February.—Attend to the foregoing general directions, and now cut turf for lawns; fork and clean the flower-borders. Plant anemones, gladiolus, perennial herbaceous roots; and transfer others, dividing the crowns, to multiply the species. In this way almost all such plants can be increased. For examples of this division of roots, select the primrose, single, double, and the polyanthus. Transplant the rooted layers of carnations, also the divided roots of campanula, lobelia, lychnis, mullpink, and dianthus sinensis. Sow in mild heat any annual flower seeds, and of auricula and mimula, in boxes or pans. We include the beautiful primula sinensis. Excite choice dahlia roots, placing them in hot-bed frames, or in troughs or pots of old tan, or any light moist substance, on the floor of a stove or vinery at work.

March.—Sow annuals, including balsam seed, collected from the best double flowers. Plant box-edgings, using much pit-sand; also evergreen shrubs of every description. Transplant autumn-sown annuals into pots, and protect them, till fresh-rooted, under glass; as Clarkia of every kind, Calliopsis, Œnothera Lindleyana, mignonette, Schizanthus pinnatus, and porrigens. Sow in the last week, in the open ground, and at the same time, a pot of each in heat, or at least under glass, stocks, foxglove, China-aster, Clarkia, dahlia, campanula, larkspur, penstemon, amaranthus, tobacco, and all the hardy annuals. Take cuttings of hydrangea from the tops of the shoots. These, if the buds be full, sometimes will produce a fine flower-head, and the effect is striking. Soil, pure heath mould, or leaf-mould, and sand. Use small pots, as for pelargonia.

April.—Plant dahlia roots in richly-manured loam, hollyhocks, carnations, biennials and perennials: at this season, every herbaceous plant is almost certain to succeed. Campanulas (the tall pyramidal), raised by cuttings of the roots in autumn, may now be transferred to pots of loam and leaf-mould; and as the plants grow, they are to be constantly shifted, till they come into pots, wherein they will bloom profusely. If placed in the borders, they will require no peculiar treatment. Sow in a pot the seeds of this variety of campanula (seedlings frequently produce the finest plants; they require profuse watering); also the seeds of the pansy or heart's-ease, to procure varieties. Propagate by cuttings, as directed for geraniums, or by single eyes, the Erythrina crista Galli, and laurifolia. In propagation pots, using the same soil, all the salvias, verbenas, rockets, double wall-flowers, and every species of fuchsia that has produced young wood. Try every plant by cuttings placed in ounce phials, three parts filled with rain-water. Bud China, noisette, and moss-roses, on dog-rose stocks. Divide the roots of dahlias, either retaining one single tuber with a sprouting eye, or twist out very cautiously a single shoot, so as to detach its base and the latent bud it contains, planting it in the smallest pot of sand and leaf-mould; a gentle hot-bed will facilitate the protrusion of roots.

May.—This is the season to stock the flower garden with those plants which have been prepared during autumn, winter, and spring; and therefore transfer, from the propagation pots, annuals raised in them, by lifting the whole mass, and depositing it in a spot prepared in the border: thus trouble and loss of time are obviated. Sow a few annual seeds in the open ground for succession. Plant the parterres with groups of fuchsias, calceolaria, petunia, Neapolitan violet, verbena; and at the latter end, form masses of the scarlet and variegated gerania, and many less prized but beautiful fancy varieties; such are, Diomede, conspicuum, succulentum speciosum, Moore's victory, Dennis's rival, &c. &c. Propagate, by cuttings, the China roses of every kind; plant them two joints deep, in a shady situation; also calceolarias of the shrubby kind, Peruvian heliotrope, &c.: by division of the roots, Neapolitan violet, placing them in beds of manured loam, twelve inches apart; the heart's-ease of the best varieties, in shady situations; the soil, rich loam and leaf-mould. These favourite prize-flowers require a frequent renewal of soil; they dwindle if retained in one site, and degenerate to the condition of the poor weak flowers of former years. Propagate, by slips, lychnis, double rocket, and wall-flower; thin out the superabundant shoots of asters, antirrhinums, penstemons, phlox, and indeed of every luxuriant herbaceous plant.

June.—Propagate, as during the last month, and plant young side-shoots of the best lobelias, in shady borders, under a hand-glass. The pipings of pinks, placed in sandy earth, are to be closely covered in the same way, till completely rooted. Salpiglossis succeeds best in the open air; the plants should be now turned out of pots, and set in a dry border. Green-house plants may now be arranged in a north aspect; the pots to stand on a deep stratum of coal-ashes. Azaleas, accacia armata, and some such plants, are greatly improved by being turned out of pots, and planted with entire balls in an open peat border.

July.—Bud roses on wild stocks. A pretty effect is produced by inserting one or two buds of the deep-red China in the common China rose. The former is strengthened in its habit, and the different tints of the two roses are very pleasing. Propagate, by cuttings, the Chinese azaleas, half-shrubby calceolarias, linums, pelargoniums, fuchsias, myrtles, and other exotic shrubs. Layer carnations in sandy earth, with a little chalk; peg them near the incision with hooks of fern-leaves. Sow the seed of mignonette in small pots, for winter; also, annual flower seeds for bloom in September.

August.—Bud, as before, but not the China rose. Plant seedling herbaceous plants, cyclamens of every kind, offset bulbs to gain strength; repot auriculas, removing the suckers, and detach the black ends of old roots with the finger and thumb. Sow the seeds of all the annuals mentioned under that head in a previous page. Use gentle heat; add any other favourites, as madia elegans, mimulus, the white night-flowering petunia, tall and dwarf larkspurs. Sow the seed of the best pansies. Take cuttings of all the fine pelargoniums that are out of flower early in the month; also of calceolarias, shrubby and half shrubby; of antirrhinum caryophylloides, penstemon gentianoides, &c.; these require no heat, but should be placed in a cold frame.

September.—Plant the crocus and some other bulbs. Transplant herbaceous perennials and pinks to permanent beds, if perfectly rooted. Propagate, by cuttings, China roses in the open borders; and by slips petunias, heliotrope, salvias, gerania, calceolaria, &c.; they require only a hand-glass and light soil. Sow auricula seed in pans in the green-house; also Clarkia, collinsia, chelone, and other annuals, to be preserved in pots all winter. If the pyramidal campanula be out of flower, take up one of the finest roots, blue and white; break it to pieces, and half filling a large pot with loam, place the pieces on the earth; fill the pot with loam, and keep it merely protected from frost all winter. Raise every geranium or other green-house plant now in open ground, and repot them in soil suitable to each. Cut back to low buds, well situated, the horse-shoe geranium, and place all the plants under glass, to recover from the removal; make cuttings of the best amputated shoots of geranium. Gradually diminish the watering of green-house plants.

October.—Plant towards the end bulbs of hyacinth, narcissus, and the common jonquil, and daffodil and anemones ...; also shrubs of every description, though evergreens generally succeed in spring cuttings, as before, if not completed. Hyacinths in pots, filled with a compost of light loam, sand, and vegetable earth, should be plunged to the rims in ashes, or light earth, under the glass of a cold frame; and when the plants begin to grow, the pots should be raised, cleaned, and placed in the green-house. Green-house plants must now be taken in, and be gradually inured to winter treatment, by the free admission of air and abatement of water. Take up the Persian cyclamen, and pot it in loam, sand, and leaf-mould. There is a geranium which merits much attention; it is called the scarlet globe, and appears to be a seedling variety of Pelargonium zonale: cuttings of it strike freely in the open border early in summer; the handsomest of those, taken up in September, and carefully potted in poor loamy soil, will flower throughout October and November, placed in the window of a south room: the flower-head assumes the figure of a Guelder rose.

November.—Bulbs; plant all, employing much sand about and above the bulbs. Protect fuchsias, if frost threaten. Screened leaves form the best substance to be placed as mulch. Dahlias should be digged up in airy and dry weather, when quite dry and clean; preserve the tubers in dry sand; damp is the worst enemy of the dahlia.

December.—Protect beds of tulips, hyacinths, and other choice bulbs or roots, with a layer of saw-dust mixed with sand, or with ashes. Saw-dust alone has been found the most effectual protector to the roots of potted plants in frames, the pots being plunged in it to the rims. If dry weather permit, lightly fork the surface of plots and borders; but at any rate, if it be frosty, scatter some light manures around the stems of shrubs and the more tender plants; it will tend to enrich the ground at the first spring regulation. Secure begonias and other plants which die down to the mould, by placing the pots in a temperate dry cellar.

Our recollection has been much assisted by referring to the excellent calendar at the end of Mr. Mantel's treatise on *Floriculture*, published in "Baxter's Library of Agriculture and Horticultural Knowledge," a work which we should be happy to recommend to every admirer of rural economy.

THE FRUIT GARDEN.

The hardy fruit usually produced in gardens of an ordinary description in Britain, are of three leading kinds—*kernel fruits*, of which the apple and pear are the principal; *stone fruits*, including the peach, apricot, plum, and cherry; and *berries*, of which there are many different species, as the gooseberry, currant, and strawberry. The kernel and stone kinds are produced from trees, and others from shrubs or more tender plants. All the garden fruits, of whatever sort, are greatly improved by a long course of cultivation from a wild state—this being a branch of vegetable economy which has engaged the unremitting attention alike of men of science and practical gardeners from a remote antiquity till the present time. Of the best means which experience has suggested for culturing fruit trees, and bringing their produce to perfection, we now propose to speak.

GENERAL MANAGEMENT OF FRUIT TREES.

Fruit trees are grown as independent plants in an orchard, in which case the tree is suffered very much to assume any height or bulk that nature permits; also trained upon walls, or constrained to grow in a particular manner upon artificial palings called *espaliers*. In whatever manner the tree is planted or designed to grow the tendency of the main stem and branches of the plant is directly upwards, and of the chief roots directly downwards. In general, the depth and spreading of the roots are proportional to the height and spreading of the branches, because the roots are the anchorage and food-seekers of the plant, and require a depth and compass of soil analogous to the bulk of the tree and its demands for nourishment. On these accounts, it is of the first importance not to stint fruit trees of a proper depth and breadth of soil corresponding to their expected dimensions.

Trees planted close to walls should have a depth of soil in proportion to the height of the wall. If the wall be six feet high, the border beneath will require to be trenched soil two feet deep; and so on to a ten-feet wall, which should have at least three feet of free penetrable soil. The principle is, the deeper the soil, the less will the roots straggle. As already said, their tendency is chiefly downwards; and it is only because they cannot get far enough down that they range abroad. Their object is to absorb nourishment wherever it can be obtained; and, abstractly considered, it is of little consequence whether this nourishment is procured beneath the main stem or at ten yards' distance. But, practically, the gardener is concerned in keeping the roots from straggling, and interlacing, as with a network, the under strata of his borders, thus impeding his operations, and perhaps robbing his culinary vegetables or bushes of a portion of their food.

It will therefore be observed, that depth of available soil is as essential in fruit tree culture as in any other department of gardening. If possible, a depth of three feet should always be obtained. Should the garden, when first taken possession of, not have more than eighteen inches or two feet of soil, our recommendation is, not to plant fruit trees upon it at all, till you have trenched the ground to a depth of three feet, and, by annual digging, mingled the lower layer with that immediately above it. (See article LAND IMPROVEMENT.)

In the course of these preparations, let the soil be well cleared of stones, meliorated by winter frosts, and enriched with old manure. Bear in remembrance, that fruit trees must never be excited by new and undecomposed manure. The material applied both before planting and also while the tree is growing, should be loam, mixed with a thoroughly rotted compost of leaves, &c. Some persons, following an old prejudice, place a paving stone a certain depth beneath to prevent the root of the tree from penetrating into the subsoil; but this is only waste of labour; for if the descent be counteracted, the roots will proceed laterally, and penetrate downwards as soon as they can conveniently do so. By giving a proper depth of soil, and keeping that soil in heart, no fear need be entertained for the tree receiving injury from the subsoil.

When we say that depth of soil is advantageous, it is necessary to guard against an impression being formed that deep planting is also required. In general, the roots of trees should be placed near the surface. Mr. M'Intosh, in his very beautiful work, "The Orchard," offers the following caution on this subject:—"Deep planting is an evil much to be guarded against; and many of the disappointments which have attended the fruit-grower may be traced to this cause. As some criterion for the guidance of the amateur, we would say, let every young fruit tree, of whatever kind, be planted at least three inches above the ground level; that is to say, let the part of the stem which was level with the surface while in the nursery, be kept three inches above the general surface of the ground when it is planted, and let the earth be heaped up to that height around it, for a couple of feet or so, in the form of a little hillock. Trees of larger size may be rather more elevated. This applies to soils of the ordinary description; but in damp soils, the elevation should be still greater. When trees are set in a pit, which should always be a third larger in diameter than that of the extent of the roots, so that they may be all spread out to their full extent, without being doubled or turned round, they should be spread as regularly as possible, and the bottom should be made perfectly level; by this means, the roots will have a horizontal direction given to them, which they will afterwards maintain. The intention of this arrangement is to induce them to extend themselves near the surface, and to prevent their extending downwards into a bad or cold subsoil.

Propagation—Grafting.

Fruit trees may be propagated by seeds, layers, cuttings, budding, suckers, or grafting. By any of these methods, a material object of the culturist is to improve, or at least not deteriorate, the quality of the plant. In a state of nature every fruit is inferior to what it will become by cultivation. This disposition to improve is taken advantage of by gardeners; and by attending to various circumstances in the economy of any individual plant, they are able to produce and propagate the best varieties. The principal means employed is to select such varieties as have attained a certain degree of perfection, and then crossing two of the most nearly allied, in order to produce an intermediate variety. The discovery of the sexuality of plants, as established by Linnæus, has rendered this a comparatively simple operation to skilled gardeners. The following is a short exposition of the method given by Mr. M'Intosh, who quotes from other authorities:—

"The means used in the process of artificially fecundating the stigma or female parts of the blossom of one flower with the pollen or male dust of another, have been beautifully described and explained by Knight and others. That eminent pomologist has obtained thousands of apple trees from seeds, many of which are of first-rate quality, by cutting out the stamens of the blossoms to be impregnated before their own pollen was ripe enough for the purpose, and afterwards, when the stigma was mature, by introducing the pollen of the other parent, either by shaking the pollen of it over the flower containing the stigma only, by introducing the flower when deprived of its petals or coloured leaves, or by transferring the pollen upon the point of a camel-hair pencil from the one flower to the other. By these means he prevented the possibility of the natural fecundation of the blossom within itself, and thus greatly increased the chances of obtaining intermediate varieties by making use of two distinct parents.

"This process is called cross-impregnation, and is in its nature highly curious. Dr. Lindley describes the action as follows:—'Pollen (the male dust) consists of extremely minute hollow balls, or bodies; their cavity is filled with fluid, in which swim particles of a figure varying from spherical to oblong, and having apparently spontaneous motion. The stigma (the female organ) is composed of very lax tissue, the intercellular passages of which have a greater diameter than the moving particles of the pollen. When a grain of pollen comes in contact with the stigma, it bursts, and discharges its contents among the lax tissue upon which it has fallen. The moving particles descend through the tissue of the style until one or two find their way, by routes specially destined by nature for their service, into a little opening in the integument of the ovulum or young seed. Once deposited there, the particle swells, increases gradually in size, separates the radicle and cotyledons, and finally becomes the embryo—that which is to give birth, when the seed is sown, to a new individual. Such being the mode in which the pollen influences the stigma, and subsequently the seed, a practical consequence of great importance necessarily follows, namely, that in all cases of cross fertilization, the new variety will take chiefly after its polliniferous or male parent; and that, at the same time, it will acquire some of the constitutional peculiarities of its mother.'"

Illustrating these principles by a reference to the propagation of varieties of apple-trees from seeds, Mr. M'Intosh observes, that "the kinds of apples that it would be advantageous to cross by artificial impregnation appear to be those which have a great many qualities in common, and some different qualities. Thus, it would be proper to cross the Golden pippin with other pippins, and even with some rennets, but it would be improper to cross it with codlings or the larger growing kinds. The numerous varieties of pippins raised by Knight and others, have been obtained by the above rule. It is, no doubt, true that a small apple—say, for example, the Golden pippin—crossed with a much larger sort, will produce a variety sufficiently distinct from the other; but it is almost equally certain that this new variety will be of inferior quality to either; 'the qualities of both parents,' as Mr. Loudon has very justly observed, 'of so very opposite natures being, as it were, rudely jumbled together in the offspring.'"

Grafting—its Theory.

Grafting, which is a practice of great antiquity, is the union of two plants in a growing state, through the medium of the circulating juices. It is now a well-known fact in surgery, that if a piece of a finger which has been accidentally chopped off be immediately applied to the stump whence it was severed, and the wound properly bandaged, it will adhere and become part of the living member as formerly. This, then, is grafting in the animal economy, and it is analogous to the grafting of one vegetable on another. The only dissimilarity is, that the piece of finger is restored to its own stump, whereas the vegetable union is between two distinct trees. But this is a point of [illegible] consequence; for it is probable that if two persons [illegible] equally good health were to have a finger chopped off at the same time, the pieces might respectively be changed, and each person might have on his hand the finger of his neighbour.

Gardeners assign five reasons for grafting:—1. The perpetuation of varieties of fruit, which could not be insured by sowing seed: 2. Increasing, with considerable rapidity, the number of trees of any desired sort: 3. Accelerating the fructification of trees which are tardy in producing their fruit: 4. Improving the qualities of fruits: and 5. Changing the sorts of fruit of one tree, and renewing its productiveness.

When a tree becomes old, but has still healthy and vigorous roots, and it is thought advisable to renew or improve its fruitful qualities, it is cut off across the lower part of the stem, and forms the *stock* on which *scions* are ingrafted, which scions taking root, become in time the fruit-bearing branches of the tree. As a general principle, the sorts to be united require to be considerably alike as respects disposition of woody fibre and sap and pulp vessels, so that no decided interruption may take place in the ascent or descent of the juices. Yet, to effect any improvement in fructification, there must be a certain difference between the varieties. For example, the wild apple-tree, which bears only crabs, too sour to be eaten, forms one of the best stocks on which a graft can be made; and for that reason alone, it is grown by nurserymen from seeds. The notice of this remarkable fact leads to a consideration of what are the radical principles on which improvement is effected by grafting. On this intricate subject we offer, in the first place, the explanations of Dr. Lindley:—"In proportion as the scion and stock approach each other closely in constitution, the less effect is produced by the latter; and, on the contrary, in proportion to the constitutional difference between the stock and the scion, is the effect of the former important. Thus, when pears are grafted or budded on the wild species, apples upon crabs, plums upon plums, and peaches upon peaches or almonds, the scion is, in regard to fertility, exactly in the same state as if it had not been grafted at all; while, on the other hand, a great increase of fertility is the result of grafting pears upon quinces, peaches upon plums, apples upon white thorn, and the like. In these latter cases, the food absorbed from the earth by the root of the stock is communicated slowly and unwillingly to the scion; under no circumstance is the communication between the one and the other as free and perfect as if their natures had been more nearly the same; the sap is impeded in its ascent, and the proper juices are impeded in their descent, whence arises that accumulation of secretion which is sure to be attended with increased fertility. No other influence than this can be exercised by the scion upon the stock. Those who fancy that the contrary takes place—that the quince, for instance, communicates some portion of its austerity to the pear—can scarcely have considered the question physiologically, or they would have seen that the whole of the food communicated from the alburnum of the quince to that of the pear is in nearly the same state as it was when it entered the roots of the former. Whatever elaboration it undergoes must necessarily take place in the foliage of the pear—where, far from the influence of the quince, secretions natural to the variety go on with no more interruption than if the quince formed no part of the system of the individual."

These explanations do not appear satisfactory; they rest upon an assumption that the sap taken up by the roots suffers no chemical change in its passage from the stock to the scion; that it is never altered in constitution till it reach the leaves. We confess we entertain strong doubts on this point, and should be glad to see the fact brought to the test of experiment by strict chemical analysis. Until this is done, all theory must be conjectural, and any expression of opinion useless. Mr. Knight, who made many valuable discoveries in pomology, coincides with Lindley in ascribing increased fertility in the scion to the partial obstruction of the descending sap; but this does not clear up the difficulty as to improvement in the variety and flavour of the fruit by grafting, which we should think arose in some manner of way from a chemical alteration in the juices. Knight arrives at a practical conclusion worthy of the notice of fruit culturists; that although increased fertility is produced by a decided difference between stock and scion, it is at the expense of durability; "but it is eligible wherever it is wished to diminish the vigour and growth of the tree, and where its durability is not thought important."

All things considered, therefore, it is preferable to ingraft the scion of any approved variety on a sound stock, properly prepared for the purpose. As already observed, crab stocks are often grown to form the foundation of good apple-trees, and so are several other stocks propagated by professional gardeners from seeds and layers. We may now describe the manner in which grafting is performed.

Scion Grafting.

Grafting is performed in two principal ways—scion or slip grafting, and grafting by approach, or in-arching

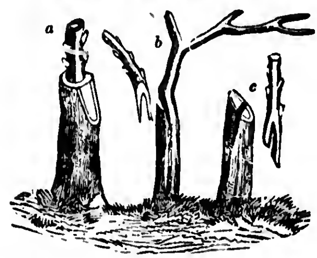

Fig. 1.

Of the first kind we have examples in the above representation, fig. 1. Three modes are shown—a, b, and c, in each of which the process consists in placing a scion in an opening or cleft of a growing stock: a is called whip grafting, b side grafting, and c tongue grafting. By either method, the scion may be a shoot of a single year's growth, cut from a tree in a healthy condition. The season for the operation is about the middle of March, when the sap is rising and the buds beginning to be developed. The grafting should not take place immediately on cutting the scion; after removal from its parent stem, place it in the ground for a few days, so that it may be partially exhausted of its juices, and be more ready to receive the ascending sap from the stock. Keep it in dry ground, and not exposed to the sun. A scion may be brought safely from a distance, by being stuck in a raw potato. Before applying to the stock, cut the extremity of the scion afresh.

Tongue grafting, by which a tongue or slip caused in the sloping cut of the scion is inserted in a corresponding notch of the stock, is the more common method of procedure. It is performed when the stock is young, so that the scion which is added forms the stem of the future tree. The cut in both pieces requires to be smooth, and the joining so neat, that the bark on one side of the scion must be even with the bark of the stock. Having joined the two pieces, bandage them together with a flat strip of mat, but not so tightly as to prevent the circulation or expansion of the fibre. Over the bandage, plaster all round a handful of soft adhesive material, formed of clay, cow-dung, and chopped straw, taking care not to disturb the united edges. This mass will form a hardened lump and may remain till midsummer, when, the union being complete, it may be removed.

The principle upon which the external plaster is applied to the junction, is that of excluding the atmosphere from the wound, and is thus scientifically explained by Rennie:—"It is to prevent the oxygen of the atmosphere from getting to the fluid pulp at the joining, where it would unite with the carbon, and form carbonic acid gas, and thereby rob the pulp of its solidity. The exclusion of light is necessary on the same account; for, as in the case of a finger cut, the oxygen would unite with the carbon, and prevent the thickening of the matter of the blood. On the same account, moisture, by supplying oxygen, would be injurious; and dryness might act both by exhausting the pulp and by causing the edges of the bark to shrivel and gape, which would facilitate the entrance of the air with its oxygen. It is also obvious, from the simple principle (never, as far as I am aware of, before stated with reference to grafting), that no composition, whatever may be said of its peculiar power of healing, can act in any other way than this, any more than the farrago of plasters and salves for healing flesh wounds and cuts, which are only good in so far as they keep the lips of the wound together, and exclude oxygen and light."

If the grafting has been properly performed, and other circumstances be favourable, the scion in two years will be in blossom, and yield a crop of fruit. What its quality will be, must depend on the nature of both stock and scion. If the scion be of a fine variety, that will remain; and if the stock be equally fine, the quality will be improved. The excellence of the scion, however, is the prime consideration, for it is the part which is immediately concerned in the production of the fruit.

For an account of the process of *budding*, which is analogous to grafting, we refer to the previous article.

In-Arching.

This is an ingenious mode of grafting, by which one growing plant, without removal, is made to strike upon another plant, and thus form a union. It may be performed in various ways, as represented in fig. 2; for example, two branches of a tree may be bent so as to meet and strike upon a wound in the main stem, by which a gap will be filled up; one growing tree, either from the ground or a pot, may be led to unite with another; or several suckers may be led from the ground arch-wise to strike upon a point in the stem, thus bringing fresh aid

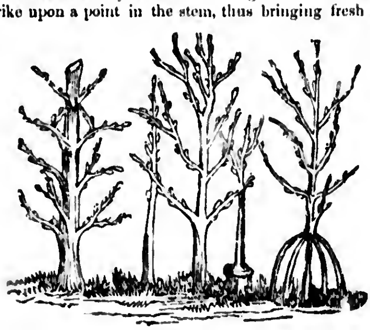

Fig. 2.

to the productive part of the tree. By means such as these, quickset hedges might be thickened like a network, so as greatly to improve their appearance and protective qualities.

KERNEL FRUIT TREES.

Kernel fruits, or *pomes*, as they are scientifically named, include the apple, pear, quince, and several others; those which require any notice here are the varieties of apples and pears.

The Apple.

The apple-tree is of universal European growth, and is believed to have been introduced into Britain by the Romans. It was greatly cultivated in the gardens of monasteries during the middle ages, and from that source the greater number of our cultivated varieties have drawn their origin. The *crab*, or wild apple, is the type of the fruit when left to degenerate, and to which it would speedily return, but for constant culture and crossing. Culture, without crossing or grafting, is found to prevent an immediate return to the crab; and therefore, when an improved variety is obtained, it will yield seeds productive of a similar variety. The extent, however, to which varieties may be preserved without crossing, has never been accurately determined, as the practice among professional gardeners is not to risk degeneracy in the fruit, and they uniformly resort to one or other of the methods of grafting above mentioned. The apple-tree, if favoured by a good soil and climate, will live to a great age, two hundred years being not an unusual duration in a fruit-bearing condition. Some orchard apples have been reported to be a thousand years old.

The varieties of cultivated apples are now innumerable. In 1834, the catalogue of the garden of the Horticultural Society of London described 1400 varieties, and there are most likely as many more. The numerous varieties are of three chief sorts—apples for the table, or to be eaten raw; apples suitable for baking and other culinary purposes; and apples for cider. Table apples are again subdivided into those which will keep, and those which will not. The choice kinds at present include Ribston pippin, which will keep till March, but is in its prime about Christmas; the Downton nonpareil, Scarlet pearmain, and Blenheim orange. The Keswick codling and Hawthornden are early ripe, but the fruit will not keep beyond October. The Nonsuch is a fine apple, and remains good in October. The Old nonpareil is in every respect deserving of its title; its flavour is high and musky, and it keeps long; few apples bring such a high price in the market in February. Other choice long keepers to be named are the Scarlet nonpareil, the Golden harvey or Brandy apple, the Winter pearmain, and the Easter apple, commonly called French crab. To this short list hundreds might be added; but those who can grow what we have enumerated, and bring them to their full complement of bearing, can require no others as stock trees. It must, however, always be borne in mind, that what will succeed well in one garden may not do so well in another, and that experience as to soil and climate, independently of advice from skilled neighbours, will in every case be necessary in the proper conducting of the fruit garden.

Mr. Loudon, in his "Encyclopædia of Gardening," mentions, that for *cottage gardens*, where the soil and situation are favourable for the production of the apple, the following sorts are recommended by Mr. Thompson:—"Where the space will admit of only one tree, the best is the Ribston pippin; where two, the Ribston pippin and Dutch mignonne; where three, the Wormsley pippin, Ribston pippin, and Dutch mignonne; where four, the Wormsley pippin, King of the pippins, Ribston pippin, and Dutch mignonne; where five, the Wormsley pippin, King of the pippins, Ribston pippin, Old nonpareil, and Downton nonpareil; where six, the Wormsley pippin, King of the pippins, Ribston pippin, Alfreston, Old nonpareil, and Downton nonpareil; where seven, the Wormsley pippin, King of the pippins, Ribston pippin, Alfreston, Dutch mignonne, Old nonpareil, and Downton nonpareil." Beyond this, Pennington's seedling and any other good sorts may be added. The same writer continues—"It often happens that one or more trees can be trained against a cottage wall or roof, or against some wall appertaining to a cottage; in these cases, the proper sorts are, Ribston pippins, Old nonpareils, and, if a large kitchen apple be required, the Bedfordshire foundling. In situations liable to spring frosts, which so often kill the blossoms of the generality of apples, the Court pendu plat is recommendable, as its blossoms expand very late in the season. Under less favourable circumstances, where the Ribston may not succeed, the Bedfordshire foundling will be a hardier substitute, or the king of the pippins, which is still hardier; the Northern greening may be planted for late kitchen use. For an autumn apple, perhaps none in this case is more to be recommended than the Keswick codling." To these observations we need only add, that the cottager will do well in all cases to prefer one or two copious-bearing trees to a number of fanciful varieties.

Standards.—Pruning and Training.

Standards are those trees which grow independently in open ground, and are classed as Large and Dwarf Standards. The proper object of cultivation is to give figure to the tree, of whichever kind, and bring it to a fertile or mature condition. Apple and pear-trees, as they approach to maturity, develop short *spurs* along the entire extent of the branches, and those spurs are the best in every respect which are produced naturally without the aid of the pruning knife. But, in addition to fruitful spurs, the trees produce a great number of superfluous wood shoots, which, if not entirely removed, or at least so curtailed as to convert them to bearing spurs, would render the tree almost useless; in short, to effect prolific fruit-bearing, the shoots must be kept in subjection, or in the state of spurs. A writer on this subject in the "Penny Cyclopædia," article *Apple*, observes—"If a tree be a free grower, on a free stock, as the crab, or a strong pippin, from seed, all the leaders will be checked by shortening them back every year to a distance from the point of origin, which varies according to their strength; where they are very strong, the leading shoots should not be reduced more than within twelve or fifteen inches of their base, but when they are weaker, they may be cut to within nine inches. By this means the onward growth of the branch is momentarily arrested, the ascending sap is impelled into the lateral buds, some of which we are sure to grow so slow as to become productive."

The foregoing directions comprise a view of the theoretical principles of pruning, and it affords an excellent groundwork for practice; but those who are strangers to the cultivation of fruit trees, and, as such, undertake the management of a plantation, will be surprised and perplexed at the anomalies which continually present themselves; it will then be self-evident that the gardening cannot, in its routine, be learned from books; that one tree assumes a certain mode of growth; another produces developments in an order which has not been foreseen or contemplated; another forms its fruitful spurs spontaneously, without solicitation or the adoption of means; while a fourth, in despite of the most rigid foreshortening, continues for years to yield nothing but growing shoots. We have seen numbers of spur trees purchased at the same period and treated upon the same principles, every one of which evinced a habit or constitution to a greater or less extent peculiar to itself; thus it is with trees as with the human genus—to be in any degree known, they must be individually and diligently observed and studied. This experimental fact being admitted, we may safely adduce the practice of pruning recommended by Mr. George Lindley for dwarf standards, in his "Guide to the Orchard," &c. (1831.) He observes, that "dwarfs on *crab stocks* are much more adapted for large and ponderous fruit than standards, as they not only produce larger fruit but are less liable to be blown down by high winds. Trees for this purpose should have their branches of an equal strength: those which have been grafted one year, or what are termed by nurserymen maiden plants, are the best; they should not be cut down when planted, but should stand a year, and then be headed down to the length of four or six inches, according to their strength; these will produce three or four shoots from each cut-down branch, which will be sufficient to form a head. At the end of the second year, two or three of the best placed of these from each branch should be selected, and shortened back to nine, twelve, or fifteen inches each, according to their strength, taking care to keep the head perfectly balanced (if the expression may be allowed), so that one side shall not be higher or more numerous in its branches than the other, and all must be kept as near as may be at an equal distance from each other. If this regularity in forming the head be attended to and effected at first, there will be no difficulty in keeping it so afterwards, by observing either to prune that bud immediately on the inside next to the centre of the tree, or that immediately on the outside. By this means, viewing it from the centre, the branches will be produced in a perpendicular line from the eye; whereas, if pruned to a bud on the right or left side of the branch, the young shoot will be produced in the same direction, so that if the branches formed round a circle be not thus pruned to the eyes on the right successively, or the left successively, a very material difference will be found; and the regularity of the tree will be destroyed in one single year's pruning."

What is here said refers only to the leading shoots which form the figure of the tree; others—side shoots (*laterals*)—are developed, and these require constant regulation. "In pruning these laterals or supernumeraries, they should be cut down to within an inch of the bottom, which will generally cause the surrounding eyes to form natural blossom spurs; but where the tree is in a vigorous state of growth, branches will probably be produced instead of spurs; if so, they must all be cut out close, except one, which must be shortened as before. In all winter prunings, care must be taken to keep the spurs short and close, none of which should at any time exceed three inches; cutting out clean all the blank spurs, which have produced fruit the previous summer, to the next perfect bud below."

It would perhaps be impossible for any writer to improve upon these directions generally; they comprise all the essentials for producing a balanced dwarf standard, that is, a tree low in stature, furnished with ten or twelve regular main branches, proceeding at a short distance from one central stem, each branch garnished from base to summit with fruitful spurs. But experience has instructed us to caution a pruner not to expect too much, but to watch the figure which his tree affects, and the course of its supernumerary shoots. If it evince a decided tendency to form short spurs naturally at a very early period, he may prune short, as Lindley directs; but if its habits be so luxuriant as to produce wood-shoots after each pruning, it will be wise to defer the summer cutting of the spring shoots till the middle of July, instead of performing it at or before midsummer; and then either to snap the shoots or to cut them to a bud situated at least five inches from their base. This pruning, late as is the season, will generally cause each shoot to break its leading eye; in August, therefore, this new shoot is to be checked by nipping off its point; and finally, in September the spring shoot is again to be cut at the eye, below the one at which it was first pruned in July. In this way the vigour of the tree will be moderated, and several of the lower buds will probably enlarge, while the leading bud only expands into a growing shoot. If these hints be understood and acted upon, a young pruner will experimentally be taught to apply them, and thereby acquire the tact to discover the constitution of his trees individually, and to coax them into a condition of maturity. At the winter regulation when the buds begin to swell, it will be easy to discern the fruitful eyes; and where any of these are discerned, the shoot projecting beyond them must be entirely amputated; and this may be done with safety, for spurs, when once fully formed, rarely break into barren shoots, though one of the eyes may do so.

Wall-Training.

The circumstance of apple-trees producing fruit only on the outer parts, which are freely exposed to the sun and air, has led to numerous contrivances for exposing the inner as well as the outer stems. One method, as is well known, is the training of the tree in a flat shape against a wall—a plan also advantageous for enjoying the heat, which the wall radiates as a reflector against the branches. A difference of opinion exists as to the comparative merits of training the main stem in a serpentine or in a straight upright direction, and also whether the branches should be led perfectly horizontal or with an upward slope. If the height of wall permit, the upright stem and fan shape, as represented in fig. 3, seems the

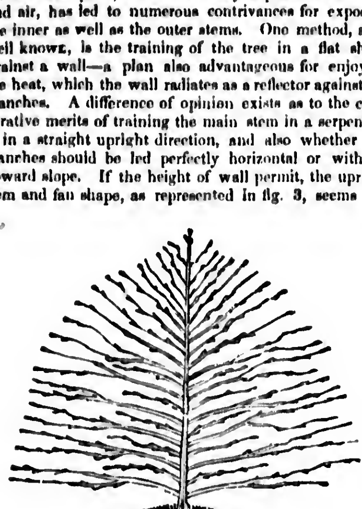

Fig 3.

most advantageous and certainly the least troublesome plan, and we would recommend unprofessional gardeners to attempt no other. Where the wall is low, the branches should proceed more horizontally; and the top being restrained by pruning, these lateral stems will gain greater vigour. In either case, the branches, great and small, will require to be held in their appointed situations on the wall by stripes of list and nails. The nailing should not be so tight as to prevent expansion in growth, or be otherwise injurious. Iron nails rust and disfigure the wall, therefore nails made of zinc are preferable. When a branch at any time becomes loose, it ought immediately to be refixed.

Espaliers.

These are rails generally formed of upright and cross-bars of wood, but sometimes made of cast-iron. The best are of wood ... d of from four to five feet in height. To these the trees are trained as on a wall, the chief difference being, that instead of being nailed, the branches are usually tied; the fastenings are soft hemp-cord or strips of bass, but twigs of willow answer much better. The situation of espaliers is generally along the sides of walks; and if the trees be carefully trained, they have a neat effect. Care must be taken that they do not prevent the sun and air from reaching the kitchen vegetables. When properly managed and well exposed, espalier-trees, observes Neill, "generally produce excellent fruit, the sun and air having access to both sides of the tree; they commonly afford abundant crops, and the fruit is not apt to be shaken by high winds. Farther, they tend to hide the crops of culinary vegetables from the eye, and to render the kitchen garden as pleasant as an avenue in the shrubbery."

The following hints on espalier training, by the author of the "Manse Garden," appear so eminently useful, that we take the liberty of giving them a place here. First, as to cultivation—"Have the ground well trenched and manured [taking a crop of vegetables the first season], and plant the trees three or four feet from the walk, and twice as near to one another as they should afterwards be when full-grown. The reasons for this close planting are, that the value of a few crops is more than the expense of the trees; your rails are sooner covered; and when the trees begin to meet and incommode one another, you can then, having ascertained their various qualities, give scope to the best, by diminishing or rooting out the less worthy. For one or two years after the meeting has taken place, you may delay the pain of execution by allowing the young shoots to pass one another on the opposite sides of the rails. To incur no more expense than is necessary, the stakes may be placed two feet apart, in which case the annual shoots will require to be conducted from one resting-place to another by pieces of lath or wild brier, or willow of two years' growth. These conductors require a firm and separate tying, distinct from that which fastens more loosely the living wood; they thus give strength to the rails, and provide for straighter training than is commonly done by having the stakes twice as thickly set, and consequently at double the expense of timber.

"Supplementary to both wall and espaliers is the following device, which has proved eminently successful:—Supposing that you have more garden ground than is necessary for the supply of vegetables, and that some part of it may be spared for a green shady walk amidst shrubs mingled with standard fruit-trees, on the south side of a row of evergreens, impervious to the eye, let a dry stone-wall be raised to the height of four or five feet, and coped with large stones, merely for strength and durability. Plant this on the north side with ivy, to assist the screen of shrubs, and in a short time not one stone will appear. From the south side take away all the good soil to a depth of two feet, a breadth of five feet, and a length equal to that of the wall, which may be sixty or a hundred feet, as you find convenient. This excavation, it is to be understood, runs close by the building, the foundation of which must, of course, have been secured by perhaps a foot of depth, and which will yet be uninjured, as the stones that cast up in removing the earth will immediately be thrown to the base in room of the materials taken away. Thus an effectual provision is made against the springing up of docks, nettles, or other troublesome weeds; the earth removed will be an invaluable treasure, whether for making compost or helping a thin soil, and the excavation itself will afford a most convenient receptacle for the immense quantities of stones which occur in trenching or raking the garden. Suppose the filling up in this manner to be nearly completed, let a row of large thin stones, set on edge, run along the southern boundary, and rise two or three inches above the surface of the ground. This will serve to keep the mass of stones distinct from the earth, that there may be no mingling in the process of digging. You have then on the one side of this excavation the low edging, and on the other a wall of four or five feet: and the design is, in the course of time, to fill up, with the riddlings of the garden or with clean stones, in whatever way, the whole space from the summit of the low edging to the top of the wall, to present an inclined plane facing the south, and nearly at right angles to the rays of the sun. On this [which is in reality a mound leaning against a wall] fruit-trees are to be trained. Before the bank is completed to its proper slope, the trees may be planted along the southern boundary, and trained for two or three years upon poles laid from the edging to the top of the wall, according to their future destination. When the surface of the sloping bank is raised within an inch or two of its proper height, let a layer of coarse sifted gravel be laid on the top

This will much improve the appearance, and increase the reflected heat, and being free from small sand and earthy particles, will give no birth to annual weeds.

"For the purpose of training, should peaches or apricots be planted, a close trellis will be requisite; but apples or pears will require nothing more than common espalier rails laid on the gravel, and held in their places by two slight spars running across, one at the top and the other at the bottom. In the mean time, the ivy produces a beautiful and beneficial effect, surmounting the wall, and adding to the closeness of shelter caused by the evergreen shrubs. It should be clipped along the top after the manner of box-edging. Nothing can exceed the real snugness of the trees so placed, or the beauty of their glowing blossoms spread out under the eye: and the quality of the fruit comes fully up to the theoretic advantages with which it is favoured. The heat is undoubtedly much greater than that of the best wall, and the open flowers find, in their humble height, a shelter, like the daisy of the field, from the sweeping blast which often scatters the petals of a higher tree like a shower of snow. Experience has fully proved the suitableness of this contrivance to all elevated situations. In some places very low and warm, the heat, so powerfully reflected, might possibly be too great; but in that case figs and nectarines might be so exposed, and would certainly take all that they can get."

THE PEAR.

The pear-tree, like that of the apple, is found in a wild state in all parts of Europe, and has been similarly domesticated and improved into many fine varieties. The tendency of the tree is to a handsome pyramidal form. It is much longer in attaining maturity than the apple-tree; and on a dry soil it will survive and continue fruitful for centuries. The tree may be propagated by seeds, layers, cuttings, budding, and grafting; it is more frequently raised from seeds than the apple, but grafting on its own species is also common, and is generally successful.

The observations already offered respecting soil for apple-trees apply equally to those of the pear kind, and nothing more need here be said either on that subject or on general culture. The pruning, however, is different, because the pear is a very independent growing tree, and, as a standard, will assume its own natural figure in opposition to all restraint. All branches which lash one another must be removed; but unless the pruner cut and deform his trees in his attempts to create fruitful spurs, there will seldom be a redundancy of wood. A little foreshortening or disbudding in the spring and summer may be useful; but, in general, as the pear can seldom become fruitful under seven or eight years from the grafting or budding, it will be prudent to watch the gradual development of the natural spurs, and to cut back the laterals to them, when formed, and not before. Mr. Knight pruned very little, shortening the main shoots occasionally, not sooner than July. He thus expressed his opinion in a letter to a professional gardener on the subject, in April, 1833:—"I would recommend the knife to be little used upon the young pear-trees, particularly upon the horizontal branches. As a general rule for pruning trees that are to be kept low in gardens, I recommend the upright shoots to be shortened about the beginning of July."

The finest pears are the Jargonelle, Marie Louise, Beurré de Capiaumont, Beurré Diel, Glout morceau, Easter beurré, and Beurré rance. The word *beurré*, which here occurs several times, is from the French word for butter: and that, as well as the other names, show how much we are indebted to our continental neighbours for perfecting this delicious fruit. In selecting pear-trees, the nature of the locality must be consulted, subject to which the jargonelle and others mentioned, also the Windsor, are general favourites. The summer, autumn, and winter bergamots are not excelled for rich muskiness of flavour. The pear requires a warmer climate than the apple, and hence some of the finer sorts, which grow well as standards in the south and central parts of England, will require a wall and shelter in northern or more keen situations.

ORCHARDS.

An orchard is a piece of ground specially devoted to the rearing of fruit trees, principally apple and pear, and is frequently an appendage of the English farm and manor house. It should be a well-fenced enclosure, and if there be room for a choice, its situation ought to be on the side of a dry knoll, sloping to the south-eastward; the best soil is a fresh sandy loam of eighteen inches in depth or upwards, reposing on a subsoil of dry gravel or rock. If the ground be wet, it must be thoroughly drained in the first place, as no fruit tree can answer its purpose if the soil be otherwise than dry. A damp clayey subsoil must be avoided; and the deep rich soil in the lowest dip of a valley is the worst situation to be chosen; for, though it may be sheltered against wind, it is most liable to keep the trees in a growing state too late in the autumn, and to be severely assailed by late frosts in the spring, when the trees are probably in flower.

Shelter is necessary to orchards against the autumnal south-west winds; but this is best obtained by high hedges or forest trees planted on that side. Winds from any other quarter need not be so much dreaded. Sheltering hills at some distance are an advantage, so as the orchard is not in the lowest dell at their base. Many orchards are almost barren, the trees covered with moss and lichen (a fine harbour for insects), only from their being too much sheltered, and deprived of a free current of drying air.

As an orchard is usually a pasture for sheep, cows, or other cattle, the trees to be planted in it must be standards; that is, trees trained in the nursery, with a clear stem six or seven feet high, from the top of which the branches diverge, and out of the reach of cattle. Sometimes the stocks are first planted, and when fairly established, are *worked*, that is, grafted or budded at the desired height.

If an orchard is to be formed out of an arable field, the ground may be prepared by the plough, laid into bands or ridges of eight yards wide, the trees to occupy the middle or crown of each ridge, these lying south and north. The trees should be planted in right lines, five, six, or eight yards asunder; and the whole area surrounded by a deep ditch and hawthorn hedge.

When the trees are planted (which should [illegible] the end of October), the ground may be laid [illegible] a crop of barley or oats, and grass seeds in the spr[illegible], and so remain.

If an orchard is to be formed in a grass field, it is drained, if necessary, and closed with a hedge and ditch as above; the trees are either planted in trenched pits or in trenched borders; that is, borders six feet wide are traced south and north, and regularly trenched fifteen inches deep, the turf being turned to the bottom. Along the middle of these borders the trees are put in at the distances already mentioned. This done, the broken ground is sown down with grass seeds, and the trees staked down and protected against cattle if they are in any danger. The pits, six feet square, are trenched and planted in like manner.

In planting the trees, the ordinary care must be bestowed as well in taking them up as replanting, each should be set on a little mound of the finest of the soil, on which the roots should be regularly spread, and kept near the surface—for deep planting must be carefully avoided; the uppermost fringe of roots should just be within the turf, but no deeper; and they should be encouraged to take a horizontal rather than a downright direction.

Orchards planted in either of these methods, if carefully performed, answer very well, if good care is taken of the trees till they are fairly established and can protect themselves.

The fruits chosen for such orchards are apples, pears, plums, and cherries, and of these, such as are known to thrive, and are most fruitful in the neighbourhood of the intended orchard; for all fruits are not equally thrifty in the same locality, and this is a point deserving the consideration of the planter.

Such orchards are planted chiefly with a view to the service of a family, any redundance being sent to market, or sold on the trees to the fruitmonger; but when fruit trees are planted as a special source of profit, a very different plan is followed. An acre or two of suitable land, with a proper exposure, is fixed on; the whole is trenched fifteen inches deep, and thoroughly drained, if necessary. The surface is levelled and laid into beds ranging south and north, and about twelve feet wide; along the middle of these trees are planted; and the intervals are occupied by two rows of small fruits, either gooseberries, currants, or raspberries. Some of the intervals may have a rank of filberts introduced, which, when kept as low bushes, and properly spurred on, are as profitable as any other kind of orchard fruit.

Such an orchard is intended to be a perfect thicket of fruit trees: all, whether yielding large or small fruit, must be kept as dwarfs, and trained in the *bush form*. Of course the sorts which are naturally of a dwarfish habit are preferred, and if not dwarfish by nature, they must be made so by art. The bush form is obtained by encouraging the lateral growth of the branches, and depressing by some means or other those which have a tendency to grow upright. A sufficient number of branches is gained by pruning while the trees are young, and so disposed that they may aggregately form a rotund, compact, but not over-crowded head, shading a circle twelve or fourteen feet in diameter, more or less, according to the fruitfulness or individual strength of the trees. This close planting and low stature of the trees render them a shelter to each other, both against the frosty winds at the time of flowering, and against the equinoctial gales of autumn.

The surface of this orchard is never dug. In dry summers, a mulching of half-decayed littery-dung is spread under the trees, and hoed in in the winter. Strawberries are introduced when the trees are young, but the ground must not be exhausted by surface-cropping.

The success of such a fruit garden depends very much on a proper selection of the kinds, and on the skill of the manager in keeping the trees fruitful and dwarfish, without the application of the knife; for this is quite practicable, and is an art which must be had recourse to in the treatment of dwarfed trees.

Cider.

In Herefordshire, Devonshire, and adjoining districts in England, orchards are maintained principally for manufacturing a beverage from their produce. *Cider* is the liquor made from apples; the trees in most estimation for the purpose being the New Foxwhelp, the Wilding, the Cherry Pearmain, and the Yellow and Red Norman. After the ripened apples are shaken from the trees, they are allowed to remain in heaps for a month on the ground, to become mellow. The process of manufacture into cider, which then commences, is described in the following succinct manner in the "Penny Cyclopædia:"—

"Cider is manufactured with very rude machinery by the following process:—The apples are thrown into a circular stone trough, usually about eighteen feet in diameter, called the *chase*, round which the *runner* a heavy circular stone, is turned by one or sometimes two horses. When the fruit has been ground until the rind and the core are so completely reduced that a handful of 'must,' when squeezed, will all pass without lumps between the fingers, and the maker sees, from the white spots that are in it, that the pips have been broken, a square horse-hair cloth is spread under a screw-press, and some of the must is poured with pails upon the hair, the edges and corners of which are folded inwards, so as to prevent its escape. Ten or twelve of these hairs are piled and filled one upon the other, and then surmounted with a frame of thick boards.* Upon this the screw is slowly worked down by a lever and with the pressure a thick brown juice exudes from the hairs, leaving within them only a dry residue, which, in years when apples are scarce, is sometimes mixed with water, ground again, and the liquor pressed out as before. This latter product is called 'water cider,' a thin, unpalatable liquor, which is given to the labourers early in the year.

The cider is received by a channel in the frame of the press upon which the hairs stand, emptying into a flat tub called a 'trin.' From the trin it is poured with buckets or 'racking cans' into casks, placed either out of doors, or in sheds where there is a free current of air. In about three or four days, more or less, according to the heat of the weather, the liquor usually will ferment; the thick heavier parts will subside as a sediment to the bottom of the cask, and the lighter become bright clear cider. This should then be 'racked' or drawn off into another cask, and the sediment be put to strain through linen bags, and what oozes from them should be restored.

It is during the fermentation that the management of cider is least understood, and there is the greatest hazard of injury. It is necessary also to know what fruit will by itself make good cider, which kinds should be ground together, and what proportions should be mixed. But it is in the preservation of strength and flavour after the cider is ground that the principal difficulty consists: *slight* fermentation will leave the liquor thick and unpalatable; *rapid* fermentation will impair both its strength and durability; *excessive* fermentation will make it sour, harsh, and thin. Other things being equal, that cider will probably prove the best in which the vinous fermentation has proceeded slowly, and has not been confounded with the acetous. The remedies used in cases of cider not clearing are either yeast or the addition of cider in a state of fermentation, isinglass, eggs, or a quart of fresh blood stirred up with the liquor, in which last case it is to be racked on the following day. These do not always prove effectual, but the common evils are excess or rapidity of fermentation; and if a better quality than farm-house or 'family drink' is sought, cider requires so much care to prevent its being spoiled, that the best and most careful makers frequently have it looked at during each night for some weeks after it is made; and if the bubbling hissing noise, the sign of fermentation, becomes frequent or too loud, the liquor is *immediately* racked off into another cask; this check often requires to be repeated several times; but although, at each racking, some portion of the strength will be lost, the body, flavour, and sweetness, will chiefly be retained. It is not the habit of the farmer to add sugar, treacle, brandy, or any colouring matter, to the liquor; it is only adulterated in the hands of cider dealers and publicans, who will not lose a hogshead; and if one has turned sour, or has been otherwise damaged, it must be 'doctored' in order to render it marketable.

---

* This is the process in the Hereford district. In Devonshire, a lever press is used, and "reed," unthrushed straw, is spread in layers in the place of hairs. The method used in the south of France for expressing oil from olives is identically the same

At the beginning of January, the cider is moved into cellars, where, by large growers, it is frequently stored in casks of great capacity, containing 1000, 1500, or even 2000 gallons; these are cheaper in proportion than smaller vessels, and are thought to preserve the cider better. In March, the liquor is bunged down; it is then fit for sale, and may be used soon afterwards, though it will greatly improve by keeping. If bottled cider is required, it should be bottled and wired in the September or October after it is made; some persons prefer an earlier time, the end of April or beginning of May; a greater degree of effervescence is thus attained, but a considerable loss accrues from the number of bottles that will burst."

Good cider is a remarkably wholesome beverage, and may be had at a very small price, the best not being above 1s. 6d. per gallon. *Perry*, or the liquor of pears, is also a pleasant and wholesome beverage, and in some instances almost approaches the quality of sparkling champagne.

STONE FRUIT TREES.

The finest wall fruits of the garden are included in this division; these are, the peach and nectarine, the plum, the cherry, and all their numerous varieties. Under these well-known names, we shall take a cursory view of each, referring the reader for minute particulars to the catalogue in Lindley's "Guide to the Orchard and Kitchen Garden," and to that of the "Fruit Cultivator," a small work of great merit, by the late Mr. Rogers of the Southampton Nursery.

Besides the familiar term, stone fruits, botanists refer all the trees which bear fruit with a kernel contained within a hard, bony shell, surrounded by a rich and saccharine pulp; this, consequently, would embrace that division which has the almond tree for its type. The peach and nectarine were till lately considered a species of the almond, but they have been separated from that family, and the peach, with its variety, the nectarine, constituted a distinct genus.

Peach and Nectarine.

Both are natives of Persia, introduced from that country in the year 1562, and extensively cultivated since that period. Each admits of two leading sub-varieties—the Melting Peaches and Nectarines, or *free stones*, and those with more solid flesh adhering to the nut, and therefore termed *cling stones*. The French consider them as one fruit, but arrange them under four divisions; but we prefer to simplify our description as above, and shall even dismiss the cling stones altogether from our catalogue, deeming them comparatively worthless, being later in their season, and of a flavour altogether inferior to the true melters.

The peach and nectarine can be raised by sowing the stones, and many excellent varieties have been so obtained; therefore it is not a fact that the trees raised from seed are wildings: but as there is no certainty of what a seedling may ultimately become, it is not prudent to trust to this mode of propagation; and though we would urge every practical gardener to make himself intimate with the process of budding—that approved and certain method to perpetuate approved varieties—yet as much time must thus elapse before a wall be stocked with fruitful trees, we think it advisable that he purchase of a good and trusty nurseryman such varieties as are found to be adapted to the locality. The peach and nectarine are seldom grafted; it is usual to select buds of trees that are approved bearers and of fertile habits, and to insert them into young vigorous stocks of the muscle plum or seedling peach. Nurserymen raise their trees in this way, preferring the plum stock; the operation is performed late in July or early in August. The buds swell, but remain torpid till the spring of the following year, at which time the head of each budded tree is cut back to an inch above the inserted bud, which then expands, and forms one or more shoots. Trees in this condition are called maidens, and many prefer such: but in general the nurseryman prunes and trains them into form during the two succeeding years, when they are sold as trained trees, at a price varying from 4s. 6d. to 7s. each. The mode of training thus commenced is usually that which is called the *fan* or *peacock's tail*. It is formed upon the principle of rejecting a central stem, and of leading all the main branches and their secondaries to assume the figure of an expanded fan. It is to obtain such trees that we recommend the planter to purchase the *trained* plants of the nursery garden. But there is another very excellent method of forming a tree, called the *Seymour training*, from the name of the gardener who introduced it. This plan requires a central stem, from which all the main shoots are trained at angles, varying according to the height of the wall and the vigour of the trees. The branches are led to the right and left alternately, at as nearly equal distances (about nine inches) as possible, and when a tree grows kindly, and the pruner is a man of dexterity and foresight, a handsome well-balanced tree is the result. To obtain these Seymour trained trees, the planter must purchase maidens, and either train them himself or employ an adroit pruner who is willing to attend to the required directions. We shall now state the principles upon which all judicious pruning is founded.

The peach produces its fruit upon the spring wood of the previous year; occasionally, also, if the habit of the tree be very vigorous, upon secondary shoots from that wood; but this is by no means desirable under ordinary circumstances, because it proves that the tree is too luxuriant in young wood, which, being developed after mid-summer, can scarcely become duly mature. A tree cannot be expected to produce or support a crop of fruit in a period short of four or five years from the budding; but during that period, the art of the gardener should be employed to lay in six or more regular branches to the right and left, which will form the skeleton or figure of the tree, and remain the permanent supporters of the young-bearing wood. In the fan method of training, secondary fruitful shoots are permitted to form at the under as well as the upper sides of these main branches; but in the Seymour training, the fertile secondaries are led off from the upper sides only; all those which break from the front (called *fore-rights* and *breast-wood*), or from the back next the wall, or from the under side, are obliterated as they appear, either by pinching them off with the finger and thumb, or by amputation with a sharp knife; this process is termed *disbudding*. The quantity of wood to be retained, year after year, so as to obtain a regularly increasing proportion of fruit, without crowding the tree with redundant wood, is chiefly produced by the judicious use of the knife in disbuddings. We will suppose the example of a tree trained in the nursery during two years, then planted in October against a wall fronting the south or south-east, and cut back in February following, so as to leave all its branches about six inches long. The shoots of the first spring form the bases of the permanent branches, and are to be nailed, as they advance, in the most regular order, leaving them at their full length till February of the second year, when the strength and condition of the tree are to be consulted. As a first rule, we are taught, and experience sanctions the rule, "that every shoot is to be shortened in proportion to its strength, by pruning to the point where the wood is firm and well ripened, by which all the pithy wood is removed, causing a supply of that which is better ripened for the ensuing year." But, in order to facilitate the ripening of the wood, it must be trained thin, retaining those shoots only that may be required for the ensuing year. After two years' growth in a good soil, we may reasonably expect that six or eight permanent shoots, a yard or four feet in length, will be formed and trained in, on each hand, and that all these branches are furnished with three or more secondaries laid in at nearly equal distances from one another, and which, by the end of June, may be a foot or more in length. The tree will continue to grow till the end of August; but disbudding must be effected repeatedly, so as to leave it pretty nearly in the form and condition just described.

It has then become a bearing tree, which condition implies a series of strong woody branches of two, three, or more years old, that have produced other shoots in the spring, which, when ripe, are of a deep reddish-brown tint on the sunny side. These latter are the fruitful shoots, and they never bear twice; but, if neglected, run on to an uncertain length, sending forth other weak laterals, which might indeed bear a little fruit, but such as could never compensate for the ruin, or at least, disfiguration, of the tree. It is a maxim among good pruners, that a peach tree should be *green* throughout or all over; that is, every space, even close to the main stem, has one or more leafy and fertile shoots. This maxim would be violated in two seasons were all the shoots permitted to extend themselves, and the tree would be found bare; every part of the centre becoming verdant and productive only at the remote extremities; hundreds of fine peaches and nectarines can be found in this condition; and, in fact, the greater proportion of those in private gardens afford irrefragible evidence of neglect or want of knowledge.

The bearing-shoots, therefore, must be shortened to twelve or fourteen inches, if strong, and the weaker to eight or ten inches, or even to half that length, if very slender. The pruner should cut sloping from behind and a little above a *treble* eye—that is, an eye with a shoot-bud between two blossoms, if there be such; for a branch or shoot not in a mature or bearing state has no treble eyes; but in furnishing a tree, it is not needful to cut away the wood-shoots as useless; because, by pruning back to an eye seated rather low on the shoot, two good fertile shoots may be provided in lieu of a barren one. A single sharp-pointed eye is the origin of a wood-shoot; the blossom-bud is more round; but by deferring the winter regulation till late in February, the condition of the two will be no longer doubtful.

When it has once been so pruned, the leading branch will break its extreme bud, which will thus elongate that branch; and the fruitful laterals will also develope several minor shoots. It is from the last that a selection must be made to effect two objects of the greatest importance. The first is, to attract the sap along the entire shoot, in order to nourish the young fruit upon it; and this will require that the shoot at the extreme point, or at least one beyond the uppermost fruit, be permitted to extend itself, and be nailed securely to the wall, when it shall have acquired some strength and toughness. The second object is to provide a shoot to succeed the one now bearing fruit; and in doing this, the lowest should be selected, because it will, by its situation, replace the present shoot in a manner most conformable with the gardener's maxim before adduced, and tend to keep the tree compact and fertile—*close home*. A third shoot ought also to be retained, to guard against emergency or accident; all the others should be removed, by disbudding, early in May. In July, also, a general regulation must take place; when, by removing useless shoots, and nailing those retained, the fruit will be duly exposed to the sun's rays. Thus the growth of shoots and fruit proceeds; and if regularity and order be maintained, the tree will, year after year, elongate, and add branch to branch, retaining complete verdure throughout. A few lines from "The Guide," by G. Lindley, will suffice to complete our concise directions:—"Should young shoots, indicating extraordinary vigour, anywhere make their appearance, they should be immediately cut out, unless where a vacant part of the wall can be filled up; because an excess of vigour in one part of the tree cannot be supported without detriment to the other. Peach trees, when in a state of health and vigour, generally throw out laterals from their stronger shoots" (he means *secondary* laterals, before alluded to); "when this is the case, they should not be cut off close, but shortened to the last eye nearest the branch" (this is, in fact to spur them, in the hope to convert the lowest bud into a fruitful one); "and if there is room, one or two of those first produced may be nailed to the wall; or the middle shoot may be cut out, leaving the two lowest laterals, and allowing them to take its place, thus frequently obtaining two fruit-bearing branches, when the former one would in all probability have been wholly unproductive.

"In the thinning of peaches and nectarines, and indeed any other drupaceous fruit, it is necessary to proceed with caution, as they are apt to fall off after having attained a considerable size. In order, therefore, to secure a crop, it will be the best way to thin them at three separate times; the first, as soon as the fruit is of the size of a hazel-nut; the second, when of the size of a small walnut; and the third, as soon as the stone has become hardened; after this, it rarely happens that either peach or nectarine falls off before it is matured."

These directions apply in every part to the order of training by the Seymour method; for all the bearing wood of one year must be replaced, if possible, by young shoots proceeding from the base of that wood; this fact, if appreciated, will of itself render any adroit man an able trainer and pruner of the peach tree.

Peach trees are but too liable to be molested by insects and mildew; the former are usually some species of the aphis, commonly called *green fly*, though, as in 1840, it was *black*. Some trees doubtless escaped; but those which were attacked suffered to an extraordinary degree, insomuch that the crop dwindled and the growth of the trees was checked—three distinct broods having succeeded each other between the middle of April and July. They obstinately resisted every kind of wash, though in general tobacco water is effectual. Scotch snuff and fumigation failed; and at last premature close-shortening was resorted to, and thus the new wood was seriously injured. We allude to this fact, as being in strict accordance with the concomitant visitation of the black aphis that locally destroyed the bean crop, and deformed kidney-beans, peas, and even the nettles and other weeds of the fields and lanes. A disease produced by frost, which is called "the bladder blight," frequently swells and distorts the leaves of peach trees; we are acquainted with no other remedy but that of timely hand-picking. By these attacks the regular training and figure of the trees are much disturbed; and at times an entire season may be irretrievably lost.

With respect to soil and preparation of a border, what we have said under the head *apple* applies strictly to the peach. As wall-peaches must have a border, we can devise no plan more effectual or simple than that of clearing out a space of the required length, of eight to twelve feet in breadth, the depth of soil at the wall to be twenty inches, sloping to fifteen inches—making a fall of five inches from back to front. To effect ample drainage, the bottom should be paved, as before recommended, with chalk or fragments of stone, &c., rammed hard, and inclining to a rubble or stone drain running parallel with the wall, to carry away the superfluous water from the bed. A natural substratum of chalk or rock would suffice, but in that case depth of soil must be provided. The bed itself should consist of the rich but not clayey loam and turf, of a common or pasture, having in it no manure whatever. The trees may, indeed, be top-dressed every winter with littery manure a yard or more round the boles, and so deep as to protect them from frost, just above the collar at the critical periods of blossoming. It will also be a great preventative of drought in summer; and of this any one may satisfy himself by raising the mulch in the very driest weather, when the soil under it will be seen black and moist, though in other parts it be parched to aridity. The fruit can be one month accelerated, and its value proportionably enhanced, by growing a tree in a pit 24 feet long, 60 inches deep at the back wall, and 30 inches at the front. The lights will thus obtain a sufficient slope, if their length be seven feet. Hundreds of fine fruit can be produced in July or August by one tree; but great watchfulness will be required about the period of blooming, to check the ravages of the aphides in their earliest approaches; by three days' neglect, we have seen the destruction of a crop and the ruin of all the bearing wood of the year, in despite of every usual application. A strong lining, twice renewed between February and June, will greatly accelerate the advance of the fruit.

Selection of a few of the finest melting peaches adapted chiefly to the midland counties.

1. *Bellegarde or Galande.	4. *Noblesse.
2. *Chancellor	5. Royal George.
3. Late Admirable.	6. Rosanna, or Yellow Alberge.

Nectarines.

1. *Elruge, or Claremont.	3. *Violet Hatios (the best.)
2. Fairchild's Early White.	

The trees marked thus (*) are stated by Lindley to be also suitable to the Highlands of Scotland.

The Apricot.

It is believed, upon the authority of Pliny and others, that the apricot is a native of Armenia, whence its present Latin name, *Armeniaca vulgaris*. It partakes of the habits of a plum and peach, and till lately was considered a plum—*Prunus Armeniaca*. It is multiplied by budding, either upon the common plum or the muscle plum. Lindley says that it is usual to bud the *Moor-park* upon the former; but he is persuaded that the tree would be better, and endure longer, were it budded upon the muscle: and if he be correct in this, we may safely assert, that all the best apricots will succeed upon that stock without having recourse to any other.

The operation of budding, like that of grafting, may be most readily acquired by observing the practice of a good budder. The season of budding is comprised between the third week of July and the 16th of August, and showery weather is propitious. The buds should be selected from shoots of the spring wood; and in taking them off, a piece of bark one inch and a half long should be retained, from which the strip of wood it contains ought to detach itself freely, without bringing with it the eye of the bud. This eye or point is a vital organ, without which a bud cannot grow. This remark applies to every kind of bud, whether it be that of the apple, pear, peach, or any of their kindred: or of any ornamental tree or shrub which admits of being thus propagated.

The best varieties of apricot are—1. The Peach apricot, fruit high-coloured, and very large. 2. Moor-park, of high flavour, and also pretty large. 3. Brussels—oval, and capable of ripening on an open standard. 4. The Roman, hardy, and an abundant bearer.

As to pruning and training, when the figure of the tree is formed by having three or four branches proceeding from a main stem, each is shortened in the winter regulation, soon after the leaves fall, to six inches, in order to obtain new branches. These are secured to the wall in May or June at five or six inches' distance from one another, removing all supernumeraries. At the second winter pruning, the leading shoots may be cut back to ten inches, the others growing upon them to six inches, more or less as position and strength indicate. In May or June following, more wood is laid in from each branch; and thus, by disbudding and winter-shortening, a regularly formed head is obtained, upon the shoots of which short fruitful spurs are duly and progressively developed. In all winter prunings and curtailments, the longest shoot that is retained ought not to exceed eighteen inches in length; thence diminishing, according to the strength of each, to nine, or even six inches.

These rules comprehend the essence of all the best practical directions; but one remark, which we seldom meet with, appears important. The apricot tree comes early into bloom, when very few leaves, if any, are expanded; and it frequently fails to set or retain its fruit. This failure we have remarked particularly with low trees horizontally trained. On the contrary, when the tree having a six-feet main stem without a branch is then trained with a central leader to the height of from twenty to forty feet, and suffered to branch obliquely to right and left, the crop of fruit is frequently very great. We also saw, at the end of March, after the severe frost of 1838, one solitary branch of a tree which had been trained upon the breast of a vinery chimney, with fruit larger than nutmegs, and foliage fully expanded, while every other branch remained torpid as any of the exposed trees of the garden. These facts prove that the high wall of a dwelling, and the proximity of a warm chimney, are most favourable to the productiveness of this very fickle tree.

The Plum.

The common plum of Britain is the type of this genus, *Prunus;* but we cannot believe that this wilding is the parent-stock of those rich and luscious fruits which have been so long cultivated throughout Europe. Plums are propagated by budding upon the common plum stock; and for standards, Lindley recommends the insertion to be made nine inches from the ground, when, under favourable circumstances, the buds will produce vigorous shoots, standard high the first year. Open standards require little attention; they should be divested of all the superfluous shoots by pruning them out close to their origin, just before the season of spring growth. But wall trees and espaliers are to be treated as espalier pear trees; that is, by training them with a central stem, and a series of horizontal branches proceeding from it on each side, nine inches apart. These branches are not to be shortened; and the spurs which form naturally upon them are to be kept short and compact as they advance in length. Artificial spurs may be obtained by July foreshortening; but as fertility is promoted by whatever checks the luxuriance of the wood, it will, we think, be preferable to train in the supernumerary laterals, depressing them below the horizontal level till some natural spurs are formed near their origin, and then to cut the shoots back to the lowest spur.

The plum ripens in September and October. Of the earlier dessert plums, the Green gage and the two Orleans are the best. Coe's Golden drop, and the Goliath, come into season in October; and for preserving, we name the Winesour, the Violette hative, the two varieties of Magnum bonum, and the prune Damson. The Imperatrice is the best late plum, being delicious in November. The soil already mentioned is favourable to the plum, though the tree will prosper in one of more binding quality.

The Cherry.

The cherry-tree, or *Cerasus*, as it was called by the Romans, has been known as a cultivated tree for at least three centuries; orchards, the produce of which was sold at a high price in the year 1540, existing to a large extent in Kent. This circumstance conferred the name of Kentish cherry on that peculiar species. Lindley enumerates and describes twenty-eight, and Rogers twenty-five different kinds of cherries; among which the best for general cultivation are the Kentish, the May-duke, the Graffien or Bigarreau, Harrison's heart the Black heart, and Morella. All may be grown as standards, but the May duke and Morella produce larger fruit when trained against a wall.

Standard trees form their own spurs, and require only a little thinning out of superfluous branches; but wall trees must be treated as the apricot and plum, avoiding, however, to shorten the leading branches. The Morella requires a somewhat different treatment, because it not only bears on spurs, but, like the peach, on young wood of the last spring. Mr. Rogers offers some remarks in the form of anecdote, which are deserving of attention:—In the Surrendon Gardens, of which he had the charge, "a north wall ten feet high had a border twelve feet wide, and very shallow, reposing on loose rubble rock. The soil was a dark hazelly loam, of rather inferior quality: the roots were very near the surface, those nearest the stem actually above it. Five trees were originally planted, but subsequently the second and fourth were removed, leaving the centre tree at thirty-two feet from the end ones. Even at this distance the branches met; and in their progress, being kept very thin of bearing wood, the crops were magnificent." The trees were simply planted on the natural surface of unprepared ground without any manure or deep trenching. "Neither was this border ever dug with spades, but slightly stirred with blunt forks, and having a little well-rotted horse-dung bestowed every second or third year. There cannot be a more mistaken notion and injurious practice, than overloading and poisoning the fruit-borders with rich dung. In the early training of the Morella, the knife should be used freely, to gain a sufficient number of leading branches—thinning out the laterals, but never shortening them."

The cherry-tree grows to a large size, and its wood is highly valued by turners and musical instrument-makers, from its suitableness for being bored and formed into smooth tubes; in the luxurious East, it is much used for the tubes of tobacco-pipes. The fruit of the cherry seems less impaired by growing in a wild state than other garden fruits; in Scotland, the wild cherries, called *geans*, are small but fine flavoured; and in Germany, the favourite liquor *Kerschwasser*, is distilled from the juice of this species of fruit.

BERRY-BEARING TREES AND SHRUBS.

In this division will be comprised the Currant and Gooseberry, both members, with all their now innumerable varieties, of the same family or genus, *Ribes*—the Raspberry, Strawberry, Cranberry, and Grape-vine.

The Currant.

The currant is a native of Britain; nevertheless we are indebted to the Dutch for the great perfection to which it has now arrived. The Dutch red and white currant are unquestionably the best produce of the garden; the Naples black is preferred. Currant-trees prosper only in cool climates, and they are somewhat arbitrary in their choice of a situation even in our own moist country; they grow to an astonishing perfection in the rich moist vales of the middle counties, but the berries dwindle in hot and arid situations. A loam such as has been so frequently mentioned, will also suit the currant, but it likes manure; and this can be advantageously and freely applied as a top-dressing in November, to remain on the surface till after the pruning in February, when it should be lightly forked into the soil without disturbing the roots.

Mr. Knight raised three or four hundred trees from seeds in the course of his scientific experiments upon crossings, but of these very few excelled their parents. One of them, the Red crystal, is superior in all respects. We have also raised currants from seeds, and have acquired one fine white variety, but have thus been instructed that seven or more years elapse ere the plants become fruitful, and therefore that propagation by cuttings is greatly preferable. Take cuttings of the young spring wood, with a small heel of the older wood attached to it; divest it of all the buds excepting five of the uppermost and those of the heel; dibble holes six inches deep in a shady bed or border, and fix a cutting firmly in each hole, by pressure and watering. They succeed perfectly if planted in August, provided they be kept moist and entirely shaded, or in a north aspect; but the season extends thence to the beginning of March. The soil should be rich and light. Cuttings may be placed at first where they are intended to remain, or they may be transplanted after they become rooted plants, cutting away all but the upper whorl of roots: in either case, cut back to two or three buds the shoots made the first spring, and subsequently prune on every side at an outside bud, to make the bush spread at top, and render it open towards the centre.

Prune for fruit just after the buds begin to swell—never before February, or the birds will reduce the expected crop; and in pruning, shorten all the leaders and spur in the laterals, till the bushes appear like deformed masses of scrubby twigs. The long pruning is comparatively worthless.

By these spurrings and shortenings, the trees progress somewhat slowly, but the fruit is produced in massive clusters from the numerous spurs. The skeleton of each bush ought to consist of nine, twelve, or fifteen bearing branches, diverging at equal distances from three lower short limbs, which emerge from one main central stem; this is the best form of a neat bush, and the knife should be exercised to keep it open in the middle. If the spring shoots push very vigorously, the first high wind generally breaks down more than half of them; but this natural pruning is frequently advantageous. The black currant requires a still more moist and cool site, and that the wood be kept young, but never pruned or spurred. Whatever shoots become black and scaly must be cut entirely out, leaving those bearing branches only which are of a delicate brown colour. The trees require frequent renewal, by taking vigorous cuttings, for old wood produces small berries. If the soil and site be congenial, and the trees be young, the berries are frequently seen nearly as large as small black cherries.

The Gooseberry.

This universally known shrub is a native of Britain, and therefore much more easily cultivated than exotics; it is, indeed, so hardy, and suitable for even keen climates, that remarkably little fostering is required to keep it in perfection. After a long course of culture, there are now hundreds of varieties of gooseberries; still, the kinds which keep their place in public estimation are few in number: these are the old rough red, dark purple, green, and yellow gooseberries; they are still pre-eminent in flavour, but as the genuine culture of all is the same in principle, a few simple rules will instruct the grower in all that he need perform to obtain healthy and productive bushes.

To propagate, take cuttings of any chosen sorts eight inches long, of the last spring's wood, having a small piece or heel of the older wood; they are inserted about the end of October to the depth of three inches. The situation should be shady, the earth rather sandy, and each cutting should be fixed firmly in the soil. It is customary to remove all the buds excepting four or five at the top, which are left to form the head, produced from one central stem: but we prefer to secure the rooting of the cutting by retaining the lowest, and planting it four or five buds deep. It is from these buds that we expect roots; and though none may be developed till spring, nature will not be idle and whenever the eyes break, and shoots elongate, it will be time enough to select the strongest and best as a leader to form a stem, obliterating all the others both below and above the surface. Should three or four eyes break at the upper part of a cutting, it will be desirable to remove all others lower on the stem, as soon as it shall be manifest, from the vigour of growth, that there are good and sufficient roots to support them. A central stem is most desirable, and people think to obtain one, and to prevent the growth of suckers, by destroying the lower buds in the first instance: we believe that the want of success and the loss of the cutting are to be traced to this practice, and therefore we disclaim it. When the head is formed, gooseberry-trees can be spurred as directed for currants, avoiding to shorten the leading branches; or at each pruning in February, a certain quantity of the last year's wood should be retained, and a corresponding portion of the two and three years' old wood cut out; thus, as it were, renewing the trees annually. Larger berries are thus obtained from strong young wood than by the spurring system.

The Raspberry.

The raspberry is a native of some counties in England, but has been greatly improved by culture. The choice sorts are—1. Red Antwerp, fruit large, of high flavour, ripe in July; but by being planted behind a north wall, can be retarded, and the season thus protracted some weeks. 2. Yellow Antwerp, light coloured, very bristly wood, of luxuriant growth; fruit admirable in flavour, luscious; peculiarly adapted to the dessert. 3. New Double-bearing; it is rather an autumnal raspberry than strictly a double bearer; still, by due and timely pruning, a second crop is frequently obtained in autumn. The raspberry is propagated by suckers taken up from among those which rise in abundance from strong plants. The fruitful shoots bear but once, and should always be cut down in August to admit air and light to the young shoots of the summer; and from these suckers (of which four or five are amply sufficient) some should be selected to renew the stock every five or six years, changing the soil and situation. Care should also be taken to remove the disorderly suckers which rise from the wandering roots. The soil for this plant should be a rich light loam. The plants, if placed in row, should stand a yard or four feet asunder. They may be supported by strong stakes made to slope to the north; and, confining the bearing shoots to them, the successional shoots will rise perpendicularly, without interfering with the others.

The Strawberry.

The strawberry is one of the few fruits indigenous to Britain, and is found, like the bilberry and juniper, in a wild state in uncultivated spots, chiefly in woods and on tangled shrubby banks. It is likewise found in all the other northern countries of Europe, particularly in Norway, among whose rocky mountains it grows in great abundance; it prevails also in the temperate regions of South America, and abounds in the colder climate of Canada and Nova Scotia. This delicious small fruit is, in short, very generally scattered over the earth, and was the delight of ancient as well as modern times. In Latin its name is *fragaria*, which is supposed to be significant of the fragrance of the fruit; the French, perhaps from this source, call it *fraise*, and hence the common surname of *Fraser*, which is of French origin, and the well-known heraldic object, the strawberry, which is borne by families of that name. The origin of our name *strawberry* is much less obvious; by some, it has been traced to an old practice of placing straw beneath the berries to keep them clean while growing; but others allege that it originated in the circumstance of the berries being anciently threaded on straws, and offered for sale in that condition. The strawberry is one of those plants to which nature has given the means of extensive multiplication. From the main bush or stems there spread forth tentacula or suckers over the surface of the ground, and these fastening themselves by a root at every joint, as many new plants spring up as there are joints. A single bush will in this manner, if, not kept within bounds, soon spread over a moderately sized garden. From this abundant growth of the strawberry, it has been inferred that the fruit is of essential importance as an article of food in summer; but this is scarcely philosophical; for to what plant has nature given the means of propagation more abundantly than the dandelion, and what is so little used or held in less esteem by mankind? Be this as it may, the strawberry is universally acknowledged to be exceedingly wholesome and refreshing as an occasional summer diet, and it is also allowed to possess certain medicinal properties, which give it a still higher value. With respect to these medicinal qualities, Phillips speaks of it as follows:—"As a dietetic fruit, the strawberry affords but little nourishment: the moderate or even plentiful use of it is salubrious, and recommended to those of inflammatory habits. Boerhaave considers the continued use of this fruit as one of the principal remedies in cases of obstruction and viscidity, and in putrid disorders. Hoffman furnishes instances of some obstinate diseases being cured by strawberries and other mild, sweet, subacid fruits, and affirms that he has known even consumptive people cured by them. Linnæus informs us that, by eating plentifully of strawberries every day, he kept himself free from gout. They promote perspiration, and dissolve the tartarous incrustations on the teeth. Strawberries should be taken sparingly by those of a cold inactive disposition where the vessels are lax, and circulation languid, or digestion weak." The medicinal qualities of the strawberry appear to us to consist somewhat in the abundance of small hard seeds on the fruit, which act mechanically on the stomach and bowels, and also in the weakness of the sub-acid; in other words, the pulpy substance is of a simple and harmless nature, remarkably easy of digestion, and at the very least cooling in its effects. Taken in moderation, it will save the use of some kinds of medicines, and, as an alterative from hard food, it cannot be too highly commended.

In most parts of England, strawberries are eaten alone, or dipped individually in sugar, before being put into the mouth; and to suit this mode of consumption, they are brought to table with their stems, which form shanks to hold by. But in Scotland they are consumed in a far more wholesale manner. There they are brought to table stripped of their stems, and are ladled out and eaten with a plenteous infusion of cream and sugar. "Strawberries and cream" is, in fact, one of the grand national treats which strangers may reckon upon seeing set before them in the early weeks of July, and to which generally full justice is done. In the neighbourhood of Edinburgh, there are a number of suburban villages deriving celebrity from their extensive strawberry grounds, and to these parties proceed from town to enjoy the fruit in perfection, that is to say, along with the richest and most delicious cream. In the vicinity of Dublin, the celebrated "Strawberry Beds" in the same manner attract immense crowds of persons in the summer evenings, when the fruit is in its prime. Those who are accustomed to see strawberries only in the small pottles in which they figure at Covent Garden market, can form but a feeble idea of the mode of consumption at either the Scotch or Irish metropolis.

Of late years there have been many changes and improvements in the strawberry world. Fifty or sixty years ago, only about a dozen sorts were known, those of the largest size being called *hautboys*.* According to horti-

* So called from being originally found in the *haut bois* or *high woods* of Bohemia.

culturists, there are now some hundreds of select varieties, produced by crossing, change of situation, and other circumstances. An old and respectable strawberry, known as the Old scarlet, was introduced from Virginia in 1625, and has been the prolific source of several varieties. The Austrian scarlet, the Roseberry, the Scotch scarlet, the Aberdeen seedling, the Grove-End scarlet, the Downton, Sir George Mackenzie's Late scarlet, Nova Scotia scarlet, Prolific hautboys, and Keen's seedling, may be noticed among hundreds of others. Latterly, some poor sorts may have been banished from the market, and given place to Keen's seedling, which combines good flavour with largeness of size, and is an excellent bearer. The object in cultivating so many varieties is to obtain a succession of fruit through the season, some sorts ripening and being ready for market in May, while others come to maturity in the course of June and July. It should be understood, however, that it is only in the neighbourhood of London that the successive cropping of strawberries, or the forcing of them at particular seasons, is methodically conducted on a large scale. In most parts of the country, the vicinity of Edinburgh included, the fruit in its different varieties comes almost at once into the market, the season lasting about three weeks, and then all is over. The exceeding precariousness of the crop, from the chance damage of rains, makes the rearing of strawberries a business of little profit, and lately it has been abandoned by a number of our market gardeners. This is a circumstance to be regretted, and we should hope that, by a greater attention to the cultivation of *late* sorts, which would not arrive at maturity till late in July and in August, a greater degree of success in rearing might be secured.

The following comprehend the general directions for culture:— The seasons for planting are March or September. The soil that all affect is a rich unctuous loam, trenched to the depth of two feet. The best and strongest rooted runners of July are always to be preferred; and these should be planted at the periods above named, with all their roots, into beds or borders recently prepared. Many persons retain their beds or rows, during an indefinite number of years, in a tolerable state of fertility; but the triennial system appears to combine every advantage, while it avoids the two extremes of annual renewals and of protracted duration. When a bed is formed and in full bearing, it will require an annual surface-dressing of loam and manure, two parts of the former to one of the latter, early in the winter, to protect the plants and receive the new roots, which always are emitted just below the lowest leaf-stalks; in March the old leaves ought to be all cut off, leaving the hearts untouched; and the beds should be cleared of litter by a wooden rake. Prior to the fruit becoming ripe, the mowings of a lawn or of any soft grass laid over the surface, will prevent the berries from being soiled by mould or worm-casts.

Triennial System of Planting.—1. A plot or border of earth being trenched, as before directed, select, after the first rain of September, a quantity of strong and well-rooted runner-plants, and, with a garden fork or trowel, set them one by one, fresh from bed, in the new ground; if in single border row, a foot apart; if in a bed, at the same distance plant from plant, but the ranks two feet asunder. Fix each plant firmly, and give water over it from the rose of a watering-pot. If a set of plants be thus merely transferred without much disturbance, and watered three times, few will fail. Hoe the ground occasionally; and prior to or during the first frost, sprinkle some manure over and around the plants, and lightly pass the wooden rake over them. Suffer no blossom to expand in the following spring, but leave the plants to acquire strength. Stir the ground occasionally, and cut off all runners.

2. In the second September, prepare and complete a corresponding plantation. Manure and dress the plants during winter, and those of No. 1 for the second time, and in March trim off the old leaves, and rake the surface. Let the plants of No. 1 bear their full complement, the fruit of which ought to be early, abundant, and of first-rate quality.

3. In September, repeat the work, and thus complete the plantations. Treat this and No. 2 exactly as directed for No. 1. In the following spring, suffer No. 1 to bear a second crop, No 2 its first crop, and obliterate the blossoms of No. 3. In the September of the fourth year, dig up all the plants of No. 1, turn the ground, manure, and replant it. Thus the routine will be completed; and thus, year after year, there will be a plot progressing in one of the three stages; and if, with each approved variety, a similar routine course be adopted—and especially if a plantation be formed in the three aspects, east, south, and north, the last under a hedge or fence, to screen it from the south sun—the season of strawberries can be extended between the latter end of May and the middle of August. For the latter period, Knight's Elton is peculiarly adapted; and they who can at that time command a supply of a fruit so fine and beautiful, will have ample cause for self-congratulation.

The Cranberry.

This is a small wild fruit, which may be easily cultivated in gardens; the plant is so exceedingly productive, that 140 bottles (five bottles to the gallon) have been known to grow within a space of two and a half square feet. The berries are used chiefly for tarts. Cranberry plants require a very moist soil, and if placed near a pond, so much the better. Give them some bog earth, and in dry weather let them be frequently irrigated.

The Grape Vine.

The vine, from the juice of whose fruit wine is made by a process of fermentation, is a plant of eastern origin, which, in the course of ages, has been introduced into all the countries of southern and central Europe, also England. Requiring a fine climate, it will not bear fruit in the open air farther north than York, and it is only in fine seasons and in good exposures, that its fruit is worth eating even in the southern parts of Britain; in general, the grapes grown in gardens about London are small, and not presentable at table. In the north of France and Germany they are little better, and we do not really get fine grapes of a proper size till we reach Italy or Portugal. In England, however, grapes produced in hot-houses surpass in size and flavour the fruit of the Portugal vines.

Throughout the continent, the practice is to grow vines in large fields, either on plains or the sides of hills, which are fully exposed to the sun. They are trained in rows, tied to stakes, and are pruned to a height of about four or five feet; on the Rhine, they seldom exceed three or four feet; and, at a distance, the ground has somewhat the appearance of being covered with staked beans or peas. In Italy, the vines are trimmed to a greater height, and are made to cling to horizontal palings, as if from the roof of a hot-house.

To those in the southern parts of England who desire to rear the vine in gardens and on walls, we offer the following directions:—The varieties most suitable for culture are—1. The White sweet-water, with round berries, somewhat tinged with yellow, and faintly streaked with red on the sunny side. 2. The White muscadine, bunches rather loose, berries not very large, yellowish, and abounding with saccharine juice. 3. The Small black cluster, with berries between red and purple, closely packed, very sweet, and luscious in flavour. 4. Turner's hardy, or the Esperione, a fruitful tree, and very certain bearer; berries of medium size, varying from dark-red to deepish-purple.

Mr. Hoare's treatise on the vine has added importance to the culture of this graceful tree, and has thrown great light upon the treatment it requires. Our limits forbid us to recur to the statements therein given, and we can only observe, that no one who possesses a gable-end, a brick-walled house, or, indeed, a wall or fence of any kind, need be without a vine; it affects no richness of soil, but will grow on the shallowest ground, over and in chalk or rock of any description; yet, if a border can be formed with a dry and well-drained bottom, the tree will be rendered more vigorous, though the fruit may not be exalted in flavour.

A sound turfy loam, to the depth of eighteen inches, rendered open by small fragments of old lime-rubbish, and a portion of crushed bones, will support any vine, and promote its fertility; and these materials can be introduced by degrees, first near the roots, then at a greater distance to replace a corresponding quantity of old soil; thus little expense will be incurred, and still less labour. But if a new border be contemplated, and outlay be not considered, it will, of course, be best to complete the work in the first instance.

Vines are propagated by single eyes, by cuttings, and by layers, placed in pots when it is intended to remove the plants to borders or vineries. The soil should be a light rich sandy earth, or perfectly decayed manure, and sand, in equal parts; but they who wish to raise vines without loss of time, should plant cuttings taken from vines of known fertility, and of the yearling shoots which are themselves actually fruitful. Each should have three bold eyes on the young wood, and each should retain at its base a small piece of the previous year's wood. The season for planting is the month of March, and the method very simple. Dibble a hole from four to six inches in front of the wall or fence, deep enough to receive the entire cutting. Mix together equal parts of black leaf-mould and white sand; put in the hole enough of this to raise the bottom one inch, and ram it hard with a blunt stick; then insert the cutting, and hold it firm in the centre of the hole, while that is filled brimful with the compost, which is brought into still closer contact with the shoot by pouring water into it two or three times. Make the ground quite even, and its surface level with the uppermost bud, then cover the cutting with a small hand-glass. If the ground is kept moderately moist, not two cuttings in a dozen will fail. If more than one shoot break, and attain the height of five or six inches, the stronger only should be retained, slipping the other off below ground. This shoot must grow till its point become spindling, when it should be nipped back; and all future growth should be thus stopped above its lowest leaf, as also the laterals that appear during the growth of the main shoot. Great care must be taken to keep the vine regularly nailed and secured by soft and roomy ties, to prevent accident, and the danger of being snapped by the wind.

As the aspects suitable to the vine are confined between south-east and a small point to the west of south, the cuttings, if not duly supplied with water, may be droughted and perish before they become completely furnished with roots; but when once established, the main shoot will grow rapidly, perhaps attaining the height of a common fence, and ripen their wood early. In the end of September, let each be cut down to an inch above the three lowest buds; mulch the ground around the stems and over the roots as winter approaches, and watch the spring progress of the eyes. If possible, obtain and secure two equal shoots; and if the wall or fence be from eight to ten feet high or more, lead these shoots horizontally right and left about six inches above the soil, and secure them by shreds and nails. If the wall be six feet or under, retain but one strong shoot, and train it perpendicularly. In September, cut back according to the strength; thus, if the wood of the single rod last mentioned measure from one-third to half an inch in thickness, and the eyes be full, and from four to six inches apart, cut the shoot at the top of the fence, removing also the remains of all laterals, and tendrils. The two horizontals will perhaps be rather slighter, yet if they be fully ripe, and furnished with bold eyes, they may be left three or four feet long on each side of the short main stem, but all the buds on the under side of each must be cut away; mulch the ground as before; and in March following fork in the manure.

Bearing Condition of the Vine.—The fourth spring will find the vines in a fruitful state; but previously, the trees prepared for a dwarf fence should be so pruned as to retain but three horizontal branches on each side of the main stems, about eighteen inches asunder, the intermediate branches being cut back to their lowest bold eye beyond the stem. This eye is designed to produce a new shoot, to take the place of the bearing shoot, which, after the fruit is taken, must be cut away. Thus the vine will henceforward produce, year by year, two systems of branches, one of which will comprise year-old bearing wood, the other a corresponding series of green wood, which will produce the fruit of the following year. This description would almost suffice to elucidate the habits of the vine; yet, to leave no doubt on a subject which involves the entire theory of pruning, it will be understood that this tree bears its fruit solely upon the green shoots of the present year, which spring from the eyes of the pale-brown wood of the previous year. When, therefore, a vine is of age, and has acquired sufficient strength to support a crop of fruit, it will generally be wise to provide a new series of bearing wood every year because the fruit of new wood (in the white varieties particularly) is always superior. In this horizontal alternate system for low fences, each new branch may safely be permitted to extend itself at least two joints beyond its predecessor, always remembering to cut back, early in the autumn, to a short distance above a bold eye seated on perfectly ripe wood; for thus the tree will acquire strength and extent at the same time; and experience proves that, in ordinary circumstances, the fertility of a tree should be moderated, and kept below the supporting power.

The trees on the second system of training for high walls must be pruned in a similar manner, and upon corresponding principles. In the autumn of the third year three out of four branches will be cut down to the lowest bold eye, and a few vertical shoots, from thirty inches to a yard apart, will remain; and these also must be pruned to a strong eye situated on mature wood. This system will furnish new bearing-wood every year, increasing in length as the power of the tree augments; while, also, the low horizontal stems will extend gradually in due proportion. At first one, or at most two bunches, must be permitted to remain upon each upright branch. In the fifth season, a greater crop may be taken, always, however, remembering to restrict the fertility of the vine, for by so doing, its vegetating power will keep in the advance, till, in the end, the entire fence will be filled with vigorous branches, annually renewed, from which a very heavy crop may be gathered, without tasking the vine in any degree that shall produce debility.

The spur system of pruning back the bearing shoot annually, may occasionally be adopted with black grapes, and not without advantage; yet the system of yearly renewal leaves the vine at the entire command of the pruner, and procures large clusters of fruit. The few remarks above offered enter little into minutiæ, but they elucidate general principles; and if applied practically, will, we believe, lead to improvement in grape-growing. We again profess to be much indebted to Mr. Hoare, and recommend his treatise to every cultivator of the vine.

The fruit of the vine grows in clusters or bunches, as many, perhaps, as a hundred grapes in the bunch. It is not desirable that so many should cluster together, for, when numerous, they are apt to be very small, and to be so compact in the mass, that those within do not ripen. Bunches with many grapes, therefore, should be thinned, by clipping out those of the smallest size, which will allow the others to grow to the proper dimensions. In very many instances, grapes grown on walls in gardens are spoiled by vermin, the interstices in the bunches being often filled with spider's webs and insects of different kinds. All this is a result of carelessness in not keeping the walls clean, and pruning and otherwise attending to the bunches. As a preventative, let the walls in winter be lime-washed, including all branches of the vines, and take some pains to remove all vermin which appear in the fruit season.

