded or aurora was seen. There appear to be but five instances in which an entire cloudless night passed, without aurora being seen at any time, namely, November 27th, December 20th, January 2d, January 5th, and February 19th. There are also seven half-nights terminating at or commencing from midnight, and some shorter periods, to which the same remark applies, but on only one complete instance of this nature was there any magnetic disturbance observed, namely, January 5th. So far, therefore, as a conclusion can be drawn from such limited data, it would appear that these phenomena are so related, that while the amount of electrical excitement necessary to produce aurora borealis, does not necessarily produce any sensible disturbance of the magnetic elements, yet the latter is almost necessarily attended by the former.

The extra observations on account of disturbance, taken up to the period at which the twilight prevented aurora from being distinguished, are classified with reference to this circumstance in the following list.

[The range of Declination and Horizontal Force is added on each occasion, taking one division of the Bifilar scale = '0003412 X at Lake Athabasca.]

. ...ť

* The actual difference between the highest and lowest readings during a period of disturbance is here called the range of scale. The deviation E and W., or + and -, are measured from the mean scale reading for the same hour and minute; thus their sum may be greater or less than the difference of scale reading, by the amount of the mean diurnal change in the interval between them.

METEOROLOGICAL.	OBSERVATIONS

Abstract from the Meteorological Journal-continued.

Di	ate.	Wind.		Temp.	gitat 9 ottilai—continaeu.
Gött. Time.	Mean Time.	Direction.	Force.	Newman corrected.	Weather.
Novemb D. H. 2 21	Der 1843. D. H. 2 13	E.S.E.	High.	° 24·7	Overcast, with dense cirro-cumuli; cleared soon after. At 21h 30 ^m a bright mass of aurora in the N. at elevation 15°. At 21h 45 ^m aurora much fainter (4, 5), and diminishing in ex- tent. At 21h 55 ^m no longer visible.
22	14	E.S.E.	High.	25.7	tent. At 21 ^h 55 ^m no longer visible. No aurora. At 22 ^h 40 ^m a faint (5) annular mass in the N.E.
23	15	E.S.E.	High.	25•5	In the N.E. Clear. A faint arch (5) in the N. At $23^{\rm h} 15^{\rm m}$ aurora appearing as if it issued, in a stream, from a source in the N., expanding as it ex- tended nearly horizontally to the N.E. at alt. 32° , in outline like the tail of a fox. At $23^{\rm h} 30^{\rm m}$ a dense but faint mass (5) moving from N.E. to N.W.; most easterly position of the De- clinometer Magnet (+0° 40') at $23^{\rm h} 30^{\rm m}$; range, $2^{\circ} 14' \cdot 2$. Lowest range of Horizontal Force (-•052 X), a little carlier. The dis- turbance observations were discontinued at $1^{\rm h}$.
35	21	E.S.E.	Mod.	23.8	Densely overcast since 0^{h} . Light snow at 4^{h} 5^{h} , and 6^{h} .
11 17 23 4 5 11 17	$\begin{bmatrix} 3 & 3 \\ 9 \\ 15 \\ 21 \\ 4 & 3 \\ 9 \end{bmatrix}$	E.S.E. 	Fresh. Fresh. Calm. Calm. Calm.	30°6 27°7 27°6 27°7 25°3	Overcast; docasional sprinkling of snow. Uniformly overcast, with dense cirro-cumuli. Observation omitted. Overcast, with light haze or fog. No change. No change from 3 ^h to the end of the day at 20 ^h .
5 28	day. 5 15	-	Calm.	16.6	Unclouded, but no appearance of aurora; Magnets slightly disturbed at 23^h 30^m . A sudden change of moderate extent in all the readings; at the same time aurora visible in streamers in the N.E. and N.W., but faint (4). At 24^h no aurora, but considerable disturb- ance. An easterly extreme of the Declinometer Magnet at 24^h (+0° 41''9), and lowest range of Horizontal Lorge (- '022 X).
65 11	21 6 3	-	Calm. Calm.	15·9 24·1	Gradually clouding over since 6 ^h ; now com-
17 23 7 5 11 17 23 8 5 11 17	9 15 21 7 3 9 15 21 8 3 9		Calm. Calm. Calm. Calm. Calm. Calm. Calm. Calm.	17:1 17:9 16:1 15:3 16:4 19:1 19:5 15:6 10:0	 pletely overcast. Uniformity overcast since 17^h. No change. A thick fog at 1^h. No change. A little snow at 9^h and 10^h. No change. A little snow at 9^h and 10^h. No change. No change. No change. Light snow, with intervals, since 14^h; light No, wind 18^h to 20^h; considerable magnetic shock between 18^h and 19^h; most easterly poosition of Declinometer (+0° 58'9) at 18^h; most westerly (-0'12'6) at 18^h 40^m; range 1° 11'4. Lowest Horizontal Force at 18^h 43^m (-'015 X).
23 95	15 21	=	Calm. Calm.	7·2 7·6	Overcast. A few particles of snow at 4 ^h , and
11 17 20	9 3 9 12	=	Calm. Calm. Calm.	8·9 4·7 -0·1	again at 9 ^h . Overcast. Partially clear. Cirro-cumuli. Unclouded since 18 ^h . At 20 ^h 15 ^m a bright auroral arch (3) extending from N.W. to N.E., elevation 28°, gathering to focus at the W. extremity. It varied but little until 20 ^h 50 ^m , when it rapidly disappeared. Lowest value of Horizontal Force (- 027 X) at 22 ^h 10 ^m ; most easterly position of Declinometer (only
23	15	-	Calm.	-1.5	+72'2) at 22 ^h 15 ^m . Unclouded. No aurora since 20 ^h 50 ^m . Extra observations were commenced at 22 ^h , on account of a somewhat low range of Hori- zontal Force, as shown above. The range of Declination was very trilling.
10 5	21	-	Calm.	1.0	Unclouded since 20 ^h , with a short interval of 0 ^h of cirro-cumuli.
11	10 3	I	Calm.	9.6 M	Unclouded. No change.