Forcing.—Of the growing of vines in hot-houses or vineries, it is not our intention to speak; but for the class of persons whom we address, the following account of a method for forcing vines in humble edifices, given by Mr. M'Intosh, in the "Orchard," seems so suitable, that we take leave to offer it:—"In many parts of the continent, and even in some few instances in this country, vines are forced in very humble edifices. The Dutch, Flemings, and Germans use pits, often not exceeding three or four feet in depth. These are sometimes heated by dung or tan being placed within them, which give out a mild, humid heat, serviceable to the vine while the buds are breaking; and this, with the proper husbanding of the solar heat by judicious ventilation, is often found sufficient to produce ripe grapes at an early period. Other instances occur of such pits being heated by a smoke flue, to which very moderate fires are applied. But what is most novel in these pits is, the vines being planted outside—the wood that is to produce the fruit is trained under the glass within, while the young wood for succeeding crops is allowed to grow without, where, under a brighter sunshine than we enjoy, the wood becomes perfectly ripened, and when the crop is gathered, the old wood, or that which produced fruit this year, is entirely cut out and replaced with the young wood hitherto growing without the pit. Vines are also ripened on the continent by having glass frames placed against the wall on which they grow, about the time the fruit is half or three parts swelled, at which period those glasses are not in use which have been employed in forcing early crops of melons, salads, &c. The solar heat collected by this contrivance ripens the fruit well, and fully matures the wood for the following season. We have it in contemplation, founded upon the success of this mode, which we have often witnessed on the continent with admiration, to erect a portable structure in the new gardens now preparing for his Grace the Duke of Buccleuch, at Dalkeith Palace, and of which the following brief description will convey a sufficient idea:—Supposing a south wall, built hollow and heated with hot water (as all our walls are to be), be planted with the early ripening sorts of grapes, late peaches, and some of the best late ripening plums, such as Coe's Golden Drop &c. The trees not to be excited in spring (which should never be attempted with hot walls), but rather retarded in their blossoming, by keeping the branches as far from the wall as possible till they begin to blossom, at which time they are to be laid in to the wall, and the blossom protected with thin canvas awnings, particularly during night. In July, at which period the roof-sashes of the early forced peach-houses and vineries will be removed, these are intended to be employed to cover the above wall in the following manner:—A permanent stone curb, twelve inches high or more (or a wooden plank of the same height will answer as well), is laid along parallel to the bottom of the wall, and at two feet distance from it. This curb is furnished with a groove an inch and a half deep and three inches wide, to receive the bottom rail of the sashes, the top rail to run in a corresponding groove, in a batten of wood fixed to permanent brackets near the top of the wall, the distance between the top and bottom grooves to be equal to the length of the sashes, the bottom rail of each sash to be furnished with two brass rollers, to facilitate their movement. The glasses, it will thus appear, will stand perpendicular to the wall, and at two feet from it, and ventilation and the necessary operations of pruning, gathering, &c., can be carried on from without, the lights being made to pass each other in the grooves, as in the manner of what is called barrack windows. The concentration of solar heat in August, September, and October, with the power of applying fire heat by means of the hot-water pipes in the walls, which may be safely used as soon as the glasses are put, will not only ripen our best autumn fruits, but also mature the wood and buds for succeeding crops. Grapes and plums may be prolonged by this mode, we think till Christmas, or indeed until the glasses be required to be again put on the early forcing-houses; and our finest Flemish pears, late peaches, and nectarines, which do not often ripen well in England on the open wall, and never in Scotland, will be brought to the highest perfection. Hot walls we have long ago proved to be of little or no value in spring but their efficacy in autumn no one can doubt, and their utility will be greatly increased by having this covering of glass before them."

For information respecting the construction and management of hot-houses and green-houses, we refer to Loudon's "Encyclopædia of Gardening," also to the beautiful works of Mr. M'Intosh (Orr & Co., London).

MISCELLANEOUS FRUITS.

The following are fruits which cannot be strictly ranked among the preceding classes, and are grown almost exclusively in gardens of a high order:—

The Fig

The fig-tree is a delicate exotic like the grape-vine, and great care is required to bring crops of the fruit to maturity in the open air. There are many kinds of the fig-tree, but the greater number are adapted to culture only under glass. The following are four excellent kinds:—The Brown Ischia; fruit large, rather globular; brown pulp; purplish-red; very rich in flavour, and melting; ripens in August. Brown Naples, colour brown without and within; a hardy fruitful tree. The Large Blue or Purple Fig, like the Brown Naples, ripens about August. It is one of the best fig-trees; fruit long and of regular figure; pulp red; of rich and fine flavour. Lee's Perpetual Bearer, which is well qualified for gentle forcing in pots. The best soil for fig-trees is a light fresh loam; but the chief essential to promote fertility is a hard and dry bottom of chalk, gravel, or artificial pavement; a dry substratum and little depth of soil (that is, from one foot to eighteen inches) are therefore what the gardener must provide, if he expects to render the trees permanently fruitful.

Culture and Training.—Both are extremely easy Rogers says, and very justly—"That the knife is seldom wanted" (that is, in shortening; though from the extreme luxuriance of the wood, it is frequently necessary to cut out many entire shoots); "pinching off the points of the young shoots during the months of May and June with the thumb and finger, is the most effectual pruning." Mr. Knight restricted himself to compressing the points of the green shoots till the substance was felt to yield under the finger and thumb, by which pressure a check is given to luxuriance, and the milky sap is diverted to the embryo fruit, which lies embedded at the base of each leaf-stalk.

But to secure fruit in due season, the pruner must recollect that, in Italy and the south of Europe, two crops of figs are produced yearly. Those large figs which are seen on fruitful trees here late in summer, are developed in spring, and would ripen early in a warm climate; but our winters check their progress, and generally destroy them. The crop which ripens in August is developed late in the preceding summers, and is extremely minute, almost invisible, in September : it is situate near the terminations of those green shoots which have been pinched or compressed : therefore the large green figs (which have properly been termed *sterilizing encumbrances*) should be displaced by mid August, and then it will frequently be seen that two minute embryos form in lieu of the one; and these, if the tree be protected, will ripen at the season mentioned. As to protection, it will be proper to unnail and bend down the upper shoots, so as to bring them into moderate compass, then to pass a few straw bands among and across them, and finally to cover the whole with a mat or canvas sheet.

In April, train in, straight and regularly, all the bearing wood; and as the trees grow, suffer the breast wood to curve forward at its pleasure, placing the points as directed. Not one shoot is to be cut shorter ; but if the wood become redundant, some branches which obscure the fruit should be entirely removed, reserving that which will manifestly be fertile, and which can be duly trained in at the regulation of the following spring.

The Filbert.

The filbert is believed to be an improved variety of the common hazel-nut. Both plants are monœcious ; that is, they produce male and fruitful blossoms very early in the year on the same tree, but separate from each other : the catkins that become visible in autumn are the males or pollen-bearing flowers : the *crimson threads* are the pointals of the fertile nut-bearing flowers. As the trees are pruned—spurred, as it is termed—in autumn, care must be taken to reserve a number of catkins, otherwise the crimson points will fail to perfect the nuts. The chief varieties of the filbert are the Red-Skinned, the White-Skinned, and the Cob or Barcelona-nut. The following are the methods of culture;—Strong suckers, taken in autumn, are either planted in the nursery, or at once in the places where they are to remain; and these grow three or four years, and are then cut down within a few inches of the ground. From the stem several strong shoots are produced, which, in the second year after cutting down, are generally shortened by one-third of their length. Regular figure and an open head are procured by placing a small hoof within the branches, to which the shoots are fastened at regular distances. In the third year, as the bush approaches maturity, short shoots (spurs) spring from the eyes, and are suffered to grow till the autumn, when they are cut back nearly to their origin, whilst, also, the leading shoots of the previous year are shortened two-thirds.

In the following spring, several small shoots arise from the base of the small branches which were cut off the preceding autumn, in consequence of the curtailment of the leading trained branches, and upon these secondary spurs the fruit may be expected; these shoots augment in number yearly, insomuch that many must be cast away. The largest are removed; the lesser remain being more fertile in their habit. Many decay yearly, but whether they do so or not, those which have borne filberts are always cut away, and a fresh succession provided as future bearers. The leading shoot is every year shortened two-thirds or more, if the tree be weak, and the whole height of the branches must not exceed six feet. In order to strengthen the tree as much as possible, the suckers of the roots are eradicated, by exposing the roots, at a moderate distance from the stem, to the frost. The excavation is in the spring filled with manure.

The crops thus produced are sometimes enormous, followed, however, by intervals of barrenness. We have not heretofore adopted the method of pruning, leaving the trees more to the order of nature; but it is right to try experiments; and when a row of young trees exists, a comparison might readily be obtained, by pruning alternate trees, or one of every three trees, by the "spur-system;" always, however, observing to keep the head of every tree open, and to cut away its upright central leader.

The Mulberry.

The mulberry is a native of Italy, introduced in 1548. The structure of its flowers and fruit is very singular; like the nut and filbert, the males are distinct from the females; the latter do not always expand at the same time as the males, and therefore are not fertilized. The calyx swells and becomes fleshy ; each individual contains one or two seeds; and a congeries of these swollen organs form what is supposed to be a single mulberry. There is but one known species of the black mulberry, and this thrives best in loam, of the quality so often named; but the bed ought to be deep, and to rest on a dry sandy subsoil. The fruit sometimes fails; and on this subject Rogers observes, that fertility may depend very much on the warmth of the weather at the time of blossoming, and on the circumstances of both male and female flowers coming forth at the same time; sometimes, also, the male catkins drop before the fruit blossoms expand. Williams, of Pitmaston, suggests that "no tree receives more benefit from the spade and dunghill than the mulberry; it ought, therefore, to be frequently dug about the roots, and occasionally assisted with manure." Others consider a velvety piece of turf as the best site; and certainly if the finest fruit fall, grass turf must preserve it clean and sound. We have known several old trees on turf never dug or disturbed, which always bore immense and fine crops; on the other hand we have seen young trees on dug and enriched ground fail year after year. When the buds expand in this third spring, it is desirable to obtain four shoots on each side of the upright stem, and all the shoots that will break from the two horizontals, which latter are to be led upright, and secured as they advance.

ARBORICULTURE.

The Oak.

Scientifically, as well as popularly, the term *Trees* includes all those plants which reach a considerable stature, and possess stems more or less solid. They are, as all must know, by far the grandest objects in the organic world, and they are not amongst the least elegant. The timber produced in the stems also renders them of very great importance in many of the arts cultivated by man, and in none more so than in that which has enabled him from ages beyond historical record to transport himself across the bosom of the deep, and communicate from one land to another the various productions of the earth.

Trees are divided, with a regard to their structure, into two great classes. Some, which spring from seeds of more than one lobe, and grow by additional layers on the outside of the stem, are for these reasons respectively called *Dicotyledonous*, or Exogenous Trees; others, which spring from seeds of one lobe only, and grow by additions in the interior of the stem (palm, sugar-cane, &c.), are called *Monocotyledonous*, or Endogenous Trees. As our treatise regards the practice of arboriculture in our own country, where there are few trees of the latter kind, we must be understood in all general descriptions to refer to the former only, unless the contrary is mentioned.

In the organization and organic functions of trees, as well as in other plants, there is some general analogy to those of animals. When cut across, they appear to the naked eye composed of fibres or thready substance; but in reality the substance of trees is almost altogether composed of vessels or tubes, through which the sap flows, like blood in the veins of an animal. Seven millions of these vessels have been counted in the surface of a square inch of wood! The vessels in trees, like those in animals, are of different sizes; but it has been ascertained that there is nothing in trees performing the same functions as the heart in the higher classes of animals—that is, propelling the blood throughout the system, and, by its return again to the heart, completing the circulation. The vessels simply extend from one end of the tree to the other, sometimes joining with each other, as the veins and arteries of animals do, and, moreover, exhibiting circles which, when the tree is cut across, have the appearance of rings. One of these circles of vessels grows round the outside of the tree (under the bark) every year, and is called *alburnum*, or sap-wood, while the inner and harder matter is called *duramen*.

A tree consists of four principal parts—the Root, the Trunk, the Branches, and the Leaves.

The *Root* consists of two parts—the body or bulb of the root, and the long branch-like fibres, great and small, which disperse themselves abroad into the soil. The body of the root differs little in substance from the trunk, but the rootlets terminate in slender spongy threads, fitted for absorbing the sap of the earth, and sending it up into the rootlets, whence it ascends into the trunk. It is observed that the earth is only exhausted of its nourishing matter in the neighbourhood of those soft extremities of the roots.

The *Trunk* is called by Linnæus *caudex ascendens*, or root above ground, an illustration perhaps more fanciful than real. In common language, the trunk is often named the *bole;* and it is this part which affords the timber for which most trees are reared. The trunk, and also the branches, are covered with *bark*, consisting of a series of thin layers, one of which is formed (next the timber) every year; while in the outside of all is a very thin layer of a different substance, called the epidermis or cuticle, analogous to the outer skin of the human body. The new inner layer which is formed every year, receives the name of *liber;* it was on this substance that the ancients, before the invention of printing, were accustomed to write; and *liber*, it is well known, is the Latin word for a book. Within the bark is the wood, consisting chiefly of vessels, great and small, which may be torn asunder from each other, and which are employed in conveying sap to the upper extremities. In the very centre of the trunk is a small space filled with a soft substance called *pith*, which is supposed to be a reservoir of nutritious matter for the development of the buds in spring.

The *Branches* require no further notice than that they precisely resemble the trunk in every respect, except that they are upon a minor scale in point of size.

The *Leaves* consist principally of tissue, like the trunk, with vessels throughout, and an external cuticle enveloping the whole; and they are connected with the branch by a small stalk called the *petiole*. The leaf is one of the most important parts of the whole tree. By a most curious process, not perfectly known to us, the crude sap rises through the wood, in the manner just described, and is elaborated or prepared into juice of a more nutritious sort, by the leaves. That process, according to some, is effected by means of an alternate contraction and dilatation of the sap-vessels, and, still more, by a respiration, perceptible and imperceptible, in the leaves, and by the action of the atmosphere; but, according to others, it is rather the exhalation from the leaves, than what are properly their respiratory functions, that effects the ascent of the crude sap. It is then converted into proper sap, or *cambium*, and, being fitted for the nutrition of the whole tree, it descends by the returning vessels of the leaf-stalk, and the longitudinal vessels of the rind or inner bark. At length it reaches the roots, which originally supplied the crude sap itself. This elaborated sap is like human food digested into chyle; and as it forms the only real nourishment of the tree, it becomes apparent that the plant must decay if stripped of its leaves.

Such is an outline of the economy of trees, of which a more minute account has been already given in the article on Vegetable Physiology.

CLASSIFICATION OF TREES.

In a view of arboriculture, trees may be classified according to their uses; for example—1. Trees which produce straight timber for masts and long planks, as the various tribes of pines. 2. Trees which afford crooked timber for knees or bends in the ribs of ships, &c., as the oak, sweet chestnut, broad-leaved elm, &c. 3. Trees which give tough pieces of timber, as the yew, holly, thorn, ash, hickory, maple, laburnum, &c. 4. Hard-wood trees, as the oak, beech, plane, walnut, box, holly, and yew. 5. Soft-wood trees, as the poplar, large willow lime, horse-chestnut, &c. 6. Wood grown for flexible suckers, and spray, to form hoops, baskets, besoms, poles, &c., as the dwarf willow, birch, &c. To these may be added woods of foreign growth, as rosewood, satinwood, and mahogany, which are employed for ornamental purposes.

According to another classification, trees are arranged as of three kinds—resinous, hard-wooded, and softwooded. Those which are resinous are also termed coniferous, from their producing seeds in cones. For the sake of clearness, we will adopt this simple arrangement, confining ourselves to trees which may be propagated in Britain.

Resinous or Coniferous Trees.

There are three tribes of these trees, one of which, the Abiétinæ, has four genera cultivated in the British islands—the Pinus, Abies, Larix, and Cedrus. Of each there are several species, all distinguished by their spicular leaves, their cone-like seed-pods, and their resinous wood. Each may be easily raised in nurseries from seed. The more common species is the

Scotch Pine, or *Pinus sylvestris*.—This is a tall and generally straight tree, with few branches on the lower part of the stem, the leaf apparatus being confined to the top of the plant, these forming a massive clump. It is indigenous to the Highlands of Scotland; but little that is generally used comes from the forests in that quarter, the greater proportion being imported from the north of Europe, where a variety of it attains great perfection. For strong beams and spars required by house-builders, this timber is exceedingly suitable; but for smoothness and whiteness of fibre, it is excelled by a tree of much inferior strength—the Canadian pine (*pinus resinosa*). On account of the heavy import duties levied on foreign pine, much of Canadian timber is employed in its stead, being thus devoted to purposes for which its properties no way qualify it.

Spruce Firs.—These are a well-known genus (*Abies*) of the Coniferæ, the more common being the Norway fir, a tree which attains great height, but no great bulk, and furnishes white deal and spars of inferior size; it is also very suitable for masts and poles of all kinds. North America produces three species of spruce, the white, red, and black, each esteemed for particular uses connected with ship-building.

The Silver Fir.—This tree, called also the Pitch Fir, displays a greater depth of branches than the other firs, and becomes a majestic tree on arriving at full age. In this country the silver firs are only seen as objects of ornament on dressed ground; but how they would answer if planted closely together, and pruned up to form clear butts of timber, is uncertain, this having never, we believe, been tried in these kingdoms. The quality of the silver fir timber of British growth is yet to be tested. The common silver fir, the balm of Gilead, and the hemlock spruce, have been long in our pleasure-grounds, but the yew-leaved, Fisher's, Douglas's, and Fraser's double balsam, are only in nurseries or in pine preserves.

The Larch.—Of this valuable genus there are several species grown in Britain and other countries; the more common is the *larix europæa*. The larch is the most beautiful in figure of any of this class of trees; shooting straight up, its elegant stem, tapering to a point, is furnished with pendulous branches, ornamented with delicate drooping spray. Its qualities are rapid growth, flexibility, and durability in situations between wet and dry, a circumstance perhaps attributable to the quantity of resin in its fibre. In many parts of the country it is gradually superseding the common fir, over which it possesses a great superiority in point of ornamental effect.

The Cedar Larch.—This tree is remarkable for its long horizontal and often crooked branches, and the great mass of dark green spicular foliage with which it is covered. It is a native of the mountains of Libanus and other high adjacent regions, where it attains great bulk, and grows to a very long age. From its solemn aspect, it forms a suitable accompaniment to cemeteries or ecclesiastical buildings, and also for sequestered glens in mountain scenery, or for extensive lawns.

Hard-Wooded Trees.

In this class are included a large number of trees with [illegible]ich every one is familiar. The list embraces — [illegible]k, a[illegible], elm, beech, chestnut, walnut, common, sycai[illegible]ntain ash, whitebeam, acacia, birch, wild [illegible]tch laburnum, holly, hazel, box, elder h[illegible]nd yew. The following are the principal [illegible]

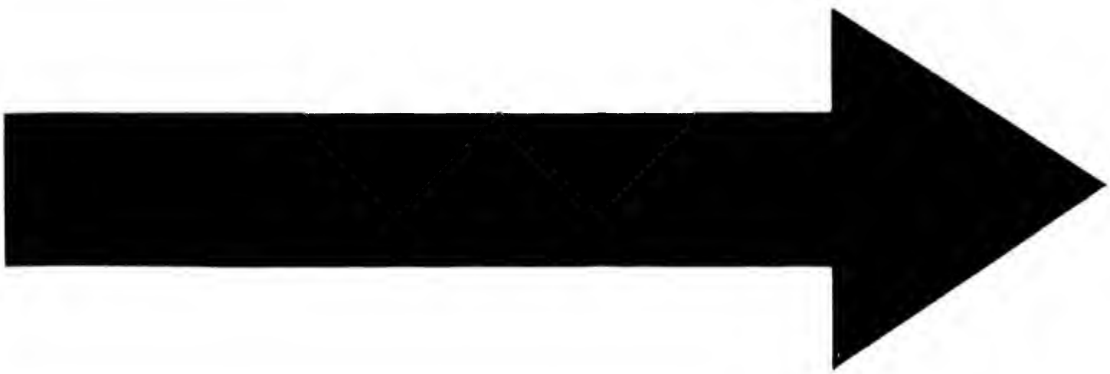
[illegible]—[illegible]his tree (the *quercus* of Linnæus) is the most [illegible]f all the timber trees grown in Britain, not only because it is a hardy native, but for the many important purposes to which its durable timber, its astringent bark, and even its nutritious fruit, are applicable; and, moreover, for the delight which it gives to the eye in sylvan landscapes, the oak being the most picturesque tree of the forest, when it has arrived at its mature age and form.

There are two sorts in our woods, whether natural or planted—namely, the stalkless, and the stalked-fruited, one of which may be only a variety of the other. The former is said to be the old Druidical British or naval oak, though the latter is more frequently met with, especially in woods which have been planted in remote ages by the hand of man. The latter, or stalked-fruited, is also of quicker growth, and is altogether what may be called a more elegant tree when full-grown. The quality of the timber of both, when any difference is observable, is more owing to the difference of soil they have grown on, perhaps, than to any specific difference of the trees.

Besides these two common sorts, which are natives, there are thirteen other species which are exotics—namely, the willow-leaved, the evergreen, ash-leaved, cile-cupped; ilex, of which there are six shrubby varieties; chestnut-leaved, scarlet, velanida, white, Italian, durmast, Luccombe, and the Turkey, of which there are four varieties. This last is a fine free-growing tree, and deserves a place in every plantation. The other exotics are chiefly planted for ornamental purposes, not being yet considered as foresters.

All the species are readily raised from their acorns (oak-corns) when they can be procured; and in default of these, most of the foreign sorts may be grafted on the common. The young plants are transplanted twice or thrice in the nursery; and when four or five years from the acorn, may go to their final stations. Any kind of damp clayey soil is suitable for the oak; but a good loam, or gravelly loam, upon a subsoil of blue ferruginous clay, produces the finest timber in the shortest time.

The Ash (*Fraxinus*, L.) is also a very valuable hardwood tree, its timber being useful for many rural purposes, and particularly for implements and machines. The common ash, being prolific in ripening seed, is dispersed pretty generally over the face of the British isles; it is, nevertheless, much better managed when planted for



timber or for underwood, unmixed with any other sort of tree. It should never be allowed a place in a hedgerow, nor on pasture-land, as its numerous surface-spreading roots engross to themselves every particle of nutritive moisture, to the destruction of all other surface-plants.

An ash tree is in its prime when, by free and vigorous growth, it has attained a diameter of about twenty inches; for though on rich gravelly loam it will continue to increase until it is four or five feet in diameter, it has probably begun to rot at the core long before it has arrived at that vast bulk. Therefore, in order to raise ash-timber of the most valuable description, it is necessary to sow or plant a piece of land of the above character thickly, placing the trees about two feet apart. These will rise rapidly; and as soon as they appear to be choking each other, one-half of the poles may be drawn, and the rest allowed to stand till they arrive at a marketable size, which is when they are from eight to twelve inches in diameter, and from forty to sixty feet high. When *ground-ash* is of these dimensions, it is suitable for every mechanical purpose where flexibility and extreme toughness are required.

Seed should be gathered in the autumn, and immediately sown in nursery-beds; or the sowing may be deferred till spring. Some of the seeds may not rise till the second or third year; but as soon as the seedlings are five or six inches high, they should be rowed out to gain strength till finally transplanted. There are several varieties of the common ash, one of which is the creeping-branched, but which, by grafting it high on the tall stem of the common one, is made a rather ornamental weeping tree. Other species are the yellow-barked, curled-leaved, various-leaved, and a great many other exotic species.

The Elm (*Ulmus*, L.) is a lofty tree, valuable both for its use in the arts and its ornamental appearance. The small-leaved or English elm is generally preferred for planting, particularly in hedgerows, avenues, and the like. This tree is not a forester, never being seen but about dwellings, or where dwelling-houses have formerly stood. It is probably an exotic, as its seeds never ripen in this country, and is therefore propagated by suckers, which rise abundantly from the old roots, which circumstance makes the tree so eligible for hedgerows; for where once planted, fell the principals as often as wanted, a succession of young stems constantly appears. They are also propagated by layers, and often by grafting on the common wych-elm, especially when wanted for dressed ground, or for avenues where it is desired that no suckers should be seen.

Besides the common wych-elm, found wild everywhere in the hedges of Britain, and which grows, where allowed, to a large size, yielding large butts of coarse-grained but useful timber, there are several other sorts raised in nurseries, namely, the cork-barked, smooth, declining-branched (a truly picturesque tree), spreading-flowered, the white, and several others. All the elms delight in a gravelly loam, or in any soil which is not too wet, and they are well worth the planter's attention. No tree bears lopping or shredding better than the elm, it being hardly possible to hurt it by dismemberment. It is raised from seed when produced.

The Beech (*Fagus sylvatica*, L.) is a native forest tree, occurring most commonly on the chalky districts of the kingdom. When full grown, it is a beautiful and stately tree, and its timber is convertible into many kinds of domestic articles, very durable when polished by the cabinet-maker, and equally so if kept constantly under water. The beech is a very fruitful tree; and its mast or nuts, together with acorns, used formerly to fatten vast droves of swine and herds of deer, the then common food of the feudal lord and his vassals. The seeds are gathered after the husks open, by beating the branches with poles which shed the mast upon large cloths spread upon the ground under the trees. Many are sold to the oil-millers, who express an oil from the seed useful for lamps and other purposes.

Young plants are readily raised from the seed sown on beds, and covered with loose soil about an inch thick. Like other seedlings, they are, when five or six inches high, rowed out on fresh ground, till large enough to be transferred to their final stations. The beech is not at all fastidious as to soil, so as there is some portion of calcareous matter present; but a subsoil of chalk or limestone is most congenial. There are several species; the white American, the dark-purple, and the iron-coloured-leaved, are ornamental, and are propagated by grafting on the common.

The Chestnut, or sweet chestnut, sometimes also called the Spanish chestnut, is a splendid forest tree, exceeding all other British plants in its huge mass of foliage; it is also valuable for its timber, which is but little inferior to the oak. In the south of Europe it is chiefly regarded as a fruit tree; but here, even in the south of England, in the finest summers, the fruit ripens but imperfectly. As a timber-tree, however, the Spanish chestnut deserves to be more generally planted than it has been of late years; and for a coppice or underwood plant it has no superior. For the number, the straightness, and durability of its poles, it excels all others, when a little trouble is taken to keep the growth properly regulated with respect to the purpose for which the crop is wanted. When timber or ornament is the object, the trees must constantly be divested of the shoots, which are apt to rise from the collet of the stem. A loamy gravel seems to suit this tree best; and young plants are easily raised from the nuts, dibbled in rows in the spring, and, while in the nursery, kept free from bottom shoots.

The Walnut.—This is chiefly regarded as a fruit tree, but it is no less valuable for its excellent timber, which, from its lightness and durability, is well adapted for gun-stocks. And where its fruit is of no great value, and especially where it does not ripen, if planted among other forest trees, it would be drawn up into a shapeable single stem, as valuable as many others. Young trees are readily raised from the nuts, like the chestnut, and are similarly managed.

The Sycamore is a hardy native tree, which attains a large size, and has the property of growing more quickly than most other hard woods. It is employed to form household utensils and objects in turnery. The maple is a species allied to the sycamore.

The Mountain Ash, familiarly known in Scotland as the *rowan-tree*, from its beautiful clusters of red rowans or berries, is a tree of small dimensions, but elegant form, and is grown principally for ornament in shrubberies.

The Acacia.—This is not only a highly ornamental, but also a highly valued timber-tree, when allowed to attain a proper size. Though a native of Virginia, and there called the *locust-tree*, it has been recommended as a coppice plant for this country, because of the very quick growth of its young shoots, which rise from roots after the stem is cut over; and for the excellent and durable quality of the poles for fencing, and particularly as props for hops and other trees. But whether planted thickly for underwood, or in more open order for timber, the acacia requires much attention from the pruner during the first five or six years of its growth. It produces large luxuriant lateral shoots, which are but slightly attached to the stem, and which, if not stopped—that is, their points pinched off when they are about one foot long—are very likely to be blown off by the wind. This care may cease after the tree or pole is ten or twelve feet high, for after that height, the growth becomes moderate. Young plants are raised from seeds or layers, and thrive on any light sandy soil. The timber is highly prized by millwrights for cogs, &c.

The Wild Cherry-tree.—This hardy native is seldom cultivated as a timber-tree, nor has it that care bestowed upon it which it really deserves. The best specimens to be met with are those which have risen by accident in woods; but when such are felled, they are readily purchased by the cabinet-makers. As mentioned in a previous article, the wood is very suitable for boring and forming musical instruments. It is therefore a tree not to be neglected by the general planter, and should have place among others. Young plants are raised from the stones, sown thickly on a bed of good soil, either in autumn or in spring, and afterwards rowed out, to receive the ordinary nursery treatment, until fit to be finally planted.

The Hornbeam.—This is a timber-tree, but it ranks as an inferior one; its timber, however, is remarkably tough and durable, and consequently invaluable to the plough and cart-wright. It is a scrubbed tortuous-growing tree, unless it has some pruning bestowed upon it when young. It is also a pretty good hedge-plant, and useful for forming screens or boundaries in gardens. Plants are raised from the keys, or seed, of which plenty are produced every year by old trees.

The Birch.—This is another inferior timber-tree, but useful as a coppice plant for many rural purposes. It is a beautiful and elegant tree, on which account it is introduced into ornamental scenery, especially if water be in the composition. Of the common birch there are several varieties, not to speak of the poplar-leaved, the tall, and the black American. Young plants are most conveniently raised from seeds, and the exotic species are raised from layers, or by grafting on the common one.

The Holly (*Ilex aquifolium*, L.) is a remarkably hardy evergreen, with smooth shining leaves furnished with prickly points. It is a native of Britain, and attains a great age, but seldom reaches a large size. Its timber is white and hard, which renders it suitable for veneering, and for making mathematical instruments. Different varieties are grown as ornamental shrubs.

The Box (*Buxus sempervirens*, L.) is generally grown as an evergreen shrub, but when planted out with a proper soil and climate, it attains a height of from 20 to 30 feet. It grows to perfection in Turkey, whence its timber is imported for use in all cases in which exceedingly fine cross grain is required. Sawn across and planed, its surface is as smooth and fine as polished metal. Box is on this account employed for wood-engravings.

The Yew (*Taxus baccata*, L.) is more frequently grown as an ornamental shrub than a forest tree, and, like the cedar, it forms a plant suitable for places consecrated to solemn feeling. Its timber is very tough, and is adapted for making bows and staves.

Soft-Wooded Trees.

In this class are included the horse-chestnut, lime, alder, poplar, and willow.

The Horse-Chestnut.—This tree is only valued for the beauty of its flowers and the majestic port of the full-grown tree in park scenery. The timber is very inferior, and the nuts are only useful for deer. There are several species of this tree—namely, the smooth, Ohio, ruddy, and the pale-flowered. All these have prickly fruit, and are easily raised from their large nuts. A section of this genus is called *Pavia*, or buck's eye, their fruit being round and smooth. But the flowers of some of these last are magnificent, being of a glowing red, and are most conspicuous in the spring or beginning of summer. Avenues of these trees, as seen in the neighbourhood of Geneva, are of the most splendid description when in flower. The pavias are often propagated by being grafted upon the common horse-chestnut, and some of them are only shrubs.

The Lime, of which there are several varieties, is a beautiful leafy tree, grown chiefly for ornament, and very suitable for avenues. Those which have most effect are the red-twigged and broad-leaved American, the latter possessing elegant pendulous flowers.

The Alder.—This tree requires a peculiar locality, that is, a damp bog-earthy soil—is but seldom ranked among forest trees, and, except to occupy a spot where nothing much better will grow, is seldom noticed. It is most profitable kept as underwood; large poles, suitable for the turner, or for piles or planking for bridges, fetching a good price. Of common species there are four varieties, together with the hoary-leaved, oblong-leaved, wave-leaved, glaucous, with several varieties of these, and some shrubby species, the most of which are propagated by cuttings, or by grafting on the common one.

The Poplar.—There are several species of this tree, as the common black poplar, the trembling poplar, the Lombardy poplar, and black Indian poplar. They grow rapidly, and rise to a great height, but narrow in mass, so as to be very conspicuous in hedgerows and landscapes. The timber is of little value; but where undrainable spots are wished to be decorated with stately trees, no better kind can be chosen.

The Willow (*Salix*, L., and usually called the *Saugh* in Scotland) is an extensive genus, comprehending those shrubby species, the osiers, used for basket work. A few species of the willow attain to the height and character of trees, the best of which, as yielding very good timber, is the white or Huntingdon; and the crack-willow make excellent pollards, furnishing every five or six years a large crop of poles indispensable to the farmer. Another of the tree willows is that elegant plant the Babylonian or weeping-branched one, which forms so suitable an accompaniment to pieces of water, whether artificial or natural. The common osier is the sort mostly cultivated for the basket-maker, and the annual crop of rods from established stools pay the owner as well as any other crop on the farm. They are all propagated by cuttings.

GROWTH OF TREES.

Trees grow spontaneously in all countries in which soil and climate will permit, and, as is well known, form forests of many hundreds of miles in extent on the North American continent. Whatever be the peculiar nature of any species of trees, it appears that the dimensions and form of all are more or less affected by their relative situation. If crowded, they have a tendency to grow tall and slender; if left abundance of space, they extend in breadth. The comparative absence or possession of air and light causes these distinctions. In a forest, each tree struggles upward, for its leaves to get a sufficiency of pure atmosphere and sun's rays, and therefore becomes all stem and top; whereas the tree in an open ground shoots out branches nearly from the bottom of the trunk, and attains a grandeur in its mass of foliage. Trees which are freely exposed are also much thicker in the trunk than those in forests. This arises not only from having plenty of air and light, but from being exercised by winds. The well-understood principle in the animal economy, of exercise strengthening a limb—as, for example, the legs of a dancing-master or the arm of a blacksmith—is extended to the vegetable kingdom, in which those plants that are gently moved to and fro by winds arrive at greater perfection of fibre than those kept altogether still.

In connection with this remarkable effect in the economy of plants, it is to be observed that all exposed trees have the largest roots; because, being liable to be blown over, they require to take a much firmer hold of the ground than if they were sheltered on all sides; in other words, the action of the tree, and the free air and light, cause numerous branches and a large breathing apparatus of leaves, and the tree must have a corresponding mass of roots for the supply of sap. So exact is this correspondence between the exposed and underground portions of the tree, that the extent of roots may always be judged of by the extent of branches, the one being of the same breadth as the other. The practical lesson acquired from these facts is, that to have trees with large bushy heads, they must be planted widely; and if wanted to be tall and slender, they should be crowded.

The generally thin soil and comparatively ungenial climate of Britain, render this country unsuitable for the growth of the more delicate and fine kinds of foreign timber; but all the forest trees already noticed, when planted and attended to with some degree of care, attain great perfection. The business of planting is seldom performed by the unprofessional culturist, being more advantageously left in the hands of nurserymen, who rear the trees from seeds, layers, or cuttings, in grounds set apart for the purpose, and at the proper time transfer them to the locality where they are to remain. For the sake of general information, we offer the following observations on different departments of this interesting subject.

ORNAMENTAL PLANTATIONS.

Even on the smallest possessions, a sprinkling of forest trees in the hedges or corners of the enclosures gives a dignity to the spot which otherwise it would not possess. There cannot be a more cheerless object in a landscape than a house, however substantially built and furnished, standing naked and alone, without a sheltering tree or bush to indicate either the taste or competence of the occupiers within. The lowliest hut, environed by two or three aged oaks or thorns, is an interesting spectacle, and far more delightful to the eye than the proudest palace unaccompanied with lofty trees.

To secure these embellishments, planting on an ornamental scale is necessary, and much good taste must be brought to bear on the subject. It is now allowed by all who have studied landscape gardening, that, in the part surrounding the mansion, trees should not be dotted about at equal distances, nor in lines; they should not be placed as blinds to the principal windows, but so arranged as to form irregular glades, diverging in as many directions from the house as can be done with effect and propriety. These glades should always be laid out with reference to some distant interesting object, or some striking feature of the surrounding country. The offices, which are generally in the rear, or at one end of the house, should be hidden by a screen of trees and shrubs; and all eye-sores, visible from the windows or elsewhere, should also be screened by plantation, which has a double advantage, namely, hiding a deformity by a profitable screen.

When it is intended to increase both the beauty and the value of an estate by planting, and whether for the personal interest of the proprietor, or with a view to that of posterity, ordinary prudence will direct him to fix on those parts which are the least valuable for agricultural purposes. The precipitous slopes of an undulating surface, where cultivation is difficult or impracticable—moist swampy hollows—or the ridges of bleak hills lying to the northward or eastward of the superior portions of the park or parks, whether arable or pasture land—will all be found the most eligible for conversion into woodland. And while such plantations yield the finest shelter and covers for game, they keep rapidly adding to the real value of the estate.

Whenever a project of planting is entertained, if only to occupy waste or worthless ground, it is not easy to separate the idea of ornament from the utility of the design, if it be no more than establishing an acre or two of coppice. For even such a feature, especially in a naked country, requires a little attention in the execution. Coppice, when properly stocked with the right sorts of plants, only appears in all seasons as a thicket of shoots of nearly equal height. Consequently, the eye of taste would condemn the plantation as too lumpish, and wanting in variety of outline. But this, though but a trifling defect, may be easily obviated by planting tufts or groups of trees, variously disposed, to remain for timber, or the same thing may be effected by leaving at the first fall a few groups of the most promising saplings, here and there irregularly over the area. These permanent groups will not injure much of the underwood, while they will give as much variety to the whole as may be necessary. This point, however, will be again adverted to when describing the manner of laying down underwoods.

As the beauty of many places constitutes their chief value, and as that beauty is mostly if not entirely owing to the tasteful disposition of the plantations, it behoves every improving proprietor to study well the genius and character of his property before he begins planting on a large scale. The safest plan, in order to avoid taking any step which may afterwards be regretted, or to be done over again, is to sketch an idea, or upon the map, a comprehensive design, embracing every thing that may be done with propriety. This being well digested and settled in the first place, may be called the general plan, and of which *as much only* as is most obviously called for, and practicably expedient, may be first of all executed, leaving the more distant and less necessary operations to be done as time and opportunity may allow.

Such a general plan of planting an estate, whatever its extent may be, requires a considerable acquaintance with the principles of landscape gardening, and can only be designed and executed properly by the owner himself (who can do nothing wrong in this way, so as he pleases himself) or by a professional adviser.

It has already been observed, that some proprietors may only think it advisable to plant the inferior portion of their acres, while others, who are determined to have a tastefully planted park or a highly embellished estate, place their groves, or groups, or single trees, on any eligible spot, without regard to the quality of the soil, whether the worst or the very best. In this case, every thing is sacrificed to obtain such a disposition of the trees as will produce the most striking pictorial effect; and such kinds only are selected as blend harmoniously with each other.

The character of the general surface surrounding a mansion fixes the style of planting and the kinds of trees. If the surface be moderately undulating, having easy swelling knolls and gently falling hollows, without asperities of any kind, such a surface is said to be beautiful, and consequently the plantations should be beautiful also; that is, composed of trees of the finest foliage and most elegant forms. If, on the contrary, the surrounding country be wild in character, and marked with bold and rugged features, as naked rocks or cliffs, deep ravines or glens, &c., then a different style of decoration must be pursued—as planting in irregular masses all the most grotesque, rugged, and sombre-tinted trees that can be selected, in order to harmonize with the natural features of the country. Such scenery is said to be picturesque; and where such tracts of country are chosen for a manorial residence, and the grounds are laid out and planted by a skilful gardener, the scenery is much more interesting to the eye of taste than any other, especially if water chance to be in the composition.

Great changes occurred in the style of planting during the eighteenth century. Up to the beginning of the reign of George I., all transplanted trees were arranged in right lines, as single, double, or quadruple avenues, or vistas, or as boundaries to the enclosed grounds belonging to royal or other palaces, colleges, and other public buildings. But about this time it was discovered that very few ranks of trees were to be seen in the works of the great masters in the schools of painting; a new idea was entertained, that, in all real scenery about to be created in the parks of the nobility and gentry of the

British Isles, ranks of trees were inadmissible, as being too stiff, formal, and not agreeable to nature. Thus a sentence of condemnation was passed upon every private avenue in the country, and they quickly disappeared before the axe of the woodman. A few only were saved, but they were curtailed in length; and now, very few new avenues are planted. Along with the avenues, all the old regularly laid-out terraces and flower-gardens were swept away, to make room for a new style, distinguished by the prevalence of *irregularity* and *curved outlines*.

Soon after this revolution in landscape gardening, a great many ridiculous pranks were played in obtaining *extreme* irregularity, and *tortuous* lines; and some of the performers got severely handled by the satirists of the day. Kent, who began the revolution, died without having gained much reputation; but his successor, the famous "Capability" Brown, became highly eminent, and was universally employed. He did more in altering the gardens and grounds of the country-seats of these kingdoms than any other professor before or since his time. His aim was to produce unmixed beauty, by neatness and general smoothness, especially near the house; for which purpose he cleared away every obstruction, whether built or planted, in order to set the mansion fairly out upon a naked grass plot or lawn. Even the kitchen gardens were removed as far off as possible; and every bush, or other appearance of inequality of the surface, was shaven off, to produce the wished-for smoothness.

In this proceeding he and his copyists fell into the opposite extreme; instead of beauty, *baldness* was the result; instead of intricacy, *tameness*; and instead of the embosoming shelter of surrounding groves, complete nakedness and exposure to every wind that blows. This exposure detracted from the consequence of the building, whatever might be its size or style of architecture; because a partial display is always more interesting than a view of the whole at once. Nevertheless, Brown had the honour of laying out many beautiful parks and gardens, which remain to this day as monuments of his good taste and judgment; but many of his immediate followers brought discredit upon his style by their very awkward imitations.

The severe animadversions published against the Brownian style, tended to correct some of Mr. Brown's most ostensible errors; and the works of Messrs. Repton, father and sons, Loudon, and others, having improved the style of English gardening, and brought it much nearer to the principles of real taste. The *clump* and the *belt* have been greatly modified; the first is now expanded into a less formal group, and while the latter has lost its continuity, it has been increased in depth, and its lengthened form as a boundary judiciously broken. Undergrowths, which were swept away by Brown, are again introduced; and the banks of lakes and rivers, formerly smoothed down to the water level, are now left more abrupt, broken, and irregularly fringed with overhanging trees, and aquatic shrubs and herbs.

PLANTING FOREST TREES.

The different methods pursued in establishing or laying down woodland, seem to have been determined by the number of acres or nature of the ground intended to be planted. To secure a full supply of the plants required, and these of the proper sort and age, it is requisite that they be previously raised from seed on the premises, or be easily procured from a nursery-man in the near neighbourhood. Where a great extent of planting is intended to be done, the former plan is most economical; but the latter, in general, is the most convenient.

To raise forest trees from seed is an easy affair; it is only choosing a piece of good mellow soil within some enclosure; this must be trenched or double-digged, laid level, and freed from stones, &c., by the rake, divided into beds four feet wide, with one foot alleys between. In the month of March, sooner or later, according to the forwardness of the season, the seeds may be sown either in drills lengthwise of the bed, and deeper or shallower according to the size of the seed; that is, nearly an inch for small, and an inch and a half for large seeds, such as acorns and chestnuts; or small seeds may be sown broadcast, by withdrawing with the rake towards the alleys about an inch of the surface each way. On the fresh soil, the seeds are thrown as regularly as possible, and covered by having the removed soil again drawn over regularly and smoothly. The seed-beds must be guarded from birds and mice; and if the weather be warm, and parching winds prevail, they should be covered occasionally with mats, and also watered, if necessary.

Seedling trees are usually transplanted into rows in nursing beds, some in the second, others in the third year; and there to stand till planted out for good, which should be done when they have arrived at a proper size—the nature and condition of the ground intended for them, as already observed, determining this point.

The surface to be planted may either be in a state of nature, and covered with heath, or with a turf of some kind or other; or it may have received some kind of preparation, as paring and burning; or ploughed, digged, or deeply trenched. It is almost unnecessary to add, that the first is in the worst, and the last in the best condition for the reception of young trees. There are many cases, however, where there is no choice but the first; and yet the success which has attended such undertakings as planting a naked hill or a barren common is a direct encouragement, and proves that such naked portions of the country may be in a few years covered with useful trees.

When a large extent of such description of land is intended to be planted, it must necessarily be executed in the most economical manner. The first step is forming an effectual fence against cattle, without which in no case should planting be attempted. If the enclosed surface be acclivous, and covered with short herbage and thin staple, two or three year old plants of larch, Scotch fir, birch, intermixed with a few oak, beech, and ash, may be inserted by a one-handed tool somewhat like a cooper's adze. One or two blows of the tool raises a triangular piece of the surface, under which the root of the plant is properly placed, and the raised sod turned back and trodden down with the foot. In this simple and expeditious way of planting, many hundred acres of hilly land have been stocked with trees; and though many of the plants are liable to suffer, if a dry summer follows the planting, a majority are sure to succeed, which well repays the cost. When such ground is level, an opening is made by first cutting the turf in the shape of a cross, and turning back the four corners from the centre, breaking up and making a hollow for the root; when the tree is placed upright, the turf is returned to its place and trodden firmly down.

There is yet another method of planting rough unprepared ground, called *pitting*. The surface-covering is first cleared off, the pit broken up with a mattock, and the loose earth thrown out with a spade; the tree is then placed, and planted with the removed soil. This method of planting is expeditiously performed when the ground works kindly; but if wet or clayey, the business is more difficult, the holes requiring to be opened, and the land drained, long before the trees can be planted safely.

All the above methods of planting forest trees are only had recourse to when the ground cannot be prepared in a superior manner. And notwithstanding the risk of being defeated in such attempts, it is quite certain that in numberless cases they have succeeded admirably; and very valuable woods now ornamenting both England and Scotland have been raised by these simple modes of planting.

When it is intended to plant a field which has been or may be ploughed, it is got in order by receiving a thorough fallow, to clear it of every kind of weed. The ploughings (with a strong team and plough) should be made as deeply as possible. Supposing the land to be got in perfect order by the middle of October, if intended for timber only, the trees may be immediately planted; but if intended for underwood as well as timber, the last ploughing may be deferred till January; and if the ground be then pretty dry and mellow, the whole may be immediately sown broadcast with a mixture of seeds, and harrowed in, after which trees may be planted at the distance of four or five feet. The mixture may consist of the seeds of oak, ash, beech, Scotch fir, and birch; and if a sprinkling of common furze be added, it will be no detriment. If Spanish chestnuts are intended to be a part of the underwood (for which they should always be preferred), the seeds should be dibbled in, as they are too large to be covered by the harrows.

This method of laying down woodland, if carefully performed, is always successful, as there is not only a full number and choice of trees for timber established, but the field answers the purpose of a nursery for many years, from which may be drawn unlimited numbers of young trees for planting elsewhere. The finest and most profitable woods we happen to be acquainted with were laid down in this way about the year 1775.

The next successful method of planting forest trees is placing them on deeply dug ground; for if digging be practicable it is proof that the land is in a good condition for their growth. The action of the spade forms a bed sufficiently deep for the generality of the best sorts for timber, and the loosened state of the soil renders the planting easy.

But by far the best preparation of the ground is trenching it eighteen or twenty inches deep. The surface, which is usually covered with vegetation of some kind, or the remains of vegetation, being turned to the bottom of the trenches, forms a fine nutritious stratum for the roots to luxuriate in; besides, the staple being opened and intermixed so thoroughly, admits all atmospheric influences, without which no plant can thrive.

When trees are planted upon either a dug or a trenched surface, seeds may also be sown and pointed in, for undergrowths are always valuable for some purpose or other. This is particularly necessary when the plantations are required as covers for game; and in park scenery, hawthorn, holly, and juniper berries, should always be sown when the trees are planted.

When ornamental plantations are made in a park, and especially if they are in view from the principal windows, they are wished to rise as quickly as possible for the sake of immediate effect. The trees, therefore, receive extraordinary treatment. The ground is not only carefully and deeply trenched, but a most liberal dressing of good rotten dung and vegetable mould—the first trenched down, and the latter dug into the surface—is bestowed, and which of course excites the trees into much stronger and more rapid growth than if only the ordinary expedients were employed. But this superior and expensive practice is seldom necessary, and much seldomer executed.

Planting on Bad Land.—The preceding directions are sufficient in all cases in which the land is tolerably dry, or which may be rendered suitable by a little preparatory culture; but when the ground is moist, and barren of all useful produce, the following methods of preparation will require to be pursued.

The first thing to be done with a piece of wet land is to drain it, and then enclose it with fences. The draining operations will consist in making wide and deep ditches around the land to receive and carry off the water, and into these smaller cross drains are to be led. (For a minute account of the best methods of draining, we refer to the article on LAND IMPROVEMENT). If the drains be finished in October, so as to allow the water to run off for three months, planting may begin about the middle of February, provided the weather be dry. "I would recommend," says a writer on this subject, "strong plants, three years old; for I have seen many small things stuck in among rank grass, but I have rarely seen any of them grow. The ordinary way of planting does well enough for the firs; it is done in this way:—A cut is made at right angles to the line of the labourers' feet, another is made at right angles to that, and the soil raised; the root of the plant is inserted; and the spade being withdrawn, the soil is or ought to be firmly trodden down around it. I say ought to be, for very often it is not. The labourers ought to have the importance of this reiterated upon them; and I would, if possible, always have a big man in preference to a little one to wield the spade. There is an emphasis in the tramp of his foot, which, for the success of the young tree, is invaluable. The other mode of planting is more tedious; but where the proposed plantation is small, I think it is worth while to give all the additional trouble. This method consists in making pits for the reception of the plants. A square piece is dug out, the plant is placed in the middle, the soil is broken and put round the roots, turf is cut in two, and being turned upside down, the halves are placed one on each side of the stem of the plant, and firmly trodden down all round. This, it will be seen, is tedious. Three plants may be planted by the first method for every one by the second; yet, where the plants are large, it is worth while to bestow the additional labour: especially in planting trees of the deciduous kind, this method ought always to be adopted. I have always found it advantageous to plant pretty close; but care must be taken to begin early to thin, otherwise the young trees fall into consumption. Ground treated in the manner now described, be it never so wet, will grow fine trees; that is to say, if there is any thing like a soil at all.

Let us next suppose the ground to be planted to consist of a thin poor soil on a hard close bottom. To plant such ground just as it lies, is a piece of the most consummate folly. Far better burn your young plants at once: they never will grow to any thing. The plan which I have now to propose has a most formidable objection against it—it is very expensive. But let the proprietor arrange the matter in this way: instead of planting, say ten acres in one year, let him plant only four. It is far better to have a few trees thriving, than a great many pining out a miserable existence, to the disfigurement of the face of nature and the bitter regret of their owner. The first thing to do is to set about trenching the ground. To the ordinary mode of trenching there is a most decided objection. That part of the soil which is at all good, is mercilessly buried at great labour and expense, and the hard till, which has about as much nutrition for plants as freestone rock, is brought up to form the soil. This will never do. We must keep the soil which is at the top still at the top, and stir the till below. At first sight there is some difficulty here, but the difficulty must be overcome, and that may be done by a little calculation as to arrangements in the matter of digging and filling up the trenches. The cost will be only a little more than that of ordinary trenching, and it is vastly superior to it. It would also be an advantage as each trench is cleaned out, to give it a rough course of picking along the bottom, which would make the soil although never so wet before, dry and sweet as a garden. The best time for performing this operation is in the months of February and March, and then only when the weather is dry. It would be well if planting could be carried on simultaneously with trenching. And see that the plants be put in *deeper than usual,* and well trod round the stem.

Ground thus treated will produce the finest trees. They will grow fast, keep free of moss, be healthy in the bark, and straight. It would be advisable, even with this trenching, to open drains throughout the whole that is planted, in order that the surface-water may be carried freely away. Land, when thus dried, becomes richer by every shower that falls. The water, in percolating through the soil, carries down with it a fresh supply of oxygen gas, which the roots of the trees, with their thousands of little mouths, are gaping to receive as their most nourishing food; and being thus fed, is it not natural that they should grow apace and be in good health? In this way you will have in six or eight years fine plantations, forming an ornament to your property and a shelter to the fields. By the other method you may plant thousands of trees; but where the soil is positively wet, you will never see any of them do more than make an ineffectual attempt to grow.

I have now a few observations to make regarding the after-treatment of trees planted in the manner now recommended. They must not be left to themselves; and if hedges be planted, they will require much care, for the first three years especially. They must be kept perfectly free from weeds, at whatever expense of labour. Thin, board-like hedges, cut close upon each side, are not the thing. I never saw any so treated do well. They must have breadth, and should be tapered on both sides to the top. But let us attend to the trees. Exactly a year after they are planted, where the ground has been trenched it will be requisite to give it a partial hoeing, that is, to cut down all tall weeds which may be overtopping any of the trees. Should any of the hard wood, in place of being green, become yellow, there is a plan which, if adopted, will completely restore them. Two years after they are planted, let them, in March or April, be cut over about three inches above the ground; in the month of July a careful person must go through and pinch off all the young buds except one, the healthiest, and the one which offers fairest to shoot into a main stem. This has a most magical effect. It insures a healthy tree, with a free bark, and perfectly straight. I have had oak, ash, and other timber thus treated, which have made beautiful shoots of upwards of two feet in one year. Trees which are on the whole thriving and sufficiently straight, but which are getting hard in the bark, I have generally improved very much by the following process:—You enter the point of a common gardening knife as near the root as possible, and run it up to the first branches. In a year or two this cut will be covered with new bark, an inch or two in breadth, greatly contributing to a free circulation of the sap, and consequently promoting the health and the growth of the tree. I have seen trees twenty and thirty years old materially benefitted by this simple process. A handy labourer will do many hundreds in a day.

If the hints I have now given be followed, I am quite confident that they will save much disappointment to proprietors who are disposed to plant, and that many fine trees will be raised on situations in which, by the common management, they never would have attained to either beauty or value."

Pruning and Thinning Plantations.

When woods are planted as sources of profit, a very material part of their subsequent management is the labour of pruning and thinning the trees. It is not enough that trees grow and be annually increasing in bulk—they should also be assisted to take the finest and most valuable forms. A round straight butt, of moderate length, is far more useful and saleable than a crooked knotty one of twice the size. To have fine timber, it is absolutely necessary to bestow a little trouble to start them fairly off, during the first ten or fifteen years of their growth. The best method of raising a plantation is by using a mixture of different sorts, which may be deemed *principals* and *secondaries*. The first are those for which the land is judged most suitable, the second are nurses or supernumeraries, intended to be drawn out as soon as they press injuriously upon the principals, or when they have attained to a useful or saleable size.

To have tall and straight stems, the trees must be planted thickly at first; that is, only about four feet apart, or even less. In this order they shelter and prompt each other to ascend; and if in the spring the woodman pays his annual visit, armed with a light keen bill and a narrow *turning-saw*, he may direct the growth with the best effect. Every lateral branch which appears to be attracting too much of the powers of the plant, and especially if, as already observed, it be contending for supremacy with the leader, should be sawn off *close* to the bole as soon as it has attained a diameter of one inch. Such a wound will be soon healed up, and present no flaw when the tree is cut up at the saw-pit. All branches of a smaller size need not be removed, for they serve to enlarge the trunk, and have no effect in distorting the grain until they attain the size when they should be pruned off. If branches are allowed to remain until they have acquired a diameter of from two to four or more inches, and then cut off either close, or, what is much worse, at some distance from the bole, the timber is sure to be deteriorated. Such wounds, it is true, will be healed over in time, but the timber will be wanting in its best property—namely, soundness and freeness from knots. All branches originate at the pith of the main stem; and whether they are alive or dead when the tree is felled, they are equally objectionable in the estimation of the builder or mechanic. The knots in fir timber are less objectionable, because they are preserved sound by the resinous quality of the sap; but neither are they desirable, if trees can be grown with a clear uninterrupted grain.

The most valuable part of a tree is the bole, and the longer and freer from knots this is, the more saleable; and if any or every tree may be made to grow into fine sound boles of fifteen or twenty feet in length by a little such attention as is recommended above, it is surely well worth the trouble and expense.

All species of the hardy pine and fir tribe intended for profit should be planted pretty thickly; the supernumeraries thinned when young, but leaving a full number of principals to grow up to a marketable bulk, or until they cease to thrive, when they will all be ready for the axe together; for such woods cannot bear to be thinned gradually like other trees, being particularly liable to die if they lose the protection of their neighbours. When planted as nurses among deciduous trees, they are easily kept within bounds, and from damaging the other trees, by pinching off, from time to time, the *leading buds* of their branches. This induces a spray-covered rather than a naked stem, and thus maintaining their character as nurses. By the same means, fir-trees may be formed into impervious screens, or sheltering hedge-like boundaries, very useful in many cases of rural improvement. Respecting the pruning of fir-trees planted for profit, and which are intended to grow up with clear-grained butts, a rule has been laid down by planters which is easily followed: it is this—prune off the lower branches every second or third year, always leaving *five tiers* of branches to form the head. This regular method of keeping the butt divested of its lower branches, and continued up to the highest convenient height, will certainly ensure fine butts of clear-grained timber, as all the knots will be small, and all near the centre of the axis. The fine clear-grained butts imported from America and the north of Europe, are trees which were never pruned; but having grown up in very close order, the lower spray was consecutively killed by the want of air and light, shut out by the close canopy of branches above. This is gaining sound timber by accident, and which may be done in any country, but by no means in such a short time as may be done by hand-pruning.

In very many instances, trees are suffered to remain in the ground considerably beyond the time they should be felled and put to the proper object of their growth. They are seen to get rotten at the core, or the branches are seen to die; still, from an unwillingness to remove what may be viewed as old friends, they are allowed to remain till accidentally destroyed. Instead of following this practice, we recommend the proprietor of forest timber to have his woods periodically examined by a person skilled in timber, who should mark all the trees that seem ready for removal, and let them be removed accordingly. Unless for particular reasons, every tree should be cut down on arriving at maturity, and a new one planted in its stead.

Trees grown for ornament in lawns, require no other pruning than what may be necessary for the removal of rotten or decaying branches; and in general it will be found advisable to leave each kind of tree to assume its own natural form. Ornamental trees are always most beautiful in their proportions when the branches and spray reach towards the ground; but this will not be the case if cattle are allowed to browse beneath and around them. These animals nibble away all the foliage and spray within reach, so as to form in park scenery what is called the *browsing line*—an even bottom of foliage, any thing but agreeable to the eye. The only plan of avoiding this inelegance is to exclude browsing animals altogether from ornamental grounds; but this is attended with opposite evils, and takes away that pleasing assemblage of forms which is the great charm of woodland scenery. Where cattle or sheep are permitted to browse, all young trees, at least, must be protected for some years by circular palings, otherwise they would be disbarked, and generally destroyed.

To ensure dryness of timber, it has been found a profitable practice to disbark the oak and larch a year or two before felling. On this point Monteath, in his "Forester's Guide," says he is decidedly of opinion, that the larch treated in this way at thirty years of age, will be found equally durable with a tree cut down at the age of fifty years, and treated in the ordinary way

Transplanting Trees

Trees may be lifted from one place to another or transplanted. The art of accomplishing this exceedingly delicate operation in tree culture, was some years ago brought to perfection by the late Sir Henry Steuart, of Allanton, whose treatise is the best authority on the subject. The transplanting of a full-grown tree has, in all ages, been deemed next to impossible; and when it was attempted, the operator thought it necessary to cut off a great number of the branches, (and consequently the leaves,) from an idea that, if suffered to remain, they would require more sap than the roots could supply in their new situation. Of course, just in as far as they deprived the tree of its branches, or, we may rather say, of its leaves, they deprive it of the principal organ of its existence, and it invariably decayed to a corresponding degree. The lopping was like a cutting off of the lungs in a human being; and it would be as absurd to expect a man in that state to be healthy and strong, as it was to hope for vigour in the stripped member of the forest.

Sir Henry Steuart, having studied the internal structure of trees, began, a good many years ago, to practise the art of transplanting on what he justly calls the preservative principle: that is, without mutilating either roots or branches, as was universally practised till his time. His seat, Allanton House, is situated on an irregular slope, on the right bank of the river Calder, which is a tributary of the Clyde. The neighbouring ground, though diversified, has no very picturesque natural points, but he contrived, by the removal of large trees, and forming an artificial lake and river, to realize in some measure the miracle of bringing new and picturesque scenery into actual existence, in an almost endless variety of combination.

The following are the rules to be attended to in the transplanting of trees. The best season for transplanting is certainly during the months of October and November; for though trees may be transplanted in any of the winter months when the weather is mild and moist, they never do so well as when removed in the first-mentioned months. Taking up a tree requires as much care as replanting it; the spade and the pick-mattock are both necessary to raise the roots from their seat; and as the most tender fibres are the most active and useful, the greatest care should be taken to preserve them entire. Neither should these delicate fibres be exposed to a dry or frosty air; they should be kept moist and shaded till again put into the ground. The root should be placed no deeper in the new place than it was in the old; and all the ramifications laid in their natural positions, and imbedded in the finest of the earth.

Trees may be transplanted from the age of one up to ten, or even twenty or more years; but when they are from four to six years from the seed, they are, both from age and bulk, in the best condition to be removed successfully. In planting with the one-handed tool, the smallest-sized plants must be used; for pitting, plants from two to three feet high may be chosen; and on digged, ploughed, or trenched ground, the young trees may be from two to six feet high, in which case the tallest may need propping against the south-west winds.

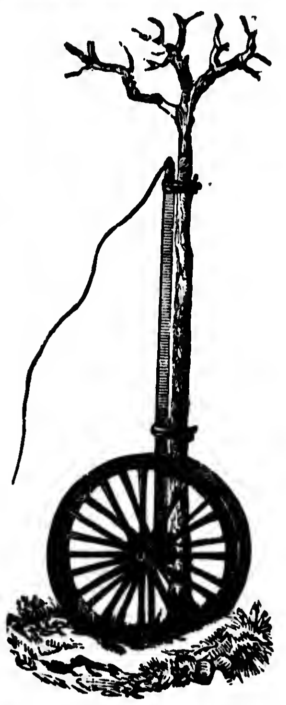
When single trees are to be planted on a lawn, a space of from four to six feet must be stripped off the turf, and rolled back; the soil within should be deeply broken up and excavated, to receive the full spread of the roots. A heap of richer loam or compost is laid in the centre, on which the tree is placed and the roots are covered with the same, and watered to consolidate the earth about the fibres. The other soil is then thrown on, and the turf returned to its place and beaten down firmly. Single trees should be staked; and if on a pasture, a cradle will be requisite to defend them from the browsing or rubbing of cattle.

Much has been written on the subject of transplanting large trees, and many successful exploits of this kind have been performed both in past and present times. Shady groves have been formed in the short space of a few months; proving that, with care, skill, and physical force properly directed, any tree of moderate size, say from twenty to forty feet high, may be transplanted with safety and success. One precaution very much facilitates the execution; it is that of digging a circular trench at a proper distance, say six feet, round the trunk, and deep enough to be below, and to cut through all the roots except three or four of the largest, which are left at equal distances to act as spurs for the better security of the tree when placed in its new situation. The trench, after the stumps of the roots are cut smoothly off, is filled with prepared compost, for a new fringe of roots to strike into, and after one or two years the tree is in a condition for removal. In doing this, a deeper trench is made on the outside of the first, into which the mould from among the roots is drawn, until the whole is loosened from the soil; the spur roots are also followed out and laid bare. The method of raising the tree by a machine is mentioned beneath. In replanting, much depends on laying out the roots, and firmly embedding them in moistened earth, and also adding a pretty heavy covering of soil round the stem, to keep the tree steady against wind.

Every tree about to be planted requires a little pruning; broken roots should be removed, and the head may require thinning. The branches should be equally balanced; and if any one appears to be a rival to the stem, it should be cut off close; so those rising with two stems should be deprived of the weakest. These remarks only apply to deciduous species; the pines and firs need no thinning when transplanted, unless some of the lower spray is dead.

Machine for Transplanting Trees.

This machine is formed on the principle of the common timber-truck, being a strong lever attached to the axle-tree of a pair of wheels. The latter are strongly constructed, at least five feet in diameter, and with a six or nine inch tire. The axle-tree is correspondingly substantial, and to its middle the pole or lever is securely fixed. The pole should be made of the best ash, seven inches square, with the edges planed off, and somewhat reduced in thickness towards the end. The length should be at least ten feet, for the longer it is, the greater the purchase in raising a tree. The pole is strengthened by side braces let into the axle, and mounted with an iron eye and ring at the point. When used, it is backed against the tree, and the pole is raised and made fast thereto, as here represented. The



wheels rest in the hollow made by baring and loosening the roots, though not upon any of them; and when all is ready, the strength of men or that of a horse, is applied to the pole chain, which is, together with the tree, pulled to the ground, the root being lifted out of the soil; and when thus borne on the machine, it is drawn away, root foremost, to its new place, previously prepared for its reception. The wheels are drawn into the new opening, the pole and tree are set at liberty, and, if the root be heavy, the tree will resume its former position with but very little assistance. The machine is then loosened from the tree, and removed out of the way; the roots are then laid out carefully, and embedded in loose soil, well consolidated and watered, which finishes the planting.

When a machine is made on purpose for removing large trees, the axle-tree may be made to fit a pair of cart-wheels for a temporary purpose; but the axle should be formed with *straight*, not *drooping*, ends, as they are usually made, because this renders raising the pole much easier. Upon the upper side of the axle there should be a thick block of wood bolted, to give more elevation to the root when drawn along; and on this an old sack, or a thick band of straw, is bound, to prevent chafing the bark of the tree.

Renovation of Decayed Trees.

In favourable circumstances as respects soil and climate, trees seem to be immortal; but in our own country, these favouring circumstances are afforded on a limited scale, and consequently we can show no trees which are beyond the reach of decay. A time invariably arrives when they begin to show symptoms of decay, and the means to be adopted to prevent, as far as possible, the occurrence of this evil, require now to be noticed. On this delicate and important department of arboriculture, we have great pleasure in laying before our readers the detail of a process discovered by the late Sir Henry Steuart, communicated in a letter to Admiral Sir T. Livingston, Bart.

"Dear Sir,—Agreeably to my promise, I shall now give you an idea of my method of reviving or resuscitating old trees, which has often succeeded with myself, and which I have recommended to others; but there is no account given of it in the notes on any treatise on the application of the science of physiology to practical tree-culture, and particularly in removing large trees for ornament or use.

"The decay of old trees, both in England and Scotland, has been a subject of general complaint during at least a century; and it is observed, with regret, that their place does not promise to be very speedily supplied by existing woods and plantations. The general causes of the decay of trees are twofold. The first proceeds from diseases to which all woody plants are subject; the second, from extreme old age, but more frequently from their having exhausted the pabulum within their reach. The pathology of the vegetable tribe, in this respect, differs materially from that of the human species. Among the sons of the forest, there are no vicious efforts made by individuals, as among us, by means of disease, to shorten life. There are no gourmands nor sensualists, by fatal indulgences and artificial luxuries, to bring on premature old age. The laws of nature in trees are allowed fairly to operate, and their existence, therefore, may be reckoned on, and even prolonged by art, to an indefinite period. It has been said that the roots of trees in a favourable soil will go abroad in search of their food at a distance from the stem equal to the entire height of the tree taken from the ground; and wherever this is found to hold good, trees will live to a very great age, especially in a deep and calcareous soil.

"Of your two fine old trees at Westquarter, Stirlingshire, which I lately examined—a holly and a double-flowering thorn—I must say that they appear to me to have declined chiefly from the *latter* of the two causes above mentioned, namely, their having exhausted the food or pabulum in their immediate neighbourhood; and, in the case of the thorn, in some measure from the ground being overstocked with other plants, that greatly crowd upon it, even to the exclusion of light and air, without which no plant can flourish. As to the holly, it seems stunted and hide-bound, and sends out no free shoots at top, such as a tree in health, in so fine a soil and climate, ought to do. The terminal growths of the thorn, also, have begun to decay; and if some salutary remedy be not speedily adopted to *excite the roots to fresh action*, it is plain that the evil will ere long extend to the greater branches, and as a necessary consequence to the trunk itself.

"The first thing that I should recommend to be done with this noble thorn, is to cut away the ivy that now strongly adheres to it. That parasitical plant has covered nearly the whole external surface of the stem. It already intercepts the kindly influence of the sun and air from the bark of the tree, under which the finer vessels of the descending sap lie, so that it may be said to prey upon the very vitals of the plant. The next object should be, to clear the ground, for a considerable space, of overshadowing shrubs and bushes. So venerable a tree, standing single, would be the most graceful ornament of the verdant turf that surrounded it.

"The second thing that I would do would be to dig a trench round the tree, not exceeding three and a half or four feet out from the stem; which trench should be five feet broad at least, and as deep as to penetrate through both the soil and subsoil, however deep either may be, until you reach the rock, gravel, pure sand, or obdurate clay (*Scotticè*, till) that may lie below. In doing this, the workmen may fearlessly cut through all the roots they meet with, leaving only three or four great ones, on the south and south-west sides, to act as *cables* in resisting the severe winds that usually blow from those quarters in every part of the island.

"Next, let whatever parts of the trench that consist of good earth, or of earth capable of being easily made so, be thrown aside, and the sand or gravel, if any, be wheeled away; so that you may obtain a depth in the trench of two feet or more, if the soil permit, of well-mixed mould. For this purpose, let good compost or rich garden mould (of which I saw abundance near the spot) be intimately mixed, by two or three times turning, with the better parts of the contents of the trench, adding about a third part of good well-rotted dung, so as that a proper chemical action may be excited throughout the mass, and the whole rendered fit for the food of plants. This done, let the trench be filled up with such compound somewhat higher than the original soil; and let the space which has been left untouched, of four feet out from the stem to the edge of the trench, be covered eight or nine inches deep, with the same prepared and friable compound, pointing it in with the spade only about three inches deep, so as not materially to injure the roots. In order to complete the process, let all the dead wood be carefully pruned away from the branches with a saw, but dressing the extremities afterwards with a sharp hedge-bill.

"In the following spring, all moss or other impurity should be scraped off the bark, and the entire stem well washed, two or three times, during the summer season, with soap and water and a soft brush.

"By following the above method, which, however elaborate it may appear in the description, will be very easily reduced to practice, I feel confident that many fine old trees in gentlemen's parks, that are now allowed to decay, might have *another century* added to their existence; because the extension of fresh pabulum at pleasure to greater limits, would be a labour well repaid, and attended with little expense, and as little difficulty. There are few persons who would not bestow more labour than this on a favourite tree; and there are perhaps fewer who will not admit that it might easily be applied to purposes of general utility as well as local ornament. The principles on which this process has been instituted are in accordance with the laws of animal as well as vegetable physiology, and will be confirmed by practice, if they be allowed to govern the process. I have uniformly found that the roots, where cut through in the opening of the trench, will send forth an immense body of vigorous ramifications, of from a foot to fifteen inches in length, during the first and second months after the operation, with thousands of capillary rootlets emanating from them, all which will go abroad in search of sap, for renovating the vigour of the tree. In a tree of considerable age, such as the two above alluded to, at your beautiful place, it is to be observed, that much figure cannot be expected to be made, during the first year, in the elongation of its terminal shoots; and for this plain reason, that effects must necessarily be preceded by their causes, whether they lie on the surface or otherwise; but the leaves will speedily become larger, and of a deeper green colour, than for some years past; and by the autumn of the second year, it will be admitted that the tree is in some sort about *to renew its youth*.

"During the early part of the first season, the new mould should be allowed to remain quite undisturbed; but towards the end of the year, the gardener or forester may cautiously look in, and he will observe the wonderful efforts towards the increase of leaves, and, by consequence, towards a fresh supply of sap, that the plant will even then have made; and after the second year, the renovating process will appear still more striking.

"These directions apply equally to both the thorn and the holly at Westquarter, with this difference, that, in consideration of the far greater exposure in which the latter is placed, I should not advise that the trench be opened nearer than within five feet of the stem; also, a greater number of large roots (to act as cables in supporting the tree), say five or six, should be left entire, running across the trench.

"The month of February or beginning of March, according to the season, before the ascending sap begins to stir, would of course be the best time to carry into effect the methods of resuscitation above detailed; and as Allanton House is at no great distance, I should have much pleasure in paying you a visit, and directing the execution myself.—With great esteem, I remain, dear Sir Thomas, your most faithful servant,

"H. STEUART."

Coppice and Fences.

Coppice or underwood is either natural or planted. Natural underwoods appear to be the remains of ancient forests, which are kept enclosed, and are felled periodically at long or short intervals, according to the purpose for which the stuff is to be applied. Planted underwoods are either willow bolts for the basket-maker, hoops for coopers, hop poles, poles for fencing and hurdle-making, stakes and headers for hedging, broom, hay-rake, and mop handles, spray for birch besoms, fagots for brickmakers and bakers, kindlers, and other firewood, and withes for binding fagots, &c.

Thriving and well-fenced and well-managed underwoods are considered more profitable than timber-woods. The first are very soon a source of income, and as such are subject to tithe, which has caused many acres of them in England to be allowed to grow up into woods, which are free from tithe. But timber and coppice may be united; the standard trees to stand thinly, and if kept pruned up, the undergrowth is not much hurt by their shade. Mixed underwoods are cut every five, seven, or ten years, unless they are entirely of oak, when they are allowed to stand longer, for the sake of having larger poles, together with the bark, which last is the principal part of the value of the fall. When such a fall is made, every superior-looking well-placed pole is left as a standard, if standards be wanting; these at last become fine trees, and are felled in their turn.

The most profitable underwood is that which has been planted, and each sort of tree kept by itself, having regard to the quality of the soil most suitable for each, if there be any difference. For instance, ash and Spanish chestnut should have the driest spots; oak and birch those which are more moist; alder and willow the moistest. All the sorts should be planted very closely together, because this not only increases the length and number but improves the form of the poles, circumstances which very much add to their value.

The ground should be prepared for underwood in the same manner as for timber-trees, either by the plough or spade. Wet land is usually laid into beds with narrow ditches between, the soil out of which serves to raise the beds, and give the roots more scope. Several wild shrubs introduce themselves among underwood, particularly hazel and hawthorn, neither of which are much objected to, as the first is a useful coppice plant, and the last is always in request about a farm.

Some of our ornamental shrubs arrive at the height of trees, and some of them produce excellent and beautiful timber; such are the cypress, holly, laburnum, and guelder rose. Large scantlings of the second and third are much prized for veneering.

The shrub usually employed for living fences is the hawthorn, which, by proper treatment, may be rendered a very effectual protection to fields. The shrubs should be planted when young, according to the required line, on the top of a dry bank; and, till they attain a sufficient size, the rows will require to be protected from cattle by palings. The way to cause the plants to increase in bulk, by throwing out lower branches to form a compact hedge, is to keep the ground free of weeds—a duty far too frequently neglected—and prune the outer struggling branches annually, when the sap is down. From neglect of these precautions, thorn hedges are frequently thin, scraggy, and almost useless in preventing the exit of sheep, and even cattle from enclosures. Besides weeding and pruning, thicken open spaces by inserting new plants when necessary.

Latterly, furze or whins have been employed with much advantage as fences, but this hardy native shrub will grow only where there is great freedom of air, and succeeds best in northern climates.

AGE AND SIZE OF TREES.

It has been mentioned in our article on VEGETABLE PHYSIOLOGY, that if a tree (of the exogenous kind) be cut transversely and examined, it will be found to consist of a number of cylinders enclosing one another like so many layers or concentric circles disposed round an axis; and that, as a circular layer is deposited every year, it is possible to ascertain the age of the tree by counting the number of the layers. M. Decandolle, one of the most celebrated botanists of modern times, has, as appears from a work on the subject, paid great attention to this method of ascertaining the age of trees. He observes, that the method of reckoning now alluded to is not liable to much error, but the inspection must be conducted with the greatest care; for the older circles become condensed into a mass, and their number can only be guessed at by measurement. "My plan," says he, "is as follows: When I have got a section of an old tree, on which I can see the circles, I place a sheet of paper upon it, extending from the centre to the circumference. On this paper I mark every circle, showing also the situation of the pith, the bark, the name of the tree, the country where it grew, and any other necessary observations. I also mark in a stronger manner the lines which indicate every *ten years*, and thus I measure their growth at *ten years'* intervals. Measuring from centre to circumference, gives me the circles; doubling this I have the diameter, and multiplying by six I have the circumference."

The learned professor then presents a table of the periods of increase in the diameter of various trees, an inspection of which proves that every tree, after having grown rapidly when young, seems at a certain age to take a regular march of growth, which may perhaps be accounted for by supposing that young trees have more room to expand in, are less pressed by the roots and branches of their neighbours, and may not have penetrated down to a hard, arid, or otherwise unfavourable soil; and also, that as trees advance in age, they still continue to form layers as thick as they previously did subsequently to the period of rapid growth. If such tables were multiplied to a sufficient extent, as we have no doubt they will be in course of time, they would form data from which, by ascertaining the circumference of a tree, its age might be known without having recourse to the destructive process of cutting deep into the growing timber. "If," says Decandolle, "one cannot get a transverse section of a trunk, then one must seek for old specimens of each kind, the date of whose planting is known, measure their circumference, deduce their average growth, and calculate from them the age of other trees of the same kind, always keeping in mind that young trees grow faster than old ones." Decandolle cites instances of trees whose ages have been ascertained according to the rules here laid down. Some of these we shall present to the reader, along with descriptions of other trees obtained from a variety of sources, particularly American publications.

A certain *Baobab tree* of Africa is considered by Humboldt as the oldest organic monument of our planet; and Adanson, a distinguished botanist, by ingenious calculations, has ascertained its age to be 5150 years. The method adopted by Adanson for finding its age, was by making a deep cut in the side of the trunk, and counting the concentric rings, by which he ascertained how much the tree had grown in three centuries; and having already learned the growth of young trees, he established his general law through the average growth. The enormous dimensions of the trunk of this tree bear a striking disproportion to the other parts. Examples of the species have been seen, which, with a trunk ninety feet in circumference, were only twelve feet in height. A still larger was seen by Mr. Golberry in the valley of the two Gagnacks, in Africa; it was thirty-four feet in diameter. The flower is of the same gigantic proportions as the tree. Such colossal masses of timber might be hollowed out into by no means straitened dwelling-houses.

One of the most celebrated trees described by travellers of recent times, is the *Great Dragon tree* of the island of Teneriffe. It derives its name of *dragon's-blood*, by which it is popularly known, from the circumstance of a liquor of a deep red colour like blood flowing from its hoary trunk during the dog-days. This exudation soon becomes dry and brittle by the action of the atmosphere, and is the true dragon's-blood of the apothecaries and other venders. The wonderful size and appearance of this tree excited the admiration of Humboldt, who thus describes it:—"We were told that the trunk of this tree, which is mentioned in some very ancient documents as marking the boundaries of a field, was as gigantic in the fifteenth century as it is at the present moment. Its height appeared to us to be about fifty or sixty feet; its circumference near the roots is forty-five feet. * * * The trunk is divided into a great number of branches, which rise in the form of a candelabrum, and are terminated by tufts of leaves, like the yucca which adorns the valley of Mexico. It still bears, every year, both leaves and fruit. Its aspect feelingly recalls to mind 'that eternal youth of nature' which is an inexhaustible source of motion and of life." This giant plant was laid prostrate by a tempest in 1822.

The fact here noticed by the learned traveller, that the tree annually bore leaves and fruit, affords indubitable proof of a very remarkable circumstance connected with the vegetable kingdom. In man and all other animals we find an organization and a process of life going on which are destined to cease at a certain period. But it is otherwise with trees. They appear to possess the power of growing on for ever without exhibiting any symptoms of decay, unless from accidental or extraneous causes. We shall quote the words of Decandolle on this point:—"As there is formed every year a ligneous deposit, and generally new organs, there is not among the vegetable creation place for that hardiness or rigidity, that obstruction of old and permanent organs, which constitute properly the *death of old age*, and, consequently, that being the case, trees can only die from accidental causes. Trees do not die from age in the true sense of the word; they have no fixed period of existence; and, consequently, some may be found that have arrived at an extraordinary age." But although a tree thus possesses in itself the elements of continual strength and youth, numerous causes step in to interrupt or destroy its existence. In corroboration of what we state, we need only allude to the facts, that soil is of limited depth—that, below the soil, there are usually hard strata, which the feelers of a plant cannot penetrate—that roots intercrossing encumber each other, and check vegetation—besides which, there are other destructive and obstructive causes which we need not occupy the reader's time by specifying. Consequently, although what the French philosopher says is quite true, that "some (trees) may be found that have arrived at an extraordinary age," yet, every circumstance considered, we are not to be surprised if the number found should prove exceedingly small, compared with the immense extent of the earth's surface which is covered with forest trees.

Cypresses of gigantic dimensions are met with in Mexico. At Atlexo there is one seventy-six feet in girth; and another at St. Maria del Tuli, in the province of Oaxaca, which is one hundred and eighteen feet in circumference! This is larger than the dragon tree of the Canaries, and all the baobabs of Africa. "But," says Humboldt, "on examining it narrowly, M. Anza observes, that what excites the admiration of travellers is not a single individual, but that three united trunks form the famous *Sabino of Santa Maria del Tuli*." The fact of the threefold nature of the stem seems to have escaped the notice of some writers; it is of importance in determining which is really the largest organic monument of our planet. There is another cypress at Chapultepec, in the same region, which is said to be one hundred and seventeen feet ten inches round, and the younger Decandolle considers it even older than the baobab of Adanson. If the measurement here given be correct, and the tree consists only of one stem, we are entitled to regard this Mexican cypress as the most gigantic and ancient tree hitherto discovered on the globe. Hunter says that in 1776 there existed in the garden of the palace of Grenada cypresses that were celebrated even in the time of the Moorish kings, and which were named *Cypressos de la Regna Sultana*, from a sultaness who was seen sitting under it with a lover, who was one of the Abencerrages. They are supposed to be eight or nine hundred years old. Strabo mentions a Persian cypress in girth as much as five men could span, and he believed it to be two thousand five hundred years old. But this must have been guess-work; at least we are not aware that he made the computation after the skilful manner of Adanson or Decandolle. Michaux, a Frenchman, has published a splendid work on the forest trees of the United States. He says that the largest stocks of the cypress are one hundred and twenty feet in height, and from twenty-five to forty feet in circumference, above the conical base, which at the surface of the earth is always three or four times as large as the continued diameter of the trunk. Cypresses are among the trees in the south of Europe which live to the most advanced age; and the custom of planting them in cemeteries and consecrated ground, ensures respect being paid to them, and thus affords botanists the means of measuring them.

Yews are believed to be the most ancient trees of Great Britain; and no doubt can exist that there are individuals of the species in England as old as the introduction of Christianity, and, there is every reason to believe, a very great deal older. It is the opinion of Decandolle, that of all European trees, the yew is that which attains the greatest age. "I have measured the deposits of one of seventy years; Œlhafen has measured one of one hundred and fifty years; and Viellard has measured one of two hundred and eighty years. These three measurements agree in proving that the yew grows a little more than one line annually in the first one hundred and fifty years, and less than a line from one hundred and fifty to two hundred and fifty. If for very aged yews we take the average of one line annually, it is probably an admission beyond the truth; and thus, in estimating the number of lines and years as equal, we make them younger than they really are." We think this reasoning very plausible, and point out to such of our readers as may have opportunities of seeing old yew trees, how easily they may ascertain their age.* The line here spoken of is one-tenth of an inch. The circumference may be taken just above the base of the tree; the third of this measurement gives the diameter, and every inch of diameter is equal to ten years. There are four measurements of venerable yews in England—those of the ancient Abbey of Fountains, near Ripon in Yorkshire, which yews were well known as early as 1155. Pennant says, that in 1770 they were 1214 lines in diameter, and, consequently, were more than twelve centuries old. Those of the churchyard of Crowhurst in Surrey, on Evelyn's authority, were 1287 lines in diameter. There are two remarkable yews still in the same cemetery, and if they be the same which Evelyn refers to, they must be fourteen centuries and a half old. The yew tree at Fortingal in Perthshire, mentioned by Pennant, in 1770, had a diameter of 2588 lines, and, consequently, we must reckon it at from twenty-five to twenty-six centuries old. The yew of Brabourn churchyard in Kent, has attained the age of 3000 years; but that at Hedsor in Bucks surpasses all others in magnitude and antiquity. It is in full health, and measures above twenty-seven feet in diameter; consequently, according to Decandolle's method of computation, this yew has reached the enormous age of 3240 years! In all likelihood, this is the most ancient specimen of European vegetation.

The elm attains a very large size, and has a very rapid growth, both in Europe and America; but the elm of the latter country has a much more majestic appearance than that of Europe. Michaux characterizes it as "the most magnificent vegetable of the temperate zone." A specimen mentioned by Decandolle, which grew near the town of Morges in Switzerland, measured seventeen feet seven inches in diameter, and was estimated at three hundred and thirty-five years of age. He informs us that it grew on an average three lines and a half yearly; but dividing its growth each century, it grew six lines annually the first, two and a half the second, and two and three-fourths the third; and this growth agrees with that of those elms planted by order of Sully, before the Chambers in France. Every one who has it in his power to ascertain the rate of growth of trees ought to do so, as he is thereby not only gratifying a rational curiosity, but conferring a benefit on science. Wherever the age of an elm or other tree is correctly known, its girth should be taken, and a plain statement of the species of tree, the nature of the soil where it grew, its diameter and age, transmitted to any journal, the special

* We are aware that at the British Association which met in 1836, a paper was read contradictory of Decandolle's computation regarding yew trees, and stating that he made the old trees too young, and the young trees too old. The experimenter asserted that the mean average of the number of lines which a tree increased in a year, was two, or one-fifth of an inch. But Decandolle is the highest authority, and we are inclined to abide by his opinion till further experiments have been made.

object of which is to take cognisance of the vegetable kingdom. We are certain that many of our readers have this in their power. Indeed, Decandolle earnestly solicits the attention of English botanists to the subject; for it is only by an extensive accumulation of individual facts that general laws can be established.

One of the most curious and beautiful of nature's productions is the Banian or Burr tree, the *Ficus Indica* of botanists. Each tree forms in itself a grove, composed of numerous stems connected together, some of which are of the size of a large tree. On the island of Nerbuddah, near Baroach, in Hindostan, there is still standing a celebrated banian, called the *Cubeer Burr*. The tradition of the natives is, that it is three thousand years old. It is supposed by some to be the same tree that was visited by Nearchus, one of Alexander the Great's officers. The large trunks of this tree amount in number to 350, the smaller ones exceed 3000, and each of these is constantly sending forth branches and hanging roots to form other trunks. The circumference of this remarkable plant is nearly 2000 feet. Milton, in his "Paradise Lost," has described one of these trees as that of whose leaves our first parents "made themselves aprons" after the fall.

———" Soon they chose
The fig-tree, not that kind for fruit renowned,
But such as at this day, to Indians known,
In Malabar or Decan, spreads her arms,
Branching so broad and long, that in the ground
The bending twigs take root, and daughters grow
About the mother-tree, a pillared shade
High over-arched, and echoing walks between."

The lime is the European tree which, in a given time, appears capable of acquiring the largest diameter. Decandolle has some observations on the rate of growth of this tree, which may prove useful. He says—"that which was planted at Fribourg in 1476, on occasion of the battle of Morat, has now a diameter of 13 feet 9 inches, which would give about two lines of annual diametric growth. This is about the rate of the increase of the growth of an oak, and therefore I suppose the tree had not found a favourable soil, and it would be nearer the truth to calculate the annual growth of the lime at four lines. There are in Europe a great number of limes of large size, and it would be interesting to have the circumference of those whose date is known. I shall mention for their size that of the Chateau of Chaillé, near Melles, in the department of the Deux Sèvres, which in 1804 measured 15 metres round (about 50 feet), and which I suppose was then five hundred and thirty-eight years old; that of Trons in the Grisons, already celebrated in 1424, which in 1798 measured 51 feet in circumference, and which I calculate to be five hundred and eighty-three years old; that of Depeham, near Norwich, which, in 1664, was 8½ yards in circumference; and that of Henstadt in Wurtemberg, which, in 1550, was so large as to have need of props, and which, in 1664, was 37 feet 4 inches in circumference. One must distinguish between the large and small leaved limes, as the former appear to grow faster than the latter." There appears to be a mistake in regard to the Depeham lime. We suspect it is the same mentioned by Sir Thomas Browne, which, he says, was 90 feet in height, and 48 feet round at a foot and a half from the ground. He also describes a poplar near Harling as of nearly the same dimensions. The largest now known in England grows in Moor Park, Herts.

The Oriental plane is one of those trees which attain the largest size, but the rate of its increase is not ascertained. In the valley of Bujukdére, about three leagues from Constantinople, there is a plane which calls to mind one which Pliny has celebrated. According to the Roman naturalist, there was a plane-tree in Lycia which had a hollow trunk capacious enough to accommodate the consul Licinius Mutianus and eighteen followers, who found within its ample cavity a retreat for the night. This living vegetable grotto was 75 feet in circumference, and the summit of the tree resembled a small forest. The plane at Constantinople is 150 feet round, and within it there is a cavity of 80 feet in circumference. This transcends the tree of Pliny. There are other very large oriental planes mentioned by Clark and others, and one of vast size was lately noticed by Mr. Quin in his voyage down the Danube. For the information of our readers, we may mention that, in the eastern states of the North American Union, the tree is called Button-wood, and in the western states Sycamore. Under the latter appellation, Mr. Flint, the distinguished geographer, styles it "the king of the western forests. It is the largest tree of our woods, and rises in the most graceful forms, with vast spreading lateral branches, covered with bark of a brilliant white. A tree of this kind near Marietta (Ohio) measured 15½ feet in diameter. We have seen one on the Big Miami (a river), which we thought still larger. Judge Tucker of Missouri cut off a section of a hollow trunk of a sycamore, and applied a roof to it, and fitted it up as a study. It was regularly cylindrical, and when furnished with a stove and other arrangements, made an ample and convenient apartment." But buildings of a more extensive description than the above have been constructed out of this tree. We learn that a hollow trunk of an enormous sycamore was fitted up with the requisite appendages, and made use of at Utica, in New York state, as a retail-shop; and it was afterwards carried to the city of New York for a show. We extract from the "New York Traveller" the following notice of such another extraordinary domicile, or in all likelihood the same as that made use of at Utica. It was exhibited in the saloon of the American Museum in New York. "A sycamore tree of most singular and extraordinary size has been brought to this city from the western part of this state. The interior is hollowed out, and will comfortably accommodate some forty or fifty persons. It is splendidly furnished as a sitting-room, and contains every article of elegance and usefulness. It has a handsome piano, sofas, glasses, and mirrors, of fit and becoming style, and is decorated with pictures and fancy articles." The reader is not to class this account with the many incredible trans-Atlantic stories which are imported into this country. We have no reason to doubt the fact; but it seems quite clear that the apartments must have been hollowed out of the tree turned lengthways, its diameter affording sufficient height for them.

There are still some trees of a very remarkable size or age which remain to be described, but we can only briefly notice the most celebrated of them. In the Garden of Olives at Jerusalem, there are now existing eight olives, which can be proved by historical documents to have existed anterior to the taking of Jerusalem by the Turks, and which, consequently, must be at least 800 years old. A writer in the "North American Review" remarks, that the largest oak, and indeed the largest tree he has seen in that country, is an oak about twenty-seven feet in circumference at the smallest part. Its age he computes at not less than 500 years, so that it must have been a majestic tree at the time when Columbus discovered the Western World. We wish he had told us its girth immediately above the base but it is quite clear that this oak must be a stupendous organic fabric.

In 1804, Decandolle saw at Gigean, near Montpelier, in France, an ivy, the trunk of which near the base was six feet round, and whose immensity he says, was truly astonishing. Another ivy, only forty-five years old, was only seven and a half inches round; so, taking it as a general type, the specimen at Gigean, in the year 1804, ought to have been of the age of 435 years. We have nowhere seen mentioned an ivy of such colossal dimensions. A writer in the "North American Review" mentions wild grape-vines of enormous size. He says that, while in the eastern states, and, we may add, in Europe, it "rarely grows larger than a stout walking-stick, in our western states it sometimes surpasses in diameter the body of a full-grown man. This fact we have verified by actual measurement."

England at one period possessed many noble and remarkable oak-trees, the remains of which are in some instances still to be seen, while in others they are only remembered by tradition. Close by the gate of the Water Walk, at Magdalen College, in Oxford, there grew an oak, which perhaps stood there a sapling when Alfred the Great founded the university; for this period only includes a space of nine hundred years, which is no great age for an oak. This tree, however, can almost produce historical evidence for the age assigned it. About five hundred years after the time of Alfred, William of Wainfleet expressly ordered his college to be founded near the Great Oak; "and an oak," says Gilpin, "could not, I think, be less than five hundred years of age to merit that title, together with the honour of fixing the site of a college." When the magnificence of Cardinal Wolsey erected the handsome tower which is so ornamental to Magdalen's, this tree might probably be in the meridian of its glory, or rather, perhaps, it had attained a green old age. At a subsequent era, in Charles II.'s time, this famed tree was much injured when the present walks were laid out. Its roots were disturbed, and from that period it declined fast, and became reduced by degrees to little more than a mere trunk. But the faithful records of history have handed down its ancient dimensions. Through a space of sixteen yards on every side from its trunk, it once flung its boughs, and under its magnificent pavilion could have been sheltered with ease three thousand men, though, in its decayed state, it could for many years do little more than shelter some luckless individual whom the driving shower had overtaken in his evening walk. In the summer of 1788, this magnificent ruin fell to the ground, alarming the college with its rushing sound. It then appeared how precariously it had stood for many years. Its grand tap-root was decayed, and it had hold of the earth only by two or three roots, of which none was more than a couple of inches in diameter. From a part of its ruins a chair has been made for the president of the college, which will long preserve its memory.

Near Worksop grew an oak, which, in respect both to its own dignity and that of its situation, deserves honourable mention. In point of grandeur, few trees equalled it. It overspread a space of ninety feet from the extremities of its opposite boughs. These dimensions will produce an area capable, on mathematical calculation, of covering a squadron of two hundred and thirty-five horse. The dignity of its station was equal to the dignity of the tree itself. It stood on a point where Yorkshire, Nottinghamshire, and Derbyshire, unite, and spread its shade over a portion of each. From the honourable station of thus fixing the boundaries of three large counties, it was equally respected through the domains of them all, and was known far and wide by the honourable distinction of the Shire Oak, by which appellation it was marked among cities, towns, and rivers, in all the larger maps of England.

In a glade in Hainhault Forest, in Essex, about a mile from Barkingside, stands an oak, which has been known through many centuries by the name of Fairlop. The tradition of the country traces it half way up the Christian era. It is still a noble tree, though it has now suffered greatly from the depredations of time. About a yard from the ground, where its rough fluted stem is thirty-six feet in circumference, it divides into eleven vast arms, yet not in the horizontal manner of an oak, but rather in that of a beech. Beneath its shade, which overspreads an area of three hundred feet in circuit, an annual fair was long held on the 2d of July, and no booth was suffered to be erected beyond the extent of its boughs.

Not far from Blandford, in Dorsetshire, once stood a tree, which five or six centuries ago was probably in its maturity, and known by the name of Damory's Oak. At the ground its circumference was sixty-eight feet, and seventeen feet above the ground its diameter was four yards. As this vast trunk decayed, it became hollow, forming a cavity, which was fifteen feet wide and seventeen feet high, capable of holding twenty men. During the civil wars, and till after the Restoration, this cave was regularly inhabited by an old man, who sold ale in it. In the violent storm in the year 1703, it suffered greatly, many of its noblest limbs having been torn from it. In the year 1765, this once magnificent production of nature was cut down and sold for fire-wood.

Queen Elizabeth has in more than one or two instances communicated her name to oak-trees of great size in England. Gilpin mentions one of those oaks which grew at Heveningham in Suffolk, of great dimensions, but in his time greatly decayed. In Elizabeth's time it was hollow, and from this circumstance the tree derives the honour of being handed down to posterity. That princess, who, from her earliest age, loved masculine amusements, used often, it is said, in her youth, to take her stand in this tree, and shoot the deer as they passed, and hence it acquired the name of Elizabeth's Oak. Sir Thomas Dick Lauder, in his notes to Gilpin, mentions another of these oaks of Queen Elizabeth, at Huntingfield, also in the county of Suffolk, measuring thirty-four feet in girth at five feet from the ground, and which, also, in the days of yore, afforded a station for the princess in the sports of the field. "Huntingfield," says Sir Thomas, "was, for a considerable period after the Norman conquest, the estate and residence of an eminent family of that name. It afterwards descended to the De la Poles, Earls of Suffolk, and, in the time of Queen Elizabeth, was the property of Henry Lord Hunsdon. Queen Elizabeth is said to have been entertained at the old mansion by Lord Hunsdon, and to have enjoyed the pleasures of the chase, in rural majesty. The approach to the house was over an arm of the river Blithe, which waters the park, and then through three great square courts. A gallery was carried along the whole length of the building, and, opening upon a balcony over the porch, gave an air of grandeur and variety to the front. The great hall was built round six straight massy oaks, which originally upheld the roof, as they grew; and upon these the foresters and yeomen of the guard used to hang their nets, cross-bows, hunting-poles, and other implements of the chase. This gives a most curious picture of the romantic notions of these olden times. In later years, the roots being decayed, the shafts were sawn off at the bottom, and the roof was supported either by irregular logs of wood or by masonry; and part of the long gallery, where the queen and her attendants used to divert themselves, was converted into a cheese chamber. Elizabeth is said to have been much pleased with the retirement of this park, filled with tall and massy timber trees, but particularly with the oak, which ever afterwards bore the appellation of the Queen's Oak. It stood about two bowshots from the old romantic hall; and tradition records that Elizabeth shot a buck, with her own hand, from this tree. The upper part of the main stem of the tree is now considerably shortened by age and accidents. The limbs, however, are bold and picturesque; and it still carries many boughs, and enough of foliage to constitute a considerable head. The trunk thickens as it rises, so that, at seven feet from the ground, it measures about thirty-three feet in circumference. Another oak, called the Duke's Walking-Stick, at the same place, is in girth, at the ground, twenty-one feet, and rises to the height of one hundred and eleven feet from the ground.

Among the trees deriving celebrity from historical events in England, one of the most considerable note was the oak in the New Forest in Hampshire, against which the arrow of Sir Walter Tyrrel glanced, which killed William Rufus, son of William the Conqueror, in the year 1100. This oak-tree, which was of exceedingly large proportions, survived till about the middle of the eighteenth century, at which period of its final decay, it was in all likelihood nine hundred years old—an interval of years embracing all that had occurred in the history of the country from the reign of Alfred the Great till that of George III. This exceedingly interesting and ancient tree at length going to utter decay, its stump was eradicated, and, to preserve the memory of its site, a monumental stone was erected upon it by the late Lord Delaware, with appropriate inscriptions.

The Skelton Oak is another of those trees which have been connected with historical transactions. This oak still survives, and stands about a mile and a half from Shrewsbury, at the spot where the Pool road diverges from that which leads to Owestry. Near this place was fought the famous battle, on the 21st of June, 1403, between Henry IV., king of England, and the forces of Harry Percy, son of the Earl of Northumberland, surnamed Hotspur, along with those of Owen Glendower. It is recorded by tradition that, prior to the engagement, this celebrated Welsh hero mounted the tree, now called the Skelton Oak, to make his observations. The tree, which has been thus in some degree associated with the transaction in which took place the death of Hotspur, is now hollow in its trunk, and can contain about a dozen people. It divides into two enormous limbs, both of which have been fractured. It is thirty-seven feet in circumference, at a foot and a half from the ground, and is otherwise proportionally large.

Scotland, though by no means a woody country, at one time possessed, and indeed still possesses, many fine large trees of various species, as oaks, elms, yews, firs, hawthorns, &c., some of which have been celebrated in the history of the country. Professor Walker of Edinburgh, in his catalogue of remarkable Scottish trees, mentions several very fine oaks. An oak at Lochwood, in Annandale, measured at six feet above the root, was fifteen feet girth, among a number of others of nearly the same size, standing not less than nine hundred feet above the level of the sea. An oak at Blarquosh, in the parish of Strathblane, in Stirlingshire, the spread of the branches of which was ninety feet in diameter, measures fifteen feet in girth at four feet from the ground. An oak in the Marquis of Tweeddale's grounds, at Yester, in Haddingtonshire, at one foot from the ground, measures about fifteen feet five inches; and at six feet, it is about fourteen. The tree called the King of the Wood, on the estate of Fernyhirst, near Jedburgh, is a beautiful tall straight oak of eighty feet in height. The girth of it is eighteen feet above the roots; and at fifteen feet, it is eleven feet six inches in circumference; and it goes on tapering gradually for nearly three-fourths of its height. And the Kepping or Trysting Tree, which grows near it, and which is much more picturesque in form, measures twenty-one feet above the roots; it speedily divides itself into two branches, which measure respectively eleven feet six inches, and fourteen feet. It is upwards of seventy feet high, and covers an area of ninety-two feet in diameter. These two trees are considered to be remnants of the great forest of Jedwood. An oak which stands near the middle of Inch Marin, in Loch Lomond, measured, in 1786, eighteen feet one inch in girth. This tree is remarkable for its fine expanded head.

But none of these trees have attained the celebrity of Wallace's Oaks, two trees of considerable antiquity, one in Stirlingshire, the other in Renfrewshire. The former which is now completely gone, in 1771 measured twenty-two feet in circumference in the trunk, and grew upon a little knoll in Torwood. From surrounding vestiges, it is believed that this oak originally mingled in the scene of Druidic worship, at a far remote period of our history. But its celebrity depended on events of a much later date. When that illustrious hero, William Wallace, roused the spirit of the Scotch nation to oppose the tyranny of Edward, he often chose the solitude of the Torwood as a place of rendezvous for his army. Here he concealed his numbers and his designs, sallying out suddenly on the enemy's garrisons, and retreating as suddenly when he feared to be overpowered. While his army lay in those woods, the oak which we are now commemorating was commonly his head-quarters. Here, it is said, the hero generally slept, the hollow trunk being capacious enough to afford shelter not only to himself but several of his associates. This tree was thence afterwards known as Wallace's Oak. There is another Wallace's Oak at Elderslie, in Renfrewshire, near the place where Wallace was born. It is a very noble tree, twenty-one feet in circumference at the ground. It is sixty-seven feet high, and its branches extend forty-five feet east, thirty-six west, thirty south, and twenty-five north, covering altogether nineteen English poles of ground. Tradition relates that Wallace and a large party of his followers hid themselves from the English among the branches of this tree, which was then in full leaf. It is a custom in Scotland to indent small portions of the wood of this famed tree in snuff-boxes, along with perhaps minute portions of a tree said to be planted by Queen Mary at Holyrood, and lately removed—of another tree which the same queen sat under near Crookston, while witnessing the battle of Langside—of the rafters of Alloway Kirk, celebrated by Burns—with pieces of various other trees and timbers either brought into notice in history, or some way connected with the popular literature and traditions of the country.

It is a very remarkable fact, that the trunks of large oak-trees are frequently dug out of the ground in Scotland, both in the mainland and islands, at places where there are now not only no trees of an ordinary size, but where, in the present day, trees will not grow. There is no way of accounting for this, but by supposing that the climate has very much changed since the period when all was one universal forest. Some very large masses of oak (says Sir Thomas Dick Lauder, in his notes to Gilpin's work) were brought up by the dredging-machine employed in deepening the line of the Caledonian Canal, in Loch Dochfour, from under sixteen feet of gravel which lay at the bottom of the lake. One of these fragments measured thirty feet round; and though it manifestly appeared to be only a small portion of the original tree, it was calculated to contain about two hundred and twenty cubic feet. It was black as ebony, and perfectly fresh and hard. Although there are fine thriving oaks in Scotland at this moment, yet few of them approach the dimensions of these fragments of the olden time.

The best elm we have recorded as of Scottish growth, was that in the parish of Roxburgh, in Teviotdale, called the Trysting-Tree, which was measured in the year 1796, and found to be thirty feet in girth. The ruins of this noble tree still remain at the Friars, near the old castle of Roxburgh. The most plausible tradition regarding the origin of the name of the Trysting-Tree is, that the lairds of Cessford and Fernyhirst, with a number of Scottish gentry, assembled there in 1547, to meet the Protector Somerset, during his rough courtship of the young Queen Mary, and to swear homage to the King of England. There can be no doubt that he was there; and this spot, which was near the old priory, was certainly a very likely place for such an assemblage. The Trysting-Tree was also famous, in later times, as the scene of much innocent pleasantry. After the Reformation, and until the present house of Fleurs was built, in 1718, the family of Roxburgh made an occasional residence of the remains of the religious house at Friars, which was then called East Roxburgh. The gardens belonging to it were kept up until the year 1780, when old Coles, who was butler to Duke John, ploughed them up, and destroyed some beautiful vestiges of antiquity. In these gardens there was a raised walk, called the Lover's Walk, between two rows of old elms, forming a vista, which terminated with the Trysting-Tree, whither the beaux and belles of these old times used to resort, to enjoy themselves, on a summer evening, and to eat the fruit, which was always sold during the absence of the family. Upon these occasions, the gentlemen were often made to walk blindfolded in the alley; and if any one failed to grope his way from one end of it to the other, without diverging from the grass into either border, he was immediately fined in a treat of fruit. What a picture would Watteau have made of so admirable a subject! Many a courtship was brought to a happy termination at this antiquated Vauxhall.

At Newbattle Abbey, the seat of the Marquis of Lothian, a few miles south from Edinburgh, there are some remarkably fine large trees, most probably planted by the monks prior to the Reformation. "Professor Walker measured a beech at this place in 1789; its trunk, where thickest, was seventeen feet in girth, and the span of the branches was eighty-nine feet. He thinks that it must have been planted between 1540 and 1560. It was blown down a short time before the year 1809. It contained upwards of one thousand measurable feet of timber (twenty loads, or twenty-five tons) and it is with reason reckoned among the largest beeches that have ever grown in Scotland. A beech at Taymouth, of a like size, and seemingly coeval with this, was blown down when it had reached above sixteen feet in girth. The large beech at Ormiston Hall, in Haddingtonshire, the bole of which we remember to have seen scooped artificially out into a shelter-house, was measured on the 10th of May, 1762, and found to be eighteen feet ten inches. We believe it was quite entire when it was destroyed by a high wind. A large beech near Oxenford Castle, in Edinburghshire, was measured on the 6th of June, 1763. At the height of three feet from the ground, it was nineteen feet six inches. This fine tree was then decaying. Professor Walker says that the beech was not copiously planted in Scotland till a little before the Revolution; and the trees planted about that period do not form, in many places, considerable timber, as at Inverary and other places. But the four trees last mentioned, which appear to be nearly contemporary, are of a much more remote era. They seem to have been planted singly, and merely as curious foreign trees, in the gardens of some eminent persons. From their dimensions and manner of growth, they may be presumed, at least, to have beech planted between 1540 and 1560, so that they may now be estimated at between two hundred and forty and two hundred and sixty years old. From the state of the Ormiston Hall and Newbottle trees, it may be concluded that the beech, if it meets with no accident, will grow with sound timber for at least two hundred and fifty years."

THE HORSE.

The Horse, well known as one of the most beautiful and useful of animals, is classified, according to the arrangements of zoologists, in the order Pachydermata, of which it constitutes a family—the *Equidæ*, along with the zebra, the ass, and several other animals. The horse, as a distinct species, differs from other members of the genus, not only in a few particulars of physical structure, but in its superior strength, spirit, and tractability. Of the absolutely natural character of the horse, however, mankind possess no certain account; for, in all the instances in which the animal is found in a wild state, the race appears to have been generally derived from a domesticated stock. The form and general qualifications of the animal are of a high order, and peculiarly susceptible of cultivation by art. The senses of smell and sight are remarkably acute, and the clearness of perception, excellence of memory, patient endurance, and gentleness, are not excelled in any other of the lower animals. The horse is altogether herbivorous, for which the structure of his teeth and lips is adapted; but he does not ruminate, and has only one stomach. His native country is believed to have been Tartary, whence the species has spread over the world, and separated into different varieties.

VARIETIES OF HORSES.

Horses exist in numerous varieties, distinguishable by size, strength, colour, and other qualifications, the result most likely of peculiarities of climate, food, and habits. The following is a brief notice of the leading varieties in which the animal is found:—

Horses in a State of Nature.

Horses are found in a state of nature, living as wild animals, in various parts of America, Asia, and Africa. In the vast plains of South America, immense troops of wild horses are to be found, which have all sprung from emancipated individuals taken to that country by the Spaniards. The geographical range of these herds extends from the shores of La Plata to Patagonia. They have increased in such astonishing rapidity, that they are to be met with in troops of many thousands. Naturally gentle in disposition, these wild horses never attack other animals, but always act upon the defensive. Their wide pastures satisfy their appetites, and, when the food of one district is exhausted, they have only to shift their stations to places where it is more abundant. They are seldom to be taken by surprise; but, if attacked, the assailant rarely comes off victorious, for the whole troop units in defence of their comrades, and frequently either tear their enemy to pieces or kick him to death. Wild horses usually retire to the confines of a forest to repose. One or more of their number are always awake to keep watch while the rest are asleep, and to warn their fellows of approaching danger, which is done by loud snorting or neighing; upon this signal they start to their feet, and either reconnoitre the enemy, or fly off with the swiftness of the wind, followed by the sentinel, and by the stallion who is patriarch of the herd.

In the desert tracts along the banks of the Don, in Russia, there are numerous troops of wild horses, which have sprung from emancipated progenitors. The Cossacks frequently take these, and breed from them, by crossing them with their domesticated horses, which are said to be thereby greatly improved. Pallas says they abound in the vicinity of the Palus Mæotis. These herds are the descendants of the Russian horses which were used at the siege of Azoph in 1696, when taken from the Turks by Peter the Great, who was compelled, from want of forage, to set at liberty nearly the whole horses belonging to his cavalry, to seek food for themselves. They are now quite wild, and associate in troops in the same manner as other wild horses. Those herds which have remained close to the alluvial and fertile banks of the river, are of a large size, owing to the rankness of their food; the ground in these situations is so extremely swampy that no solid edifice can be erected near the river, the whole surrounding country being little better than a morass. The herds which inhabit the higher mountain districts have all the appearance of the horses from which they sprung. It is supposed that the troops found in the plains of Great Tartary are descended from the same source as those of the banks of the Don and the Ukraine.

In South America there are no regular stables, the horses being either kept in pastures, which are fenced, or in what they call *corrals*, which consist of a circular enclosure of rough posts, driven into the ground so close, that a horse cannot pass through between them. In these, however, the mares and foals are never confined, but are allowed to graze about at freedom. The natives, however, usually keep one horse tied at the door of their hut, to be ready in case of immediate need, which is fed on a scanty meal of maize at night. If an additional horse is wanted, the *gaucho* (or native inhabitant of the plains) goes to the corral with his *lasso*, and fetches one which may have been only subdued the preceding day; or he will go to the plain where they are grazing at freedom, and bring one which he has backed for the first time; and when these horses have been once used, they are either put into the corral and fed with maize, or returned to the plain to feed at liberty. The lasso is a very simple contrivance, but of great power in the hands of the gaucho, who is accustomed to use it from his youngest years, or at least to see it done, and he puts it in practice as soon as he has sufficient strength to use it. Miers, in his Travels in Chili,* gives the following account of it:—

"The *lasso* is a missile weapon, used by every native of the United Provinces and Chili. It is a very strong plaited thong, of equal thickness, half an inch in diameter, and forty feet long, made of stripes of green hide, plaited like a whip-thong, and rendered supple by grease. It has at one end an iron ring, about an inch and a half in diameter, through which the thong is passed, and this forms a running noose. The gaucho, or native peon, is generally mounted on horseback when he uses the lasso; one end of the thong is affixed to his saddle-girth; the remainder he coils carefully in his left hand, leaving about twelve feet belonging to the noose end in a coil, and a half of which he holds in his right hand. He then swings this long noose horizontally round his head, the weight of the iron ring at the end of the noose assisting in giving to it, by a continued circular motion, a sufficient force to project it the whole length of the line."

It is sometimes necessary to break in a number of horses at once: in this event, they drive a whole herd of wild horses into the corral at one time. This scene was witnessed by Miers, who thus describes it:—"The corral was quite full of horses, most of which were young ones about two or three years old. The *copitar* (chief gaucho), mounted on a strong steady horse, rode into the corral, and threw his lasso over the neck of a young horse, and dragged him to the gate. For some time he was very unwilling to leave his comrades; but the moment he was forced out of the corral, his first idea was to gallop away; however, a timely jerk of the lasso checked him in the most effectual way. The peons now ran after him on foot, and threw a lasso over his fore-legs just above the fetlock, and, twitching it, they pulled his legs from under him so suddenly, that I really thought the fall he got had killed him. In one instant a gaucho was seated on his head, and with his long knife, and in a few seconds, cut off the whole of the horse's mane, while another cut the hair from the end of his tail. This, they told me, was a mark that the horse had been once mounted. They then put a piece of hide into his mouth, to serve for a bit, and a strong hide halter on his head. The gaucho who was to mount arranged his spurs, which were unusually long and sharp, and while two men held the horse by his ears, he put on the saddle, which he girthed extremely tight. He then caught hold of the horse's ear, and in an instant vaulted into the saddle, upon which the men who held the horse by the halter threw the end to the rider, and from that moment no one seemed to take any further notice of him. The horse instantly began to jump in a manner which made it very difficult for the rider to keep his seat, and quite different from the kick or plunge of our English horse: however, the gaucho's spurs soon set him going, and off he galloped, doing every thing in his power to throw his rider.

"Another horse was immediately brought from the corral: and so quick was the operation, that twelve gauchos were mounted in a space which I think hardly exceeded an hour. It was wonderful to see the different manner in which different horses behaved. Some would actually scream while the gauchos were girthing the saddle upon their backs; some would instantly lie down and roll upon it, while some would stand without being held, their legs stiff, and in unnatural positions; their necks half-bent towards their tails, and looking vicious and obstinate; and I could not help thinking that I would not have mounted one of those for any reward that could be offered me, for they were invariably the most difficult to subdue.

"It was now curious to look around and see the gauchos on the horizon, in different directions, trying to bring their horses back to the corral, which is the most difficult part of their work; for the poor creatures had been so scared there, that they were unwilling to return to the place. It was amusing to see the antics of the horses: they were jumping and dancing in different ways, while the right arm of the gauchos was seen flogging them. At last they brought the horses back, apparently subdued and broken in. The saddles and bridles were taken off, and the young horses trotted off towards the corral, neighing to one another."

There is a remarkable difference in the dispositions of the Asiatic and South American wild horses: those of the former country can never be properly tamed unless trained very young; if taken when adults, they frequently break out into violent fits of rage in after life, exhibiting every mark of natural wildness; while those of America can be brought to perfect obedience, and even rendered somewhat docile, within a few weeks, nay, sometimes days. It would be difficult to account for this opposition of temper, unless we can suppose that it is influenced by climate.

The Arabian Horse.

The Arabian Horse is considered to occupy the highest rank among the numerous cultivated varieties, and imbodies that qualification in its purest condition, known in England by the term *thorough-bred*. By the wandering tribes of Arabia, he has been skilfully subdued and domesticated, and exhibits, with great beauty of figure, spirit, docility, and intelligence. The pure Arabians are somewhat smaller than our race-horses, seldom exceeding fourteen hands two inches in height. Their heads are very beautiful, clean, and wide between the jaws; the forehead is broad and square; the face flat; the muzzle short and fine; the eyes prominent and brilliant; the ears small and handsome; the nostrils large and open; the skin of the head thin, through which may be distinctly traced the whole veins of the head. The body may, as a whole, be considered too light, and the breast rather narrow; but behind the arms, the chest generally swells out greatly, leaving ample room for the lungs to play. The shoulder is superior to that of any other breed; the scapulæ, or shoulder-blades, incline backwards, nearly in an angle of 45 degrees; the withers are high and arched; the neck beautifully curved, and the mane and tail long, thin, and flowing; the legs are fine, thin, and wiry, with the pasterns placed somewhat oblique, which has led some to suppose that the strength was thereby lessened, which is by no means the case; the bone is of uncommon density, and the prominent muscles of the fore-arm and thigh prove that the Arabian is fully equal to all that has been said of his physical powers.

The Arabs of the desert have made the breeding of horses their sole occupation for ages bygone; and, from their strict attention to certain rules, they may be justly regarded as the first breeders in the world. They take infinite trouble in grooming their steeds, and are extremely regular in their hours of feeding them morning and evening. They get but little drink, and that is supplied to them two or three times a day; they conceive that much water not only destroys their shape, but also affects their breathing. In spring they are pastured on dry aromatic herbage; and during the rest of the year they are fed on barley, with a small quantity of straw; and they are the hardiest horses in the world. The Arab trains his horse by kindness, and never on any occasion strikes it; the consequence is, that the animal shows a degree of affection and tractability in which most British horses are quite deficient. The Arab horse is employed only for riding, and possesses great fleetness.

The following interesting account of the hardihood of the Arabian is given by M. Chateaubriand, in his Travels in Greece—"They are never put under shelter, but left exposed to the most intense heat of the sun, tied by all four legs to stakes driven in the ground, so that they cannot stir. The saddle is now taken from their backs. They frequently drink but once, and have only one feed of barley in twenty-four hours. This rigid treatment, so far from wearing them out, gives them sobriety and speed. I have often admired an Arabian steed thus tied down to the burning sands, his hair loosely flowing, his head bowed between his legs to find a little shade, and stealing with his wild eye an oblique glance of his master. Release his legs from the shackles, spring upon his back, and he will 'paw in the valley, he will rejoice in his strength, he will swallow the ground in the fierceness of his rage;' and you recognise the original picture of Job."

The Arabs are exceedingly particular regarding the pedigree of their horses; and they have amongst them a breed which they declare has descended from a horse of King Solomon. It must not, however, be supposed that all the horses of that country are of the finer kinds; for the Arabs have three distinct breeds: the two inferior kinds, they say, were introduced from India and Greece. The superior kinds they call nobles; and they are never sold without a pedigree, which is more scrupulously attended to than with human beings in Europe.

British Race-Horse.

The British Race-Horse is a cultivated breed, originally sprung from the Arabian, and to which is traced the quality of being *thorough-bred*. The skins of race-horses are delicate, with short hair, usually tending to the bright brown or bay generally characteristic of the horses of the East, and sometimes the gray, prevalent likewise amongst the Arabs and Barbs. They are frequently chestnut, which may be looked upon as a mixture of the dun or tan colour of some of the races of Northern Europe with the finer brown or bay; and sometimes, though very rarely, they are of the bright black common to the great horses of the plains of Germany. They are of medium height, rarely exceeding fifteen hands. Their form is that which an almost exclusive attention to the property of speed has tended to produce. They have the broad forehead, the brilliant eyes, the delicate muzzle, the expanded nostrils, and the wide throat, characteristic of their eastern progenitors. Their light body is comparatively long, and suited to the extended stride. Their chest is deep, so as to give due space to the lungs, but comparatively narrow, preventing the fore extremities from being over-loaded, and the limbs from being thrown too far asunder in the gallop. Their shoulder is oblique, to give freedom of motion to the humerus, and their haunch is long and deep, beyond that of any other known race of horses, indicating the length of those bones of the hinder extremities on which the power of progression essentially depends. Their limbs are long and muscular to the knee and hock, and below, tendinous and delicate; and their pasterns being long and oblique, give elasticity to the limbs.

The pedigree of race-horses is always a matter of consequence to the breeder and purchaser of these animals, and is preserved with the same degree of care as the genealogy of many a noble family. By jockeys and others, therefore, a list or stud-book is kept of the sires and dams of their horses, which can be exhibited if required. The pedigree of many fine racers of the present day is traced through stud-books to the Darley Arabian, a horse purchased by a Mr. Darley at Aleppo, from which it was imported to England. One of its immediate descendants was the famous Flying Childers, bred by Mr. Childers of Carr-House. This beautiful racer is reputed to have been the fleetest runner ever known in England, or perhaps in the world. On one occasion, he ran round the course in Newmarket, which measures 3 miles, 6 furlongs, and 93 yards, in 6 minutes and 40 seconds.

Horse-racing, which, in the opinion of competent judges, is unnecessary, as far as keeping up serviceable breeds of horses is concerned, is usually spoken of as the *turf*, from its being performed on stretches of turf-ground at Newmarket, Epsom, and various other places. Among an idle and in many instances a profligate class of persons, this *sport*, as it is termed, affords scope for a most extensive system of fraud, betting, gambling, and general dissoluteness of behaviour; in a word, this cruel pastime may be described as a great canker lying at the root of society in England; and, countenanced by the high in rank, is at the present moment not the least effective of the many drags on social advancement. The framers and conservators of the laws of the turf, are the members of an association called the Jockey Club, whose principal betting-rooms are at Newmarket, and at the establishment of Mr. Tattersal in London. At these places of resort, noblemen, gentlemen, turf-speculators, sharpers, and jockeys of all shades meet to bet on the result of certain races; and there, also, they attend on certain settling days to pay the losses and receive the gains of their wagers. When we find so open a system of gambling largely supported, and rendered in appearance *respectable*, by the higher classes, need we feel surprised at the alleged degeneracy of the bulk of the lower orders? Horse-racing, with all its train of evils, may certainly be considered a disgrace of the age; and, as one of the relics of barbarism, along with cock-fighting, bull-baiting, and prize-fighting, we should rejoice to see it for ever abandoned.

Hunters—Saddle-Horses.

The Hunter is a combination of the thorough-bred race-horse and half-bred horses of greater strength and bone; but changes are continually taking place in its character. The older race of hunters has been giving place to one of lighter form and higher breeding, and even the thorough-bred horse is now employed by numerous sportsmen. In his improved state, the hunter may rank as a saddle-horse of the first class, combining strength with fleetness. The prime qualities of a hunter may be briefly summed up—head small, neck thin, crest firm and arched, a light mouth, broad chest, body short and compact, the hocks well bent, power behind to push him over difficulties, and broad well-made feet turned outward. He is prepared for his duties by physic, air, and exercise. To do him justice, the hunter should not work above three days a week; and, after a hard day's run, he ought certainly to have two or three days of rest. We cordially coincide in the following remarks on the cruelty of abusing this noble animal—"It is very conceivable, and does sometimes happen, that, entering as fully as his master into the sports of the day, the horse disdains to yield to fatigue, and voluntarily presses on, until nature is exhausted, and he falls, and dies; but much oftener the poor animal has intelligibly enough hinted his distress; unwilling to give in, yet painfully and falteringly holding on. The merciless rider, rather than give up one hour's enjoyment, tortures him with whip and spur, until he drops and expires. Although the hunter may be unwilling to relinquish the chase, he who 'is merciful to his beast' will soon recognise the symptoms of excessive and dangerous distress. To the drooping pace, and staggering gait, and heaving flank, and heavy bearing on hand, will be added a very peculiar noise. The inexperienced person will fancy it to be the beating of the heart; but that has almost ceased to beat, and the lungs are becoming gorged with blood. It is the convulsive motion of the muscles of the belly, called into violent action to assist in the laborious office of breathing. The man who proceeds a single mile after this, ought to suffer the punishment he is inflicting."—(*Library of Useful Knowledge.*)

The Charger or Cavalry Horse partakes of the qualities of the hunter—great strength and spirit, without which he would be unable to bear the toil of warfare in a rough country.

The proper kind of Saddle-Horse is only a variety of the hunter, possessing less or more *blood*, according to the nature of the work required of him, and the taste of the breeder. Of the great varieties of saddle-horses, there may be said to be a chain of connection, as respects spirit and form, from the racer to the cart-horse; and therefore the station which any individual occupies is almost undefinable. The saddle-horses of England are celebrated for their beauty and action; and nowhere are seen so many of elegant forms as in London. Latterly, the breeds have been tending to greater lightness, the state of the roads not now requiring the strength of limb which was at one time necessary.

Coach-Horses.

The better kind of Coach-Horses owe their origin to the Cleveland bay, and are principally bred in Yorkshire, Durham, and the southern districts of Northumberland, and some few have been produced in Lincolnshire. The coach-horse is produced by a cross of the Cleveland mare with a three-fourth or thorough-bred horse, which is possessed of sufficient substance and height. The produce of these is the coach-horse of the highest repute, and most likely to possess good action. His points are advantageously placed, with a deep and well-proportioned body, strong and clean bone under the knee, and his feet open, sound, and tough. He possesses a fine knee action, lifts his feet high, which gives an elegance to his paces and action: he carries his head well, and has a fine elevated crest. The full-sized coach-horse is, in fact, only an overgrown hunter, too large for that sport.

The carriage-horse, reduced to drawing stage-coaches, is generally used in a very disgraceful manner. Urged with a heavy draught to the height of his speed, and almost incessantly wrought, whipped unmercifully, and poorly groomed, his fate is often melancholy in the extreme. It ought to be recollected that, in proportion as the load or draught is increased, so is the animal's power of speed lessened; and therefore to make him both draw a heavy weight, and run also, is to put him beyond his natural powers, and his muscular energy suffers accordingly. We shall afterwards advert to the principles which ought to regulate both draught and speed.

The Hackney.

The term *Hackney*, in common use, is employed to denote a kind of horse fitted for general services, and is therefore understood to exclude the horses of the highest breeding, as the thorough-bred horse and hunter; and there is further associated with the idea of a hackney, an animal of moderate size, not exceeding fifteen hands, and possessing action, strength, and temper. Our present breed of hackneys have a considerable portion of racing blood in them, varying from a half to seven-eighths. The latter are too highly bred for the general purpose of a roadster, as their legs and feet are rather tender; and their long paces and straight-kneed action are ill-adapted for the road, being more fitted for cantering and running than the trot, which is the distinguishing characteristic of a good hackney. Indeed, they should never be permitted to go at any other pace than a trot, which is undoubtedly much better adapted for the road than cantering.

Nothing is more essential in a hackney than sound strong fore legs, and also well-formed hind ones; his feet must be quite sound and free from corns, to which hard-ridden horses are very liable; and he ought only to lift his fore legs moderately high. Some are of opinion that he cannot lift them too high, and conceive, while he is possessed of this quality, he never will come down. There is a medium, however, in this, as a horse that raises his fore legs too high in trotting is always disagreeable in his action, which greatly shakes and fatigues his rider; besides, he batters his hoofs to pieces in a few years. The principal thing to be attended to, is the manner in which the hackney puts his feet to the ground; for if his toes first touch the road, he is sure to be a stumbler. The foot should come flat down on the whole sole at once, otherwise the horse is not to be depended upon in his trotting. A hackney should be particularly even-tempered, and not given to starting. The thorough-bred hackney ought to possess two qualities, indispensable to the safety of the rider—he should never shy at any thing on the road, and his motion at a trot should be much more smooth than that of a half-bred horse.

The Cart-Horse.

The Cart-Horses of Great Britain are extremely variable in point of size as well as in shape, differing in almost every county. One principal character, however, is weight, to give more physical force in the draught. They should not be above sixteen hands high, with a light, well-shaped head and neck, short pointed ears, with brisk sparkling eyes; their chests should be full and deep, with large and strong shoulders, but rather low in front than otherwise. The back should be straight, and rather long, but not too much so, as this always impairs his general strength; the animal should stand wide on all his four legs, and considerably wider behind than before; he ought to have great pliability in the knee-joints, and be able to bend them well, which assist in producing a brisk and active step in walking, a quality of much consequence in a cart or wagon horse. The height to be desired in a draught-horse, however, will depend upon the purpose for which he is to be employed.

In the midland counties of England—Warwickshire, Derbyshire, Leicestershire, Lincolnshire, and Nottinghamshire, there is a very large breed called the great cart-horse. It was bred in the lowland rich alluvial pastures of the plains of these counties, from the Flemish and Dutch horses, with the larger English breed. Mr. Bakewell introduced horses, and also mares, from the Netherlands, and thus produced those fine animals with Belgic blood, both on the side of the sire and dam.

The very large horses of seventeen hands and upwards, are only useful for the purposes of brewers' drays, wagons, and the slop-carts of London. It is, however, doubted if they answer the better for their gigantic size; and all who have written on the subject consider that they are inferior in point of strength, on account of their bulk; for by the feeding which is required to increase their dimensions, little of muscular fibre is produced, the growth being principally in the cellular tissue and fat; and the additional quantity of food required to keep up their system must more than counterbalance any advantage to be reaped from their size. Latterly, considerable pains have been taken to improve the qualities of ordinary cart-horses, among which we include those required in agriculture. A breed called the Clydesdale is highly valued, for either cart or plough. Animals of the Clydesdale breed reach to a large size, and are not unfrequently to be met with sixteen and a half hands high. These animals are strong and hardy, but their heads are coarse, and they are rather flat on the sides and hinder quarters. The usual colour of these horses is gray or brown. This breed is supposed to have originated about one hundred and thirty years ago, between the common Scotch mare and the Flanders horse.

Ponies.

A horse beneath thirteen hands is called a pony, but this definition is not very strictly attended to, and the same thing may be said of the *galloway*. The old Scottish galloways, which took their name from the district of Galloway, in the south-western extremity of the country, are now nearly extinct. They were stout, compact animals, sure-footed, and of great endurance, and on these accounts invaluable in travelling over rugged and mountainous districts. The beauty and speed of the galloway were supposed to have arisen from the breed having been the produce of the Spanish jennets that escaped from the wreck of the Spanish armada, and these, crossed with our Scottish horses, gave rise to this esteemed breed. But we apprehend they were famous at a date long prior to that event, as this district is known to have supplied Edward I. with great numbers of horses. This breed seldom exceeded fourteen hands in height: their colour was generally bright bay or brown, with black legs, small head and neck, and their legs peculiarly deep and clean. A compact stout-built pony, of from thirteen to fourteen hands high, and possessing some of the qualifications of the Galloway, is called a *cob*, which is valuable as a steady pacer, at an easy rate.

The small ponies of the Highlands of Scotland and Shetland (usually called *shelties*) may almost be termed wild animals; for they go at large in herds on the hills and wastes, and are not shod till caught and put into training. They are docile and tractable, and being very sure-footed, are the best adapted for boys' riding. Of their remarkable sagacity in passing fords and dangerous morasses, numerous accounts have been given. The Rev. Mr. Hall, in his "Travels through Scotland," mentions, "When these animal come to any boggy piece of ground, they first put their nose to it, and then pat on it in a peculiar way with one of their fore feet; and from the sound and feeling of the ground, they know whether it will bear them. They do the same with ice, and determine in a minute whether they will proceed."

The Welsh pony is more handsomely formed than that of Shetland; has a small head, high withers, deep round body, and excellent feet. The Exmoor ponies are also very stout, hardy, and useful in the fatigues of rural sporting. The ponies of Dartmoor are likewise a hardy, sure-footed race, well adapted for riding in wild districts. The ponies of Norway and Sweden, which are of a dingy cream colour, and of which there are now occasional importations to Britain, are considerably larger than the Shetland or Welsh breeds, but also hardy and very docile.

REARING OF HORSES.

The breeding and rearing of horses are carried on professionally in England, chiefly in Yorkshire; but many private gentlemen and farmers also address themselves to it as a means of pecuniary profit and the improvement of their animal stock. We do not pretend here to offer any specific directions on this branch of our subject, it being one in which the public at large are not particularly interested, and a few observations seem all that is necessary.

The circumstance which the breeder of horses requires to keep most in mind, is, that the qualities, good or bad, of the animal are hereditary. Finely made horses produce finely made descendants, and *vice versa;* heavy cart-horses never produce animals possessing the qualities of racers. Thus, the bone, blood, and general make are directly transmissible; and, in the case of crossing, the produce is found to possess a proportional share of both sire and dam. Cross-breeding between extremely different horses is not found advantageous: it is a generally recognised principle, that the nearer the resemblance between the parents, so will the produce be more satisfactory. Mr. N. H. Smith, in his *Observations on Breeding for the Turf*, remarks, that "the stock of some mares will frequently partake most of the dam, and that of others most of the sire; and sometimes one foal will partake most of the mare, and the next perhaps most of the horse, &c. It also occasionally happens that the produce bears some resemblance to its grandsire, grandam, or other distant kindred; and although this does not perhaps often occur, so as to be very perceptible, yet, as their qualities must, in a lesser or greater degree, descend to their progeny, it has always had its due weight, and hence the value and partiality to blood, or ancestral excellences, transmitted through many generations." He further observes, however, "that he is disposed to attribute more in general to the dam than to the sire, inasmuch as he is decidedly of opinion that a good mare put to the worst thorough-bred horse would be much more likely to produce a runner, than a bad mare put to the most fashionable stallion in England; and therefore a person possessing good mares may bring any stallion into repute." The grand aim of the breeder must be the propagating of excellences and avoiding defects; but this is not to be accomplished, as respects important alterations, all at once; improvements in this, as in every thing else, being the work of time and a judicious experience. Breeding in

-in, as it is called, or between close relationships, is decidedly pernicious, and should by all means be avoided.

The season for mares is about February and March, but in some cases it continues later; and the term of gestation is generally over eleven months. The foal remains with the mother till weaned, which takes place earlier or later according to the quantity of milk, the strength of the animals, and the season of the year. On removal, it requires to be carefully attended to, and provided with soft nourishing diet.

The operation of cutting is seldom performed on thorough-bred colts, but with all others it is common. It is an operation which ought by all means to be left to the veterinary surgeon or skilful farrier. The best authorities recommend it to take place with young cart-horses when four or five months old, but if for carriage or light work, it may very properly be postponed till the animal is twelve months old. The use of the operation is to render the horse more submissive than if left in an entire state, and to devote him altogether to the work he is required to perform. The advantages, whatever they are, it may be supposed are in some measure lessened by the lowering of spirit. The practice, however, is universally recognised in England as one indispensable where great numbers of horses are congregated, and required to be kept in good condition.

Breaking, or reducing the young animal into obedience, is a most important point in the education of the horse. If previously accustomed to handling, the difficulty of breaking will be much lessened. Racing colts are now begun to be broken at one year old, and saddle colts at two years, and are finally and fully broken and trained, some at three, and few later than four years old. Breaking horses is a regular business, and is best left to the person who is well accustomed to it, provided he follow a judicious course of treatment. As in the training of children, gentleness yet firmness ought to be a prevailing principle of management. The chief apparatus of breaking is a powerful bridle or head tackle, with boots or pads strapped on the legs, to prevent them knocking against each other.

The young horse is to a certain extent trained before his back is mounted, all the preliminary part of the process of subduing being accomplished while he is led by the bitted tackle. His back is not to be mounted till he is evidently able to endure the load without injury to his figure; too early mounting is apt to make him hollow-backed for life. In putting on a saddle for the first time, great caution should be taken; let the girths be drawn loosely, the crupper smooth, and keep the stirrups from dangling. In short, the animal requires on this trying occasion to be treated with as much kindness as it is possible to employ.

Having, by the various means which are adopted, brought the animal into subjection, and in effect taught him that he must in future act the part of a dutiful servant to an indulgent but firm master, the next step is to teach him his paces. These are partly artificial. Commence with slow and regular walking, whenever he is inclined to bolt, bringing him back to the steady pace you desire. After he has been accustomed to slow paces on a methodic plan, go on to the slow trot, then the quick trot, and lastly the canter and gallop. By no means allow him to mix these paces, that is, half-canter and half-trot, which would be an ungainly hobble; but let him know that he must for the time being keep to one kind of pace. The skill of the breaker consists in enforcing these lessons, and teaching the animal to change readily and neatly from one pace to another, by little more intimation than a twitch of the rein. Lawrence recommends that "a graceful canter should be encouraged, commencing with the proper or off-leg foremost, and the nag accustomed to be pulled up from the canter to the trot without unseemly and unpleasant blundering. The lessons should not be too long or fatiguing, but the young animal kept in as cheerful and easy a state as possible." The first shoeing ought to be performed with great care, so as to alarm the animal as little as possible.*

The Teeth—Age.

The horse attains maturity at five years old, and he is in his prime till eight or nine. If no unfair play be used, his age may be judged of from his teeth, or, as it is called, *mark of mouth*. We shall give a short account of this part of the animal's economy.

At five years old, when the teeth have been fully developed, the horse possesses six teeth in the front of each jaw, called the incisors or *nippers*; it is with these teeth that he bites. At a short distance from each end of the row of incisors, and in each jaw, there is a solitary canine tooth; these canine teeth are technically named *tushes*. At a greater distance inward in each jaw, and on each side, there are six grinders—the whole apparatus being designed to bite or crop the herbage, to tear and to chew. At five and a half years old, the nippers are marked by a natural cavity formed in the substance between the outer and inner walls, and it is the presence or absence of these darkish marks that certifies the age of the animal. When the horse reaches six years, the marks in the two front nippers in the nether jaw are filled up, and the tushes are blunted. At seven years the two nippers next the middle ones are also filled up; at eight, the two outer ones are filled up also, and the tushes are round and shortened. The lower nipper teeth are now all smooth; the marks are gone; but in the teeth of the upper jaw marks remain a year or two longer. At eight years the disgraceful practice of *Bishoping*—a term given from the name of the inventor—is often resorted to, for the purpose of imitating the obliterated marks. An engraving tool is employed to cut the surface, and a hot iron is then applied to give a permanent dark stain. This infamous trick may impose on the ignorant; but a person skilled in horses can easily detect the imposition, from the stains being diffused around the marks, and other appearances.

As a horse, if well treated, remains in excellent working condition till twelve and even later, the disappearance of the marks on the teeth is often of little consequence. Some horses are as valuable to their owners at fifteen years as they are at eight; and for ordinary saddle-work, ten or twelve may be considered an age sufficiently young. It is important, however, that the teeth are capable of mastication; for if the animal is unable to chew his food properly, he cannot be kept in good condition, or fit for the performance of his duties. In consequence of the very general abuse of horses, few live till twenty-five years old, and the instances of any living till above thirty are rare.

Terms applied to Horses.

Horsemen employ terms to horses which are not strictly adhered to in ordinary language. A male horse left uncut is said to be an *entire horse*, to distinguish it from the *gelding*, or cut animal. A female horse is always spoken

* In connection with the breeding of horses, we may say a few words respecting *mules*, or the hybrid offspring of the horse and ass. The mule-proper is the produce of a male-ass and mare; when the parents are the horse and she-ass, the produce is called a *hinny*. The mule is the superior animal, partaking to a larger degree in the qualities of the horse; it is more robust, plump, and hardy, and better adapted for all the ordinary purposes of riding and draught. The hinny is more thinly made, has a longer head, and is altogether more like the ass than the horse. Mules of both kinds live to a very old age, and when properly trained, they are tractable and very serviceable animals. There are comparatively few mules in Britain; but in Spain, and some other countries of southern Europe, also in Spanish America, they are numerous, and are used in carriages of people of the highest rank. According to a well-known principle in natural economy, by which intermixture of kindred species is not allowed to go beyond a single step, and only for one generation, mules do not breed; and the stock requires to be kept up by a recurrence to the common parentage.

of as a *mare*. A young male horse is called a *colt*, and a young female a *filly*. *Thorough-bred*, as already noticed, is applied only to horses (we include mares, of course) whose pedigree can be traced to an Arabian origin, without stain or any common intermixture. When the pedigree of the racer is to a certain degree stained, the animal is called a *cocktail*. The term *blood* is of more loose signification, but what is generally understood by it is a horse which is thorough-bred, or of the blood of the Arabian, and consequently shows a fine spirit and action. A horse may be half-bred, three parts bred, and so on, according to his pedigree. The half-bred is produced from a racer and a common mare. Some of the best riding-horses are of this stamp. The term *welter horse* is applied to racers who are able to carry the highest weight.

Horses are measured by hands, four inches being reckoned to the hand; the measure is taken at the fore leg and shoulder. To all the more prominent parts of the body and members certain technical names are applied; for example, to take the fore extremities first, the *muzzle* includes the lips, mouth, and nostrils; the *withers* are the sharp protuberance over the shoulders between the back and neck; the breast is the *counter*; the *arm* is the upper part of the fore-leg, but enveloped in the muscle of the shoulder; beneath it is the *fore-arm*, which is the higher part of the visible leg, and extends downward to the *knee*; below the knee we have another stretch called the *shank*, which extends to the *pastern*, or, as we might call it, the ankle; the *fetlock* is behind the pastern; beneath are the feet. A few of the hinder extremities are named as follow: the *croup*, which extends from the loins to the root of the tail or rump; the *flank*, extending from the ribs to the haunches; and the *leg* or thigh, which reaches down to the *hock* or middle joint of the hind leg, corresponding to the knee in the fore-leg. The left side of a horse is called his *near* side; and his right the *off* side.

The greater number of British horses are of a dark colour, inclining to black or brown, but of innumerable shades. One kind of brown is called bay, and another the chestnut; a yellowish chestnut is termed the sorrel. The roan is a blending of red and whitish tones. The gray is a mixture of white and black hairs, and in old age becomes altogether white. The dark colours are the most esteemed for their physical qualities, and patches of white on the legs are considered defects or foul markings.

STABLE MANAGEMENT.

The horse, as has been already mentioned, possesses very delicate senses, and is nice in its habits, in which respect it differs very materially from black cattle. In a state of nature, the animal seems to be best adapted for a mild and genial climate, and to rejoice in freedom and space. When reduced to domestication, as it is with us, care should be taken to violate as little as possible its natural tastes and habits. Its delicacy of constitution, augmented in no small degree by an artificial mode of life, should warrant the best attentions of its keepers; and whatever be the nature of its work, it should be treated with kindness, regularly fed, and supplied with pure water, allowed a cleanly and well-ventilated habitation, and its body and limbs preserved free from dirt and all offensive matter that may cling to them. The leading features of management may be defined as follows:—

The Stable.

The stable varies in size, according to the number of horses kept. Of whatever dimensions, the situation should be dry and airy; if in any respect damp or fœtid, the animals will assuredly contract disease. When the stable is calculated to contain many horses, it is seldom regular in temperature, from the fluctuation of numbers in it at any one time. To avoid this defect, the best size, in ordinary circumstances, is that which will accommodate six or eight horses, leaving plenty of room to each.

A stable with a row of stalls only on one side, is better than one with double rows; if double, the space between should not be less than eight or ten feet wide. Sixteen feet is a proper width for a stable with a single row, six of the feet being allowed for the depth of the stalls; each stall should also be six feet wide, but commonly five and a half are only given. The floor of the stalls should be neatly paved, slope very little from head to feet, and be bounded by a gutter, with gratings to carry off all liquid refuse. The gangway, or space beyond the stalls, should be also paved in a neat manner; and care ought to be taken that rats are effectually excluded from the walls or any part of the flooring. The stalls should be lined with smooth wood. The stable should have only one door, and that not opposite a stall; it ought to be at least four and a half or five feet wide, and eight feet high. A pinchedness in any of these details is far from economical.

The inner walls of stables are often kept shamefully dirty. They ought by all means to be well whitewashed, at regular intervals, in order to extinguish vermin and wipe off impurities. The interior ought to be well lighted with windows, which should be kept clean, and never permitted to remain in a broken condition. A little carelessness in this respect may occasion the loss of a horse; for broken windows in stables are about as dangerous to the health of the inmates as broken windows in a dwelling-house.

When we say that the stable should be well lighted, we certainly oppose one of the most vulgar prejudices respecting horse management. In most instances, stables are kept as dark as dungeons, greatly to the injury and discomfort of the inmates. It is impossible to understand what can be rationally designed by keeping horses standing during their waking hours in the dark. Nature never intended any thing of the kind; and we say the practice should be abolished. Mr Stewart pleads as warmly as we do on this point. "A horse was never known to thrive better for being kept in a dark stable. The dealer may hide his horse in darkness: and perhaps he may believe that they fatten sooner there than in the light of day. But he might as well tell the truth at once, and say that he wants to keep them out of sight till they are ready for the market. When a horse is brought from a dark stable to the open air, he sees very indistinctly; he stares about him, and carries his head high, and he steps high. Dark stables may thus suit the purposes of dealers, but they are certainly not the most suitable for horses. They are said to injure the eyes. There is not perhaps an animal so liable to blindness as the horse. It cannot be said that darkness is the cause; but it is well known that the eyes suffer most frequently where there is no light. Whether a dark stable be pernicious to the eyes or not, it is always a bad stable. It has too many invisible holes and corners about it ever to be thoroughly cleaned. All these things considered, it is evident that the stable ought to be well lighted." The preferable plan of lighting is by skylights, made to open when required for the sake of improving the ventilation.

Hay-loft and Racks.

The hay-loft, or place of deposit for hay, ought not, as is usually the case, to be over the stable, but adjacent; and a chamber, level with the floor of the stable, is preferable. The reason for this is, that the hay may be preserved free from the breath of the animals and effluvia which rises from the stalls. Lawrence strongly opposes the use of hay-lofts over stables:—"According to the good old and present custom, it is the receptacle of all kinds of impurities as well as hay · the excrement of cats and mice, and exuviæ of spiders, and the accumulated and sacred dust of perhaps half a century. Add to these trifles the perpetually ascending clouds of steam from the stabling below, contaminating, drying, and exhausting the hay of its fragrance, and of every pure and beneficial quality. Hay should remain in the stack, in order to have it in its utmost fragrance and moisture of quality, to be cut often, and taken fresh to the horses, there being a clean and cool hay-room, near the stable, to contain small quantities. The gangway and walls of the stable should be perfectly clear of all encumbrances of chests, pails, brooms, shelves, saddles, or lumber of any kind, for which extra rooms are the proper place." In cases where haylofts are used, let them be kept as clean as possible, and allow no opening to the racks. The hay must be brought down in small quantities and placed in the racks.

Hay-racks of the best material and form are made of iron, the bars rounded, and two inches from each other. The rack need not traverse the whole breadth of the stall, because in such a plan rubbish collects in the corners. A size to hold from a half to a whole stone of hay, will be sufficient in most instances: and the form should be that of a convex or bulged grating from the wall, placed a little above the head of the horse. A rack of this or any other shape cannot be kept too clean; the bars should be daily rubbed, and all old bits of hay removed.

Mangers.

The manger, from which the corn and other kinds of food are eaten, is also best made of cast-iron, and need not be larger than a foot in length and breadth, and about nine inches deep. The old-fashioned wooden mangers, traversing the extremity of the stall, are absurdly large, and as they sometimes are splintered, they injure the animal when feeding or at rest. The form and dimensions of the manger, however, are of much less importance than being kept in a high state of cleanliness. All horses are nice feeders, but some are more fastidious than others, and will not partake of food from a foul manger, or one even which has been blown upon. Let the groom, therefore, keep his horse's manger as clean as he would do his own dish, and at all events do not allow it to get dusty or out of order.

The manger is only for dry food. Some attentive stable-keepers also provide a manger for water, and this seems to be highly judicious. Drinking from pails is a slovenly practice, independently of its being inefficacious. It is now allowed that horses, when stalled, should have a little fresh water beside them to drink, if they feel the desire to do so; and it may be doubted if any horse will drink whose nature does not need this refreshment. Be this as it may, a good plan is to have in one corner at the head of the stall, an iron manger, shaped like that for corn, and into which pure water can be made to flow from a pipe when the groom thinks proper. A waste pipe beneath should be provided to run off the water which is left, or which becomes impure from the dropping of particles of matter from the animal's mouth. A little consideration will point out how this very convenient arrangement can be accomplished.

Bedding.

The good horse sleeps in a lying posture, his legs being partly drawn under him, and his head remaining up. A horse that habitually sleeps standing, or will not lie down at night, is usually reckoned to be of little value; for it is indispensable to doing his duty during the day that he rests well at night. The preparation of a bed for the animal, ought to be one of the most pleasing parts of a stable-keeper's duty; and he should perform it well. The best bed is made of wheat-straw, but when that is dear, or cannot be got, the straw of oats may suit the purpose. The more even and less rumpled the litter, the better. The bed should be made level, or sloping slightly from the sides and head towards the centre, and be completely free of hard lumps. All ought to be smooth, clean, soft, and the depth of litter perhaps seven or eight inches.

Every morning the soiled litter is to be taken away to the dung-yard, and the clean portion separated and placed at the head of the stall, or in some other convenient situation, ready to be employed again at night. It is disgraceful niggardliness to bed horses with foul litter, or to stint them of what is required for their comfort, and seldom fails to bring its own punishment in the injured health and appearance of the animal.

Ventilation—Cleaning.

Ventilation, or a means for the provision of fresh air, is of the first importance in the economy of the stable. Small apertures at different places should be made in the walls, to allow the entrance of pure air, and the escape of such as has been vitiated. A better plan for the removal of the foul air, especially from stables in which a number of horses are kept, would consist in leading it away in a tube from the roof to the flue of a fire. (See our article VENTILATION.) Architects, generally, do not make any provision of this nature in stables, and as few stable-keepers think of instituting such an effectual process of ventilation, we can only here state, as a general principle, that means of some kind should be adopted to keep the atmosphere of the stable in an equable temperature, and as pure as possible, both night and day. We invite attention to the following observation on this point by an intelligent writer:—

"If the stable is close, the air will not only be hot, but foul. The breathing of every animal contaminates it: and when, in the course of the night, with every aperture, even the key-hole, stopped, it passes again and again through the lungs, the blood cannot undergo its proper and healthy change; digestion cannot be so perfectly performed, and all the functions of life are injured. Let the owner of the valuable horse think of his passing twenty or twenty-two out of the twenty-four hours in this debilitating atmosphere. Nature does wonders in enabling every animal to accommodate itself to the situation in which it is placed, and the horse that lives in the stable-oven suffers less from it than would scarcely be conceived possible; but he does not and cannot possess the power and the hardihood which he would acquire under other circumstances. The air of the improperly close stable is still further contaminated by the urine and dung, which rapidly ferment in the heat, and give out stimulating and unwholesome vapours. When a person first enters an ill-managed stable, and especially early in the morning, he is annoyed not only by the heat of the confined air, but by a pungent smell, resembling hartshorn; and can he wonder at the inflammation of the eyes, and the chronic cough, and the inflammation of the lungs, with which the animal, who has been shut up in this vitiated atmosphere all night, is often attacked, or if glanders and farcy should occasionally break out in such stables? It has been ascertained by chemical experiment, that the urine of the horse contains in it an exceedingly large quantity of hartshorn, and not only so, but that, influenced by the heat of a crowded stable, and possibly by other decompositions that are going forward at the same time, this ammoniacal vapour begins to be rapidly given out almost immediately after the urine is voided. When disease begins to appear among the inhabitants of these ill ventilated places, is it wonderful that it should rapidly spread among them, and that the plague-spot should be, as it were, placed on the door of such a stable?

When distemper appears in spring or in autumn, it is in very many cases to be traced first of all to such a pest-house. The horses belonging to a small establishment, and rationally treated, have it comparatively seldom, or have it lightly; but among the inmates of a crowded stable, it is sure to display itself, and there it is most of all fatal. The experience of every veterinary surgeon, and of every large proprietor of horses, will corroborate this statement."—(*Library of Useful Knowledge.*)

The more cleanly the stable is kept, the more easily will it be ventilated. Stables are in general kept in a most offensively foul condition. In the first place, they are often ill-paved, and the refuse of the animals getting imbedded in the interstices of the stones of the stall and gutter, keeps up a constant exhalation. Then there is no proper provision for disposing of the foul litter and urine. It is customary to rake out the used litter and other impurities to a dung-heap immediately outside the door, and there it steams and loses its value, besides being a nuisance to passengers. Instead of this bad economy, let all be raked or shovelled out to a dung-pit covered in from the outer atmosphere, so that every particle of the ammoniacal gases may be preserved. Into this pit, let a smooth channel from the stalls convey rapidly and effectually all liquid refuse. Any man who willingly allows the liquid manures of his stable to run to waste, may with great justice be said to be daily picking his own pocket. Should the gaseous odour be intense, and the quantity of litter in the heap incapable of absorbing it, add now and then a spadeful of earth or any absorbent material that will decompose.

The stable should be clean swept, brushed, and thoroughly ventilated, every morning, leaving impurities neither on the ground nor in the atmosphere. Good feeding and regular exercise may partly neutralize the effects of uncleanliness; but in the event of epidemical influenza, glanders, and other diseases, these effects become sadly manifest; and then, as Mr. Stewart humanely observes, "the proprietor begins to look about him. It is time for him to know that God has not given him absolute and unconditional control over his fellow tenants of the earth. Oppression has wide dominions, but there are limits which cannot be passed; and death reveals the operation of a wise and beneficent law."

Stable Furniture—Stablemen.

Every stable is to be provided with proper receptacles for hay and straw. The oats, peas, beans, bran, &c., should be kept in one large chest with divisions, or separate chests, and if possible be placed in an apartment separate from the stable. For small stables an adjoining room should be fitted up neatly for the accommodation of the corn chest, the saddles, and other apparatus; all saddles, bridles, and small articles being properly hung on hooks on the wall, or placed on other appropriate supports. A cupboard for combs, brushes, &c., will be an advantage. If the stable be not supplied with water in pipes, a well should be at hand.

Horses require to be under the charge of persons who understand the business of attending to them in all their varied wants. Some persons seem to imagine that any boy or lad will do for taking care of a horse. This is both inhumane and bad policy. Where only one horse is kept, a steady lad, under the directions of his master and instructed in the line of his duty, will often be found sufficient; but he requires constant looking after, for all young persons, and some old ones too, are disposed to play pranks with horses, and rob them of their food. The ordinary class of ostlers are not regularly instructed in the qualities and wants of the horse. All they know is empirical, and their prejudices are frequently absurd. Let all such persons, therefore, be estimated at their just value; and on committing your horse to any of them at an inn, see that he does his duty both as respects cleaning and feeding. A kind master always sees that his horse gets its proper measure of corn, and stands by till he eats it.

In stables in which two or more horses are kept, a regular groom should be employed; and this person should reside close by the stable, so as to be always at hand. The qualifications of a groom ought to be steadiness of conduct, promptitude in a case of difficulty, openness to advice or instructions, experience in well-managed stables, taste for cleanliness: and he should be as desirous of making his charge comfortable as he would be of his own person.

In large establishments, there are head and under-grooms, strappers, and stable-boys—the latter a kind of loose appendages to the concern, who act as drudges to the superior officers, and look forward to promotion. In establishments of moderate size, the groom and driver or coachman, are the only functionaries. It is the duty of the groom to attend to the horses in every particular, when in or about the stable, and when taking exercise. The duty of the driver is more particularly to keep the chaise or other vehicle clean, and also to clean the harness.

If all horses were good-tempered, or rendered docile by kind treatment, they might be advantageously left at liberty in their stalls; circumstances, however, require that they should be restrained; but this should be done with as little pain to them as possible. The halter or rein from the head gear should be led to a ring at the head of the stall, leaving the animal at liberty to lie down in an easy posture. The rein, whether of rope or chain, should not be tied to the ring. It should go through the ring, and drop down with a plummet at the extremity to keep it down, yet allowing the animal to pull it up or allow it to sink at pleasure. A shorter halter may be employed during the day than at night, so as to keep him from straggling backwards into the passage or gangway.

Some horses are most restive in restraint, and commit tricks to loosen themselves; and others, by awkwardness of movement, get *cast*, that is, benumbed or cramped, when lying; and it is necessary to employ skill and force to raise them to their feet. A soft bed and abundance of room are the best preventives for this kind of accident.

Grooming—Dressing.

The skins of horses are liable to become clogged with a scurf of dried perspiration, along with particles of dust and mud, which collect and lodge among the hairs. It is of great importance to remove these impurities by currying and brushing, for the sake of the health of the animal, independently of the value of the operation as respects the appearance of his coat. The degree to which this species of grooming is carried, will of course very much depend on circumstances; but, as a general rule, it should take place every morning before the horse is led forth to the labour of the day.

The grooming is commenced while the animal is in his stall, his wrapping-cloth, if he have one, being removed, and the restraining rein being lengthened, to allow his standing a little back into the gangway. If restive, his head must be tied up. All refuse having been previously removed, a little of his bedding may be drawn out for his hind-feet to stand upon. The first thing done is to curry him with a curry-comb—a flat iron instrument, with rows of short blunted teeth and a handle; by being drawn along the surface of the body and limbs, it rakes up the lumps of hair, and generally loosens and brings up all extraneous substances. The groom commences with the neck and shoulders; next he goes to the body, hinder quarters, belly, and legs, both sides being treated alike. The curry-comb must not in any case be used roughly, and with thin-skinned horses its application must be very gentle. If the horse be regularly groomed, and its work not dirty, a gentle scrubbing with the curry-comb will in most cases suffice. In performing the operation, a brush may be held in the other hand, with which to clear out the teeth when necessary. After the curry-comb has gone its rounds, apply the brush in turn, going over the whole surface with it, from head to heels, to remove all raised impurities, and to lay the coat smooth. Lately, a rough hair-glove has been introduced into use as an improvement upon the brush; and it certainly possesses the advantage of being more easily applied to nooks and corners than the brush. Should the horse be changing his coat, which he does twice a year, the curry-comb must not be used at all; a rubbing with a straw-wisp being perhaps sufficient.

After the currying and brushing, the groom proceeds to comb the fore-lock, mane, and tail, so as to make all the hairs lie straight. This finishes the grooming, but if the legs or feet be white, they will perhaps require washing with warm water and soap, to prevent the growth of a yellow appearance, and then dried with a wisp. We have only to add, that if horses are not groomed regularly in this manner, they will inevitably lose their health, or be troubled with parasitical animals lodging beneath the hairs; and never have a glossy and cheerful appearance. Some horses have a great repugnance to being groomed, but this generally arises from harsh treatment while they were young: if treated considerately, they will feel pleased with the friction, and grateful for the attention bestowed on them.

The cleaning of a horse after work is as necessary as the morning grooming. When a horse is brought to the stable in a state of perspiration, it should not be taken in to be at rest all at once, but be walked gently about till it becomes moderately cool. This allows the excitement of the blood-vessels and muscles to be allayed gradually, and prevents any sudden stoppage of the pores of the skin. To assist in drying and cooling down the animal, he may be scraped or rubbed with wisps. Wisping is preferable.

After the horse has been walked and wisped, his legs and feet should be washed with water and a brush or sponge, and also his belly, if it be dirty with sparks of mud; but after any such washing, every part should be thoroughly dried with a fresh wisp. Never leave a horse with wet legs or feet. In the country, it is not unusual to walk horses into a river to wash their legs—a practice most detrimental to their health, and which should not be allowed.

When the horse has been cleaned and dried, the cloth may be thrown over him, and tied to his stall. The cloth used in summer should be more light than that used for winter. It is customary for grooms to exercise horses with the stable-cloths wrapped round them, and then, perhaps, the next hour they are taken out saddled, and without any cloth at all. This seems an inconsistency. The use of cloths is to protect the animal's loins from cold, and is unnecessary in fine weather. If the horse has to stand still out of doors, and the weather be ungenial, his loins ought by all means to be protected by an oiled cloth, to keep out wet. The horse is very susceptible of injury by exposure of the loins; and it will be observed that, to shelter that part, cavalry soldiers wear a long riding-cloak, which falls loosely over the hinder part of the animal.

Trimming.

Nature gives the horse a beautiful flowing tail and mane, for the purpose of whisking off flies and for other uses; but mankind, in taking the creature under their protection, have, in many instances, and for no good reason as far as we are aware, deprived it of these graceful personal appendages. The most contemptible piece of this rash interference has been the docking of the tail, and causing it to cock up, thus leaving the rear of the animal exposed. The tail should be left flowing to a point, and only trimmed to a limited extent; and the same thing may be said of the mane. Nature has likewise given the animal long hairs on the legs independently of the fetlocks. These various appendages have likewise not been given unnecessarily; they answer as a kind of thatch to carry off the moisture which trickles down the legs, so as to keep the feet dry and the legs warm. These parts, therefore, should be trimmed sparingly, and the fouler the work, the more should be left on. Any trimming should be executed tastefully with a comb and pair of scissors. It is customary to clip away the long hairs about the ears and muzzle, but this also must be performed with great discretion. These hairs have their uses, those about the ears in particular, and harm may be done by their removal.

Management of the Feet.

When the horse has been stabled for the night, it will be the duty of the groom to see that the hoofs, above and below, have been cleaned, particles of sand removed from the crevices of the shoes, and the feet generally in a good condition. The feet have a tendency to harden and crack, and thus a good horse may become lame. The fore feet are most liable to this serious evil. To prevent hardness and soreness of feet, it is customary to stop them at night with a soft moist material, most commonly pieces of horse-dung, which is crammed into the sole. No special directions on this point can be given; for some thin-soled horses do not require stopping, and the hind feet are seldom in need of any thing of the kind. When the frog is liable to thrush, the feet require to be kept dry, and cleaned and attended to with peculiar care. To prevent over-dryness of hoofs, as well as to prevent the undue action of moisture, it is advisable to anoint the horny part of the feet with an ointment made of tar, fish-oil, and bees-wax, melted together in equal proportions; but this should not be done unless it is absolutely required. If well washed and kept clean, the feet will seldom require any of this kind of varnishing.

When at large in a wild state, horses, as may be supposed, go barefooted like all the other lower animals. The hoofs grow with a slight curve up in front, but this does not seem to impair their speed. If domesticated horses were always to walk on turf, and not be obliged to carry or draw a weight, their feet might remain unshod; but the circumstances of their condition make it necessary to protect the hoofs from tear and wear by means of shoes. Horse-shoes have been used of many different shapes and materials; but it is needless here to speak of any others than the iron shoes in common use. The shoe must be of weight conformable to the powers and uses of the animal, but exactly to suit the curve of the hoof, flat and of equal thickness, and be secured by nails to the hoof. The proper paring of the hoof before shoeing, and the shoeing itself, are matters to be left to the discretion of regular farriers. As a general principle, care must be taken not to drive the nails into any tender part, and the hoof should be as little broken as possible. A gentleman's horse should be shod at regular intervals, and a shoe never suffered to come off from too long usage.

Exercise.

Every horse ought to be exercised daily in the open air. The exercise should be in the early part of the day: when not exercised by work, he must be walked out and trotted on purpose. An authority already quoted observes:—"The horse that, with the usual stable feeding, stands idle for three or four days, as is the case in many establishments must suffer. He is disposed to fever, or to grease, or, most of all, to diseases of the foot; and if, after these three or four days of inactivity, he is ridden fast and far, is almost sure to have inflammation of the lungs or of the feet. A gentleman or tradesman's horse suffers a great deal more from idleness than he does from work. A stable-fed horse should have two hours' exercise every day, if he is to be kept free from disease. Nothing of extraordinary or even of ordinary labour can be effected on the road or in the field without sufficient and regular exercise. It is this alone which can give energy to the system, or develop the powers of any animal. In training the hunter and the race-horse, regular exercise is the most important of all considerations, however it may be forgotten in the usual management of the stable. The exercised horse will discharge his task, and sometimes a severe one, with ease and pleasure, while the idle and neglected one will be fatigued ere half his labour be accomplished, and if he be pushed a little too far, dangerous inflammation will ensue. How often, nevertheless, does it happen, that the horse which has stood inactive in the stable three or four days, is ridden or driven thirty or forty miles in the course of a single day? This rest is often purposely given to prepare for extra-exertion—to lay in a stock of strength for the performance of the task required of him; and then the owner is surprised and dissatisfied if the animal is fairly knocked up, or, possibly, becomes seriously ill. Nothing is so common or so preposterous as for a person to buy a horse from a dealer's stable, where he has been idly fattening for sale many a day, and immediately to give him a long run after the hounds, and complain bitterly, and think that he has been imposed upon, if the animal is exhausted before the end of the chase, or is compelled to be led home suffering from violent inflammation. Regular and gradually increasing exercise would have made the same horse appear a treasure to his owner. Exercise should be somewhat proportioned to the age of the horse. A young horse requires more than an old one. Nature has given to young animals of every kind a disposition to activity; but the exercise must not be violent. A great deal depends upon the manner in which it is given. To preserve the temper, and to promote health, it should be moderate, at least at the beginning and the termination. The rapid trot, or even the gallop, may be resorted to in the middle of the exercise, but the horse must be brought in cool. If the owner would seldom intrust his horse to boys, and would insist on the exercise being taken within sight or in the neighborhood of his residence, many an accident and irreparable injury would be avoided. It should be the owner's pleasure, and is his interest, personally to attend to all these things."—(*Lib. Use. Know.*)

Watering and Feeding.

A horse should be exercised a little after being watered. He should on no account be allowed to drink when heated, particularly if heated to the extent of perspiring. The only refreshment allowed in these circumstances is a rinsing of the mouth, and the muzzle may be washed and relieved of froth. When not permitted to take water of his own accord in the stall, let him be offered a pail three or four times a day; and after drinking copiously at either a pail or pond, he may be trotted or gently cantered, the motion being generative of heat, and at least prevents any chill.

Horses are fed on different materials in different countries; but principally on the various kinds of grasses and cereal grains. The Germans give them feeds of brown bread while on [illegible]; in India, rice and spices are employed for their [illegible]; in England, the chief articles of food are oats and hay, with inferior proportions of beans, peas, cut straw, and bran. The quantity and also the nature of the food will depend on the habits of the animal, and the work to which he is put. If the work be hard, he must be fed to a considerable extent on oats, which are more nutritious than most other articles in use; but if the work be light, a lighter diet of hay, with perhaps only a small quantity of oats, will suffice. The stomach of the horse being small, he cannot eat much at a time; and it is always preferable to feed him often, and at regular intervals, than to offer him large feeds at irregular periods. There is another reason for offering small feeds; the horse nauseates food which he has blown upon or previously touched, and will accordingly reject it if offered a second time, or allowed to stand beside him. For various reasons, therefore, it is better to give him only a little at a time, so as to leave none behind. If the animal be a poor feeder, or apt to waste his food, the more care must be taken in this respect.

Oats ought to be sound, old, and dry. If musty, reject them. In almost all cases it is preferable to have them bruised; for by this they are more easily digested and nourishing than if left whole. It is now customary to mix oats with chaff composed of the cuttings of clover or meadow hay, and the straw of wheat, oats, or barley. In some stables a machine is kept to cut these materials. The length of the cuttings should be about half an inch. Bruised oats have a tendency to scour the animal; but the infusion of chaff counteracts this quality.

Of hay, clover, and meadow hay, little need be said. They should be sound and sweet-flavoured, without any mustiness. The hay should, if possible, be a year old, and well saved for use in an adjacent stack. Some horses are fond of peas; but they require to be given with caution, as they are apt to swell in the stomach. Almost all horses are inordinately fond of carrots, which, when administered in small quantities do not purge the animal, and improve his coat. A respectable authority states, that "for agricultural and cart-horses, eight pounds of oats and two of beans should be added to every twenty pounds of chaff; and thirty-four or thirty-six pounds of the mixture will be sufficient for any moderate-sized horse [daily] with fair or even hard work." In this estimate, no hay is supposed to be given. When the horse is fed on the last two articles, hay and oats, four feeds, or nine or ten pounds of oats per day, will be a fair allowance, during winter, and in the case of moderate work; but, in summer, half the quantity, along with a proportion of green herbage, will suffice. Many gentlemen follow a general rule of allowing twelve pounds of oats per day to each riding-horse, and this is given in three or four meals. A pony, having but moderate work, will be well fed on six pounds of oats per day, with a fair proportion of hay. Latterly, sago has come into use as an article of horse diet; and we believe it is highly nutritive, and may be employed to a certain extent to supersede oats, or to be mixed with them. It should be partially softened by preparation.

Several serious diseases arise from improper feeding, particularly at intervals during hard labour; and on this point we refer to our observations on

THE DISEASES OF HORSES.

In consequence of the general mismanagement and ill treatment of horses, they are exposed to a number of formidable diseases. Those of most frequent occurrence are glanders, inflammation of the lungs, broken-wind, inflammation of the bowels, and certain illnesses of the feet and legs. Referring our readers to larger works on the Horse for full information on these diseases, and recommending all unskilled persons at once to hand over their horse to a veterinary surgeon when unwell, we propose only to give a few hints as to the best means of prevention. The institution of schools of veterinary surgery, at which the anatomy, peculiar nature, and diseases of horses are explained by men skilled in this important department of science, has been of great use in improving the qualities of horses, preserving their lives, and saving them from much needless distress.

Glanders.

This is a disease of the nose, in some measure resembling the effects of a cold. It is believed to be occasioned by breathing vitiated air, and takes the form of an irritation of the delicate membranes of the nostrils, accompanied by an offensive discharge. Glanders is highly infectious, and may be communicated hereditarily. When not removed in time, it will perhaps terminate in farcy, a disease of the veins, which causes swellings called farcy-buds. The preventive of either of these dangerous maladies, is cleanliness in the stable and pure ventilation.

Inflammation.

The more ordinary inflammation is that of the lungs, and is caused by sudden changes of temperature; it is in reality the grand disorder of the horse, and its effects are only paralleled by those of pulmonary consumption in the human species. Already we have spoken of the great impropriety of exposing horses, while heated, to cold draughts. Allowing them to stand any length of time in the open air, in cold or moist weather, is equally objectionable, and positively cruel. No gentleman having proper regard for the health of his horses, or for his own pocket, will permit his horses to stand waiting in the street at night; and many in London, rather than do so, make a practice of not employing their own carriage late in the evening, and procure a hackney-coach instead. Inflammation of the lungs, however, will arise from various causes besides cold, and these have engaged the most serious attention of veterinarians. Some time ago, the Highland Society of Scotland offered a premium for the best essay on the *inflammatory complaints generally* of farm-horses, and the prize was awarded to Mr. Matthew M. Milburn, Thorpfield, near Thirsk, Yorkshire, whose paper appeared in one of the numbers of the Quarterly Journal of Agriculture. Some of the parts of the essay appear to us so worthy of being made known to persons who have the management of horses, that we take the liberty of giving them publicly in our pages.

After showing that there is not any particular predisposition to disease in the breeds of horses usually employed in heavy draught, nor in the particular conformation of the animals, Mr. Milburn proceeds to say, that "The post-horse, and such as are required to perform fast work, are more liable to attacks of diseases of the brain, the nerves, and the lungs, simply because their work consists of rapid and powerful exertion; the farm-horse, the animal of long and steady exertion, to gripes, inflammation of the bowels, and stomach-staggers—results, as I shall presently show, of a management unsuited to the character of the labour we require from them. The stomach of the horse is remarkably small—smaller in proportion to his size, and the quantity of food he requires, than any other domestic animal. Nature intends for him a supply of nutritious food, and that *at short intervals;* wherein he materially differs from the ox, whose capacious stomach will contain food which will not be digested for hours. The post-horse, the hunter, and the carriage-horse, have food of the most nutritious description and the time during which they are worked is necessarily short, owing to the extreme exertion required; they return to their food; and although their appetite may for a time be impaired, and their stomach and bowels affected by the general debility of the system, yet they recover their tone as soon as the rest of the frame admits of their taking food. The farmer's horse, on the contrary, has food of a less nourishing nature; his rack is filled with straw, or at best with clover; the ploughman rises early, gives him a feed of corn, and leads him to his work, where he continues for seven, eight, and even nine hours, and his whole day's work is completed before he is allowed to eat. We do not find the ox, worked under similar circumstances, so affected in the stomach and bowels, simply because his capacious stomach, when filled, requires many hours to empty, while, as we have seen, it is different with the horse. Debilitated and hungry, the horse returns, and his rack is plentifully supplied, and a good feed of corn given him, and he is left to himself; he eats voraciously, half masticates his food, loads his debilitated stomach, and his digestive organs are weakened, and permanently injured. This course is repeated—a habit of voracity is acquired, and at no very remote period the food lodges and obstructs the pyloric orifice (the passage from the stomach to the bowels), fermentation ensues, gas is evolved, the stomach is distended, he grows sluggish and sleepy, drops his head upon his manger; or he is delirious, and evinces that the sympathy which exists between the stomach and the brain has excited the latter organ; he rolls, paws, and is seized with convulsions; at length he expires, and he has died of stomach-staggers. The half-masticated food has irritated the bowels, extra exertion of the muscles has been required to propel the fæces to the rectum, and cholic or cramp (spasms) of the bowels has followed, or a course of continued irritation, or of continued cholic, or both, has ended in inflammation of the bowels. I remember a beautiful farm-horse, which, owing to the distance of part of the farm to which he belonged from the buildings, was worked the long hours described, and finished his day's work before his bait. He was constantly subject to attacks of the gripes, which were subdued; but he died of stomach-staggers. The same stable, then so often subject to diseases, is now, by a change in the system, completely free from them. Another case, however occurred; a beautiful compact little mare was constantly afflicted by cholic; she eventually died of inflammation of the intestines.

"There are other parts of the management to which horses employed in agriculture are subject, which induce diseases of the bowels. For instance, a boy returning from work, with heated and sweating horses, to save himself trouble, allows them to drink copiously at some pool or stream he passes. Suddenly one or more of the horses exhibit symptoms of gripes; they suddenly lie down, roll about, look at their sides, rise up, seem relieved, and again speedily relapse; the sudden application of the cold water has produced spasms in the bowels, through which it has passed. This is neglected, or perhaps gin or whisky, aided by pepper, is administered as a remedy, and severe and general inflammation of the bowels is the result; this is mistaken for another attack, and again the poison is administered and the inflammation increased, and death follows. The horse of heavy work, too, is longer exposed to the inclemencies of the weather than the animal of light work. In the former, the rain is allowed to fall upon him for hours, and it is allowed *to dry upon his back;* the sympathy between the skin and the alimentary organs is known to every groom; obstructed perspiration, and consequent irritability, is conveyed from the one to the other, and disease is the consequence. It is true, the latter is also partly exposed to the rain, but for shorter periods, and the wisp and brush are liberally applied when he enters the stable; a determination of blood takes place to the skin, perspiration is excited, and disease thus prevented.

"Of the best means of preventing these diseases in farm-horses, we will now treat. We have attributed the peculiar liability to them in farm-horses to mismanagement, with the exception of certain instances of peculiar formation of the animals; and although the farmer must necessarily work his horses longer hours than the horse of rapid work is capable, there is no necessity for depriving the animal so long of food. No horse should work more than five or six hours without a bait. If we examine the history of the stables of large farmers, whose fields necessarily lie at a great distance from the buildings, and where they are worked long in consequence, and compare it with that of small farmers, under the contrary circumstances, we shall find a striking difference as respects the health of the animals. The case referred to above, strikingly illustrates the truth of this observation. But it may be asked, how is it possible to bait the animals so far from home? The difficulty seems to be in procuring food upon the spot; for if this is not done, the precaution will be neglected, and, at any rate, the land will be occupied by it. This, however, may be remedied. In the case, for instance, of a field intended for turnips, which has to be worked during the spring, a part of it, half an acre, or in proportion to the size of the field, may be sown with winter-tares, a few of which may be mown off, and given to the animals green, without carrying them from the field, interfering with any crop, or wasting any time in carrying the horses to a distance. If the field be intended for summer fallow, the spring tare will answer, and which may be used in the same manner, instead of allowing the poor animals greedily and indiscriminately to crop the leaves of the hedges at every turning, from the impulse of hunger. There is another easy way of baiting which some carters adopt, and which might be applied to the farmer's horse, especially when carting. It consists in securing a bag, containing corn, over the animal's mouth and nose, by a string, which passes over the poll, and is locally denominated a 'nose-bag,' or 'horse-poke,' and which should be removed when he has finished his feed. To prevent the effects of the wet upon the skin, an unexpensive glazed cloth may be thrown over the horse's back, and secured to the collar and traces. This may by some be considered very troublesome, but it will be found, that when it is once begun, it will be considered no more trouble than carrying the rest of the harness, and if disease is prevented, the trouble amounts to nothing. To counteract as much as possible any habits of greedy feeding which the horse may have acquired, his corn should be mixed with chopped straw or chopped clover, which will secure its proper mastication, and prevent many troublesome complaints, as well as render all the nutrition of the food available. These may be substituted by an admixture of clean chaff with corn, a plan which is pursued in a farm stable with which I am acquainted, and is found a useful practice. It would save the animals much time in eating, if all their food was chopped, and perhaps steamed; but on this subject we have not sufficient data to determine with accuracy."

The cure, it has been hinted, must generally be left to the veterinary practitioner, whose chief object should be to empty the stomach. In severe cases, an ounce of laudanum and a drachm of pounded ginger, in a quart of warm ale, may be used with probable success.

Broken-Windedness.

When the breathing of a horse is rapid and laborious, it is said to be *thick-winded*; and when it breathes irregularly, the inspiration taking one effort and the expiration two, it is called *broken-winded*. Inflammation of the lungs from cold is the cause of thick-windedness, the condition of these organs preventing the full action of the air-tubes. This complaint, if not removed, will most likely terminate in the broken-winded condition; but broken-windedness will take place without this premonitory symptom. The main cause of broken-windedness is sharp work after over-feeding—causing the animal to run while his stomach is full. The distended membrane presses upon the lungs, and causes a rupture in the air-cells, by which several cells are thrown into one. Thus the breathing is at once rendered irregular by imperfect muscular action in the parts.

This disease is almost invariably the result of sheer carelessness in the persons whose duty it is to superintend the feeding of the horse. The case stands as follows:—"Suppose a horse to be a gross feeder, and to have filled his stomach with straw and hay, and provender that occupies a great bulk, and contains little nourishment, the lungs are squeezed into a less than the natural compass. Let the horse be now suddenly and smartly exercised; more blood must be purified, and in the violent effort to accomplish this, some of the cells give way. Therefore we do not find broken-winded horses on the race-course, for although every exertion of speed is required from them, their food lies in small compass, and the stomach is not distended, and the lungs have room to play, and care is taken that their exertion shall be required when the stomach is nearly empty. Carriage and coach-horses are seldom broken-winded, unless they bring the disease to their work, for they too live principally on corn, and their work is regular, and care is taken that they shall not be fed immediately before their work. The farmer's horse is the broken-winded horse, because the food on which he is fed is bulky, and too often selected on account of its cheapness; because there is little regularity in the management of most of the farmer's stables, or the work of his teams; and because, after many an hour's fasting, the horses are often suffered to gorge themselves with this bulky food; and then, with the stomach pressing upon the lungs, and almost impeding ordinary respiration, they are put again to work, and sometimes to that which requires considerable exertion.

"This disease depends as much upon the cramped state of the lungs, from the pressure of an over-gorged stomach, in the ordinary state of the animal, as on the effects of over exertion. The agriculturist knows that many a horse becomes broken-winded in the straw-yard. There is little nutriment in the provender which he there finds; and to obtain enough for the support of life, he is compelled to keep the stomach constantly full, and pressing upon the lungs. Some have come up from grass broken-winded that went out perfectly sound.

"The cure of a broken-winded horse no one ever witnessed; yet much may be done in the way of palliation. The food of the animal should consist of much nutriment condensed into a small compass; the quantity of oats should be increased, and that of hay proportionably diminished; the bowels should be gently relaxed by the frequent use of mashes; the water should be given sparingly through the day, although at night the thirst of the animal should be fully satisfied; and exercise should never be taken when the stomach is full."—(*Lib. Use. Know.*)

Curb—Bog-Spavin—Bone-Spavin.

The hock-joint is particularly liable to derangement, so as to render the animal unsound. One of these affections is called *curb*, which arises from over-exertion of the ligaments, and takes the form of an enlargement a few inches beneath the joint of the hock. A more serious complaint of the hock is the *bog-spavin*, which takes place from over-exertion, and is an inflammation in the vesicles containing the lubricating material for the joint. This disease is almost incurable; and the poor animal is in general only fit for ordinary and moderate work all the rest of his life. The *bone-spavin* is a still more formidable disease. It is an affection of the bones of the hock-joint, caused by violent action, or any kind of shoeing which throws an undue strain on certain ligaments, and deranges the action of the bones. A bony deposit takes place, the joint is stiffened, and the consequence is a lameness or stiff motion in the hind legs. Blistering, as a counter-irritant, and rest, are the chief remedies prescribed for the complaint; but the best thing of all is not to overload the horse, or put him to any violent exertion, so as to prevent not only this but other similar complaints.

Physicking

Horses that are attended to with the greatest care occasionally get into a condition which requires physic, that is, purgative medicine; as, for example, when they have been too long on hard food and require a laxative, when they get into a heated state of body from constant work, when their bowels get overloaded or disordered, or when they are getting too fat. The most simple laxative is a *bran-mash*. Bran is put into a pail and softened with boiling water; when cooled sufficiently, it is given to the animal as the last feed at night, instead of corn or hay. About half a pailful is a dose. Horses used by commercial travellers or others during the whole week, and fed on corn, are indulged in a mash on Saturday night; and this, with the rest on Sunday, keeps them in good condition.

When a working-horse is lamed, or becomes sick, and must remain idle for a few days, he requires to be relieved by a dose of physic. Generally, this consists of from four to nine drachms of Barbadoes aloes, powdered and formed into a round moistened mass, fit to be swallowed. It requires to be administered by a skilful groom, who will push it over the throat adroitly without alarming the animal. Sometimes the powder is mixed with a little Castile soap. An hour or less after taking physic, a bran-mash should be given, and then the horse be gently exercised; on his return to the stable he may be offered a drink of water from which the chill is taken, or as warm as he will take it.

We should consider it imprudent to offer any further explanations of the materia medica of horses; and again recommend all unskilled or but partially instructed persons not to attempt doctoring their horses themselves, but to call in at once the advice of a veterinary surgeon.

ADVICE IN PURCHASING A HORSE.

The purchasing of a horse is ordinarily a matter of very serious difficulty, in consequence of the proverbial trickiness of dealers, and the many defective points in the animal's constitution which cannot be seen with all the care that may be bestowed. In offering any hints on this important particular, we must refer to the instructions of authorities whose testimony is worthy of confidence. Mr. Stewart has written a valuable little manual, entitled, "Advice to the Purchasers of Horses," which should be in the hands of all who have frequent occasion to make purchases. The following are a few of his admonitions:—

"In buying a horse, one of the chief requisites to be attended to, is the degree of nervous energy which the animal possesses; and it is the union of this energy with good conformation that makes many horses invaluable. Its absence or presence, however, is not likely to be discovered by the purchaser without a trial, and to avoid disappointment in this respect, it is therefore advisable to obtain one prior to purchase. The horse should be set to the work he will be called on to perform; and if he is intended for the saddle or single harness, he should have no companion on his trial, for many horses work well in company that are downright sluggards when alone.

"Some horses have an unpleasant way of going, or are difficult to manage, or have some vice which is only displayed when at work. These are so many more reasons for having a trial prior to striking a bargain. But if that cannot be obtained, some sort of conclusion regarding the animal's spirit may be drawn from his general appearance. The way he carries his head, his attention to surrounding objects, his gait, and the lively motion of his ears, may all or each be looked to as indicative of 'bottom' or willingness to work. It is only however, in a private stable, or in that of a respectable dealer, that these *criteria* can be depended upon; for in a market-place, the animal is too much excited by the cracking of whips, and the too frequent application of them, to be judged of as regards his temper. Neither must the buyer be thrown off his guard by the animation which horses display at an auction, or on coming out of the stable of a petty dealer; for it is a fact which cannot be too well made known, that there are many unprincipled dealers who make it their business, before showing a horse, to 'put some life in him,' that is, they torture him with the lash, till, between pain and fear, the poor animal is so much excited as to bound from side to side with his utmost agility, at the least sound or movement of the bystanders."

This writer continues, in relation to the head and other parts of the animal:—"The head, as being a part not at all contributing to progression, should in the saddle-horse be small, that it may be light—the nostrils expanded to admit plenty of air, and the space between the branches of the lower jaw, called the channel, should be wide, that there may be plenty of room for the head of the windpipe. In the draught-horse, a heavy head is not, as far as utility is concerned, an objection, for it enables him to throw some weight into the collar; and hence, excepting its ugliness, it is rather an advantage if he is used entirely for draught. But it makes the saddle-horse bear heavy on the hand of the rider, makes him liable to stumble, and, when placed at the end of a long neck, is apt to wear out the fore feet and legs by its great weight. The neck of the saddle-horse should be thin, not too much arched, and rather short than long, for the same reason that the head should be light: and, in the draught-horse, it may be thick, stallion-like, and sufficiently long to afford plenty of room for the collar, and for the same reason that the head may be large in this animal. The windpipe should be large, and standing well out from the neck, that the air may have an easy passage to and from the lungs. The horse used for both carrying and drawing should have a head and neck neither too light nor too heavy.

"That the saddle-horse may be safe, and have extensive action, it is necessary that the withers be high. This advantage is indicated by the horse standing well up before; and it is usual, in showing a horse, to exaggerate the height of the forehand, by making him stand with his fore feet on a somewhat elevated spot. A horse with low withers appears thick and cloddy about the shoulder. In the ass and mule, the withers are very low, and the shoulders very flat, and this is the reason why they are so unpleasant to ride, and why it is next to impossible to keep the saddle in its proper place without the aid of a crupper. High withers, however, are not essential to the racer or the draught-horse. The former does all his work by leaps, and that is performed best when the horse stands somewhat higher behind than before: neither are high withers necessary to the draught-horse; but in the roadster they are as important as the safety of the rider is, for a horse with a low forehand is easily thrown on his knees. In the draught-horse, this tendency towards the ground is obviated by the support the collar affords.

"The chest should be deep and wide in all horses, but especially so in one intended for quick work, in order that there may be plenty of room for those important organs, the lungs.

"The back should not be too long nor too short; for though length is favourable to an extended stride and rapid motion, yet it makes the horse weak, and unable either to draw or carry any considerable weight. On the other hand, if the back be too short, the horse's action must be confined; and short-backed horses, in general, make an unpleasant noise when trotting, by striking the shoe of the hind foot against the shoe of the fore one: and though they are in general very hardy, and capable of enduring much fatigue, and of living on but little food, yet a back of middling length is better by far than one immoderately short or long. The back should be nearly straight.

"In the saddle-horse, and where safety is desirable, the position of the fore leg is worthy of attention. It should be placed well forward, and descend perpendicularly to the ground, the toe being nearly in a line with the point of the shoulder. The pastern should neither be turned in nor out. When they are turned inwards, the horse is in general very liable to cut the fetlock-joint by striking the opposite foot against it. The draught-horse may be excused though he leans a little over his fore legs, but the saddle-horse will be apt to stumble if he does so."

Minute attention should be bestowed on the examination of the fore legs and feet; these, in fact, are the great trying points. If the feet be not round and full, so as to stand firmly and flatly on the ground, and if tender or thin in the hoofs, the animal is not to be trusted for saddle-work. Mr. Lawrence on this subject remarks—"The feet of saddle-horses, be they ever so sound and good in nature, detract greatly from the value of the nag, unless they stand even on the ground; since, if they deviate inward or outward, the horse will either knock or cut in the speed, that is to say, will strike and wound the opposite pasterns, either with his toe or his heel; and if he bend his knees much, and is a high goer, will cut the inside of the knee joint. Nature has been very favourable in the hinder hoofs, with which we have seldom much trouble; but there is, now and then, a most perilous defect in them; namely, when the horse is so formed in his hinder quarters, that he overreaches, and wounds his fore heels with the toes of his hind feet." The defect here spoken of will be observed to cause an unpleasant clattering noise in trotting.

The fore legs, from the knees downwards, should be clean made, sound and flexible at the joints. Bad usage knocks up a horse, or founders him; and his legs, being in a kind of benumbed state, will either wholly or partially refuse to perform their office. By ease and physicking the horse recovers; but his system has been shaken, and he is apt to come down. This is a fearful defect in a horse; for no one is for a moment safe on his back. Weakness in the fetlock-joint will also cause a horse to stumble and come down, and is therefore an equally serious defect. When the horse stumbles, so as to come down on his knees, the likelihood is that the knees are broken; and it is well known that wounds of this nature never heal over to resemble the original. The horse with broken knees is, in short, damaged for life, at least in as far as he is a marketable commodity. A good horse, however, may be thrown down on his knees by a bad rider, merely from his head not being held well up while running or quick trotting downhill over a hard road. Such a circumstance as this ought not in general to injure the character of a horse; but it is indisputable that it does so in the estimation of buyers.