	Abstract from the Meteorological Journal—continued.										
	Da	ıte.		Wi	nd.	Temp.					
Gö Tir			Mean Time. Direction.		Force.	Newman corrected.	Weather.				
De D. 8			N.N.E.	Light.	° 15·1	Covered with cirrus haze. A bank of clouds					
	11	8	8	s.s.w.	Light.	28*4	round the horizon. Overcast, but mostly clear since 5 ^h .				
	17		9	W.S.W.	Light.	20.7	Again overcast, but unclouded from 13^{h} to 16^{h} . A marked magnetic shock at 18^{h} . Most easterly reading of Declinometer at that hour $(+0^{o} 47' 4)$. Most westerly position at $19^{h} 7.2^{m}$ $(-0^{o} 11' 3)$ range $0^{o} 58' 7$.				
	23		15	W.S.W.	Light.	19•8	Nearly overcast, with cirro-cumuli and strati.				
9	5		21		Calm.	19.6	Overcast, with cirro-cumuli and strati.				
	11	9	3	W.N.W.	Light.	13.0	Hazy cirri and strati round the horizon.				
	17		9	-	Calm.	8.1	Unclouded since 13 ^h . After the close of the observations at 20 ^h , a brilliant auror a was witnessed and described by Serjeant Henry; at				

the witnessed and described by Serjeant Henry; at 20^h 22^m it appeared in a stream, extending across the zenith in a S.W. direction from a point in the opposite quarter, at an elevation of 54^p, like steam escaping from a tube, nar-row, very brilliant (2), and of a light but decided green tint. Magnets disturbed at 20^h 27^m. It broke up into bands crossing the meridian, in the zenith, but equally brilliant. At 20^h 30^m the bands divided into waves, which dispensed with rapid motion, and soon after disappeared. at after disappeared.

Overcast. Sleet at 22^h.

- Dull and overcast, with occasional sleet since 23h

²⁵⁵.
²⁶⁶.
Snowing. Wind abated, and it began to snow at 3h.

Snowing, without intermission. Snowing, but lightly, and so down to 19^h. Occasional snow. A few stars visible S, of the zenith.

Unclouded since 2h.

- Unclouded, but hazy. Unclouded since 11^h.
- Unclouded. A faint arch of aurora (5) at eleva-tion 30°. Unclouded. The same at elevation 35°. Unclouded. The same in operceptible change. Beginning to cloud over, having been clear for 24 bours

24 hours.

24 nours. Overcast, with close packed cirro-cumuli. Partially clear. Began soon after to snow. Clear overhead, otherwise clouded. Nearly covered with cirri and cirro-strati. A few clear spaces.

Idw crear spaces. Light cirra and cirro-cumuli. Unclouded since 13³. An arch of aurora (4) at an elevation of 15⁹. Overcast since 22^h. Snowing fast at 0^h.

Overcast.

Overcast. Without break since 22^h. Cleared up at 15^h. Partially clouded again, and so on to the end of the observations at 20^h.

Heavy clouds round the horizon, but clear overhead Beginning to snow lightly.

Beginning to snow lightly. Ceased snowing since 10^h. Continually overcast. Sleet at 18^h. Overcast. Snowing lightly. Overcast. Wind since 2^h. Lightly overcast. Clear at 1^h. Overcast. High N.E. wind prevailing since 14^h. Began to snow at 18^h.

Da	te.	Wi	nd.	Tempe	rature.		
Gött. Time.	Mean Time.	Direction.	Force.	Newman corrected.	Dollond as observed.	Weather.	
Januar D. H. 24 16	y 1844. D. H. 24 8		Calm.	~ 44*0	~40`8	Unclouded. A heavy and brilliant arch near the zenith (), form rather irregular. Width about 5° , and nearly motionless. At 16 ^h 15 ^m aurora in the zenith, diverging from points on the E. and W. sides, not in straight beams, but with a wavy or serpentine outline, and breaking up into narrow streaks. At 16 ^h 30 ^m a brilliant narrow band, very irregular in outline at about 15 ^o beyond the zenith to the S. Faint detached masses both to the N. and S. of it, at 16 ^h 45 ^m . The arch was 55 ^o beyond the zenith, or 35 ^o above the southern horizon, and fainter. There was a little very faint aurors in the N.	
17	9	-	Calm.	-41.5	-41.9	Unclouded. Another arch () approaching the zenith, at present 30° from it, broad and diffused. At 17^{h} 15^{m} faint detached patches of great extent in the N.E. and N.W. near the horizon, also some detached patches of no regular shape, and streamers. At 17^{h} 30^{m} no aurora was visible, save a faint luminous haze near the horizon. Auroral light was observed at Toronto at 17^{h} , but the sky was co- vered with clouds all night. Aurora was also seen at North Salem, N.Y. (Regent's Reports), but the hour is not named.	
21	13	-	Calm.	-41.3	-41.7	Unclouded. Hazy. The most west- erly position of the Declinometer $(-0^{\circ} 44'5)$ was at $20^{\circ} 25^{\circ}$. At $21^{h} 30^{\circ}$ wast quantities of faint cirrus aurora () in various parts of the sky, without motion. At $21^{h} 45^{\circ}$ no aurora was visible.	
22	14	-	Calm.	-46.6	-44'0	Partially clouded. No aurora visible. At 22 ^h 40 ^m a faint mass of aurora () moving slowly from the N.E. along the eastern horizon (eleva- tion not recorded) gathering to a focus a' the N.E. extremity. The lowest value of the Horizontal Force at this time.	
23	15		Calm.	-46.2	-44'1	Unclouded. A large dense mass of aurora (2) S.E. by S. at elevation 10°. It suddenly broke up into a num- iter of patches, which were scat- tered at various elevations, and all disappeared before 23 ^h 15 ^m .	
25 0	16		Calm.	-47.0	-44.4	Unclouded. Hazy. No aurora visible. The most casterly position of the Declinometer ($+2^{\circ}$ 10' 1), at 0 ^h 15 ^m , range 3° 4'8. At 0 ^h 45 ^m a faint luminous haze was distinguishable S. of the zenith. The mercury was observed to be solid from 15 ^h to this hour. No more aurora was seen, but the magnetic disturbance lasted until about 5 ^h . In that portion which occurred from 15 ^h to 19 ^h a tolerably decided correspondence may be distinguished in the movements at Lake Athabasca, and those at Toronto and Greenwich; at the latter stations the greatest degree of disturbance occurred at this time.