Horses are sold either with or without warranty. At sales at repositories, the terms of warranty are generally announced in a public manner; but when the sale is private, no warranty is binding which is not expressed in writing in the receipt. The principle that a price above ten pounds warrants a horse sound, is not now recognised as binding. The warranty must be something different from a mere understanding or illusory custom. "When a horse," says Mr. Lawrence, "is simply warranted sound, that does not extend either to his qualifications or disposition; it merely guaranties that the animal, at the time of sale, is neither lame, blind, broken-winded, or in any respect diseased, or has any impending cause of unsoundness. Broken knees do not impede a sound warrant." We offer these hints on warranty with much diffidence for the rules on the subject are constantly altering by legal decisions.

THE DUTIES OF HORSES.

Draught.

The horse is equally willing to make himself useful as a beast of burden or draught; but his powers are best adapted for draught, and particularly on a level road. The formation of his body does not suit him for climbing or going up-hill with a load; and his strength is always exerted to greatest advantage when he can throw his centre of gravity forward as a makeweight. The amount of load which he can draw in a wheeled vehicle, depends on the arrangement of the load to the pull. The pulling point is across the shoulders, and the most advantageous method is to make the line of traction proceed *direct* from the shoulders to the load—in no shape bent or distracted from its course. The load should be placed lower than the line of the shoulders, thus making the line of traction go by a straight slope to the seat of resistance. The load should not be at a greater distance than will allow freedom of motion to the hind legs. If the load be placed too low, a part of the power will be uselessly spent in lifting it.

According to the calculations of James Watt, the weight which a horse can draw, called a *horse power*, is 1,980,000 lbs. raised one foot high per hour, or 33,000 lbs. raised one foot per minute. The weight is supposed to hang at the end of a rope passing over a freely moving pulley. This calculation is based on considerations more favourable than those which usually attend horse-labour. There are, in reality, no rules to guide the imposing of loads on horses; for every thing depends on the degree of friction on the wheels of the carriage, the nature of the road, and the strength of the animal in question. One thing is certain, that a horse always exerts his power better by himself than when yoked with others. The load which it requires four horses to draw unitedly, if divided, could be drawn with equal ease by three. The following observations in the Scotsman newspaper (June 1839), referring to the operations of Sir C. Stuart Menteith, deserve to be noticed:—

"From the experience this gentleman has had in the use of animal power upon common roads, he is of opinion that the most economical mode of employing horses in draught is to give every horse his own carriage, and that he should solely depend upon his own exertions in drawing the load, as otherwise it is well known that it is difficult to find either man or beast equally willing or capable to make the same exertion, or to have the same spirit or motion; and at the same time never to exceed six miles on one stage, and to be performed twice daily. In a stage of three miles and a half, Sir C. Stuart Menteith employs wagons weighing eighteen cwt., in which horses draw three tons. The road is in general upon a declivity of one foot of fall for every eight sixteen, or eighteen feet, with several ascents of one foot in every thirty feet, up which a horse draws the load of three tons, and a wagon of eighteen cwt.; but in order to facilitate the ascent, a continuous line of sandstone railroad is first laid down, upon which a plate of iron, six inches wide, by a quarter of an inch thick, is fixed down. In order to enable a horse to bring a load of three tons down any rate of descent, a friction-break has been employed, similar to the one in common use in Belgium, from which Sir C. Stuart Menteith derived this important application. The break is a strong plank, fixed to the back of a cart or wagon, which, by means of a screw, the carter presses against the two hind wheels of the machine, so as to give a sufficiency of friction to retard the too rapid descent of the carriage. This plan has been employed with great success by Mr. Croal coach proprietor in Edinburgh, from the suggestion of Sir C. Stuart Menteith, who has now used it more than fourteen years upon his coal-wagons. The mode adopted by Mr. Croal is to fix a lying axle to the plank pressing upon the hind wheels of a coach, and which is turned by an upright shaft, with a bevel wheel connecting the two shafts, and turned by a winch by the hand of the coach-guard, without moving from his seat. Were this break applied to every coach, the lives and limbs of thousands would be preserved, as the guard would be able to stop horses when running away with a carriage—as it is thought the treble, as it were, of the weight of a coach is to be drawn, if the two hind wheels are prevented from revolving by the break. This kind of break enables a coachman to drive with perfect security down a descent of any length, and at any rate of speed. If the employment of horse wagons, weighing from twelve to thirteen cwt., were adopted in conveying coal through the streets of London, one horse would do the work of two; at present, four immense horses draw three chaldrons of coal, or four tons one cwt., in a wagon weighing two tons; so that the shaft-horse is obliged to draw a weight of six tons in turning out of one street into another, which is the greatest cruelty to which a poor animal can be subjected."

The larger the size of wheels in a vehicle, within a reasonable proportion, so is the friction in overcoming obstacles on the road less, and so is the draught more easy to the horses. The benefits of large wheels, however, have often been completely lost by not making them run fairly in an upright position. The custom has been to make them *dished* or bevelled outward from the axle, and to cause the axle to lean downward at each extremity to accommodate this peculiar shape. It is of importance to understand that a wheel always runs best when its tire is of equal diameter, when the spokes are at right angles to the axle, and when the axle projects straight out. This is exemplified in the trundling of a hoop: a hoop which is perfectly upright and even on the rim, requires less force to send it forward and keep it moving than if it were bevelled, and inclined to go round in a circle. For the sake of convenience, wheels may be a little dished, though now that the roads are good, that is scarcely necessary.

The power of draught of a horse depends on the rate at which he is compelled to proceed. He exerts his power to most advantage at a fair pull, when moving at the rate of from two and a half to three miles per hour. If he go at a greater speed, he is less able to draw. As a general rule, if the speed be doubled, the load should be halved; and if the speed be twice doubled, the load should be quartered; yet this will only hold as correct for short distances. Much work may be procured from a horse if he be impelled only for short stages. A horse in a stage-coach, running only five miles at a time and then resting for a few hours, will last at least four times longer than another horse of equal power which runs ten miles at a time. This is well understood by all stage-coach proprietors, and short stages have now almost everywhere superseded long ones. Such a fact should also be known to all private travellers. Whether employed in a gig, chaise, or for riding, the horse on a journey should take his day's work in two distinct stages; one in the morning, and another in the afternoon, when rested and refreshened. He should also, to remain in good condition, have a rest during the whole of Sunday. In journeying with light loads, a distance of from twenty to twenty-five miles is considered a sufficient day's task.

Riding.

The art of riding or equitation forms a regular branch of instruction, and is seldom well performed by those who have not been regularly taught. It is not to be supposed that any thing we can say can supersede the instructions of the riding-school; but it may be of use to offer a few hints on the subject from the best authorities.

Riding should be performed in that manner which is least calculated to oppress the horse and fatigue the rider, and which will be most secure for both parties. The first principle in horsemanship is, that the horse and his rider should act and react on each other, as if governed by one common feeling. To attain this end, the rider must acquire the knack of balancing himself properly on the animal, and establishing the means of making himself understood through certain movements of hand and body. A good horseman will act according to the following directions, given in Walker's Manly Exercises:—"The place of the rider's seat is that part of the saddle into which the rider's body would naturally slide were he to ride without stirrups. This seat is to be preserved only by a proper balance of the body, and its adaptation to even the most violent counteractions of the horse. In relation to the thighs, the rider, sitting in the middle of the saddle, must rest chiefly upon their division, vulgarly called the fork, and very slightly upon the hips The thighs, turned inward, must rest flat upon the sides of the saddle, without grasping; for the rider's weight gives sufficient hold, and the pressure of the thighs on the saddle would only lift him above it. The knees must be stretched down and kept back, so as to place the thighs several degrees short of a perpendicular; but no gripe must be made with them, unless there be danger of losing all other hold. If the thighs are upon their inner or flat side of the saddle, both the legs and the feet will be turned as they ought to be. Thus turned, they must be on a line parallel to that of the rider's body, and hang near the horse's sides, but must not touch; yet they may give an additional hold to the seat, when necessary, and the calves must act in support of the aids of the hands. The heels are to be sunk, and the toes to be raised, and as near the horse as the heels, which prevents the heel touching the horse. As to the body, the head must be firm, yet free; the shoulders thrown back and kept square, so that no pull of the bridle may bring them forward. The chest must be advanced, and the small of the back bent a little forward. The upper parts of the arms must hang perpendicularly from the shoulders, the lower parts at right angles with the upper, so as to form a horizontal line from the elbow to the little finger. The elbows must be lightly closed to the hips, and, without stiffness, kept steady, or they destroy the hand. The wrist must be rounded a little outwards. The hands should be about three inches from the body, and from the pommel of the saddle, and from four to six inches apart; the thumbs and knuckles pointing towards each other, and the finger-nails towards the body. When the rider is in the proper position on horseback without stirrups, his nose, breast, knee, and instep, are nearly in a line; and with stirrups, his nose, breast, knee, and toe, are in a line. The man and the horse throughout are to be of a piece. When the horse is at liberty, or disunited, as it is termed, the rider sits at his ease; and, as he collects and unites his horse, so he collects and unites himself. There must, however, be no stiffness of manner more than in sitting on a chair; for it is ease and elegance which distinguish the gentleman."

Riding, to one accustomed to it, is best performed with a curb and snaffle bridle; the curb, however, being only employed to bring the animal up by pressure on the mouth, when occasion requires. As some horses have a much more delicate mouth than others, the nature of the bridle must depend on circumstances. In holding the reins, a union of firmness, gentleness, and lightness, is the essential requisite. The foregoing authority alludes to the manner in which the reins are to operate on the mouth of the animal:—"The hand being connected with the reins, the reins to the bit, the bit operat ing in the curb on the bars, and in the snaffle on the lips, the rider cannot move the hand, and scarcely even a finger, without the horse's mouth being more or less affected. This is called the *correspondence*. If, moreover, the hand be held steady, as the horse advances in the trot, the fingers will feel, by the contraction of the reins, a slight tug, occasioned by the cadence of every step; and this tug, by means of the correspondence, is reciprocally felt in the horse's mouth. This is called the *appuy*. While this relation is preserved between the hand and mouth, the horse is in perfect obedience to the rider, and the hand directs him, in any position or action, with such ease, that the horse seems to work by the will of the rider rather than by the power of his hand. This is called the *support*. Now, the correspondence or effective communication between the hand and mouth—the appuy, or strength of the operation in the mouth; the support, or aid, the hand gives in the position or action, are always maintained in the *manège* and all united paces. Without these, a horse is under no immediate control, as in the extended gallop or at full speed, where it may require a hundred yards to pull before we can stop him. The degree of correspondence, appuy, and support, depends, in horses otherwise similar, on the relative situation of the hand. The act of raising the rider's hand increases his power; and this, raising the horse's head, diminishes his power. The depressing of the rider's hand, on the contrary, diminishes his power; and this, depressing the horse's head, increases his power. On these depend the unitedness or disunitedness in the action of the horse."

Much may be done to animate a horse, either in riding or drawing, by addressing a cheerful word to him, instead of the lashing and scolding with which he is too frequently visited. If a horse requires correction or urging by the whip, he should only be touched lightly behind the girth and saddle, never on any account on the head or in a fore part of the body. Some carters strike their horses with sticks over the head and legs, and yell to them like savages—two practices equally detestable, which we should be glad to see abolished. We have also seen riders so lost to humanity, as to whip their horses when restive over the head and ears. Should a rider find that his horse designs to baffle him, he must be pressed by the legs, urged lightly with the spur, and kept in his proper track, but not drawn up with the curb, or terrified by abuse.

The most common pace in road-riding is the trot, which in effect is a rapid walk, and most difficult for a rider to perform with address and a small degree of fatigue to himself. In slow trotting, the body should adhere to the saddle, and when it becomes fast or rough, the body may be raised at the proper moments to ease the jolting. This rising of the body, however, is to be a result of the horse's action, not an effort of the rider. The proper method is to rise and fall with the leading foot, the body rising from the seat when the leading foot is elevated, and falling when the foot sinks. Unskilful riders make an unnecessary effort by trying to rise and fall in the saddle.

In the course of either slow or fast riding, the horse may trouble his rider by plunging, shying, or restiveness. If he kick and plunge, sit upright, hold on by the legs, and do not vex him by any lashing; when let alone, he is not long in coming out of his freak. When he shies, or flies to one side, as if afraid of something, press him on the side to which he is flying, keep up his head, and bring him into his track. Pressing both legs against his sides will generally keep him from running backward. When he becomes restive, that is, turns round, and has a disinclination to go in the way he is required, the rider must keep him in his track by dint of pressure, a touch of the spur, and the hand. If he has been accustomed to spurs, and finds that your heels are not provided with these appendages, your case is very hopeless. We must allow Walker to point out the course to be pursued with a restive horse. If he persists in turning round, the rider must continue "to attack his unguarded side, turn him two or three times, and let the heel and spur, if necessary, assist the hand, before he can arm or defend himself against it. If he still refuse to go the right way, the rider must take care that he go no other, and immediately change his attack, turning him about and reining him backward, which the horse is easily compelled to do when he sets himself against going forward. In these contests, the rider must be collected, and have an eye to the surrounding objects; for restive horses try their utmost to place their riders in awkward situations, by sidling to other horses, carriages, the foot-pavement, the houses, &c. In this case, the rider, instead of pulling him from the wall, must bend his head to it, by which his side next the wall is rendered concave, and his utmost endeavours to do injury are prevented. The instant, therefore, that the rider perceives his horse sidling to any object, he must turn his head to that object, and back him from it. There are some horses who set themselves like stocks, setting all endeavours to move them at defiance. There, happily, their defence can in no way endanger the rider. It must, however, be converted to punishment. Let them stand, make no attempt to move them, and in a short space—frequently less than a minute—they will move of themselves."

The same author recommends the rider to remain perfectly cool in all these awkward circumstances. "When passion," he observes, "possesses the rider, it prevents that concord and unity taking place which ever should subsist between the rider and his horse. He should always be disposed to amity, and never suffer the most obstinate resistance of the horse to put him out of temper. If the contest does not demand his utmost exertion of strength, he should be able to hum a tune, or converse with the same composure and indifference as though his horse were all obedience. By these means, the instant a horse finds himself foiled, he desists, having no provocation to contend farther, and is abashed at his own weakness. It is the absence of passion which, added to cool observation, makes the English the best riders and drivers in the world."

Neither in the above section nor elsewhere have we said any thing of the accoutrements of the horse, as all articles of this kind must be left to the taste of the party concerned. The harness made by all saddlers is now both handsome and commodious, and so well calculated for the comfort of the animals, that it would be superfluous to say any thing respecting it, further than to recommend its always being kept clean and glossy, and that it nowhere galls or presses unduly on the animal's body. A properly bred and carefully treated horse is proud of his harness as well as his coat being kept in good condition; and these, like other points in the economy of this highly useful animal, we press on the attention of all whose duty includes the care of horses.

In concluding this comprehensive treatise, which aspires only to be a manual for horse management in ordinary circumstances, we have much pleasure in referring for full information on the subject to a variety of excellent treatises of recent date: among others—"The Horse," in the "Farmers' Series—Library of Useful Knowledge," which we have occasionally quoted; "Stable Management," and "Advice to the Purchasers of Horses," by Mr. Stewart (Blackwood and Sons), two volumes, which can be recommended for their great practical utility; also, Walker's "Manly Exercises" (W. S. Orr and Co., London), for instructions in Equitation.

CATTLE AND DAIRY HUSBANDRY.

Next to the horse, the cow is justly valued as the most useful animal which man has been able to domesticate and retain permanently in his service. The ox tribe, of which it is the female, belongs to the order *Ruminantia*, in the class *Mammalia*, these terms implying that the animals ruminate or chew their food a second time, and have mammæ or teats with which they suckle their young. In the ox tribe there are different genera and species, all more or less differing from each other; and of the domesticated ox, the varieties from the effect of cultivation are now very numerous. The ox, in one or other of its genera, and for the sake of its labour as a beast of draught, its flesh, or the milk of its female, has been domesticated and carefully reared from the earliest times, in some countries having been raised to the rank of a divinity, or at least held as an object of extreme veneration.

The domesticated species of oxen common to Britain and adjacent parts of Europe, is, in all its varieties, materially altered from its wild parentage. Influenced by climate, peculiar feeding, and training in a state of subjection, its bony structure is diminished in bulk and power, its ferocity tamed, and its tractability greatly improved. Our observations in the present sheet will refer chiefly to the cow, on which very great changes have been effected by domestication; the most remarkable of these alterations has been in the capacity for giving milk. In a wild state, the udder is small, and shrinks into an insignificant compass when the duty of suckling is over; but when domesticated for the sake of its milk, and that liquid is drawn copiously from it by artificial means, the lacteal or milk-secreting vessels enlarge, and the udder expands, so as to become a prominent feature in the animal. In this manner, by constant exercise, the economy of the cultivated species of cows has been permanently altered, and rendered suitable to the demands which are constantly made on it. Yet it is important to remark, that those milk-yielding powers are not equal in the different varieties or breeds of cows. Some breeds, from the influence of circumstances which it is here unnecessary to inquire into, give a large quantity of milk, but of a thin or poor quality, while others yield less milk, but of a good or rich quality. Whether, then, the cow-keeper wish *quantity* or *quality*, is the question for him to solve in making a selection of stock. In general, near large towns where the demand for milk is considerable, the object of dairymen is to keep cows which will give a large quantity of milk, no matter of what sort. Private families in the country are usually more regardful of the quality of the article they wish a little milk which is good, some fine cream, and perhaps, also, some sweet butter and cheese, and on that account are more careful in the choice of their cows. The following is a list of breeds which may aid the selection of cows in these different respects.

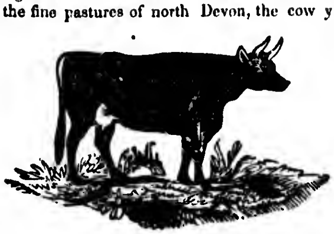
BREEDS OF CATTLE.

The breeds of cattle throughout the United Kingdom vary in different districts from the small hardy varieties of the north Highlands, to the bulky and handsome breeds of the southern parts of England. It has been customary to classify the whole according to the comparative length of the horns—as the long-horned, short-horned, middle-horned, crumpled-horned, and hornless or polled breeds. Besides these, there are many intermixed breeds. The middle-horned cows, which are found in the north of Devon, the east of Sussex, Herefordshire, and Gloucestershire are among the most valuable and beautiful varieties of the animal.

The intelligent author of the work on Cattle, published by the Society for the Diffusion of Useful Knowledge, thus describes what ought to be the proper form and shape of cattle:—"Whatever be the breed, there are certain conformations which are indispensable to the thriving valuable ox or cow. If there is one part of the frame the form of which, more than of any other, renders the animal valuable, it is the chest. There must be room enough for the heart to beat and the lungs to play, or sufficient blood for the purposes of nutriment and strength will not be circulated; nor will it thoroughly undergo that vital change which is essential to the proper discharge of every function. We look, therefore, first of all, to the wide and deep girth about the heart and lungs. We must have both: the proportion in which the one or the other may preponderate, will depend on the service we require from the animal; we can excuse a slight degree of flatness of the sides, for he will be lighter in the forehand, and more active; but the grazier must have width as well as depth. And not only about the heart and lungs, but over the whole of the ribs, must we have both length and roundness; the *hooped* as well as the deep barrel is essential; there must be room for the capacious paunch, room for the materials from which the blood is to be provided. The beast should also be ribbed home; there should be little space between the ribs and the hips. This seems to be indispensable in the ox, as it regards a good healthy constitution and a propensity to fatten; but a largeness and drooping of the belly, notwithstanding that the symmetry of the animal is not improved, are considered advantageous in the cow, because room is thus left for the udder; and if these qualities are accompanied by swelling milk veins, her value in the dairy is generally increased. This roundness and depth of the barrel, however, are most advantageous in proportion as found behind the point of the elbow more than between the shoulders and legs; or low down between the legs rather than upwards towards the withers: for the heaviness before, and the comparative bulk of the coarser parts of the animal, are thus diminished, which is always a very great consideration. The loins should be wide. Of this there can be no doubt, for they are the prime parts; they should seem to extend far along the back, and although the belly should not hang down, the flanks should be round and deep. Of the hips it is superfluous to say that, without being ragged, they should be large; round rather than wide, and presenting, when handled, plenty of muscle and fat. The thighs should be full and long, close together when viewed from behind, and the farther down they continue close the better. The legs may occasionally vary in length according to the destination of the animal; but shortness is a good general rule, for there is an almost inseparable connection between length of leg and lightness of carcass, and shortness of leg and propensity to fatten. The bones of the leg (and they are taken as a sample of the bony structure of the frame generally), should be small, but not too small—small enough for the well-known accompaniment, a propensity to fatten—small enough to please the consumer; but not so small as to indicate delicacy of constitution and liability to disease. Lastly, the hide—the most important thing of all—should be thin, but not so thin as to indicate that the animal can endure no hardship; movable, mellow, but not too loose, and particularly well covered with fine and soft hair."

Of the various breeds and cross-breeds of cows now in use, there are a few which enjoy the best reputation. We may name, for example, the *Old Yorkshire Stock*, a cross between the Teeswater and Holderness breed; the *Long-horned* or *Lancashire breed*, the *Short-horned* or *Dutch breed*, the *Middle-horned breeds of Devonshire, Sussex*, and *Hereford*, the *Ayrshire breed*, the *Alderney breed*, &c. Some of these merit particular attention. We should first point to the

Devonshire Cow.—The Devonshire is a handsome breed of cattle, well set upon their legs, straight along the back, small muzzle, generally red in colour, and both as oxen and cows, they feed well at an early age. The cow is much smaller than the bull, but roomy for breeding, and is distinguished for her clear round eye and general loveliness and neatness of features. Fed on the fine pastures of north Devon, the cow yields a



Devonshire Cow.

rich quality of milk, and in reasonable abundance. The north Devon breed prevails in some parts of Somersetshire, and has been introduced into other quarters of the country, but is not considered suitable in situations greatly differing from its native country as respects climate and herbage.

Herefordshire Cow.—The Hereford breed of cattle is larger than that of north Devon. It is broad across the

Hereford Cow.

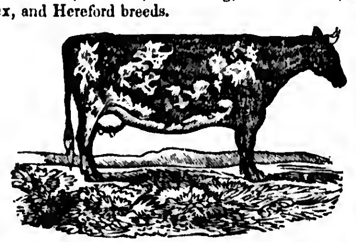
hind quarters, narrow at the surloin, neck and head well proportioned, horns of a medium size, turned up at the points, colour deep red, but with face and some other parts generally white, and countenance cheerful and sagacious. This cow is reckoned among the best in England as respects the production of milk, and when too old for that purpose, it fattens to a greater weight than the north Devons.

The *Galloway breed* of cattle is well known for various valuable qualities, and easily distinguished by the want of horns. It is broad across the back, with a very slight curve between the head and quarters, broad at the loins, the whole body having a fine round appearance. The head is of a moderate size, with large rough ears, chest deep, legs short, and clean in the neck. The prevailing colour is black, those of this colour being thought the most hardy, although this varies. This breed is highly esteemed, as there is no other kind which arrives at maturity so soon, and their flesh is of the finest quality. The milk is very fine, but is not obtained in very large quantities. Great numbers of this breed are sent annually to Smithfield market; and it is remarkable that they are generally in as good condition after the journey as before. The Suffolk dun, also a hornless breed, is supposed to be a variety of the Galloway, from their general resemblance.

The *Ayrshire breed*, which is considered the most valuable in Scotland, is of the small sized and middle horned race: its origin is unknown, as it has been long

Ayrshire Bull.

settled in the county from which it derives its name. In modern times, the breed has been improved by judicious selection, coupling, and general treatment. The common characteristics of this excellent variety of cows are thus described by Mr. Aiton in his "Survey of Ayrshire:"—"Head small, rather long and narrow at the muzzle; eye small, smart, and lively; horns small, crooked, and set at considerable distances from each other; neck long, rather slender, tapering towards the head, with no loose skin below; shoulders thin; fore quarters light; hind quarters large; back straight, broad behind, the joints rather loose and open; carcass deep; legs small, short, with firm joints; udder capacious, stretching forward; the milk veins large and prominent; teats short, all pointing outwards." The Ayrshire cow is very docile, feeds well, is easily managed, and, as a dairy cow, is equal to any other. It is inferior, however, for feeding, to the Devon, Sussex, and Hereford breeds.



Ayrshire Cow.

Many of the Ayrshire dairy cows, when properly fed will yield from 6 to 8 gallons per day during a part of the summer. The quantity varies much during the year, from 1½ to 6 gallons, or more; and the highest average of the milk yielded by this breed is 1000 gallons per annum. It is only some of the finest cows that will yield such a quantity as this, and from 500 to 750 gallons may be calculated as the most general yearly produce. Every 2¼ gallons of milk will afford 1 pound of butter, of 16 ounces to the pound, or 8 gallons will give 3 pounds. About 26 gallons of milk will give a stone of cheese, 14 pounds to the stone, and a good milch cow will thus yield 36 stones annually, which, at 10s. per stone, is £18 per annum for this article alone.

The *Short-horned* or Dutch breed is considered of great value, both for milking and feeding. There are many varieties of it, known by the names of the counties where they have been raised. The best of these varieties are large in the carcass, well proportioned, broad across the loins, chine full, legs short, head small but handsome, neck deep, but in keeping with the size of the body, colour generally red and white mixed, or what is called flecked, hide thin. The flesh of this breed is thick, close grained, retaining the juices well; and from this circumstance is in request for victualling ships going on long voyages.

Regarding the milking qualities of this breed, Mr. Dickson, an eminent cattle-dealer, who has had the most extensive experience throughout the whole country, says —"It has been frequently asserted that the short-horned cows are bad milkers; indeed, that no sort of cattle are so deficient in milk. But this deficiency of milk does not proceed from the circumstance of the cows being of the short-horned kind. Had the flesh been neglected as much as the milk by the eminent breeders, and the property of giving milk as much cherished as the development of flesh, the short-horned cows would have been deep milkers. Indeed, it is not to be doubted that, where the general secreting powers of the animal system have been increased, the power of secreting milk will be increased with the power of secreting fat; all that seems requisite is to encourage the power of that secretion which is most wanted for the time. It would be to desire an impossibility to desire the full development of flesh, fat, and milk, at the same time; but there is no absurdity in desiring a large secretion of flesh and fat at one time, and a large secretion of milk at another, from the same cow. Accordingly, this is the very character which has been acquired by short-horned cows. They will yield from six to sixteen quarts a day throughout the season; and they are such constant milkers, that they seldom remain dry above six weeks or two months before the time of calving. I know a Scotch breeder who had a short-horned cow which gave fifteen quarts a day during the flush of the grass in the summer, and never went dry for two seasons. A cross between a Galloway cow and a short-horned bull in Berwickshire yielded twenty pints a day during the best of the season, and she had to be milked five times a day to keep her easy." We have thus considered it our duty to give the opinion of Mr. Dixon regarding the value of the short-horned breed of cows as a dairy stock, seeing that the demand for short-horned bulls has of late years been great in many of the counties of both England and Scotland. It seems, however, a well-confirmed opinion, that the breed which of all others appears to be gaining ground throughout the United Kingdom for abundant produce on ordinary pasture, is the Ayrshire kyloe, which is described as without a parallel under a similar soil, climate, and relative circumstances, either for the dairy, or feeding for the shambles. But the ever-variable circumstances in climate, soil, shelter, and the quality and quantity of the pasturage, as well as the winter feeding and general treatment, will always have an effect upon the stock.

The *Improved Kerry* is an Irish breed, of rather diminutive size, hardy, and which can subsist on scanty pasture. This renders them exceedingly well adapted for hilly pastures, and for cottagers who may not have the best food to offer their stock Their milk and butter are rich in quality, and for their size they are good milkers. They are quiet enough when let alone, but if the least irritated, no fence can contain them. The Irish cows have improved very much of late years, in consequence of crossing; and they are now in many respects thought equal to the breeds of either England or Scotland.

The *Long-horned* or Lancashire is distinguished by the length of its horns, the thickness of its hide, and the large size of its hoofs. It is far from being a handsome animal; nor is it held in very general estimation either for milking or feeding.

Highland breeds.—The cattle of the Highlands of Scotland are of small bulk, and very hardy. The most esteemed are those belonging to the Western Highlands and Isles, called the Argyleshire breed, and frequently *kyloes*. It is thought that this breed might be much improved by judicious crossing, as was seen in the case of the Ayrshire kyloe, formerly mentioned. This breed is rather handsome in appearance; the horns are long and upright, head large, neck short and deep, legs of a good length, and the beef is in general estimation. The cattle of the Highlands and Isles are bred on an extensive scale of farming for the purpose of sending to the southern markets. Small in size at first, they increase in bulk as they are transferred to a more genial climate and richer pasturage as they proceed southward, till, by annual stages, they reach the neighbourhood of London, when they are large and heavy. The breeds may therefore be considered more an object of culture for the shambles than the dairy.

The *Alderney breed* of cattle is awkwardly shaped, with short bent horns, and light red, dun, or fawn-coloured skins. The appetite of the cow is voracious, and it yields little milk, but that is of an exceedingly rich quality, and the animal is on that account preferred by families who do not regard the expense of keep.

Remarks on Breeds.

We have thus briefly treated of some ot the many breeds of cattle considered valuable as dairy stock in Britain; but we pretend not to give any decided opinion as to which is best. The merits of each kind have been vigorously contested by their respective advocates, and it would be extremely difficult to decide between them. Upon the form and qualifications of a perfect cow, it ought to be observed, that whatever breed is selected, there is a wide difference between the form of one meant for fattening and that intended for the dairy. The first should resemble the ox as nearly as possible; while the latter should be long and thin on the head, with a brisk quiet eye, lank in the neck, narrow across the shoulders, but broad at the haunches; and there should be no tendency to become fat. The udder should be large and full looking, but not protruding too far behind; the teats all pointing out and downwards, equal in size, and rather long and tapering. A cow with a high backbone, large head, small udder, and showing an inclination to become fat, will be found to be a bad milker. This description applies to all breeds; and of course the difference between a cow for fattening and one for yielding milk will be comparative.

Mr. Aiton mentions the following as the most important qualities of the dairy cow:—"Tameness and docility of temper greatly enhance its value. One that is quiet and contented feeds at ease, does not break over fences, or hurt herself or other cattle, will always yield more milk than those who are of a turbulent disposition. To render them docile, they ought to be gently treated, frequently handled when young, and never struck or frightened. Some degree of hardiness, however, a sound constitution, and a moderate degree of life and spirits, are qualities to be wished for in a milch cow, and what those of Ayrshire generally possess. Some have thought that a cow living on a small quantity of food was a valuable quality, but that will depend on the quantity of milk given by the cow that eats little compared with those that eat much. If the cow that eats little gives as much milk as the one that eats more, it certainly is a valuable quality; but of this I entertain doubts, which forty years' experience and observation have served to confirm. Speculative writers affirm that some cows will fatten as well, and yield as much milk, when fed on coarse as others will do on rich food. Cows that have been reared and fed on coarse pasture will yield some milk of a good quality, and from which the best butter may be extracted; while a cow that has been reared and fed on much better pasture, would, if turned on that which is bad, give scarcely any milk. But if a cow that has been accustomed to feed on bad pasture be put on that which is better, she will greatly increase in milk, and fatten much faster. If two cows of the same age and condition, and which have been reared and fed on food of equal quality, are put, the one on bad food, and the other on that which is good, the latter will yield four times the milk, and fatten four times faster than the former. A cow need not always be fed on green clover, cabbages, and cauliflower; but she will neither fatten nor yield milk if she gets no better fare than rushes, bent, and sage grass."

A writer in the "Farmer's Magazine," a few years ago, presented the following doggrel lines, as combining what are popularly considered the good points of a cow, such as is common among the short-horned breed of Yorkshire:—

"She's long in her face, she's fine in her horn,
She'll quickly get fat without cake or corn;
She's clean in her jaws, and full in her chine,
She's heavy in flank, and wide in her loin.

"She's broad in her ribs, and long in her rump,
A straight and flat back, without e'er a hump;
She's wide in her hips, and calm in her eyes,
She's fine in her shoulders, and thin in her thighs.

"She's light in her neck, and small in her tail,
She's wide in her breast, and good at the pail,
She's fine in her bone, and silky of skin—
She's a grazier's without, and a butcher's within."

To ensure the perpetuation of valuable qualities in cows, it is necessary to breed from good bulls of a similar variety to the cows. The heifer or young cow, if properly pastured, should begin to breed at two years, or not beyond two and a half years old. The cow is at her prime at from four to six years, and declines into old age at ten or eleven years, when it is customary to fatten her for market. Dairymen, in selecting cows, prefer those which have had their third or fourth calf when they have attained their fifth or sixth year. The bull is in his prime at three years, and should not be used after eight or nine years old.

GENERAL MANAGEMENT OF COWS.

Calving.

The cow goes with young nine calendar months, or 270 days; but this length of time is liable to variation, from the effect of circumstances. A calf is most likely to survive and be healthy which has gone exactly the nine months. Cows come into season at different periods of the year, in which state they remain for a few days, after which the affection ceases, but it afterwards returns in three or four weeks. The farmer watches these periods, and permits the company of the bull at such a time as will produce the young at a time of the year when grass is plentiful for the nourishment of the mother. This should be an advanced period of spring, for the cow will require nourishing diet some time before she drops her calf as well as afterwards.

A cow may be kept in milk up to the time of her calving, by daily taking a quantity from her; but this is most injurious to the fœtus, and the excitement of the new upon the old milk is apt to produce local inflammation. In towns, where dairymen care nothing for the calf, and must have milk at all risks, cows are often maltreated by being milked to the last; but no one who conducts a dairy on proper principles will be guilty of this inhumanity. The best plan is to allow the cow to go gradually dry, and not milk her at all for six or eight weeks before calving. This will keep her in a reasonably good condition, and save extra food, which it is not advantageous to give on a luxuriant scale, because high feeding at this period may induce inflammation and fever at calving.

No animal is so liable to abortion as the cow: it takes place at uncertain periods during the pregnancy; sometimes it occurs from fright, teazing by other cattle in the field, or over-high condition; but also not unfrequently from some bad habit acquired by the animal. It has been found that the habit is infectious; and when once it has got among a parcel of cows, it can be banished only with the greatest difficulty. In all cases the aborted fœtus should be buried deep and far from the cow pasture; the cow physicked, and its parts washed with chloride of lime; the cow-house thoroughly lime-washed and otherwise purified; and lastly, the cow fattened and sent to market.

If in a state of health, no difficulty will occur at the parturition; but should the case be otherwise, we prefer leaving the cow-keeper to ask assistance from a person of practical skill, or veterinary surgeon, than to offer any speculative advices on the subject. With respect to the treatment after calving, we beg to quote the following directions from the volume on Cattle, "Library of Useful Knowledge:"—"Parturition having been accomplished, the cow should be left quietly with the calf; the licking and cleaning of which, and the eating of the placenta, if it is soon discharged, will employ and amuse her. It is a cruel thing to separate the mother from the young so soon; the cow will pine, and will be deprived of that medicine which nature designed for her in the moisture which hangs about the calf, and even in the placenta itself; and the calf will lose that gentle friction and motion which help to give it the immediate use of all its limbs, and which, in the language of Mr. Berry, 'increases the languid circulation of the blood, and produces a genial warmth in the half-exhausted and chilled little animal.' A warm mash should be put before her, and warm gruel, or water from which some of the coldness has been taken off. Two or three hours afterwards, it will be prudent to give an aperient drink, consisting of a pound of Epsom salts and two drachms of ginger. This may tend to prevent milk fever and garget in the udder. Attention should likewise be paid to the state of the udder. If the teats are sore, and the bag generally hard and tender, she should be gently but carefully milked three or four times every day. The natural and the effectual preventative of this, however, is to let the calf suck her at least three times in the day if it is tied up in the cow-house, or to run with her in the pasture, and take the teat when it pleases. The tendency to inflammation of the udder is much diminished by the calf frequently sucking; or should the cow be feverish, nothing sooths or quiets her so much as the presence of the little one." For instructions respecting the condition and diseases of cows at and after calving, we must refer to the valuable work above quoted.

Treatment of the Calf.—If the calf be a male, and is to be pastured and fattened for market, or to be bred as a working ox, it should be cut between the first and third months; if deferred later, the operation is dangerous.

Whether calves are kept for veal or for stock, they are begun to be fed in the same manner, by sucking milk from a dish. As they naturally seek for the teat when their nose is put to the dish, the fingers of the attendant may be put into their mouth when in the milk, and this will set them going in the art of artificial sucking. "The milk" (says the author of "Clerical Economics"), "should be given to them sparingly at first, to render their appetite more keen, and prevent them from loathing at their food. For the first two weeks they should be fed on the milk first drawn from the cow, locally termed the *forebroads*, which abounds with serum: and as they grow up, the quantity of milk is gradually increased to as much as the calves can be made to drink. After the first two or three weeks, by all means give them plenty of milk, warm from their mother; and let it be that which is last drawn from the cow, locally termed *afterings*, which are much richer. Keep abundance of dry litter under them. Have them in a place that is well aired, and of a uniform temperature, neither too hot nor too cold; let the apartment be quite dark, excepting when the door is opened to give them food. If they enjoy the light, they become too sportive, and will not fatten. Take care they are fastened to the wall, in such a way, by 'swivels,' that they cannot hang themselves. Never let them make their escape at the door, or, by their running and jumping, they will do more injury to themselves in three minutes than a week's feeding will make up. Don't keep them till they become too old, because, when they begin to grow to the bone, they require more milk than the manse can generally produce; and whenever they cease to advance in the fattening process, they begin to recede, and the milk for a week or two is lost. They should be kept from four to seven weeks, according as milk may be abundant and rich. If a calf be kept long, during the last two or three weeks it will require the richest part of the milk of at least two or three cows to bring it to the highest pitch of fatness. When the milk begins to fall short of the calf's appetite, some mix eggs and others peas-meal into their food; others try infusions of hay, oil-cake, and linseed; but none of these additions are approved of by those who feed calves to the greatest perfection. Meal is understood to darken the flesh, web, and lights of the animal; but sago has of late years been almost, from the first two or three weeks, boiled and mixed in its liquid state with the milk, and to great advantage. Begin with a saucerful of it or so, and gradually increase the quantity. Calves are very fond of chalk, and they also feel the want of salt. If a calf happens to be dropt about the middle of summer, when the processes of butter and cheese making wont admit of their being fattened to perfection, they are sometimes, even at the manse, brought sparingly forward for two or three months on whey and skimmed milk; and in November, when veal is very high priced, they are fattened at considerable cost, and sold so as to yield a great return, owing both to their weight and the high markets at that season of scarcity. A calf well managed, in ordinary seasons and prices, should yield, when sold, six or seven shillings for every week it is old."

Cow-house—Cleaning.

The cow-house should be airy, and well ventilated; of moderate temperature, and kept very clean. The stalls for the cows should be paved with small stones, slope gently towards the foot, where there should be a clear run of a gutter to carry off the urine to a pit outside. The stalls must be daily scraped and swept, and all refuse carried out to the dung-heap. In general, far too little litter is allowed. The cow should have plenty of straw bedding, kept in a cleanly condition; and this, when soiled, is to be mixed with the dung for manure. The only fastening for the cow should be a chain to go round the neck, with the other end round an upright post, but easily movable up and down, and allowing room for the animal shifting its position. The feeding manger or stone trough is on the ground, and ought to be kept free of all impurities; for though the cow is not so nice as the horse, it has a disinclination for food not fresh and cleanly.

Except in dairies of a high order, it is customary to keep cows in a shamefully unclean condition. The floor of their habitation is filthy, the walls ragged and full of vermin, and the hides of the animals dusty or barkened with dirt. Persons who keep ' are not aware of the loss they incur from allowing .n to live in this uncleanly state. Some people seem to think that they do quite enough for their cows if they give them food and shelter; but besides this, they require to be kept very cleanly, though seldom indulged in that luxury. The cow should be curried daily like the horse: its hide should be freed from all impurities, and relieved from every thing that causes uneasiness. When you see a cow rubbing itself against a post, you may depend on it that the animal is ill kept, and requires a good scrubbing. Irritation of the skin from impurities also causes them to lick themselves, a habit which is injurious, for the hairs taken into the stomach form a compact round mass, which may destroy the animal. If well curried, any danger from this catastrophe is avoided, the health is generally improved, and this improves the quality of the milk, besides increasing the quantity. A cottager might easily make two or three shillings more of his cow weekly by attention to this point; and if he at the same time took pains to preserve all the liquid refuse of the cow-house, he might double that amount. How strange to reflect, that many decent and well-meaning, but ignorant and rather lazily-disposed people, are suffering a loss of four or five shillings weekly from no other cause than this! It is long, however, before old habits are eradicated, and new and better ones introduced.

Feeding.

The cow requires to be supplied with an abundance of food, not to make her fat, which is not desirable, but to keep up a regular secretion of milk in the system. The feeding must be regular, from early morning to night, and pure water must also be offered at proper intervals, if the cow has not the liberty of going to the water herself.

Regarding the nature of the food of cows, although soiling, or artificial feeding in the house, is at all times economical, there can be no doubt that the best milk and butter are produced by cows fed on natural pasture; and although the quantity of milk is not so great, yet the butter has a sweet taste, never to be discovered in the produce of soiled cows. It was formerly the case in Scotland, and the practice is still continued in some parts, to put the cows out to grass in spring, in such an emaciated state that a considerable part of the best season was gone before they yielded the quantity of milk they would otherwise have done. On well-enclosed farms, it is the custom of many to keep their cows out both night and day, from May till the end of October, so long as a full bite can be obtained; and some bring them into the house twice a-day to be milked. In moorish and unenclosed districts, they are put under the charge of a herd through the day, and are brought into the byres during the night. Soiling, or feeding entirely in the house or court-yard, is but seldom practised, except by some farmers in arable districts. Although complete soiling is only occasionally resorted to, yet a considerable quantity of rich green food is served out to the dairy stock in their stalls at night, and in the heat of the day, by such farmers as bring their cows into the house at these times. This mode of feeding is more especially followed when the pasture begins to fail; the second crops of clover and tares, cabbages, coleworts and other garden produce, are all given to the cows in the house at this period. It is upon this system that the whole perfection of the Flemish husbandry is founded, and it could be put in practice, with the most beneficial results, in many other countries. In Holland, the cows, when fed in the house, have their drink of water invariably mixed with oil-cake, rye, or oat-meal. Dairy cows are allowed to be much injured by being denied a due supply of salt, which is said to improve the quality and increase the quantity of the milk. In the best managed dairies in Scotland, when the cows are taken in for the winter, they are never put out to the fields until spring, when the grass has risen so much as to afford a full bite. In the moorish districts, however, they are put out to the fields for some hours every day when the weather will permit. In these districts, the winter food is turnips with marsh meadow hay, occasionally straw and boiled chaff.

In the richer districts, turnips and straw are given and occasionally some clover hay in spring, or when the cows have calved. Upon this subject nothing need be added, but that the quantity and quality of the milk will be in proportion to the nourishment in the food. White turnips afford a good quantity of milk, but they impart a very disagreeable taste, which may be removed, however, by steaming or boiling the turnips, or by putting a small quantity of dissolved saltpetre into the milk when new drawn. The quality of the milk depends a great deal on the cow, influenced, however, by the food she eats. Linseed, peas, and oat-meal, produce rich milk; and a mixture of bran and grains has been recommended as food in winter. Brewers' grains are said to produce a large quantity of milk, but very thin, the quality being somewhat similar to that sold in large towns, yielding neither good cream nor butter. It has been found of some importance to feed cows frequently—three or four times a-day in summer, and five or six in winter, and to give them no more at a time than they can eat cleanly.

What has been stated regarding the feeding of cows applies principally to those kept on dairy farms. In establishments for the supplying of large towns with milk, the method of feeding is somewhat different; there the practice is to feed them chiefly on distillers' wash, brewers' grains, and every sort of liquid stuff that will produce a large quantity of milk, without reference to its quality. The Edinburgh cow-keepers begin to feed with grain, dreg, and bran mixed together, at five o'clock in the morning, feed again at one o'clock afternoon, and a third time at seven or eight o'clock in the evening; grass in summer, and turnips and potatoes in winter, being given in the two intervals. The grass is laid upon the straw, in order to impart to it a certain flavour, and make it palatable; it is eaten after the grass; and in winter, straw or hay is given after the turnips. Part of the turnips and potatoes are boiled, particularly when there is a scarcity of grains.

The following is mentioned in the "Farmer's Magazine," vol. xv., as an improved mode of feeding milch cows, near Farnham, in Surrey:—"Go to the cow-stall at six o'clock in the morning, winter and summer: give each cow half a bushel of the mangel-wurzel, carrots, turnips, or potatoes, cut; at seven o'clock, the hour the dairy-maid comes to milk them, give each some hay, and let them feed till they are *all* milked. If any cow refuses hay, give her something she will eat, such as grains, carrots, &c., during the time she is milking, as it is *absolutely necessary* the cow should feed whilst milking. As soon as the woman has finished milking in the morning, turn the cows into the airing ground, and let there be plenty of *fresh water* in the troughs; at nine o'clock, give each cow three gallons of the mixture (as under—to eight gallons of grains add four gallons of bran or pollard); when they have eaten that, put some hay into the cribs; at twelve o'clock give each three gallons of the mixture as before. If any cow looks for more, give her another gallon. On the contrary, if she will not eat what you give her, take it out of the manger, for never, at one time, let a cow have more than she will eat up *clean*. Mind you keep your mangers clean, that they do not get sour. At two o'clock, give each cow half a bushel of carrots, mangel-wurzel, or turnips; look the turnips, &c., over well, before you give them to the cows, as one rotten turnip, &c., will give a bad taste to the milk, and most likely spoil a whole dairy of butter. At four o'clock, put the cows into the stall to be milked; feed them on hay as you did at milking-time in the morning, keeping in mind that the cow, whilst milking, must feed on something. At six o'clock, give each cow three gallons of the mixture as before. Rack them up at eight o'clock. Twice a week put into each cow's feed at noon a quart of malt-dust." The writer of these directions adds, that the daily expense of subsisting each cow on the above feed would be about two shillings.

Milking.

Cows are milked twice or thrice a-day, according to circumstances. If twice, morning and night; if thrice, morning, noon, and night. They should not go too long unmilked, for, independently of the uneasiness to the poor animal, it is severely injurious.

The act of milking is one which requires great caution; for if not carefully and properly done, the quantity of the milk will be diminished, and the quality inferior, the milk which comes last out of the udder being always the richest. It should, therefore, be thoroughly drawn from the cows until not a drop more can be obtained, both to ensure a continuance of the usual supply of milk, and also to get the richest which the cows afford. Cows should be soothed by mild usage, especially when young; for to a person whom they dislike, they never give their milk freely. The teats should be always clean washed before milking, and when tender, they ought to be fomented with warm water. The milking and management of the cow should, in these circumstances, be only intrusted to servants of character, on whom the utmost reliance can be placed. In the southern and midland counties of England, it is a common practice to employ men to milk the cows, an operation which seems better fitted for females, who are likely to do the work in a more gentle and cleanly manner, which is of essential importance.

The writer in the "Farmer's Magazine," above quoted, gives the following explicit directions to the dairy-maid in regard to milking:—"Go to the cow-stall at seven o'clock; take with you *cold water* and a sponge, and wash each cow's udder clean before milking; dowse the udder well with *cold* water, winter and summer, as it braces and repels heats. Keep your hands and arms clean. Milk each cow as dry as you can, morning and evening, and when you have milked each cow as you *suppose* dry, begin again with the cow you first milked and drip them each; for the principal reason of cows failing in their milk is, from negligence in not milking the cow dry, *particularly* at the time the calf is taken from the cow. Suffer no one to milk a cow but yourself, and have no gossiping in the stall. Every Saturday night give in an exact account of the quantity of milk each cow has given in the week."

THE DAIRY.

The dairy should be cool, airy, dry, and free from vermin of all kinds. To prevent the intrusion of flies, the windows or ventilators ought to be covered with a fine wire gauze. The floor should be laid with smooth glazed tiles, and also the lower part of the walls; the benches on which the milk pans are to be placed are feet when made of stone or slate, and about thirty inches broad. The ceiling should be at least eight feet from the floor, and finished in every respect like that of an ordinary dwelling-house. A slate roof is preferable to one of tile, as it tends to keep the temperature more equable. Cleanliness is of the most essential consequence in dairy management, and, if not strictly looked after, may cause considerable loss. It is this which has raised the produce of the dairies of Holland so much in public estimation. Every article in which milk is placed, more especially when made of wood, ought to be washed in boiling water, and a little soda or lime dissolved in it. If milk should happen to sour in any dish, the acid thus generated will injure any which may be afterwards put into it; but if washed with water in which an alkali has been dissolved, the acid will be destroyed.

The utensils of a dairy are very numerous. The principal are milk-pails, shallow coolers for holding the milk, sieves for straining it through after it is taken from the cow, dishes for skimming the cream, churns for making the butter, scales, weights, &c. For making cheese, there are likewise ladders, vats, tubs, curd-breakers, and presses; and various other articles will be required, which it is almost impossible to enumerate. In form, these vessels, with a few exceptions, are alike throughout Great Britain; and even in other countries there is little variation. The majority of them are made of wood; but in some of the best dairies in England and Scotland, it is now the practice to have the coolers made of cast-iron, wood lined with tin in the inside, or glazed earthenware. Maple is the wood generally used in England for the manufacture of these dishes; both from its lightness, and being easily cut, it can be finished in a neater style. In Holland, the milk dishes are very commonly made of brass; and certainly brass or iron is to be preferred to wood, because the dishes made from either of these materials are more durable, and can be easier cleaned. It has been objected to earthenware vessels, that, being glazed with lead, the acid of the milk acting upon the glaze forms a very noxious poison. This, however, is scarcely correct; it would require a much stronger acid than that of milk to decompose the glaze; and in some parts of England lead has been long used, and never objected to. Zinc pans are now coming into use, and they can be safely recommended for their cool and cleanly qualities, besides being economical. We have seen it stated that cream rises best in zinc pans.

Cheese-presses are usually made of stone of various weights, according to the size of the cheese. Granite is preferred for this purpose, on account of its great weight. A lever was a method long practised, one end of which being placed in a hole in the wall, the sinker acted as a fulcrum, and one or two unhewn stones hung on the end of the pole produced the pressure. Another kind of press consisted of a stone weight placed upon the sinker, which was raised and depressed either by a block and tackle or a screw. The kind most commonly used at present is a lever with a double wheel, which occupies little space, is easily worked, and allows of the weight being better regulated than by a stone placed upon the sinker.

Churning is now, in all large dairy establishments, performed by machinery, worked either by horse or water power, or attached to a thrashing-machine, if there is one near the dairy. Churns vary in size from ten to fifty, and even one hundred gallons, according to the size of the establishment. The plunge-churn, which has the appearance of a barrel placed on its end, is that most commonly used—the plunge being worked by a lever connected with a shaft and crank, moved by a wheel outside. The common hand-churns are of various forms, either upright with a plunge, or horizontal with arms inside, which are turned by an iron handle. A churn formed like a cradle is much used in Canada, and has been strongly recommended for adoption in this country. It is rocked regularly by a child sitting astride, who may thus be usefully employed while amusing himself. Great care should be taken to wash churns thoroughly with boiling water, both immediately after they have been used, and before they are again to be put into operation; and those churns which admit of being easily cleaned are always to be recommended, even although they should not be so elegant in construction.

DAIRY PRODUCE.

Milk.

Milk consists of three materials blended together, called in science the butteraceous, lactic, and serous kinds of matter, which can be separated by artificial means, so as to form *butter*, the milk called *butter-milk*, and *serum* or whey. The whey is little else than water, slightly saline, and is generally the chief ingredient in the milk. When taken from the cow, milk should be removed to the dairy or milk-house, and after being sieved, placed in shallow pans, to throw up the butteraceous matter termed cream, which, being lightest, floats on the top.

The following observations on milk and its management, made by Dr. Anderson, in his "Recreations," are worthy of the consideration of cow-keepers:—

"Of the milk drawn from any cow at one time, that part which comes off at the first is always thinner, and of a much worse quality for making butter, than that afterwards obtained; and this richness continues to increase progressively to the very last drop that can be obtained from the udder.

"If milk be put into a dish and allowed to stand still, it throws up cream; the portion of cream rising first to the surface is richer in quality and greater in quantity than that which rises in a second equal space of time; and the cream which rises in the second interval of time is greater in quantity and richer in quality than that which rises in a third equal space of time; that of the third is greater than that of the fourth, and so of the rest; the cream that rises continuing progressively to decrease in quantity and to decline in quality so long as any rises to the surface.

"Thick milk always throws up a much smaller proportion of the cream which it actually contains than milk that is thinner; but the cream is of a richer quality; and if water be added to that thick milk, it will afford a considerably greater quantity of cream, and consequently more butter than it would have done if allowed to remain pure; but its quality is, at the same time, greatly debased.

"Milk which is put into a bucket or other proper vessel, and carried in it to a considerable distance, so as to be much agitated, and in part cooled before it be put into the milk-pans to settle for cream, never throws up so much or so rich cream as if the same milk had been put into the milk-pans directly after it was milked.

"From these fundamental facts, the reflecting dairyist will derive many important practical rules. Some of these we shall enumerate, and leave the rest to be discovered. Cows should be milked as near the dairy as possible, in order to prevent the necessity of carrying and cooling the milk before it is put into the creaming dishes. Every cow's milk should be kept separate, till the peculiar properties of each are so well known as to admit of their being classed, when those that are most nearly allied may be mixed together. When it is intended to make butter of a very fine quality, reject entirely the milk of all those cows which yield cream of a bad quality, and also keep the milk that is first drawn from the cow at each milking entirely separate from that which is last obtained, as the quality of the butter must otherwise be greatly debased, without materially augmenting its quantity. For the same purpose, take only the cream that is first separated from the first drawn milk. Butter of the very best quality can only be economically made in those dairies where cheese is also made; because in them the best part of each cow's milk can be set apart for throwing up cream, the best part of this cream can be taken in order to be made into butter, and the remainder, or all the rest of the milk and cream of the dairy, can be turned into cheese. The spontaneous separation of cream, and the production of butter, are never effected but in consequence of the production of acid in the milk. Hence it is, that where the whole milk is set apart for the separation of cream, and the whole of the cream is separated, the milk must necessarily have turned sour before it is made into cheese; and no very excellent cheese can be made from milk which has once attained that state."

We now pass on to a consideration of the most valuable ingredient in the dairy produce—

Butter.

Butter is made of cream, freed from its milky and serous properties. This is effected by churning. Some imagine that no butter can be good except such as is made from fresh cream; but this is a mistake, as cream requires to have a little acidity before the butter will form. The length of time which the cream should stand before churning has never been clearly ascertained; from three to seven days, however, may be considered as the proper period. A more important matter than the length of time which cream requires to stand, is the degree of temperature at which the cream will turn into butter. This has been ascertained from experiment to be from 45 to 75 degrees of Fahrenheit. In Holland, when the cream is too cold, hot water is put into the churn to raise the temperature to 70 or 75 degrees. The best quality of butter is obtained at a temperature of 51 degrees, according to experiments performed by Mr. Pooler; and the greatest quantity at a temperature of 46 degrees. During the process of churning, the agitation will increase the heat to about five degrees more than it was when the cream was put into the churn. Mr. Pooler is of opinion, that the greater quantity of butter is obtained by the increased heat causing more milk to remain amongst the butter; and this, of course, must decrease its quality.

In some of the dairies in the neighbourhood of Edinburgh, and in all those near Glasgow, the butter is made by churning the cream and the milk together. This is done in order to obtain the buttermilk, the demand for which is always great in large cities. When the milk and cream are to be churned together, the milk is kept in the coolers for from twelve to twenty-four hours, and then poured into a milk-tub. It remains here until required for churning; and will, during this time, have coagulated. If a certain quantity of milk is put into the milk-tub, and has coagulated before any more has creamed, the coagulated milk must in no way be disturbed, or, if the two quantities are mixed together, too much fermentation may be the consequence. The milk is not churned till it has become acid; and when once coagulation has taken place, it should be churned as early as convenient. If the milk has not fermented before churning, the buttermilk will keep for a much longer time, will have an agreeable taste, and will bear to be mixed with a little water. When the milk has fermented before being churned, the buttermilk will never be so good, nor will it keep for such a length of time as the former.

The operation of churning, whether it be of cream alone, or cream and milk, is performed in the same manner. The milk requires more time than cream to complete the process, from two to three hours being considered necessary, while cream alone may be effectually churned in an hour and a half. It is necessary that the operation should be slow in warm weather; for if done too hastily, the butter will be soft and white. If the cream is at too high a temperature, the churn should be cooled with cold spring water, to reduce it to the proper degree of heat. In winter, again, the operation of churning should be done as quickly as possible, the action being regular; and the churn should be warmed, to raise the temperature of the milk or cream. The air which is generated in the churn should be allowed to escape, or it will impede the process by the froth which it creates.

After the churning is performed, the butter should be washed in cold spring water, with a little salt in it, two or three times, to extract all the milk which may be lodging about the mass. It is said by some that the butter retains its sweetness much longer when no water is used; and others affirm that the washing improves the flavour. The extraction of the milk from butter will reduce its weight; but it appears from the experiments of Mr. Pooler upon the temperature of the cream, that the less milk which is in the butter its quality is proportionably improved. Kneading and beating the butter too much render it tough and gluey. After the milk has been carefully extracted, if the butter is to be salted, it should be mixed with the finest salt, in the proportion of ten ounces to the stone of fourteen pounds, more or less, according to the time the butter is to be preserved. The butter and salt should be well mixed together with the hand; and in Ireland it is customary to add a little saltpetre. A compound of one part sugar, one part nitre, and two parts of the best Spanish salt, finely powdered together, has been highly recommended for preserving butter. It is used in the proportion of one ounce to the pound: and it is said to give a flavour to the butter which no other kind ever acquires.

For making butter casks or kegs, the wood of the lime-tree is highly recommended, as containing no acid; and after it the white oak and the ash. When wood contains acid, it acts powerfully upon the salt in the butter, converting it into brine. Fir has also been recommended for making casks; and, indeed, any wood will answer if boiled for a few hours, for by this process the pyrolignous acid will be entirely taken out.

In salting, the butter should never be put into the firkins in layers; but the surface should be left every day rough and unbroken, so as to unite better with that of the succeeding churning. The quality may likewise be better preserved by covering it over with a clean linen cloth dipped in pickle, and placing it in a cool situation.

Buttermilk.

This is the liquid which remains in the churn after removing the butter. If skimmed milk has been employed for churning, the buttermilk is thin, poor, and easily sours; but if from the churning of the entire milk, the buttermilk is more thick and rich, and is considered by many a delicious beverage. Good buttermilk is at all events exceedingly wholesome and nutritious. In Ireland, it is largely used at meals with potatoes; in Scotland, it is more frequently employed as a relish with oatmeal porridge; and for this purpose large quantities are brought to Edinburgh, Glasgow, and other towns, from the adjoining rural districts. In England, the buttermilk of farmers is usually employed in feeding pigs.

Corstorphine Cream.

This is a preparation of milk, which derives its name from Corstorphine, a village three miles west from Edinburgh, where it was once made in perfection. It consists of the curd of soured or *lappered* milk, from which the whey is poured, along with fresh cream and a little sugar. In former times it was a favourite supper dish in Edinburgh, but is now altogether out of use.

Devonshire Clouted Cream.

This is a preparation of the rich milk of Devonshire, and may be said to be a kind of half-formed butter, such is the solidness of its consistency. In Vancouver's "Survey of Devonshire," the following is described as the mode of preparing this delicious article:—"The milk is put into tin or earthen pans, holding about ten or twelve quarts each. The evening's meal is placed the following morning, and the morning's milk is placed in the afternoon, upon a broad iron plate heated by a small furnace, or otherwise over stoves, where, exposed to a gentle fire, they remain until after the whole body of cream is supposed to have formed upon the surface; which being gently removed by the edge of a spoon or ladle, small air-bubbles will begin to rise, that denote the approach of a boiling heat, when the pans must be removed from off the heated plate or stoves. The cream remains upon the milk in this state until quite cold, when it may be removed into a churn, or, as is more frequently the case, into an open vessel, and then moved by the hand with a stick about a foot long, at the end of which is fixed a sort of peel from four to six inches in diameter, and with which about twelve pounds of butter may be separated from the buttermilk at a time—the butter in both cases being found to separate much more freely, and sooner to coagulate into a mass, than in the ordinary way, when churned from raw cream that may have been several days in gathering; and at the same time will answer a more valuable purpose in preserving, which should be first salted in the usual way, then placed in convenient-sized egg-shaped earthen crocks, and always kept covered with a pickle, made strong enough to float and buoy up about half out of the brine a new-laid egg. This cream, before churning, is the celebrated clouted cream of Devon."

Cheese.

Cheese may be made from cream alone, or from the whole milk; the object in either case being in the first place to separate the serum from the other materials. This is effected by curdling the cream or milk, by the infusion of an acid, the refuse being the serum or whey, which is of scarcely any value. No acidulous substance is found so suitable for curdling milk as *rennet*, which is formed of the gastric juice of a calf that has been fed on milk. Some persons preserve the maws or stomach bags of calves with the curd contained in them; others employ the stomach bags alone, putting a few handfuls of salt into and around them. They are then rolled up, and hung in a warm place to dry, and are kept for some time before they are used. The stomach is never made use of in Gloucestershire until it is a twelvemonth old; for, if used before this, it is said to swell the cheese, making it full of *eyes* or holes. The usual way of preparing the rennet in England, is to add to every six skins or stomachs two gallons of brine, and two lemons, which take away any unpleasant taste, and give the rennet an agreeable flavour. A large quantity is made at a time; and it is never used until it has stood at least two months. A method of preparing rennet, recommended by the late Mr. Marshall, is as follows:—

"Take the maw of a newly-killed calf, and clean it of its contents, salt the bag, and put it into an earthen jar for three or four days, till it forms a pickle; then take it from the jar, and hang it up to dry; after which it is to be replaced in the jar, the covering of which should be pierced with a few holes to admit the air; and allowed to remain in the jar for twelve months. When wanted for use, a handful each of leaves of sweet briar, dog rose, and bramble, with three or four handfuls of salt, are to be boiled together for a quarter of an hour, when the liquid is to be strained off, and allowed to cool. The maw is then to be put into the liquid, together with a lemon stuck round with cloves; and the longer it remains in the liquid, the stronger and better will the rennet be; half a pint of the liquid is sufficient to turn fifty gallons of milk." As almost every dairy county in England has its own particular method of steeping and salting the maws and preparing the rennet, we shall only give the method pursued in Ayrshire, the most important dairy district in Scotland. The stomach of the calf is examined, and all impurities such as straw, removed from the curdled milk. Two handfuls of salt are then put into and around the bag, which is hung in a warm place to dry thoroughly. It is seldom used before it is a year old, and even a longer period is thought to improve it. When wanted to prepare rennet, the bag is cut into small pieces, and put into a jar, with a handful or two of salt, and a quantity of boiled soft water, cooled down to about sixty-five degrees, or new whey taken off the curd is put into the jar. The quantity of water or whey will vary according to the quality of the yirning; and if it is that of a new-dropped calf, three English pints will be enough; but if fed for four or five weeks, two quarts will be about the quantity required. This is allowed to stand in the jar for two or three days, and is then strained off, and another pint of water placed upon the maw, which, after standing three days, is added to the first infusion. If any impurities appear in the liquid, it should be carefully strained through a sieve, and the whole can be bottled and used as wanted. A glassful of whisky is sometimes put into each bottle; but this is not common. The liquid thus prepared may be used either immediately, or kept months if required, and a table-spoonful will coagulate thirty gallons of milk in the course of ten minutes; whereas the English rennet requires nearly three hours for this purpose.

Dunlop Cheese.—Dunlop cheese has of late come into very general repute; and although nowhere so well made as in the parish of Ayrshire, from which it derives its name, it is now manufactured in Galloway, in the counties of Renfrew, Lanark, and Ayr, and is extending to others. The cheeses are made of various sizes, from a quarter to half a hundred weight; and the process of making them is as follows:—Sweet milk for Dunlop cheese is composed of all the milk as it is yielded by the cows without having the cream separated from it. When so many cows are kept upon a farm that a cheese can be made every time they are milked, the milk is passed through a seive into the vat, and formed into a curd by the rennet. But when the cows are not so numerous as to afford milk sufficient to form a cheese at each milking, it is put into the coolers about six or eight inches deep. At the next milking the cream is skimmed off, and without being heated, the milk is put into the curd-vat along with that just drawn from the cows. The milk is then raised to a temperature above blood heat, or in summer to 90 degrees, and in winter 95 degrees. If coagulated much warmer, the curd becomes too adhesive; some of the butteraceous matter is lost in the whey, and the cheese will be found dry, tough, and tasteless. If too cold, on the other hand, the curd, which is then soft, does not part readily with the serum, and the cheese is so wanting in firmness that it is difficult to get it to keep together. Even after the utmost care has been taken to extract the whey and give solidity to the cheese, holes, which in provincial language are termed *eyes*, whey-drops, and springs, frequently break out, and render the cheese either rancid or insipid.

It is not enough that the milk be brought to a right temperature when the rennet is applied, but the milk must be kept neither too hot nor too cold from the time it is taken from the cow. The temperature of the milk-house ought to be kept as equal as possible, never rising above 55 nor sinking below 50 degrees. In operations so critical as those of the dairy, where any material alteration in the temperature will affect the quality of the cheese, this ought at all times to be ascertained. Instead of this, the general practice is for the dairy maid merely to pass her fingers through the milk, than which nothing can be more uncertain. A thermometer ought not only to be in every milk-house, but also in every byre, as extremes of heat or cold, or sudden changes in the temperature, have a great effect upon the secretion of milk.

About a table-spoonful of the liquid rennet is considered sufficient for 100 quarts of milk, and the curd is formed by it in twelve or fifteen minutes; but in some dairies, the curd does not appear in less than forty-five or sixty minutes, although double the quantity of rennet is used. This must be owing either to a want of strength in the rennet, or from some peculiarity in the herbage upon which the cows have been fed. The curd, when formed, should be broken with the skimming-dish or the hand as soon as possible, but without pressing as the least violence has been found to make it come off white, and thus weaken the quality of the cheese. The whey may be run off by lifting the tub gently on its edge, and allowing it to flow into a vessel placed beside the tub. The curd should then be allowed to stand until the whey had gathered in another part, and this is also poured off.

When quite freed from the whey and the curd has acquired a little consistency, it is cut with the cheese-knife, gently at first, and more minutely as it hardens, after which it is put into the drainer, a square vessel with small holes in the bottom, and a cover to fit inside. The lid is placed upon the curd, with a cloth thrown over it, and pressure is applied according to the quantity of curd; and in this state it is allowed to stand for about half an hour. It is then cut into pieces about two inches square; the whey is again discharged, and double the former weight is placed upon it. This process of cutting it smaller every half hour, and increasing the weight until the pressure is 100 lbs., is continued for three or four hours. It is then cut very small, and thoroughly salted; thirteen ounces of salt to twenty-four pounds English of the curd being sufficient.

A clean cheese-cloth, rinsed in warm water and wrung out, being then placed in the chessel, the curd is put in, and half a hundredweight laid on it for an hour. It is then put under a press of two hundredweight, where it remains during an hour and a half, after which it is taken out, and a fresh cloth placed in the chessel. The cheese is then placed upside down, and laid, with increased weight under the press, letting it remain three or four hours in the press at a time, and at each shifting get a clean dry cloth. Some have shortened the process of pressing by placing the cheese, when it comes from the press for the first time, into water heated to about 95 or 100 degrees, where it remains till the water becomes milk-warm. The cheese is then dried well, and again placed under the press.

When ultimately taken from the press the cheeses are generally exposed for about a week to a considerable degree of drought, turned over every twenty-four hours, and rubbed with a dry cloth. They are then removed to the store-room, which should be in a cool exposure between damp and dry, without the sun being allowed to shine on them, or a great current of air admitted—this gradual mode of ripening being found essential to prevent the fermenting and swelling of the cheese and cracking of the rind. The mode of sweating cheeses, after they come from the press, and before they are laid up to dry, although common in England, is not approved of nor practised in Ayrshire. Yet Dunlop cheeses do not crack in the skin except when the milk has begun to acidify before being coagulated, or when they are exposed to too much drought at first. Whey springs, or eyes, are seldom seen in the cheeses of Ayrshire. Cheese, like butter, is sometimes coloured with an infusion of annato, but the practice is far from being common. The Dunlop or Ayrshire cheeses have not so high a flavour and spicy taste as some of the English, owing, perhaps, to the inferiority of the pasture, and to the greater pains taken in the English dairies to give the cheese an acrid taste.

Cheshire Cheese.—It has been remarked, that although good imitations of the cheese made in the English counties have been produced elsewhere, yet in no trial has a cheese possessing the true Cheshire flavour been made. This is attributed to the abundance of the saline particles in the earth, resulting from the numerous salt springs in that county. Cheshire is almost entirely a dairy county, its arable husbandry being neither extensive nor of a superior character. It is said to possess thirty-two thousand dairy cows; the quantity of cheese made annually is estimated at eleven thousand five hundred tons, and the average quantity afforded by each cow at three hundred pounds. In making the cheese, the practice followed is to set the evening's milk apart till the following morning, when the cream is skimmed off, and two or three gallons put into a brass pan, which is immediately placed in hot water and rendered scalding hot. Half of the milk thus heated is poured upon the night's milk, and the other half mixed with the cream, which is rendered thinner by the mixture. This is done by the dairy-woman while the other servants are milking the cows; and the morning's milk being immediately added to that of the previous, evening the whole mass is set together for cheese. The rennet and colouring being then put into the tub, the whole is well stirred, and a wooden cover put over the tub, with a linen cloth thrown over it. It in general requires an hour and a half before the milk curdles; and if the cream should rise to the surface in this time, the whole must be again well stirred, which is done every time the cream rises, until coagulation takes place.

When the curd is formed, if it be firm, it is cut with the cheese-knife, and then cut across, making the incisions about an inch distant from each other. The curd is then broken by the dairy-woman, until every part of it is made as small as possible, about forty minutes being generally spent in this process, when the curd is left about half an hour to subside, covered over with a cloth. After this, the curd is put in a favourable position in the tub to drain, and a weight of about sixty pounds put upon it, in order to press out the whey, which is drained to the lower side of the tub and laded out. When well drained, the curd is turned upside down, and pressed as before. It is cut into pieces of about nine inches square, which are piled one above another, and pressed both with the hand and the weight, so long as the whey continues to flow.

These pieces are then cut into three parts of about the same size, which are broken very small, and salted at the rate of three handfuls to each. They are then put into a cheese-vat, furnished with a coarse cheese cloth. The curd is heaped in the vat in a conical shape the cone being covered with a cloth, to prevent any curd from falling off. As soon as the curd adheres together, a weight of about sixty pounds is put upon it, and several iron skewers are stuck through it by holes in the sides of the vat. These holes are made in order to allow any whey remaining in the curd to escape. The weight and skewers are then removed, and the curd is broken as small as possible, half way down the vat. The pressing and skewering are again repeated, and a clean cloth is put over the upper part of the curd, which is then taken out of the vat, and put into it again upside down, and broken half way down as before. When no more whey can be extracted, the curd is turned in the vat, and rinsed in warm whey. The curd is still kept above the edge of the vat, being bound round with strong tape to keep it in a proper shape. The cheese is next put into the press, which has generally the power of fourteen or sixteen hundredweight, and is then well skewered with strong wires, eighteen or twenty inches long, and sharp at the points. The vat is furnished with holes on the sides to receive the skewers; and after being about half an hour in the press, the cheese is again turned, and supplied with a clean cloth. It is turned again and again several times for forty-eight hours, each time supplied with a clean cloth, and is then put mid-deep into salt, its top covered with salt, where it remains for three days, its position being reversed each day. When taken out of the vat, it is put into a wooden hoop or girth of the same breadth as the thickness of the cheese, and is placed on the salting bench, where it stands about eight days, being well salted during that time. The cheese is then washed in lukewarm water, and after being wiped, is placed on the drying bench, where it remains about seven days; it is then again washed and dried as before, and rubbed all over with sweet butter. After this, it is placed in the warmest part of the cheese-room, and rubbed each day with sweet butter for the first seven days.

These cheeses vary in size, being in some dairies nearly a hundred and forty pounds in weight. The quantity of salt made use of during the process is uncertain; three pounds to a cheese of sixty pounds is thought to be about the amount; but much of this is lost in the salting house. Whether the cheese acquires much saltness during the steeping and rubbing, is uncertain, though much salt is expended in these operations.

Gloucester Cheese.—The double Gloucester cheese, which is held in such high repute, is almost wholly made in the vale of Berkley in Gloucestershire. Its excellence is said to depend much upon the quality of the land, and the great attention which is paid to the management of the dairies. The quantity of cheese made in this vale annually, is about one thousand two hundred tons, and each cow is estimated to yield three hundred and fifty pounds. It is usually made in the months of May, June, and July, and the process of manufacturing is as follows:—

When the curd is considered firm enough for breaking, it is cut gently and slowly into squares of about an inch; and after standing, to allow the whey to gather, it is again cut at this time into larger pieces than before, and slowly at first. This cutting is gradually quickened, the incisions being made near to each other. The lumps of curd are lifted with the skimming spoon in one hand, and cut with a knife in the other hand, while suspended. The curd is now allowed to settle about a quarter of an hour, when the whey is taken from it by being poured through a fine hair sieve, the dairymaid, at the same time, cutting the curd so that all the whey may escape. The curd is then pressed down with the hand into vats, covered with large cheese-cloths of fine canvas, and placed in the press for half an hour. It is then put into a mill, which crumbles it to small pieces, thus saving the labour of squeezing and rubbing with the hands; and this operation is thought a great improvement in the making of cheese.

The whey is next completely extracted, and the curd put as compactly as possible into the vat, heaped above the vat just so far that it can be pressed down to a level with the edge. A cheese-cloth is then spread over the vat and a little hot water thrown over the cloth, which has a tendency to harden the outside of the cheese, and prevent it from cracking. The curd is next turned out of the vat into the cloth, and the inside of the vat being washed in whey, the inverted curd with the cloth is returned to the vat. The cloth is then folded over, and the vat put into the press for two hours, when it is taken out, and dry cloths applied through the course of the day. It is then replaced in the press until salted, which is generally performed about twenty-four hours after it is made. In salting, the cheese is rubbed with finely powdered salt; and this is thought to make the cheese smoother and more solid than when the salting process is performed upon the curd. The cheese is after this returned to the vat, and put under the press, in which more than one are placed, the newest one at the bottom, and the oldest on the top. The salting is repeated three times, twenty-four hours being allowed to intervene between each; and the cheese is finally taken from the press to the cheese-room in the course of five days. In the cheese-room it is turned over every day for a month, when it is cleaned of all scurf, and rubbed over with a woollen cloth, dipped in a paint made of Indian red or Spanish brown and small beer. As soon as the paint is dry, the cheese is rubbed once a week with a cloth.

The quantity of salt employed is about three and a half pounds; and one pound of annato is sufficient to colour half a ton of cheese.

The true characteristics of double Gloucester consist in its great richness, together with the mildness of its flavour. The single Gloucester differs in no respect in the making from the double sort, except that it is thinner; the weight of each seldom exceeding twelve pounds, while the double is generally about twenty-two pounds. This cheese is sometimes made less rich by being mixed with skimmed milk.

Stilton Cheese.—This cheese is made by putting the night's cream, without any portion of skimmed milk, into the next morning's milk; but those who wish to make it very fine, add still more cream; and thus its richness depends upon the quantity of cream made use of. Butter is also said sometimes to be used in its manufacture. The rennet is then added without any colouring; and when the curd has formed, it is taken out without being broken, and put whole into a sieve or drainer. In the drainer it is pressed with weights until all the whey is extracted, and when dry, put into a hooped chessel. The outer coat being salted, it is then put into the press, and when sufficiently firm, it is taken out of the chessel, and bound tightly in a cloth. This cloth is changed every day until the cheese is quite dry, when it is removed; and the cheese requires no further care except occasional brushing and turning. The Stilton cheese, although small, not weighing more than twelve pounds, requires two years to bring to full maturity.

Parmesan Cheese.—This famous cheese is manufactured in that part of Italy which lies between Cremona and Lodi, comprising the richest portion of the Milanese territory. The cows are kept in the house nearly all the year round, and fed in summer with cut grass from the rich irrigated meadows of the country. Some of the cheeses are so large as to contain nearly 180 lbs. and the milk of 100 cows is required to produce one of this size. This cheese is made from the milk of the evening, which is skimmed in the morning and at noon, and the milk of the morning, which is also skimmed at noon. These two milks are put together into a large copper caldron, which is hung on the arm of a lever, and can be taken off and put on the fire at pleasure. The milk is heated in this vessel to about 120 degrees, and then removed from the fire and kept quiet until all internal motion has ceased.

The rennet is then added, and in an hour the curd will have formed, when it is again put on the fire and heated to a temperature of 145 degrees. While heating, the mass is briskly stirred, till the curd separates in small pieces, when part of the whey is run off, and a little saffron added to colour the cheese. When the curd is sufficiently broken, nearly the whole of the whey is taken out, and two pailfuls of cold water are thrown in. The temperature is thus reduced so far as to allow the dairymen to collect the curd, by passing a cloth under it and gathering up the corners. It is now pressed into a frame of wood, placed on a solid platform, with a heavy weight on the top. In the course of the night the curd cools, parts with the whey, and assumes a firm consistence. The next day one side is rubbed with salt, and the succeeding day the cheese is turned, and the other side rubbed in the same manner, this alternate salting being continued for forty days. After this, the outer surface of the cheese is pared off, the fresh surface rubbed with linseed oil, the convex side is coloured red, and the cheese is fit for sale.

It appears that this highly esteemed cheese is altogether made from skimmed milk, and yet all the pores are filled with an oily substance. This seems too rich to be imparted by the butteraceous matter of milk which has been deprived of its cream, and it is generally supposed that some portion of oil is mixed with the curd. This, however, has not been ascertained to be the case.*

Swiss Cheese.—The finest cheese made in Switzerland is that of Gruyere, in the canton of Friburg. It is rich in quality, and generally flavoured with a powdered dry herb, the *Melilotus officinalis*. The cheeses weigh from forty to sixty pounds each, and are exported in large quantities.

Mr. Laing, in his work, "Notes of a traveller," thus alludes to the primitive dairy operations of the small pastoral farmers in Switzerland:—"Each parish has its *alp*, that is, its common pasture for the cows of the parish, and each inhabitant is entitled to a cow's grazing, from June to October, on this common pasture. Few, however, have cows in sufficient number to repay the labour of attending them at the summer grazing in the alps. The properties are too small, in general, to keep more than five or six cows all winter; and few can keep more than three. Yet these small proprietors contrive to send cheese to market as large as our Cheshire dairy-farmers with their dairy stocks of forty or fifty cows; and, as the price of Gruyere cheeses shows, incomparably better in quality. Each parish in Switzerland hires a man, generally from the district of Gruyere in the canton of Friburg, to take care of the herd, and make the cheese; and if the man comes from Gruyere, all that he makes is called Gruyere cheese, although made far enough from Gruyere. One cheeseman, one pressman or assistant, and one cowherd, are considered necessary for every forty cows. The owners of the cows get credit, each of them, in a book daily, for the quantity of milk given by each cow. The cheeseman and his assistants milk the cows, put the milk altogether, and make cheese of it; and at the end of the season each owner receives the weight of cheese proportionable to the quantity of milk his cows have delivered. By this co-operative plan, instead of the small-sized, unmarketable cheeses only, which each could produce out of his three or four cows' milk, he has the same weight in large marketable cheese superior in quality, because made by people who attend to no other business. The cheeseman and his assistants are paid so much per head of the cows, in money or in cheese, or sometimes they hire the cows, and pay the owners in money or cheese. In October, the cows are brought home, and the home grass-lands having been mown for hay twice during the summer, the winter food is provided, and a very small area of land keeps a cow, when the home grass has not been burdened with summer grazing. The pasture in these alps, or summer grazings, is abundant and rich. In some of the upper valleys, inhabited winter as well as summer, but in which the corn-crops are secondary, and dairy produce the main object—as, for instance, Grindewald—a man with a house suitably situated is permanently established for receiving the milk of the neighbourhood. Each family takes care of and milks its own cow or cows, keeps the milk wanted for family use, and sends the rest of it daily to the cheeseman, who gives each family credit for the milk delivered each day; and the cheese made during the season is divided, or very usually the cheese is marketed, and the money divided; and in this way cheeses of great weight are manufactured, although no one cow-owner has milk enough to make one of marketable size. I went one warm forenoon, while ascending the Rhigi, into one of these dairy houses. From the want of dairymaids or females about the place, and the appearance of the cow-man and his boys, I thought it prudent to sit down on the bench outside of the smoky dwelling room, and to ask for a bowl of milk there. It was brought me in a remarkably clean wooden bowl, and I had some curiosity, when, clean or dirty, my milk was swallowed, to see where it came from. The man took me to a separate wooden building; and instead of the disgusting dirt and sluttishness I had expected, I found the most unpretending cleanliness in this rough milk room; nothing was in it but the wooden vessels belonging to the dairy, but these were of unexceptionable nicety; and all those holding the milk were standing in a broad rill of water led from the neighbouring burn, and rippling through the centre of the room, and prevented, by a little side sluice, from running too full, and mingling with the milk. This burn running through gave a freshness and cleanliness to every article; although the whole was of rude construction, and evidently for use, not show. The cows were stabled, I found, at some distance from the milk-house, that the effluvia of their breath and dung might not taint the milk. Cheese is almost the only agricultural product of Switzerland that is exported; and it is manufactured by these small farmers certainly as well, with as much intelligence, cleanliness, and advantage, as by large farmers."

Whey.

Whey, or the thin watery serum of milk, is of a pale-greenish hue, and saline in taste, and forms an agreeable beverage when cool. Some dairy-farmers in England are in the habit of extracting a little butter from it; but with careful management, this practice would be quite unnecessary, as it is only when the milk has been coagulated too hot that any quantity of butter will remain in this liquid. In Scotland, the whey is used as food by the farmers and their families in making oatmeal porridge and a saving of nearly one-third of meal is effected when the porridge is made of whey instead of water. By boiling, what is called float whey is obtained, which, when mixed with a little sweet milk, is thought little inferior to curd. Whey is also very valuable in feeding swine; and it is estimated that the whey of three or four cows will, in the course of one season, with little additional food, fatten a pig to the weight of twelve or fourteen stones.

LONDON DAIRY MANAGEMENT.

The quantity of fresh milk annually consumed in the British metropolis was lately calculated to be 39,420,000 quarts, costing £985,500, and being the produce of 12,000 cows, kept principally in large dairy establishments in all parts of the environs. The milk is generally of the best kind when drawn from the animals; but, between the dairy and the consumer, it passes through several hands, each of whom takes a profit upon it, and increases the quantity of saleable liquid by large infusions of water, chalk, &c. In the condition it usually reaches the public, it is shamefully adulterated. The charge of deteriorating the quality of the article is seldom made upon the cow-keepers, whose establishments are, for the most part, models of good management. As it may be interesting to our readers to have some account of these large dairies, we present the following particulars:—

The two largest dairy establishments are those of Mr. Flight (known as Laycock's dairy) and of Messrs. Rhodes. Flight's is one of the curiosities of London; it covers fourteen acres of ground, surrounded by a high wall, and

* For our information upon the manufacture of cheese in the English counties, we have been indebted to the British Husbandry; and the different county reports; and for the account of the Parmesan cheese, principally to the Journal de Physique.

including buildings for the different purposes required. In the cow-house there are upwards of 400 cows, the whole of which are fed in stalls. The food is very properly varied; at one time they have mangel worzel; then they have turnips, carrots, cabbages, and clover; and when fattening for market, they are fed on oil-cake and other articles. All are curried daily. Adjoining the cow-house is an hospital for unwell cows, or cows which are calving. The milk-house is kept beautifully clean, being scouered daily with hot water.

With respect to Rhodes's dairy, which is situated at Islington, Mr. Loudon, in his "Encyclopædia of Agriculture," has condensed the following description of its extent and mode of management from various publications: "The number of cows kept by the present Messrs. Rhodes exceeds, on an average of the year, four hundred: at one time these individuals are said to have had upwards of a thousand cows in their different establishments. The surface on which the buildings are placed is a slope of two or three acres, facing the east; and its inclination is about one inch in six feet. The sheds run in the direction of the slope; as well for the natural drainage of the gutters, and the more easily scraping, sweeping, and wheeling out of the manure, as for supplying water for drinking to small cast-iron troughs, which are fixed in the walls, at the heads of the cattle, in such a manner as that the one trough may be supplied from the other throughout the whole length of the shed. The sheds are twenty-four feet wide; the side walls about eight feet high; the roof of tiles, with rising shutters for ventilation, and with panes of glass, glazed into cast-iron skeleton tiles, for light. The floor is nearly flat, with a gutter along the centre; and a row of stalls, each seven feet and a half wide, and adapted for two cows, runs along the sides. The cows are fastened by chains and rings, which rings run on upright iron rods, in the corners of the stalls; the common mode being departed from only in having iron rods instead of wooden posts. A trough or manger, formed of stone, slate, or cement, of the ordinary size of those used for horses, and with its upper surface about eighteen inches from the ground, is fixed at the head of each stall. Four sheds are placed parallel and close to each other, and in the party walls are openings, about a foot in breadth and four feet high, opposite each cow. The bottom of these openings is about nine inches higher than the upper surface of the troughs, and is formed by the upper surface of the one-foot-square cast-iron cisterns, which contain the water for drinking. Each cistern serves two cows, which, of course, are in different sheds, but adjoining and opposite each other. All these troughs are supplied from one large cistern by pipes, in a manner which can be so readily conceived that we shall not stop to offer a description. Each of these troughs has a wooden cover, which is put on during the time the cows are eating their grains, to prevent their drinking at the same time, and dropping grains in the water. At the upper end, and at one corner of this quadruple range of sheds, is the dairy, which consists of three rooms of about twelve feet square: the outer or measuring-room; the middle or scalding-room, with a fire-place and a boiler; and the inner or milk and butter-room, separated by a passage from the last. At the lower end of the range is a square yard, surrounded by sheds; one for fattening the cows when they have ceased to give milk, and the others for store and breeding pigs. The pigs are kept for the purpose of consuming the casual stock of skim milk which occasionally remains on hand, owing to the fluctuations in the demand. This milk is kept in a well, walled with brick laid in cement, about six feet in diameter, and twelve feet deep. The milk becomes sour there in a very short time; and, as is well known, is found most nourishing to the pigs when given in that state. Breeding swine are found most profitable, the sucking pigs being sold for roasting. Beyond this yard is a deep and wide pit or pond, into which the dung is emptied from a platform of boards projecting into it. The only remaining building wanted to complete the dairy establishment is a house or pit for containing the exhausted malt (grains), on which the cows are chiefly fed. Messrs. Rhodes have a building or pit of this description at some distance, where they have a smaller establishment. There are a stack-yard, sheds, and pits for roots, straw, and hay, a place for cutting hay into chaff, cart-sheds, stables, a counting-house, and other buildings and places common to all such establishments, which it is not necessary to describe.

"The cows in Rhodes's dairy are purchased newly calved in the cow market held in Islington every Monday. They are kept as long as they continue to give not less than two gallons of milk a day, and are then fattened on oil-cake, grains, and cut clover hay, for the butcher. The short-horned breed is preferred, partly for the usual reason of being more abundant milkers than the long horns, partly because the shortness of their horns allows them to be placed closer together, and partly because this breed is more frequently brought to market than any other. The Ayrshire breed has been tried to the number of 150 at a time, and highly approved of, as affording a very rich cream, as fattening in a very short time when they have left off giving milk, and as producing a beef which sold much higher than that of the short horns. The difficulty, however, in procuring this breed was found so great, that Mr. Rhodes was obliged to leave it off. The length of time during which a cow treated as in this establishment, continues to give milk, varies from six months to the almost incredible period of two years. We were assured of there being at this moment several cows among the 390 which we saw, that had stood in their places even more than two years, and continued to give upwards of one gallon of milk daily.

"The treatment of the cows in Rhodes's dairy differs from that in most other establishments. The cows are never untied during the whole period that they remain in the house. In most other establishments, if not in all, stall-fed cows or cattle are let out at least once a day to drink; but these animals have clear water continually before them. They are kept very clean, and the sheds are so remarkably well ventilated, by means of the openings in the roofs, that the air seemed to us purer than that of any cow-house we had ever before examined; probably from its direct perpendicular entrance through the roof, this, in moderate weather, being certainly far preferable to its horizontal entrance through the side walls.

"The principal food of the cows in Rhodes's dairy, as in all the other London establishments, consists of grains; that is, malt after it has been used by the brewer or the distiller. As the brewing seasons are chiefly autumn and spring, a stock of grains is laid in at these seasons sufficient for the rest of the year. The grains are generally laid in pits bottomed and lined with brickwork set in cement, from ten to twenty feet deep, about twelve or sixteen feet wide, and of any convenient length. The grains are firmly trodden down by men, the heaps being finished like hay-ricks, or ridges in which potatoes are laid up for the winter, and covered with from six to nine inches of moist earth or mud, to keep out the rain and frost in winter, and the heat in summer. As a cow consumes about a bushel of grains a day, it is easy to calculate the quantity required to be laid in. The grains are warm, smoking, and in a state of fermentation when put in, and they continue fit for use for several years, becoming somewhat sour, but they are, it is said, as much relished by the cows as when fresh. It is common to keep grains two or three years; but in this establishment they have been kept nine years, and found perfectly good. The exclusion of the air almost prevents the increase of the fermentation and consequent decomposition. What is called distiller's wash, which is the remainder after distillation of a decoction of ground malt and meal, is also given to cows, but more frequently to such as are fattening than to those in milk. The present price of brewers' grains is fourpence halfpenny per bushel; of distillers' grains, on account of the meal they contain, ninepence a bushel; of wash, thirty-six gallons for sixpence.

"Salt is given to the cows in Rhodes's dairy at the rate of two ounces each cow a day. It is mixed with the grains, which are supplied before milking, about three o'clock in the morning; and in the afternoon, about two o'clock, just before milking. Of green food or roots, portions are supplied alternately with the grains; and in winter, when tares or green grass cannot be procured, after the turnips, potatoes, or mangel-wurzel have been eaten, a portion of dry hay is given.

"The produce of this dairy is almost entirely milk and cream for private families and for public hospitals and other institutions. A number of the public establishments are supplied directly from the dairy by contract; but private families are principally supplied by milk-dealers: these have what are called milk-walks; that is, a certain number of customers, whom they call upon with supplies twice a day; and they are thus enabled to ascertain the average of what their customers consume, and to contract with Messrs. Rhodes for this average. The latter calculate the number of cows sufficient to give the dealer the supply wanted, and this number the dealer undertakes to milk twice a day, namely, at three o'clock in the morning and at three in the afternoon. The milk is measured to the dealer, and should he have milked more than his quantity, it remains with the dairyman; but should the cows have been deficient in the quantity, it is made good from the milk of other cows, milked on account of the contracts of the establishment. As the supply of the cows and the demand of the dealers are continually varying, it often happens that considerable quantities of milk remain on the dairyman's hands, frequently, we are told, as much as sixty or seventy gallons a day. This quantity is placed in shallow earthen vessels, to throw up the cream in the usual manner; this cream is churned, and the butter sold." The skimmed milk, it is added, as well as the butter-milk, are, as is usual in English dairies, given to the pigs.

GENERAL MANAGEMENT OF CATTLE.

Diseases.

Cattle are subject to various diseases, the result of improper treatment, or of causes connected with climate which it is difficult to avert. By attention to feeding, housing and cleaning, as already noticed, much may be done to prevent some of the more fatal distempers. Cattle that have passed their lives, both day and night, in the open air, are generally so hardy that they are not injured by a wetting of the skin, and are liable to few of the complaints of dairy or stall-fed animals. Cows, being compelled to lead an artificial mode of life, are the most delicate in every respect, and require the most careful treatment. They should not be left out all night, and when they return from the field wet, it is always a safe and humane plan to dry them with a wisp of straw. The diseases to which they are most liable are of an inflammatory kind, and for these the veterinary surgeon prescribes bleeding, and perhaps some medicines to be taken internally. Leaving cow-keepers to seek the advice of these professional men, or at least of persons possessing practical skill, we need here only allude to three chief disorders for the sake of general information. The first we shall mention is

The Hove.

The hove, or blown, in cattle is a swelling in the paunch, caused generally by eating wet grass or clover in warm weather. The substance ferments, and the membrane becomes distended by the creation of air or gas, which cannot find the means of escape; and if not taken off artificially, the animal will be suffocated. Mr Loudon, in his "Encyclopædia of Agriculture," mentions the following methods of relief from this fatal distension:—

"There are three modes of relieving the complaint, which may be adverted to according to the degree of distension and length of time it has existed. These are internal medicines; the introduction of a *probang* of some kind into the paunch by the throat; and the puncturing it by the sides. Dr. Whyatt, of Edinburgh, is said to have cured eighteen out of twenty hoved cows, by giving a pint of gin to each. Oil, by condensing the air, has been successfully tried. Any other substance, also that has a strong power of absorbing air may be advantageously given. Common salt and water, made strongly saline, is a usual country remedy. New milk, with a proportion of tar equal to one-sixth of the milk, is highly spoken of. A strong solution of prepared ammonia in water often brings off a great quantity of air, and relieves the animal. Any of these internal remedies may be made use of when the disease has recently taken place, and is not in a violent degree; but when otherwise, the introduction of an instrument is proper, and is now very generally resorted to. The one principally in use is a species of probang, invented by Dr. Munroe, of Edinburgh. Another, consisting of a cane of six feet in length, and of considerable diameter, having a bulbous knob of wood, has been invented by Eager, which is a more simple machine, but hardly so efficacious. It is probable that, in cases of emergency, even the larger end of a common cart-whip, dexterously used, might answer the end. But by far the best instrument for relieving hoven cattle, as well as for clystering them, is Read's enema apparatus, which is alike applicable to horses, cattle, and dogs. It consists of a syringe, to which tubes of different kinds are applied, according to the purpose and the kind of animal to be operated upon. There is a long flexible tube for giving an enema to horses and cattle, and a smaller one for dogs. To relieve hoven bullocks effectually, it is necessary not only to free the stomach from an accumulation of gas, but from the fermenting pultaceous mixture which generates it: for this purpose a tube is applied to the extremity of the syringe, and then passed into the animal's stomach through the mouth, and being put in action, the offending matter is discharged by a side opening. When the same operation is performed on sheep, a smaller tube is made use of. The characteristic excellency of Read's instrument is, that there is no limit to the quantity of fluid that may be injected or extracted. The same syringe is used for extracting poison from the stomach of man, for smoking insects, extinguishing fires, and syringing fruit trees. The introduction of any of these instruments may be effected by the help of an assistant, who should hold the horn of the animal by one hand, and the dividing cartilage of the nose with the other; while the operator himself, taking the tongue in his left hand, employs his right in skilfully and carefully introducing the instrument; the assistant bringing the head and neck into such an attitude as to make the passage nearly straight, which will greatly facilitate the operation. But when no instruments can be procured, or as cases may occur when, indeed, it is not advisable to try them, as when the disease has existed a considerable time, or the animal has become outrageous, or the stomach so much distended with air that there is danger of immediate suffocation or bursting, in these instances the puncture of the maw must be instantly performed, which is called *paunching*. This may be done with the greatest ease, midway between the ilium or haunch-bone and the last rib of the left side, to which the paunch is cline: a sharp penknife is frequently used; and persons in veterinary practice should always keep a long trocar, which will be found much the more efficacious, and by far the most safe, as it permits the air escaping certainly and quickly, at the same time that it prevents its entrance into the cavity of the abdomen, which would occasion an equal distension. As soon as the air is perfectly evacuated, and the paunch resumes its office, the trocar may be removed; and in whatever way it is done, the wound should be carefully closed with sticking-plaster or other adhesive matter. It is necessary to observe, that this operation is so safe, that whenever a medical assistant cannot be obtained, no person should hesitate a moment about doing it himself. After relief has been afforded by means of either the probang or the paunching, a stimulant drink may be very properly given: half a pint of common gin, or one ounce of spirit of hartshorn in a pint of ale, or two ounces of spirit of turpentine in ale, may any of them be used as an assistant stimulus. When, also, the cud is again chewed, still some relaxation of the digestive organs may remain; at first, therefore, feed sparingly, and give, for a few mornings, a tonic."

The apparatus mentioned above, with directions for use, may now be had from the principal makers of or dealers in agricultural implements. The cane tube, to employ in emergencies, no cow keeper should be without.

Epidemic Murrain.

The malignant epidemic, generally called murrain, is a species of catarrh, affecting the respiratory organs, and is most frequent in damp climates or ill-drained parts of the country. The writer of the work on cattle, already quoted from (Lib. Use. Know.), thus speaks of its nature and remedies:—"There are few diseases that assume, in its earlier or later stages, a greater variety of form; but, disarmed somewhat of its virulence in modern times, or at least not having appeared in all its terrors for some years past, it will generally be distinguished by some or the greater part of the following symptoms:—

"There will be cough, frequent and painful, and in many cases for a week or more before there is any other marked symptom. The farmer may not always be aware of this, but he will find it out if he inquires about it; and he will be fully aware of the importance of the fact before we have done with this division of our subject.

"After a few days, some heaving of the flanks will be added to the cough; the pulse will be small, hard, frequent, and sometimes irregular; the mouth hot; the root of the horn cold; the fæces sometimes hard and black, at others liquid and black, and then very fœtid. Presently afterwards, that of which we have to speak again and again, is observed—extreme tenderness along the spine, and particularly over the loins.

"The cough becomes more frequent and convulsive, and a brown or bloody matter runs from the nostrils and mouth; the eyes are swelled and weeping; the patient grinds his teeth; there is frequent spasmodic contraction about the nostrils; and the animal rarely lies down, or, if he does, rises again immediately.

The eyes soon afterwards become unusually dull; the pulse remains small, but it has become feeble; the respiration is quicker; the flanks are tucked up; the tenderness on the loins is removed; insensibility is stealing over the frame; and the fæces are more loaded with mucus, and more fœtid. The patient moans and lows, and grinds his teeth almost incessantly; the head is agitated by a convulsive motion; blood begins to mingle with the fæces; the breath, and even the perspiration becomes offensive; and the beast staggers as he walks.

"Tumours and boils now, or often earlier, appear on various parts. If they are to come forward, the sooner they rise the better, for much depends on what becomes of them. If the animal has sufficient strength for them to go through the usual process of suppuration, although the sloughing and the stench may be greater than could be thought possible, the beast will have a chance to recover; but if there is not energy to bring them forward —if they become stationary—and, most assuredly, if they recede and disappear, the patient will die.

"The treatment of this disease is most unsatisfactory. If the farmer could be brought to attend more to this cough in cattle, if, here, he had recognised the violent and increasing cough and, although he had not dreamed of murrain, had bled and physicked the beast on account of the cough, the disease would probably have been arrested, or at least its virulence would have abated.

"The early stage even of murrain is one of fever, and the treatment should correspond with this—bleeding. Physic should be cautiously yet not timorously resorted to. For sedative medicines there will rarely be room, except the cough should continue. Small doses of purgative medicine, with more of the aromatic than we generally add, will be serviceable, effecting the present purpose, and not hastening or increasing the debility which generally is at hand; but if the bowels are sufficiently open, or diarrhœa should threaten, and yet symptoms of fever should be apparent, no purgatives must be given, but the sedatives should be mingled with some vegetable tonic. The peculiar fœtid diarrhœa must be met with astringents, mingled also with vegetable tonics. In combating the pustular and sloughing gangrenous stage, the chloride of lime will be the best external application; while a little of it administered with the other medicines inwardly, may possibly lessen the tendency to general decomposition. The external application of it should not be confined to the ulcerated parts alone, but it should be plentifully sprinkled over and about the beast; and the infected animal should be immediately removed from the sound ones."

Red-Water.

This disease, indicated at first by the redness of the urine, is properly inflammation of the kidneys, and arises from an undue determination of blood to these parts of the animal. The cause of this local inflammation is generally connected with the nature of the food. In many instances, it is found to have arisen from the cattle eating plants of a noxious quality, and which, as it appears, are not confined to any particular species of soil. When in its aggravated form, the disease becomes what is called *black-Water*. On the slightest indication of the early stages of the distemper, the cattle ought to be immediately shifted to different pastures, or housed and stall-fed for a short period; and if this simple precaution prove unavailing in restoring health, each animal affected should be copiously, and if necessary frequently, bled; and let that active treatment be followed up by purgatives, so as to clear out and restore a proper tone to the bowels. Should these means fail, let a skilled practitioner be consulted. On no account listen to the absurd advices of superstitious and ignorant people either on this or any other disease of cow or bullock. In every quarter of the country, there are persons who, from total ignorance of the physiology of cattle, and the natural causes and action of disease, ascribe calamities of this kind to witchcraft or other supernatural influences. Let all such quacks, and their irrational salvos, be carefully shunned.

Fattening Cattle for Market.

The stall-feeding or soiling of cattle is considered to possess several advantages over feeding in the fields. In field-feeding the animals waste a certain quantity of pasture by treading and lying upon it, and by dropping their dung, the grass which grows on the dung spots being ever after rejected; the animals also spend time in seeking for the herbage which suits their fancy, and much is allowed to go to seed untouched. In stall-feeding, the whole time is devoted to eating and ruminating, while no food is lost, and the animals are brought to a higher condition. Another important advantage of soiling is, that it uses up the waste straw of a farm as litter, and thus furnishes a plentiful supply of that indispensable article, manure, for the fields. Some feeders tie up their cattle to the stall while preparing for market; but others permit them to roam about on a thick bed of straw in an enclosure in the farm yard, with a shed to retire to for shelter, the feeding in this case being from racks. Unless for a period during the final process of fattening, the straw-yard method is reckoned the best for keeping the cattle in a healthy state, and consequently for producing beef of the finest kind. The practice of feeding cattle for a considerable length of time, in darkened stalls, on oil-cake, carrots, mangel wurzel, &c., produces, as is well known, a great deposition of fat, and swells the animals to a monstrous size. The beef, however, of such overfed cattle is never fine. The fat with which it is loaded easily escapes in cooking, and leaves lean of an inferior quality. The best sign of good meat is its being *marbled*, or the fat and lean well mixed, when brought to the table, and this is not to be expected from beef fed in an unnatural condition.

Speaking on this subject, the writer of the article Agriculture, in the "Encyclopædia Britannica," observes —"The age at which cattle are fattened depends upon the manner in which they have been reared, upon the properties of the breed in regard to a propensity to fatten earlier or later in life, and on the circumstances of their being employed in breeding, in labour, for the dairy, or reared solely for the butcher. In the latter case, the most improved breeds are fit for the shambles when about three years old, and very few of any large breed are kept more than a year longer. As to cows and working oxen, the age of fattening must necessarily be more indefinite; in most instances, the latter are put up to feed after working three years, or in the seventh or eighth year of their age."

Many of the cattle fed for the metropolitan markets, as formerly mentioned, have originally been brought from the Highlands and isles of Scotland, also from Wales and Ireland. "The Highland cattle often pass through three different hands or more before they come to the butcher. They are improved at every stage by a greater quantity and better quality of food, instead of being suddenly transported from poor to rich feeding; and while each successive owner applies his produce to the best advantage, and receives a suitable return according to its value, from the advance of price, the consumer at least purchases his beef cheaper, and of a much superior quality, than if the cattle had been sent to the shambles from any of the intermediate stages.

"The West Highland cattle make this progress oftener than the larger cattle of the north-eastern counties. Many of them are brought to Dumbartonshire and other places at the age of two years and two years and a half, wintered on coarse pastures, with a small allowance of bog-hay or straw, and moved to lower grounds next summer. They are then driven farther south, where they get turnips in straw-yards through the following winter, and in April are in high condition for early grass, upon which they make themselves fat in the month of June.

"The larger varieties of the north-eastern counties do not leave the breeder at so early an age. They are seldom brought to market till they are three or three years and a half old, and then frequently in good condition for being fattened either on grass or turnips. A great many of the Aberdeenshire cattle are bought for the straw-yards of the southern counties, get a few turnips through winter and spring, and are either driven to England in April, or fattened at home in the course of the ensuing summer. The Fife cattle, like the other breeds of the Lowlands, are generally sold to the graziers at three years old, having got a liberal allowance of turnips during the preceding winter."*

Rules for Selecting Cattle

In selecting cattle for feeding, their qualities may be in some measure known by examining the hide, horns, &c. "It is well known that the grazier and the butcher judge of the aptitude that any animal has to fatten from the touch of the skin. When the hide feels soft and silky it strongly indicates a tendency in the animal to take on meat; and it is evident that a fine and soft skin must be more pliable, and more easily stretched out to receive any extraordinary quantity of flesh, than a thick or tough one. At the same time, thick hides are of great importance in various manufactures. Indeed, they are necessary in cold countries, where cattle are much exposed to the inclemency of the seasons; and, in the best breeds of Highland cattle, the skin is thick in proportion to their size, without being so tough as to be prejudicial to their capacity of fattening. It appears, from Columella's description of the best kind of ox, that the advantage of a soft skin is not a new discovery, but was perfectly well known to the husbandmen of ancient Italy." These are the observations of Sir John Sinclair,† who adds the following as a summary of good points to be attended to in choosing cattle. They should be—1. Of a moderate size, unless where the food is of a nature peculiarly forcing; 2. Of a shape the most likely to yield profit to the farmer; 3. Of a docile disposition, without being deficient in spirit; 4. Hardy, and not liable to disease; 5. Easily maintained, and on food not of a costly nature; 6. Arriving soon at maturity; 7. Producing considerable quantities of milk; 8. Having flesh of an excellent quality; 9. Having a tendency to take on fat; 10. Having a valuable hide; and, lastly, Calculated (should it be judged necessary) for working." It is thought best to begin to break-in oxen at three years old, and to give them full work at four.

With respect to judging of cattle by their horns and teeth, we offer the following observations from the "Cyclopædia of Practical Husbandry, by Martin Doyle" (Rev. Mr. Hickey).

"The ordinary guide for ascertaining the precise age of cattle is the horn, which is also indicative of the breed; at three years old (this is laid down as a rule) the horns are perfectly smooth, after this a ring appears near the root, and annually afterwards a new circle, so that, by adding two years to the first ring, the age is calculated; but the contributors to the volume so frequently quoted, have clearly shown that this is a very uncertain mode of judging; 'that the rings are only distinct in the cow;' and that 'if a heifer goes to the bull when she is two years old, or a little before or after that time, there is an immediate change in the horn, and the first ring appears; so that a real three-year old would carry the mark of a four-year old.' 'In the bull they are either not seen until five, or they cannot be traced at all;' nor in the ox do they 'appear until he is five years old, and they are often confused;' besides, there is also an instrument called a rasp, which has been said to make many an arm ache a little before a large fair.' Without any delusive intentions, however, an ugly set in the horns of young cattle is often remedied by filing a little off the sides of the tips opposite to the direction which it is desired that the horns should take.

"Some men have an antipathy to horns altogether, and would even carry their dislike so far as to extirpate them from the brows of all their cattle; they can indulge their taste by paring off the tops of the horns when they first break through the skin. Perhaps it is not generally known, that the larger the horn the thinner the skull.

* General Report of Scotland, vol. viii, p. 64.
† Farmer's Magazine, vol. viii.

"The age is indicated with unerring certainty by the teeth, to those who have judgment and experience, until the animal reaches the age of six or seven; until two years old, no teeth are cast, at that age two new teeth are cut; at three, two more are cut; and in the two succeeding years, two in each year; at five the mouth is said to be full, though not completely so until six, because until that period the two corner teeth (the last in renewal) are not perfectly up. The front or *incisor* teeth are those considered, for a full grown beast has altogether thirty-two teeth."

Method of ascertaining the Weight of Cattle while Living.

"This is of the utmost utility for all those who are not experienced judges by the eye, and by the following directions, the weight can be ascertained within a mere trifle:—Take a string, put it round the beast, standing square, just behind the shoulder-blade; measure on a foot-rule the feet and inches the animal is in circumference; this is called the girth; then, with the string, measure from the bone of the tail which plumbs the line with the hinder part of the buttock; direct the line along the back to the fore part of the shoulder-blade; take the dimensions of the foot-rule as before, which is the length, and work the figures in the following manner:—Girth of the bullock, 6 feet four inches; length, 5 feet 3 inches; which, multiplied together, make 31 square superficial feet; that again multiplied by 23 (the number of pounds allowed to each superficial foot of cattle measuring less than 7 and more than 5 in girth), makes 713 pounds and, allowing 14 pounds to the stone, is 50 stone 13 pounds. Where the animal measures less than 9 and more than 7 feet in girth, 31 is the number of pounds to each superficial foot. Again, suppose a pig or any small beast should measure 2 feet in girth, and two feet along the back, which, multiplied together, make 4 square feet; that multiplied by 11, the number of pounds allowed for each square foot of cattle measuring less than 3 feet in girth, makes 44 pounds; which, divided by 14, to bring it to stones, is 3 stone 2 pounds. Again, suppose a calf, a sheep, &c., should measure 4 feet 6 inches in girth, and 3 feet 9 inches in length, which, multiplied together, make 16¼ square feet; that multiplied by 16, the number of pounds allowed to all cattle measuring less than 5 feet, and more than 3 in girth, makes 264 pounds; which, divided by 14, to bring it into stones, is 18 stones 12 pounds. The dimensions of the girth and length of black cattle, sheep, calves, or hogs, may be as exactly taken this way as is at all necessary for any computation or valuation of stock, and will answer exactly to the four quarters, sinking the offal, and which every man, who can get even a bit of chalk, can easily perform. A deduction must be made for a half-fatted beast of 1 stone in 20, from that of a fat one; and for a cow that has had calves, 1 stone must be allowed, and another for not being properly fat."*

* Cattle Keeper's Guide.

SHEEP.

In the *Ruminant* order of the Mammalia, a distinguished place is given to the sheep, the flesh and wool of which have been recognised as alike of the greatest use to man from the earliest ages. In our own country, within the last half century, the different breeds of sheep have been improved by the growing intelligence, skill, and industry, of the farmers: and their management has, under high patronage, been brought to a degree of perfection perhaps nowhere else attained. It may be added that, as the sciences of anatomy, physiology, botany, and chemistry, are every year throwing new light on those laws of nature, which regulate the structure, health, nutrition, and reproduction of the animal kingdom, we may entertain the hope of still further improvement in this department of rural economy.

DIFFERENT BREEDS OF SHEEP.

The varieties of sheep that now exist in different parts of the globe, have all been reduced by Cuvier into four distinct species.

1. (*Ovis Ammon*)—the Argali; this species is remarkable for its soft reddish hair, a short tail, and a mane under its neck. It inhabits the rocky districts of Barbary and the more elevated parts of Egypt. 2. (*Ovis Tragelaphus*)—the bearded sheep of Africa. 3. (*Ovis Mismon.*) 4. (*Ovis Montana*)—the Mouflin of America; but this species, which inhabits the rocky mountains of North America, is now believed to be identical with the Argali, which inhabits the mountains of Central Asia, and the higher plains of Siberia northwards to Kamschatka. This leaves only three distinct species of wild sheep as yet discovered.

It is still a point in dispute from which of these races our domestic sheep have been derived; nor is the question, in our circumstances, of great practical importance, though its solution is very desirable in a physiological point of view. Whether the wild races may be regarded as of one species, as some naturalists contend, or of different species, according to others, the best judges are next to unanimous that the domestic races of this country are of one species; and what are called different breeds are nothing more than varieties, the result of different culture, food, and climate. The influence of these conditions, in diversifying the character and condition of sheep, will be adverted to under their proper heads.

The following may be regarded as the principal breeds of this country:—1. The Zetland sheep; 2. The Dun-wooled sheep; 3. The Black-faced heath sheep; 4. The Moorland sheep; 5. The Cheviot sheep; 6. The horned varieties of fine-wooled sheep of Norfolk, Wiltshire, and Dorset; 7. The Ryeland sheep; 8. The South down sheep; 9. The Merino sheep; 10. The Devonshire Notts, Romney Marsh, old Lincolnshire, Teeswater, and Old Leicester sheep; 11. The New Leicester and Improved Teeswater sheep.

1. The *Zetland sheep* inhabits those islands from which they derive their name, and extend to the Faroe Islands and the Hebrides. In general, they have no horns. The finest fabrics are made of their wool, which forms a fine fur. This wool is mixed with a species of coarse hair, which forms a covering for the animal when the wool falls off. A similar species are known to inhabit the most northerly parts of Europe, from which it is supposed the fine-wooled sheep of our northern islands and Highlands have been derived. They are hardy in constitution, and well adapted to the soil and pastures on which they are reared, but would ill repay their cultivation in Lowland districts.

2. The *Dun-wooled breed*.—The dun colour of this species is not confined to the wool, but extends to the face and legs. They seem at one time to have been cultivated very extensively, and remnants of them still exist in Scotland, Wales, and the Isle of Man.

3. *The Black-faced heath breed*, being the most hardy and active of all our sheep, are the proper inhabitants of every country abounding in elevated heathy mountains. They have spiral horns, their legs and faces are black, with a short, firm, and compact body; their wool is coarse, weighing from 3 to 4 lbs. per fleece; they fatten readily on good pastures, and yield the most delicious mutton, weighing from 10 to 16 lbs. per quarter. They still exist in considerable numbers in the more elevated mountains of Yorkshire, Cumberland, Westmoreland, Argyleshire, and the central Highlands of Scotland.

4. *The Moorland sheep of Devonshire* are sometimes termed the Exmoor and Dartmoor, from the different districts of Devonshire in which they are reared. They have horns, with legs and faces white, wool long, with a hardy constitution, and are said to be well adapted to the wet lands which they occupy. Their wool weighs 4 lbs. the fleece; but they are rather small, and in some respects ill formed.

5. *The Cheviot breed* derive their name from the Cheviot mountains, in which they are indigenous. They are longer and heavier than the black-faced. Their wool is fine; a medium fleece weighs about 3 lbs.; a carcass, when fat, weighs from 12 to 18 lbs. per quarter. Their faces are white; their legs are long, clean, and small boned, and clad with wool to the hough. Their only defect of form is a want of depth in the chest; yet, with this exception, their size, general form, hardy constitution, and fine wool, are a combination of qualities in which, as a breed for mountain pasturage, they are yet unrivalled in this country.

6. *The Horned varieties of fine wooled sheep of Norfolk, Wiltshire, and Dorset*.—This breed of sheep have short wool, in which they differ from the black-faced sheep, and moorland sheep of Devonshire, and from the Cheviot, in having large spiral horns. They are not much lighter than the Cheviots, but they are ill formed, and thin, flat in the ribs, and slow feeders; a medium fleece weighs about 2 lbs. It is believed that the South-down will eventually displace them. The Wiltshire sheep are still heavier than those of Norfolk, being the largest of our fine wooled sheep; they are said to thrive well in the downs of Wiltshire, but they are also giving ground to the South-downs. The Dorset sheep have horns, white faces and legs; their three-year-old wethers weigh from 16 to 20 lbs. per quarter; their wool is less fine, but heavier than that of Wiltshire, weighing from 3 to 4 lbs. the fleece. The peculiar advantage of this breed is, that the ewes admit the ram at so early a period that they generally have lambs in the months of September and October, which find a ready market in large towns for winter consumption.

7. *The Ryeland breed* derive their name from a southern district in Herefordshire, which at one time was regarded as incapable of growing any thing but rye. This species are white-faced, and without horns; their general form is tolerable; they fall short of the improved breeds in being more flat in the ribs, and less level in the back; their wool is fine, weighing from 1½ to 2 lbs.; their mutton is delicate; they arrive soon at maturity, and fatten easily, and weigh from 12 to 16 lbs. per quarter: this breed has been crossed by the Spanish Merino. The produce of this cross were at one time in high fame in England, under the name of the Anglo-Merino; and though their wool is said to have been of a fine quality, the breed has for long declined in popular favour.

8. *The South-down breed*.—This species have no horns; their legs and faces gray. They have fine wool, which is from two to three inches in length, and weighs from 2½ to 3 lbs. per fleece; they are slightly deficient in depth and breadth of chest, but their mutton is excellent, and highly flavoured; they are kindly feeders, and when fat, their average weight may be stated at from 15 to 18 lbs. per quarter. This species of sheep have, from time immemorial, been reared upon the chalky soils of Sussex, but are now widely extended, and thrive excellently not only on the chalk downs and light soils of England, but on the sheltered lawns of Scotland. In a note to the author from Lord Pitmilly, near St. Andrews, are the following facts:—"I generally keep about a score of South-down ewes for early lambs; they pasture in the lawn with the black-faced wethers kept for family use. The lambs dropped early in winter 1839–40, not being wanted, were sent to Edinburgh; ten of the ewes lambed again in September, 1840, and again in March, 1841. Some of them had twin lambs; all did well. The September lambs I sold in August, 1841, when eleven months old, at 30s. a piece. I ascribe the fact of the ewes thriving so well to the dry ground, and to their being put every night, summer and winter, into a shed, and well bedded; they have no extra food, except at lambing time, when they get a little oil-cake or sliced turnip." The above note is highly deserving the attention of breeders of this species of sheep, it testifying to the greatest degree of fecundity of which I have yet heard.

9. *The Merino breed*.—This species of sheep is supposed to have been originally from Africa. Marcus Columella saw a variety from that country at some of the games exhibited at Rome. He procured some of them for his own farm, crossed them with the breeds of Tarentum, and sent the offspring of this cross to Spain. In Spain they soon rose to such perfection and celebrity, that they attracted the attention of breeders of stock in other nations, and this breed may now be found in every part of the globe. They were imported into England for the first time in 1769. The Ryeland and other fine-wooled breeds of England were crossed by Merino rams in 1792. The Merino breed of rams were cultivated with great care by his late majesty, King George III. The sales of his majesty's stock which commenced in the year 1804, attracted such general attention in England that a society was formed for promoting the breed in 1811; but the high expectations which were formed of the result of this cross with native sheep were far from being realized. The quality of the wool of the native sheep was improved, but the increased value of the fleece was an inadequate compensation for defects in the character of the animals themselves, which proved less hardy than the parent stock, were slow feeders, and very defective in form.

The Merinos that have been naturalized in this country retain their natural characters, except that they become larger in the carcass, and the wool longer and heavier, than in Spain; but the Merino, as a feeding animal, is too small and ill-formed, and the mutton deficient both in quantity and quality. These points have given rise to some controversy; but in the forcible language of Professor Low—"It is vain that some breeders still contend for the superiority of the pure Merino; the general judgment of farmers is against them, and with perfect reason."*

The Merino sheep are cultivated in Spain and Germany with a greater regard to the wool than to the weight and value of the animal; but the farmers in England think it more profitable to raise the weight and value of the mutton, and it is believed, by those well qualified to judge, that the best of the Merino sheep, under the more rigorous climate of Great Britain, would never yield mutton equal in quality to that of Spain. The wool of this breed is finer than that of any other sheep. In Spain, the fleece of the ram weighs 8 lbs and that of the ewe 5 lbs.; but this wool having such a large quantity of yolk, which absorbs every kind of impurity with which it comes in contact, the wool loses three-fifths of its weight by being properly washed.

10. *The Devonshire Notts, Romney Marsh, Old Lincolnshire, Teeswater, and Old Leicestershire sheep.*—The Devonshire Notts consist of two varieties. The one is called the Dun-faced Notts, from the colour of the face; this is a coarse animal, with flat ribs and crooked back, but it yields a fleece weighing 10 lbs., and when fat, weighs 22 lbs. per quarter when only thirty months old. The second variety is called the Hampton Notts; it resembles the former in many respects, but is easier fed, yields less wool, and has a white face and legs. Both varieties have been crossed by the Leicester, by which both breeds have been much improved.

The Romney Marsh breeds are very large animals, with white faces and legs, and yield a heavy fleece, the quality good of its kind. Their general structure is defective, the chest being narrow and the extremities coarse. The result of their being crossed by the New Leicester is still a point in dispute—one party alleging, that though the quantity of wool has been lessened, and the size of the animal diminished by the cross, yet the tendency to fatten and their general form have been much improved. On the other hand, some well-informed breeders say, that besides the loss of the quantity and quality of the wool, the constitution of the animal is rendered less fitted to the cold and marshy pastures on which it feeds.

The Old Lincolnshire breed are large, coarse, ill-shaped, slow feeders, and yield indifferent mutton, but a fleece of very heavy long wool. The Teeswater breed were originally derived from the former and pastured on the rich lands on the banks of the Tees, from which they derive their name; but Professor Low remarks, that "it is entirely changed by crossing with the Dishly breed, and that the old unimproved race of the Tees is now scarcely to be found." They are very large, and attain a greater weight than almost any other breed, the two-year-old wethers weighing from 25 to 30 lbs., and yielding a long and heavy fleece of wool.

The Old Leicester is a variety of the coarse long-wooled breeds. On rich pastures they feed to a great weight; but being regarded as slow feeders, their general character has either been changed by crossing, or altogether abandoned for more improved breeds.

11. *The New Leicester and Improved Teeswater breeds.*—Mr. Bakewell of Dishly, in the county of Leicester, has the honour of forming this most important breed of sheep. He turned his attention to improving the form of feeding animals about the year 1755. The exact method he followed in forming his breed of sheep is not accurately known, as he is said to have observed a prudent reserve on the subject. But we now know that there is but one way of correcting the defective form of an animal, namely, by breeding for a course of years from animals of the most perfect form, till the defects are removed and the properties sought for obtained.

The great properties of the New Leicester for the farmer, are their early maturity and disposition to fatten, in which they excel all other breeds. They are less in size than several other breeds, and their wool is deemed inferior to the Cheviot; but this breed is now cultivated with great success in almost every part of England.

That class of sheep now known by the name of the Improved Teeswater, is derived from the old breed. Its improvement has been chiefly effected by crossing with the New Leicester. They are not so large as the older race, but are still the largest of our improved breeds; productive in lambs, and yield a good fleece; yet their form renders them less fitted for general cultivation than the New Leicester.

CHOICE OF BREEDS.

If the farmer has rendered himself master of the constitution and character of the different breeds of domestic sheep, already given, and with the general and peculiar character of the climate, soil, and pasturage of the locality on which he is to settle, the selection of the breed that will, upon the whole, yield him the highest profit, will not be a matter of very difficult calculation. But should an error be committed on this head in the first trial, very slight experience would enable a practical farmer to correct it, unless he belong to that class of persons to whom the lessons of history and experience convey neither knowledge nor correction.

The breeds best adapted to the soil and climate of the different districts of Great Britain, are arranged by that distinguished agriculturist, Professor Low, in the following manner:—"The breeds of sheep, then, of this country, may be divided into two classes—the sheep of the mountains, lower moors, and downs, and the sheep of the plains. The sheep of the first class have sometimes horns, and sometimes want them. The finest of them have no horns, namely, the Cheviot and South-down. One of them, the black-faced heath breed, has coarse wool; another of them, the Moorland sheep of Devonshire, has long but not coarse wool; and all the others have short and fine wool.

"Of the moorland and down breeds, as they may be called, the hardiest is the black-faced heath breed, and this property points it out as the most suitable for a high and rugged country, where artificial food cannot be procured. The breed next to this in hardy properties, but surpassing it in the weight of the individuals, is the Cheviot. Where the pasture contains a sufficiency of grasses, this breed deserves the preference over any other known to us for a mountainous country. The next breed deserving of cultivation is the Southdown. This breed is suited to the chalky and sandy downs of the south of England. It is in this respect a very valuable breed, but it is unsuited to the more rough and elevated pastures to which the black-faced and Cheviot are adapted

"The moorland and down breeds appear to be the most deserving of cultivation in this country. Of the larger breeds of the plains, the New Leicester is the best adapted to general cultivation, and wherever an improved system of tillage is established, this admirable breed may be introduced. The Leicester, the Cheviot, and the black-faced, have for long been regarded as the breeds best adapted for the different districts of Scotland. That those three breeds have nearly stood in the same numerical ratio to one another for some years, is a good proof that each has been placed in that locality best fitted by nature for promoting its health and productiveness. The Leicester is admirably adapted to the rich and alluvial soils of our cultivated plains; the Cheviot breed is peculiarly adapted to the grassy mountains chiefly formed of the transition series of rocks; then, our most elevated mountain ranges, formed chiefly of primitive rocks, and

* Low's Elements of Agriculture, p. 542.

covered with heath, on which none but the black-faced, the most active and hardy of our breeds, could survive."*

The above arrangements have generally been acquiesced in as the best possible by the farmers of Scotland. But the claims of South-downs for the middle range of the Highland pastures in Scotland have been urged lately by a gentleman neither destitute of talent for observation, and aided by twenty years' practical experience. This gentleman, Mr. H. Watson, Keillor Farm, shall be allowed to plead the claims of the South-downs in his own words:—"Having, during the last twenty-five years, been in the management or possession of a considerable breeding flock of South-down ewes, varying at different times from 500 to 1000 in number, and during that period having had good opportunities of drawing close comparisons between that and the other breeds of mountain sheep, namely, the Cheviot and black-faced, I have come to the conclusion (and am acting upon it in my own practice), that from a pasture ranging from 500 to 1200 feet above the level of the sea, having a moderate portion of green sward, the rest whin and heather, there can be no more profitable stock of sheep kept than a flock of South-downs of the best sort. My chief reasons for having preferred this breed are, that the South-down sheep, although naturally spirited and active, are easily controlled by a good shepherd; can go over more ground for their food than any other kind of sheep, without stopping their growth; and when tried by severe storms in winter, will brave it better than even the black-faced Highland sheep; and although reduced very low in spring, sooner pick up condition than the other short-wooled sheep. As a proof of the South-downs' inclination to fatten, when put to good keep, I may mention a fact, that while I have seldom been able to produce a fat Cheviot ewe the same season that she has reared a lamb, I never fail to make good fat of the cast South-downs off grass. Their wool is so closely matted on their backs, and about the head and neck, as to be almost impervious to rain or snow; hence, so soon as the storm ceases, they appear dry and comfortable, their coat not the least disordered, and altogether free from that *drouked* (Anglice, drenched) appearance which longer-wooled sheep exhibit even for days after a winter storm. In all my experience, the South-down sheep have kept remarkably healthy. I have never seen an instance of rot in my flock; while, during the last twenty years, I have been forced to clear off a lot of Cheviot and also of black-faced ewes, from that incurable disease. This, however, may have been owing more to the unsoundness of the pasture from which I got them than from any peculiarity of the animals themselves. My average loss in the South-down lot has invariably been much under that of any other sheep I have bred. They are hardy, and easily managed at lambing-time; affectionate mothers, and, on moderate keep, give a great quantity of milk; and if there is any inducement for early lambs, they will go with the ram almost as soon as the lamb is weaned. When crossed with a well-bred Leicester ram, and brought into good keep, they produce perhaps the most profitable lamb that is bred, taking wool and carcass into account. I have for the last ten years put all the ewes I could spare from pure breeding to this sort of crossing, lambing the ewes on turnips in spring, then turning them, as soon as the season would permit, to the hill pasture (the Sidlaws) till weaning-time, when the lambs are brought to the in-field pastures, and put to turnips for the winter, on which food they are kept for about 2d per week each, and kept on the earliest grass in spring; so that in a month or six weeks after they are clipped, they are fit for the butcher, who values this cross almost as high as the pure bred South-down. The wool is of the finest quality for combing, and fetches the highest price of any British grown wool, generally from 2s. to 2s. 2d. per lb.; and the clip in a good season will average about 6 lbs. At sixteen months old, I have never realized less than 40s. each, wool and mutton. In Smithfield, this cross is much sought after.

"On lands where folding is found necessary, the South-down submits to this treatment better than any other breed of sheep; such, indeed, in all cases where I have put them to the test, is their spirit and hardiness, that nothing short of ill treatment seems to injure them. Combining these facts, I can have no hesitation in recommending a South-down flock of sheep in preference to every other, on such situations as I have described, namely, too high to be occupied during the whole season by a flock of Leicesters, and under that level which the native black-faced sheep only can thrive upon.

"So far as I know, it is not yet sufficiently ascertained by experience how far a cross between the South-down and Leicester may be carried, so as to keep up the activity of the former with the well-known fattening qualities of the latter. Another train of breeding through the black-faced and South-down sheep, whose habits seem so much akin, seems likely to succeed. By this cross, improvement in quality of wool would be gained, while that of the mutton would not be deteriorated."

On the other side, Professor Low remarks:—"The South-down breed is best suited to the chalky and sandy downs of the south of England. It is in this respect a very valuable breed; but it is unsuited to the more rough and elevated pastures to which the black-faced and Cheviot are adapted."*

In Ireland, the breed of sheep has been much improved since the beginning of the present century. About that time, Mr. Culley attended the celebrated fair at Ballinasloe, and thus describes the Irish sheep of that period:—"I am sorry to say I never saw such ugly sheep as I saw there. The worst breeds we have in Great Britain are much superior. One would almost imagine that the sheep breeders in Ireland have taken as much pains to breed awkward sheep as many of the people in England have taken to breed handsome ones. I know nothing to recommend them except their size, which might please some old-fashioned breeders, who can get no kind of stock large enough. But I will endeavour to describe them, and leave my readers to judge for themselves. These sheep are supported by very long thick crooked gray legs, their heads long and ugly, with large flagging ears; gray faces, and eyes sunk; necks long, and set on behind the shoulders; breast narrow and short; hollow both before and behind the shoulders; flat-sided, with high narrow herring backs; hind-quarters drooping, and tail set low. In short, they are almost in every respect contrary to what a well-formed sheep should be."†

But an immense improvement was soon effected by Mr. St. George, and Mr. Astley of Odston, who imported a valuable selection from the flocks of the best breeders of the New Leicesters; and by carefully breeding from these, their sheep soon obtained a degree of perfection little inferior to those of England. They soon began to let their tups at very high prices. They let thirty rams, in 1800, at £1744. One of them was to have been 150 guineas. Mr. Casan, near Tipperary, was the person who had hired this famous animal, and had the misfortune of having him murdered the night after he had arrived at his farm, by some malignant opposer of the new breed.

The Irish sheep, since the introduction of the improved breeds, are now able to compete in the markets with the English breeders. There is no entry in the books of the Custom-House, of sheep exported from Ireland farther back than the year 1797, and in that year there is an entry of 1875. The number had increased in 1811 to

* Low's Elements of Agriculture, p. 545-6.

* Low's Elements of Agriculture.
† Culley on Live Stock, p. 166.

26,029; and the sheep exported from Ireland to Liverpool in 1831 was 134,762; and in 1832 amounted to 44,260; and, in addition to this immense number of sheep, 20,000 lambs, in good market condition, annually cross the Irish channel. And at the Fair of Ballinasloe, the number of sheep exhibited range from 80,000 to nearly 100,000. The most valuable sheep-husbandry in Ireland exists at present in Roscommon, Galway, Clare, Limerick, and Tipperary. But with all this advance, there is much still to be done in the management of sheep in Ireland. The soil and climate are in many places peculiarly adapted for sheep husbandry. And from the progress Ireland has made within the last forty years, there need be no misgivings regarding her future eminence in sheep-husbandry. Could the native talents and energies of Ireland be directed to the cultivation of the soil, arts, and commerce, instead of being perverted and enfeebled by fierce and feverish political agitation, from the genius of her people, the richness of the soil, the mildness of the climate, her geographical position, the number of her ports and harbours, the facilities for inland navigation, she might soon rival in wealth and civilization the most favoured nation of Europe.

The rising importance of Australia, its being a British colony, the progress it has already made in sheep-husbandry, entitle it to some notice in a treatise on sheep-farming. It had no native sheep; and the first importation was of an extremely ugly and ill-shaped race from Bengal. The fine dry and temperate climate, however, soon improved the breed in a most remarkable degree. In the course of two or three years they were changed so much for the better, that the hair disappeared, and in its stead arose a fleece of tolerable fineness. An importation of the Leicester and South-down breeds followed, which at once doubled the value both of the carcass and the fleece, though colonists at that period bred more for the mutton than the fleece. The increase at first was slow; there were only 6124 in the whole settlement in 1800, twelve years after the arrival of the first ship. The Merino were next imported, and the result far exceeded expectation. Three or four crosses with the prevalent stock of the colony, produced a breed of sheep that yielded wool equal in fineness to the pure Merino of Europe.

From this period, the number of free settlers rapidly increased in the colony, and in three years the number of sheep had amounted to 10,157; in 1813, to 55,121; in 1818, to 170,420; and in 1828, to 536,391.* Mr. Macarther, the great improver of the Australian sheep, and who raised the wool to a very superior quality, stated, on his examination on the trial of Colonel Johnson, in 1811—"That, to the best of his knowledge and belief, he had circulated among the settlers £20,000 worth of breeding animals, all raised by himself." And in answer to another question he says—"I have sent an immense quantity to the market to be slaughtered; and I am sure I may fairly estimate that, from my present stock, the colony will be supplied with at least 100,000 lbs. weight annually. It is perhaps proper that I should state to the court, that the stock from which such large supplies have been obtained originally consisted only of about six or seven cows, and about thirty ewes; and that from these I have raised 1000 or 1200 head of horned cattle, and at least 10,000 or 12,000 sheep."† And the increasing quantity and quality of the wool shows the progressive improvement of sheep-husbandry in Australia and Van Diemen's Land. They exported wool in 1832, to the amount of 237,757 lbs., and in 1833, to 3,516,869.‡ And with regard to the quality of the wool, the market price, in March, 1834, for the best Australian wool, was 4s. 6d. per lb., and for the best Saxon, 5s. 6d. per lb., and for the best Spanish Merino, 4s. per lb. These facts, which outweigh all speculation on the subject, prove that sheep, well bred and managed in Australia, yield a return of at least 70 or 80 per cent. per annum. And as sheep-husbandry must, for a long series of years, form the chief branch of rural industry in Australia, it cannot be regarded as unphilosophical to contemplate still higher results when we know that a higher degree of knowledge, energy, and enterprise, will annually be transferred from the mother country to the sheep-husbandry of that interesting colony.

IMPROVEMENT OF BREEDS OF SHEEP.

The first point of essential importance to be attended to by the sheep-farmer in every part of the globe, is the selection of a breed whose size and constitutional qualities best accord with the climate and the pastures on which they are to feed. An error of any magnitude on this point would be attended with fatal effects on the health and productiveness of the flock, and thus ruin the finances of the farmer.

It is true that sheep can exist in almost every country, and may be said to reach nearly from the equator to the poles. They are found approaching the eternal snows and icy barriers of the arctic regions; they are found at great elevations in the Cordilleres of South America, and in the still more elevated Himalaya Mountains of Asia. Yet though sheep can be reared within an immense range of latitude and temperature, it is equally true that the climate and soil fix the limits within which our domestic breeds can be cultivated with advantage The climate wears down the rocks, and thus forms the soil, and hence the natural pastures of all countries.

The climate, and the condition of existence which it induces, affect, with irresistible force, the structure, health, and reproductiveness of men and animals from the equator to the poles. The laws of nature cannot be transgressed with impunity. But this condition being accurately adjusted, the next objects which the sheep-farmer ought to keep steadily in view, are the quantity and quality of the mutton and the wool. Nature has perhaps forbidden that the same sheep should, in any circumstances, yield the greatest weight of the best mutton, and a fleece of the greatest value. The farmer will be able easily to determine, from the country, climate, and various other considerations, to which of these he should direct his chief attention. In England, for example, the farmer finds it more profitable to promote the weight and quality of the mutton than the wool, while the farmer in Spain and Germany finds it his interest to attend more to the wool than the mutton.

The properties most desirable in the sheep are—1. Size; 2. Form; 3. Early maturity; 4. Constitutional hardiness; 5. Productiveness; 6. Disposition to fatten; 7. Lightness of offal; on each of which points we shall proceed to treat in detail.

1. The *size* of the sheep must be regulated by the climate, the pasture, and the steepness or levelness of the lands on which it is to feed. One rule never to be violated is, that the size of the sheep should bear some reference to the nature of the pasture. And very heavy sheep are unsuited to very elevated and precipitous mountain ranges.

On the subject of size, a practical question of very considerable importance is still undetermined, and that is, what is the ratio of food consumed by a large animal and one of moderate size. The result of an experiment is given by Dr. Parry,* where it is stated, that by breeding small sheep instead of large ones, the numbers were increased from 660 to 890 ewes and lambs, and the profit from £450 to above £724. But this experiment, and

* Communications to the Board of Agriculture, vol. [illegible] p. 150

all others that have been tried, have never contained all the elements necessary to determine the question with any thing like philosophical accuracy.

2. The *form* of the sheep should consist of that happy combination of anatomical structure on which the health and productiveness of the animal depend; and the points of practical men must be tested by this internal anatomical structure. That eminent surgeon, Mr. Cline, in his Communications to the Board of Agriculture, states—"That the lungs of an animal are the first objects to be attended to, for on their size and soundness the health and strength of an animal principally depend: that the external indications of the size of the lungs are the form and size of the chest, and its breadth in particular: that the head should be small, as by this the birth is facilitated, and affords other advantages in feeding, and as it generally indicates that the animal is of a good breed: that the length of the neck should be in proportion to the size of the animal, that it may collect its food with ease; and that the muscles and tendons should be large, by which the animal is enabled to travel with greater facility; and the bones should be small and clean."

We may here add a description of the best proportions of a Cheviot ram, by the late Mr. Culley of Northumberland:—"His head should be fine and small; his nostrils wide and expanded; his eyes prominent, and rather bold and daring; ears thin; his collar full from the breast and shoulders, but tapering gradually all the way to where the neck and head join, which should be very fine and graceful, being perfectly free from any coarse leather hanging down; the shoulders broad and full, which must at the same time join so easy to the collar forward, and chine backward, as to leave not the least hollow in either place; the mutton upon his arm or fore-thigh must come quite to the knee; his legs upright, with a clean fine bone, being equally clear from superfluous skin and coarse hairy wool, from the knee and hough downwards; the breast broad and well forward, which will keep his fore legs at a proper wideness; his girth or chest full and deep, and instead of a hollow behind the shoulders, that part, by some called the fore flank, should be quite full; the back and loins broad, flat, and straight, from which the ribs must rise with a fine circular arch; his belly straight, the quarters long and full, with the mutton quite down to the hough, which should neither stand in nor out; his twist or junction of the inside of the thighs deep, wide, and full, which, with the broad breast, will keep his four legs open and upright; the whole body covered with a thin pelt, and that with fine bright soft wool. The nearer any breed of sheep comes up to the above description, the nearer they approach towards excellence of form; and there is little doubt, but if the same attention and pains were taken to improve any particular breed that has been taken with a certain variety of the Lincolnshire, the same advantages would be obtained."*

3. *Early Maturity* is a property of great importance to the farmer who breeds and feeds all his own sheep for the shambles; they not only make a quicker return for their food, but yield a higher profit to the breeder than slow-feeding animals. This valuable property of early maturity can be induced by breeding, food, and treatment. The New Leicester breed possess this property in a higher degree than any other of our domestic breeds, and they also yield a greater quantity of mutton on the same quantity of food than any other breed.

4. *Constitutional hardiness.*—In a rigorous climate, and in bleak and elevated mountains, in which artificial food cannot be obtained, this quality is indispensable. But a farmer will seldom make a wrong selection in circumstances so obvious.

* See Culley on Live-Stock.

5. *Productiveness.*—This is a property which characterizes some varieties of sheep and other animals; it may be extended by careful selection in breeding, and from food and treatment. Pets have almost invariably twin lambs. The draft ewes from the mountains of Scotland have generally twins when taken to a milder climate, and kept on superior food.

6. *Disposition to Fatten.*—This property is of very great importance to feeders, as his sheep can be made fit for the market both in a shorter period and with a less quantity of food. None of our domestic breeds possess this quality in greater perfection than the New Leicester; this quality also may be ascertained by examining the depth and breadth of the chest, according to Sir John S. Sibright. And the great John Hunter found that easy corpulence was concomitant with small bones; it is also accompanied with a pliable, soft, and mellow skin.

7. *Lightness of offal.*—It is obvious that, to whatever extent the weight of the offal can be diminished, the value of the animal is increased. The perfection of an animal is, when the dead weight of all the eatable parts approaches the nearest to the weight of the animal when alive.

The following statement of the live and dead weight of a Devonshire ox, aged 3 years and 10 months, will explain the manner in which these accounts are drawn up:—

			Stones
Live weight,			114
Offal.	Stones.	lbs	
Tallow,	10	6	
Hide,	6	3	
Head and tongue,	2	9	
Heart, liver, and lungs,	2	7

Entrails and blood,	11	13—35	
Carcass, or four quarters,			79—11

Principles of Breeding.—The fundamental and essential principles of improving any of our domestic animals by breeding, consist in a skilful selection of those males and females, the union of whose qualities will remove the defects and induce the properties desired. The sheep-farmer can neither raise nor keep his flock in the highest perfection of which the climate and pasture admit, without a rigid adherence to this primary principle. It was upon this principle that Bakewell formed his celebrated breed of sheep, and it is the only principle upon which any breed can be raised to the highest perfection of which it admits. *Breeding in and in*, as it is called, has given rise to a long controversy, which our increasing knowledge of the physiology of the animal economy, and a wider induction of facts, carefully observed and accurately recorded, will speedily bring to a final close. The facts now collected from a wide surface, and attested by men skilled in the sciences of physiology and anatomy, as well as by practical breeders of live-stock, establish the important fact, that, breeding by too near affinities, the offspring degenerates. It is a law of nature and applies to men and animals, and even plants. The accurate experiments of Mr. Knight establish the fact, that in the vegetable as well as in the animal kingdom, the offspring of male and female plants, when not related, possess always more strength and vigour than those of near affinities. Sir John S. Sibright tried many experiments by breeding in and in with dogs, fowls, and pigeons, and found that the offspring uniformly degenerated.† Sir John Sinclair relates an experiment with pigs, which he carried so far that the females almost ceased to breed; and if they did breed, the offspring was so small and delicate that they died as soon as they were born.‡ To breed, therefore, from the same race, but of different families, is now established as the only system that will secure the highest results in the different breeds.

* Code of Agriculture, p. 92. † Code of Agriculture
‡ See Sir S. Sibright's Essay, p. 13.

Crossing.—This is a means of improving a breed that requires many concurring circumstances to ensure success. The climate and the food must accord with the size and constitution of the animal that is to be produced. To increase the size of a breed of sheep, without augmenting or improving their food, would be a ruinous enterprise, and in the face of all principle. The attempt to increase size by crossing with heavier rams from another country requires also great care that the food and climate be adapted to the condition and character of the expected race; for it is in proportion as size is gained by crossing, that delicacy of constitution and liability to disease are increased. The constitutional qualities of a race of sheep will not accommodate themselves to the soil or climate of a country differing much in pasturage and temperature from that on which it has been long a native, without time, great care, skill, and attention. Were we to cross our mountain Cheviot ewes with Leicester rams, the offspring would labour under two fatal disadvantages—a constitution too delicate for the climate, and a size above the pasture. An attempt was made in Scotland some years ago to raise the quality of the wool of our mountain sheep by crossing them with Cheviot rams, and the result was a complete failure.

The influence of Sex.—It is now generally admitted that the male has a higher influence on the character of the offspring than the female. This law is in beautiful accordance with that beneficent design so visible in the arrangements of nature, as it enables man to bring the domestic animals to their most profitable condition in a far shorter period than if the law had been reversed. There is another fact perfectly established, that the male by one connection has a higher influence on the second generation than its actual father. This shows that no important change in the character of a breed can be effected, unless the crossing is continued until the fourth or fifth generation.

Age of the Parents; its Effects on the Sex of the Offspring.—Some very interesting experiments were begun some years ago, the results of which, so far as they go, tend to establish, as a general law of nature, that the offspring of a young ram and ewe, of from four to five years old, will in general be a feminine, while that of an old ram and young ewe will in general be masculine. Could such a law be practically acted upon, it would be of immense advantage to breeders of stock in every country, but particularly to breeders of stock in such a country as Australia, in which the rapid increase of the number of stock is an object of such paramount importance. There is an able paper on this curious subject in the first number of the "Quarterly Journal of Agriculture," containing the results of the experiments made in France, from which the following facts and views are extracted. In the "Annales d'Agriculture Française," vols. xxxvii. and xxxviii., some very interesting experiments are recorded, which have lately been made in France, on the breeding of live stock. M. Charles Giron de Buzareingues proposed, at a meeting of the Agricultural Society of Severac, on the 3d of July, 1826, to divide a flock of sheep into two equal parts, so that a greater number of males or females, at choice of the proprietor, should be produced from each of them. Two of the members of the society offered their flocks to become subjects of his experiments; and the results have now been communicated, which are in accordance with the author's expectations. The first experiment was conducted in the following manner:—He recommended very young rams to be put to the flock of ewes from which the proprietor wished the greater number of females in their offspring, and also, that during the season when the rams were with the ewes, they should have more abundant pasture than the others; while to the flock from which the proprietor wished to obtain male lambs chiefly, he recommended him to put strong and vigorous rams four or five years old. The following tabular view contains the result of his experiments, which are highly in favour of the views of M Giron:—

Flock for Female Lambs. Age of the Mothers.	Sex of the Lambs. Males.	Fem.	Flock for Male Lambs. Age of the Mothers.	Sex of the Lambs. Males.	Fem.
Two years old,	14	26	Two years old	7	3
Three years,	16	29	Three years,	15	14
Four years,	6	21	Four years,	33	14
Total,	35	76	Total,	55	31
Five years and older,	18	8	Five years and older,	25	24
Total,	53	84	Total,	80	55
N.B.—Three twin births in this flock. Two rams served it, one fifteen months, the other nearly two years old.			N.B.—No twin births in this flock. Two strong rams, one four, the other five years old, served it.		

"The general law, as far as we are able to detect it, seems to be, that when animals are in good condition, plentifully supplied with food, and kept from breeding as fast as they might do, they are most likely to produce females; or, in other words, when a race of animals is in circumstances favourable for its increase, nature produces the greatest number of that sex which, in animals that do not pair, is most efficient for increasing the number of the race. But if they are in a bad climate, or on stinted pasture, or if they have already given birth to a numerous offspring, then nature, setting limits to the increase of the race, produces more males than females. Yet, perhaps, it may be premature to attempt to deduce any law from experiments which have not yet been sufficiently extended. M. Giron is disposed to ascribe much of the effect to the age of the ram, independent of the condition of the ewe."* The author of this treatise has uniformly observed, that in every favourable season, when his stock was in high condition, he had a much larger number of female lambs than of males; and in one of the most favourable seasons that has occurred during his own personal experience, the female lambs exceeded the males to the number of ninety, in a flock of 600 ewes. The ewes had no artificial food at any season of the year; they lived entirely on the natural grasses of our mountain pastures. They got bog and lea hay in snow storms, but nothing else.

GENERAL MANAGEMENT OF SHEEP.

The management of sheep must be varied according to the nature and character of the breed, the soil and climate, character of the pastures, natural or artificial, the position of the farm in reference to markets, and whether all the sheep upon the farm can be prepared for the butcher, or must all be sold lean, as is the case with those farmers whose flocks subsist entirely on the natural grasses of our mountain pastures; and whether early lambs would be profitable or otherwise. These and many other circumstances must regulate the proper time for admitting the rams to the ewes, and hence the lambing season, the proper time for washing, shearing, dipping, smearing, &c. Different names are applied to sheep at different periods of their age. A young sheep remains a *lamb* from birth till the first smearing time. From this till the first clipping it is called a *hog*. From the first to the second clipping it is termed a *gimmer*. It is now

* Quarterly Journal of Agriculture, No. 1.

called a *young ewe*, till it bears its first lamb. When male sheep are cut, they are denominated *wedders;* and, according to their age, are called wedder hogs, &c. At three years old, the wedder is in its prime for mutton.

Lambing.

The period at which sheep begin to breed is in the autumn of the second year after birth, when both rams and ewes are at their maturity. In the British islands, the company of the ram is permitted at the beginning of October. The ewe goes with young about 152 days, or between twenty-one and twenty-two weeks, and consequently the lambing season is at the beginning of March. It is of high importance that sheep, during gestation, should be managed with peculiar gentleness and care, the rash use of the dog being attended with the most pernicious consequences. The ewes should be well but not over-fed, as the ewes being in too high condition greatly increases the risk in lambing. Though parturition, being a natural process, cannot be regarded as a disease, still, in sheep, as well as in many of our domestic animals, it is attended with some risk; and in certain states of the atmosphere, and ewes in too high condition, the loss is often very considerable from inflammation.

"As the period of parturition approaches (observes an intelligent writer in the "Penny Cyclopædia"), the attention of the shepherd should increase. There should be no *dogging* then, but the ewes should be driven to some sheltered enclosure, and there left as much as possible undisturbed. Should abortion take place with regard to any of them, although it does not spread through the flock as in cattle, yet the ewe should be immediately removed to another enclosure, and small doses of Epsom salts with gentian and ginger, administered to her, no great quantity of nutritive food being allowed.

"The ewes should now be moved as near home as convenience will permit, in order that they may be under the immediate observation of the lamber. The operation of *clatting*, or the removal of the hair from under the tail and around the udder, should be effected on every long-wooled ewe, otherwise the lamb may be prevented from sucking by means of the dirt which often accumulates there, and the lamber may not be able at all times to ascertain what ewes have actually lambed. The clatting before the approach of winter is both a useless, cruel, and dangerous operation.

"The period of lambing having actually commenced, the shepherd must be on the alert, yet not unnecessarily worrying or disturbing the ewes. The process of nature should be permitted quietly to take its course, unless the sufferings of the mother are unusually great, or the progress of the labour has been arrested during several hours, or eighteen or twenty hours or more have passed since the labour commenced. His own experience, or the tuition of his elders, will teach him the course which he must pursue.

"If any of the newly-dropped lambs are weak, or scarcely able to stand, he must give them a little of the milk, which at these times he should always carry about him, or he must place them in some sheltered warm place; in the course of a little while, the young one will probably be able to join its dam. The lambing-field often presents at this period a strange spectacle. 'Some of the younger ewes, in the pain and confusion and fright of their first parturition, abandon their lambs. Many of them, when the udder begins to fill, will search out their offspring with unerring precision; others will search in vain for it in every part of the field with incessant and piteous bleating; others, again, will hang over their dead offspring, from which nothing can separate them; while a few, strangely forgetting that they are mothers, will graze unconcernedly with the rest of the flock.'

"The shepherd will often have not a little to do in order to reconcile some of the mothers to their twin offspring. The ewe will occasionally refuse to acknowledge one of the lambs. The shepherd will have to reconcile the little one to its unnatural parent, or to find a better mother for it. If the mothers obstinately refuse to do their duty, they must be folded by themselves until they are better disposed; and, on the other hand, if the little one is weak and perverse, it must be repeatedly forced to swallow a portion of her milk, until it acknowledges the food which nature designed for it."

Male lambs are cut nine or ten days after birth. Weaning or removal from the mother takes place from three to four months after birth, according to circumstances. In weaning, the ewes and lambs must be separated so far that they will not hear the bleatings of each other. The lambs are at first put on the tenderest herbage that can be selected. Some ewes may have so much milk that the udders will swell when deprived of the lambs, and this will require to be attended to by the shepherd at this trying season of his labours.

Food.

The best kind of food for sheep is nutritious grassy pasture, growing on a dry and firm soil. The sheep is most assiduous in picking up food, and will range over a great space in quest of the herbage which it is fond of. In the Highlands of Scotland, and in Australia, where the herbage is scanty, the sheep farm requires to be very large—twelve miles in length and breadth is no unusual size of a Highland sheep-farm. In countries liable to be covered with snow in winter, grass, hay, or some other vegetable material, must be preserved for the subsistence of the flocks when their ordinary walks are under a snowy mantle. Natural meadow hay and turnips are used in Scotland for winter keep, when ordinary resources fail; and the employment of these, in the case of heavy drifts, sometimes saves large numbers of sheep. If the flock can be conveniently driven to a cleared hay field, such is done in preference to carrying food to the animals: there should be one field for the rams and another for the lambs, or for sheep in a weakly condition. A general rule for sheep intended for the butcher is, that they should never be allowed to turn lean, but be kept in a constant state of improvement; and that kind of food should be selected that will bring the animals to the highest profit in the shortest time and at the least expense. In well-managed store-farms, sheep are now allowed many kinds of food little thought of in former times, and are, besides, provided with troughs of pure water, and a trough of salt, that they may lick when their taste leads them to that indulgence. In all artificial feeding, the food should be free of dirt or any insect spawn.

Heedless farmers are sometimes apt to purchase and keep more sheep than they can conveniently feed on their grounds, which causes a serious evil. To overstock a farm, where artificial food cannot be obtained, is one of the most fatal errors a farmer can commit. It does not only diminish the quantity, but also fouls and deteriorates the quality of the food. A farm may be overstocked for a few years, but death will by and by not only lessen the numbers, but diminish to a great extent the health and productiveness of those that survive. Avarice and ignorance have tempted not a few farmers to carry on this unequal struggle against the laws of nature and humanity for years, but it has always ended, as it ever must, either in the farmer's ruin, or reformation of his plan.

Herding.

The tendency which most sheep have to ramble, renders it necessary for them to be attended by a shepherd and his dog. The duties of a shepherd are very irksome, and require to be performed by a man of firm resolution, good temper, and discretion. To keep the flock within hounds may be troublesome, but much may be done in the way of preventive; and at all events, the sheep must not be harassed and chased as if they were so many wild beasts. Being naturally of a timid and gentle nature, the sheep ought to be treated with a degree of gentleness, and taught rather to look up to their shepherd as a friendly protector than a tyrant. Lazy shepherds, who do not exercise a judicious foresight in keeping the flock to its ground, try to remedy the evil by hounding the dog after the stragglers, besides giving no small toil to their own limbs in running. We are desirous to lay it down as a rule, well known to all good shepherds, that there should be *only a rare and cautious use of the dog.* Much also depends on the dog being of the proper breed, and well trained to his duty. A good dog gives little tongue; he is seldom heard to bark: his great knack consists in getting speedily and quietly round the further extremity of the flock, and then driving them slowly before him in the direction which his master has pointed out. A wave of the hand in a certain direction, and the word, *There*, are usually enough as a sign. Under-bred dogs bark at and fly upon the poor animals, chasing them hither and thither, without any rational purpose. All such dogs should be destroyed as unfit for the important duties which they are intended to perform. A first-rate shepherd's dog is invaluable to the store farmer, and he should grudge no reasonable price to get him.

Shelter—Sheepfolds.

In those districts which are exposed to storms, it is important to afford shelter to the flocks. Where there are jutting or overhanging rocks or bushes, the sheep will crowd under their lee, and so far protect themselves from harm; but where the country is bare, it will be necessary to erect artificial walls or enclosures of turf and stone, to which they can be led in cases of emergency. On the exposed hill-sides of Scotland, it is usual to build circular folds, locally termed *stells*, of sufficient size for a *cut*, or parcel of sheep. The stell is a rude enclosure, formed of a stone and turf wall about four feet in height, and is placed on a piece of ground known to be seldom drifted. Besides these, there should be on every sheep-farm ample and conveniently situated folds for the various sortings of sheep, such as for weaning lambs, shearing, and drafting or drawing out any animals required. These folds are ordinarily constructed of flakes or movable palings.

Shearing—Wool.

The winter coat of the sheep begins to be ragged in spring or early in summer, while the lambs are in course of being suckled; and towards June, the wool is seen to be falling off in lumps, or caught in every bramble. To save the wool in time, and relieve the animal, it is the practice to sheer them about the middle of June, when the lambs have been weaned, and the weather is genial. In any case, however, it should not be done till the new wool is observed to be pushing off the old. Previous to sheering, all the sheep should be collected and washed in a running brook or pool, to rid the fleece of impurities. Some shepherds employ a little soap in this operation. On being washed, the animals should be put into a clean field or fold to dry. Fine weather should be selected for washing. The shearing is performed a day or two after, by means of large sheers made for the purpose. In shearing, care should be taken not to break or tumble the wool, but to take off the fleece neatly, and without injuring the skin of the animal.

Australian Wool Management.—Mr. Walter Buchanan has written directions to the wool-growers of Australia respecting the management of wool, from which we make the following extract:—"It is of great importance that the fleece should be well washed, that the wool may be brought to market with as bright a colour as possible. Every convenience, and a very plentiful supply of pure water, should therefore be provided; a running stream being most desirable. The preferable mode of washing is that which is performed before shearing, according to the German manner. Some growers have tried the plan of washing after the fleeces have been shorn and sorted, and, as is supposed, to have used tepid water, following the French and Spanish method; but this has not been approved of by the buyers generally, and particularly by those who buy for combing purposes.

"The breaking of the fleece and washing after shearing, give the wool more the appearance of Spanish than of German wool, and it is consequently reduced to a lower standard of comparison. It is well known that the sheep of those German flocks that are best washed, are, after that operation, driven into some shed strewed with clean litter, or penned up with hurdles on clean grass; that the utmost care is taken to prevent their exposure to dirt, or whatever else might tend to sully their whiteness; and that they are not shorn until a sufficient degree of moisture is deposited in the fleece, by perspiration, to impart a soft handle to the wool. It may here be added, that it is very important, if possible, to prevent the sheep from filling their fleeces with grass seeds, broken leaves, and other extraneous substances, which cannot be removed in the operation of washing, and which are productive of labour and expense in every process of manufacturing, in some cases, indeed, render ing wool almost unsaleable. It may be here observed, that so conscious are the Spaniards of the superiority of the German mode of washing and assorting, that they are making every effort to introduce it.

"In order to assimilate the Australian wool as much as possible with the German, in preparing it for market, the fleeces should not be broken, but merely divested of the breech and stained locks, and so assorted or arranged, that each package may contain fleeces of the same character as to colour, length of staple, firmness of hair, and general quality.

"If the washing has been performed at the same time and place, and with an equal degree of care, the colour is likely to be uniform, and it will then only be necessary to attend to the separation of the fleeces as to length, fineness, and general quality: but if a larger grower has flocks of different breeds, and fed on different soils, care should be taken that the fleeces be separated, first as to colour, and then again as to length, fineness, &c.

"The fleeces, being assorted, as already suggested, should be spread one upon another, the neck of the second fleece being laid upon the tail of the first, and so on alternately, to the extent of eight or ten fleeces, according to their size and weight. When so spread, the two sides should be folded towards the middle, then rolled together, beginning at each end, and meeting in the centre, and the roll or bundle so formed held together by a slight pack-thread. The bagging should be of a close, firm, and tough nature. The material hitherto most generally used has been sail canvas, which very ill resists bad weather on a long voyage; and when received here, even in favourable condition, is so dry and crisp that it will tear like paper: a thicker, twilled, more flexible, and tough material, would be preferable. The size and form of the package may be in length about nine feet, and width four feet, sewed up on the two long sides and at one end, the other end being left open, and the sheet so formed being suspended, with the open end upwards, to receive the bundles, made up as before directed, which are to be put in one at a time, one of the flat sides of the roll or bundle being put downwards, and so on in succession, being well trod down, until sufficiently filled for the mouth to be closed. This is the German mode of packing; but it is doubtful whether smaller packages, of the dimensions that have been hitherto sent from the colonies, may not be more convenient for so long a voyage. The operation of screwing should be discontinued where it has been practised, as the screw pressure, and remaining compressed during the voyage, occasion the wool to be caked and matted together in a manner that is highly prejudicial to its appearance on arrival. The practice, also, of winding up each fleece separately, and twisting a portion into a band, is productive, in a minor degree, of the same prejudicial effect; and it is to avoid this that the making German bundles of eight or ten fleeces is suggested."

Qualities of Wool.—Improving the quality of the wool, or at least of not allowing it to deteriorate, is now an object of as great importance to the British store-farmer as in raising the weight of the carcass. The finest wools are those purchased for making broad cloths, merino, and mousseline-de-laine fabrics (*laine* is the French word for wool). "The wool of which good broad cloth is made," observes Dr. Ure, in his "Dictionary of Arts," "should be not only shorter, but, generally speaking, finer and softer than the worsted wools, in order to fit them for the fulling process;" and to judge of this degree of fineness, great nicety of discernment is required. "There are four distinct qualities of wool upon every sheep; the finest being upon the spine, from the neck to within six inches of the tail, including one-third of the breadth of the back; the second covers the flanks between the thighs and the shoulders; the third clothes the neck and the rump; and the fourth extends upon the lower part of the neck and breast down to the feet, as also upon a part of the shoulders and thighs, to the bottom of the hind quarter. These should be torn asunder, and sorted immediately after the shearing.

"The harshness of wools is dependent not solely upon the breed of the animal, or the climate, but is owing to certain peculiarities in the pasture, derived from the soil. It is known that, in sheep fed upon chalky districts, wool is apt to get coarse; but in those upon a rich loamy soil, it becomes soft and silky. The ardent sun of Spain renders the fleece of the Merino breed harsher than it is in the milder climate of Saxony.

"All wool, in its natural state, contains a quantity of a peculiar potash-soap, secreted by the animal, called in this country the *yolk*, which may be washed out by water alone, with which it forms a sort of lather. It constitutes from 25 to 50 per cent. of the wool, being most abundant in the Merino breed of sheep; and however favourable to the growth of the wool on the living animal, should be taken out soon after it is shorn, lest it injure the fibres by fermentation, and cause them to become hard and brittle. After being washed in water, somewhat more than lukewarm, the wool should be well pressed, and carefully dried."

The quantity of wool imported annually into the United Kingdom, a large portion of which is now from Australia, has latterly been about 60,000,000 lbs.—a quantity not nearly equal to that produced from native flocks. As the imported wools are chiefly of a finer quality than those of native growth, so far is the large importation from injuring the British wool growers, that it is the means of giving them higher prices for their commodity. It has been satisfactorily shown by cloth-makers before a parliamentary committee, that unless they imported foreign wool to mix with that of Britain, they could not produce the finer class of goods, and, consequently, that British wool would be much less in demand.

Smearing.

Smearing is a process of anointing the skins of sheep with certain ingredients, principally for the purpose of rendering the animal less liable to injury from winter cold (the unguent being a slight counter-irritant), and of destroying the vermin which lodge among the roots of the wool. Smearing with a mixture of tar and butter was general in Scotland in former times. The proportions varied in different districts; but in general 6 lbs. of butter to a gallon of tar were deemed sufficient for twenty sheep. The time for laying on this salve was in the end of October and beginning of November, before the rams are admitted to the ewes, which, in the mountain farms of Scotland, is in general about the 22d of November. The smearing with butter and tar has very much declined of late years, and various other preparations, such as butter and oil, turpentine, arsenic with a solution of soft soap, and various other baths, are used instead of butter and tar. Which of the various baths now in use are the best, it would be difficult to determine, as each has its advocates. On this, as on other subjects, the store farmer, without running rashly into experiments, ought to have his mind open to well-considered improvements, and adopt such measures as are supported by respectable authorities.

DISEASES OF SHEEP.

The sheep is subject to a great variety of diseases; but the most formidable, and by far the most destructive, is

The Rot.

It is unfortunate that in the early stages of rot the disease gives no external intimation of having commenced its destined fatal career; for it is at the beginning of most diseases that human skill is most efficacious in arresting their progress. But sheep in the early stages of the rot, instead of showing symptoms of disease and decay, acquire a great tendency to fatten, which has been turned to advantage by Mr. Bakewell and others. But after the disease has undermined the general health, the animal becomes listless and unwilling to move, leaves its companions, and sinks rapidly in flesh; its eye becomes sunk, dull, and glassy; the wool comes easily from the skin, the breath becomes fetid; the bowels variable, at one time loose, with a black purging, and at another costive; the skin becomes yellow, and sometimes spotted with black; emaciation now becomes more rapid; general fever is induced, and death ensues. There are various methods by which practical men endeavour to ascertain the incipient symptoms of the disease, but the two following are the most general:—

The first is by handling the sheep on the small of the back, and if the flesh feel firm and solid, the animal is judged sound, but if the flesh feel flabby and soft, and give a cracking sound when rubbed against the ribs, the animal is unsound. The other method is by examining the small veins at the corners of the eyes, and if filled with yellow serum instead of blood, the animal is pronounced unsound; but the greatest practical tact and talent will not always ensure success in discovering the early stages of this insidious disease.

Appearances on Dissection.—The whole cellular tissue is filled with a yellow serous fluid; the muscles are pale, and appear as having been macerated, being soft and flabby; the kidneys are infiltrated, pale, and flaccid; the mesenteric glands distended with a yellow serous fluid; the lungs filled with tubercles; the heart enlarged and softened; the peritoneum thickened; the bowels are often distended with water, and sometimes grown together. But the liver is the primary seat of the disease; its whole structure is in different states of disease; one part is scirrhous and indurated, and another soft and ulcerated, and the biliary ducts are filled with flukes. This appears to the author the origin of the disease which has involved so many organs, and effected such a vast disorganization of the whole animal frame.

Causes of Rot.—In endeavouring to ascertain the cause of this disease, it seems unnatural to begin by inquiring whether those parasites which are found in such numbers in the biliary ducts of the liver, are the cause or effect of the disease. The parasites named the liver fluke, the *fasciola* of Linnæus, the *distoma hepaticum* of Rudolphi, the *planaria* of Goese, are not peculiar to the sheep, but have been found in the biliary ducts of the goat, deer, ox, horse, ass, hog, dog, rabbit, guinea-pig, and various other animals, and even in the human being. The parasite is of a brownish-yellow colour, and resembles a small sole divested of its fins; in size it may be seen from that of a pin-head to an inch and a quarter in length, and half an inch in breadth.* It is supposed to be a hermaphrodite, as no distinction of sex has yet been made out. The spawn or eggs of this parasite are found in great numbers in the biliary ducts of the liver; these eggs are also found in every part of the intestinal canal, and very often seen in the dung of a sound sheep, though always numerous in that of a diseased one. This animalcule, and many other of the *entozoa*, have never been found out of the intestines, but this is not positive proof that they cannot or do not exist out of the body. Mr. Blacklock, in his very valuable treatise on sheep, after laying flat all his opponents, comes to the following conclusion:—"From all this data, the conclusion must at once be drawn, that as living flukes cannot reach the liver from without, they must, of necessity, be produced only in particular states of the animal they inhabit; how they originate we cannot of course determine, and this is not the place to hazard a physiological conjecture; but it will be found that their appearance in the bile is always preceded by tuberculous deposits on the lungs and liver."†

That Frommon found the fluke worm in the fœtus of the sheep is a strong fact, but not decisive; for Mr. Blacklock must know that, although he is anatomically correct when he states that there is no direct vascular communication between the fœtal and maternal side, yet the indirect communication may be sufficient. And besides this, Mr. Blacklock's views on this point are extremely unphilosophical when he says—"That living flukes cannot reach the liver from without, they (the flukes) must, of necessity, be produced only in particular states of the animal they (the flukes) inhabit." This is just saying that the flukes inhabit the animal before its particular states produce them. This must mean that the eggs of the flukes exist in the liver of the sheep, ready to be hatched by the peculiar states of the animal; and as these eggs could not, according to Mr. Blacklock, reach the liver from without, the only other alternative is, that the liver lays the eggs when in healthy state, and hatches them when diseased. This wont do; equivocal generation is absurd. But the limits prescribed forbid the author pursuing this interesting inquiry farther: he must simply state his belief that the ova of the fluke are not generated by the liver of the sheep, but find their way to that organ by means not yet ascertained; but these ova are not vivified in the liver except under certain states of that viscus. The ease with which Mr. Bakewell could induce rot in his sheep, by putting them on ground which he had previously flooded for that purpose, shows that other circumstances must concur to produce the disease. It is not caused by scanty food, as has often been alleged, for sheep may be starved to death without producing rot; the fact that the sheep has an extraordinary tendency to acquire fat in the early stages of the disease, shows that the causes act as a stimulant at first, and originate a slight degree of inflammation in the liver, as the first step in the progress of this fatal disease. But the numerous and well-attested facts now obtained from various climes and countries, lead to the conclusion that the nature of the soil and pasture, and the character of the seasons, are the chief agents in causing rot. This view is confirmed by the fact, that rot is most prevalent in wet seasons, and is nearly confined to lands subject to be occasionally flooded with water at certain seasons of the year, and to soils naturally moist and marshy. Moist and level lands of retentive soil, from which water is slowly evaporated by the sun, and a temperature favourable to the decomposition of vegetable matter—on such lands, when not thoroughly drained, rot may be said to be indigenous, while on lands that are dry and hanging, the disease is unknown. The nature of the plants which the soil produces is not so important as the plants being kept in a morbid state by that degree of moisture and heat favourable to their decomposition. These views will be amply verified by any one who will take an accurate survey of the midland, eastern, and southern counties of England, in which the disease is most destructive. Besides supporting the views here advocated, the following passage from the pen of M. Hammond, the founder of the veterinary school in Egypt, is highly interesting to every sheep-farmer:—"It appears every year in Egypt after the falling of the Nile, and it follows and keeps pace with the subsidence of the waters; desolation and death accompany it wherever it passes, and it annually destroys at least 160,000 sheep. As soon as the waters of the Nile subside, the pastures which were submerged are speedily covered by a tender rushy grass: the sheep are exceedingly fond of it, and they are permitted to feed on it all day long; in the course of a very little time they begin to get fat, when, if possible, they are sold; their flesh is then exceedingly delicate, but soon after this the disease begins to appear, and the mortality commences. The disease is more frequent and fatal when the sheep are first turned on the newly recovered pasture than when the ground becomes dried and the rushy grass harder. But if the sheep pasture in the midst of mud, or on the borders of the marshes and canals, rot attends every step; the rot does not occur in elevated countries, where the sheep feed on dry aromatic herbage. The Bedouins sell all the sheep which they can before they quit the Nile, for then they are in high and prime condition, after which they lose not a moment in reassembling their flocks and driving them back to the desert."*

Prevention and Treatment of Rot.—If the true causes of rot have been accurately given, every farmer has in his own hands the most efficient means for its prevention; on all lands that can be defended from being flooded with water, and on all lands whose levels admit of thorough drainage, the manner and amount of drainage must be determined by the position of the land, whether level or hanging, and by the character of the soil, and the quantity of the moisture to be removed, and on all these points the farmer must decide for himself, or be guided by the advice of a competent judge. The only indispensable rule is, that the drainage must be thorough, in order to be effectual; and if the drainage is carried to this point, the farmer will have the pleasure to see the rot, that dreadful scourge of his flock, disappear. This important point is established by practical men whose testimony cannot be impeached, that there would be no rotten sheep found, even upon the most spongy lands in the country. The treatment of rot is confined to narrow limits, from the curious fact that sheep, in the early stages of rot, acquire fat with singular rapidity; the best thing the farmer can do, as soon as he finds his flock tainted, is to sell them to the butcher for what they will bring in the market; from the condition of the sheep, this forced sale may be attended with considerable loss, but it will be a loss inferior to that sustained in the vain attempt to effect a general cure.

Tainted flocks have recovered, it has been alleged, by being sent to pasture on salt marshes; but though the efficiency of such pasture were admitted, it is a remedy which only a few farmers could obtain. To change the

flock to a more dry and elevated part of the farm, when this is practicable, has been attended with favourable results. The free use of salt is universally admitted to be the best medicine within the reach of the farmer for checking the progress of this deadly disease. That many cures have been effected by the proper use of salt, is attested by persons of the highest character and intelligence. Sir John Sinclair states, that at Mr. Mosselman's farm at Chenoi, beyond the Wavre, he found that salt was used for sheep, and that, by allowing them to lick it, the rot was completely cured.* And as the only explanation of sheep taking on fat rapidly, in the early stage of the disease, is, that the digestive organs are stimulated for a time by inflammation of the liver, perhaps the disease might be checked *in limine* by copious bleeding; but the disease can scarcely ever be detected at that period in which bleeding would be proper, and bleeding late in this, as in almost all diseases, is fatal. But in this disease the sheep-farmer must direct his energies and care to the prevention rather than the cure, though some of the remedies just mentioned may be of service at the beginning; yet, from the insidious nature of the disease, it can undermine the constitution before it is perceived, to that extent which no known remedies can restore, so that every sheep-farmer must rest his hopes of safety, not in curatives, but in the vigorous use of the means of prevention.

Braxy.

Braxy, or Sickness, is an inflammatory disease, whose ravages are chiefly confined to hogs, and those in the highest condition are most liable to be attacked. This disease is not nearly so destructive as it was formerly, when hogs were hirsled; this has been accounted for by alleging the inexperience of hogs in selecting their food, and their tendency to feed too much on the succulent parts of their pasture. Braxy, being entirely an inflammatory affection, may be excited by a variety of causes, such as drinking cold water in a heated state; any great or sudden change of temperature; by hail, snow, or rain; feeding on soft rank grasses, which are apt to excite fermentation, and, by extrication of gas, distending the stomach, thus originating inflammation, and sometimes producing sudden death by pressure on the diaphragm. One very frequent cause of braxy is that kind of frosty mornings which load the pastures with hoar-frost. The hogs, from feeding chiefly on dry and binding pastures at that season of the year (from November till March), eat the succulent spots of grass laden with hoar-frost very greedily, and thus the temperature of the stomach is so suddenly lowered to icy coldness, that violent inflammation is immediately produced, and death often ensues in a few hours. In the list of the causes of braxy, the improper use of the dog must not be omitted. It is as clear as a sunbeam, that nothing is more fitted to produce inflammation than once heating a sheep by incessant use of the dog, at seasons of the year so liable to sudden and great falls of temperature.

Symptoms of Braxy.—The animal appears uneasy, often lying down and rising up, standing with its head down and back raised, taking no food, but often drinking water; fever then ensues, when the pulse becomes strong and quick, respiration laborious and rapid, the skin hot, and the wool clapped; the eyes are languid, watery, and half-closed; it ceases to follow the flock, and soon dies.

Appearances on Dissection.—On opening the body, the appearances vary according to the parts affected. Sometimes only the reed is affected, and all the rest of the viscera appear perfectly healthy, and the flesh not at all affected. In other cases the effects of violent inflammation are visible through the whole viscera, and the flesh of the whole animal is in a state of rapid putrefaction.

Treatment of Braxy.—From the nature of the disease, it is obvious that the first and most effective remedy is prompt and copious bleeding from the jugular veins, this being effected, the constipation of the bowels must be removed; the best purgative for this purpose is Epsom salts, two ounces for a dose, dissolved in warm water, and followed by thin warm gruels; these remedies would generally prove effectual if applied at an early stage of the disease; but in a large flock of mountain sheep the disease is frequently not observed by the shepherd till too late for any remedy. The best preventive of the disease in mountain sheep is skilful and attentive herding, by preventing the young sheep from fastening too much on succulent spots, and by seeing they graze regularly over every part of the pasture, and be allowed perfect repose for rumination undisturbed by the dog.

Sturdy.

The proximate cause of this formidable disease is hydatids formed in the brain, or by an accumulation of water or serum in the ventricles of the same organ. Many ingenious writers, both in France and in our own country, have favoured the public with a few facts and much speculation to account for the manner in which hydatids reach the brain, and the causes of the accumulation of water in the ventricles; but none of these speculations are in the least degree satisfactory, and many of them can be shown to be absurd, from the known anatomy and physiology of the brain of the sheep. Many plans have been adopted to extract the hydatids from the brain. Hogg, the Ettrick Shepherd, was successful by the use of the wire. He says—"When I was a youth, I was engaged for many years in herding a large parcel of lambs, whose bleating brought all the sturdies in the neighbourhood to them, and with whom I was exceedingly plagued; but as I was frequently knitting stockings, I fell upon the following plan:—I caught every sturdied sheep that I could lay my hands upon, and probed them up the nostrils to the very brain with one of my wires, and I beheld with no small degree of pleasure, that by this simple operation I cured many sheep to different owners; but I kept all my projects to myself, for I had no authority to try my skill on any of them;" and he adds, "that several years passed before I failed in this operation in any one instance;"* but nothing approaching this success has ever attended the operation in the hands of any of Mr. Hogg's disciples; though, when the hydatid is situated in the ventricles, or in the upper portion of the brain, some farmers and shepherds have acquired such tact in the use of the wire as to cure considerable numbers.

But the operation performed with the trocar, and various other instruments that have been used, is liable to many inconveniences and great danger. If the hydatid is situated in the base of the brain, it cannot be reached by the nostril; then there is great danger of rupturing some of the numerous blood-vessels of the brain, and thus producing inflammation—a disease as fatal as the one attempted to be cured. The use of the trephane is also attended with difficulty and danger. It lays open at once an immense vacuum in the brain to the action of the atmosphere, and its consequent irritation, and hence the risk of inflammation. When the situation of the hydatid can be ascertained by the softening of a portion of the skull, to destroy the vitality of the hydatid by perforating it with the trocar or other sharp instruments, is perhaps the method attended with the least danger of exciting inflammation, and hence the most likely to succeed. But the extent to which the disease must have injured the brain, before the softening of the bone to reveal the position of the hydatid, is an insuperable evil, diminishing the chances of success in any mode of co-

* Hogg on Sheep, p. 58, 59.

ducing the operation that can be devised. There is no medicine that can justly be regarded as of any avail. But carefully observed and accurately recorded facts may yet throw some light on the remote causes of this formidable disease, under that higher anatomical and physiological knowledge which has within these few years been brought to bear on the diseases of our domestic animals.

Pining.

This disease, it is said, was unknown in this country before the sheep-walks were thoroughly drained and the moles exterminated. If this statement is correct, the cause of the disease must obviously be too dry and binding pasture; and in accordance with this view, constipation of the bowels is always present in this disease. To open the bowels freely, and change to a more nutritive pasture, are the obvious remedies; and when both can be readily applied, seldom fail of complete success.

Dysentery.

This disease begins with violent discharges from the bowels of a green slimy mixture, which in progress of time becomes mixed with blood. It has often been confounded with diarrhœa, from which it differs in many particulars. Diarrhœa attacks young sheep, particularly hogs, occasioned by a sudden rush of grass in the spring, or from too sudden a change from a scanty to an over-rich pasture; when such are the causes of diarrhœa, the mere change to a drier pasture will effect a cure. But dysentery attacks old sheep, and generally does not commence till June or July. Many writers allege that this disease is highly contagious, but the best established facts do not sustain the allegation. The disease prevails in fouled pastures, and in seasons characterized by a peculiar state of the atmosphere with regard to heat and moisture, a certain combination of which renders the disease so fatal to our army, especially in tropical climates. In the treatment of this disease, bleeding is a proper remedy in an early stage; but if late, gentle purgatives alone must be used; Epsom salts or castor oil, with 25 to 30 drops of laudanum, are the best purgatives. Mr. Stevenson also used an infusion of logwood, and doses of ipecacuanha in numerous cases, with great effect.*

Trembling.

Trembling, or Louping Ill, in mountain flocks, is a disease caused by cold east winds, which are prevalent in April and May, and at which season this disease, after a bad winter, is often very destructive. The animal sometimes leaps from the ground and falls down dead, but more generally it is seized with trembling, loses the power of its legs, and lies on its side, grinding its teeth, and moving its limbs with great violence. The appearances, on dissection, are very uniform; great congestion of blood in the liver and lungs, and particularly the heart, which is invariably gorged with dark blood; and the brain is also sometimes congested; the whole flesh of the body is as white as if the animal had been killed by bleeding.

These appearances, and various experiments, led the writer of this paper to view the disease as the effect of a lost balance in the circulation; the cold east wind acting on the surface of the animal when she is just beginning to return from the lowest point by the coming grass, drives the blood from the surface, congests the lungs and liver, and overpowers the action of the heart with a rush of dark venous blood. The numbness of the limbs, caused by the heart being unable to send the circulation to the extremities, has led some writers to regard the disease as a kind of palsy.

The Treatment. Copious bleeding in the first stage of the attack will often restore the balance of the circulation; but if the animal has been affected some time, it is often difficult to obtain a sufficient quantity of blood, which has been thrown from the surface upon the heart and other internal organs. In this state, the animal must be put into a tub of hot water at 98 degrees, which will cause the blood to flow, and thus restore the action of the heart, and tend to restore the balance of the circulation. After a sufficient quantity of blood has been drawn, doses of Epsom salts, dissolved in warm water, and followed with thin warm gruels, must be given till the bowels are freely opened. The prompt application of these remedies on the first attack of the disease, would in general be successful; but, like many other diseases of sheep, it is not observed till the action of the heart has become too feeble for any remedies to restore the lost balance of the circulation. The same views of the nature, causes, and treatment of this destructive disease, are supported by numerous facts and experiments brought forward by Mr. Tod, in his prize essay, published in the Transactions of the Highland Society of Scotland.

Foot-Rot.

Foot-rot is a disease most prevalent in luxuriant meadows, and in all soft grassy lands saturated with moisture. The opinions entertained regarding the cause of this disease are discordant in the extreme. Some writers contend that it is comparatively a modern disease, and was first mentioned by two French physicians, M. Etienne and M. Liebault, who published some cases of the disease in "La Maison Rustique," in the year 1529. Lullin says that it was brought from Piedmont to Geneva, in the year 1786, and that the foot-rot did not exist among Swiss sheep before that period; and in a report of the management of Flemish sheep in 1763, published by authority, foot-rot is not once mentioned. In our own country, it is mentioned by Sir Anthony Fitzherbert in the year 1523. But whatever may have been its history and progress in other countries, it was very prevalent in Great Britain in 1749. Ellis, who wrote in that year, says, "that it raged particularly in the counties around the metropolis. The ewes were seized with foot-rot, which was communicated to other sound ewes and to the lambs which they suckled; and most of the meadows are so much infected with this sheep malady, that few of the suckling ewes are ever clear of it in a greater or less degree, and the pain and anguish therefore keep them poor in flesh, and lessen their milk; so that two or three ewes thus affected give no more milk than one full milch ewe that is in perfect health."*

It will aid the reader to follow with greater clearness the following discussions regarding the nature and causes of foot-rot, to have first a correct view of the healthy anatomical structure of the foot of the sheep, at least in as far as this very formidable disease is concerned. "There are some points of importance," says that eminent veterinary surgeon, Mr. Dick, "to be kept in view, in order to understand properly either the functions of the foot of the sheep, or the nature of the diseases to which it is liable. The foot presents a structure and arrangement of parts well adapted to the natural habits of the animal. It is divided into two digits or toes, which are shod with a hoof composed of different parts, similar in many respects to the hoof of the horse. Each hoof is principally composed of the crust or wall, and the sole. The crust, extending along the outside of the foot round the toe, and turning inwards, is continued about half way back between each toe on the inside. The sole fills the space on the inferior surface of the hoof between these parts of the

* See Transactions of the Highland Society.

* See Ellis's Shepherd's Sure Guide, p. 298

crust, and being continued backwards, becomes softer as it proceeds, assuming somewhat the structure of the substance of the frog in the foot of a horse, and performing at the same time analogous functions. The whole hoof, too, is secreted from the vascular tissue underneath. There are, besides, two supplementary digits at the fetlock. Now, this diversity of structure is for particular purposes. The crust, like that in the foot of the horse, being harder and tougher than the sole, keeps up a sharp edge on the outer margin, and is mainly intended to resist the wear and tear to which the foot of the animal is exposed."*

This structure of the foot of the sheep is extremely well adapted to Alpine ranges, which are the native abodes of the sheep in their natural state. "Dwelling by preference," in the language of Mr. Wilson, "among the steepest and most inaccessible summits of lofty mountains, among its native fastnesses, it is seen to bound from rock to rock with inconceivable swiftness and agility."†

From these facts, it is easy to perceive how our domestic sheep are subject to foot-rot, when confined to a limited range on soft and rich pastures, and in wet and grassy lands. In these situations, the growth of the crust of the hoof exceeds the wear and tear, and soon overlaps the sole, and in this situation is either rent or broken off, when sand or dirt reach the vascular parts of the foot, and hence inflammation is produced. The animal then becomes lame, suppuration takes place, and ulcers discharge fœtid matter; and if these ulcers go on unchecked, they throw out fungous granulations; and if these be allowed to go on the hoof falls off. When the disease reaches to this extent, the constitutional disturbance is very great from high inflammatory fever, and the animal rapidly loses flesh, and, if unrelieved, dies of fever and starvation.

Such being the nature and causes of the disease, the author of this paper thinks the views of Mr. Dick rest upon a more secure and philosophical foundation than any other writer that has come under his observation. And if these views are admitted, the treatment and means of prevention are very obvious. To pare away all the detached hoof, and dress the diseased part with some caustic, perhaps the muriate of antimony, has the greatest weight of authority. But as prevention is in all cases to be preferred to cure, the shepherd should keep a vigilant eye upon the flock, and pare regularly on lands that require it. By the simple means here recommended, the writer has prevented the disease from injuring his flock of sheep for more than twelve years, though the lands were subject to the disease. But if foot-rot be as virulently infectious as it is affirmed to be by a whole host of writers, many of whom are men of high character and attainments, very different means both of prevention and treatment must be adopted. As the decision of the question whether foot-rot be infectious or non-infectious, is of great practical importance to every sheep-farmer, the evidence on both sides of the question would require to be stated with perfect candour, in order to arrive at the truth. In so far as evidence has been produced, the argument inclines to the side of those who contend for the non-contagiousness of the disease. Mr. Dick very reasonably asks, "Has any one ever attempted to produce the disease by inoculation? If it is highly infectious, surely it will at once be produced by inoculation. But this is not such an easy matter as one would expect, from a disease which is supposed to infect a whole field, and that, too, even if it be of five hundred acres in extent. Goheir, a French veterinarian, first applied a piece of horn from a diseased foot, covered with the matter, to the sole of a sound foot without effect; secondly, he rubbed a diseased foot against a sound one, without effect; thirdly, he pared the sound foot, and having applied a piece of diseased hoof, the disease afterwards appeared; but in this case the foot afterwards got well of itself, and there seems to have been a doubt in the mind of Goheir as to whether it was truly foot-rot or not. Other French veterinarians have tried similar experiments, and particularly Vielhan of Tulle, and Favre of Geneva; and although I have not seen an account of their experiments, it is said they succeeded in producing the disease by inoculation. Now, it will be asked, Is not this a sufficient proof of its infectious nature? I answer that it is not. It appears to me that this is a strong proof against it. If it is produced with so much difficulty by the direct application of matter, is it not absurd to suppose that a few sheep with diseased feet should infect a whole field. I have not seen an account of the manner in which the experiments of the French veterinarians have been performed; I know not what quantity of matter was employed, neither have we any account of counter-experiments, nor whether any were tried to prove whether a similar effect would not have been produced by the application of any other morbid matter; for example, whether the matter of grease from the heels of horses, or from thrushes would not have produced similar effects. I have little doubt of such being the case; that suppuration might be produced by inoculating with that or almost any other matter, if, in the operation, the wound was made sufficiently deep; nor would I doubt that disease would be produced if matter was spread over the foot in sufficient quantity, and applied for a sufficient time." The same writer continues—"I repeat, that it is absurd to suppose that, if applied to the hoof, it would produce the disease. The hoof is not governed by the laws of living matter; it is totally insensible, and it has not a circulation, neither has it nerves; it absorbs moisture only like a piece of inert matter, and it is not acted upon as a living part. Matter from the foot of a diseased sheep might as well produce the disease in a tree; nay, even more likely, because it is a living body, which the hoof is not. Why, then, are we to suppose the hoof to be acted upon by matter from diseased feet, and that, too, after the matter has been exposed to the influence of the atmosphere? But rain and sun, we must suppose, have no influence upon it. Arsenic may be diluted with water to such an extent as to be swallowed with impunity, but water seems to increase the virulence of the matter of foot-rot. It is true that heat and moisture will reduce, after sufficient exposure, animal matter to a putrid mass of the same consistency and properties, but the influence of these agents is lost upon the matter of foot-rot. The plague is now known not to be so infectious as it was once thought to be, but the foot-rot will still affect the most extensive domains. The upas-tree may annihilate the existence of all that comes within its pestiferous shade, but what is that to the infection of the foot-rot when a single sheep will contaminate a mountain? Nay, it will act even upon parts totally devoid of vitality; and such, too, is the eccentricity of its action, that it will allow its neighbouring toe to escape, and still infect the whole ground. But I need not discuss this point farther at present, as I trust I have already shown that all ideas of its infectious nature are merely chimerical."*

In support of these views, Mr. Black, farm overseer to his Grace the Duke of Buccleuch, states that he had thirteen score of black-faced sheep, the greater part of which was affected with foot-rot, and many of them crawling about on their knees. He turned

them into a drier pasture, on which were seven score of Leicester and Cheviot sheep. All of the diseased sheep, except four, recovered, and not one of the Leicesters or Cheviots was infected. This is a very strong fact, from the pressure of which the contagionists cannot easily escape.