April	1844			······		
D. H.	1		N W hoN	Mod.	§.3	Unclouded. A sprinkling of snow at 2 ^h , 3 ^h ,
66	5		N.W.byN.			and 4 ^h . Light cirrous clouds, 0.9 of blue sky.
12	6	8	-	Calm.	16.4	Tight offices clouds, o our state and the 18h 15m an
18		9		Calm.	8.9	Nearly unclouded. No aurora. At $18^{h} 15^{m}$ an arch of aurora () extending from E. to W.N.W., extremities at 20° elevation, but rising to 78° in the centre, rather irregular above the elevation of 45° , width 11°, in motion; also, two faint arches from E. to N., at elevation 25° and 38° . Extra observations were commenced, but the disturbance mani- fested was slight. At $18^{h} 30^{m}$ the arch was in the zenith, where it separated into three bands or arches; the general form was regular at the N.W. end, but at the opposite extremity was curved almost to a circle, at the elevation of 18°. Most westerly reading of Declination ($-0^{\circ} 27'.4$) at $18^{h} 30^{m}$. At $18^{h} 45^{m}$ the arch appeared in three detached portions, extending from the zenith to the N.W., slightly in motion. There was also a bright patch in the N., at elevation 20° , and faint haze () in various parts of the sky. Nearly unclouded. A faint arch of aurors (5), at elevation 34° . The most easterly reading of the Declinenter was observed at $10^{h} 45^{m}$
19		10	-	Calm.	6.5	
20		11	-	Calm.	3.6	$(+0^{\circ}16^{\circ}5)$; range only 0° 45° 5°. Unclouded. A double arch of aurora () of striated appearance, at an elevation of 27°, rather brighter than before.
7 23	nday.	7 14	-	Calm.	15.3	Hazy. A faint arch of aurora extending from E. to N.W., elevation 56°.
:8 0		15	-	Calm.	13.2	Unclouded.
6		21	-	Calm.	23.7	Unclouded.
12		8 8	S. by W		42.5	Nearly overcast, with light cirro-cumuli, 0.3 of blue sky.
18		6		Light.	,	Overcast since 13 ^h . Unclouded. Wind gusty.
×90		15			37.1	Unalouded
6		21		High. Brisk.	1	Overcast, and fresh N.N.W. wind since 7 ^b
12		98	1		23.7	Overcast, and fresh N.N.W. wind since 7 th Heavy snow soon after 12 ^h . Hazy, but only partially clouded. Light snow at 15 ^h and 16 ^h .
18 20		1) W. by N 1 W. by P			at 15 ^h and 16 ^h . Unclouded. No aurora. At 20 ^h 45 ^m the auror appeared as a broad arch, crossing the zenit from E. to W. by N., brightest and mos regular in the S.E., up to an elevation of 49 from thence about 9° wide to a distance of 30° from the zenith towards the W. It wa extending itself with moderate motion. N
21		1	2 W. by I	N. Mod.	. 17*1	disturbañce. Aurora was extending in the N.N.W. with violent whirling motion, from an elevation of 25° to 68°, exhibiting faint tints of pink an yellow, with several long streaks rising to wards the zenith in the N. and S. Tr most westerly reading of the Declinometer ($-0^\circ 4' 4$) was at 21° 6°. At 21° 15° a fain band of aurora extended across the zenit and a very bright mass of streamers () roo to the zenith from an elevation of 14° E. by S so closely arranged as to resemble a sing striated beam, but in violent motion, a beautifully tinted. At 21° 30° four fai transverse bands () extended across the meridian near the zenith, from an elevation of 30° above the horizon in the S.E. to elevation of 25° in the N.W., having a se pentine outline and a moderate motion. 21° 46° vertical beams of aurora and detach haze in various parts of the sky.

	Da	te.		Wi	nđ.	Temp.	
	itt. me.	Me Tir	ean ne.	Direction.	Force.	Newman corrected.	Weather.
р. 9	Apri H. 22	1844. D. 9	п. 13		Calm.	° 16*4	Unclouded. The aurora as last described. At $22^{h} 15^{m}$ the same. At $22^{h} 30^{m}$ it had nearly disappeared, leaving only a few vertical beams, and streaks of light moderately bright near the horizon. The most easterly reading of the Declinometer (+1° 10') was at $22^{h} 45^{m}$.
10	0		15	W. by N.	Mod.	14.9	range 1° 16'.6. Unclouded, but hazy.
	6		21	N.W.byN.	Fresh.	20.4	Nearly overcast.
	12	10	8		Calm.	22.8	Nearly unclouded.
	18		9	_	Calm.	12.7	Unclouded. A vertical mass of aurora rising in the S.E., elevation 24°. At 18 ^h 15 ^m faint vertical beams extending from N.N.E. to E. near the horizon. Imperfect arches rather brighter () rising from the S.E. and N.W., in the latter quarter approaching the zenith, in the former rising to 60° elevation. At 18 ^h 30 ^m vertical beams still stationary, and ranging from N.N.E. to E., also an imperfect annular body of aurora in the N.N.E., at an elevation of 40°, and about 23° in diameter. Imperfect arches, and cirrus aurora or haze in various parts of the sky. At 18 ^h 45 ^m the aurora had nearly disappeared. The instru- ments were watched and scale readings taken every 15 ^m during this display, but no disturb- ance was manifested.
	20		11	-	Calm.	11.9	Unclouded. A faint arch of aurora from E. to N. at elevation 28°.
	21		12		Calm.	7.1	Unclouded: A heavy band of aurora, mode- rately bright, crossing the zenith from S.E. to W. by N., of irregular form, with rapid sor- pentine changes, faintly coloured, it vanished in a few minutes, and at 21h 6 th or nothing but a few faint streamers and cirrus aurora was visible; this continued with little change to 21 ^h 45 ^m , and at 22 ^h there was no aurora visible. The magnets considerably disturbed. Most easterly reading of Declinometor (+1° 27'3) at 21 ^h 6 ^m , most westerly reading (-0° 6'9), at 22 ^h 3 ^m , range 1° 26'2.
11	0		15	-	Calm.	2.2	Unclouded.

	19		10	N.W.	Light.	26.9	hazy. Unclouded. An arch of aurora () at an alti- tude of 33°, which separated at 19 ^h 40 ^m into, faint serpentine bands of little density, in moderate motion, and apparently at a con- siderable elevation in the atmosphere. No, disturbance.
	20		11	N.W.:	Light.	25.2	Dispersed portions of aurora still visible.