The Scab.

This frequent and very mischievous disease has annoyed the cultivators of sheep in different parts of the world from time immemorial. It is mentioned by Ovid,* Livy,† and in the Georgics it is very graphically described by Virgil. In our own country it is mentioned by our earliest writers; and in Italy, France, and Germany, there is scarcely a writer on sheep who does not describe this prevalent and ruinous disease.

Symptoms of the Disease.—The sheep becomes restless, scratching itself, tearing off the wool with its teeth, and rubbing violently against any post, stone, or gate. When the skin is carefully examined, there are seen numerous pustules, which, having broken and run together, form large patches of scab. The back and shoulders are generally first affected. The general health of the animal sinks in proportion to the extent of the eruption and the virulence of the disease, and if allowed to proceed unchecked, it brings on general inflammation, and the animal dies in a most miserable condition.

It is now ascertained that this disease in sheep is caused by minute insects of the class *acari*. M. Walz, a German veterinarian, has given a very curious and interesting account of the operations of these acari, which are said to burrow in the skin of the sheep, and reappear again about the sixteenth day with a numerous brood. These young insects commence operations at once, and propagate in the same manner till the poor sheep sinks under myriads of his destroyers. The work of M. Walz contains drawings of these insects, highly magnified. The subject deserves further investigation, being of great importance to the sheep farmer.

The treatment of scab is thus rendered very simple—the destruction of the insect which caused it. Infusions of tobacco, hellebore, or arsenic, have all been employed with success. In bad cases, the mercurial ointment has been applied with the happiest effect. A very good receipt is a decoction of tobacco and spirit of turpentine, with a little soft soap, and sulphur vivum.

The only caution necessary to be given in the use of any of these remedies, is to take care that they be brought thoroughly in contact with every part of the skin of the affected animal, lest any of the burrowed acari escape. And all folds or sheds in which infected sheep have been confined, and all gates, posts, and other rubbing places, must undergo thorough purification. Besides the acari, sheep are liable to be attacked by various other insects, such as the flesh-fly, and a species of aphis called the sheep-louse. The maggot only prevails in the moist and warm summer months, but inc[illegible] in numbers with amazing rapidity, and requires great watchfulness on the part of the shepherd, as they soon destroy a large portion of the skin and flesh of the sheep, if unchecked. The aphis also creates great irritation, but both species are easily destroyed by any of the preparations already detailed. The tick (*acarus reduvius*) is also a very formidable insect to sheep. It almost buries itself in the skin, and adheres so firmly by six legs, very muscular and powerful, and so armed with serrated claws, that it can scarcely be disengaged from its hold, but will yield, like most insects which infest the sheep, to the application of a mercurial preparation.

THE ALPACA.

It is perhaps not very generally known that attempts are now making, under the most respectable auspices, to introduce the alpaca, or Peruvian sheep, into the number of our domestic animals. As the subject is of vast importance in a national as well as individual point of view, we propose offering a few explanatory observations upon it.

Nature, as is well known, furnishes animals expressly suited to the climate, vegetable productions, and other circumstances connected with the locality which they are destined to inhabit. The Andes, and other high mountain ranges and slopes of South America, are accordingly provided with several species of sheep adapted, by their habits, to these lofty regions of scanty vegetation, and which so materially differ from the sheep of this and other European countries, as to seem a perfectly distinct tribe of animals. The two most common of these South American sheep are the llama and alpaca, and they abound most extensively in Peru. The llama is somewhat taller than the alpaca, and though in some respects a remarkable animal, its peculiarities are not such as to render it so especially interesting as the alpaca, for purposes of practical utility out of its native regions. The alpaca, which it is proposed to domesticate in Britain, is an animal combining the appearance of the common European sheep with that of the goat, and partly of the deer and camel. Like the sheep, the alpaca is lanigerous or wool-coated; in its general structure it is light, and possesses limbs adapted for springing and leaping like the goat; it resembles the deer in skin, flesh, and general appearance; and though without the camel's deformities, it is gifted like him with patience and docility, being often used as a beast of burden by the natives of South America. The height of the alpaca is from three to four feet, when measured from the ground to the top of the back; the eyes are large, black, soft, and expressive; the animal has no horns; the neck is long, slender, curved backwards, and finely set; the head handsome, and the muzzle and ears lengthened; the hoof is horny, and divided; the tail long, and resembling what is called a switch-tail; the body has a tapering towards the loins, resembling that of the greyhound; and, as regards other points, the alpaca has partly the characters of the sheep (its incisors on the lower jaw, for example, and six molar teeth on each side,) and partly those of the camel (the most remarkable being a similar reservoir in the stomach for fluids, suiting the creature to an arid climate.) To common observers the alpaca might seem to be a fine tall goat, with small head and no horns, but of more gentle and fleecy appearance than that animal.

The wool of the alpaca forms, of course, a point of peculiar importance, taking into view the proposal for introducing the animal into Great Britain. The colour of the wool varies considerably, the majority of the tribe being of a tint intermediate between black and brown, while others are of a pure white. The texture is admitted on all hands to be peculiarly fine. In a memoir on this subject, written by Mr. W. Walton, and printed for the Natural History Society of Liverpool, the wool is thus described:—"With the polite assistance of the secretary of the Polytechnic Institution, I was enabled to examine the anatomical structure of three samples of alpaca wool through a lens magnifying one million times. The colours of those subjected to the power of the microscope were white, black, and gray. When thrown upon the disc, each filament appeared equal in thickness to a man-of-war's topsail halyard, perfectly distinct, and the fibrous structure more evident than in the wool of common sheep. White was the first sample tried, and it produced an effect at the same time singular and pleasing. The

* Metamorph. lib. vii.

† Tit. Liv. iv., cap. 30.

surface appeared polished and distinguished by glittering brightness, almost, I could say, refulgence, which is wanting in sheep's wool. The general results produced by afterwards showing the black sample were the same, excepting that the shade on the disc was more opaque, and the brilliancy of each filament diminished. The gray exhibited a medium between the contrasts, and helped to show both to advantage.

"There are instances of alpaca wool measuring thirty inches long; frequently it is seen twenty inches, and it averages from eight to twelve. In the sample, there appeared to be no under wool—no closer and immediate covering. No shorter hair, or wool, could, in fact be perceived; the very reverse of what is observed when a morsel of an elk's or camel's coat is examined. Alpaca wool is also straighter than that of sheep, never appearing in those spiral curls which distinguish our piles, more particularly when the bearer of the fleece has been smeared. The smallness of the fibre, its softness and pliability, coupled with its elasticity, equally add to its value. There is, in the mass, what is technically called a *trueness*, that is, an equal growth and an exemption from shaggy portions, accompanied by a soundness, by which is meant the general strength of the fibre—properties certainly of the first import to the manufacturer. In consequence of this characteristic disposition, alpaca wool breaks less in the act of combing, is freer from shreds, spins easily, and not being so harsh or so stubborn, does not injure the machinery so much. The thread spun with it is also finer and truer. In the manufacture of fine goods, it is agreed that the pile cannot be too soft or too silky, provided the strength of the fibre is not impaired. As well as I could, I have compared the strength of a filament of alpaca with those of other wools, and found it the strongest; and as it is devoid of that irregularity of surface—the knots and joints which some persons liken to those of a bamboo cane—the cloth made from it must consequently be less harsh to the touch."

But the qualities of the alpaca wool for manufacturing purposes do not rest upon mere conjecture. "The merits of alpaca wool have for some time past attracted the notice of manufacturers and consequently of merchants; and through the advice of Mr. Danson and other enterprising individuals, the importations of it have within the last six years considerably increased. Mr. J. J. Hegan, of Liverpool, has been the largest importer, and it is believed that his house alone, since 1836, has imported 25,000 bales,* sold to the consumers at from 1s. 8d. to 2s. 6d. per lb. Other houses receive considerable quantities. One million lbs. arrived there in the course of February, 1841. During his tour in Scotland, Mr. Danson urged the expediency of introducing the alpaca into the Highlands, and pointed out the benefits which would accrue from this measure. In illustration of his views he exhibited samples of the wool, and specimens of articles manufactured in England from it, imitating silk, some as black as jet, although of the natural colour, and without the aid of dye. He very ably contended, that this wool would not enter into competition with that of our ordinary sheep, and, from the fineness and transparency of the filament, was peculiarly well adapted for the fine shawl trade of Paisley and Glasgow." Even these trials have been made under disadvantages, for the alpaca wool has only reached this country in a dirty and also in a mixed state, the wool of inferior breeds forming almost always a large proportion of the bales containing it.

The value of the wool being once determined, the next question is, Have we space and food for the alpaca in Britain? On this point, after some arguments in proof of his views, Mr. Walton reaches the following conclusions, which appear to be essentially correct:—"We therefore have, and must continue to have, large tracts, neither cropped with grain nor depastured by cattle, consisting of chains of barren hills, running in various directions through the United Kingdom, moors, heath, moss, lands, &c., wholly unproductive, the amount of which may be set down at from twelve to fourteen millions of acres. And would it not be highly expedient to stock these lands with another domestic animal, yielding a commodity of such a nature as to reward the farmer for his care, and besides triple in value by the beneficial application of labour—an animal requiring no additional subsistence for its support, and consequently not likely to interfere with any cattle already on our farms! Besides, if an improved race of domestic animals could be put even into our occupied lands, would it not be advisable to do so, even at the cost of diminishing in part the existing breeds?

Another material question is, Could the alpaca live in this country? "Although delicate in appearance, the alpaca is, perhaps, one of the hardiest animals of the creation. His abstinence has already been noticed. Nature has provided him with a thick skin and a warm fleece, and as he never perspires like the ordinary sheep, he is not so susceptible of cold. There is, therefore, no necessity to smear his coat with tar and butter, as the farmers are obliged to do with their flocks in Scotland—a process which, besides being troublesome and expensive, injures the wool, as it is no longer fit to make into white goods, nor will it take light and bright colours.

"'The Highland hills,' says the Ettrick Shepherd, 'are, for the most part, of a pyramidal form, very high, and commonly so steep and rugged, that to the eye of the traveller they have an appearance perfectly tremendous. The sides and banks of the glens and rivulets are commonly covered, or mixed, with a rich short grass, intermingled with numberless aromatic herbs and flowers. The extensive flats and sloping declivities around the bottom and lower parts are covered with a coarse mossy turf, interspersed with thin sapless heather, which has stood in the same squalid form since the time that it first made its appearance on the retreat of the universal deluge, mixed with some of the moss-stalks called ling and deer hair.' This is the description which so experienced a man as the Ettrick Shepherd gives of 'that vast range of stupendous mountains, deep glens, and trackless forests,' which (he says) 'at the first view every unprejudiced man must acknowledge nature never intended for the rearing of cattle,' and where no one (adds he) 'will hesitate whether sheep or goats are the most feasible stock.' What pen could have sketched a more faithful picture of the Andes mountains—those high and secluded regions, inaccessible to other animals, where the alpaca lives 'an inmate of the cloud and storm,' gathering subsistence from edible plants which otherwise would be left to wither on the land?" We are aware of only one doubtful circumstance as to the successful domestication of the alpaca in any of the British islands, particularly in the Highlands—this is the *humidity of our climate*. If the alpaca can resist damp as well as our South-downs, we shall have nothing to fear on the score of hardiness in other respects.

Mr. Walton alludes to the strong enamel on the alpaca's teeth, as fitting the creature peculiarly for rocky and mountainous pasturage. In the case of snow-storms, too, on our elevated ranges, by which so many of our common sheep are apt to be smothered every severe winter, the remarkable docility of the alpaca renders him almost secure, with little comparative toil to the herdsman. "Peruvian sheep have, in

* Each bale averages from 55 to 90 lbs.

fact, an unerring foresight of the coming danger, long before their tender (if they happen to have one) sees above him a threatening cloud or dreams of a drift. Instinctively they know the safest side of a crag, as if they saw the point of the compass from which the storm was approaching, and thus admonished collect their young, and fly to the *stell* which nature provided for them, even before the conflict of the elements and the roaming of the winds shall have commenced. If within reach, the alpaca asks protection at the cottage door where at other moments he had been welcomed." Again—"Another great advantage in the alpaca is, that he is not liable to the many diseases incidental to common sheep, and which have so often raged like a pestilence among the tenants of the Scotch hills. In Peru, where the circumstances are as near as possible alike, the llama and alpaca are not hurt by changes of diet incidental to the seasons. This may arise partly from their greater abstemiousness and discernment, and partly from their having a wider range, and consequently more choice of food. It is, however, a fact, which I have ascertained from natives, that the Peruvian breeds are not so liable to bowel complaints as ours, and their constitution being much stronger, they are consequently less affected by sudden transitions from one food to another. The distemper called pining, or daising, very usual in the west of Scotland, which occasions a thinness of blood, and when, though the animal continues to feed greedily, it pines away to a mere skeleton, is unknown on the Andes: neither are the fawns there liable to the many accidents which attend the feeding, herding, and folding of lambs among us. As regards vermin, they are much clearer." With respect to other diseases, though the alpaca is not exempt from some of them, its hardy constitution seems to render their influence less extended and destructive.

In reality, the experiment of keeping the alpaca in Great Britain has already been tried on a considerable scale, and the wool has been found to be even improved by the change of site. "The Earl of Derby, with that patriotic spirit and splendid taste which have distinguished him through a long life, also stepped forward among the first breeders, and his lordship has now at Knowsley a little flock of llamas and alpacas, amounting to fourteen, two of which were bred on the spot, whose wool is finer, softer, and more beautiful than that on the backs of their parents. The proof that the wool improves with our pasture is, in fact, established in this instance. The young are eight-and-twenty months old, and already the first has wool upon it six inches long. A fine male alpaca, shorn three years ago, has at present a coat upon it from eighteen to twenty inches long, thus proving that the wool grows from six to eight inches yearly, if regularly shorn. Speaking of the practicability of introducing the Peruvian sheep more generally, in a letter addressed to William Danson, Esq., of Liverpool, who, accompanied by a friend, visited Knowsley at the beginning of the current month, [April, 1841,] his lordship says that 'he certainly knows of nothing likely to prevent the propagation of the animal in this country. On the contrary,' he adds, 'the gentlemen will see in these grounds living specimens that they can and will do so, one female having produced in each of the two last seasons, and the young are doing well.' His lordship then expresses his anxious desire 'to obtain the remainder of the species, more especially the vicuna.' Already does this interesting animal adorn the pleasure-grounds of the Marquis of Breadalbane, at Aberfeldy, Perthshire; J. J. Hegan, Esq., Harrow Hall, Cheshire; Charles Tayleure, Esq., near Liverpool: Mr. Stephenson of Oban, and others. The Duke of Montrose has lately become a purchaser of alpacas; and Earl Fitzwilliam has also bought a llama at £80. Various isolated trials in other countries have proved equally successful." Messrs. Ducrow, Wombwell, and other proprietors of menageries, have also kept specimens of Peruvian sheep, which have been at once wonderful for docility, and have lived healthily upon the usual food procurable for animals in Great Britain.

From the tone in which this notice has been drawn up, it may be observed that the statements before us have been convincing in our eyes, in so far, at least, as regards the propriety of making fair and full experiments on the subject of the alpaca. This animal, we conceive, without infringing materially on the keeping of sheep, might prove the means of enlarging the profession of the pastoral farmer, and of varying, extending and improving our manufactures. From the alpaca wool which we do procure at present, yarn is spun, which the French import at from 6s. to 12s. per lb. In conclusion we give a few additional words from Mr. Walton. "When we consider the great improvement which we have attained in sheep's wool, there is every reason to look for a similar success in that of the alpaca; and in devising means to increase the productive power of the country, we ought never to forget, that there have been periods in our history when we were dependent upon foreign supplies for the raw material required for our woollen manufactures, and that the best way to be independent, is not to be under the necessity of buying that which it is in our own power to grow. The task of obtaining suitable breeds of the alpaca is by no means a difficult one; and in our attempts to naturalize them, we ought to feel the more encouraged, when we reflect on the recent changes in the growth and supplies of sheep's wool, and how soon a farming stock propagates under judicious management. It must be equally borne in mind, that in using alpaca wool we are not competing with that of our own sheep, but rather with that of the Angora goat (mohair) and silk; and the manufacture, it has been ascertained, does not cost half so much as that of the latter."

One other point calls for notice. Our present breeds of sheep are of essential importance as food to man. The flesh of the alpaca is spoken of as excellent by Acosta, Garcilasso de la Vega, and other writers on Peru. Of the various breeds of sheep on the Andes, "the alpaca (says Garcilasso de la Vega) is chiefly valued for its flesh." General O'Brien, an Irish gentleman in the Peruvian service, speaks of the flesh as "delicious," and likely also to improve much on the animal being placed on milder pastures than those of the Peruvian mountains. The flavour resembles that of venison, and, from all accounts, could not fail to command as fair a price in our markets as mutton, beef, or any other kind of meat.

PIGS, GOATS, RABBITS, POULTRY, CAGE BIRDS, &c.

PIGS.

As a source of sustenance and emolument to the humbler classes of society, the pig is only second in importance to the cow, and in many instances is found to be more available and useful than that animal. As an object of natural history, it is placed amongst the *Pachydermata* or thick-skinned order of the Mammalia, the hog, wild boar, and probably also the peccary of South America, being varieties of the same family. The most remarkable characteristic of the common pig is its long roundish snout, given for the purpose of grubbing in the earth for roots and other kinds of food; the feet are cloven, and each possesses four toes; the body is thinly covered with bristles, and the female is provided with from twelve to sixteen teats. The jaws of the pig are powerful, and the teeth with which they are furnished are very formidable, particularly in the wild varieties. Swine do not ruminate, and from this and other peculiarities, they can feed either on vegetable or animal substances, and thus form a kind of link between the herbivorous and carnivorous class of animals.

The particular breeds of pigs most esteemed in Great Britain are the Berkshire and Chinese breeds. These are also the breeds best marked by distinctive features; though, by crossings, and peculiarities of feeding and position, varieties, differing in a slight degree from one another, have been raised up in almost every county in England. The Berkshire breed, the parent stock of most of them, are marked by bodies of a reddish-brown tint, with black spots, large pendant ears, short legs, and small bones. This species of hog fattens to an enormous weight under good management, some having been killed which amounted to upwards of twelve hundredweight. The Chinese breed vary in colour from white to black, and from a piebald to a sandy hue. They are neat in form, comparatively speaking, and yield excellent flesh. They are usually not very large in size, but vary in this respect, and, of course, in weight also. The gigantic white and black breed of Cheshire, the white pigs of Suffolk and Hampshire, and the piebald hogs of Sussex and Shropshire, may be mentioned as the best known among the district-breeds of England. They are coarser, generally speaking, than the Berkshire and Chinese varieties. Both of these have been pretty extensively introduced into Scotland, where a less valuable white breed appears to have been earlier located, if not indigenous. There is also a small gray pig, apparently aboriginal, which feeds in herds on the natural pasture of the Highland hills, and furnishes very sweet flesh. By artificial feeding, it can be raised to a considerable bulk. But the breed most commonly esteemed both in England and Scotland, is a mixture of the Chinese dark-coloured swine with the Berkshire, or some of the large varieties of British swine. This cross possesses many good qualities, and is peculiarly prolific. Either belonging or allied to the Berkshire variety, is the Hampshire *hock*, a small black pig suitable for cottagers, for it is easily fed and fattened, and is therefore highly esteemed.

Littering.—The sow is very prolific, compared with other large-sized quadrupeds. She commences breeding at about twelve months old, and generally brings forth twice a year, her period of gestation being sixteen weeks. The number of young varies considerably; it is frequently below ten, and occasionally rises to twenty. The young pig is exceedingly delicate; and the brood-sow should not be allowed to furrow in winter, but in spring and autumn, when the weather is less severe and food more abundant. Another peril to the litter arises from the semi-carnivorous habits of the mother, which lead her to forget the dues of nature, and devour her own brood. She ought therefore to be well watched, and fed abundantly at such periods. The male, for the same reason, must be excluded altogether. Not unfrequently, moreover, the young are crushed to death by the mother, in consequence of their nestling unseen below the straw. To prevent this risk, a small quantity only of straw, dry and short, should be placed below them. The young are weaned when six weeks old; and after weaning, it is essentially necessary to feed the young with meal and milk, or meal and water.

The brood-sow ought to have an ample abdomen, and ought to be in good condition when breeding, otherwise little good can be expected of her progeny. Many persons labour under the mistaken notion that swine while breeding, should be kept lean; but nothing can be more erroneous; for, after farrowing, great part of those juices which would be converted into milk, were she in good condition, will naturally go towards nourishing her system. When required for the purpose of fattening, the male young pigs are cut, and the females spayed, which is an analogous process. These operations should be intrusted to a farrier or other skilled person.

Pig-houses.—Although swine are found to succeed in all countries, and their constitutions have been accommodated to every climate, yet they are found to degenerate and thrive ill either in the extremes of heat or cold. In a native state we find them, when inhabiting countries towards either extreme, seeking situations most adapted to their constitution. Swine, in a domesticated state, require to be kept very dry and warm, otherwise they will never thrive. It will be noticed that in cold weather they invariably bury themselves among the straw and litter with which they are supplied as bedding, thus pointing out their natural desire for heat. The piggery should therefore be in some well-sheltered spot, and, if possible, with a south or west exposure. If kept in small styes, there should be a small aperture at each end of them, so as to admit the free passage of air through them for ventilation. These may be kept open constantly during the summer months, but only allowed to be open for air once every second day in winter, and that in the forenoon, while they must be carefully shut up in the evening. Pigs will be found to grow notwithstanding the neglect of all these precautions; but we know, from experience, that they will grow much faster and will be more healthy with them.

In most cases pigs are kept in a shamefully filthy condition; their stye ill ventilated, the straw dirty, their small court-yard no better than a wet dunghill, and consequently the skin of the animal begrimed with scurf and all sorts of impurities. We cannot too strongly reprehend this infamous treatment of the pig, which is not naturally dirty, as some suppose, but loves to be kept dry and clean, as well as warm, as any one may observe by the delight it evidently takes in having its hide scratched and scrubbed. Let us, then, beseech all pig-keepers under whose eye this sheet may come, to preserve the stye in the most dry and clean condition possible, to change the straw frequently, and to curry the skin of the pig at least once a week. By doing so, without a particle of additional food, the animal will thrive and fatten in a very superior degree, while the flesh will be more pure and delicate. So true is this, that any man who keeps his pig dirty, may be said to be picking his own pocket, as he will realize less money for its carcass than if he had taken a little trouble to clean it.

To insure comfort to the pig or pigs, let the stye consist of at least two compartments—a sleeping apartment and an open court-yard, the one opening into the other. The sleeping apartment should be well-built and slated, for the sake of dryness, and the floor, formed of strong planks, should slope outwards to the door. The outer court should be paved in a substantial manner with large flag-stones, sloping also in a particular direction, to which the liquid refuse can flow into a gutter. It is advantageous for the erection to be near the dunghill, to which all liquid may run, and solid materials be carried without loss. Keep plenty of straw both in the pig-house and its court, in order to absorb moisture or dung, and let all be raked out regularly, and renewed. The money lost by allowing the dung to go to waste by mere evaporation—flying off into the atmosphere—no one can calculate. The open court of the pig-house should, if possible, lie to the sun, as the inmates are fond of basking in his beams. The feeding utensils placed in the court should consist of two strong troughs, which cannot be easily knocked over. These should be daily washed and scoured to keep them sweet.

Feeding.—In rural situations, where extensive woods exist, and where the grass is otherwise of no value, the feeding and breeding of pigs will be found very profitable to the cottager; for, where they have a wide range, they will require little food save what they find for themselves in grazing under the trees, and in digging for worms and roots of various kinds—for which latter task their long and strong snouts peculiarly fit them. Artificial feeding is only resorted to in winter, and when the pigs are to be fattened for the market or table. It is more common, however, for the cottager to keep one or two pigs entirely within a stye, to add to the means of subsistence of his own family; and even when kept with this limited view, the pig is a creature of no little consequence. As Cobbett acutely and pithily observes—"The sight of a flitch or two of bacon on the rack, tends more to keep a poor man from poaching and stealing, than whole volumes of penal statutes. They are great softeners of the temper, and promoters of domestic harmony."

When a young pig is to be purchased for feeding and killing, it is advisable to buy one which will be about sixteen months old at Christmas, that, or some time in January being the preferable period of slaughtering the animal. Unless for delicate pork, it should not be killed less than a year old. During the summer, the pig may be fed on any refuse from the kitchen or garden, including turnip and potato parings, table-waste, cabbage blades, &c.; but if barley-dust, or grains from a distillery, can be economically procured, either forms a good article of diet. Let it be kept in remembrance that the finer the feeding the finer will be the pork. The food should at all events be of a vegetable kind, or principally so; nothing beyond slops from the table being to be tolerated in the shape of animal food. Whatever be given, let it be offered in small quantities and frequently, it being a matter of importance never to allow the pig to become violently hungry. The half-starving system of feeding is poor policy, and is repaid by a lank poor carcass scarcely worth killing.

Farmers possess great advantages for feeding pigs. The straw-yard of itself affords continual support to them; and many pigs reach the age of one year without having received any food but what they themselves have gathered, yet are in good condition. What with the sweepings of the barn, and the straw, turnips, and clover, lying about a steading, with the refuse of the kitchen, a farmer, it has been calculated, may sustain swine in the proportion of one to every seven or eight acres of land under crop, without being conscious of the consumption made by them. In few instances are swine reared in such numbers as to have crops specially laid out for them, though some writers assert, that they would yield, in such a case, greater profits than other live-stock habitually reared in the same way.

About the month of September, the process of fattening pigs should commence, whether they be designed for pork or bacon. If for pork, the fattening need not be carried to the same extent. In either case a nourishing diet must be given, the only precaution being not to commence feeding too rapidly, otherwise surfeit may be produced. The best materials for feeding are barley and peas-meal; and if milk, either skimmed or churned, can be given at the same time, it will greatly facilitate the feeding, and improve the quality of the flesh. Many persons feed their pigs on potatoes, but in that case the flesh is not so solid and good, and the fat is somewhat loose and flabby. Soft meat may do very well for pigs when they are growing, but it is not the food which should be given when they are fed for killing. Those who feed pigs for their own use, generally give them a feed or two of corn daily for fourteen days before they are killed, and give them nothing else but churned or skimmed milk to drink; and for a day before killing the pig should not get any food. Where people's circumstances will not permit any of the modes of feeding for killing which we have above pointed out, boiled potatoes, mixed with a handful or two of oatmeal, may be resorted to as a substitute. It is undeniable, notwithstanding what has been said above, that the Irish peasantry produce excellent pork by feeding their pigs almost entirely on potatoes. It is not so fat as the pork produced from peas and barley, but it is on that account the better suited to stomachs unaccustomed to very strong food. When the time arrives for slaughtering, let it be done in a humane and neat style by a butcher, so as to avoid all mangling or injury to the flesh.

Pork.—The carcass of a pig is less frequently consumed as fresh than as salted pork, and the preparation of the salted article for home consumption or exportation forms a large and flourishing business. Those who pursue the occupation cut the carcass in pieces, and pack it in kits formed to hold from one to two hundred pounds, weight. A brine is then made by dissolving salt in water, until the mixture is so thick that an egg will swim in it. This is boiled, and poured upon the pork after it has cooled. Russian pork, always much esteemed, is steeped in a brine containing 2 lbs. of loaf sugar, and 3 oz. of saltpetre, to 6 lbs. of salt, the whole being boiled in six gallons of water. After brine is added to pork in kits, the end of the receptacle is fixed in, and the article is usually sufficiently cured in a few days. Four days are enough for small pork. People who pickle pork for private use must take care that the brine covers the meat, otherwise it will require to be turned daily. The same pickle may be several times used, if reboiled, and slightly strengthened anew.

Brawn.—Boars are also fattened for the purpose of procuring an article for the table called *brawn.* Male pigs of all ages are put into feeding with this view, but those experienced in such matters prefer them of the age of two years. They are kept separately, in pens which will not permit of their turning round, perfect inactivity being held to conduce to their fattening. Their food is beans, with water, into which a small quantity of sulphur has been put. The collar of the animal is the part prepared for brawn, by the processes of pickling and drying. A large collar will weigh about thirty pounds, and is valued at about £3 in the market. The lean parts of the animal are commonly used for sausage-meat.

Hams are the cured hind-legs of the pig, and are considered the finest parts of the animal. The following are general directions for curing them:—In the first place, the legs require to be cut in a neat rounded form, and it is usual to prepare a number at a time. Being properly prepared, pack them with rock-salt in a suitable tub or cask, being careful not to lay the flat sides of the large pieces upon each other, and filling the intervals with hocks, jowls, &c. To every 300 lbs. of meat, then take 20 lbs. of rock-salt, or Onondago coarse salt, 1 lb. of saltpetre, and 14 lbs. of brown sugar, or half a gallon of good molasses, and as much water (pure spring water is the best) as will cover the meat; put the whole in a clean vessel; boil and scum; then set it aside to cool, and pour it on the meat till the whole is covered some three or four inches. Hams weighing from 12 to 15 lbs. must lie in the pickle about five weeks; from 15 to 25 lbs., six weeks; from 25 to 45 lbs., seven weeks. On taking them out, soak them in cold water two or three hours, to remove the surface salt, then wipe and dry them. It is a good plan in cutting up, to take off feet and hocks with a saw instead of an axe, as it leaves a smooth surface, and no fractures for the lodgment of the fly. Some make only six pieces of a trimmed hog for salting, but it is more convenient, when intended for domestic use, to have the side pork, as it is called, cut in small pieces. The goodness of hams and shoulders, and their preservation, depend greatly on their smoking, as well as salting. The requisites of a smoke-house are, that it should be perfectly dry; not warmed by the fire that makes the smoke; so far from the fire, that any vapour thrown off in the smoke may be condensed before reaching the meat; so close, as to exclude all flies, mice, &c., and yet capable of ventilation and escape of smoke. The Westphalian hams are the most celebrated in Europe, and are principally cured at and exported from Hamburg. The smoking of these is performed in extensive chambers in the upper stories of high buildings, some of four or five stories; and the smoke is conveyed to these rooms from fires in the cellar, through tubes on which the vapour is condensed and heat absorbed, so that the smoke is both dry and cool when it comes in contact with the meat. They are thus perfectly dry, and acquire a colour and flavour unknown to those smoked by the common method. Hams, after being smoked, may be kept any length of time by being packed in any dry dust, which will keep them from the air. Bran is usually employed for this purpose. When fully smoked and dried, the meat may be hung up in a dry airy room; and if liable to be attacked by the bacon-fly, or other insects, draw over it a loose cotton bag, tied closely with a string. The small part of a ham should always be hung downwards in the process of smoking, or when suspended for preservation.

Bacon is the whole side of a pig cured. The method of preparation is as follows:—After being killed, the carcass should not be scalded to remove the bristles, as in the case of pork, but singed off by being covered lightly with straw, to which fire is applied. When the burning straw has cleared one side, the other side may be cleared in the like manner. By this means all the hair is to be singed clean off, but without scorching the flesh, and then the skin is to be well scraped as a finish. This singeing process gives a fine firmness to the bacon, which scalded bacon never possesses. In Hampshire, as Mr. Cobbett informs us in his "Cottage Economy," the plan of singeing is universally followed; and pig-keepers could not have a better example. The next steps in the process are related as follows by this writer:—"The inwards are next taken out, and if the wife be not a slattern, here, in the mere offal, in the mere garbage, there is food, and delicate food too, for a large family for a week, and hog's pudding's for the children. The butcher the next day cuts the hog up, and then the house is filled with meat; souse, griskins, blade-bones, thigh-bones, spare-ribs, chines, belly-pieces, cheeks, all coming into use one after the other, and the last of the latter not before the end of about four or five weeks. All the other parts taken away, the two sides that remain, and that are called *flitches*, are to be cured for bacon. They are first rubbed with salt on their insides, or flesh sides, then placed one on the other, the flesh sides uppermost, in a salting trough, which has a gutter round its edges to drain away the brine; for, to have sweet and fine bacon, the flitches must not lie sopping in brine, which gives it that sort of taste which barrel-pork and sea-junk have, and than which nothing is more villanous. Every one knows how different is the taste of fresh dry salt from that of salt in a dissolved state; the one is savoury, the other nauseous. Therefore change the salt often; once in four or five days. As to the time required for making the flitches sufficiently salt, it depends on circumstances—the thickness of the flitch, the state of the weather, the place wherein the salting is going on. It takes a longer time for a thick than for a thin flitch; it takes longer in dry than in damp weather; it takes longer in a dry than in a damp place. But for the flitches of a hog of twelve score, in weather not very dry nor very damp, about six weeks may do; and as yours is to be fat, which receives little injury from over-salting, give time enough, for you are to have bacon till Christmas comes again. The place for salting should, like a dairy, always be cool, but always admit a free circulation of air; confined air, though cool, will taint meat sooner than the mid-day sun accompanied with a breeze. The flitches of bacon are now to be smoked, for smoking is a great deal better than merely drying, as is the fashion in the dairy counties in the west of England. When there were plenty of *farm*-houses, there were plenty of places to smoke bacon in; since farmers have lived in gentlemen's houses, and the main part of the farm-houses have been knocked down, these places are not so plenty. However, there is scarcely any neighborhood without a chimney left to hang bacon up in. Two precautions are necessary: first, to hang the flitches where no rain comes down upon them; second, not to let them be so near the fire as to melt. These precautions taken, the next is, that the smoke must proceed from *wood*, not turf, peat or coal. Stubble or litter might do, but the trouble would be great. Fir or deal smoke is not fit for the purpose. I take it, that the absence of wood, as fuel, in the dairy countries and in the north, has led to the making of pork and dried bacon. As to the time that it requires to smoke a flitch, it must depend a good deal upon whether there be a constant fire beneath, and whether the fire be large or small. A month may do, if the fire be pretty constant, and such as a farm-house fire usually is; but over-smoking, or rather too long hanging in the air, makes the bacon rust. Great attention should therefore be paid to this matter. The flitch ought not to be dried up to the hardness of a board, and yet it ought to be perfectly dry. Before you hang it up, lay it on the floor, scatter the flesh-side pretty thickly over with bran, or with some fine saw-dust other than that of deal or fir. Rub it on the flesh, or pat it well down upon it. This keeps the smoke from getting into the little openings, and makes a sort of crust to be dried on, and, in short, keeps the flesh cleaner than it would otherwise

&c." Other writers recommend plans slightly differing from the preceding, but the English, unquestionably, are most skilled in the mode of preparing superior bacon; and whatever other characteristics were displayed by the author quoted, he at least knew thoroughly all the processes incidental to farm management in his native land.

Lard is that part of the fat of the hog which easily melts, and forms a soft grease. The saving of this material is of great importance, for it may be put to many uses in household economy. Martin Doyle, in his "Cyclopædia of Agriculture," makes the following observations on this subject:—"The lard should be of *two* qualities; the finest and whitest (that taken from the sides) should be chopped into small pieces in a pan, over a slow fire, and kept constantly stirred, lest it should stick to the sides of the boiler; then strained and put into bladders, turned inside out, and thoroughly purified, by having all the fat cut out, and being well blown, and perfectly dried in the open air; when the wind is pressed out, they are to be put into a little salt pickle for a few days, then washed in lukewarm water, after which they may be turned by means of a stick. That of the first quality, when well made, is far better than any salt butter for cookery, and, from the delicacy of its colour, is used by confectioners for the finest kinds of cake and pastry. The inferior lard is obtained from the *intestines*, and is treated as the fine lard in every particular. The feet, when taken off, are chopped in two or three places, and put into brine, in which they may be kept until required."

The same author continues—"Both the hair and bristles are serviceable for brush-makers' and cabinet-makers' purposes. No part of the pig is useless; even the intestines are converted into an inferior kind of lard, by being cut open and washed clean, and (after the water is well pressed out of them) melted in the same way as lard; this substance is very useful for making candles, greasing wheels, and such purposes."

GOATS.

Goats form one of the families of the *Ruminant* order of Mammalia. The common domesticated goat is usually about the size of the sheep, though less round in form, and is marked by keen eyes, long hair, and generally bent horns; the males, called familiarly in England *billies*, have a long beard; but the females, or *nannies*, are seldom provided with that appendage. Whether in a state of nature or tamed, the goat is remarkably swift and agile, and will browse fearlessly on the most rugged precipices. We find, from ancient writers, that goats have long formed part of the stock of mountain-herdsmen, and were tended with even greater care in former than in present days. In many respects, indeed, the animal is valuable. Its skin is convertible to several useful purposes, and the flesh of the full-grown goat is good, though scarcely equal in quality to that of the sheep. But it is for the milk, chiefly, that the goat is prized, the qualities of that secretion being not only very nutritious but even medicinal. Where cottagers have not the means of keeping a cow, a goat will be found a very useful animal, being easily fed, and contented with grasses which are rejected by the cow and the sheep. To those peasants who live in the neighbourhood of mountainous countries, the trouble and expense of keeping a couple of goats will be nothing, as they will find sufficient nourishment in the most heathy, rough, or barren grounds. Heaths, also, which are unfit for any kind of pasture, will afford this animal an ample supply of food; and it requires no care or attention, easily providing for itself proper and sufficient food. In some countries, goats render considerable service to mankind, the flesh of the old ones being salted as winter provision, and the milk is used in many places for the making of cheese. The flesh of the kid is highly palatable, being equal if not superior in flavour to the most delicate lamb.

In Britain, the goat produces generally two young at a time, sometimes three, rarely four. In warmer climates it is more prolific, and produces four or five at once though the breed is found to degenerate. The time of gestation is five months. The male is capable of propagating at one year old, and the female at seven months, but the fruits of a generation so premature are generally weak and defective; their best time is at the age of two years, or eighteen months at soonest. A goat is old at six years, although its life sometimes extends to fifteen.

If goats are properly trained, they will return to their owners twice a day to be milked, and prefer sleeping under a roof when accustomed to it. The milk of the goat is sweet, and not so apt to curdle upon the stomach as that of the cow; it is therefore preferable for those whose digestion is but weak. The peculiarity of this animal's food gives the milk a flavour different from that of either the cow or the sheep; for, as it generally feeds upon shrubby pastures and heathy mountains, there is a savoury mildness in the taste, very pleasing to such as are fond of that aliment. The quantity of milk produced daily by a goat is from three half pints to a quart, which yields rich and excellent cream. If properly attended to, a goat will yield milk for eleven months in the year. In several parts of Switzerland and the Highlands of Scotland, the goat is the chief possession of the inhabitants. On those mountains where no other useful animal could find subsistence, the goat contrives to glean sufficient living, and supplies the hardy natives with what they consider a varied luxury. They lie upon beds made of their skins, which are soft, clean, and wholesome; they live upon their milk, with oat-bread; they convert part of it into butter, and some into cheese; and the flesh furnishes an excellent food, if killed in the proper season, and salted. They are fattened in the same manner as sheep: but taking every precaution, the flesh is never so good or so sweet in our climate as that of mutton. It is otherwise between the tropics. The sheep there becomes flabby and lean, while the flesh of the goat rather seems to improve, and in some places is cultivated in preference to that of the sheep. The cream of goat's milk coagulates as easily as that of cow's, and yields a larger proportion of curd. The cheese is of an excellent quality, and high flavoured; and although, to appearance, it looks poor, it has a very delicate relish, and strongly resembles Parmesan cheese. Some farmers have been in the practice of adding a little goat's milk to that of cow's, which materially improves the flavour. In winter, when native food becomes scarce, the goat will feed upon turnip-peelings, potato-peelings, cabbage-leaves, and other refuse of a house. In addition to the other products yielded by the goat, its tallow, we should mention, is also an article of some importance. It is much purer and finer than that of sheep, and brings a high price, being calculated to make candles of a very superior quality.

Cobbett advocates the keeping of a goat by cottagers. "There is one great inconvenience belonging to goats, that is, they bark all young trees that they come near; so that if they get into a garden, they destroy every thing. But there are seldom trees on commons except such as are too large to be injured by goats; and I can see no reason against keeping a goat where a cow cannot be kept. Nothing is so hardy; nothing is so little nice as to its food. Goats will pick peelings out of the kennel and eat them. They will eat mouldy bread or biscuit, fusty hay, and almost rotten straw, furze-bushes, heath thistles; and, indeed, what will they not eat, when they will make a hearty meal on *paper*, brown or white, printed on or not printed on, and give milk all the while! They will lie in any dog-hole. They do very well clogged, or stumped out. And then they are very healthy things into the bargain, however closely they may be confined. When sea-voyages are so stormy as to kill geese, ducks, fowls, and almost pigs, the goats are well and lively; and when a dog of no kind can keep the deck for a minute, a goat will skip about upon it as bold as brass."

In Britain, no attempts have been made, at least successfully, to introduce foreign breeds of goats, though in France this has been done to a considerable extent. The Cashmere goat, famous for its long silky hair, or wool, has been brought to the country mentioned, and there bred with the Thibet goat, a hardier species, but almost equally esteemed for its wool. The manufactures producible from this material, as the Cashmere shawls have long testified, are scarcely to be surpassed for fineness, and yield immense prices. It is probable that, in our warmest districts, a cross of these foreign goats with the common breed might be successfully and advantageously effected.

RABBITS.

Rabbits belong to the family of *Leporidæ*, members of the *Rodentia* or Gnawing Order of animals. Their form and appearance are too well known to require any general description. In a wild state, rabbits live in holes in the earth; and where the proprietor permits of their accumulation for sport, they collect in great numbers, undermining with their burrows whole plains or tracts of land, and forming what are called *warrens*. Their amazing fecundity renders the keeping of a few of them in a tame state an object of some consequence in cottage economy. The rabbit breeds seven times in the year, and generally produces eight young at a time. At the age of five months, the animal begins to breed; and, taking an estimate perfectly within bounds, it is supposed that a pair of wild rabbits, which breed no oftener than seven times in a year, would multiply in the course of four years to the amazing amount of a *million and a quarter*, if the young were preserved. But many of them die, being injured by the cold and damp, or devoured by the male, or *buck*.

Experienced rabbit-breeders conceive too frequent breeding to be injurious; but even when proper rules are observed in this respect, three domesticated females (*does*) and a buck will give a family a rabbit for dinner at least twice a week. This is a matter of some consequence. By keeping a few of these pretty little creatures, which wild vegetables will almost entirely supply with food, the poor man may derive ten times the benefit to be gained by violating the laws, and poaching on the game-preserves of his rich neighbours. A stock of rabbits is easily set a-going; they may usually be bought under one shilling, and sometimes even at twopence a pair. It is of importance, in making such a purchase, to attend to the kinds which furnish the best food.

The short-legged stout rabbits are generally supposed to be the most healthy, and also the best breeders. The large hare-coloured variety is much esteemed by some people; but the white, or white mottled with black or yellow, are more delicate in flesh. The gray, and some of the blacks, approach nearer to the flavour of the wild rabbit than any others. With respect to the colours of these animals, gray is considered the worst of all colours; black is the next in gradation; fawn, and white, and gray, hold the third place in estimation; pure white, with red eyes, is by some reckoned equal with, and by others superior to, these; tortoise-shell (a rich brown and white, and brown, gray, and white), and black and white, rank the highest; mouse-colour, though little noticed by fanciers in general, is much admired by a few.

The most important part of the duty of the rabbit fancier is to erect his rabbit-house or hutch on proper principles. Two objects are particularly necessary to be attended to. The house or rabbitry must be kept always dry and well aired; because the rabbit, in its natural state, prefers a dry and airy habitation. Rabbits are sometimes placed in boxes, but whether kept in these or in regularly erected houses, the place must be kept quite dry, as too much humidity will cause the rabbits to rot. Where considerable numbers are together, fresh air is of great moment; still they should not be exposed to draughts, which may bring on a disease called the snuffles—a dangerous and frequently fatal malady.

Persons who live in large towns will in general find considerable difficulty in keeping rabbits, as it is seldom they have open grounds behind their houses wherein they might construct their rabbitry. In cases of this nature, rabbits might be kept on a small scale, in wooden hutches, open in front, with spokes like a cage, and having a division to separate the sleeping apartment from the feeding-place, and a small door betwixt the one place and the other. But it will be found, on trial, that rabbits do not thrive well when put in cages, or confined in this manner. The genuine rabbitry must be a small house constructed on purpose, where the animals will have liberty to feed and amuse themselves. These houses may be built about four feet square, and the same in height, with a sloping roof, covered with thatch, or some other substance that will carry off the rain. This house ought to be paved on the floor, so as to prevent the rabbits from burrowing, and undermining the walls. It should be well laid with dry straw or meadow-hay, and possess several boxes with the open side downwards, and holes for the rabbits to go in and out. It would also be as well for these holes to be provided with doors, which you could shut when necessary. To this house there ought to be attached a little open court, also paved, and covered completely with open spokes, so as to give air and light, as well as to afford you an opportunity of seeing the creatures feeding.

On the subject of feeding rabbits, the following extract may be offered from "The Boys' Own Book"—a pleasing work addressed to the young:—

"If too much food be given at once, the animals will get disgusted with and refuse it, so that a rabbit may be nearly starved by affording it too great a quantity of food. Most persons feed their rabbits twice, but for our own part we feed ours thrice a day. To a full-grown doe, without a litter, in the morning we give a little hay or dry clover, and a few such vegetables as are in season; in the afternoon we put two handfuls of good corn into her trough; and at night we give her a boiled potato or two, more vegetables, and, if her hutch be clear of what we gave her in the morning, but by no means otherwise, a little more hay or clover. If you give rabbits more hay than they can eat in a few hours, except it be a doe just about to litter, they will tread it under foot, and waste it; if you give them but a moderate quantity at a time, they will eat and enjoy it. Generally speaking, rabbits prefer green or moist food to corn; but it is necessary to make them eat a sufficient proportion of solid food, to keep them in health; occasionally, instead of corn, we give our rabbits a few split or whole gray peas. When a doe has a litter by her side, and also for rabbits recently weaned, we soak the peas a few hours previously to putting them in the trough. If a rabbit will not eat a proper quantity of corn, we mix a small quantity of squeezed tea-leaves with her portion, and stint her proportionately in green meat. Tea-leaves, in small quantities, well squeezed, may at all times be given, by way of a treat; but it is highly improper to make them a daily substitute for green meat.

"Almost all the vegetables and roots used for the table may be given to rabbits; in preference to all others, we choose celery, parsley, and the roots and tops of carrots and in this choice the animals themselves heartily agree with us; lettuces, the leaves, and, what are much better, the stumps of cabbages and cauliflowers, they eat with avidity, but they must be given to them with a sparing hand; turnips, parsnips, and even potatoes in a raw state, we occasionally afford our stock, on an emergency, when better roots or good greens are scarce. In the spring time, no soft meat is better for them than tares, so that they be not wet; in fact, no green meat ought to be given to rabbits when there is much moisture on its surface. We have heard of some country persons feeding their rabbits on marsh-mallows, but we never did so ourselves. Dandelions, milk-thistles, or sow-thistles, we know, by long experience, they take in preference to all other food, except celery, parsley, and carrots; and nothing, as green meat, we are convinced, can be better for them.

"It must be remembered, that a doe will eat nearly twice as much when suckling as at other times; and when her litter begins to eat, the allowance of food must be gradually increased. In our own rabbitry, we never admit chaff, and grains only in a dearth of green food. If we can obtain neither greens, roots, nor grains, at feeding-time, we make it a practice to moisten the corn with water, milk, or, as we before stated, with tea-leaves. Though a rabbit must be restricted from rioting in green or soft meat according to its own appetite, for its own sake, yet it is cruel to afford it only such food as will increase rather than appease its thirst; for this reason, in such a case as we have mentioned, we moisten the grain; and some rabbits will even do well with an occasional table-spoonful of water, beer, or milk; but it is a dangerous experiment to try the effect of a liquid on their stomachs.

"If well fed, and kept warm, does will breed all the year; but most fanciers are contented with five litters a year, and let them rest during the winter. It is a disadvantage, rather than otherwise, to have above six produced in a litter, as the young rabbits, when that is the case, are almost invariably weak and puny; and even if they be reduced to a moderate quantity, by removing some of them to another doe, or otherwise, they rarely become remarkable for their size or beauty.

"Diseases may in a great measure be prevented by regularity in feeding, good food, and cleanliness. The refuse of vegetables should always be scrupulously rejected. For the liver complaint, to which rabbits are subject, there is no cure; when they are attacked by it, fatten them, if possible, for the table. The snuffles are occasioned by damp or cold. If there be any cure for this disorder, it must be dryness in their hutches and food. Squeezed tea-leaves generally restore a doe to health, if weak, or otherwise affected after kindling. [A little bread moistened with warm milk may also be advantageously given to a doe at this critical period.] When old rabbits are attacked by a looseness, dry food will in general restore them; but do what you will, it is very difficult, and in most cases impossible, to save young ones from sinking under it; dry food for them, as well as for the old ones, is the only remedy.

"Be careful (continues this author) to keep your rabbit-hutches particularly clean; a short hoe, or a trowel, and a hand-brush, will be necessary for this purpose. Do not handle your rabbits, particularly the young ones, too much; when you lift them, take them with one hand by the ears, and place the other under the lower part of their backs."

When rabbits are to be used as food, it is commonly deemed beneficial to feed them for a short time on hay, and afterwards on shellings and oats, when the flesh will grow very delicate in flavour. As an example of the ordinary extent to which rabbits may be made productive, with common care, the case of a labouring man in the country may be mentioned, who, in a small wooden house enclosed by a railing, fed a batch of rabbits, and killed annually about twenty dozen, still maintaining his stock unbroken. What with the skins, flesh, and sales of young, he turned the animals to great account, yet he scarcely expended a penny upon them, and even trouble was entirely spared to him, when he had fairly put his children in the way of management.

GUINEA PIG.

This animal is misnamed when called a pig, being one variety of the Gnawing Animals (*Rodentia*), and technically termed the *cavia cobaya*. It comes from South America, and is smaller than the common rabbit, with a body of variegated colours—white, black, fawn, or a mixture of all three tints, being common characteristics. Some of them have deep red eyes, and the whole tribe are remarkable for the want of tails. They feed on grain, bread, or kitchen vegetables, showing a marked preference for parsley. They bring forth from four to twelve young at a time, and begin to breed at the age of two months, repeating the process of parturition so often that a thousand young might readily spring from a single pair in the year. But these little creatures are very tender, and many of them perish, soon after birth, through natural causes and accidents. Guinea pigs are of no use, their flesh being of a very inferior quality, but they form a pretty ornament to the court-yard. In their habits, they are extremely quick and restless, and spend much of their time in cleaning one another, having such a predilection for tidiness, that the mother will even take a permanent dislike to her young, if any of them chance to get dirtied. They are gentle in disposition, and seem so objectless in their habits, that Buffon compares them to living machines, calculated only to represent and perpetuate a species. It is believed they frighten away mice from a house, and are sometimes kept for that purpose.

POULTRY.

Poultry (from *poule*, French for hen) is a term applied to different kinds of large birds in a state of domestication, as the chicken or barn-door fowl, turkey, goose, pea-fowl, and guinea-fowl. The most numerous and important in every respect are those first mentioned.

Chickens.

The chicken is classed by naturalists in the tribe of the *Gallinaceæ*, forming part of the order *Rasores*, or Scraping-Birds. It is needless to describe minutely the appearance of the barn-door fowl. The most prominent characteristics of the cock, or male-bird, are a thin indented comb, with wattles on each side under the beak; a tail rising in an arch, and a great variegation of colours. The female, or hen, is smaller as regards body, comb, and wattles, and her tints are less vivid. The domestication of this bird seems to have taken place in the earliest times, and Persia is usually supposed to have been the place of its origin. Many varieties of it have been enumerated as existing in Britain; but the differences betwixt these, in the majority of cases, seem to lie as much in colour as in any more important features. The best marked kinds are the following:—The Dunghill Fowl, Game Fowl, Dorking Fowl, Poland Fowl, Spanish Fowl, and Bantam.

The first of these varieties is a mongrel one, arising from crosses with all the other breeds; but it is the common and most useful variety. The best fowls of this sort are of middle size and dark colour, and have white, clean legs; the pure white dunghill-fowls are held to be the weakest in constitution, and to lay fewest eggs. It has been usually agreed to call the game fowl the proper English fowl. The body is erect and slender, and the colours showy, particularly those of the cock. In comparison with other breeds, the game bird is like the race horse beside that which draws the cart and plough. The flesh, moreover, is peculiarly white and delicate in flavour, while, though small, the eggs are also of a very superior quality. There is a peculiarity of disposition, however, in this variety of the domestic fowl, which while for ages the source of a cruel species of sport, has always impaired the real utility of the creature to a very great degree. We allude to the pugnacious spirit which has gained for the fowl its peculiar name. So strongly-marked is this propensity, that broods scarcely feathered are found occasionally to have reduced themselves to utter blindness by reciprocal battling. Even when the breed is crossed and recrossed, a tincture of the love of fighting still remains, rendering such admixtures of species the source of risk and trouble, though in other respects very advantageous. Hence, game-cocks are bred on a large scale almost solely for the battles of the cock-pit. Where persons prefer to have a game-cock in their poultry yard, their choice, according to the best authorities, should be directed to birds of some one or other of the following colours:—dark-red, dark black-breasted red, dark gray, mealy gray, and red dun. The Dorking fowl is named from a town in Surrey, where it has long been bred in great numbers. It is a large bird, well-shaped, with a long capacious body, short legs, and five claws upon each foot instead of four. One spur characterizes other breeds of the common fowl, but the Dorking fowl has two spurs on each leg. These distinctive marks seem to be of old standing in peculiar breeds, as both Aristotle and Pliny mention five-toed fowls. Though, from repeated crossings, the Dorking fowls are now found of all colours, white or yellowish-white is supposed to have been the primitive and genuine tint. They lay large eggs, and in great plenty. The Poland (Polish or Paduan) fowl is much valued by breeders, but is seldom found perfectly pure in Britain. The species was imported principally from Holland, and when unmixed, was uniformly of a black colour, with a white crest or tuft on the heads of both cock and hen. Their form is plump and deep, and the legs of the best sorts not too long. They are called *everlasting* layers, from the number of eggs produced by them, and from their disinclination to sit and hatch, which office is usually done for their eggs by other hens. The Spanish fowl is of large size, and lays large eggs. It is of the Polish family, and is almost uniformly marked by a black body, black legs, and large red combs. In London and its vicinity, the breed is now extremely common, being valued for the size of the eggs; but it is supposed to be inferior in some respects to other breeds, though yielding good food. The bantam fowl is well known for its small size, and its feathered grotesque-looking limbs. It was originally a native of India, and the nankeen-coloured and black birds are the most esteemed. The bantam should have a rose-comb, a full tail, and a lively carriage, and should not weigh above one pound. It has been recently discovered that the characteristic of feathered legs is not an improvement, the birds with clean bright limbs being the best. The flesh of this breed of fowls is peculiarly delicate.

Besides these well-marked varieties of the common domestic fowl, there are a number of others brought from foreign countries, which have produced mixtures pretty familiar to breeders. The Turkish, Malay, Rumkin, Russian, and Barbary species, may be mentioned as the principal of these. It need only be observed here, that all the crested mixtures or varieties of fowls, are much esteemed, as possessing the best qualities of the race. All or any of these breeds of domestic fowls are valuable to the cottager, even one good laying hen being a treasure to an humble family.

Hen House.—The artificial assistance given by the cottager in housing the birds, is usually of the scantiest order. The upper part of the space at the door of the cottage, or the *baulks* (loft), is often the nightly roost of two or three hens, and the roadside is their daily walk. Yet, with the petty scraps of food furnished in addition to their own pickings there, these hens will lay good eggs, and produce fine birds. At farm-steadings, it is common for the hens to roost among the beams of the stables or cattle sheds, and to lay in holes formed by scraping away a portion of lime on the top of the side-walls. Very little pains might give to the humblest families much better and ampler accommodation for poultry. We quote on this subject the directions given in a little work by Mr. Peter Boswell of Greenlaw:—"Always in the building of a cottage, and sometimes even where there was no intention of the kind when it was built, very ample accommodation for poultry can be provided, almost without a shilling of additional expense. To this purpose a part of the space next the roof, so often unoccupied and useless, might easily be devoted. To accomplish the object, a part of it next the kitchen fire gable end should be partitioned off, floored, and fitted up with *baulks* and laying-places. This could be done either on a large or a small scale, according to the inclination or the means of the projector. An opening of sufficient width should be made in the wall, at the height of the lower ceiling, through which the fowls could be conducted, by means of a *hen-ladder*, to the enclosure prepared for them below. There must be a hatchway somewhere, to afford access for the purpose of inspection and cleaning. If the attics are sufficiently high, it may be placed anywhere, but evidently with greatest convenience in the passage of the house; but if they are low, the nearer it is to the space portioned off for the reception of the fowls the better. This is a location for poultry possessing many advantages. Having their berth immediately above the cottage kitchen, they are secured in a proper degree of dryness and warmth, which in winter, especially with the spring-hatched pullets, will tell well in the production of eggs. Perhaps this is the best hen-house locality for securing eggs in winter which can be suggested to the frugal and judicious. Besides, the fowls are here free from many dangers, and safe from many enemies, to which they are exposed in a lower and more open situation."

Another simple poultry-house of small size may be formed by building a shed against the gable of the house, opposite to the part warmed by the kitchen fire, and placing cross-bars in it for roosting, with boxes for laying in, or quantities of fresh straw. There should always be an opening to allow of the cleaning out, once a week at least, of the poultry-house—a process too often neglected, but very essential to the health of the poultry. They never will thrive long amid uncleanness; and even with the utmost care, a place where poultry have been long kept becomes what the housewives call tainted, and there they will thrive no longer. The surface of the ground becomes saturated with their exuviæ, and is therefore no longer healthy. To avoid this effect, some poulterers in the country frequently change the sites of their poultry-houses, to obtain fresh ground; and to guard against the same misfortune, farmers, who cannot change their hen-houses and yards, purify the houses by fumigations of blazing pitch, by washing with hot lime-water, and by strewing large quantities of pure sand both within and without the poultry-houses. Washing the floor of the house every week is necessary; for which purpose it is of advantage that it be paved either with stones, bricks, or tiles. But as these three modes are expensive, a good flooring, which is cheaper, may be formed by using a composition composed of lime and smithy ashes, together with the riddlings of common kitchen ashes; these having been all finely broken, must be mixed together with water, and put on the floor with a mason's trowel, and nicely smoothed on the surface. If this is put on a floor which is in a tolerably dry situation, and allowed to harden before being used, it will become nearly as solid and compact as stone, and is almost as durable. The inside of the laying-boxes requires frequent washing with hot lime-water, to free them from vermin, which greatly torment the sitting-hens. For the same purpose, poultry should always have a heap of dry sand or fine ashes laid under some covered place, or thick tree, near their yard, for them to dust themselves in; this being their resource for getting rid of the vermin with which they are annoyed.

The office of keeping and managing domestic fowls should be performed by some individual whom the hens know, as the voice and presence of a stranger scare the fowls, and disturb the operations of the hen-house. To distribute food and drink at regular hours, to visit the nests, to remove eggs as soon as laid, and carry them to a cool place, to examine by candle-light what eggs are fecundated, and place these under the hen, and mark the time, are among the daily duties to be performed by the keeper. When the hens lay in a secret place, the keeper may readily discover it by placing a few grains of salt in the oviduct, which hurries on the process of laying, and causes the hen to retire to the spot anew.

Feeding.—Most persons are doubtless aware that fowls swallow food without mastication. That process is rendered unnecessary by the provision of a *crop*, an organ which is somewhat similar to the first stomach of the cow, and in which the food from the gullet is macerated, and partly dissolved by secreted fluids. From the crop the food passes downwards into a second small cavity, where it is partly acted on by a digestive juice; and, finally, it is transferred to the gizzard, or last stomach which is furnished with muscular and cartilaginous linings of very great strength. In the gizzard the partially softened food is triturated, and converted into a thin paste, fit to be received into the chyle-gut, and finally absorbed into the circulation. Such is the power of the gizzard in almost all kinds of poultry, that hollow globes of glass are reduced in it to fine powder in a few hours. The most rough and jagged bodies do no injury to the coats of the gizzard. Spallanzani even introduced a ball of lead, with twelve strong needles so fixed in it that their points projected a fourth of an inch from the surface, and the result was, that all the needles, with the exception of one or two, were ground down in a short time to the surface of the ball, while those left were reduced to mere stumps. It is remarkable that, to add to the triturating powers of the gizzard, fowls are gifted with the instinct of swallowing stones with their food.

Fowls, when left to roam at large, pick up all sorts of seeds, grains, worms, larvæ of insects, or any other edible substances they can discover, either on the surface of the ground or by scraping. They also pick a little grass, as a stomachic. The more that hens can be allowed to run about and pick up their own food, the better for their own health and the pockets of their keeper. When secluded, and fed altogether in an artificial manner, their keep becomes expensive, and is, on the whole, seldom compensated by their produce. We have, indeed, great hesitation in advising any one to keep fowls who cannot unexpensively give them plenty of refuse from the table or kitchen, or permit them to range in a field or lane in quest of what seems proper for their natural appetite. The very pleasure of ranging and scraping seems advantageous to the animals.

If kept in a court-yard or pen, and requiring altogether artificial feeding, their natural tastes should be consulted as far as conveniently practicable. They should be fed regularly, and with a miscellaneous kind of diet; allowed at all times access to clean water for drinking, and have earth, sand or dust, to scrape at pleasure and roll themselves in. A certain quantity of chalk or lime should also be scattered about for them to pick up, as that material is required by them in the production of eggs. Speaking on this subject, Professor Gregory of Aberdeen, in a letter to a friend, published in a newspaper, observes—"As I suppose you keep poultry, I may tell you that it has been ascertained that, if you mix with their food a sufficient quantity of egg-shells, or chalk, which they eat greedily, they will lay, other things being equal, twice or thrice as many eggs as before. A well-fed fowl is disposed to lay a vast number of eggs, but cannot do so without the materials for the shells, however nourishing in other respects her food may be; indeed a fowl fed on food and water free from carbonate of lime, and not finding any in the soil, or in the shape of mortar, which they often eat off the walls, would lay no eggs at all, with the best will in the world."

In a state of domestication, the hard food of which fowls seem most fond are peas and barley (oats they do not like); and besides a proportion of these, they may be given crumbs of bread, lumps of boiled potatoes, not too cold, or any other refuse. They are much pleased to pick a bone; the pickings warm them, and excite their laying propensities. If they can be supplied with caterpillars, worms, and maggots, the same end will be served. Any species of animal food, however, should be administered sparingly; and the staple articles of diet must always be of a vegetable nature. When wanted for killing, the quantity of food may be increased and be more substantial; they should also be kept more within the coop. A fortnight's feeding in this way will bring a fowl of a good breed up to a plump condition.

Laying.—The ordinary productiveness of the hen is truly astonishing, as it usually lays, in the course of a year, two hundred eggs, provided it be allowed to go at liberty, is well fed, and has a plentiful supply of water. Many instances have been known of hens laying three hundred in a year. This is a singular provision in nature, and it would appear to have been intended peculiarly for the use of man, as the hen usually incubates only once in a year, although she will occasionally bring out two broods. Few hens are capable of hatching more than from twelve to fifteen eggs; so that, allowing they were all to sit twice a year, and bring out fifteen at a time, there would still be at least one hundred and seventy spare eggs for the use of man. It is therefore evident that, in situations where hens can pick up their food, they must prove very profitable; for, supposing that the eggs of one fowl during the year were sold, without any of them being hatched, they would bring (if near a large city) on an average ninepence per dozen, or fourteen shillings, and the hen herself would be worth two shillings at least. As the number of eggs which are annually brought out by a hen bear no proportion to the number which she lays, schemes have been imagined to hatch all the eggs of a hen, and thus turn her produce to the greatest advantage; so that, in place of twelve or fourteen chickens, upwards of two hundred may be produced.

Hens will lay eggs which have received no impregnation, but from these, as a matter of course, no hatching can take place; they are equally good, however, for eating. When the chief object is to breed chickens, a cock should be allowed to walk with ten or twelve hens; but when eggs are principally required, the number of hens may be from fifteen to twenty. Endeavour to procure a cock of a good breed, not game, and let him be in his prime, which is at eighteen months to two years old. Cocks will last two years, after which they lose their liveliness of colours, and become languid, inactive, and mere consumers of food. It is fit, therefore, that younger cocks should then take their place in the poultry-yard. It is common to make choice of a young cock by pitting one or two against each other, and selecting the most courageous, which is always the favourite of the yard.

Some remarks have been made on the colours of the best hens of the different varieties. As to other qualities, M. Parmentier recommends that they should be chosen of a middling size, robust constitution, large head, bright eyes, and pendant comb. Crowers should be rejected, and those that are of quarrelsome tempers, such hens being rarely good hatchers or layers. Old hens, or those above four or five years old, are of little use when added to a stock; and when the comb and claws are rough, it is a sign that they have ceased to lay.

If left to themselves, hens would produce, like some wild birds, two broods in the year. Early spring, and, after a cessation, the end of summer are the two seasons at which they begin naturally to lay. In the depth of winter, under ordinary circumstances, hens very rarely lay eggs, though, by artificial means, they can be made to do so. If the temperature of the place where they are kept be raised by a stove, or otherwise, they will produce eggs. The fowls of the Irish peasantry, which are usually kept in the cabins of the owners, lay often in winter, in consequence of the warmth of their quarters; and there can be no doubt that warmth affords the most effective means of procuring new-laid eggs in winter, though stimulating food may aid in producing the same result. The fecundity of hens varies considerably. Some lay but once in three days, others every second day, and others every day. In order to induce laying, each hen should have its own nest, made with soft straw, and furnished with a piece of chalk as a decoy. The signs which indicate when a hen is about to lay are well known. She cackles frequently, walks restless about, and shows a brighter redness in her comb and wattles. After the process of laying is over, she utters a loud and peculiar note, to which the other fowls usually respond. Shortly after the egg is laid, it should be removed, for the heat of the hen soon corrupts it. When the eggs are taken away by the poultry-keeper, they should immediately be laid in a cool and dry place. If allowed to absorb damp, they soon spoil; indeed, one drop of water upon the shell quickly taints the whole egg. Various methods have been tried to prevent the absorption of air through the shell, and preserve the freshness of the eggs. A not uncommon plan is to keep them secluded from the air in bran, rye, or ashes, which may do very well where the eggs are to be kept in this way till eaten, but is utterly useless if quantities of them have to be sent to market. We beg to offer a plain piece of advice to cottagers on this subject, which, if properly acted upon, will give them the means of at all times commanding the highest price for *fresh eggs*, although situated a hundred miles or more from the place of sale. *Smear all your eggs with a bit of fresh butter the moment you get hold of them.* Do not load the shell with grease, but merely give a light varnish. The butter must be good. By this simple process of smearing, which does not taint the interior in the slightest degree, the egg is as fresh at the breakfast table when three months old as if just newly laid, and possesses all the delicious milkiness which the freshest eggs possess. Scarcely any thing is more common than to hear complaints of the difficulty of getting fresh eggs, and all a result of the sheer negligence of fowl-keepers. By the plan we mentioned there need never be such a thing as a bad egg heard of.

Hatching.—When eggs are to be hatched, it is necessary to pay attention to the choice of proper ones for the purpose. The company of the male bird renders the hen productive of fecundated eggs, and, as already noticed, it is only eggs of this kind which are available for producing young. The eggs must also be fresh; from the time they are laid, they should lie aside in a cool place. It is said to be possible to ascertain from the appearance of the egg, whether the forthcoming progeny is to be male or female; but we greatly doubt the truth of the popular notions on this subject. When eggs are left to be brought forth by the hen, a certain number is placed under her in the nest, when she is in the full inclination to sit. From nine to twelve eggs are placed, according to the extent of the breast and wings; and the time required for hatching is twenty-one days. Sometimes a hen will desert her eggs, a circumstance which may occasionally be traced to an uncomfortable condition of the skin, caused by vermin or want of cleanliness, and this affords a strong reason for keeping the hen-house clean, and giving the animals the means of purifying their feathers. Occasionally, the hen is vicious, or, in short, a bad sitter, and experience in pitching on the best hatching hens is the only remedy. Sometimes a hen will break her eggs with her feet, and in all such cases, the broken eggs must be removed as soon as observed, otherwise the hen may eat them, and from that may be tempted to break and eat the sound ones, and spoil the whole batch.

It has generally been found, that hens which are the best layers are the worst sitters. Those best adapted have short legs, a broad body, large wings, well furnished with feathers, their nails and spurs not too long or sharp. The desire to sit is made known by a particular sort of clucking; and a feverish state ensues, in which the natural heat of the hen's body is very much increased. The inclination, or, as physiologists term it, the *storge*, soon becomes a strong and ungovernable passion. The hen flutters about, hangs her wings, bristles up her feathers, searches everywhere for eggs to sit upon; and if she finds any, whether laid by herself or others, she immediately sets herself upon them.

With a proper provision of food at hand, warmth, quiet, and dryness, a good hatching hen will give little trouble, and in due time the brood will come forth; one or two eggs may perhaps remain unhatched or addled, but their loss is of little consequence. As soon as the hen hears the chirp of her young, she has a tendency to walk off with them, leaving the unhatched eggs to their fate; it is therefore advisable to watch the birth of the chicks, and to remove each as soon as it becomes dry, which may be in a few hours afterwards. By this means, the hen will sit to hatch the whole; yet she should not be wearied by too long sitting. If all the eggs are not hatched at the end of twelve or fifteen hours after the first chick makes its appearance, in all probability they are addled, and may be abandoned. The chicks must be kept in a warm place during the first day, and at night restored to the mother, who now assumes her maternal duties. The food given to the young chicks should be split grits, which they require no teaching to pick up; afterwards the ordinary food of the poultry-yard, or what the mother discovers for their use, is sufficient. Some give the yolks of hard-boiled eggs or curd, when a nourishing diet seems advisable. The extreme solicitude of the hen for her young, or the brood which may be imposed upon her, is well known. She leads them about in quest of food, defends them by violent gesticulations and the weapons which nature has given her, calls them around her by a peculiar clucking cry, and gathers them carefully under her wings to shelter them from danger, or to keep them warm at night. This maternal care is bestowed as long as the chickens require her assistance: as soon as they can shift for themselves, the mutual attachment ceases, and all knowledge of each other is lost. The young now go to roost, and the mother again begins to lay. Young hens, usually called pullets, begin to lay the spring after they are hatched.

Artificial Hatching.—As heat is all that is necessary to incubation, eggs may be hatched artificially, without the intervention of the hen. This practice was common in Egypt in very early times, and has since been adopted in many other quarters. In London, a year or two ago, a hatching apparatus, called the *Eccaleobion*, was constructed on a large scale, and was most successful in its results. An oven, consisting of eight floors or compartments, was employed to contain the eggs, while they were subjected to heat from steam-pipes. Each compartment held from two to three hundred eggs, and the whole exhibited the hatching process in all its various stages. The regularity with which the temperature was maintained, as well as accommodated to each peculiar stage of the process, brought out the chick with much greater certainty than when the incubation was performed by the hen, which sometimes cannot be kept steadily to the work. A visiter to the Eccaleobion gave the following account in "Chambers's Edinburgh Journal," No. 400, of the management of the chick after hatching:— 'The superintendent of the oven politely exhibited a compartment in which the eggs were chipping. Some had chipped the day before, others that day, and some would not be chipped till the morrow; in a few cases we observed the beak of the chick boring its way through the shell, and getting itself emancipated. When the little creatures are ushered into the world, they are not immediately removed out of the oven, but are allowed to remain a few hours till they become dry; they are then removed and put into a glass-case, on the table at the end of the room. This case is very shallow, and the glass cover can be easily pushed aside to permit the superintendent handling them if required. They are here for the first time fed, though not for twenty-four hours after being hatched; the material scattered among them is small bruised grits, or particles little larger than meal; these they eagerly pick up without any teaching, their instinctive desire for food being a sufficient monitor. After the brood has been kept in the glass-case (which is partially open) for two or three days, and been thus gradually accustomed to the atmosphere, they are removed to one of the divisions in the railed enclosure on the floor. Here hundreds are seen running about, uttering peepy cries, picking up grits, or otherwise amusing themselves, all being apparently in as lively and thriving a condition as if trotting about in a barn-yard. At six in the evening they are put to bed for the night in coops, twelve together in a coop: these coops are small wooden boxes, lined with flannel, and furnished with a flannel curtain in front, to seclude and keep the inmates as warm and comfortable as if under the wing of a mother. At six or seven in the morning they are again allowed to come forth into their court-yard, which being strewed with sand, and provided with food and water, affords them all the advantages of a run in an open ground.

"I made some inquiries respecting the failures in hatching, and deaths, and received the following information: —The eggs are usually purchased from Leadenhall market, and, consequently, not being altogether fresh, or otherwise suitable, one half of them fail in hatching. Once hatched, they are safe, for not more than one dies out of fifty which are brought into existence. If good and suitable eggs could be procured in all seasons, the failures in hatching would be comparatively trifling. Bad eggs, therefore, are the weak point in the establishment; and I should recommend the proprietor to complete his arrangements, by adding an egg-laying department to those which he has for hatching. This might be done by keeping a regular poultry-yard, either in connection with the place or in the country. The apparatus for hatching is capable of producing forty thousand chickens in a year, and, making allowance for failures, the actual produce cannot fall far short of half that number. When three weeks old, as I was informed, the chickens are taken to market, and sold for a shilling each. Thus, we should suppose, the Eccaleobion turns out at least a thousand pounds' worth of chickens annually—no bad revenue, it will be said, after paying expenses, but not greater than the ingenious contriver and proprietor, Mr. William Bucknell, deserves." The writer concludes by calling the attention of the public to the ease with which similar establishments might be got up in all large towns. The price of poultry, he argues, might be greatly lowered in the market, and the dietary resources of the common people materially improved and extended.

Capons.—The best modes of fattening fowls for the table have been adverted to. The process of converting chickens into capons, however, ought also to be noticed here. By removing the reproductive and oviparous organs from the male and hen chickens respectively, a great change is produced on them as regards voice and habits, and they can be made remarkably fat for the table. Capons are chiefly reared in Sussex, Essex, and one or two other counties around London. They can be trained to watch chickens, hatch eggs, and do many useful offices of the poultry-yard. Upon the whole, however, the special benefit derived from rearing capons does not counterbalance the trouble which they give.

Diseases.—Chickens are liable to various diseases, demanding attention from the poultry-keeper. The *pip* is the most common; it consists of a catarrhal thickening of the membrane of the tongue, causing a dangerous and obvious obstruction to respiration. It may be cured in most cases by throwing the fowl on its back, holding open the beak, and scraping or pealing off the membrane with a needle or the nail. The part may be wetted with salt or vinegar afterwards, and a little fresh butter pushed over the throat. Dr. Bechstein recommends giving a mixture of butter, pepper, garlic, and horse-radish, as an internal remedy. But the operation is most effective. *Thirst* sometimes attacks fowls like a fever, and often arises simply from dry food, though more frequently symptomatic of indigestion, or some internal and deep-seated derangement. Careful attention to diet is the first and great point in all such cases. If *constipation* appear to be present, bread soaked in warm milk, boiled carrots or cabbages, earth-worms, chopped suet, or hot potatoes with dripping, will be found useful. A clyster of sweet oil should be tried in severe cases. Where a tonic seems to be required, a little iron rust may be mixed with the food, and will generally relieve atrophy or loss of flesh. Where diarrhœa or scouring is observed, iron or alum may be given in small quantities. There is also a species of influenza, called the *roup*, which is often epidemical in the poultry-yard, and causes much havoc among the young birds. The eyes become swollen, a discharge comes from the nostrils, and the fowl gapes continually, showing much difficulty of breathing. Some observers have ascribed this complaint to worms in the windpipe, and have recommended their extraction by an operation; but warmth, cleanliness, and soft food, and such laxatives as sulphur, with frequent ablutions of the eyes and nostrils, are more likely perhaps, to do good, and are not attended with danger. Where general fever has been observed in fowls, the use of a little nitre has been found very advantageous. Saffron is another remedy very often employed in relieving the symptoms of sickness in fowls.

Many of these remarks will apply equally well to the diseases of geese and the other species of domestic poultry yet to be noticed, and this subject, therefore, need not again be adverted to in detail.

Turkeys.

The turkey, like the common chicken, has been included by naturalists in the *Gallinaceous* family of birds, and possesses the main characteristics common to the whole. It is certainly one of the most valuable fowls which have been naturalized in this country, but is very difficult to rear. The turkey-hen lays from fifteen to twenty eggs, and then sits upon them. She will bring out two broods in a year. The eggs are of a pale yellowish-white colour, finely streaked and spotted with reddish-yellow. They are a most delicious food, much more delicate in their flavour than those of the common nen. In England or Scotland, however, the eggs are seldom to be met with for sale, being deemed too valuable to be used as food. In Ireland they are to be got in the markets in great abundance, especially in the midland counties, where we have bought them at ninepence per dozen. In that country, when the turkey-hen has laid about half a dozen eggs, they afterwards take away one daily, by which means the hens are induced to produce a greater number of eggs than otherwise. This they assist by means of stimulating food, such as hemp-seed and buck-wheat. There is an interval of a day between the laying of each egg. It is said that the first two eggs which she lays are unfruitful. A turkey-hen can seldom hatch more than from sixteen to eighteen eggs. The time of incubation varies from twenty-seven to twenty-eight days, at which time the young begin to pierce their shelly prison, and emerge from it. When they first come forth, they are extremely weak, and much assiduous care is necessary to rear them. The first thing to be attended to is, to remove them to a situation where they are not exposed to the sun's rays, which at first are too powerful for them. A woody place is the most suitable to their natural habits. Nothing is so destructive to them as rain, from which they must be protected.

When young turkeys accidentally get wet, they should be brought into a house, carefully dried by applying soft towels to them, and then placed near a fire, and fed upon bread, which has been mixed with a small proportion of ground pepper or ginger. It should be made up in the form of small peas. If the bread is too dry for this purpose, it may be moistened with a little sweet milk. Should the turkey-poults refuse to eat it, a few of these pellets may be forced down their throats. Even heavy dews prove destructive to them, and frost is no less injurious in its effects. These must therefore be most carefully guarded against, when the hens incubate in March or early in April. Dry and sandy situations are most congenial for breeding turkeys, and especially elevated situations where large woods are contiguous. A single male turkey is sufficient for twelve or sixteen females, although the former number is probably the safest, to prevent sterility in the eggs, which is frequently the case with those of turkeys. Eggs should never be intrusted to the care of a female until she is at least two years of age, and they may be kept for the purpose of incubation till they reach their tenth year. The largest and strongest hens should always be kept for this purpose. During the time the hen is sitting, it becomes necessary to place food near her; as otherwise, from her assiduity, she may be starved to death, as turkey-hens seldom move from their nest during the whole time of incubation.

Where farmers rear turkeys in great numbers, they do not indulge the hen by allowing her to sit as soon as she has done laying, but keep them from her until all the other hens have ceased to lay, as it is of consequence that they should all be hatched about one time. When hens are unhappy during this interval, they may be indulged with hen's eggs. When they have all ceased to lay, each of them is provided with a nest ranged close to the wall, in a barn or other convenient place, and each is supplied with from sixteen to twenty of her own eggs. The windows and doors are then closed, and only opened once in the twenty-four hours for the admission of air, and for the purpose of feeding the hens. They are taken off their nests, fed and replaced, and again shut up. On the twenty-sixth day, the person who is intrusted with the management of the birds examines all the eggs, and removes those that are addled; feeds the hens, and does not again disturb them till the poults have emerged from their shells and have become perfectly dry, from the heat of the parent bird; as to be subjected to cold at this time would certainly kill them. When the young birds are thoroughly dried, two of the broods are joined together, and the care of them intrusted to a single hen; and those which have been deprived of their offspring are again placed on hen's or duck's eggs, and subjected a second time to the tedious operation of incubation, in which case it is not unusual for them to bring out thirty eggs. We cannot recommend this practice in point of humanity; for the poor hens, when they have accomplished their second sitting, are literally reduced to skin and bone, and frequently so weak as hardly to be able to walk.

As before hinted at, great care should be taken of the young turkey-poults; besides warmth, proper food, and shade, the nearer they are to a pure running stream the better, as they drink a great deal, and nothing is of greater importance to their being successfully reared than fresh drink. They must be also carefully protected from strong gusts of wind, and on the slightest appearance of a thunder-storm, should be immediately taken into a house. They should get no food for twenty-four hours after they leave the egg. Their first food should be hard-boiled eggs finely chopped, and mixed with crumbs of bread. Curd is also an excellent food for them. When they are about a week old, boiled peas and minced scallions are given to them. If eggs are continued, the shells should be minced down with their food to assist digestion, or some very coarse sand, or minute pebbles. They should be fed thrice a day; and as they get older, a mixture of lettuce-milk will be found beneficial, together with minced nettles. Barley boiled in milk is another excellent food at this period, and then oats boiled in milk. In short, the constitution of young turkeys requires at all ages every kind of stimulating food. When about three weeks old, their meat should consist of a mixture of minced lettuce, nettles, curdled milk, hard-boiled yolks of eggs, bran, and dried camomile; but when all these cannot be readily obtained, part of them must be used. Fennel and wild endive, with all plants which are of a tonic character, may be safely given to them. Too much lettuce, however, has been found to be injurious. When poults are about a month old, they should be turned out, along with the parent bird, into the fields or plantations, where they will find sufficient food for themselves. Grass, worms, all kinds of insects and snails, are their favourite food, and nature dictates to them such vegetables as are conducive to their general health. As their feet are at first very tender, and subject to inflammation from the pricking of nettles and thistles, they ought to be rubbed with spirits, which has the effect of hardening the skin, and fortifying them against these plants.

The glandulous fleshy parts and barbles of their heads begin to develop when they are from six weeks to two months old. This is a critical period with the poults, and unusual care must be bestowed on them, as they now become weak and often sickly. A little brine mixed with their food will be found very beneficial, or spirits much diluted with water. A paste made of fennel, pepper, hempseed, and parsley, has been found an excellent remedy when afflicted with an inflammation in the wattles, to which they are liable when growing. They are very subject to this if the weather happens to be broken and changeable at the time these tubercles are growing. These parts swell and grow very red, which frequently proves fatal to them. If, therefore, such be the state of the weather at this critical period, the paste above recommended should be given although they are perfectly healthy, which will be found an excellent preventative. When the inflammation becomes very great, recourse is often had to bleeding in the axillary vein, which frequently recovers them.

Soon after the turkey-poults have acquired their first feathers, they are subject to a disease which is very fatal to them, if not attended to. This distemper produces great debility, and the birds appear languid and drooping, and almost totally neglect their food. Their tail and wing-feathers assume a whitish appearance, and their plumage has a bristled aspect. This is occasioned by a disease in two or three of the rump-feathers. On examination, the tubes of these will be found filled with blood. The only remedy for this disease is to pluck them out, when the bird will speedily acquire its wonted health and spirits.

In fattening turkeys for the table, various methods are resorted to. Some feed them on barley-meal mixed with skim-milk, and confine them to a coop during this time; others merely confine them to a house; while a third class allow them to run quite at liberty; which latter practice, from the experience of those on whose judgment we can most rely, is by far the best method. Care should, however, be taken to feed them abundantly before they are allowed to range about in the morning, and a meal should also be prepared for them at midday, to which they will generally repair homewards of their own accord. They should be fed at night, before roosting, with oat-meal and skim-milk; and a day or two previous to their being killed, they should get oats exclusively. We have found, from experience, that when turkeys are purchased for the table, and cooped up, they will never increase in bulk, however plentifully they may be supplied with food and fresh water, but, on the contrary, are very liable to lose flesh. When feeding them for use, a change of food will also be found beneficial. Boiled carrots and Swedish turnips, or potatoes mixed with a little barley or oat-meal, will be greedily taken by them. A cruel method is practised by some to render turkeys very fat, which is termed cramming. This is done by forming a paste of crumbs of bread, flour, minced suet, and sweet-milk, or even cream, into small balls about the bulk of a marble, which is passed over the throat after full ordinary meals.

Pea-Fowl.

The peacock, also one of the Gallinaceous tribe of birds, came originally, it is said, from India, and was well known to the ancient Greeks and Romans, who introduced it into their mythology. The great beauty of its tail, so ample in extent and so rich in colours, rendered it indeed not unworthy of such preferment.

One peacock is usually kept with three or four hens. The female is extremely fastidious about a spot to lay in, and generally leaves any artificial nest for the grass of some neighbouring coppice, where she lays under the branches of a shrub, in a well-concealed situation. One reason for this is the propensity of the cock to break the eggs if he discover them. When the eggs of the pea-hen are gathered in sufficient numbers, whether from a natural or artificial nest, it is a common practice to place them under a common hen, which hatches them in thirty days, and makes an excellent step-mother to the young chicks. These are very tender at first, but soon grow vigorous, even in a chilly climate. Barley-meal paste, mixed with cheese or curd prepared from milk, with alum, ants' eggs, meal-worms, and hard-boiled egg, are among the common articles of diet given to the young. The grown-up pea-fowl feeds on boiled barley or other common grains, and is a dangerous neighbor to corn or wheat fields and gardens. On the other hand, they are voraciously fond of such creatures as frogs, lizards, and the like, and keep grounds clear of such nuisances. In moulting-time, it is requisite to be more careful of these fowls than at other times, and to give them good grain, with a little honey, and fresh water. Though the tongues and livers of peacocks were ranked among the dainties of the Roman epicures, the bird is rarely killed for the table now-a-days. Yet it always bears a high price, being one of the most beautiful of the feathered race, and an object on which the eye ever delights to dwell, though its screaming note by no means gives a corresponding pleasure to the ear.

The Guinea-Fowl.

This stranger is found native in Africa, as its name indicates, and it also exists in an indigenous state in South America. The Guinea-fowl or Pintado is about the size of the common hen, and the male differs very little in appearance from the female. Three species exist in considerable numbers in Europe, namely, the crested, the mitred, and Egyptian varieties. A very beautiful sort is marked by a pure white tint of body but the most familiar hues are dark-gray and black. The bird is less tame than other common poultry, and prefers to live in a half-wild condition in its native regions, perching and living on trees like undomesticated birds. It is a spirited creature, and will battle even with the turkey. The guinea-hens require great attention at the time of laying, making their nests by preference in corners of the woods. The common hen is usually made to rear their broods. In the market, guinea-fowls always bear a high price, both on account of their flesh, which is of a good quality, and because they form a very pretty variety of the poultry stock. Their food is grain, of the various kinds given to ordinary barn-door fowls, with which they assimilate closely in habits.

The Goose.

The goose differs in many respects from the fowls already noticed, being aquatic in its habits. It is marked by a flat bill and webbed feet, characters also possessed by the duck and swan, which, in conjunction with the goose, may be held as forming a distinct family (*Anatidæ*) of the feathered aquatic tribes.

Our common tame goose is the wild species domesticated, known to naturalists by the name of the fen or stubble-goose. Where people have a right of common, or live in the vicinity of marshy heaths, the breeding and rearing of geese will prove very profitable, for in such situations they are kept at a trifling expense; they are very hardy, and live to a great age. If properly kept, and fed regularly, although sparingly, they will lay upwards of a hundred eggs yearly. If these are set under large hens, each having half a dozen, with the assistance of the goose herself, they may be nearly all hatched. For the first three or four days, they must be kept warm and dry, and fed on barley-meal or oat-meal mixed with milk, if it is easily procured; if not, let these ingredients be mixed with water. They will begin to grow in about a week. For a week or two the goslings should not be turned out till late in the morning, and should always be taken in early in the evening. In Ireland the tenantry depend much on the breeding of these birds and turkeys to pay their rent; and with those who are industrious and favourably situated for rearing geese, they even do more in many instances. In the early part of the year they are allowed to feed on grass, on heaths, meadows, and commons; and as most of the peasantry have small bits of corn land of their own, the geese are turned out on the stubble to pluck what grass is left; and they also fatten upon it, and improve the flavour of their flesh.

Although water be the natural element of geese, yet it is a curious fact that they feed much faster in situations remote from rivers and streams. To fatten geese it is necessary to give them a little corn daily, with the addition of some raw Swedish turnips, carrots, mangel-wurzel leaves, lucerne, tares, cabbage leaves, and lettuces. They should not be allowed to run at large when they are fattening, as they do not acquire flesh nearly so fast when allowed to take much exercise. Therefore, those who can only afford to bring up a goose or two, should confine them in a crib or some such place about the beginning of July, and feed them upon the ingredients above recommended, with a daily supply of clean water for drink. If, on the contrary, from a dozen to twenty are kept, a large pen of from fifteen to twenty feet square must be made, and well covered with straw in the bottom, and a covered house in a corner for protection against the sun and rain when required, because exposure to either of these is not good. It will be observed that, about noon, if geese are at liberty, they will seek some shady spot to avoid the influence of the sun; and when confined in small places, they have not sufficient room to flap their wings and dry themselves after being wetted; nor have they room to move about so as to keep themselves warm. There should be three troughs in the pen, one for dry oats, another for vegetables—which ought always to be cut down—and a third for clean water, of which they must always have a plentiful supply. It must be remembered, that the riper the cabbages and lettuces which they are supplied with, the better. In the neighbourhood of large towns, the most profitable way of disposing of geese is in a dead state; as nearly the same sum can be obtained for them as if they were alive, and then you have the feathers, which are valuable, and may be sold to much advantage by themselves when you have collected a stone weight or more.

Geese are kept in vast quantities in the fens of Lincolnshire, several persons there having as many as a thousand breeders. They are bred for the sake of their quills and feathers, as well as for their carcass; it is therefore customary to strip them partially of the fine downy feathers, and leave them to grow afresh, and also to take quills from their wings—both practices barbarous in the extreme, however they may be attempted to be justified. Geese breed in general, only once a year, but if well kept, they sometimes hatch twice in a season. The best method for promoting this is to feed them with corn, barley, malt, fresh grains, and, as a stimulant, they should get a mixture of pollard and ale. During their sitting, each bird has a space allotted to it, in rows of wicker pens placed one above another, and the goose-herd, who has the care of them, drives the whole flock to water thrice a day, and, bringing them back to their habitation, places every bird (without missing one) in its own nest. One gander is generally put to five geese. The time of incubation varies from twenty-seven to thirty days. The goose begins to lay in March, but the time of the month depends upon the state of the atmosphere. When goslings are first allowed to go at large with their dam, every plant of hemlock which grows within the extent of their range should be pulled up, as they are very apt to eat it, and it generally proves fatal to them. Nightshade is also equally pernicious to them, and they have been known to be poisoned by eating sprigs of yew-tree.

Ducks.

Ducks are a kind of fowl easily kept, particularly near ponds or streams of water. In such situations, even the poorest families may have half a dozen of them running about without the least inconvenience. In keeping them in a domestic state, one drake is usually put to five ducks. The ducks begin to lay in February; their time of laying being either at night or early in the morning. They are extremely apt to deposit their eggs at some sequestered spot, and to conceal them with leaves or straw. From eleven to fifteen eggs is the number which a duck can properly cover. The time of incubation is about thirty-one days. The place where they incubate should be as quiet and retired as possible; and if they have liberty, they will give no trouble whatever in feeding, as the duck, when she feels the call of hunger, covers her eggs carefully up, and seeks food for herself, either by going to the streams or ditches in her neighbourhood, or, if such are not at hand, she will come to the cottage and intimate her wants by her squalling When the young are hatched, they should be left to the care of the duck, who will lead them forth in due time; and when she does so, prepare a coop for them, which should be placed on short grass, if the weather is mild; and if cold or stormy, they should be kept under cover. The future strength of the brood will depend much upon the care that is taken of them for the first three or four weeks after they have emerged from the shell. Ducklings will begin to wash themselves the first day after they are hatched, if they find water at hand. Therefore, a flat dish filled with that element should be always within their reach. Many persons are in the practice of clipping the tail, and the down beneath it, in ducklings, if the weather is wet during the first weeks of their existence. This is to prevent them from draggling themselves, which has a tendency to produce intestinal diseases. From a fortnight to three weeks is all that is necessary to confine them to the coop.

The first thing on which ducklings are fed is a mixture of barley, peas or oat-meal, and water. They may afterwards be fed upon a mixture of buckwheat and any of the above-named meals. The greatest attention must be paid to keeping their bed warm and dry; and with young ducks a frequent change of straw is absolutely necessary, as their beds soon get dirty and wet.

Ducks are not such attentive guardians of their young as hens, and therefore it is a common practice to place duck eggs under a sitting hen, and leave her to hatch them as her own progeny. When the young ducks so hatched make their appearance, the hen does not appear aware of the imposition, but takes at once to her duties with all a mother's fondness. The natural desire of the ducklings to plunge into water and swim away from the shore vexes her, but she watches for their return, and does all in her power to provide the means of subsistence. She scrapes for them, which a duck would not; she shelters them under her dry and warm bosom and wings, and altogether makes a better nurse than their own proper parent.

In feeding ducks for use, peas and oat-meal are to be preferred. It is said that barley-meal renders their flesh soft and insipid. Bruised oats should be given to them freely for some weeks before they are killed, which renders their flesh solid and well tasted; and the same general principles recommended in the feeding of geese should be kept in view. It has been found that the offal of butchers' shops feeds ducks quickly, and that this does not impair the flavour of their flesh. In very many instances, ducks are reared in situations where there are no pools of clean water for them to dabble in, and the poor animals are compelled to grub with their bills in all sorts of nauseous puddles, which, of course, makes their flesh rank and offensive. They should in all cases have a pool of clean water to swim in, and are best reared near a natural meadow, where they can search for their appropriate food.

Those who have paid much attention to the management of domestic poultry, assert that geese and ducks should be kept apart from other fowls. The former should have their houses ranged along the banks of a piece of water with a fence, and sufficiently extensive for walks in front, with doors for their access to the water, which can be closed at pleasure.

Swans.

Swans are a class of aquatic fowls kept for ornament rather then use. The flesh, even of the young, is black, hard, and rank, while that of the old is too tough for mastication. The eggs, also, are not peculiarly palatable; and there is little inducement to rear them, in short, if mere pecuniary advantage be looked to, excepting on the score of the skin, feathers, and down, which are articles of considerable value. At the same [illegible] if the swan be not a productive bird, few animated [illegible] can be compared with it as regards ornament. [illegible] size, snow-white plumage, and graceful form, render it a most attractive spectacle upon the bosom of a pool or loch. It is a hardy, long-lived fowl, and associates in pairs. The food of the swan consists usually of seeds, roots, and plants, rendered succulent by water. When fed in a barn-yard, it seldom thrives, being more decidedly aquatic in its habits than ducks or geese. From the colour of the European swan being so uniformly white, a black swan used once to be proverbially spoken of as an impossibility, but black swans have been found of late in Australia.

Pigeons.

Pigeons are among the most ornamental and useful appendages of a rural dwelling. If permitted to fly abroad to seek their food, little expense will be incurred for their keep, while the value of their young will be of some importance to cottagers. The pigeon has a great power of flight, and will go to a distance of many miles in quest of the means of subsistence; but wherever it may fly, it never fails to return home. The leading features of the district around its habitation appear to be impressed on its memory, and, flying at a great height, and with a wonderful power of vision, it sees the well-remembered landmarks, and directs its path homeward. This habit of seeking for the place at which it was reared, makes it difficult to keep pigeons in any new home; the best plan of inducing them to settle in a new abode, is to clip one wing, which prevents their flying; and keep them in a cot near the ground, till they get accustomed to the place.

Many persons keep their pigeons in the space between the garret and roof of their dwelling-house, with holes at which they go out and in; and this arrangement answers very well, for the animal's lodging must be dry and comfortable. A more regular plan is to furnish them with a properly-constructed dove-cot, aloof from any building. The cot should consist of a substantial wooden box, with a sloping roof, and divided interiorly by partitions into as many cells as pairs are to be kept, for each pair requires a distinct cell. Each cell should be twelve inches deep from front to back, and sixteen inches broad; the entrance hole should not be opposite the centre of the cell, but at a side, so that the pigeons may build their nest a little out of sight. In front of each cell there should be a slip of wood to rest and coo upon; but as different pairs incessantly quarrel about the right of walking on these slips, and are apt to fight for the possession of cells, it is best to separate the slips with upright partitions; and it would be an improvement to have two or three small cots instead of one large one. The cot, of whatever size or form, should be elevated on a wall facing the south-east, or otherwise placed at such a height as will be out of the reach of cats and other vermin. The cot should be painted white, as the pigeon is attracted by that colour. Gravel should be strewed on the ground in front of the dove-cot, the birds being fond of picking it; and a little straw or hay is necessary for the nests.—Cleanliness is indispensable to the health of the birds, and a scouring out of the cot should therefore take place regularly. The quantity of dung produced in the nests is very great, and its removal to the compost heap will amply repay the trouble of cleaning.

In commencing to keep pigeons, a pair or two should be procured which have not flown, and they should be shut up for a time, and well fed. Their chief food is grain, and the kind which they prefer to all others is dried tares. Small horsebeans are another favourite article of diet, and very nutritious to them. Wheat, barley, oats, and peas, with rape, hemp, and canary seeds, are also prized by them, but should not be made the constant articles of food under any circumstances.

The house-dove or common pigeon, as is well known, begins to breed about the age of nine months, and breeds every month. During breeding time, they associate in pairs, and pay court to each other with their bills; the female lays two eggs, and the young ones that are produced are for the most part a male and female. When the eggs are laid, the female, in the space of fifteen days, not including the three days during which she is employed in laying, continues to hatch, relieved at intervals by the male. From three or four o'clock in the evening, till nine the next day, the female continues to sit; she is then relieved by the male, who takes his place from ten till three, while his mate is feeding abroad. In this manner they sit alternately till the young come out. Kept with ordinary care, a pair will give to the breeder nine pairs or so in a year, and will continue to do this for four years. The bird lives for eight years, but is useless for breeding long before attaining that age. On the whole, the cottager who keeps a few pairs may have a palatable addition to his diet frequently during the year with very little trouble.

With regard to the best breeds of the common domesticated pigeon, it is difficult to give any useful instructions. They have been cultivated to a great extent, and many distinct varieties have been formed, but the differences rest chiefly in colours, and the special value of each lies in the taste of the *fancier*. The leading varieties of fancy pigeons are known by the names of the English Pouter, the Dutch Cropper, the Horseman, the Unloper, the Dragoon, the Tumbler, the Leghorn and Spanish Runt, the Trumpeter, the Nun, the Fan-tail, and the Capuchin. The peculiarities of some of these breeds are very odd. The tumbler, for instance, derives its name from a practice of tumbling in the air while on the wing. Instead of pursuing a steady straightforward flight, it turns over, or casts somersets backward, whirling round heels over head as expertly as a first-rate rope-dancer does when he makes the back spring. The fan-tail derives its name from the circumstance of its having a remarkably broad tail, which it has the power of spreading out like the tail of a turkeycock. The prime quality of the bird consists in its ability to make its tail touch its head, and surround it with a wide glory of feathers. If it cannot do this, it is valueless to the fancier, no matter how excellent are its other properties. Amusing as this absurdity is, it is not so laughable as the qualities which recommend the English pouter to public favour. This bird, which is a cross between a horseman and a cropper, possesses the remarkable property of blowing out its breast or crop to such an extent that it rises to a level with its beak, and the bird appears to look over the top of an inflated bladder.

Carrier Pigeons.—Pigeons have been put to the remarkable purpose of acting as carriers for letters or other light objects. A particular species, larger than common, is trained for the purpose, and in some countries the rearing of them forms a lucrative employment. The instinct which has rendered the carrier-pigeon so serviceable, is the strong desire manifested by all pigeons to return to the place of its ordinary residence; and man has adopted various precautionary measures in order to make their return on particular occasions more certain. A male and female are usually kept together and treated well; and one of these, when taken elsewhere, is supposed to have the greater inducement to come back. It is even considered by some that the bird should have left eggs in the process of incubation, or unfledged young ones, at home, in order to make the return certain; but probably these are superfluous precautions. It is obvious that the carrier-pigeon can only be put to use in conformity with some contemplated plan, for which the proper preparations have been made. It must have been taken from a place to which it is wished that it should return, and it must, at the moment when its services are wanted, be temporarily at the place from which the intelligence is to be conveyed. It is usually taken to that place hoodwinked, or in a covered baske. · the instinct by which it finds its way back upon its own wings, must of course be independent of all knowledge of the intermediate localities. When the moment for employing it has arrived, the individual requiring its services writes a small billet upon thin paper, which is placed lengthwise under the wing, and fastened by a pin to one of the feathers, with some precautions to prevent the pin from pricking, and the paper from filling with air. On being released the carrier ascends to a great height, takes one or two turns in the air, and then commences its forward career, at the rate of forty miles in the hour, or about a thousand a day.

GOLD FISH.

These beautiful little creatures, which now form pets of the drawing-room, being originally from a warm climate, require to be kept in apartments of a genial temperature. They are usually kept in a crystal globe which stands on a table, and the water should be changed daily. The water must not be given in a cold state, but allowed to stand in a warm room for an hour before being put into the globe: this precaution may not be necessary in summer. The food given may consist of small crumbs of bread, and small flies; the fish are fond of the blows of the blue-bottle flies; a little duckweed may be offered on the surface of the water.

Gold fish breed freely in ponds or tanks in pleasure-grounds, but they require to be removed during severe weather in winter. They thrive well in all seasons in ponds into which a little warm water is constantly flowing. In the beautiful work of Yarrel on British Fishes, the author speaks on gold fish as follows:—"It is well known, that in manufacturing districts, where there is an inadequate supply of cold water for the condensation of the steam-engines, recourse is had to what are called engine-dams, or ponds, into which the water from the steam-engine (or condensed steam) is thrown for the purpose of being cooled. In these dams, the average temperature of which is about eighty degrees, it is common to keep gold fish; and it is a notorious fact, that they multiply in these situations much more rapidly than in ponds of lower temperature exposed to the variations of the climate. Gold fish are by no means useless inhabitants of these dams; they consume the refuse grease, which would otherwise impede the cooling of the water by accumulating on its surface."

CAGE BIRDS.

The birds usually domesticated in cages in Britain are canaries, goldfinches, larks, thrushes, blackbirds, and parrots. The only means by which these or any other species of birds can be reared and preserved in a healthy condition, is to accommodate each as far as possible with the food, space for exercise, and other conveniences which the animal would enjoy in a state of nature. The most difficult thing to afford is space: where a room or aviary can be fitted up with all requisite accommodations—perches to resemble trees and branches, grass, moss, and other plants, patches of gravel or sand, secluded places for nests, a trough of clear water, &c.—the birds will thrive, breed, and be cheerful; but such accommodations can rarely be afforded; and the aviary, for the most part, is only a cage more or less ornamentally formed of wood and wires.

Placed in this state of confinement, no birds could possibly exist unless great care is bestowed in furnishing them with food and fresh water daily, keeping their habitation very clean, and placing them in a cheerful situation in a parlour, where they can enjoy the light. Birds that are produced in confinement are more contented than those who have known freedom; but the latter may be reconciled to this new state, and made to sing with their accustomed gayety. A good plan of reconciling a newly caught bird to the cage is said to be as follows:—For two or three hours leave it in tranquillity, and then plunge it into fresh water. This exhausts it; but on recovery, it arranges its feathers, becomes hungry, and takes at once to its food. The wetting, however, should take place only during sunshine, so that the feathers may be speedily dried.

The food of cage birds is very various. 1. Canaries, goldfinches, and siskins, live only on seeds. 2. Quails, larks, chaffinches, and bullfinches, feed on both seeds and insects. 3. Nightingales, redbreasts, thrushes, and blackbirds, take berries and insects. Referring to these classes of birds, Bechstein observes—"Experience teaches me that a mixture of crushed canary, hemp, and rape-seed, is the favourite food of canaries; goldfinches and siskins prefer poppy-seed, and sometimes a little crushed hemp-seed; linnets and bullfinches like the rape-seed alone. It is better to soak it for the young chaffinches, bullfinches, and others; in order to do this, as much rape-seed as is wanted should be put into a jar, covered with water, and placed in a moderate heat, in winter near the fire, in summer in the sun. If this is done, in the morning, after feeding the birds, the soaked seed will do for the next morning. All of them ought to have green food besides, as chickweed, cabbage-leaves, lettuce, endive, and water-cresses. Sand should be put in the bottom of the cages, as it seems necessary for digestion.

"Amongst those of the second class, the quails like cheese and the crumbs of bread; the lark barley-meal with cabbage, chopped cress, poppy-seed mixed with bread crumbs, and in winter, oats; the chaffinches, rape-seed, and sometimes, in summer, a little crushed hemp-seed. Too much hemp-seed, however, is hurtful to birds, and should only be given as a delicacy now and then, for when they eat too much of it they become asthmatic, blind, and generally die of consumption. Yellow-hammers like the same food as the larks, without the vegetables; the tits like hemp-seed, pine-seed, bacon, meat, suet, bread, walnuts, almonds, and filberts." The same author proceeds to describe two kinds of paste, simple and cheap, and which may be termed a universal food for birds.

"To make the first paste, take a white loaf which is well baked and stale, put it into fresh water, and leave it there until quite soaked through, then squeeze out the water and pour boiled milk over the loaf, adding about two-thirds of barley-meal with the bran well sifted out, or, what is still better, wheat-meal; but as this is dearer, it may be done without.

"For the second paste, grate a carrot very nicely, (this root may be kept a whole year if buried in sand), then soak a small white loaf in fresh water, press the water out, and put it and the grated carrot into an earthen pan, add two handfuls of barley or wheat-meal, and mix the whole well together with a pestle.

"These pastes should be made fresh every morning, as they soon become sour, particularly the first, and consequently hurtful. For this purpose I have a feeding-trough, round which there is room enough for half my birds. It is better to have it made of earthenware, stone, or delft ware, rather than wood, as being more easily cleaned, and not so likely to cause the food to become sour.

"The first paste agrees so well with all my birds, which are not more than thirty or forty, at liberty in the room, that they are always healthy, and preserve their feathers, so that they have no appearance of being prisoners. Those which live only on seeds, or only on insects, eat this food with equal avidity; and chaffinches, linnets, goldfinches, siskins, canaries, fauvettes, red-breasts, all species of larks, quails, yellow-hammers, buntings, blue-breasts, and red-starts, may be seen eating out of the same dish. Sometimes, as a delicacy, they may be given a little hemp, poppy, and rape-seed, crumbs of bread and ants eggs. One of these is necessary for the birds of the third and fourth class.

"Every morning fresh water must be given to the birds, both for drinking and bathing. When a great many are left at liberty, one dish will do for them all, about eight inches long and two in depth and width, divided into several partitions, by which means they are prevented from plunging entirely into the water, and in consequence making the place always dirty and damp. A vessel of the same size and shape will do for holding the universal paste, but then it must have no partitions. Quails and larks require sand, which does for them instead of water for bathing.

"Some birds swallow directly whatever is thrown to them: great care must be taken to avoid giving them any thing with pepper on it, or bad meat. This must be a general rule. I shall also remark, that food sufficient for one day only must be given to birds kept in cages, for they are accustomed to scatter it about, picking out the best, and leaving only the worst for the next morning; this makes them pine, and puts them out of humour."

Canaries.

These birds are the chief pets of the parlour, and the method of treating them requires to be given at some length. Being originally from a warm climate, they are tender, and must be kept in rooms of an agreeable temperature; if exposed to cold either in rooms or the open air, they pine and die. In dry weather in summer, their cage should be hung in the open air, or at least in the sunshine. If the apartment is kept too hot, they will moult at an improper season, and this must be avoided. Only one male should be allowed in a cage. Females for breeding are the better for having a large cage, as it affords them space for exercise. The greatest care must be taken to clean the cage, of whatever dimensions, and to scatter a little fine sand on the bottom of it. Each should be provided with three cross-sticks as perches, a small glass trough for water fixed outside at the extremity of one of the sticks. The water must be changed daily, or even more frequently.

Some persons, from mistaken kindness, offer pieces of nun cake and other inappropriate food to canaries, and the little creatures being fond of these things, they do themselves a great injury by eating of them. A canary in high song will at once be rendered mute by partaking of any improper food of this sort. As already mentioned, the food must be of a simple and natural kind; besides the seeds and other things described, they should be supplied daily with a little green vegetables; such as chickweed in spring, lettuce and radish-leaves in summer, endive, water-cress, and slices of sweet apple in winter. As they like to wash their feathers, a cup of fresh water may be placed in the cage daily. In the moulting season, it is recommended to put a nail into the water they drink, in order to strengthen the system by the slight infusion of iron matter.

The breeding of canaries requires additional accommodations. The breeder must have a large cage, into which the pair of birds is put about the middle of April. At the upper part of the cage, at one end, boxes for the nests are placed, with holes to go out and in by; and in the centre of the cage, near a perch, a net-work bag is hung filled with cotton, wool, moss, hair, and other soft materials, for the birds to use for their nests. The female only builds; and about ten days after pairing, she lays the first egg. She ordinarily lays six eggs, one every day; but each egg is to be taken away as laid, leaving an ivory one only; and when done laying, replace all the six. The period of incubation is thirteen days. When the young are hatched, finely minced egg and bread are placed at the feeding-trough, to enable the parents to carry suitable food to their young.

Blackbirds.

The male blackbird is a handsome creature, lively in manner, and possessing some sweet "wood notes wild," which sound most agreeably from a garden or the outside of a window. The bird requires a large wicker cage, which, whenever weather permits, ought to be hung in the open air. In a state of nature, the black bird eats berries, seeds, insects, larvæ, and worms. It loves to run about a grass-plot in the spring mornings, and pick up any stray worm which is straggling from its hole. This habit suggests the propriety of giving it, when in confinement, both vegetable and animal food. The universal paste will answer; but if too heating, which it is liable to be, give bits of bread, flies, cockchaffers, worms; and failing these, chopped raw meat. A rough bone from the table will also not be inappropriate. A short experience will show upon which kinds of food the creature thrives best, and let that be adhered to. Give also plenty of pure water to drink; and once a week, when the sun shines, set a basin of water in the cage for it to bate in and clean itself. Let the cage be carefully and regularly cleaned.

Parrots.

Under this head may be classed a number of beaked birds of similar character, as parrots, parrakeets, cockatoos, and maccaws, all possessing beautiful plumage of green, yellow, or grayish tints. They are chiefly from South America, and require the warmth of a dwelling-house to keep them alive in this country. All possess harsh voices, and would on that account be considered a positive nuisance by most persons except for the oddity of their being able to repeat certain words; but this is a quality possessed by some in greater perfection than others. Each kind of these birds may be treated much in the same manner. They are allowed a large cage formed of strong wires, with thick round bars to perch upon, and a ring at top to swing from by their hooked beak. All the parts must be of tin, for they would soon pick wood to pieces. In the Zoological Gardens, they are usually seen perched on a cross-bar of tin at the top of a staff, but chained by the leg to prevent their escape.

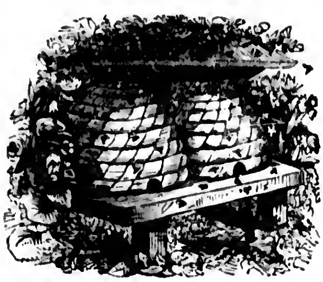
The food offered to parrots, maccaws, &c., is chiefly bread steeped in milk, nuts, or any other simple article. Care must be taken never to give them any thing with salt or pepper. On the subject of feeding them, Bechstein makes the following observations:—"In its native country, the fruit of the palm-tree is its principal food; our fruit it also likes, but white bread soaked in milk agrees with it better; biscuit does not hurt it; but meat, sweetmeats, and other niceties, are very injurious; and though at first it does not appear to be injured, it becomes unhealthy, its feathers stand up separate, it pecks and tears them, above all those on the first joint of the pinion, and it even makes holes in different parts of its body. It drinks little—this is perhaps occasioned by its eating nothing dry. Many bird fanciers say that the best food for parrots is simply the crumbs of white bread, well baked, without salt, soaked in water, and then slightly squeezed in the hand. But though this appears to agree with them pretty well, it is, however, certain that now and then something else ought to be added. I have observed, indeed, that parrots which are thus fed are very thin, have hardly strength to bear moulting, and sometimes even do not moult at all; in that case they become asthmatic, and die of consumption. It is clear that feeding them only on this food, which has very little if any moisture in it, is not sufficient to nourish them properly, at least during the moulting season, and while the feathers are growing again. I never saw a parrot in better health than one which belonged to a lady, who fed it on white bread soaked in boiled milk, having more milk than the bread would absorb, which the parrot drank with apparent pleasure; there was also put into the drawer of its cage some sea biscuit, or white bread soaked in boiling water; it was also given fruit when in season. It is necessary to be very careful that the milk is not sour.

"Some young maccaws are fed on hemp-seed, which must always be of the year before, as the new would be too warm and dangerous. Yet they must not be fed entirely on this food, but there must be added white bread soaked in milk or water, as has already been mentioned, some fruit and nuts, but never bitter almonds, as they will infallibly kill all young animals. In all cases the excrements of the bird will indicate the state of its health, and whether the food ought to be changed or not.

"Although maccaws rarely want to drink, as their food is very moist, yet they must not be left without water, which is generally placed in one of the divisions of their tin drawer. It is also a good thing to entice them to bathe; nothing is more favourable to their health, or better facilitates the painful operation of moulting, or keeps their feathers in better order. A little attention to these favourites, deprived of their liberty, their natural climate, and food, cannot be too much trouble to amiable persons who are fond of them, and to whom these pretty birds become greatly attached."

The cockatoo is generally esteemed as of milder temper than the parrot. Of this species, Buffon observes—"Cockatoos, which may be known by their tuft, are not easily taught to speak; and there is one species which does not speak at all; but this is in some measure compensated for by the great facility with which they are tamed; in some parts of India they are even so far domesticated that they will build their nests on the roofs of the houses; this facility of education is owing to their intelligence, which is very superior to that of other parrots. They listen, understand, and obey; but it is in vain that they make the same efforts to repeat what is said to them; they seem to wish to make up for it by other expressions of feeling and by affectionate caresses. There is a mildness and grace in all their movements, which greatly add to their beauty. In March, 1775, there were two, a male and female, at the fair of St. Germain, in Paris, which obeyed with great docility the orders given them, either to spread out their tuft, or salute people with a bend of the head, or to touch different objects with their beak and tongue, or to reply to questions from their master with a mark of assent, which clearly expressed a silent *yes*: they also showed by repeated signs the number of persons in the room, the hour of day, the colour of clothes, &c.; they kissed one another by touching their beaks, and even caressed each other; this showed a wish to pair, and the master affirms that they often do so even in our climates. Though the cockatoos, like other parrots, use their bill in ascending and descending, yet they have not their heavy disagreeable step; on the contrary, they are very active, and hop about very nimbly."

BEES.



The subject of Bees, which is equally extensive and interesting, has for many ages attracted the attention of mankind. The Sacred Writings, the most ancient of which we have any knowledge, show in numerous places how strongly the fathers of the Jewish people had been impressed by the peculiarities in the natural history of the Bee; and we know that Aristotle and other philosophers of old Greece deemed the subject worthy of years of patient investigation. Virgil, also, and many other Roman writers, dwelt on it with enthusiasm in their writings; while, in much later times, Swammerdam and other distinguished cultivators of science have pursued the same track with undiminished ardour. The most zealous of these inquirers was Francis Huber (born at Geneva 1750, died 1831), who, though labouring under the deprivation of sight, by the aid of his wife formed a most valuable collection of observations on the habits of bees, and to whose work we shall have occasion to refer. Societies have also been formed for the sole purpose of investigating this portion of natural history. A mere summary of the interesting essays, therefore, which this insect, so universally appreciated, has called forth, would occupy a very large space. On the present occasion, an attempt can only be made to cull from the most approved sources such details as may form a complete history of the Bee, though at the same time it must necessarily be a concise one, along with directions for the practical management of this most useful animal.

Bees are arranged by zoologists into the family of the *Apidæ* (from *apis*, a bee), in the order *Hymenoptera* (having four unequal membranaceous wings) of the Insect class. The Social Apidæ form the principal division of the family, their type being the *Apis Mellifica*, the Honey-making, or, in common phrase, the Honey-Bee. It is so called not from an exclusive peculiarity, but because it is the species which has long yielded to man the rich product indicated in its name. As the observations to follow will have reference to the Honey-Bee, it may simply be mentioned that the description of this genus involves all the main features in the natural history of its less important congeners, the Wild or Humble Bees, the special peculiarities of which will be briefly adverted to in the conclusion.

HONEY BEES.

Of the family of the Social Apidæ or Honey-Bees, two species seem to exist in Europe, the one found in the north, and the other in the south; but, making allowance for a slight deepening of tint from brown to red in the rings of the body in the case of the more southerly insect, the description of the common hive bee of Britain will apply to the other in all important respects. A hive of honey or garden-bees contains three orders of inhabitants, the external characters of which differ considerably, while their uses and functions in the community are most markedly distinct. The most important, and by far the most numerous order is that of the *workers*, or *working-bees*, formerly regarded as neuters in respect of sex, but now more properly considered as undeveloped females. The second order is composed of the males of the hive, termed the *drones*. There is usually but one perfect member of the third order present at a time in a hive, and this is the *queen-bee*, the sole female of the community.

The working honey-bee has a body about half an inch in length, blackish-brown in hue, and covered with close-set hairs, which are feather-shaped, and assist the creature materially in collecting the farina of flowers. The *head*, which is a flattened triangle in shape, is attached to the chest by a thin ligament; and the chest or *thorax*, which is of a spherical form, is united in a similar slight way to the *abdomen*. The abdomen is divided into six scaly rings, which shorten the body by slipping over one another to a certain extent. These three external divisions of the insect's body have all of them appendages of peculiar interest and utility. The head is provided with a double visual apparatus. In front are placed two *eyes*, consisting each of numerous hexagonal plates, studded with hairs to ward off the dust or pollen of flowers; and three small eyes are also to be found on the very top of the head, intended, doubtless, both to heighten the general sense of seeing, which the creature so peculiarly requires, and to give a defensive vision upwards from the cups of flowers. The *antennæ*, however, which are two slender tubes springing from betwixt the front eyes, and curving outwards on each side, most probably fulfil many of the purposes of vision in the dark interior of the hive. These instruments have each of them twelve articulations, and terminate in a knob, gifted with the most delicate sensitiveness. By the flexibility of the antennæ, the bee is enabled to feel and grasp any object in its way; and there can be little doubt that it is chiefly by means of these it builds its combs, feeds the young, fills the honey-cells, and performs the other operations of the hive. Bees also use the same instruments for the recognition of one another.

The mouth of the bee is a very complex structure, and one wonderfully fitted for its duties. Its most important parts are the *mandibles*, the *tongue*, the *proboscis*, and *labial feelers*. The mandibles are merely the two sides of the upper jaw, split vertically, and movable to such a degree as to enable the insect to break down food betwixt them, to manipulate wax, and use them otherwise as serviceable tools. They are furnished with teeth at their ends, two in number. The tongue of the bee is extremely small, and indeed is scarcely admitted by some naturalists to exist at all, the proboscis being often signified by that name. Many of the usual functions of such an instrument are indeed performed by the proboscis, a long slender projection composed of about forty cartilaginous rings, fringed with fine hairs. From the base of this, on each side, rise the labial feelers, instruments also fringed or feathered interiorly; and outside of these are the lower jaws, similarly provided with hairs. When the feelers and jaws close in on the proboscis, they form a sheath or defence to it. Naturalists used to term the proboscis a tube; but they now know that it acts by rolling about and lapping up, by means of the fringes around it, every thing to which it is applied. The gathered material is then conveyed into the gullet at its base, whence it passes into the internal organs. Thus we find the mandibles of the upper jaw ready to break and prepare the food for the sweeping-up apparatus of the lower parts. While perfect in action in an expanded state, the whole, moreover, can be so folded together as to form one strong well-protected instrument.

To the trunk or thorax of the bee exteriorly are attached the muscles of the wings and legs. The wings consist of two pairs of unequal size, which are hooked to one another, in order to act in concord and steady the movements in flying. The bee has three pairs of legs, of which the anterior pair are the shortest and the posterior the longest. All of them are formed upon the same principle as the limbs of man, having articulations for the thigh, leg and foot, with some minor joints in the latter part. The hind legs are marked by a special and beautiful provision. This is a cup-like cavity on the *tibia* or fore-leg, intended for the important purpose of receiving the kneaded pollen which the bee collects in its wanderings. The legs are all thickly studded with hairs, and more particular the cavity mentioned, in which the materials require to be retained securely. Another provision of the bee's limbs consists in a pair of hooks attached to each foot, by means of which the animal suspends itself from the roof of the hive or any similar position. Beneath or behind the wings the *spiracles* or air openings are found, which admit air for the purpose of permeating the chest, and probably the whole body, for the oxygenation of the circulating system. Huber completely proved both that respiration is essentially necessary to bees, and that the spiracles are the instruments by which it is effected. He found that they die in an exhausted receiver and become asphyxiated when shut up in numbers in close bottles. They perish in water only if the spiracles are under the surface; and the use of these apertures is then made apparent by the bubbles which escape from them under water. As will be shown, also, bees carefully ventilate their hives. Therefore, though no blood has been detected in bees or other insects, these tiny spiracles are of no slight consequence in the physical economy of the insect, oxygen being apparently not less necessary to the vitality of its circulating fluids than to those of warm-blooded animals.

Besides these appendages and contents of the chest, that region is traversed by the *œsophagus* or gullet, on its way to the digestive and other organs situated in the abdomen. These organs consist of the *honey-bag*, the *stomach*, the *wax-pockets*, and the *intestines*, with the *venom-bag* and *sting*. The honey-bag, sometimes called the first stomach, though digestion never takes place there, is an enlargement of the gullet into a pea-sized bag, pointed in front, with two pouches behind. In this receptacle is lodged the fluid or saccharine portion of the bee's gatherings, and by the muscularity of the coats it can be regurgitated to fill the honey-cells of the hive. A short passage leads to the second or true stomach, which receives the food for the nourishment of the bee, and also the saccharine matter from which the wax is secreted. The small intestines receive the digested food from the stomach, and from them it appears to be absorbed for the purposes of nutrition. Wax, it was once thought, was pollen elaborated in the stomach and ejected by the moth; but it is entirely derived, it is now known, from the honey or saccharine matter consumed by the insect; and John Hunter discovered two small pouches in the lower part of the abdomen, from vessels on the surface of which it is secreted. After accumulating for a time in these pouches, scales of it appear externally below one or other of the four medial rings of the abdomen, and are withdrawn by the bee itself or those around it. Close to the stomach is found the last important organ of the abdomen, the sting. Much beautiful mechanism is observed on a microscopical examination of this weapon, so powerful in comparison to its bulk. It consists of two long darts, adhering longitudinally, and strongly protected by one principal sheath. This sheath is supposed to be first thrust out in stinging, and its power to pierce may be conjectured from the fact that, when viewed through a glass which magnifies a fine needle-point to the breadth of a quarter of an inch, the extremity of the sheath ends so finely as to be invisible. The sheath once inserted, then the two still finer darts follow, and make a further puncture. The use of this is to receive the poison, which is conducted to the end of the sheath in a groove; and in order that the conjoined darts may not be withdrawn too soon for this purpose, they have each nine or ten barbs at the point to retain them. When the weapon is withdrawn, the poison is thus left with a cavity to enter, causing a deeper festering. The insect ejects the poison by means of a muscle encircling the bag at the base of the sting, in which bag the venom is secreted. The chemical composition of the poison has not been discovered, though it has so far the nature of an acid as to redden the vegetable blues. Altogether, Paley is fully justified in pointing to the defensive weapon of the bee as a wondrous union of mechanical and chemical perfection.

The manner in which the bee collects the food which forms the various secretions alluded to is worthy of note. The hairs with which its body and feet are covered, are the main instruments used for this end. By means of the hairs on the feet, the insect usually begins its collection of the pollen in the corolla which it has entered, and, after kneading the dust into balls, finally places it in the baskets of the hind legs. But the creature is not content with the product of this process. Rolling its body round and round, it brushes off the pollen still more cleanly, gathers it into two heaps with its active brushes, and loads its baskets to the brim. Even afterwards, they sometimes fly home like dusty millers, and brush their jackets when unloaded. The pollen is understood to be brought home by the working-bees more peculiarly as food for the young. The fluid secretions contained in the nectarea of flowers, and honey-dew, which is a deposition of certain aphides on plants, serve as other natural varieties of the bee's food; and the insect also drinks large quantities of water.

The senses of bees have been in part touched upon already. The means of *vision* bestowed on them, it was mentioned, consist of the many-lensed eyes in front, and the supplementary organ above. Inquirers have been staggered by the seeming contradictions connected with the vision of the bee. After collecting its store of food, its first movement is to rise aloft in the air, and look for the site of its home. Having determined this in an instant, however distant the hive may be, it goes for the point with the directness of a cannon-ball, and usually alights at its own door, though the whole country be crowded with hives. Yet if the hive, or its door, has been shifted to a slight extent, the insect seems confused, and cannot find its way. The conclusion from this is, that the eyes of the bee have a lengthened focus, suiting them for the main purposes of its existence. But the consequent inability to determine accurately on short distances has been compensated to the creature by the antennæ, which then become a highly serviceable resource. The sense of *taste* in bees has been the subject of much argumentation. Huber was of opinion that it was the most imperfect of their senses, and they have been observed to resort to putrid marshes for water, even when they were not restricted in their choice. Xenophon found his men seriously injured by taking honey produced by bees which had fed on deleterious plants. But, on the other hand, it has been noticed that they reject many substances, and prefer others, when a choice is allowed them; and it has been conjectured that they go to marshes purposely for the salt in their waters. Moreover, what renders the honey deleterious to man, may not be hurtful to bees. Honey, formed from a particular flower in the Jerseys, was found unfit for use from its intoxicating qualities; yet the bees throve wonderfully upon it at the same time. Their taste in selecting the richest flowers is likewise unquestionable. No doubt the sense of *smell* comes into operation on these occasions, as well as the sense of taste. Betwixt the influence and effects of the two, indeed, it is scarcely possible to discriminate. Even in the case of the human being, it is an established fact that the powers commonly ascribed to the sense of taste are to a remarkable degree dependent on the sense of smell. If the eyes be bandaged, and the apertures of the nose well shut up, the most experienced judge will be at a loss to determine between any two kinds of ardent spirits, or other pungent substances. The most nauseous medicines also, much as they may usually seem to affect the taste, will be found almost insipid if the site of the sense of smell be closed up while they are swallowed. In bees, the site of the two senses seems to be almost one and the same. Many experiments of Huber seem to prove that the sense of smell lies in the mouth, and that it is very acute. He found that they hate the odour of turpentine, yet on plugging up the mouth they showed no disgust when placed beside that liquid. He concealed honey at considerable distances, and they in a very short time detected the hidden treasure. The acuteness of their sense of smell, in truth, is sufficiently proved by their admirable skill in tracking out, over hill and dale, the most fragrant flower-parterres and beds of mountain heath. The sense of *hearing* has been denied to bees by many observers, while others describe the antennæ as their organs of hearing. The probabilities are in favour of the latter position. Noise, produced by the wings, and varied to suit particular purposes, is well known to be used as a means of intercommunication; and Huber, though doubtful about the faculty, avers that by a particular sound, emitted from the mouth apparently, the queen will render the whole hive silent and motionless in one instant. A certain sound, too, heard in the hive before swarming, is always followed by definite consequences. Such facts as these go far to establish the possession of hearing by bees; as signals by sound, made when the eyes could not detect the movement attending their production, would otherwise be valueless. The antennæ have been mentioned as possessed, if not of hearing, at least of a delicate sense of *touch*. Huber points out a moonlight night as the best time for observing the uses of the antennæ in this respect. The bees, guarding against the intrusion of moths, have not light enough to see fully, and they circumambulate their door with the antennæ stretched right before them. The instant a moth is felt, it is destroyed. When the queen of a hive is lost, the antennæ forms a curious means of spreading intelligence. Bee after bee protrudes its antennæ, and crossing them with those of its next neighbour, disseminates, in this way, the sad news over the hive. Besides the antennæ, the feelers have been shown by experiment to possess a considerable degree of sensibility, and to serve in part as organs of touch.

Such are the anatomical and physiological characteristics of the common or working-bee. The duties of this order include almost the whole business of the bee community, as will be shown afterwards in detail. Hives differ greatly, of course, in the number of their inmates, taking them even at the same season. Some contain but a few thousands; others from twenty to thirty, forty, and even fifty thousand. Of these the drones compose but a thirtieth part, or little more; all the rest, with the exception of the queen, are workers.

Drones or Males.

The drones differ considerably in outward appearance from the workers. They are bulkier and flatter in body, with a round head, a shorter proboscis, and an antennæ with an additional articulation; they have no basket-cavity on their hind-legs, and their abdomen contains too means of secreting neither honey, wax, nor poison, while the productive organs are there found instead. They are called drones from the peculiarly loud noise which they make with their wings. It has been said that the drone is the male of the hive. He lives but for the reproduction of the race, and when the object of his existence is accomplished, he is doomed to die. The workers, who have their own winter food and that of the coming young to provide, instinctively pass sentence of death, at the fitting time, on a class that live only to feed, and who, if they ever stir from their luxurious nests, go out for pleasure, not toil. With the exceptions specified, the description given of the worker-bee applies also to the drone.

Queen Bees.

The queen-bee is of larger size than either the drone or the worker. She has an elongated body, blackish above and tinted with yellow inferiorly, while the presence of two ovaries, or egg-receptacles in the abdomen, demonstrate her sex. She has also a sting, considerably bent. The Germans call the queen the *mother-bee*; and this is the most appropriate name, since her functions are those of a parent rather than a potentate. Her sole province is to lay the eggs, from which issue those annual multitudes that perpetuate the race in new communities. The progress of all kinds of bees, from the larva state to maturity, will fall to be described in an ensuing section; but it may in the mean time be observed, that the queen-bee usually commences laying eggs on the fifth day of her age, and often continues without intermission from early spring to the end of September, laying in the warmest season about two-hundred eggs a day. Such are the general characteristics and functions of the mother-bee.

We propose now to give an account of the natural and regular operations of a colony of bees, from the moment of their introduction to a completely unfurnished habitation to the establishment of a perfect hive.

PROCEEDINGS OF BEES FROM FIRST SETTLEMENT IN THE HIVE.

The breeding of young bees commences in February, and a hive, however thinned by the previous winter, becomes, under ordinarily favourable circumstances, crowded to excess in midsummer. Besides the developed bees, it abounds in eggs and young ones not matured. That fine instinct which, in the case of bees, occasionally prompts to acts almost above the power of reason, relieves this crowded state of things. The queen-bee, the proper mother of at least the great body of the hive, resolves upon departure with a swarm. The phenomena attending that departure will be noticed under a separate section; in the mean time let it be supposed that the queen has led off a colony, and that by the care of the owner of the bees, the swarm is lodged in a new and empty hive.

The first object of the community is to clean out their new lodging thoroughly, if they find this not done beforehand. The next great object is to block up all the chinks of the hive, smooth its projecting parts, and lay a stable foundation for the future works of the interior. Besides the wax which they use so extensively in their architecture, bees also employ, particularly at first, a remarkable substance called *propolis*, from the Greek words *pro* and *polis* (before the city), as indicating its use on the superficial parts of the hive. Propolis is a grayish-brown resin, of an aromatic odour, and better fitted by its tenacity for cementing than wax. Huber first showed distinctly that the bees gather this from the poplar, alder, birch, and willow trees, but more especially from the first of these trees. The ingenious naturalist alluded to, suspecting Reaumur to be wrong in referring the propolis to the pine, placed near his hives some wild-poplar branches, which the bees soon discovered, and flocked to in great numbers. In the heat of the day, when the vicious matter is ductile, it is thus carried off by the insect. A small thready portion is detached, kneaded with the mandibles, and then, by means of the four feet, placed in the basket of the hind legs, a smart pat or two being given to secure it there. Another portion, similarly kneaded to make it portable, and a little drier, is basketed in the same way, till as much is procured as the insect can carry. Sometimes the patient creature will spend half a hour in the mere kneading of a portion of propolis; and occasionally other bees will come behind and rob the little labourer of its whole load, for a succession of times, without eliciting the slightest symptom of impatience. When a bee reaches the hive with its load, the propolis adheres so firmly, that the insect has to present its limbs to the workers in the hive, who detach it, and immediately use it, while yet ductile, to fill all the crevices of the hive, and smooth the projecting parts, so as to prevent hurts being received in the dark. Another remarkable use is made of the propolis. From the hour of their entrance into the hive, bees are liable to the intrusion of other creatures. A fly they can soon remove, but what are they to do with a snail? They can sting it to death, to be sure, in an instant, but their puny strength is totally insufficient to remove the carcass. In this dilemma, they completely obviate the disagreeable effects of the presence of a large putrefying body, by covering it with propolis, which hardens over the mass, and gives them a pleasant aroma in place of a fœtid odour. With the propolis, moreover, they often narrow the entrance to the hive, forming a secure barrier, when they have reason to dread the intrusion of the death's-head moth, their great enemy in some countries.

In the mean time, while some workers are using the propolis for the purposes first stated, others are commencing the preparation of the cells or combs. The propolis is employed to attach these to the edges of the hive, but wax is the component material of the cells themselves. We shall find, in noticing the after arrangements of the completed hive, that the working-bees are naturally divided into two great classes; but at the outset of their labours, when the cells are being constructed, they form *three* sections, each of which pursues its allotted toil with admirable order and regularity. One section produces the material for the combs, and forms it roughly into cells; the second division follows the first, examines and adjusts the angles, removes all the superfluous wax, and perfects the work; while the third band passes continually out and in, seeking and bringing provisions, chiefly pollen, for the second section, which never quits the hive. The first class flies abroad at intervals, it being necessary that they should have rich saccharine food for the secretion of the wax. As the secretion goes on best in a state of repose, bands of the wax producers, after feeding fully, suspend themselves in clusters from the roof, each hanging from the hind legs of the one above, till the wax scales are formed, and they are prepared to take up the work. This clustering occurs on the very entrance of a swarm into a hive, when a seeming inactivity of several hours takes place, till the production of wax is set a going. It will be seen that the second section, the architects-proper, have the most unremitting toil to perform. They never quit it when once begun, excepting to turn to the little waiters of the third section and indicate their hunger by holding out their trunk, when the caterer either spirts out a drop or two of honey or furnishes pollen from the stores brought in.

Cells.

But if the labour of the architect class be severe, their work, when complete, is a marvel of instinctive ingenuity. Bees always begin their work, in ordinary circumstances, at the ceiling, suspending their structures from it. Their combs, or clusters of cells, are arranged in vertical and parallel strata, with a space of about half an inch betwixt contiguous pairs; and each comb is nearly an inch in thickness. At the outset, when one wax-making bee leaves the suspended cluster alluded to, and lays the foundation of a cell, others follow in rapid succession, not only adding their wax to that of the first, but soon commencing new combs, one on each side; and so the work goes on, in most cases, until the whole roof is covered with foundations. The architects-proper, also, are meanwhile at their finishing work. They have, says Reaumur, to solve this difficult geometrical problem: "A quantity of wax being given, to form of it similar and equal cells of a determinate capacity, but of the largest size in proportion to the matter employed, and disposed in such a manner as to occupy the least possible space in the hive." Wonderful to reflect upon, this problem is solved by bees in all its conditions, in their construction of hexagonal or *six-sided* cells. The square and the equilateral triangle are the only other two figures of cells which could make them all equal and similar without interstices. But cells of these figures would have either consumed more material or have been weaker; and they would also have consumed more space, being less adapted to the form of the bee. In short, the hexagonal form combines all the requisites of economy and capacity. Another wonderful arrangement is seen in the construction of the bottoms of the cells. Each of these is composed of three rhombs, or plates of wax in the shape of card-diamonds, disposed in such a manner as to form a hollow pyramid, the apex of which forms the angles of the bases of three cells on the opposite side, giving to each of them one of the three diamond-shaped plates which is required to form their bases. Now, the three rhombs, composing each cell-bottom, have the two obtuse angles each of 110 degrees, and, consequently, each of the two acute angles of 70 degrees. Koenig, on being desired by Reaumur to calculate the exact angle which would give the greatest economy of wax in a cell of such capacity, found that the angle should be 109 degrees 26 minutes, or 110 degrees nearly. Other geometricians have arrived at similar conclusions. The problem is one of great difficulty, yet the bee practically solves it at once, under the guidance of the Great Geometrician who made both the bee and the law on which it proceeds. Attempts have been made to ascribe the form of the cells to the peculiar shape of the head of the bee, and the instruments which it employs; but all such explanations have been found liable to insuperable objections.

The cells of the bee are extremely delicate, two or three plates or sides being of the consistence only of a common leaf of paper. They are made strong, however, by mutual support and other means. Besides a sort of froth which the insect mixes with the wax, the cells, at first of a dull white, soon appear yellow on the interior, the change arising from the plastering over them of a compound varnish of wax and propolis. Each cell is soldered, too, at its mouth by a similar compound of a reddish colour, having in it more propolis; and threads of the same substance are laid around the walls to bind and strengthen them. It is now to be observed that all cells are not alike. They have four different uses in the economy of the hive, and are constructed variously to suit these. One set of cells is for holding the eggs or embryos of worker-bees; a second for those of males or drones; a third for those of young queens, hence called royal cells; and a fourth set are for the reception of honey and pollen. The first are generally about five lines in depth (or less than half an inch), and two lines and two-fifths in diameter. The cells of the young males are much less numerous, and measure from six to seven lines in depth, by three and a half in diameter. It is worthy of note, that in passing from the construction of worker-cells to those of drones, in the same comb, the architects do not alter the size at once, but gradually, thus disordering in the slightest possible degree the delicate arrangement of the bases of the cells. In shifting from larger to smaller, the same rule is observed. A small number only of royal cells, about ten or twelve, are constructed on ordinary occasions. They are about an inch in depth, and nearly one-third of an inch in width, with walls about an eighth of an inch in thickness. After the breeding season is over, the cells both of worker and male bees are used for holding honey. Those made purposely for that end are chiefly marked by a greater divergence from a horizontal plane, that the honey may be better secured; and it is curious to observe that, in a very warm season, these wise insects give the floor a still greater dip from the mouth inwards. As the store enlarges, they seal up the mouth with a ring of wax, to which they gradually add concentric layers till the cell is filled, when they close it altogether. Pollen is kept in cells of considerable size.

Laying of Eggs.

A very short time elapses ere a great number of cells are constructed; for, in the height of the honey season, a good swarm has been known to build *four thousand* in a day. The queen-mother very soon begins the task of laying eggs. A thousand conjectures have been hazarded as to the mode in which the fecundation of the female bee takes place. No observer has yet been able to discover any contact with the drones in the hive. It was supposed by Swammerdam that a certain aura or odour from the drones was all that was necessary to render the eggs of the queen productive; while M. Debrau imagined that the eggs, as in the case of frogs and fishes, were fecundated by a fluid from the drone after being laid. M. Hattorf thought, again, that the queen was fecundated by herself alone. All these opinions M. Huber refuted in a satisfactory manner, by separations and confinements of the insects in various ways. He at length came to the belief, founded on experiments which appear almost decisive of the question, that the female bee never becomes fruitful in the hive, but requires to go abroad for that purpose; and it has been also thought probable that the fecundation takes place by contact in the air, as is known to occur in the case of winged ants. The number of drones in a hive has been thought a most unintelligible circumstance. Mr. Huber's views explain the matter fully. It is essential that they should be numerous, that the female may have a chance of meeting them abroad; and it is to be observed that she always quits the hive at the hour when the drones leave it, or immediately afterwards. One intercourse is sufficient, according to Huber's experiments, to render the female bee productive for at least two seasons; and if the intercourse takes place at the end of the year, the consequent laying of eggs may be deferred to the ensuing spring. The cold weather has a strong influence in this respect. M. Huber's conclusions may be more fully ascertained by reference to his interesting work.

M. Huber discovered that the queen begins to lay eggs forty-six hours after returning from the flight during which fecundation takes place. For the space of eleven months, under ordinary circumstances, a queen, at her first laying, produces the eggs of worker-bees alone. At the end of the space mentioned, a considerable laying of the eggs of drones commences and soon after the appearance of these, the workers of the hive, with a strange instinct, begin to prepare royal cells for the queen-eggs that are certain to follow. Altogether, the fruitfulness of the female bee is amazing, from one to two hundred eggs a day being the usual amount of her produce. One hundred thousand is said to be no very uncommon number of young for her to give origin to in a season. A swarm consisting of 2000 or 3000 in the beginning of the year, will throw off in June swarms amounting to

40,000 or 50,000; in many cases the first swarm, and in some the cast or second swarm, throw off colonies of 10,000 or 12,000; and yet the original stock is left augmented to the number of 18,000 or 20,000. Occasionally, a first swarm even casts twice.

Transformation of Worker-bees.

A fertilized queen is so impatient to begin her laying of worker-eggs, that, in a new hive, she only waits till a few inches of comb are erected. Before depositing the egg, she carefully examines the cell, and, if satisfied, turns and drops into it from the oviduct an egg of an oval shape and bluish-white tint. Here the egg remains for three days attached by a viscous fluid to the corner of the cell; and, on the fourth, the thin outer shell of the egg bursts, exposing a small lively worm. Now come into play the *nurses* or nursing-bees, one of the two great classes into which Huber and others consider the labourers of the hive to be divided. The other class are the *wax-workers.* Both elaborate honey, but the latter class alone make wax and form combs. Again, the nurses, whose figure may be distinguished from its being more ovoidal than the others, are those who alone take care of the young. As soon as the egg is hatched, they watch over the larva or worm with the tenderest and most incessant care, administering copious supplies of mixed pollen, honey, and water, which the nursling devours with avidity. Like other larvæ, it soon grows so as to cast its cuticle; and, five days after chipping the shell, it has become large enough to fill the cell, lying coiled up like a ring. It now ceases to eat, and the bees seal up the cell with wax. Left to itself, the larva begins the process of spinning a cocoon round its body, which it does in thirty-six hours, the material being a fine silken thread from the mouth of the spinner. In three days more it is converted into the state of *pupa* or chrysalis, when all the parts of the future bee become gradually visible through the transparent covering, assuming a darker hue day by day, and progressing to the state of the complete *imago* or insect. On the twentieth day from the deposition of the egg, the young bee begins to cut through its prison-door with its mandibles, and in half an hour makes its escape. Old writers say that the elder bees fondly caress and feed the new-comer; but later observers, of no mean authority, declare that, on the contrary, they seem to think their duty ended with the closing up of the cell, and leave the young stranger to shift for itself in the busy world. One thing, however, is done by the elder bees. They instantly clean out the vacated cell, and prepare it again for eggs or honey, leaving at the same time the silk cocoon adhering to the walls.

Eggs of Drones—Royal Eggs.

The passage of male eggs through the larva and pupa state is attended with the very same phenomena as in the case of the eggs of workers, with the exception that the process occupies a little more time, twenty-four days in all being spent in the change. The cause of male eggs being laid, in ordinary circumstances, only after eleven months have been passed in the laying of worker-eggs, was explained by Huber. He conceived eleven months to be necessary to perfect the male eggs, and was of opinion that the arrangement of the eggs in the ovaries was such as to permit and even compel the retention of both male and royal eggs until they were fully matured. This idea seems to be confirmed by the ordinary course of things in the hive, but certain anomalous facts startingly contravene it. Huber himself found, that if a young queen had not the opportunity of proving fertile within twenty days of her birth, all her after-product consisted of drones, and drones alone; and, what is still more curious, he discovered that she began to produce these drones at the time when she should have laid worker-eggs, namely, within forty-six hours after fecundation. The gestation of eleven months seemed totally unnecessary in such cases of retarded fecundation. Huber confessed himself incapable of explaining this remarkable circumstance. Though we do not understand it, however, it only tends to make us marvel more and more at the perfection of order in the bee economy. The queen-bee is never voluntarily guilty of that breach of the laws of her being which produces such remarkable effects; and, if artificially confined till she is twenty days old, her violent agitation shows her sense of the departure from the order of nature into which she is forced.

The raising of workers and drones from the egg to the insect state is a simple matter in comparison with the same transition in the case of queen-bees. The royal eggs, which the queen begins to lay twenty days after she has commenced the deposition of male ones, differ in no respect from common eggs. But on the royal larva, when it breaks from its three days' confinement in the shell, the nurses bestow peculiar attentions. They watch it incessantly, and feed it with a rich *jelly*, slightly acescent, and given in such quantities that the royal cell is usually wet with it. In five days the young majesty of the hive has grown, so as prepared to spin its web, and the bees wax up the cell. The cocoon is spun in twenty-four hours; two days and a half of inactivity follow; the larva is then transformed into a pupa, or a *nymph*, as the insect in this state is more often called; and, after other four or five days have passed, the royal insect is complete, the whole time occupied in the metamorphosis being sixteen days.

Young Queens.

We have now arrived at one of the most extraordinary points in the history of the hive. The young queen, or rather queens, do not issue from their cells when perfect, like workers and drones. They are not permitted, unless the old or regnant queen has quitted the hive with a swarm, or the seat of royalty is in any other way vacated. They therefore close the royal cells more firmly, leaving only a small aperture to introduce food; and, acting as if aware that they may need a queen in case of swarming, they at such times will not permit the old queen to approach the cells. Her struggles to do so are often violent, and her dire hostility to her own sex leads her, if she gets near the cells, to destroy them instantly, whether in the state of full insect or nymph. The strength of this instinctive hate is even such, that a young queen no sooner leaves her own cell than she feels its stirrings.

According to Huber, there can only be a single queen in a hive. The mere offspring of two could scarcely coexist in the same hive; and it is wonderful to observe by how many accessory circumstances nature has ensured the death of one or other of any two placed in the same community. The first thought of a young queen, it has been seen, is to kill her yet undeveloped rivals. Nature has given her the chance, for, as more queen-eggs than one are seldom laid daily, one is usually the oldest. If, however, two do quit the cell at the same instant, they rush into combat with the most headlong fury. If a stranger enters a hive, its queen-regnant flies to the field without a moment's hesitation. In short, in all ordinary circumstances, two queens, brought into contact, fight. But they might *both* die in the contest, and the community be left without a queen. Nature demands but one victim, and she has arranged that but one victim shall fall. Bees are only vulnerable in the belly; and Huber observed that, whenever two royal combatants were so locked together that they could mutually plant their stings in the fatal part, their instinct caused them to separate precipitately without harm on either side. The combat only closes when one can get an advantage of position, and kill its rival with safety. Again, the worker-bees might interpose to prevent these mortal combats. On the contrary, their instinct is to prevent the queens from parting, and force on a fatal issue. Alluding to one battle, Huber says that it seemed as if 'the bees anticipated the combat in which these queens were about to engage, and were impatient to behold the issue of it, for they retained their prisoners only when they appeared to withdraw from each other; and if one less restrained seemed desirous of approaching her rival, all the bees forming the clusters gave way to allow her full liberty for the attack; then if the queens testified a disposition to fly, they returned to enclose them." Another remarkable provision for ensuring the existence of but one queen in a hive, is beheld in the peculiar mode in which the royal larvæ spin their cocoons. Other bees spin perfectly close cases; the queen-larvæ spin cocoons which envelop only the head, thorax, and first ring of the abdomen, leaving a part open behind. Huber thus explains this minute but important peculiarity:—"Of several royal nymphs in a hive, the first transformed attacks the rest, and stings them to death. But were these nymphs enveloped in a complete cocoon, she could not accomplish it. Why? Because the silk is of so close a texture, that the sting could not penetrate, or if it did, the barbs would be retained by the meshes of the cocoon, and the queen, unable to retract it, would become the victim of her own fury. Thus, that the queen might destroy her rivals, it was necessary the last rings of the body should remain uncovered; therefore, the royal nymphs must only form imperfect cocoons. You will observe that the last rings alone should be exposed, for the sting can penetrate no other part; the head and thorax are protected by connected shelly plates which it cannot pierce. Hitherto, philosophers have claimed our admiration of nature in her care of preserving and multiplying the species. But from the facts I relate, we must now admire her precautions in exposing certain individuals to a mortal hazard." Examining further into the causes of the open cocoon of the royal nymphs, Huber came to the conclusion that it arose from the figure of their cells, and was designed for the purpose of exposing them to the certainty of destruction.

Loss of a Queen.

If bees, by death or artificial means, are deprived of their queen, the event has a marked influence in the hive. We do not allude to the case in which a stranger kills the queen-regnant; for if such a thing happens, as naturalists conceive it scarcely ever can do under natural circumstances, on account of the wariness of the bees to prevent intrusion, the victorious stranger mounts the vacant throne, and reigns in peace. We refer, however, to the removal of a queen without the introduction of any other. In such a case, the following results ensue, according to Huber:*—"Bees do not immediately observe the removal of their queen; their labours are uninterrupted; they watch over the young, and perform all their ordinary occupations. But in a few hours, agitation ensues; all appears a scene of tumult in the hive. A singular humming is heard; the bees desert their young, and rush over the surface of the combs with a delirious impetuosity. Then they discover their queen is no longer among them. But how do they become sensible of it? How do the bees on the surface of the comb discover that the queen is not on the next comb? It is supposed that the alarming intelligence of the loss is communicated by the strokes on the antennæ, which bees are uniformly observed to give to each other at these times. The insects then appear to seek for their lost queen, some rushing hurriedly out to make the search abroad. At the end of five hours, the commotion greatly ceases, and an instinctive recourse to the means of supplying the vacancy takes place. If they have royal larvæ, they turn their whole attention to them. If they have only the larvæ of working-bees, they immediately select two or three of them, pull down the neighbouring cells at the cost of the lives of the young within them, and construct a royal cell around each of the selected larvæ—the consequence of which proceeding will be immediately explained. If they have no larvæ at all on the loss of their queen, still they build several royal cells, as if so far at least to supply the emergency. If a stranger queen be introduced in such a state of things, within twelve hours after the loss of their own sovereign, the new-comer is treated as an intruder, and the bees surround her so closely that she commonly dies from privation of air, suffocation being the resource of bees in such cases. If the stranger be introduced within eighteen hours, they also surround her, but leave her sooner. To show that they possess memory, it is only necessary now to re-introduce their own queen, when they will show every symptom of recognition and joy. But their memory is short-lived, for, if the stranger be not introduced till twenty-four hours elapse, she receives a treatment very different from that experienced at an earlier period. "I introduced," continues the ingenious naturalist, "a fertile queen, eleven months old, into a glass hive. The bees were twenty-four hours deprived of their queen, and had already begun the construction of twelve royal cells. Immediately on placing this female stranger on the comb, the workers near her touched her with their antennæ, and, passing their trunks over every part of her body, they gave her honey. Then these gave place to others that treated her exactly in the same manner. All vibrated their wings at once, and ranged themselves in a circle around their sovereign. Hence resulted a kind of agitation which gradually communicated to the workers situated on the same surface of the comb, and induced them to come and reconnoitre, in their turn, what was going on. They soon arrived; and having broke through the circle formed by the first, approached the queen, touched her with the antennæ, and gave her honey. After this little ceremony they retired, and, placing themselves behind the others, enlarged the circle. There they vibrated their wings, and buzzed without tumult or disorder, as if experiencing some very agreeable sensation. The queen had not yet left the place where I had put her, but in a quarter of an hour she began to move. The bees, far from opposing her, opened the circle at that part to which she turned, followed her, and formed a guard around. She was oppressed with the necessity of laying, and dropped her eggs. Finally, after an abode of four hours, she began to deposit male eggs in the cells she met with.

"While these events passed on the surface of the comb where the queen stood, all was quiet on the other side. There the workers were apparently ignorant of a queen's arrival in the hive. They laboured with great activity at the royal cells, as if ignorant that they no longer stood in need of them: they watched over the royal worms, supplied them with jelly, and the like. But the queen having at length come to this side, she was received with the same respect that she had experienced from their companions on the other side of the comb. They encompassed her, gave her honey, and touched her with their antennæ; and, what proved better that they treated her as a mother, was their immediately desisting from work at the royal cells: they removed the worms, and devoured the food collected around them. From this moment the queen was recognised by all her people, and conducted herself in this new habitation as if it had been her native hive."

Making of a Queen

If one queen is not so introduced to supply the loss of another, and no royal larvæ exist, one of the most

* In this article we refer very frequently, it will be perceived, to Huber. The truth is, an examination of many late works has proved to us that in their best parts, they give but a transcript of his views and experiments. This is no reproach, being a natural consequence, merely, of Huber's wonderful acuteness and accuracy. Our quotations are made from a well-executed translation, published at Edinburgh by Mr. John Anderson, in 1806

wonderful phenomena of the hive takes place. It has been stated that bees, on losing their queen, build a royal cell around an ordinary worker-bee larvæ, or several of them, if the larvæ are abundant. These, by peculiar feeding, are formed and developed into *queens*, thus proving that the worker-bees, commonly viewed at one time as neuters, are in reality undeveloped females. This remarkable discovery was made by Schirach. Having used smoke about a hive, he so annoyed the queen that she flew away, and the circumstance of the bees immediately building royal cells around common larvæ, when they had no royal larvæ, revealed to him the truth. Huber proved the same thing by the succeeding experiment:—"I put some pieces of comb, containing worker's eggs in the cells, of the same kind as those already hatched, into a hive deprived of a queen. The same day several cells were enlarged by the bees, and converted into royal cells, and the worms supplied with a thick bed of jelly. Five were then removed from these cells, and five common worms, which, forty-eight hours before, we had seen come from the egg, substituted for them. The bees did not seem aware of the change; they watched over the new worms the same as over those chosen by themselves; they continued enlarging the cells, and closed them at the usual time. When they had hatched on them seven days, we removed the cells to see the queens that were to be produced. Two were excluded, almost at the same moment, of the largest size, and well formed in every respect. The term of the other cells having elapsed, and no queen appearing, we opened them. In one was a dead queen, but still a nymph; the other two were empty. The worms had spun their silk cocoons, but died before passing into their nymphine state, and presented only a dry skin. I can conceive nothing more conclusive than this experiment. It demonstrates that bees have the power of converting the worms of workers into queens, since they succeeded in procuring queens by operating on the worms which we ourselves had selected." This curious provision seems intended to preserve the communities of bees, in any emergency, from the danger of wanting that all-important member, the queen; and it is reasonably conjectured that the evolution of a queen from a worker-larvæ is dependent on the effects of the royal food upon the ovarian system.

Fertile Worker-Bees

Another most remarkable fact observable in the economy of the hive was discovered by M. Riem. Common worker-bees, that naturalist proved, sometimes lay fertile eggs. It was reserved for Huber to determine this, and also to explain the cause. He in the first place found that, in a hive deprived of its queen, the eggs of drones were laid. Though he did not put faith in what had been said by some naturalists respecting the existence of *small* queens, he nevertheless satisfied himself, by directing a careful examination to be made of each individual bee in the hive, that no queen was among them, every one having the little basket on the hind leg, and a straight sting. Thus convinced of the reality of Schirach's discovery, Huber, having detected several workers laying eggs, examined them, and found the ovaries partially developed. He now bethought him that the only known cause of such development is the use of the food or jelly given to the royal larvæ. Led into this train of thought, he speedily discovered that all the fruitful worker-bees are born in hives where no queen exists, and where worker-larvæ are transformed to queens; and he further found that they are always born in cells adjacent to those of the larvæ-queens. Continued investigation brought him to the belief, finally, "that when bees give the *royal treatment* to certain worms, they either by accident or by a particular instinct, the principle of which is unknown to me, drop some particles of royal jelly into cells contiguous to those containing the worms destined for queens;" whence the expansion of the ovaries to a certain degree. That expansion is imperfect. As in the case of retarded fecundation in queens, the fruitful worker-bees produce nothing but drones. In this fact, it seems to us, may possibly be found the principle of the unexplained instinct in question. May the instinct which leads them to create queens from worker-larvæ, not also prompt them so to dispense the royal food to common larvæ as to supply the hive with new drones for the new queens? This end is at least gained by the mode in which the worker-bees become productive. Ovaries, in a rudimental state, have been found by late observers in all working-bees.

Mutilations of Queens.

Before leaving the particular subject of queens, the remarkable effects of mutilations upon them may be mentioned. Huber cut off one antenna from a queen, without any marked effects; but when he cut off both, the case was different. "From this moment there was a great alteration in her conduct. She traversed the combs with extraordinary vivacity. Scarcely had the workers time to separate and recede before her; she dropped her eggs without taking care to deposit them in any cell. The hive not being very populous, part was without combs. Hither she seemed particularly earnest to repair, and long remained motionless. She appeared to avoid the bees; however, several workers followed her into this solitude, and treated her with the most evident respect. She seldom required honey from them, but, when that occurred, she directed her trunk with an uncertain kind of feeling, sometimes on the head and sometimes on the limbs of the workers, and if it did reach their mouths, it was by chance. At other times she returned upon the combs, then quitted them to traverse the glass sides of the hive: and always dropped eggs during her various motions. Sometimes she appeared tormented with the desire of leaving her habitation. She rushed towards the opening, and entered the glass tube adapted there; but the external orifice being too small, after fruitless exertion, she returned. Notwithstanding these symptoms of delirium, the bees did not cease to render her the same attention as they ever pay to their queens, but this one received it with indifference. All that I describe appeared to me the consequence of amputating the antennæ." Another similarly mutilated queen was placed beside her; they had both lost their combativeness. Finally, on being again left alone, the poor mutilated queen quitted the hive, unheeded, and abandoned to her fate. This evidence of the high value of the antennæ was gained on the whole in a manner which even a Huber's ardour for science can scarcely excuse.

Massacre of the Drones.

Another of the great natural phenomena of the hive is the massacring of the drones. It was at one time asserted that the worker-bees did not use their stings against the stingless males, but merely pushed them out to die; this idea, however, resulted from the massacre being always committed at the bottom of the hive whither the poor drones retire in clusters in July and August, as if aware of the doom impending over them. As usual, by one of his ingenious expedients, Huber discovered the truth. Six swarms were put on glass tables, beneath which the watchers placed themselves. "This contrivance succeeded to admiration. On the 4th of July, we saw the workers actually massacre the males, in the whole six swarms, at the same hour, and with the same peculiarities. The glass table was covered with bees full of animation, which flew upon the drones as they came from the bottom of the hive; seized them by the antennæ, the limbs, and the wings, and after having dragged them about, or, so to speak, after quartering them, they killed them by repeated stings directed between the rings of the belly. The moment that this formidable weapon reached them was the last of their existence; they stretched their wings and expired. At the same time, as if the workers did not consider them as dead as they appeared to us, they still struck the sting so deep that it could hardly be withdrawn, and these bees were obliged to turn round upon themselves before the stings could be disengaged.

Next day, having resumed our former position, we witnessed new scenes of carnage. During three hours, the bees furiously destroyed the males. They had massacred all their own on the preceding evening, but now attacked those which, driven from the neighbouring hives, had taken refuge among them. We saw them also tear some remaining nymphs from the combs; they greedily sucked all the fluid from the abdomen, and then carried them away. The following days no drones remained in the hives.

These two observations seem to me decisive. It is incontestible that nature has charged the workers with the destruction of the males at certain seasons of the year. But what means does she use to excite their fury against them? This is a question that I cannot pretend to answer. However, an observation that I have made may one day lead to the solution of the problem. The males are never destroyed in hives deprived of queens; on the contrary, while a savage massacre prevails in other places, they there find an asylum. They are tolerated and fed, and many are seen even in the middle of January. They are also preserved in hives, which, without a queen properly so called, have some individuals of that species that lay the eggs of males, and in those whose half-fecundated queens, if I may use the expression, propagate only drones. Therefore, the massacre takes place in none but hives where the queens are completely fertile, and it never begins until the season of swarming is past."

Swarming.

We have now only another of the great natural operations of the hive to advert to, before coming to the consideration of the artificial provisions which have been discovered and employed by man for augmenting the usefulness of this interesting insect. Swarming is the operation referred to, which usually takes place, in temperate climes, in May and June, though additional swarms, and swarms from swarms, are commonly later. In noticing the proceedings of a community from its first settlement, it was mentioned that the old queen led off the first swarm, and did so as if under alarm at the number of royal embryos, usually from twelve to twenty, which were in progress to maturity, and which the worker-bees would not allow her to approach. Other causes also operate, beyond doubt, in a certain degree. The increased heat of the hive from crowding, for example, in all likelihood influences the movement. Bees cannot do without freedom of respiration and fresh air, and it has surprised many observers to find the air usually pure, and below 80 degrees, in a hive ordinarily filled. The insects, however, have been discovered to manage this by active ventilation in their own way. A number of them are always to be seen near the inner, and sometimes the outer side of the opening of the hive, vibrating their wings with great rapidity, and sending the entering air backwards in a smart current. One band relieves another at this task. These means of ventilation, however, seem to become comparatively ineffective when the hive gets over-crowded. The heat often rises to about 100 degrees, the bees are driven to the door in clusters, while the warmth makes the hive visibly moist. At the same time, the old queen's alarm at the growth of the royal young seems to have its influence. She would fain kill them, but the worker-bees lose all respect for her, biting and beating her off with violence. The way in which they defend the royal young at swarming time is indeed most remarkable. If, at any other season, they bring up queens from worker-larvæ, the first queen that leaves the cell is allowed to kill the rest at pleasure. But when casting colonies, the workers, as if from the sense that various swarms may be cast off, and various queens required, will not permit the old queen to touch the young, whom nature has given them the strange power of keeping alive, for better security, in their cells. Nor will they allow the first young one to whom they grant freedom to touch the rest. Huber illustrates this subject beautifully. Suppose an old queen to have left a very populous hive, as described with a swarm. "After the departure of the colony, the remaining workers set another queen at liberty, and treat her with equal indifference as the first. They drive her from the royal cells; she also, perpetually harassed, becomes agitated, departs, and carries a new swarm along with her. In a populous hive this scene is repeated three or four times during the spring. The number of bees being then so much reduced, they are no longer capable of preserving a strict watch over the royal cells several females are therefore enabled to leave their confinement at once; they seek each other, fight, and the queen at last victorious reigns peaceably over the republic.

"The longest intervals we have observed between the departure of each natural swarm have been from seven to nine days. This is the time that usually elapses from the period of the first colony being led out by the old queen until the next swarm is conducted by the first young queen set at liberty. The interval between the second and third is still shorter; and the fourth sometimes departs on the day after the third. In hives left to themselves, fifteen or eighteen days are usually sufficient for the throwing of the four swarms, if the weather continues favourable, as I shall explain.

"A swarm is never seen except in a fine day, or, to speak more correctly, at a time of the day when the sun shines and the air is calm. sometimes we have observed all the precursors of swarming—disorder and agitation—but a cloud passed before the sun, and tranquillity was restored; the bees thought no more of swarming. An hour afterwards, the sun having again appeared, the tumult was renewed; it rapidly augmented, and the swarm departed.

"Bees generally seem much alarmed at the prospect of bad weather. While ranging in the fields, the passing of a cloud before the sun induces them precipitately to return. I am led to think that they are disquieted by the sudden diminution of light. For if the sky is uniformly obscure, and there is no alteration in clearness or in the clouds dispelling, they proceed to the fields for their ordinary collections, and the first drops of a soft rain do not make them return with much precipitation.

"I am persuaded that the necessity of a fine day for swarming is one reason that has induced nature to admit of bees protracting the captivity of their young queens in the royal cells. I will not deny that they sometimes seem to use this right in an arbitrary manner. However, the confinement of the queen is always longer when bad weather lasts several days together. Here the final object cannot be mistaken. If the young females were at liberty to leave their cradles during those bad days, there would be a plurality of queens in the hive, consequently combats; and victims would fall. Bad weather might continue so long that all the queens might at once have undergone their last metamorphosis, or attained their liberty. One victorious over the whole would enjoy the throne; and the hive, which should naturally produce several swarms, could give only one

Thus the multiplication of the species would have been left to the chance of rain or fine weather, instead of which it is rendered independent of either by the wise dispositions of nature. By allowing only a single female to escape at once, the formation of swarms is secured. This explanation appears so simple, that it is superfluous to insist farther on it."

Our author adds, that another important circumstance resulting from the captivity of queens is, that they are in a condition to fly when the bees have given them liberty, and are therefore capable of profiting by the first moment of sunshine to depart at the head of a colony.

Dangers during Swarming.

The capture of the queen, when a swarm has settled on some bush or tree, is, it should be added, the first step towards lodging a swarm in a new hive. If she be placed in it, with two or three bees, the rest will soon follow. A strong glove will enable any one to handle the bees without risk, as they are less disposed to sting when they are swarming than at other times. It sometimes happens, however, that a swarm may settle on the person of any individual who may be near it, in which case presence of mind is absolutely necessary for the preservation of life. The following anecdote, related by Thorley, is strikingly illustrative of what has now been advanced:—

"One of my swarms settled among the close twisted branches of a codling tree; and not to be got into a hive without help, my maid-servant being in the garden, offered her assistance to hold the hive while I dislodged the bees. Having never been acquainted with bees, she put a linen cloth over her head and shoulders to guard and secure her from their swords. A few of the bees fell into the hive, some upon the ground, but the main body upon the cloth which covered her upper garments. I took the hive out of her hands, when she said that the bees had got under the covering, and were crowding up towards her breast and face, which put her in a trembling posture. When I perceived the veil was of no farther service, she gave me leave to remove it. This done, a most affecting spectacle was presented, filling me with the deepest distress and concern, as I thought myself the unhappy instrument of drawing her into so imminent hazard of her life. Had she enraged them, all assistance had been vain, and nothing less than her life would have atoned for the offence. I used all the arguments I could think of, begging her, with all the earnestness in my power, to stand her ground, and keep her present posture. The bees had now got in a great body upon her breast, about her neck and up to her chin, and I began to search among them for their queen. I immediately seized her, taking her from among the crowd, along with some of the commoners, and put them together into the hive. Here I watched her for some time; and as I did not observe that she came out, I conceived that the whole body would quickly abandon their settlement; but instead of that, I soon observed them gathering closer together, without the least signal for departing. Upon this I immediately reflected that either there must be another sovereign, or that the same was returned. I directly commenced a second search, and in a short time, with a most agreeable surprise, found a second or the same. She strove, by entering farther into the crow , to escape me; but I re-conducted her, with a great number of the populace, into the hive. And now the perilous scene began to change to one indefinitely more pleasing and agreeable. The bees, missing their queen, began to dislodge and repair to the hive, crowding into it in multitudes, and in the greatest hurry imaginable; and in the space of two or three minutes the maid had not one single bee about her, neither had she so much as one sting, a small number of which would quickly have stopped her breath."

ARTIFICIAL MANAGEMENT OF BEES.

The artificial management of bees forms, in some measure, a branch of the present subject perfectly distinct from the consideration of the natural operations of bees, of their various classes, of the phenomena attending their transformation, and of their social economy in general. Many able writers of recent days have given to the public their experience of the best modes of preserving these insect communities, and rendering them most productive. And, in the first place, the local situation of an apiary, or accumulation of beehives, has been held of especial consequence.

Site of Apiaries.

The hive must be sheltered in a particular manner from the action of high winds. A wall or hedge is not sufficient to yield the requisite protection; houses or lofty trees are necessary to insure it. The reason of this is, that the bees, returning homewards, require a calm air at a considerable height above their dwellings, otherwise, when they attempt to alight, they are dashed to the ground and killed, their exhausted strength disabling them from coping with a wind of any force. A low position, enclosed with woods, suits them best. Bees drink much, and a fountain or brook is essential to them; deep pools or cisterns very often cause their death by drowning. Shallow troughs, filled with moss or floating wood, are recommended as a substitute for shallow rills. It is an error, according to the experienced bee-keeper De Gelieu, to suppose that hives should be placed full in the sun. Bees, he says, live and thrive in shady places of moderate and uniform temperature, and hence their partiality for forests. Besides, exposure to all the extremes of the solar heat melts and spoils the honey. At least, if exposure to the sun be beneficial at all, that exposure should last only for a comparatively short time, or from about ten o'clock till noon. Hives should not be placed on upper floors, on account of the increased danger from wind. At the same time, a bee-house ought to be so made as to cause a free passage of air, though not of strong currents, at all periods, with openings both anteriorly and posteriorly. A covered shed or verandah is perhaps the best form of a bee-house, yielding both a shade and shelter from the wet. Where hives are simply placed on open stands, these should be about sixteen inches from the ground, and each three or four feet apart. Shifting is condemned by almost all bee observers as very hurtful to the bees.

Hives.

The important question of the size, form, and materials of the hive, has of course received much attention. Whatever be the form of hive adopted, it is found that bees accommodate their labours to it, and fashion their combs of honey accordingly.

Straw hives, or *skeps*, as they are called in Scotland, of which a sketch is afforded by our frontispiece, are the hives most commonly used in cottage-gardens; and being easily and cheaply constructed, they still maintain their place, though much better habitations could be suggested. They are of a roundish form, ordinarily measuring about twelve inches deep and nine inches wide in the lower part. Made of unbroken rye-straw, or any other straw of a strong and elastic fibre and well bound, they will, if tolerably well sheltered, last many years. It is customary to place sticks across the interior, from an idea that such are necessary for supporting the combs; but Mr. Taylor, in his *Bee-Keeper's Manual*,* combats this opinion. "The sticks," observes that intelligent writer, "are only an annoyance to the bees; and there is little fear of the combs falling, except in

* This is a valuable practical treatise, which it affords us pleasure to recommend. It was published by R. Groombridge, Paternoster Row, London, in 1839.

very deep hives: at any rate it may be prevented by contracting the lower part a little. The best way of doing this is by working a wooden hoop inside the bottom band of the hive, as recommended by Dr. Bevan, who says, 'It should be perforated through its whole course, and the perforations made in an oblique direction, so distant from each other as to cause all the stitches of the hive to range in a uniform manner.' The hoop gives greater stability to the hive, preserves the lower edge from decay, and affords facility in moving it. I advise a circular piece of wood (turned with a groove at the edge, to retain it in its place) to be worked into the crown, having through it an inch and a half hole. With a little ingenuity, the bees may be fed through this opening—a better method than the ordinary one at the bottom of a hive. A piece of wood or tin will commonly cover the hole; but at times, and especially in winter, it may be used for the purpose of ventillation, and allowing escape to the impure air of the hive. In this case, a bit of perforated tin or zinc should be placed over it, which, when stopped up by the bees, can be replaced by a clean one. An earthen pan is a common cover to a straw hive, and this may be slightly raised by wedges on the four sides, to permit a small space underneath. Of whatever material the outer covering consists, it must project so far on all sides as to protect the hive from the least moisture. This cannot be too much guarded against; and whether of wood or straw, all hives ought to be well painted at the beginning, and periodically afterwards."

Wooden Hives.—These are superior to straw skeps, the square shape being better adapted for the deposit of combs than the round form. Mr. Taylor's observations may be likewise quoted on this important point. "It matters not much of what wood the boxes are made, provided it is sound, thoroughly seasoned, and well put together. Different opinions are entertained as to the best size of bee-boxes, but I think that much must depend on the number of bees they are to contain, and on the honey locality; there must also be a reference to the proposed mode of working them; for, where no swarming is permitted, a larger hive may be advantageously used. A good size is twelve inches square, and nine inches deep withinside; the thickness throughout being not less than an inch. The top of the box ought to project on all sides nearly three-quarters of an inch, for better protection and appearance, and as affording convenience for lifting. On the top a two-inch hole should be cut in the centre, for placing a bell-glass, and for the purpose of feeding; and another hole to receive a ventillator may be made near the back window, that position being better for inspection, and less in the way of the bees, than the centre of the hive, which is, or ought to be, the seat of breeding, and should not be disturbed. A window may be placed at the back and front, five inches high and six or seven inches wide. The best and neatest way of securing the windows that I have seen, is by a sliding shutter of zinc. Round the window there must be a projecting moulding, mitred at the corners. On one side the piece of moulding is movable, and to the back of this is screwed a plate of sheet zinc. This passes into a rabbet to receive it, cut, on the remaining three sides, at the back of the lower edge of the moulding. To prevent any wet from lodging at the bottom moulding, an opening or two may easily be cut through, on the under side, to allow its escape. For the sake of uniformity of appearance, blank windows may be made opposite to the real ones. Hives of this kind require to be placed under some cover or shed, as a protection from wet and a hot sun."

To these explanations it should be added that the hive of either form must be placed on a clean wooden floor or board; and if there be several hives together, each should have its own separate floor. Do not cement the hives to the board, that being a duty which the bees will themselves perform; all that may be given is a slight luting of clay, or any easily removable material. The entrance to the hive requires to be small, a little larger than a shilling, but rather wider than deep, and ought to be at the lower edge of the hive, on the side which is exposed. Numberless have been the plans invented to enlarge hives as they may be required, both to permit of the greater accumulation of honey, and to render swarming unnecessary. Capes or hoods are the simplest of these inventions. In order to use capes, hives must have a stoppered hole at the top. A small additional hive of light structure is placed over this at the proper time, the stopper being removed. This serves as a second magazine for honey. Storyed hives are merely hives made originally with one or two storys, for the same end. Wildman's hive, the Grecian hive, and Lombard's hive, are specimens of hives made on this principle. Collateral hives, again, such as Nutt's, effect the same ends by being placed side by side, and giving increased accommodation, when necessary, either for swarms or stores. But of all such hives, our readers will probably prefer to know the one used by Huber. We quote an account of it given in the *Naturalist's Library*. Huber's leaf-hive, as he called it, "consists of eight frames, each 18 inches high [a height of 14 inches is preferable] and 10 inches wide inside, having the uprights and top cross pieces one and a half inch broad, and one thick, so that the eight frames, when placed close together, constitute a hive 18 inches high, 12 inches between end and end, and 10 inches between back and front, all inside measure. The frames are held together by a flat sliding-bar on each side, secured by wedges and pins. To the first and eighth of these frames is attached a frame with glass, and covered with a shutter. The body of the hive is protected by a sloping roof, and the entrance is made through the thickness of the floor-board. We dislike the sliding-bars, with their pins and wedges, which are so far inconvenient, that in drawing them out, all the frames are liable to open, and the observer is exposed to some hazard of annoyance, from the bees issuing out at every joint; and we have substituted for them hinges on one side, and a hook-and-eye on each frame on the other; we can thus open any particular leaf without meddling with the rest. In taking honey from this hive, the bee-master has the whole interior completely under his eye and at his disposal, and can choose what combs best suit his purpose, both as to quantity and quality; taking care, however, to do so only at such periods as will leave the bees time to replenish the vacancy before the termination of the honey season. It is also well adapted for artificial swarming. By separating the hives into halves, the honey, brood-combs, and bees, will, generally speaking, be equally divided; and by supplying each half with four empty frames, we shall have two hives, one half empty, equal in number of bees, of brood, and even of stores. One of the new hives will possess the queen; and if the operation has been performed at the proper time—that is to say, a week or ten days before the period of natural swarming—the probability is, there will be royal brood coming forward in the other; at all events, there will be plenty of eggs and larvæ of the proper age for forming an artificial queen."

Use of Capes.—It will be observed from these quotations, that experienced apiarians, who work on a large scale, now employ, for the most part, hives so contrived as to remedy all the inconveniences resulting from the straggling of swarms and the old custom of killing by brimstone. As the use of single straw hives, however, formed upon the simplest plan, still prevails among those who have but one or two hives in all, the cape may be regarded as the easiest means of affording enlarged accommodation in such cases, and the mode of taking away the honey from it is very plain and easy. It is only necessary to remove the cape, invert it, and cover it with a handkerchief, leaving a little opening on one side. A few taps will cause the bees to quit the cape and return to the hive, after which the honey can of course be readily removed. This may be done frequently in the same season. De Gelieu mentions that in one season he drew from one of his straw hives that did not swarm seventy-two pounds of fine honey-comb, by merely emptying the capes as they were filled.

Union of Swarms.

It is strongly recommended by experienced men, that swarms should be more often united than they are. Five thousand bees are estimated to weigh a pound; and, according to most bee-keepers, a swarm ought to weigh nearly four pounds. As a hive often casts off successive colonies, each far below this weight, it then becomes proper to unite two or more of them; seeing that one strong population supports itself better, and is incomparably more profitable, than several feeble colonies, which must be frequently in want of assistance. To those who keep bees on a small and cheap scale, convenience also dictates the junction of swarms in such cases. De Gelieu thus describes his mode of practice:*—"When two small swarms come off the same day, I gather them separately, and leave them at the foot of the tree or bush on which they have alighted. Towards evening I spread a table-cloth on the ground, on which, by a smart and sudden movement, I shake all the bees out of one of the hives, and immediately take the other and place it gently over the bees that are heaped together on the cloth, and they instantly ascend into it, flapping their wings, and join those which, not having been disturbed, are quiet in their new abode. Early next morning I remove this newly united hive to the place it is destined to occupy. This double population works with double success, and in the most perfect harmony; and generally becomes a powerful colony, from which a great profit is derived. Two feeble swarms may be united after the same manner, although one of them may have come off some days later than the other, and the first may have constructed combs; taking care, however, not to make the first one enter the second, but the second the first, as the bees will ascend more readily to join those that have already begun to make honey and to hatch brood; and next day they will proceed together with increased ardour with the work which the first had already begun, and which will now advance more rapidly from the increase of the labourers. It is to be understood that, after this union, the hive should be placed early next morning in the same place where the oldest of the swarms has already passed some days." On many occasions, the circumstance of two queens passing out at once is the cause of a colony going off in two halves, and the removal of one of the queens is necessary, to facilitate the cordial junction into one community. Artificial swarming may be effected by expelling a body of bees, and lodging them in a new hive with a quantity of comb removed with them. Tobacco smoke is used for the expulsion.

Summer Management of Bees.

The feeding of bees at different seasons is an important point to the bee-keeper. In summer they feed themselves, and of course a good supply of the requisite material is then essential to their well-doing. The most highly cultivated districts are not so favourable to bees as those in which wild heaths, commons, and woods prevail; or where white clover, saint-foin, buck-wheat, mustard, and cole-seed, are produced in abundance. Bee-keepers, however, may do something to further the supply of summer food. Mr. Payne recommends the planting of quantities of the common kinds of crocus, single blue hepaticas, black hellebore, and some other early flowering plants. Various kinds of thyme and mignonette may be grown to purpose, and the bees are especially fond of the salvia nemorosa and the snowberry plant. But on the natural products of the country, generally speaking, bees must rely for summer food, if the weather be such as to permit of their gathering it. Should a succession of coarse bad weather occur, however, at the beginning of summer, and particularly after a swarm has entered a new hive, most apiarians think it essentially necessary to give honey, or syrup of sugar and water, to the newly hived stock. If no proper brook or fount be at hand, water should always form a part of the summer provision. The bees being at full work in this season, the door of the hive should be opened to its whole extent, and not closed, as is more or less requisite at other times. In the hives formed upon improved plans, ventilators constitute a part of the apparatus, and thermometers are introduced to regulate their use. Though these are valuable adjuncts certainly, they are not indispensable; seeing that the bees, as already mentioned, contrive to ventilate to some extent for themselves. Where artificial ventilation can be effected, it is recommended that the temperature should be maintained at from 65 to 80 degrees of Fahrenheit. It is recommended, on evenings when the moths are numerous, to place a small grating before the hive; and it will also be advisable to destroy any wasps, spiders, earwigs, or other insects settled near the hives.

Autumnal Management.

The autumnal period has long been the most calamitous for bees, not through the injuries of enemies or weather, but from the improper management of bee-keepers. After the carcasses of the drones, strewn in multitudes before the hive, have indicated that, with the beginning of August, has come the close of the rich honey season, the bee-keeper deems it time to take from the hive the reward of his care and attention. The use of storied hives or extra boxes, renders it easy to take away a portion of honey early in the season, and this is called *virgin honey*. Even with a common straw-hive, it has been found possible to take away the honey, and retain the bees in the hive. Wildman, the famous experimenter on bees, recommended that the hive should be taken into a dark room, and there struck repeatedly till the bees are forced to ascend into an empty hive. The combs are then cut out with a thin knife, and the bees finally returned to the old hive. But this plan is seldom pursued, being at once dangerous and destructive to the brood combs.

It is generally reckoned advantageous to change the pasturage for a week or two before taking the honey-harvest. About mid-autumn, the ordinary food of bees begins to fail and their stock of honey to decrease daily. By a removal of three weeks to a healthy district, a hive not only loses nothing, but frequently gains as much as ten or twelve pounds of honey in ordinarily favourable circumstances. So well is this known by bee-keepers near Edinburgh, that one shepherd on the healthy Pentland hills receives in charge several scores of hives annually, for the heath-feeding.

Honey-Harvest.

After the autumnal accession of honey has been obtained, and the bees have been brought home again, the question comes to be, in what manner the harvest should be reaped. By partially depriving each of a portion of comb, and leaving some for food? By suffocating one-half the communities, taking their entire honey, and leaving the other hives with their honey untouched, to serve as stock? Or finally, by removing the bees from

* The work we here quoted is entitled "The Bee Preserver;" translated from the French of Jonas de Gelieu, by a lady in Edinburgh, and published by John Anderson junior, Edinburgh, 1829.

one-half the hives to the other half, forming united stocks, and acquiring all the honey of the evacuated ones? These three plans are known by the several names of *partial deprivation* (commonly and most easily practised with improved hives, as already described), *suffocation*, and *union of stocks*. "The practice of partial deprivation," says the *Naturalist's Library*,* "has never yet become general, because it is liable to frequent failure, even in improved hives, and because the full benefit is not derived from it at the very commencement of the system. The liability to failure, the first of the objections stated, is owing, in most instances, not to the *mode*, but to the *period* of the operation. According to the too common practice of those who are friendly to deprivation, a portion of honey is abstracted from the hives about the beginning or middle of September; and the owner compliments himself on his moderation, in being content with a part instead of the whole, and on his humanity in saving the lives of his industrious favourites; while in nine instances out of ten he finds, on the arrival of March, that his moderation and humanity have been altogether unavailing, and that he has saved them from a violent death by suffocation, only to expose them to the more tardy but not less cruel death by starvation. Whereas, if deprivation take place soon after the swarming season, as already recommended, and is managed with discretion, the issue will be very different, and ultimately more profitable to the owner, than the almost universally practised mode by suffocation, which is too well known to need description. The latter system may yield a greater return in proportion to the hives operated upon; but in the former, there is a much greater number of hives available. For example, suppose two apiaries, each containing five stock-hives at the end of July, exclusive of as many swarms recently thrown. The owner of the one, practising the depriving system, takes from each of his stocks 10 pounds of honey, making an amount of 50 pounds as his honey-harvest. The owner of the other, and abettor of suffocation, proceeds in September to smoke his five old hives, and receives from each 25 pounds of honey, making an amount of 125 pounds as his honey-harvest—between two and three times the quantity of the other. In the following year, the depriver has his five old stock-hives, and the five swarms now become stock-hives; from the whole ten he now takes a hundred pounds of honey, while at the same time his apiary is augmented by the addition of ten new swarms, making twenty for the following year; while his rival possesses only his former number of five, yielding 125 pounds. In the next year, that is, two years from the commencement of the comparative trial, the depriver has twenty stock-hives, yielding 200 pounds, and so on by a geometrical ratio; while the other remains at his original 125 pounds. This calculation is made on the supposition that each owner takes but one swarm from each stock, and without making any allowance for losses and failures, which will affect the produce of both in honey and bees, but to which both are liable."

The writer of this comprehensive treatise proceeds to point out the advantages of the humane principle of sparing the lives of these useful insects. "It is pitiable to reflect, that the small degree of additional trouble required in uniting them, should prove so effectual an obstacle to this conservative practice. Yet the operation with each hive so treated, need not occupy more than fifteen or twenty minutes. In the evening, when all are quiet, turn up the hive which is to be operated upon, fixing it in a chair from which the stuffed bottom has been removed; place an empty hive above it, wrap a cloth round the point of junction, to prevent the bees from coming out and annoying the operator; then, with a short stick or stone in each hand, beat round the sides, but *gently*, for fear of loosening the combs. In five minutes, the panic-struck insects will hastily mount into the empty hive, with a loud humming noise, expressive of trepidation. The hives are then separated—that containing the bees is placed on its usual pedestal, and the other containing the honey is carried off. The union is next to be effected. Turn up the stock-hive which is to receive the addition to its population; with a bunch of feathers, or a small watering-pan, such as is used for watering flower-beds, drench them with a solution of ale and sugar, or water and sugar, made a little warm. Do the same to the expelled bees; and then, placing these last over the stock, mouth to mouth, a smart rap on the top of the hive will drive them down among the bees and combs of the undermost hive. Place this last on its pedestal, and the operation is completed. The strong flavour of the solution will prevent them from distinguishing between friend and stranger; and their first movement, after recovering from their panic, will be to lick the liquid from one another's bodies. This mode of operating is applicable to all kinds of hives." With regard to the two queens, one would assuredly kill the other in a very short time; but the best way is to remove one of them before union.

One argument employed by advocates of the plan of suffocation by introducing the fumes of brimstone or other noxious effluvia, is, that by the union of stocks, you have an immense number of mouths to feed, of which the killing plan relieves you. Only inexperienced bee-keepers, however, could use this reasoning. De Gelieu having discovered the remarkable fact, that the increase of numbers in the winter hives is far from producing a proportionate increase of consumption. From fifteen to twenty pounds of honey, or from three to four pots, are requisite for the winter maintenance of a single hive of ordinary strength, with which the plan of union has not been practised. De Gelieu placed such a hive, with such a store, beside one into which three full communities had been introduced, and he found, on weighing the latter in the spring, that its inhabitants had scarcely used one pound of honey more than those of the single-stocked hive. The experimenter even went further. To a hive already amply stocked, he added the swarms of four other hives, and found on weighing it in the spring, that "the total diminution of honey did not exceed three pounds more than took place in ordinary single hives." Had they not been thus united, he says, each of these stocks would have cost him much more money than they were worth, and, indeed, the most of them "would to a certainty have perished." The cause of this strange fact by which nature seems to point to the plan of autumnal unions as the best possible for both bees and bee-keepers, is yet unknown.