Abstract from the Meteorological Journal-continued.

	Date.		Win	ıd.	Temp.	
Gött. Time	M. Ti	ean me.	Direction.	Force.	Newman corrected.	Weather.
D. H	oril 1844 D. unday.		S.E.	Mod.	° 22:6	Unclouded. A bright arch of aurora () from
						E. to N. at 35° of elevation, terminating in a curve or hook at the E. end, at 14° elevation. Long vertical streamers in slight motion from N. to N.E. Dense masses of aurora in the zenith, and in various parts of the sky. The magnets slightly disturbed. Most westerly reading of Declination (-0° 19'1) at 21°, At 21° 15° the features of the aurora were much the same, but considerably fainter. At 21° 30° it had nearly disappeared, excepting faint haze, and a faint imperfect arch from E. to N. at elevation 18°. At 21° 45° there was a faint arch from N.E. to N. at an elevation 27°. At 22° no aurora was visible.
-15 0		15	-		20.6	Unclouded. At 1 ^h the same. No aurora visible, but a considerable degree of disturbance, for which the extra observations were resumed, and continued to 3 ^h . Most easterly reading of the Declinometer (+1° 38'7) at 1 ^h 42 ^m , range since 21 ^h , 2° 16'0.
6 12 18 19	15	21 3 9 10	S.E. S.E. S.E.	V. light. V. light. V. light. Calm.	27 °1 43 °5 32 °5 32 °7	Unclouded. Clouded, light cirrus and haze. Uniformly overcast, with light haze. Unclouded since 18 ⁵ . A faint arch crossing the meridian near the zenith from E. to W.N.W., form irregular in the highest portion, expand- ing with moderate motion. No disturbance, but readings taken overy 15 ^m . At 19 ^h 15 ^m the
	-					The magnets were now observed at intervals of one minute, and showed a slight degree of disturbance, the mean observed at intervals of one minute, and extending the second at the second motion. At 19 ^a 30 ^m the bands were extending with rapid motion to the S. of the zenith, but much fainter than at the last observation. At 19 ^a 45 ^m about half of the sky was covered with aurora in vertical streamers, and cirrus masses of moderate brightness. The magnets were now observed at intervals of one minute, and showed a slight degree of disturbance, the Declination ranging to the W. of its mean position. Most westerly read- ing (-0^{c} 23° 9) at 19 ^b 54 ^m .
2(11	-	Calm.	32.2	ing $(-0^{\circ} 23' 9)$ at 10 ^h 54 ^m . Unclouded. A long range of vertical streamers, faintly coloured, extended from E. nearly to the N., at elevation of 24°, pulsating or dancing with rapid motion. Cirrus aurora, or haze, in various parts of the sky. Most easterly reading of the Declination $(+0^{\circ} 10' 7)$ at 20 ^h 3 ^m , range, 0° 40' 6; a remarkably small quantity for so considerable a display of aurora. At 20 ^h 15 ^m there were no traces of the aurora visible.
23		14		Calm.	26.4	Unclouded since 20 ^h . No observation from 23 ^h to 3 ^h .
16 (1	21	N.W.	V. light.	41.4	A few light cirrus, but nearly unclouded since 3 ^h . Unclouded
19 14		3 5	N.W.byN.	Mod. Calm.	49•5 46•5	Unclouded. Light cirro-cumulus and haze. The Bifilar and Inclinometer began to give evidence of a state of disturbance; the Declination also ranged considerably to the westward of its mean position at this hour. Extra observa- tions were commenced and continued for sixteen hours
17			-	Calm.	38.2	sitteen hours. Hazy. Disturbance still continuing, the Decli- nation exclusively to the west of its mean position. At 17 ^h 38 ^m aurora was first ob- served rising in the S.E. in two curved streams, moderately bright; elevation above the horizon, 35° and 40°. At this same hour the following entry occurs in the Metcorolo- gical Register at Toronto :"Clear overhead; " clouded round the horizon. A faint light " apparent behind the clouds in the N.W, " horizon."

Abstract from the Meteorological Journal-continued.

Da	ate.	Wi	nd.	Temp.		
Gött. Time.	Mean Time.	Direction.	Force.	Newman corrected.		
April D. H. 16 18	1844. D. H. 16 9	-	Calm.	37.7	Unclouded., No aurora described, but at To- ronto an entry similar to the last is found: "A faint auroral light behind the clouds in "the northern horizon." After which it was clouded at that station, and began to rain at 20 ^h 40 ^m . At 18 ^h 45 ^m imperfect striated arches of aurora extended from E, to N, and from	
19	10	-	Calm.	32.9	S. to N.M.E., moderately bright. A very faint double arch or band crossed the zenith from S. to N.W. Bright cirrus aurora, or haze, in various parts of the sky. Unclouded. The aurora nearly the same as at $18^{h} 45^{m}$. At $19^{h} 15^{m}$ scarcely any traces of aurora, but considerable disturbance, the Declination ranging to the castward. At $19^{h} 45^{m}$ two narrow serpentine bands of aurora crossed the sky, near the zenith, from N.W. by N. to S., moderately bright, and with slight motion. The most westerly read- ing of the Declinometer $(-1^{\circ} 17')^{\circ}$ was at	
20	n	-	Calm.	30*4	10 th 50 th . Unclouded. A broad band of aurora in vielent motion, extending from the S.E. to the zenith, with vertical streamers pulsating or dancing in the N. Extra observations were commenced at Toronto at this hour, and con- tinued for sixteen hours. At 20 th 15 th long vertical streamers in the S.E. and N.E., in moderate motion. At 20 th 45 th aurora extend- ing from E. to W., and passing near the zenith, in the form of an arch of moderate hvichtness finithy coloured at the centor	
21	12	_	Calm.	28*2	end. The extreme casterly reading as the route ($\pm 0^{\circ}$ 39'3) was at this time. Unclouded. The aurorarising from the E and W, in fine vertical streamers, in rapid mo- tion. They all united to form a star or corona near the zonith, having a diameter of 7°, its exact position not recorded. At 21 ^h 15 ^m no traces of the aurora remained, except a few fine streamers in the N. At 21 ^h 45 ^m all trace had	
22	13	-	Calm.	28*6	disappeared. Unclouded. Aurora reappeared, of irregular form, moderately bright, and extending from N. to S.W., in slight motion. Extra obser- vations were commenced at Greenwich at this hour, in consequence of a change of De- clination of 8' 45" between 20 ^h and 22 ^h . Soon after the same hour the range of Declination at Toronto passed to the westward of the mean, and did not rise to the mean value during the remainder of the observations. At, $22^h 15^m$ no traces of aurora were visible; tho same at $22^h 30^m$ and $22^h 45^m$.	
23	14		Calm.	28.0	Unclouded. Aurora visible, in vertical stream- ers and dense cirrous patches, both N. and. S. At $23^h 45^m$ a sleuder serpentine band crossing the zenith. The most westerly read- ing of the Declination at Toronto ($-0^5 54' \cdot 5$) was observed at $23^h 25^m$; range, $1^2 4t' \cdot 3$.	
17 0	15	_	Calm.	27*6	Aurora no longer visible; day dawning. The disturbance still continued, and soon after 1 ^h exceeded the limits of the scales of all the instruments. Most easterly reading of the Declinometer (+6° 32′0 nearly) at 1 ^h 24 ^m ; range not less than 8° 10′, possibly somewhat greater. The more active part of this dis- turbance, which was the greatest observed, appears to have terminated about 8 ^h 66tt, or 11 A.M. of mean time at the station. It is remarkable that its relative extent was by no means so great at Toronto, where the range- observed has been often exceeded, and was quite inconsiderable at Greenwich. Disre- garding minor changes, it may be described	

÷

<u> </u>	D	ate.		Wi	nd.	Temp.	
	ött. ime.		ean me.	Direction.	Force.	Newman corrected.	Weather.
	,					A:	to have consisted at Toronto, as regards the Declination, of a great easterly excursion, having a maximum at 21 ^h , and followed by a westerly excursion, giving one minimum at or near $23^{h} 30^{m}$, and another at $0^{h} 15^{m}$, the two being separated by a marked return to the eastward at 0^{h} . The succeeding maximum is at 3^{n} , after which the changes of this element are unimportant. Referring to the obser- vations at Fort Simpson, there is no general feature corresponding to either of these. Great and rapid changes of Declination pre- vailed during the whole continuance of the observations, but the most important of these, between 1 ^h and 1 ^h 30 ^m , when the ele- ment reached the user large deviation of
р. 17	April H. 6 12	1844. D. 16 16	н. 21 3		C m.	40°5 50:0	 ment reached the very large deviation of 6°32 from its normal value. A the same hour, has no corresponding feature at Toronto, where at that period the changes of Declination were moderate. As regards the Horizontal Force, we have at Toronto a minimum soon after 20%, succeeded by a very decided increase of force, having a maximum two hours later; this is followed by two minima, the most considerable between 23^a and 0^a, and the other soon after 1^b, after which there is a very gradual return towards the mean value of the element for several hours. It is curious to observe that a feature very much resembling the first of these, namely, a maximum, between two minima, occurs at Fort Simpson three hours earlier, at 19^a instead of 22^b, but in relative extent is not so great. To the minimum in question at Toronto, there is no feature corresponding at Fort Simpson ; on the other thand, each of the two succeeding minima at Toronto has correspondence which cannot be regarded as accidental with a minimum at Fort Simpson, and the second, which at the latter station exceeds any other observed, is but moderate at Toronto.
					Ω.		0.7 of blue sky. A few cirro-cumuli and cirro- strati. A slight degree of disturbance was observed from $13^{\rm m}$ to $14^{\rm m}$, the Declinometer ranging to the westward of its mean position. Most westerly reading ($-0^{\circ} 20'$.9) at $13^{\rm m} 9^{\rm m}$.
	18 22		9 14		Calm. Calm.	38*3 33*2	Unclouded, but hazy.
1,8	22 0		14 15	_		-	Almost unclouded. A few vertical beams of aurora in the N. No observation. At 23 ^h and at 2 ^h calm and un- clouded.

26	0	25	15	N. by W.	Light.	87.8	Unclouded. Wind fallen since 23 ^h .
	6 16		21	N.W.	V. light.	44.5	Overcast again since 1 ^h .
	12 18	26	8 9	e. E.	V. light. V. light.	46•5 40•7	Overcast. Overcast with dense cirro-cumuli; began to rain soon after. A considerable disturbance, which commenced with a westerly range of Declination, prevailed from $18^{\rm h}$ to $2^{\rm h}$. Most westerly reading $(-1^{\circ} 15^{\circ} 1)$ at $18^{\rm h}$; most easterly $(+0^{\circ} 26^{\circ} 7)$ at $27^{\rm d} \ 0^{\rm h} 18^{\rm m}$; range, $1^{\circ} 58^{\circ} 5$. This disturbance was marked by a constant state of vibration in the magnets, which was not usual. No aurora was visible at $0^{\rm h}$, when it was for a short period un- clouded.
27	0	ł	15	-	Calm.	84.5	Continued rain since 18 ^h , at present mixed with
	6		21	_	Calm.	41.9	sleet. Overcast. Ceased rain and snow after 1 ^h .
	12	27	3	N. by W.	V. light.	50'1	Overcast, with close cirro-cumuli.
	18	ļ	9	-	Calm.	86.8	Dense cirro-cumuli, closely packed.
28	Sun 21	18 5 Sunday. 21 28 12 0 18 6 21	12	-	Calm.	29.6	Unclouded. A broad and diffused but faint () arch of aurora, extending through the zenith from S.E. to N.W. At 21^{a} 15 ^a faint auroral haze alone. A considerable disturb- ance prevailed from 21^{a} to 8^{a} , commencing with a westerly range of the Declinometer. Most westerly reading (-0° 28'6) at 21^{a} 43 ^a ; most easterly reading (+1° 46'5) at 2^{a} 3 ^a ; range 2° 36'8. No aurora was visible at 22^{a} , when it was unclouded.
29			15	E.	V. light.	29.6	A few light cirro-strati.
	6]	21	S.W.	High.	48.5	Wind high, with gusts. Sky covered with cirro- cumuli.
	12	29	8	s.s.w.	Light.	53.8	Covered with cumuli and cirro-cumuli.
	18		9	-	Calm.	43.7	Hazy, but unclouded.
30	0		15 21	 s.e.	Calm. V. light.	34.0	Overcast with uniform haze. A moderate dis- turbance was observed from 0 ^h to 2 ^h . The range of Declination easterly. Most easterly reading $(+1^{\circ} 27' 9)$ at 0 ^h 18 ^m ; most westerly $(-0^{\circ} 7' 3)$ at 1 ^h 3 ^m ; range, 1^{\circ} 36' 4. The sky was overcast during its continuance. Lightly overcast.
	12	30	3	N.W.	Mod.	43.3	Fine drizzling rain commencing. Observations at intervals of 15 ^w were taken from 14 ^h to 16 ^h in consequence of high range of Horizontal Force and prevailing westerly range of Decli- nation, but no disturbance was observed. Most westerly reading (-0 13') at 14*30 ^w . This amount of deviation from the mean is large for that hour, having been exceeded only four times.
м	18 ay.		9	N.	High.	23.7	Rain from 0 ^h to 15 ^h , which changed to snow, and so continues.
1	0		15	N. by W.	V.high.	14.6	Strong northerly gale prevailing since 19 ^h , at- tended by snow down to 20 ^h ; overcast tho whole time. At 21 ^h a considerable disturbance commenced, and was observed down to 1 ⁴ 1 ^h . Most easterly reading (+2° 18'3) at 21 ^h 36 ^m . Most westerly (-0° 26'7) at 22 ^h 51 ^m ; range, 2° 44'8.
,	6	T.	21	N. by W.	High.	18.9	Nearly unclouded.
	12		iy. 8	N.	Brisk.	26'8	Covered with close cirro-cumuli.

Abstract from the Meteorological Journal-continued,

-	Da	te.	Win	n d.	Temp.	
Göi Tin		Mean Time.	Direction.	Force.	Newman corrected.	Weather.
		11111E. 1844 D. H. 21 15 16 21 22 3 9	S.E. S.E. S.E. S.E. S.E.	Fŕesh. Fresh. Fresh. Fresh.	<u>°</u> 31·1 37·9 50·5 42·7	No observation. At 23 ^h wind S. and fresh. Overcast, with thick cirro-cumuli Light cirri prevailing. A great disturbance began to be observed at 21 ^o 1 ^h , and prevailed throughout this day and part of the Declino- meter on the 22 ^d (+1 ^o 56' 8) was at 1 ^h 33 ^m ; the most westerly (-0 ^o 43' 4) at 12 ^h 24 ^m ; range, 3 ^o 40'. Light cirri prevailing. Overcast, with cirro-cumuli. Uniform light haze. Auroral light was visible in the N. at Toronto at 17 ^h , 18 ^h , and 19 ^h Gött., accompanied at 17 ^h by an arch of small streamers, extending from N.W. to N.E., about 14 ^o wide in the centre, with an eleva- tion of 40 ^o . The extra observations, which were discontinued at Fort Simpson at 4 ^h
23	0	15	_	Calm.	86.2	Gott., were resumed at 12^n , and continued to 19^h . One hour later a disturbance began to be observed at Toronto, the observations being there continued to 20^h . Overcast. Light rain at 22^h . Extra observa- tions were resumed at 23^n , and continued io 3^h . The most westerly reading of the Decli- nometer being $(-0^o 44' 5)$ at $0^h 51^m$; the most easterly $(+1^2 44') 0$ at $1^h 45$; range, $2^o 33' 4$. Of the separate portions of the disturbance observed at Fort Simpson, the middle one only has an imperfect correspondence with the disturbance at Toronto, principally shown by the charges of Horizontal Force; the first and last portions, which comprise the greatest changes, do not appear to have extended to Toronto.
	6	21	-	Calm.	48.6	Uniform light haze.
	12	23 3	S.E.	V. light.	61.2	Uniform light haze.
24	18 0	9 15	S.E.	Light Calm.	53·8 44·4	Cirro-cumuli, with haze. Overcast, with cirri and cumuli. A slight dis- turbance was observed from 0 ^h to 4 ^h . The most westerly reading (-0° 2' 9) at 0 ^h 57 ⁿ ; the most easterly (+0° 54' 2) at 1 ^h 33 ^m ;
	6	21	N.W.	V. light.	57.7	Uniform light haze.
	12	24 3	-	Calm.	63*5	Uniform light haze. Magnetic term day began
	18	9	-	Calm.	56.4	at 10 ^h . Unclouded. Occasional cirro and cirro-strati
25	0	15	E.	Light.	45.0	since 14 ^h . Unclouded, but hazy.
	6	21	S.E.	V. light.	58.7	Overcast since 5 ^h .
	12	25 3	-	Calm.		Uniform light haze. A constant but moderate degree of disturbance prevailed during the whole of the term day, which terminated at 10 ^h , and also characterizes the term obser- vations at Toronto. There is no decided cor- respondence in the changes of the Declination at the two stations; but there is some cor- respondence in the changes of Horizontal Force between 12 ^h and 14 ^h Gött. on the 24th, and again at 9 ^h Gött. on the 25th.

END OF THE OBSERVATIONS AT FORT SIMPSON.

# MAGNETICAL ABSTRACTS.

Note.—Regular Observations which were followed by Extra Readings, in consequence of disturbance, are distinguished by *Italic* figures throughout the following Abstracts. The Daily Means of imperfect days are derived from the 8-hourly series that may be complete. At Lake Athabasca 0^h Gött.=15^h 55^m M.T., or 3^h 55^m A.M. At Fort Simpson 0^h Gött.=15^h 14[•]6^m M.T., or 3^h 14[•]6^m A.M.

Visible aurora. Hourly readings taken during disturbances are distinguished by a difference of type.
 Omitted from the Means, as not being complete days.
 By the five complete 8-hourly series.
 Taken at 23^h 30^m.
 Twenty minutes late.

# LAKE ATHABASCA-continued.

Abstract of Hourly Observations made during the months of November and December 1843.

Fifteen minutes late.
 ^k Five minutes late.
 ^k Not included in the mean, the day being incomplete.
 Increasing numbers denote a movement of the north end of the magnet towards the East.

# LAKE ATHABASCA—continued.

                                                    | 1