The combs, by whatever process procured, should be deprived of the honey at once, while a natural warmth remains in them. Various kinds of drainers have been used for separating the honey, and keeping it as much as possible from the external air. The honey which runs off naturally without breaking down the combs, and passes through muslin, is held to be the finest. A second kind is cured by cutting the combs in pieces, and letting the honey pass through a drainer, under exposure to a gentle heat. A third quality is procured by subsequently putting the combs in a vessel placed on a fire; the product, strained through canvas, is used in feeding bees. The separated wax of the combs is introduced into a woollen bag, firmly tied at the mouth, and put into boiling water. The pure wax oozes through, and is skimmed off the surface, where it floats. It is then to be allowed to cool slowly. The best honey is supposed to be that formed from heath. The famous bees of Hymettus were nourished by that plant.

* "Naturalist's Library," conducted by Sir William Jardine. Entomology vol vi.—*Bees*. Edinburgh: W. H. Lizars. 1840. This beautiful miscellany requires no panegyric from the writer of these pages.

Honey is used as condiment at the table, and is also employed in medicine. In ancient times in Britain, it formed the basis of a beverage called *Mead*, and from the common practice of drinking it for a month after a wedding, came the expression *honeymoon*. In course of time mead was superseded by beer, wine, and other liquors, but is still allowed by writers on diet to be wholesome as a drink, and certainly less pernicious than the ordinary kinds of intoxicating fluids. As some bee-keepers, to whom our pages are addressed, may wish to attempt the manufacture of mead for domestic use, we offer the following as one of the best methods for its preparation, from the Encyclopædia Britannica:—"Into twelve gallons of water put the albumen [or white] of six eggs, mixing these well together, and to the mixture adding twenty pounds of honey. Let the liquor boil an hour; and when boiled, add cinnamon, ginger, cloves, mace, and rosemary. As soon as it is cold, put a spoonful of yeast to it, and barrel it, keeping the vessel filled as it works; when it has done working, stop it up close; and when fine, bottle it off for use."

Winter and Spring Management.

In winter and early spring, bees require to be tended with great care. In the case of those hives which have been entirely deprived of their honey, systematic feeding is of course indispensable in winter; but few bee-keepers of any experience ever willingly follow any other plan than that of leaving to bees a winter supply of their own produce. Some bee-keepers remove their hives into the house in winter; but this is an unwise practice, as the bees must then be kept continually in confinement. Though the door of the hive should be carefully narrowed or shut up in very cold weather, at which time every bee that issues perishes, yet advantage should be taken of every fine day to let them abroad. Where feeding is necessary, the following rules have been laid down for the management of common hives in winter and early spring. Bees must be fed only when the weather is fine and warm, to prevent the temperature of the hive from being injured; and a large quantity should never be given at once, for the bees are so greedy of food, that they will rather fill the brood cells with it than relinquish their treasure. The quantity of food which ought to be given to a hive may be calculated in the proportion of two pounds a month; but if the weather be very cold, a less quantity will suffice. When a hive is fed in the spring, it should always be after sunset, when the bees have returned from the fields; otherwise the most disastrous consequences may ensue, from the robberies committed by the bees of other hives. If they are fed in the morning, it must be before sunrise, and the entrance instantly stopped to keep out depredators; for, as the bees leave the hive on the very first appearance of day-light, a later period would prevent the return of all those who had left the hive previous to the entrance being secured.

Relative to the substances which are proper for the feeding of bees, many different opinions exist; but the following may be considered among the most beneficial as well as economical articles of diet:—To two quarts of good ale put one pound of moist sugar; boil them until the sugar is wholly dissolved, carefully skimming it; when it is cold, it will be found of the consistency of honey, and it may be given to bees in the following manner:—If the bees are in the plain cottage hive, an eek of the same diameter as the hive must be provided, and from three to four hands in height. When the sun is set, and the bees have retired, let the hive be gently raised, and the eek placed on the stool; then, having filled a soup-plate with the food, place it on the eek, and put down the hive. To prevent the bees being drowned in the liquid, it is necessary to place some straws over the plate, and over the straws a piece of paper, either thickly perforated or cut into nicks; these nicks, however, must not run parallel with the straws, but either across or diagonally; the entrance must then be closed, and the plate removed on the following morning, and the whole of the liquid will be transferred into the combs.

Diseases and Enemies of Bees.

Bees, according to the conclusions of De Gelieu, after sixty-four years' experience, have "no real disease; they are always in good health as long as they are at liberty, and when they are warm enough, and have plenty of food." In early spring, however, they are found liable to an affection called dysentery, which is known by the marks on the board of dark-coloured evacuations, by the offensive smell, and by the frequent deaths. This disease certainly results, in most cases, from long confinement in a damp and impure air. By lifting the hive to expel the vitiated air, scraping, washing, and drying the board, and removi[illegible] the dead bodies, the complaint, says Mr. Taylor, [illegible] remedied even in the most extreme cases. [illegible]ved with honey and water, has been recom[illegible] a cure; but the experienced apiarian [illegible]ceives all dietetic remedies to do more [illegible]ood. A little chloride of lime, he suggest[illegible] beneficially in washing the board. One point [illegible]oticed here, that exposure to the sun is held [illegible] injurious to the hives in winter. This caution is necessary, as bee-keepers, when they suspect dampness, might fall into an error on this score.

A few of De Gelieu's hints respecting the chief foes of the bee-tribe may be useful to bee-keepers. After observing that the possessors of bees, often from an ignorant excess of care, are among their greatest enemies, he says—"Ants are their least dangerous enemies; true, the bees cannot sting them to death, because they are small and well defended with armour, but they seize hold of them with their teeth, and carry them to a distance. Had they not this means of getting rid of them, their colonies could not exist in the vast forests full of ant's nests, and where they thrive so well, in spite of the horrible massacres that annually take place.

"Moths are little known, and never injurious, in the high valleys, nor on the mountains; but they attack and destroy a vast number of hives in the plains or in the vineyards, where they are a great scourge. As soon as a moth has penetrated a weak hive, it establishes itself in a comb, envelopes itself in a silken web, multiplies rapidly, consuming the wax, and spreading its destructive galleries from side to side, until, arriving at a certain point, the evil has scarcely a remedy.

"The only means of saving the colony is to imitate the surgeon, who cuts off a diseased limb to save the other—every bit of infected comb must be cut out, leaving only those occupied by the bees. And the bees must then be liberally fed, by giving them every evening as much honey as will maintain them until the fields shall yield them a sufficient quantity. Thus I have preserved hives whose circumstances seemed to be desperate.

"Spiders annoy the bees much. The bees get entangled in their webs, and are not able to extricate themselves. Here cleanliness is the best protection; therefore care should be taken to sweep the webs away from the hive and its avenues as fast as they appear.

"Birds eat a prodigious quantity of bees, especially in spring, when the trees are in blossom; and the poultry, also, that roam about or near the water where the bees go to quench their thirst, gobble up a great many.

"Mice, especially the red mouse, or *sorex araneus*, sometimes penetrate a hive in the winter time, either from the entrance being left too wide, or by gnawing a hole for themselves in the straw. They eat the honey, and even the bees, when clustered together on the side of the hive,

in which position they are unable to defend themselves, and scarcely even see the enemy.

"Wasps are also reckoned among the numerous enemies of bees. I have, however, seldom seen a hive destroyed by wasps; although they are larger, stronger, and armed with a formidable sting, and an impenetrable cuirass, they seldom dare enter a well-stocked hive. Once attacked, they soon fall beneath the united efforts of these brave citizens, who sacrifice themselves to defend the place of their nativity. Wasps only appear in great numbers when the fruit is ripening, and then they range unceasingly round the hives, and enter the weak ones, or those of which the too spacious lodging bears no proportion to the number of its inhabitants. There are three ways of providing against the attacks of wasps. The first is, to unite weak hives by doubling or tripling the population, thereby enabling them to defend themselves. The second is, to contract the entrances as soon as the swarming time is over, after the massacre of the drones; and the third is, to destroy their nests.

"The bees are continually fighting between themselves, and robbing each other: avarice, not necessity, leads them to do so, it being almost always the strongest and best provisioned hives that pillage the weak ones. When once a bee has been able to introduce itself into a hive, and carry away a load of honey without being arrested, it will return a hundred times the same day; and, making it known to its companions, they will then come in hordes, nor cease their pillage till there is nothing left to take. In one day the whole of the honey will be carried off, and with a determination which one can scarcely have an idea of without seeing it. This kind of pillage is most frequent in the spring and autumn, and it is easier to prevent than to stop it; and, for this purpose, the entrance of the hives ought to be straitened in proportion to the population."

WILD BEES.

Besides the garden or hive-bees, as already mentioned, there are various other species of bees, which have never been domesticated by man, though many of them construct hives and produce honey. Of such of these wanderers of the wilds as are indigenous to Britain, it may be interesting, more especially to the young, to learn some brief particulars. The most common species of the wild or *humble* bee (*bombus*) is an insect at least double the size of the hive-bee, with a black head and body, having yellow rings crossing the latter anteriorily and superiorily, and white and black rings alternating at the posterior extremities.

Both on account of their peculiar habits and selected places of residence, this and another wild species called the moss bee, are unfitted for domestication. Few of them survive the rigours of winter, but one, a female, that does escape, manages, for a season, the resuscitation of the breed. Abroad, it flies in early, and, alone and unaided, sets laboriously to work in constructing its nest, piercing the earth or moss, as its instinct may be, and excavating a small chamber wherein to lay its eggs. It does not make wax and cells for the young. These come to maturity in the cocoons which they spin for themselves in the larva state; and when they emerge, these cocoons form stores for food. The solitary bee feeds alone in its earliest progeny, but these soon multiply around it, enlarge the cells, gather honey, and feed the increasing young. The wants of the young go on increasing for a great part of the summer, and the quantity of honey they consume is very large: towards the middle or latter part of September, however, the energies of the bees begin to wax fainter, and little further progress is made in adding to the colony, or in collecting honey. Cold and showery days begin, even by this time, to thin the number of the insect population, who are now seen creeping slowly, with damp and heavy wings, upon the stalks and petals of flowers, where they were formerly seen actively buzzing about in search of honey. The stores of the honey-cups have not outlasted the wants of the young unfledged bees, of which they were the proper food; and if the nests be examined now, these cups are found quite empty. The bees which survive the accidents of rain, cold, and frost (for they are now frequently overtaken by frosty nights in their languid journey homeward), by degrees forsake the nest and its furniture, leaving the latter a prey to mice, beetles, or other animals. To shelter themselves for the winter, they seek out some dry bank (not preferring one exposed to the sun), where they penetrate to the depth of eighteen inches or two feet into the earth, pushing up the earth behind them, and leaving no visible track by which they have descended. In these situations they are often found by labourers and others in digging the earth; and such people are often greatly puzzled to imagine how the insect can have reached such a depth. Persons who have attended to the habits of wild bees can often fix on the spots where they take refuge, digging for and finding them with the greatest certainty.

The experiment of domesticating the different kinds of wild bees has been tried; and it was found, that by removing their nest cautiously in an evening, and placing it in a quiet situation, in a garden or other place where they could be observed, they went on with their works without apparent alarm or interruption. During the whole summer, they continued to prosecute their occupations with the same industry as other bees; but about September, as we have mentioned, the hive began to turn languid, and the numbers which appeared going and coming about the entrance became daily smaller. It was imagined they had taken refuge within the hive; but when this was opened, after all seemed to have ceased their labours, every thing was found empty and deserted; there was neither bees nor honey; the stronger and younger insects, no doubt, having gone to make burrows for themselves in the earth, and the older ones having gradually fallen victims to the accidents of approaching winter.

Our wild bees, therefore, appear to possess their brief lives but for self-enjoyment, or rather to form one of that order of beings created by the great Author of all as if for the purpose of leaving no corner of the universe without its utmost allotment of sentient and enjoying things. And surely, in copse and forest, by dale and mead, on river-bank and mountain-side, there is enough and to spare of the food which it seeks for the humble bee. Though our British wild bees may not be convertable to man's uses, however, there are wild bees which are not so situated. In Cashmere, there are several kinds of bees, which have the habits requisite for domestication; and that country, with the north of India, appears to be the native soil of these genera of honey-bees. The inhabitants have a way of domesticating them which might be imitated with success in this country. In building dwelling-houses, they leave certain cavities in the wall, with a very small aperture to the outside, like the entrance to a hive, but quite open inwards; this inner part is covered afterwards with a frame, having a door which opens at pleasure; into these cavities, which are much superior, in the essential respects of warmth and security, to our bee-hives, the insects are admitted: and here they carry on their labours during the summer. The people of the house, by opening the interior door, can see them at work whenever they please, and can remove a honey-comb at any time without distressing the hive; the only precaution necessary being to blow in at the back part as much smoke as will make the bees fly out at the front entrance. English travellers have seen the operation performed, and the bees quietly return. This plan of lodging bees might be followed here to great advantage, if not in dwelling-houses, at least in the offices about farms, where a bee-hive would be at once cheaper, more secure, and more ornamental, than the masses of straw now used; which, besides affording no security against human plunderers, are the haunts of all sorts of vermin.

In the warm regions of the south of Europe, a black species of wild bee is found, which, according to the naturalist Reaumur, constructs its nest in a remarkable manner by boring into timber. "She usually selects the putrescent uprights of arbours, espaliers, or the props of vines; but sometimes she will attack garden seats, thick doors, and window-shutters; the piece that she chooses is usually cylindrical, and perpendicular to the horizon. Her strong maxillæ are the instruments she employs in boring it; beginning on one side for a little way, she points her course obliquely downwards, and then forwards in a direction parallel with its sides, till she has bored a tunnel of from twelve to fifteen inches in length, and seven or eight lines in diameter. A passage is left where she enters or first begins to bore, and another at the end of the pipe. As the industrious animal proceeds in her employment, she clears away the wood that she detaches, throwing it upon the ground, where it appears like a small heap of sawdust. Thus, we see, she has prepared a long cylinder in the middle of the wood, sheltered from the weather and external injuries, and fit for her purposes. But how is she to divide it into cells? What materials can she employ for making the floors and ceilings of her apartments? The sawdust is at hand, and this supplies her with all that she wants to make this part of her mansion complete. Beginning at the bottom of the cylinder, she deposits an egg, and then lays in a store of pollen, mixed with honey, sufficient for the nutriment of the little animal it is to produce. At the height of seven or eight lines, which is the depth of each cell, she next constructs, of particles of the sawdust glued together, and also to the sides of the tunnel, what may be called an annular stage or scaffolding. When this is sufficiently hardened, its anterior edge affords a support for a second ring of the same materials, and thus the ceiling is gradually formed of these concentric circles, till there remains only a small orifice in its centre; and this is also filled up with a circular mass of agglutinated particles of the sawdust. This partition exhibits the appearance of as many concentric circles as the animal has made joinings, and is about the thickness of a French crown-piece; it serves for the ceiling of the lower, and the floor of the upper apartment. One cell being completed, she proceeds to another, which she furnishes and finishes in the same manner; and so on till she has divided her whole tunnel into apartments, which are usually about twelve." At the proper season the young come forth, each in its turn, from these long and ingeniously contrived tunnels.

Bee-Hunts in the Wilds of America.

In some countries the honey-bee still roams in an undomesticated state, taking up its abode in the hollows of trees or other suitable places of shelter, and annually throwing off swarms which seek new habitations. In the western parts of North America, colonies of bees enjoying this wild freedom are frequently observed by travellers; and the discovery of their rude hives, for the sake of their store of honey, forms a kind of profession to a class of persons known by the name of bee-hunters. On the subject of these sports, Washington Irving speaks as follows, in his "Tour in the Prairies of the Far West:"—

"The beautiful forests in which we were encamped abounded in bee-trees; that is to say, trees in the decayed trunks of which wild bees had established their hives. It is surprising in what countless swarms the bees have overspread the Far West within but a moderate number of years. The Indians consider them the harbinger of the white man, as the buffalo is of the red man; and say, that in proportion as the bee advances, the Indian and the buffalo retire. We are always accustomed to associate the hum of the bee-hive with the farm-house and the flower-garden, and to consider those industrious little animals as connected with the busy haunts of men; and I am told that the wild bee is seldom to be met with at any great distance from the frontier. They have been the heralds of civilization, steadfastly preceding it, as it advanced from the Atlantic borders; and some of the ancient settlers of the West pretend to give the very year when the honey-bee first crossed the Mississippi. The Indians, with surprise, found the mouldering trees of their forests suddenly teeming with ambrosial sweets; and nothing, I am told, can exceed the greedy relish with which they banquet, for the first time, upon this unbought luxury of the wilderness. At present the honey-bee swarms, in myriads, in the noble groves and forests that skirt and intersect the prairies, and extend along the alluvial bottoms of the rivers. It seems to me as if these beautiful regions answer literally to the description of the land of promise—'a land flowing with milk and honey;' for the rich pasturage of the prairies is calculated to sustain herds of cattle as countless as the sands upon the sea-shore, while the flowers with which they are enamelled render them a very paradise for the nectar-seeking bee.

"We had not been long in the camp, when a party set out in quest of a bee-tree, and being curious to witness the sport, I gladly accepted an invitation to accompany them. The party was headed by a veteran bee-hunter, a tall lank fellow, in homespun garb that hung loosely about his limbs, and a straw hat, shaped not unlike a bee-hive; a comrade, equally uncouth in garb, and without a hat, straddled along at his heels, with a long rifle on his shoulder. To these succeeded half a dozen others, some with axes, and some with rifles; for no one stirs from the camp without fire-arms, so that he may be ready either for wild deer or wild Indian. After proceeding some distance, we came to an open glade on the skirts of the forest. Here our leader halted, and then advanced quietly to a low bush, on the top of which I perceived a piece of honey-comb. This, I found, was the bait or lure for the wild bees. Several were humming about it, and diving into its cells. When they had laiden themselves with honey, they would rise up in the air, and dart off in one straight line, almost with the velocity of a bullet. The hunters watched attentively the course they took, and then set off in the same direction, stumbling along over twisted roots and fallen trees, with their eyes turned up to the sky. In this way they traced the honey-laden bees to their hive, in the hollow trunk of a blasted oak, where, after buzzing about for a moment, they entered a hole about sixty feet from the ground. Two of the bee-hunters now plied their axes vigorously at the foot of the tree, to level it with the ground. The mere spectators and amateurs, in the mean time, drew off to a cautious distance, to be out of the way of the falling of the tree and the vengeance of its inmates. The jarring blows of the axe seemed to have no effect in alarming or agitating this most industrious community. They continued to ply at their usual occupations—some arriving full-freighted into port, others sallying forth on new expeditions, like so many merchantmen in a money-making metropolis, little suspicious of impending bankruptcy and downfall: even a loud crack, which announced the disrupture of the trunk, failed to divert their attention from the intense pursuit of gain: at length down came the tree with a tremendous crash, bursting open from end to end, and displaying all the hoarded treasures of the commonwealth. One of the hunters immediately ran up with a wisp of lighted hay, as a defence against the bees. The latter, however, made no attack, and sought no revenge: they seemed stupified by the catas trophe, and, unauspicious of its cause, remained crawling and buzzing about the ruins, without offering us any molestation. Every one of the party now fell to, with spoon and hunting-knife, to scoop out the flakes of honeycomb with which the hollow trunk was stored. Some of them were of old date, and a deep brown colour; others were beautifully white, and the honey in their cells was almost limpid. Such of the combs as were entire were placed in camp-kettles, to be conveyed to the encampment; those which had been shivered in the fall were devoured upon the spot. Every stark bee-hunter was to be seen with a rich morsel in his hand, dripping about his fingers, and disappearing as rapidly as a cream tart before the holiday appetite of a schoolboy. Nor was it the bee-hunters alone that profited by the downfall of this industrious community. As if the bees would carry through the similitude of their habits with those of laborious and gainful man, I beheld numbers from rival hives, arriving on eager wing, to enrich themselves with the ruins of their neighbours. These busied themselves as eagerly and cheerily as so many wreckers on an Indiaman that has been driven on shore—plunging into the cells of the broken honeycombs, banqueting greedily on the spoil, and then winging their way full-freighted to their homes. As to the poor proprietors of the ruin, they seemed to have no heart to do any thing, not even to taste the nectar that flowed around them, but crawled backwards and forwards, in vacant desolation, as I have seen a poor fellow, with his hands in his pockets, whistling vacantly and despondingly about the ruins of his house that had been burned. It is difficult to describe the bewilderment and confusion of the bees of the bankrupt hive, who had been absent at the time of the catastrophe, and who arrived, from time to time, with full cargoes from abroad. At first they wheeled about in the air, in the place where the fallen tree had once reared its head, astonished at finding all a vacuum. At length, as if comprehending their disaster, they settled down in clusters on a dry branch of a neighbouring tree, from whence they seemed to contemplate the prostrate ruin, and to buzz forth doleful lamentations over the downfall of their republic. It was a scene on which the 'melancholy Jacques' might have moralized by the hour."

In various parts of Africa, hunting for the nests of wild bees is similarly pursued by the natives of that extensive continent. In Alexander's "Expedition into the Interior of Africa," we find the following notice of a hunt of this kind:—"One of the Hottentots observed a number of bees entering a hole in the ground, which had formerly belonged to some animal of the weasel kind. As he made signs for us to come to him, we turned that way, fearing he had met with some accident; and when the people began to unearth the bees, I did not expect that we should escape without being severely stung. But they knew so well how to manage an affair of this kind, that they robbed the poor insects with the greatest ease and safety. Before they commenced digging, a fire was made near the hole, and constantly supplied with damp fuel to produce a cloud of smoke. In this the workmen were completely enveloped; so that the bees returning from the fields were prevented from approaching, and those which flew out of the nest were driven by it to a distance. Yet the rest of our party, to avoid their resentment, found it prudent either to ride off, or stand also in the smoke. About three pounds of honey were obteined, which, excepting a small share which I reserved till tea-time, they instantly devoured in the comb; and some of the Hottentots professed to be equally fond of the larvæ. The honey appeared unusually liquid, and nearly as thin as water, yet it seemed as sweet, and of as delicate a taste, as the best honey of England. Whilst I was engaged in the chase one day on foot with a Namaqua attendant, he picked up a small stone, looked at it earnestly, then over the plain, and threw it down again. I asked what it was; he said there was the mark of a bee on it; taking it up, I alao saw on it a small pointed drop of wax [properly excrement], which had fallen from a bee in its flight. The Namaqua noticed the direction the point of the drop indicated, and walking on he picked up another stone, also with a drop of wax on it, and so on at considerable intervals, till, getting behind a crag, he looked up, and bees were seen flying across the sky, and in and out of a cleft in the face of the rock. Here, of course, was the honey he was in pursuit of. A dry bush is selected, fire is made, the cliff is ascended, and the nest is robbed in the smoke."

Park, in his Travels, mentions, that the African wild-bees are often a formidable enemy to the caravans of the travellers crossing tha desert. The following incident, as he relates, took place near Doofroo:—"We had no sooner unloaded the asses, than some of the people, being in search of honey, unfortunately disturbed a large swarm of bees. They came out in immense numbers, and attacked men and beasts at the same time. Luckily most of the asses were loose, and galloped up the valley; but the horses and people were very much stung, and obliged to scamper off in all directions; in fact, for half an hour, the bees seemed completely to have put an end to our journey. In the evening, when they became less troublesome, and we could venture to collect our cattle, we found many of them much stung and swelled about the head. Three asses were missing; one died in the evening, and one next morning. Our guide lost his horse, and many of the people were much stung about the hands and face."

Honey-bees exist in great numbers in Australia. In the account of an expedition in that country by Major Mitchell, that gentleman observes—"We were now 'in a land flowing with milk and honey;' for the natives, with their new tomahawks [illegible]ted it in abundance from the hollow branches of t[illegible]; and it seemed that, in the season, they could find it almost everywhere. To such inexpert clowns, as they probably thought us, the honey and the bees were inaccessible, and indeed invisible, save when the natives cut it out and brought it to us in little sheets of bark, thus displaying a degree of ingenuity and skill in supplying their wants, which we, with all our science, could not hope to attain. They would catch one of the bees, and attach to it, with some rosin or gum, the light down of the swan or owl: thus laden, the bee would make for the branch of some lofty tree, and so betray its home of sweets to its keen-eyed pursuers, whose bee-chase presented indeed a laughable scene."

THE DOG—FIELD SPORTS.

The dog is an animal which seems to have been destined by the Creator to be the friend and assistant of man. Throughout the dangers and difficulties which beset the human being, particularly in an inartificial state of society, the dog has ever proved himself the kindly defender of his life and property, as well as a powerful and essential auxiliary in subduing other animals to his purpose. Without the assistance of the dog, man would not even yet have obtained a beneficial dominion over the various races of wild animals of the earth, or been able to watch with sufficient care those creatures formed for his food.

According to naturalists, the dog belongs to the family of the *Canidæ* (from *canis*, Latin for dog, hence, *canine* species), in the order *Carnivora*, class Mammalia. In the same family are united the wolf, fox, and jackal, and these so nearly approach the dog in physical construction, and certain habits and qualities, that some authorities are inclined to consider them of the same species. The resemblance in some respects, and great dissimilarity in others, between dogs, wolves, foxes, and jackals, is, however, not more remarkable than the general similarity of dogs to each other, as far as an apparent unity of species is concerned; while, at the same time, there is a striking difference of form and character between opposite breeds. One dog is large, another small; one is smooth in the skin, another rough; one has a long head, in another the head is short; one has an exquisite sense of smell, another has comparatively little of that power; and so on. We have an animal which watches our flocks; another which tracks and hunts down noxious wild beasts; another which destroys and digs out vermin from the earth; another which guards our houses and lives while we are asleep; another which seeks out for game in our field-sports; another which will plunge into the deepest waters, and save us from being drowned; besides many other varieties, all less or more distinct in character. The difference is so very remarkable, that the *varieties* would be entitled to be classed as of different *species* of animals, unless for the fact that they all breed together, and perpetuate mixed or mongrel varieties. This circumstance led Buffon and other naturalists to infer that all dogs whatsoever are but of one species; the physiological theory being, that no two different species can produce fertile descendants. Buffon further concluded, from a course of observations, that all are sprung from one common root, the shepherd's dog; and that climate, food, and peculiar training, have been the causes of the departure from the primeval stock. The line of argument adopted in support of this theory is, that in the animal, as in the vegetable kingdom (see article Fruit-Garden), improved or very remarkable varieties can be produced by selecting kinds, and breeding from them alone; as, for example, taking the two largest dogs of a breed, and breeding from them; then taking the two largest which this pair produces, and breeding from them also; and so on, till a large variety of dogs is ultimately formed. And further, that if each generation be trained in a particular way, the variety will come to possess properties agreeable to the kind of cultivation bestowed upon it. Such, there is reason to believe, is the true explanation of the extraordinary differences of size and character in the canine species. We must view these dissimilarities as a result of a course of treatment from the earliest period of civilization till modern times. The ancient Egyptians, and after them the Greeks, are recorded to have paid considerable attention to the training of dogs, and, as is well known, this formed a favourite study in connection with the field-sports of later ages. Doubts may very naturally be entertained respecting the power of transmitting acquired qualities from one generation to another, of any species of animals; but investigations into the subject afford some remarkable proofs of what can be accomplished by means of careful training or teaching.

EFFECTS OF TRAINING.

In the latter part of the last century, one Bisset, a native of Perth, by trade a shoemaker, having applied himself with great perseverance to the teaching of animals, succeeded in making a set of cats play in harmony on the dulcimer, uniting their voices to the tones of the instrument; and this singular orchestra was exhibited, to the perfect satisfaction of the public, for a succession of nights, in the Haymarket theatre. He it was who trained that "learned pig," of which our fathers used to speak so highly, the animal having been exhibited in every part of the empire. At a somewhat earlier period, a Saxon peasant boy trained a dog to the pronunciation of words. The boy had observed in the dog's voice an indistinct resemblance to certain sounds of the human voice, and was thus prompted to endeavour to teach him to speak. The animal was three years old at the beginning of his instructions—a circumstance which must have been unfavourable to the object; yet, by dint of great labour and perseverance, in three years the boy had taught it to articulate thirty words. It used to astonish its visiters by calling for tea, coffee, chocolate, &c.; but it is proper to remark, that it required the words to be pronounced by its master beforehand, and it never appeared to become quite reconciled to the exhibitions which it was forced to make. The learned Leibnitz reported on this wonderful animal to the French Academy, attesting that he had seen the dog and heard it speak; so that there does not appear the slightest ground for doubting the fact, such as it was. All doubt on the question of possibility may, indeed, be considered as set at rest by the recent exhibition of the educated dogs in London—animals which could play at dominoes and chess, and even indicate when their adversaries made false moves. These creatures were visited and *played with* by thousands, and we never have heard that a deception of any kind as to the reality of their acquired powers was detected.

Laying aside such extraordinary examples as these, the ordinary training conferred on horses, dogs, and other domesticated animals seems to be sufficient to establish the general fact of animal educability. We have no more forcible illustrations of the principle than in the uses which are now made of certain of the canine tribe in rural sports. The pointer, setter, springing spaniel, and all that class of dogs, are understood to be descended from one stock, the Spanish spaniel, with a slight crossing from the fox-hound, for the sake of increasing the speed. The original animal may be considered as a record of the original powers, to which every thing else must be regarded as an addition made by human training. Now, the original animal is only gifted by nature with a fine scent for game, and a disposition to make a momentary pause on seeing it, for the purpose of springing upon it.* Man has converted this inclination to a temporary pause into a habit of making a full stop, and the animal, instead of gratifying its destructive tendency by flying upon the game, has been trained to be contented with witnessing a vicarious execution by the gun of his master.

It is a mistake to suppose that only the spaniel tribe is capable of serving sportsmen in the capacity of pointers and setters. There are other classes of dogs which perseverance would enable, to a certain extent, to act in the same way. Gervase Markham, who wrote on sports in the sixteenth century, speaks of having seen dogs of the bastard tumbler kind adapted to act as setters, though not so well as those of the spaniel kind. Mr. Blaine is of opinion that this power can be cultivated in most dogs.† It has even been elicited in another and very different class of animals—the hog. Some years ago, Mr. Toomer, gamekeeper to Sir Henry Mildmay, bethought him of teaching a pig to act as a pointer, having been struck by the scenting powers of the animal in its search for palatable roots under ground. He began by allowing a young female pig to accompany his pointers, in their breaking lessons, to the field. Within a fortnight, to his own surprise, she was able to hunt and point partridges and rabbits. There being an abundance of creatures near the keeper's lodge, her education advanced rapidly by frequent exercise and in a few weeks she was able to retrieve game as well as the best pointer. *Slut*, as this extraordinary animal was called, was considered to have a more acute scent than any pointer in the charge of the keeper; and it was a kennel of the highest character. They hunted her principally on moors and heaths; and it often happened, that when left behind, she would come of her own accord and join the pointers. "She has often stood a jack snipe when all the pointers had passed it: she would back the dogs when they pointed, but the dogs refused to back her until spoke to—Toomer's dogs being all trained to make a general halt when the word was given, whether any dog pointed or not, so that she has been frequently standing in the midst of a field of pointers. In consequence of the dogs being not much inclined to hunt when she was with them (for they dropped their sterns, and showed symptoms of jealousy), she did not very often accompany them, except for the novelty. Her pace was mostly a trot; she was seldom known to gallop, except when called to go out shooting: she would then come home off the forest at full stretch, and be as much elated as a dog at being shown the gun. She always expressed great pleasure when game, either dead or living, was placed before her. She has frequently stood a single partridge at forty yards' distance, her nose in a direct line to the bird; after standing some considerable time, she would drop like a setter, still keeping her nose in an exact line, and would continue in that position until the game moved; if it took wing, she would come up to the place, and draw slowly after it; and when the bird dropped, she would stand it as before."*

These facts, together with what common observation presents to us in domesticated parrots, blackbirds, ravens, magpies, monkeys, &c., place the educability of animals upon a basis, in our opinion, not to be shaken. But the most wonderful thing, and the most convincing part of the proof, remains, in the fact of the transmission of *acquired qualities* by animals to progeny. The habit which education has conferred upon the pointer appears in his puppy, who may be seen earnestly standing at swallows and pigeons in a farm-yard, before he has ever once seen such a thing done by his seniors, or received the least instruction. Here only the object is amiss; the act itself is perfect. As may be readily supposed, the puppy of a race of English pointers can be trained to the whole business of the field in one-tenth of the time which the most experienced breaker would require to effect any improvement upon the simple instinct of the *pause* in an original Spanish spaniel. On the subject of the hereditary transmission of acquired qualities by animals, we have some curious information from the venerable naturalist, Mr. T. A. Knight.

In a communication to the Royal Society, in 1807, Mr. Knight cited several instances of domesticated animals inheriting the acquired habits of their parents. "In all animals," he says, "this is observable; but in the dog it exists to a wonderful extent; and the offspring appears to inherit not only the passions and propensities, but even the resentments, of the family from which it springs. I ascertained that a terrier, whose parents had been in the habit of fighting with polecats, will instantly show every mark of anger when he first perceives the scent of that animal, though the animal itself be wholly concealed from his sight. A young spaniel brought up with the terriers showed no marks of emotion at the scent of the polecat, but it pursued a woodcock, the first time it saw one, with clamour and exultation: and a young pointer, which I am certain had never seen a partridge, stood trembling with anxiety, its eyes fixed and its muscles rigid, when conducted into the midst of a covey of those birds. Yet each of these dogs are mere varieties of the same species, and to that species none of these habits are given by nature. The peculiarities of character can therefore be traced to no other source than the acquired habits of the parents, which are inherited by the offspring, and become what I call *instinctive hereditary propensities.*"

It appears from another communication made by Mr. Knight to the same society, in 1837, that he had then been pursuing investigations on this subject for nearly sixty years. He proceeds in that communication to give a general account of his investigations:—"At the period," he says, "at which my experiments commenced, well-bred and well-taught springing spaniels were abundant, and I readily obtained possession of as many as I wanted. I had, at first, no other object than that of obtaining dogs of great excellence; but within a very short time, some facts came under my observation which very strongly arrested my attention. In several instances, young and wholly inexperienced dogs appeared very nearly as expert in finding woodcocks as their experienced parents. The woods in which I was accustomed to shoot did not contain pheasants, nor much game of any other kind, and I therefore resolved never to shoot at any thing except woodcocks, conceiving that by so doing the hereditary propensities above mentioned would become more obvious and decided in the young and untaught animals; and I had the satisfaction, in more than one instance, to see some of these find as many woodcocks, and give tongue as correctly, as the best of my older dogs.

* Thoughts and Recollections, by one of the last Century London: Murray. 1825.

† Encyclopædia of Rural Sports, 792

* Daniel's Rural Sports.

"Woodcocks are driven in frosty weather, as is well known, to seek their food in springs and rills of unfrozen water, and I found that my old dogs knew about as well as I did the degree of frost which would drive the woodcocks to such places; and this knowledge proved very troublesome to me, for I could not sufficiently restrain them. I therefore left the old experienced dogs at home, and took only the wholly inexperienced young dogs; but, to my astonishment, some of these, in several instances, confined themselves as closely to the unfrozen grounds as their parents would have done. When I first observed this, I suspected that woodcocks might have been upon the unfrozen ground during the preceding night; but I could not discover (as I think I should have done had this been the case) any traces of their having been there; and as I could not do so, I was led to conclude that the young dogs were guided by feelings and propensities similar to those of their parents.

"The subjects of my observation in these cases were all the offspring of well-instructed parents, of five or six years old or more; and I thought it not improbable that instinctive hereditary propensities might be stronger in these than in the offspring of very young and inexperienced parents. Experience proved this opinion to be well founded, and led me to believe that these propensities might be made to cease to exist, and others to be given; and that the same breed of dogs which displayed so strongly an hereditary disposition to hunt after woodcocks, might be made ultimately to display a similar propensity to hunt after trufles; and it may, I think, be reasonably doubted whether any dog, having the habits and propensities of the springing spaniel, would ever have been known, if the art of shooting birds on the wing had not been acquired.

"I possessed one young spaniel, of which the male parent, apparently a well-bred springing spaniel, had been taught to do a great number of extraordinary tricks, and of which the female parent was a well-bred springing spaniel; the puppy had been taught, before it came into my possession, a part of the accomplishments of its male parent. In one instance I had walked out with my gun and a servant, without any dog; and having seen a woodcock, I sent for the dog above mentioned, which the servant brought to me. A month afterwards, I sent my servant for it again, under similar circumstances, when it acted as if it had inferred that the track by which the servant had come from me would lead it to me. It left my servant within twenty yards of my house, and was with me in a very few minutes, though the distance which it had to run exceeded a mile. I repeated this experiment at different times, and after considerable intervals, and uniformly with the same results, the dog always coming to me without the servant. I could mention several other instances, nearly as singular, of the sagacity of this animal, which I imagined to have derived its extraordinary powers in some degree from the highly cultivated intellect of its male parent."

To conclude these preliminary observations on dogs. A gentleman of our acquaintance, and of scientific acquirements, obtained some years ago a pup which had been produced in London by a female of the celebrated St. Bernard's breed. The young animal was brought to Scotland, where it was never observed to give any particular tokens of a power of tracking footsteps until winter, when the ground became covered with snow. It *then* showed the most active inclination to follow footsteps; and so great was its power of doing so under these circumstances, that when its master had crossed a field in the most curvilinear way, and caused other persons to cross his path in all directions, it nevertheless followed his course with the greatest precision. Here was a perfect revival of the habit of its Alpine fathers, with a degree of specialty as to external conditions, at which, it seems to us, we cannot sufficiently wonder

We thus see that not only does what metaphysicians call the *law of habit* exercise a sway in the intellects of animals, but that modification which takes place in human communities, and passes under the comprehensive name of civilization, also affects the lower tribes of creation. A race of animals, like a race of men, is civilizable; and we cannot doubt that the same softening influences which have produced the advanced nations of Europe, have operated upon the animals existing in the same countries, and made them very different from what they were in early times. It cannot escape remark, that the whole principle of civilization acquires strength from having its basis thus widened. We become the more confident in the improvability of our own species, when we find that even the lower animals are capable of being improved, through a succession of generations, by the constant presence of a meliorating agency.

GENERAL CHARACTER OF DOGS.

The dog has six incisory or cutting teeth in both jaws; beyond which there are, on each side, both above and below, a canine tooth; and still farther into the mouth are six cheek-teeth, or molars, in each side of the upper jaw. The three first are sharp and cutting, which Cuvier calls false molars. The next tooth on each side is a carnivorous tooth, furnished with two cutting lobes, beyond which the other two teeth on each side are flat. There are seven cheek-teeth, on both sides, in the under jaw; four of these are false molars, a carnivorous tooth, with the posterior part flat, and behind it two tuberculous teeth. The muzzle is elongated, subject to great variety of length in different varieties. The tongue is smooth and soft; the ears erect in the wild varieties, and in some of the tame ones, but, in the latter kinds, for the most part pendulous. The fore-feet are provided with five toes, and the hind-feet with four toes, furnished with rather longish nails, obtuse at their points, and not retractile. The females are provided with both inguinal and ventral teats. The pupils of the eyes are circular.

The female goes with young sixty-three days, and generally produces from three to five at a birth, and sometimes even twelve, which are at first blind, in which state they continue for from nine days to a fortnight. About the end of two months, their faculties begin to develop themselves. They shed their first teeth at the end of six months, which are replaced by others that do not exfoliate. At twenty months, or two years, dogs arrive at their full vigour.

The males continue to propagate for nearly their whole lives, while the female discontinues having young ones at about the age of eight or nine years.

The average age to which dogs live is about fourteen years; they frequently, however, live to sixteen, and even have been known to attain the age of twenty years. In their latter days, dogs frequently suffer greatly from decay, and various diseases. They are extremely subject to rheumatism, from their liability to exposure to rain, and damp beds.

Until dogs have attained seven or eight years, their teeth are white, smooth, and acutely pointed; but after this age they become yellow spotted, and their points assume an uneven and jagged appearance. At this time, also, the hair of the muzzle and around the eyes assumes a hoary appearance, and becomes whiter as they increase in years.

The dog is naturally carnivorous, but when domesticated, he does not refuse farinaceous food. He uses grass as a vomit; and drinks by lapping with his long flexible tongue. He does not sensibly perspire by the skin; the superfluous moisture of the body escapes at the mouth by panting, when heated, and by the extraordinary diuretic habits of the animal. The sense of smell is different in different varieties, but in all is sufficiently strong and refined to enable the dog to seek out and follow his master even among a crowd. His sense of hearing is also quick. He expresses anger by growling or barking, but also barks when joyful; and shows delight by the wagging of his tail. He sleeps very lightly, so as to be awakened by the slightest noise; and during his slumbers he is apt to dream, as is indicated by starting, whining, and short barks.

The most remarkable feature in the character of the dog is his attachment to man. In wild unpeopled countries, dogs are known to live in hordes, and seek their prey like other untamed animals; but brought into connection with human society, the dog leaves his own species without regret, and is only happy when belonging to a master to whom he can be faithful as a friend, servant, or companion. In this condition of domestication his ambition seems to be the desire to please; he is seen to come crouching along, to lay his force, his courage, and all his useful talents, at the feet of his master: he waits his orders, to which he pays implicit obedience: he consults his looks, and a single glance is sufficient to put him in motion: he is more faithful than even the most boasted among men: he is constant in his affections, friendly without interest, and grateful for the slightest favours: much more mindful of benefits received than injuries offered, he is not driven off by unkindness: he still continues humble, submissive, and imploring; his only hope to be serviceable, his only terror to displease: he licks the hand that has just been raised to strike him, and at last disarms resentment by submissive perseverance.

More docile than man, as Buffon observes, more obedient than any other animal, he is not only instructed in a short time, but he also conforms to the dispositions and manners of those who command him. He takes his tone from the house he inhabits; like the rest of the domestics, he is disdainful among the great, and churlish among clowns. He knows a beggar by his clothes, by his voice, or his gestures, and forbids his approach. When, at night, the protection of the house is committed to his care, he seems proud of the charge; he continues a watchful sentinel; he goes his rounds, scents strangers at a distance, and gives them a warning of his being upon duty. If they attempt to break in upon his territories, he becomes more fierce, flies at them, threatens, fights, and either conquers alone, or alarms those who have most interest in coming to his assistance; however, when he has conquered, he quietly reposes upon his spoil, and abstains from abusing—thus giving at once a lesson of courage, temperance, and fidelity.

CLASSIFICATION OF VARIETIES.

Cuvier, the eminent French naturalist, formed a classification of dogs, founded on the shape of the head, and length of the jaws and muzzle. These he has separated into three great groups, as follows:—

I. Matins.—These have a head more or less elongated; the parietal bones insensibly approaching each other, and the condyles of the lower jaw placed in a horizontal line with the upper cheek-teeth.

II. Spaniels.—The head moderately elongated; the parietal bones do not approach each other above the temples, but diverge and swell out, so as to enlarge the forehead and cavity of the brain. In this group are included all the varieties of dogs which are of the greatest utility to man, and also the most intelligent.

III. Dogues.—The muzzle more or less shortened; the skull high; the frontal sinuses considerable; the condyle of the lower jaw extending above the line of the upper cheek-teeth. The cranium is smaller in this group than in the two previous, owing to the formation of the head.

Following this arrangement, the three groups have, for convenience, been divided into distinct sections, as follows:—

Division I.—Head Elongated.

Section 1. Wild and half-reclaimed dogs, which hunt in packs.

Section 2. Domesticated dogs, which hunt in packs or singly, principally by the eye, although sometimes by the scent.

Section 3. Domesticated dogs, which hunt singly, and always by the eye.

Division II.—Head less Elongated than former Division.

Section 4. Pastoral dogs, or such as are employed in domestic purposes.

Section 5. Water-dogs, which delight in swimming, having their feet in general semi-webbed.

Section 6. Fowlers, or dogs whose natural inclination is to chase and point birds, and hunt singly by the scent.

Section 7. Hounds, which hunt in packs, by the scent.

Section 8. Mongrel hounds, which hunt singly, either by the scent or eye.

Division III.—Head much Shortened.

Section 9. Watch-dogs, which have no propensity for hunting.

We shall now present a short notice of the different varieties of breeds in each of the several divisions and sections.

Division I.—Dogs with Lengthened Heads.

Section 1. Half-reclaimed dogs, which hunt in packs.

The *Dingo*, or *Australian Dog*.—The head of this dog is not unlike that of a wolf, on which account Bewick calls it the New South Wales wolf. The muzzle is long and pointed, with short erect ears. He is two feet six inches in length, and about two feet in height. His fur is composed of a mixture of silky and woolly hairs, and is of a deep yellowish-brown colour; and his tail is long and bushy, resembling that of a fox. This dog is of a ferocious disposition. Pennant mentions one which was brought to this country, and that leaped on the back of an ass, and had nearly destroyed it before a rescue could take place.

The *Dhole* is the native wild-dog of India, and bears a strong resemblance to the dingo, but without the bushy tail of that species; he is of a uniform bright-red colour. Differently from other dogs which hunt in packs, according to the account given by Captain Williamson, this species always hunts mute, and only utters a soft whispering sound when in high chase, and near his prey. The dhole is exceedingly swift of foot, and soon overtakes most animals which are the objects of his pursuit. It is said they are exceedingly fond of the flesh of the tiger, and that, in consequence, this animal is prevented from propagating to that extent which would soon overrun and lay waste all the countries which it inhabits. This predilection is confirmed by Bishop Heber, who states, upon the authority of the peasants of Khayra, which borders the frontiers of China, that a tiger is often killed and torn to pieces by the wild dogs, which give tongue like foxhounds or harriers. It is in the unfrequented wilds of the western frontiers of India that the dhole takes up his abode, lurking amongst the extensive jungles which cover mighty tracts of that territory.

The *Pariah* is the common village dog of India. He has a small sharp head, with short pricked ears, a slender body, and particularly drawn up about the abdominal region; his chest is deep, his limbs light, and his colour is of a reddish-brown. The native Indians use these in hunting the tiger and wild boar. They are very fierce, and follow their game with much avidity.

The *Ekia* is the native dog of Africa, and in all likelihood sprung from the same stock as the dhole. They are said to be of various colours, as black, brown, white and yellowish. They are eaten by the negroes. The African wild dogs, like those of India, hunt in packs.

The South American Dog is not unlike the dingo, and is about the size of the springer, with short and pricked ears, like most other wild dogs. The hair on his tail is long and bristly; he is of a brownish-gray colour on the back, with sandy-coloured spots on the legs and flanks. In general aspect, he greatly resembles the wolf, but is much smaller in size.

There is another South American dog called the Alco, of which there are two varieties. The head of the Alco is very small, and the ears pendulous, thus differing from almost all other wild dogs. The back is somewhat curved, and the tail rather short. It is said that the Spaniards found this dog among the natives on the first discovery of America. Herrera says, that Columbus found in America many dogs which did not bark. But there is reason to suppose that whatever may have been the original types of the South American dogs, they have been greatly altered by intermixture with descendants of those introduced at the conquest by the Spaniards.

The *North American Dog.*—We have no very distinct account of this variety, but it is said to resemble the dingo in its pricked ears and general conformation. It is remarkable for the acuteness of its scent, and very expert in the detection of its prey, or animals which it may be trained to pursue.

Section 2. Domesticated dogs, which hunt in packs or singly, principally by the eye, although sometimes by the scent.

The *Irish Greyhound* ranks among the noblest of the canine race; his mien is striking, full of dignity, and his conformation beautiful. In his general shape he bears a strong resemblance to the common greyhound, but is much taller, and more robust. He is not fitted for pursuing the more speedy animals of the chase. His use in early times was to free the country of wolves and wild boars, which abounded in England and Ireland. The hair is short and smooth, and the colour of these dogs is fawn or pale cinnamon. The Marquis of Sligo had some of this breed, which were of various colours; some were brown and white, and others black and white. The ordinary height of the Irish greyhound is about three feet, although they have been known to reach four feet. Goldsmith, who had seen several of this breed, says they were about four feet high, and as tall as a calf of a year old.

The *Albanian Dog.*—This variety is about the size of a full-sized mastiff. His hair is very fine and close set, and of a silky texture, variously clouded with brown; his tail is long and bushy, and carried like that of a Newfoundland dog; his muzzle is pointed, and rather long; his legs are strong and muscular, which fit him well for hunting the wild boar, in which sport he was much used in ancient times; he was also used in hunting wolves, and in protecting sheep-folds from thieves.

The *French Matin* has an elongated head, and flat above; his ears are erect, and slightly pendulous towards the tips; the hair of a yellowish fawn-colour, with darker, oblique, and parallel indistinct rays traversing the whole of his fur. His height is about two feet, and his length three feet. He is strong, muscular, and active, and very courageous. He evinces great eagerness in hunting the wild boar and wolf, in which sport he is frequently employed. Pennant thinks this variety is a descendant of the Irish greyhound.

The *Scottish Highland Greyhound.*—This dog will either hunt in packs or singly. He is an animal of great size and strength, and at the same time very swift of foot. In size, he nearly equals the Irish greyhound. His head is long, and the nose sharp; his ears short, somewhat pendulous at the tips; his eyes are brilliant and very penetrating, and half concealed by the long crisped hairs which cover his face and whole body. He is remarkable for the depth of his chest, and tapers gradually towards the loins, which are of great strength, and very muscular; his back is slightly arched; his hind quarters are powerfully formed, and his limbs strong and straight. The possession of these combined qualities particularly fit him for long endurance in the chase. His usual colour is a reddish sand-colour, mixed with white; his tail is long and shaggy, which he carries high, like the staghound, although not quite so erect. It is this noble dog which was used by the Scottish Highland chieftains in their great hunting parties, and is supposed to have descended in regular succession from the dogs of Ossian.

The *Russian Greyhound* is nearly as large as the Irish greyhound, resembling him in shape as nearly as possible, but covered with long bushy hair, his general colour is a dark reddish-brown. He is sometimes hunted in small packs, and as frequently single, in which case he not unfrequently will kill a wolf, deer, or wild boar, without any aid whatever. When used in coursing, he is taken to the field in slips, in the same manner as is practised with greyhounds.

Section 3. Domesticated dogs, which hunt singly, and always by the eye.

The *Gazehound.*—This is a dog, the breed of which is now lost. It was hunted in the same manner as the greyhound, and took foxes and hares by running them down. It is said by Bewick that it was employed in stag-hunting, which we think is rather doubtful, as, although the stag is an animal of great speed, yet the contest between it and a dog possessing the swiftness of a greyhound would be but very unequal. No representation of this dog has been preserved, which is much to be regretted, as we are but imperfectly acquainted with its appearance.

The *Greyhound* is the fleetest of all dogs, which is in consequence of his peculiar conformation. His head is long, tapered, and shaped like that of a snake; his neck long and slender; his ears somewhat erect and pricked, slightly pendulous at their tips; the tail ought to be very fine, pointed, and the hair on it very short; the chest should be wide and deep; the belly drawn up, with strong loins, and with large and prominent hip-muscles. This dog is by no means so intelligent as many other varieties, and he is, in consequence, much less susceptible of education. He has, however, very fine feelings, and seems to be much alive to caresses, which excite him to such a degree as to produce a quick pulsation of the heart. This may be felt beating against his side with much vigour. He is one of the most elegantly formed of all the canine species.

The *Scotch Greyhound.*—This dog is formed exactly like the common greyhound, and differs from it merely by being of a larger size, and in the hair being longer and hairy. Its general colour is reddish-brown, or of a sand colour.

The *Italian Greyhound.*—This dog is merely a miniature of the common greyhound, being only about half the size of that dog. It has a very fine skin of a silky texture, and is so tender as to be easily injured by cold or wet. It is used only as a *pet*, being quite valueless in all other respects.

The *Turkish Greyhound* is still smaller than the Italian greyhound, being little more than half its bulk, and is entirely divested of hair, except on the tail, where it is few and scattered. Its usual colour is blackish lead colour. It abounds in Turkish towns, where it forms a dreadful nuisance to travellers.

Division II.—Head less elongated than former division.

Section 4. Pastoral dogs, or such as are employed in domestic purposes.

The *Shepherd's Dog.*—This dog is covered with long, flowing, somewhat woolly, hair; his muzzle is long and pointed, and his ears erect, and slightly bent downwards at the tips; his tail is long and bushy, and the usual colour of his f is black and white, or varied with black and gray; the backs of his fore-legs have also long hairs. The peculiar and highly useful qualities of this dog seem to be rather intuitive than acquired; indeed, nothing can hardly exceed the quickness with which he can be taught any lesson; and certainly no other dog has the same patient perseverance and courageous fidelity, and at the same time possessed of the greatest discrimination. The labour of a shepherd, with the assistance of this faithful and intelligent animal, is comparatively an easy task; and it is hardly possible to fancy a more arduous employment than it would be, if divested of the services of the dog: for without him, how could he collect extensive flocks scattered over high and widely-spread mountain ranges? The shepherd's dog is possessed of great sagacity, gratitude, and self-denial, as is well known from innumerable anecdotes.

The *Cur* or *Watch Dog* differs from the shepherd's dog in being nearly smooth; he is stronger in his make, and has half-pricked ears, and his tail is rather short, and slightly feathered beneath. He is a trusty and useful servant to the farmer and grazier, and is chiefly employed in driving cattle; and being larger and stronger than the shepherd's dog, from which he is sprung, he is better qualified for the grazier and farmer. He bites with great keenness, and always makes his attack at the heels. His sagacity is very great, and he soon knows his master's fields, and watches with great assiduity the cattle which are in them.

The *German Dog* is a small-sized animal, with bushy turned-up tail, bushy neck, small muzzle, and is generally of a cream colour, but also sometimes black. His manner is brisk, and his character that of great fidelity. He is seen all over central Germany, where he appears to be employed chiefly as a mery companion to man, and also for watching. A few are beginning to be seen in England.

SECTION 5. Water-dogs, which delight in swimming, having their feet in general semi-webbed.

The *Pomeranian* or *Wolf Dog* has the hair on the head short, as is also that on the feet and ears; but it is long and silky on the body and tail, which last is curled up in a spiral form. His colour is white, black, gray, or sometimes yellowish; his head is long, and his muzzle pointed; his ears are short and pricked. He is possessed of intelligence nearly equal to that of the shepherd's dog.

The *Siberian Dog* has much the appearance of the Pomeranian dog, and is very nearly allied to him, except that he is covered with long hair even on the head and paws. In their native country, four of these dogs are attached by pairs to a sledge, and in front of them is placed a leader, on the proper training of which much of the useful services of the others depend. These sledges are just large enough to contain one person, who directs them with his voice, and in which he is partially assisted by a stick. The reins are fastened to the dogs' necks by a collar. These dogs, thus yoked, have been known to drag a sledge from seventy to eighty miles in a day; and so powerful is their scent, that they contrive to keep or the beaten track by that means alone, even although it be hid by showers of snow.

The *Greenland Dog* is of a large size, strong in the bone, and its fur consists of long, thick-set, woolly-like hair; his muzzle is sharp, and his ears short and pricked; his tail is thick, very bushy, and spirally twisted.

The *Iceland Dog* is shorter in the hair than the above variety; his ears are pricked, but slightly bent downwards on the tips. His general colour is white, with patches of black differently disposed.

The *Esquimaux Dog*.—This highly useful variety is described by M. Desmarest as having the head shaped like that of the wolf dog, the tail is spreading and curved, and the ears erect. The hair is thinly scattered, and consists of two sorts, the one silky, the other thick and fine, and somewhat curled, and so detached from the other that it may be pulled off in flakes from the animal.

The *Hare-Indian Dog* has a narrow, elongated, and pointed muzzle; his ears are broad at the base, and pointed towards the tips, and perfectly erect; his legs are long and slender, and his tail thick, bushy, and curved slightly upwards, but by no means so decidedly curved as that of the Esquimaux dog. His body is covered with long straight hairs, the ground colour of which is white, marked with large irregular patches of grayish-black, intermingled with various shades of brown. Dr. Richardson says it has neither courage nor strength for pulling down any of the larger animals.

The *Newfoundland Dog*.—This beautiful and intelligent dog is remarkable for the symmetry of his form and the acuteness of his understanding. He measures, from the tip of the nose to the point of the tail, six feet and a half, the length of the tail itself being two feet; from the one fore foot to the other, over the shoulders, five feet eight inches; the girth behind the shoulders, three feet four inches; the length of his head is fourteen inches. He has webbed feet, in consequence of which he is a dexterous swimmer. His hair is long, flowing, and slightly curled, and his tail very bushy, particularly in the lower side, and he carries it in a very graceful manner. The docility of the Newfoundland dog is very great; there are innumerable most striking anecdotes of his sagacity and benevolence of disposition, particularly with reference to his saving persons from drowning. During the gale on Thursday, June 11, 1829, a vessel was driven on the beach at Lydd; no boats could get off to the assistance of the crew, who were, however, all saved and brought ashore through the activity of a fine Newfoundland dog. The surf was rolling furiously, and eight poor fellows were crying for aid, which the spectators could not afford them, when one man directed the attention of his dog to the vessel, and the intelligent animal at once swam towards it, and the crew joyfully made fast a rope to a piece of wood, which the dog seized and swam with to his master on shore; a line of communication was thus formed, and the eight mariners rescued from a watery grave.

The *Russian Dog* is somewhat larger and stronger than the Newfoundland dog; he is a cross between that variety and the Siberian dog, and has now become a distinct race. His head is large, with his ears pendulous and rather full-sized; his tail is curled over his back; his hair is very long and shaggy, consisting of black and white patches.

The *Great Rough Water-Dog* is web-footed, swims with great ease, and dives with much dexterity; his hair is long and curly, and he is of various colours; his legs and feet are also thickly covered with thick and bushy hair.

The *Large Water-Spaniel* is about the size of the English setter, but of a stronger make. His face is smooth, as also the front of his legs, while the rest of his body is covered with small crisp curls, usually of a dark liver-brown colour. This dog is very valuable in the sport of shooting wild fowl.

The *Small Water-Spaniel*, or *Poodle*.—This is a breed between the large water-dog and the springer: he is thickly covered with fine hair, all of which is in distinct small curls, more like an effort of art than of nature. It is one of the most active of dogs. Its general colour is white, and sometimes it has various black patches. It dives with much dexterity, and will leap from a very great height into the water; we have seen one leap over Tyne Bridge at Newcastle, a height of nearly fifty feet.

The *Shock Dog* is the smallest of the water-dog varieties, and is probably bred between the smaller Spaniel or King Charles's dog and the poodle. Its hair is extremely long and flowing, so much so that its ears and eyes are nearly concealed from view by it. It is used as a lapdog.

SECTION 6. Fowlers, or dogs whose inclination is to chase and point birds, and hunt singly by the scent.

The *Springer.*—This variety is shaped much like the English setter, but shorter in the body and legs in proportion to his size, being about two-fifths less than that dog; the hair is long and shaggy, and the ears very long and pendulous, and covered with long waved hairs. He is usually of a white colour, with patches of liver-colour or chestnut. He is, however, sometimes black, and at other times entirely of a liver-coloured brown.

The *Cocker* is about a third less than the springer, and like it in all respects. It is used as well as that variety for raising woodcocks and snipes, in which exercise they are both very expert.

The *King Charles's Dog* is still less than the cocker, and distinguished by the very great length of his ears. Its hair is silky, and this, with its gentleness and small size, has rendered it a favourite pet of ladies of fashion. Of late it has been fashionable for ladies to carry these little creatures in their arms while walking in the streets of London. They are sold at a high price.

The *Comforter* is another diminutive variety of this race, chiefly used as a lapdog. It is supposed to be a cross between the Maltese and King Charles's dog.

The *Maltese* and *Lion Dogs* are descendants from nearly the same stock.

The *Alpine Spaniel*, or *Great St. Bernard Dog*, exceeds other varieties of the spaniel for size and beauty. Its usual height is two feet at the shoulders, and he is six feet in length from the nose to the tip of the tail. Two of these dogs are sent out from the monastery of the Great St. Bernard, situated among the Alps of Switzerland, to scour the mountains during snow-storms, in search of lost or wearied travellers—the one with a warm cloak fastened to his back, and the other with a basket tied round his neck, containing a bottle with some cordial, and bread. In this employment they manifest great judgment, and seem to understand perfectly the import of their mission. They are frequently of the greatest use in meeting the travellers who in those stormy and dangerous regions often fall victims to the inclemency of the weather. It is said that if they meet with a traveller who has sunk under the fatigue and inclemency of the blast, they will lie close to him, until by their warmth they restore heat and energy to the animation which is nearly suspended, and thus frequently will save the life of the sufferer. Should they discover a traveller to have fallen into some deep pit or fissure, whence he is unable to ascend, and if they are unable to render him any assistance, they will return to the convent and give the alarm to the monks, and then conduct them to the place where the unfortunate traveller is immured.

The *Old English Setter.*—It is supposed that this breed was produced between the large water-spaniel and the Spanish pointer; they were much more curled than the present breed of setters, and were very steady in the field, but not so rapid in their movements.

The *English Setter* is a mixed breed between the water-spaniel, Spanish pointer, and the springer, which has attained a very high degree of perfection as a sporting dog. He is one of the most beautiful, lively, and active of dogs.

The *Spanish Pointer* is the stock from which the English pointer has sprung. He is one of the most staunch of all dogs used in the sports of the field, although he is considered too heavy for the present improved mode of sporting, and has now nearly become extinct in Great Britain.

The *English Pointer* was obtained by a cross of the Spanish pointer and fox-hound, and is unrivalled for the rapidity of his movements in the field, and the beauty and symmetry of his form. Since his first production, he has been improved by being re-crossed with the harrier. He is subject to considerable variety in point of size.

The *Small Pointer.*—This is a diminutive breed, being only about two feet from the point of the nose to the tip of the tail, and scarcely a foot in height, and is a complete and beautiful miniature of the large pointer. They have proved themselves excellent sporting dogs, but their small size renders them unfit for use in rough land.

The *Russian Pointer* is much like the Spanish pointer in shape, but his hair is long and hairy.

The *Dalmatian* is a handsome animal, beautifully spotted black on a white skin. In his native country he is employed as a pointer, but imported into England he has there lost all qualities for sporting, and is kept merely as an attendant on carriages. While most other dogs attach themselves to man, this one seems to care for nothing but horses. He lives by choice in the stable, and is happiest when running at the heels of the horses; even his own species he abandons in following out his prevailing taste. He barks little, and is docile.

SECTION 7. Hounds which hunt in packs by the scent.

The *English Terrier.*—This beautiful dog is too well known to require any description. He is possessed of great courage, and is famous for killing all kinds of vermin, and is a useful attendant upon a pack of fox-hounds, for getting into the earth when the fox has taken his hole, and driving him out. His hair is smooth. His general colour is black, with tanned cheeks, and the inside of his legs are of the same colour. They are now to be met with of a brown, and even white colour, but these have unquestionably an admixture of some other breed in them.

The *Scotch Terrier.*—This breed has short wiry hair, very rough, and is much shorter in the legs than the English terrier. His usual colour is sandy, but he is to be found black, and also gray. He bites with great keenness and is a bold and determined dog. He will attack dogs of any size; and when he fixes on an animal, he maintains his hold with great pertinacity. He is much used as an attendant upon packs of fox-hounds, and forms an excellent killer of vermin.

The *Talbot* is one of the primitive breeds of British dogs, and is the same which was used by the ancient Britons in the chase of the deer and other wild animals. It is now, we believe, extinct, or at least not in common use.

Bloodhound.—This is a powerful and sagacious animal, generally of a dark colour, with brown markings, and is endowed with a keen scent. On being led upon the footsteps of any animal or man, he will follow them up with unerring precision. This has led to the breed being employed for tracking criminals, or the unhappy victims of oppression. By the Spaniards a breed was taken to Cuba to track the natives, and this race of animals still exists in that island. A correspondent in a newspaper thus speaks of them :—

"At a period not very remote, the unfortunate negroes in the Spanish settlements were frequently torn to pieces by the Cuba bloodhounds. In fact, under the title of Chasseurs, the Spaniards maintained regular regiments of these dogs and their attendants. In pursuing or hunting the runaway negroes, the chasseur is generally accompanied by two dogs, and armed with a *couteau de chasse*, or straight sword; and we are informed that these bloodhounds, when well and properly trained, on coming up with the object of pursuit, will not kill him unless resistance is offered, but bark at and terrify him till he stops, when they crouch near him, and, by barking, give their keepers notice, who approach accordingly, and secure their prisoner.

"Dallas, in his account of the Maroon War in Jamaica, mentions an importation of these Cuba bloodhounds, in order to assist the regular troops in reducing the refractory Maroons. It may seem strange that dogs were called to the assistance of well-disciplined soldiers, but, in order to elucidate the subject, it must be observed, that the armed Maroons, under the conduct of various cunning leaders, particularly of Cudjoe, Smith, and Johnson, aware of their own inferiority in point of that organization which constitutes the strength and essence of a regular army, cautiously avoided meeting their opponents on the plain; on the contrary, they retired to the impenetrable fastnesses of the woods and mountains, and by means of ambuscades, contrived so to harass the troops, that the governor of Jamaica ultimately procured a company of these dogs and their attendants from Cuba, which arrived at Jamaica under the command of Don Manuel de Sejas; and a tolerable idea of these dogs may be formed from a review which took place immediately after their arrival. General Walpole, who conducted the war against the Maroons, being anxious to review these chasseurs, left head-quarters the morning after they landed, accompanied by Col. Skinner, and arrived in a post-chaise at Seven Rivers. Notice of the general's approach having been given, the chasseurs were taken to a distance from the house, in order to advance when he arrived. The Spaniards were drawn up in a line at the end of a gentle declivity, and consisted of upwards of forty men, with their dogs in front unmuzzled, and held by cotton ropes, as it was intended to ascertain what effect would be produced on the dogs if actually engaged under a fire of the Maroons. The Spaniards, upon the word being given, fired their fusees, when the dogs pressed forward with almost ungovernable fury, amidst the shouts of their keepers, whom they dragged along with irresistible impetuosity. Some of these ferocious animals, maddened by the shout of attack, and held in check by the ropes, actually seized upon the gun-stocks in the hands of the chasseurs, and tore pieces out of them. The unfortunate Maroons, who had successfully opposed all the efforts of regular troops, were panic-struck on the arrival of the bloodhounds, and surrendered without once daring to come in contact with animals which at best could oppose but a feeble resistance to fire-arms."

The *Staghound* is the largest of all the British dogs of the chase; he has a noble and dignified aspect, and possesses great sagacity and endurance in the chase; this dog is also supposed to be a direct descendant of one of our original British dogs.

The *Foxhound* has a much larger muzzle than the staghound, and his head is small in proportion to the size of his body; his ears are very long and pendulous, although less so than those of the staghound and bloodhound. Though a determined enemy of the fox, this active hound is by no means destitute of warm affections. A foxhound bitch, belonging to the Kivington Hunt, near Bolton, on the 8th November, 1792, during the chase, pupped four whelps, which she carefully covered in a rush aisle, and immediately afterwards joined the pack. In a short time after, she pupped another, which she carried in her mouth during the remainder of a hard chase of many miles, to the great astonishment of a number of spectators, after which she returned to the place where she had dropped the four.

The *Harrier*.—This dog is used in hare-hunting, and was originally obtained by a double-cross between the small beagle and southern hound. He is very eager in the pursuit of the hare. There are few instances of any of the deer tribe being hunted with success by dogs of so small a description as harriers.

The *Beagle* is the smallest of the dogs of the chase. He is possessed of a very acute sense of smelling, and pursues the hare with unwearied steadiness; and what he wants in speed and strength he makes up by his perseverance.

The *Otter-Hound* is a cross between the large southern hound and the large rough terrier. He has a large head, with pendulous ears, and his whole fur is of a [illegible] texture, and rather long; his colour is either sandy or black. Otter-hunting was a favourite sport in ancient times, but is now nearly lost in this country.

The *Bull-Terrier* is a cross between the bull-dog and the terrier, as its name implies, and has now assumed the character of a distinct breed. It is much used by the gentlemen of the fancy as a fighting dog.

SECTION 8. Mongrel hounds, which hunt singly either by the scent or eye.

The *Lurcher* is a cross between the greyhound and harrier, and re-crossed with the terrier. His limbs are strong; his head less sharp than that of a greyhound; his ears are short, erect, and half-pricked; and his hair coarse and wiry. He is much used by poachers, and is famous for killing rabbits, as he has a fine scent, and runs his game without giving tongue.

The *Leymmer* and the *Tumbler* are imperfectly known dogs, which are now nearly if not entirely extinct. They hunted both by the scent and eye.

The *Turnspit* is a small dog with a long body and short crooked limbs, and was much used in turning the spit before the invention of jacks. Breeds between this now useless variety of dogs and mongrel terriers and hounds, appear to form the nondescript and ugly races of animals which haunt the streets of our large towns, but whose numbers are now diminishing by the proper interference of the police.

Division III.—With Short Heads.

SECTION 9. Watch-dogs, which have no propensity for hunting.

The *Mastiff* has a large flat head, and a short and blunted muzzle; his lips are full, and hanging considerably over the lower jaw; his ears, although rather small, are pendulous. He has a sullen and grave aspect, and is excellent as a watch-dog; his voice is loud and deep-toned. He is a dog of large size, and is supposed to have been produced between the Irish greyhound and bull-dog. Like the dog next mentioned, he is ferocious in disposition, and of little practical use.

The *Bull-Dog*.—This dog is remarkable for the depth of his chest and the strength of the whole muscles of his body. His head is large, flattened above, and his muzzle much blunted, with the under jaw projecting considerably beyond the upper one; his eyes are set far apart, and project considerably from his head; his power of smelling is less acute than any other of the canine race, on which account he is a dangerous dog, for he has frequently been known to lay hold of his master without discriminating the difference between him and a stranger. He is the boldest and most obstinate of all dogs, and has been known to hold his adversary so determinedly that his legs have been cut off without making him desist.

Many instances have been recorded of the invincible courage of the English bull-dog, but we scarcely recollect one in which so much unconquerable spirit and tenacity of life have ever been displayed, as on the following occasion:—A short time since, a large dog of this species, from some cause that was not observed, suddenly flew at a fine cart-horse that was standing at the end of the Salthouse Dock, Liverpool, and fixing his lacerating teeth in his shoulder, defied every effort to get him off. At first he was beaten with cart-whips and sticks, with such fury as seemed to break his bones; but this being unavailing, a carpenter with an adze in his hand came up and beat him with the blunt iron head of the instrument, till it was thought he had pounded him to a jelly; but the dog never moved a tooth. A man then took out a large pointed clasp-knife, with which he stabbed him repeatedly in the back, loins, and ribs, but with no better success. At length one of the spectators, who appeared to have more strength of sinew and arm than the rest, squeezed the ferocious beast so tightly about the throat, that at length he turned up the white of his eyes and relaxed his jaws. The man threw him off to a distance, but the dog immediately went round the crowd, got behind the horse, and again seized him by the under part of the thigh. As no terms could now be kept with this untameable brute, he was again loosened and thrown into the dock to drown. He instantly, however, rose to the surface, when a sailor struck him a supposed deadly blow on the head with a handspike, which again sent him to the bottom. He arose once more, and was again sent down in the same manner. And this process was repeated five or six times. At length one of the bystanders, who either possessed or assumed some right or property in the dog, overcome by his amazing tenacity of life, and weary of persecution, got him out, and walked off with this prodigy of English courage, to all appearance very little the worse for the horrible punishment he had undergone.

Since the very proper disuse of bull-baiting, this ferocious variety of the dog has fortunately diminished in number.

The *Pug Dog* is descended from the bull-dog, by a cross with the small Danish dog, and resembles the former so much in appearance that he may be considered as a miniature of that variety. He is a useless dog, and with generally a bad temper, has no good quality to recommend him.

GENERAL MANAGEMENT OF DOGS.

As formerly mentioned, dogs are very susceptible of education, and will fall into such habits as are impressed upon them by a course of training. Whatever be the peculiar variety of dog kept in or about a dwelling-house, it is important that he be at least taught good manners; as for example, to be silent and lie down when bidden, to refrain from leaping on the knees of persons visiting the family, and not to sit staring at meals, watching every bit that is put in the mouth. To make a dog behave properly in these and other points, he must be carefully taught when young, and for this purpose his master requires to employ a judicious mixture of severity and gentleness. He must be made fully aware that he must do as he is bid; that if he do not he will be punished, but that if he obey he will be rewarded. As all dogs are very tractable in such matters, they will soon learn to know the meaning of a look, a sign, or a word, and will act accordingly. As very few persons take the trouble to teach domestic dogs either one line of conduct or another, we see on all occasions instances of the natural consequences of neglect.

Breeding.

The best dogs are produced from parents not less than two years old, to which period a valuable bitch should be reserved. During her heats before this time she should be locked up, and be treated with a little cooling medicine. All who are interested in preserving the breed of their dogs, should on no account suffer a cross. In every instance let the male and female be of the true breed designed, not mixed or deteriorated. If a slight alteration of character be desirable, breed from the nearest varieties. Breed always from the healthiest and best shaped animals. Mongrel breeds are good for nothing.

Breeders of sporting dogs require to pay marked attention to these principles. According to the author of the "Oakleigh Shooting Guide," the theory respecting pointers is, "that the further any dog is removed from the original Spanish pointer the worse the dog is; and consequently that all attempts to cross the pointer with any other blood must necessarily deteriorate the breed. The greyhound is seldom or never crossed to give him additional fleetness, nor the hound to improve his nose; why, then, should the pointer be crossed with dogs which, in so far as the sports of the field are concerned, scarcely inherit one quality in common with him? Attempts, however, are constantly made to improve the pointer by a cross with the blood-hound, fox-hound, Newfoundland dog, or mastiff, sometimes with a view of improving his appearance, and bringing him to some fancied standard of perfection, but in reality inducing a deformity. The best pointer is the offspring of a pointer bitch by a pointer dog; such a one is nearly broken by nature. The Spanish [or true] pointer seldom requires the whip; the hound pointer has never enough of it." The same writer continues—"Dogs should be constantly shot over during the season by a successful shot, and exercised during the shooting recess by some person who understands well the management of them, otherwise they will fall off in value—the half-bred ones will become unmanageable, and even the thorough-bred ones will acquire disorderly habits."

It appears that female dogs, before or during a state of heat, are liable to receive mental impressions of the appearance of male dogs with which they have been in company, and these remembrances will affect their progeny even for years afterwards. We beg to refer to "Blaine's Encyclopædia of Rural Sports," p. 412, for some interesting information on this subject.

Whelps, at a month old, are deprived of their dew claws; and if the tail be too long, a small piece may be pinched off. The ears of some dogs are also pared about this period. It is not customary to cut male dogs, except those which are intended for pets; the operation renders the animal a much more docile and agreeable companion. There is a prejudice of very old standing, that dogs have a worm beneath their tongue, and that the removal of this, called *worming*, deprives the animal of the power of biting, should it become rabid. No worm exists; and it is doubtful if the process is of any use. That which is called a worm is merely a minute ligament or fibrous cord in the bridle beneath the tongue; and when the bridle is cut, the ligament may be drawn forward and separated at both extremities; the contraction of the ligament, on extraction, resembles the movement of a worm, and hence the origin of the term.

Feeding.

Some of the most troublesome traits in the dog's behaviour arise from mismanagement in feeding. If a dog be half-hungered, he cannot be blamed for watching the breakfast or dinner table. We advise all who indulge themselves with keeping dogs, not to leave their feeding to the chance scraps of either the kitchen or the parlour. Give the dog his own regular meals, and with food suitable to his wants or the duty he has to perform. The food should be chiefly flesh of some kind, boiled and cold; if given raw, it has a tendency to foster ferocity of disposition, and will cause the animal to be offensive in smell. No pet-dog, especially, should ever be allowed to eat raw meat. Any common pieces of flesh or tripe will answer for dog's meat. Some persons give liver, which is decidedly bad; it relaxes the bowels, and is otherwise objectionable. Besides the piece of boiled meat considered necessary, give dogs a few bones from the dinner table; they are fond of these, and they are useful in cleaning and preserving their teeth, and keeping their bowels in order. If the dogs will take it, they should also be given a little farinaceous food, as morsels of bread or a little oatmeal porridge with milk.

The nature of the dog leads him to feed well when food is offered to his appetite, and to feed seldom. Once a day, therefore, is in ordinary circumstances sufficiently frequent for his meals. Present him with his allowance in the morning or forenoon, and give him no more till next day. He, however, requires to drink frequently; and it is a leading rule in keeping a dog, to have at all times a pan of clean cold water ready for his use. Change the water daily, or oftener.

For the feeding of hounds, Daniel recommends that flesh-meat should be alternated with a diet of oatmeal porridge, made with broth in which meat has been boiled. Greens boiled in their meat is also proper. "A horse killed and given to the hounds whilst warm, after a very hard day, is an excellent meal; but they should not hunt till the third day after it. The bones broken are good for poor hounds, as there is great proof in them. Sheep trotters are very sweet food; and bullock's paunches may also be of service, in a scarcity of horse-flesh. Hounds should be sharp-set before hunting; they run the better for it." The same excellent authority continues to observe that hounds should be fed once when returned from the fatigues of the chase, and again sometime afterwards. "It is the best plan to feed twice the hounds that have been out. Some hounds will feed better the second time than the first; besides, turning them out from the lodging-house refreshes them; they stretch their limbs, and the litter being shaken up, and the kennel cleaned out, they settle themselves better on the benches afterwards. At all times, after being fed, the hounds should be turned into the grass court to empty themselves; it will not a little contribute to the cleanliness of the kennel."

Lodging—Kennel Treatment.

Dogs require to be lodged in a dry situation, at a moderate temperature. The practice of keeping dogs out all night during frosty weather, or of putting them into cold coach-houses, is most inhumane and disgraceful. Dogs kept for watching the outside of premises should be provided with a comfortable dog-house of wood, bedded with clean straw, and sheltered from cutting winds. A dog kept in a dwelling-house should have an appointed place, as in a lobby, for sleeping; its birth should consist of a basket, open box, or small house, according to the taste of the animal. A spaniel will not go into a dog-house; a terrier prefers it. In any case the berth should be laid with a piece of carpet or blanket, which must be frequently washed and dried.

Damp is seriously injurious to dogs. It produces rheumatisms, which show themselves by lameness in the shoulders, and other disorders detrimental to their usefulness. It is therefore of great importance to build kennels in airy situations, and to keep them dry and airy. The best kennels are paved with tiles or stone, but on the floors there are raised benches, littered with straw in winter, on which the dogs repose. The straw should be daily changed, nothing being of so much consequence as cleanliness, both for the sake of general health, and preserving the powers of scent of the animals. For this latter purpose, some keepers of packs of hounds have a change of rooms, one being used while the others are becoming sweet after cleaning. On this subject Daniel observes: "The excellent sense of smelling, so peculiar to the hound, is what our sport entirely depends on; care, therefore, must be taken to preserve it, and the utmost cleanliness is the surest method: to keep the kennel sweet cannot be too much recommended, and is on no account to be neglected. The exactness of the master in this particular will ensure that of the feeder.

"Hounds that come home lame should not be taken out the next hunting day, since they may appear sound without being so. At the beginning of a season the eyes of hounds are frequently injured; such hounds should not be hunted; and if their eyes continue weak, should lose a little blood. Such as have sore feet should have them well washed out with brine or pot-liquor. Hounds unable to work should be permitted to run about the house; it will be of great use to them; and such as are ill or lame ought to be turned into a kennel by themselves; here it will be more easy to give that attention both to their medicine and food which is requisite."

Hounds which are properly disciplined are obedient in a very extraordinary degree to the orders of the huntsman. "To see," says the writer of the article *Hunting*, in the Encyclopædia Britannica, "sixty couples of hounds, animals all hungry as tigers, standing aloof in their yard, and without even hearing, much less feeling, the whip, not daring to move until the order is given to them. And what is the order given? Why, at the words 'come over, bitches,' or 'come over, dogs,' every hound of each individual sex comes forward, as the sex it belongs to may be called for, leaving those of the other sex in their places. Then the act of drawing them to the feeding troughs is an exceedingly interesting sight—often, with the door wide open, having nothing to do but to call each hound by its name, which of course he answers readily to. The expression of countenance, too, at this time is well worthy of notice; and that of earnest solicitation, of entreaty, we might almost say of importunity, cannot be more forcibly displayed than in the face of a hungry hound awaiting his turn to draw. He appears absolutely to watch the lips of the huntsman, anticipating his own name."

Health—Disease.

All dogs whatsoever, but those designed for field sports in particular, require to be kept in what is called "condition," that is, neither too fat nor too lean, but the body in that hardy and active state that will enable the animal to perform its duties. If loaded with flesh or fat it will not possess wind, or a due power of quick breathing, for any length of time in the chase. Colonel Cook observes, on what constitutes a proper condition—"The ribs should be visible and the flank moderately hollow, but the loins must be well filled up in a dog in perfect condition. When dogs exhibit general fullness and too much flesh, commence by physic and a regular course of exercise, which should be mild at first, but increased until it is severe. Avoid too great a privation of food, otherwise the conditioning process will be retarded."

To keep a dog in a state of good health, he must not only be regularly fed and admitted freely to water, but be allowed plenty of exercise daily in the open air, and kept in a cleanly condition. If his bowels appear relaxed, he is not in sound health; and as a preventative of this, let his food, as already said, be substantial, and consist partly of bones; let him also have access to grass; every proper kennel has a grass-yard to which the dogs can resort. In the pan of water used by house-dogs, put a piece of brimstone; it slightly affects the water by lying in it, and helps to keep the animals cool.

All dogs are liable to be troubled with fleas, which they get from the ground; the skin also contracts dirt, and from that or other causes becomes offensive in smell. The remedy is cleanliness. Every lap or house-dog should be washed at least once a week with soap and water. Some dogs have a great dislike to washing, but it must nevertheless be performed. After washing thoroughly, rub the animal dry with a hard cloth, and comb and brush it. If there be fleas, a small-toothed comb will remove them, and they should be killed as they appear. Wash and dry delicate dogs before the fire.

On the subject of physicking as a preventative of disease, or when there are symptoms of diseased skin, a little sulphur and antimony is recommended, mixed with the meat, or done up as a bolus or pill, and in this latter form pushed over the throat. "Once a week or fortnight," says Daniel, "during the hunting season, hounds should have one pound of sulphur given them in their meat; and when the season is over, half a pound of antimony should be added to the sulphur, and well mixed with the meat. This cools, and is doubtless of service to them."

Mange.—This is a cutaneous disease in dogs, very closely resembling itch in the human species, but more inveterate, and is hereditary as well as contagious. Mr Blaine, in his "Encyclopædia of Rural Sports," thus speaks of this nauseous complaint:—"Of all the causes which beget mange, and they are not few, the acrid effluvium from their own secretions is the most common; when it is generated by numbers, particularly when it is confined within a limited space, it is sure to appear. Close confinement of any dog will commonly produce it, and more certainly so if it be at the same time fed on salt provisions; thus there are few dogs on ship-board that do not contract it except such as are allowed full liberty of the deck. Food too nutritive in quality, and too considerable in quantity, is productive of mange; and, on the contrary, food in a great measure withheld, or being very poor in quality, is equally a parent of the disease." The same authority gives several receipts of medicine to be employed; the leading are—powdered sulphur, four ounces; muriate of ammonia (sal-ammoniac) powdered, half an ounce; aloes powdered, one drachm; Venice turpentine, half an ounce; lard or other fatty matter, six ounces; the whole to be mixed and administered in boluses. In all bad cases, however, we should recommend no one to attempt doctoring his dog, but to apply to a regular practitioner.

Distemper.—The disease called the Distemper is most common among dogs which are much kept in the house and subjected to artificial treatment. The disorder is epidemical, affects the constitution, and is very difficult of removal. W. H. Scott, in his work on "British Field Sports," thus describes the symptoms of distemper in a young dog:—"Sudden loss of usual spirit, activity, and appetite; drowsiness, dullness of the eyes, and lying at length with the nose to the ground; coldness of the extremities, ears and legs, and heat of the head and body; sudden emaciation, and excessive weakness, particularly in the hinder quarters, which begin to sink and drag after the animal; an apparent tendency to evacuate from the bowels, a little at a time; sometimes vomiting; eyes and nose often, but not always, affected with a catarrhal discharge. In an advanced stage of the distemper, such symptoms will occur as spasmodic and convulsive twitchings, the nervous and muscular systems being materially affected; giddiness and turning round, foaming at the mouth, and fits. The disease is then often taken for incipient madness, into which it might not improbably degenerate." The same authority adds—"I have found daily mild doses of from two to three grains of calomel alone, lapped by the animal in milk, continued for four or five days, with intermissions when necessary, fully sufficient to carry it safely through the disease, even when the fever has been very high. James's powder has, however, always proved the most certain remedy." To aid recovery nourishing diet should be given. In cases of severity consult the veterinary surgeon.

Madness.—Canine madness, rabies, or hydrophobia, is the most fatal malady to which dogs are subject, and for which, as far as we have heard, there is no certain cure. Blaine considers that rabies is never produced spontaneously in dogs or any other animals, but is invariably the effect of inoculation by a bite from a dog already mad. But as the disease must have commenced spontaneously in some dog at first, we do not understand why it may not do so again; in short, the doctrine, in the exclusive form in which it is put, seems untenable. Rabies is little known in hot or cold countries; it is common chiefly in temperate regions, but shows itself principally in summer, when it may be supposed to be excited by a feverish condition of body.

The leading symptom of the rabid state is an apparent discomfort and unsettledness of purpose, with a desire to gnaw and eat any thing within reach, as straw, wood, coal, or any other rubbish; as the disease advances, the animal snaps and bites at everybody, or any animal near it. This is, however, no effect of bad temper; the dog has no wish to go out of his way to bite; he is under the influence of a derangement which makes him catch only at what is near. Like the unnatural appetite he possesses, the snapping propensity may also partly arise from the irritated state of the stomach and intestines, both of which are greatly inflamed. The throat is likewise livid, and by a constriction of parts, soon prevents the animal from swallowing. That the rabid dog has a terror of water (hence the origin of the name *hydrophobia*), is now beginning to be doubted; and at all events it is not an invariable symptom, for mad dogs have been known to lap water the day before their death. In the later stages of the disease paralysis ensues, and from the fourth to the seventh day the dog expires. It is humanity to shoot the animal before this final catastrophe.

With respect to the production of rabies in the human species, there have latterly been some very grave doubts. An idea has been started, and supported with considerable plausibility of argument by certain medical practitioners, that hydrophobia in the human being is merely a nervous affection, very much if not almost altogether arising from the influence of the imagination; the person bit fancies he is going mad, and mad he becomes. It is very desirable that the medical world should investigate and arrive at some determinate conclusion respecting this remarkable doctrine; meanwhile, till the matter is settled one way or other, we must speak of rabies in the human subject as a real disease, against which every reasonable precaution should be adopted. On being bit, it is always safe to wash the wound immediately, and have the parts burnt with a hot iron, or cut out. In every case let a skilled surgeon be immediately consulted—one who will not hesitate to act with promptitude and decision.

Many cures have been mentioned for the bite of a mad dog. We shall notice a few. The following, according to Blaine, is the famous Herefordshire cure, commonly called *Webb's drink*:—"Take the fresh leaves of the tree box, two ounces; of the fresh leaves of rue, two ounces; of sage, half an ounce; chop these finely, and after boiling them in a pint of water to half a pint, strain and press out the liquor; beat them in a mortar, or otherwise bruise them thoroughly, and boil them again in a pint of new milk, until the quantity decreases to half a pint, which press out as before. After this, mix both the boiled liquors, which will make three doses for a human subject. Double this quantity will form three doses for a horse or cow; two-thirds of it is sufficient for a large dog, calf, sheep, or hog; half the quantity is required for a middle-sized dog; and one-third for a smaller one. These three doses are said to be sufficient; and one of them is directed to be given every morning fasting." Blaine has not much confidence in this remedy, but allows it is worth trying.

Mr. Murray, known as a lecturer on chemistry, mentions, in a letter to a newspaper, the following remedy:—"Let a mixture of two parts of nitric and one part of muriatic acid, both by measure (evolving chlorine in a concentrated form), be applied to the wound as soon as possible, and more than once." He adds, that he has found this a preventive.

M. Buisson, a Parisian physician, declares that madness from the bite of a rabid dog may be thoroughly cured by fumigating the patient in a hot vapour bath, and afterwards keeping up the copious perspiration in bed; this he recommends to be done for several successive nights.*

FIELD SPORTS.

Conducted on principles of moderation, humanity, and fair play, the sports of the field may be said to be those exhilirating and healthful pursuits by which the tribes of

* See an account of Buisson's proceedings in "Chambers's Edinburgh Journal," No. 257.

wild animals are made subservient to man's use, or removed from a sphere in which they are inconvenient and unsuitable. In taking amusement from such sports, it is the glory of the true English gentleman to avoid every proceeding which can give unnecessary pain to the animals over which he claims dominion, and to discountenance by every means in his power such odious abuses of sport as baiting, worrying at the stake, or any other method of protracting the death of the creatures who have the misfortune to be objects of the chase.

Our space will permit us only to notice the leading field sports of Britain in past and present times.

FALCONRY.—DEER HUNTING.

Falconry was the favourite field sport of the middle ages, as shooting with the gun is the predominant one of the present day. It appears, in this country, to have declined and gone out of use in the seventeenth century, in consequence of the gun having then become, by the addition of the lock and flint, a much more ready means of bringing down game than the use of hawks had ever been. Falconry, while it existed, was the peculiar sport of kings, and princes, and nobles, many of whom were painted in life with their hawks seated on their wrist, and were sculptured on their tombs after death with the same creature placed at their feet, thus marking the special regard in which they held the animal which was the means of giving them so much amusement.

The sport, we need scarcely remark, was founded on the natural instinct of the rapacious order of the feathered creation, as the chase may be said to be founded on the instinct of the dog to pursue the hare, fox, and other animals. The rapacious order of birds, of which the eagle, falcon, and owl, are the three principal types, are formed in such a way as evidently fits them for pursuing, seizing, and destroying the smaller birds; a part in creation which at first sight appears to involve much cruelty, but which has been clearly shown to be intended to save rather than to produce pain, and to be indispensable to a system of things in which one leading feature is, that there shall always be as many living creatures as can possibly be supported. The falcon family were alone employed for purposes of sport, as alone possessing the required docility, and of this family two or three species were more frequently used than any other. Of those possessing long wings, the falcon proper and the gerfalcon; and of the short-winged, the goshawk and sparrow-hawk, seem to have been the favourite kinds. Species called the hobby, the kestral, the merlin, and buzzard, were the next in request. The female, which is in all the varieties of this tribe considerably larger than the male, was alone employed in sport, and the common names of all the species apply to that sex, the male having usually some distinctive appellation: thus the male of the gerfalcon was called the *jerkin*, of the falcon proper the *tierce gentle*, of the goshawk the *tiercel*, and of the sparrow-hawk the *musket*.

These birds naturally choose retired habitations. The falcon, in particular, builds her nests amongst cliffs in wild and unpeopled regions. In order to fit birds for the sport of falconry, it was necessary to take them from the nest at a very early stage of their existence (then technically called *eyasses*), or to ensnare them in their more mature age, and then train them for the purpose. A falcon in its natural state was said to be a *haggard;* hence, apparently, the term by which we still express a wild or agitated aspect. The first step in training the falcon was to *man* it, or accustom it to the presence of human beings. Feeding was the grand source of the power which its keeper acquired over it. When it did as required, it was fed, and thus taught to know that it had done right—and not otherwise. If extremely refractory, a stream of cold water was directed at its head, as an admonition that nothing was to be gained by such conduct. From the very first, the animal was accoutred with certain paraphernalia, the *names* of which at least must be familiar to most readers. First, its head was covered by a leathern *hood* fitting close all around, so as to shut up its eyes, and calculated, by a slit behind, to be readily slipped on and off. On the top of the hood there was a tuft of feathers, which usually has a graceful effect in the old pictures representing ladies or gentlemen travelling with their hawks upon their wrist. Leathern straps, called *jesses*, a few inches in length, were fitted to the legs of the bird by a button slipping through a slit or loop. Close beside the end attached to each leg was a small spherical *bell*, like that of a child's rattle, and composed of silver for clearness of sound, the one being in some nice instances made a semitone higher than the other. The other end of the jesses were furnished each with a ring, which could be readily fitted upon the swivel designed to connect them both with the *leash*, a long slender strap, sometimes prolonged by a *creance* or common cord, and designed as a tether by which to restrain the animal, at the same time that it should be allowed considerable room for free motion. Two great objects in training were to teach the bird to fly at its proper game, and to habituate it to come back to the hand of its master, after on any occasion having been let free in pursuit of its prey. For the first of these ends, in the case of long-winged birds, an implement termed the *lure* was used. It consisted either of a stick or of a cord, on the end of which were fixed pieces of flesh, with a bunch of the feathers of the prey which it was designed that the bird should fly at, or perhaps an actual resemblance of the prey in its entire form. The falcon being set loose by one man, another stood at a distance waiving the lure around his head, thus tempting the animal to advance and strike at it. A whistle was the implement used to *reclaim* or bring back the hawk. When a hawk was to be kept on the hand, strong gloves were worn for protection from its talons. It may here be remarked, that the training of falcons was altogether a most laborious business, and that trained birds were accordingly to be only purchased at a high price. At the beginning of the seventeenth century, a trained goshawk and tiercel brought one hundred marks, and it was considered a favour to part with them. The extreme labour attending the training of the animals must have been sufficient in early times to confine the sport to persons of birth and fortune, if there were no other cause; and it must also have conduced to the rapid decline and extinction of the sport, after a ready means of killing wild-fowl by the gun became attainable.

The sport, after being long given up, was revived in England a few years ago by Colonel Thornton, the Duke of St. Albans, and a few other gentlemen, chiefly through the influence of a taste for whatever is elegant and romantic in the usages of our forefathers. It is said to be a gallant and goodly sight, when a train of well-mounted English ladies and gentlemen rides forth in a clear sunshiny day, to pursue this sport, attended by their falconers, each with his hawk on his wrist. In the present day, as of yore, various kinds of feathered game are flown at. Heron-hawking is, we believe, in greatest esteem. The heron, as must be generally known, is a large bird in appearance, with a long neck, long legs, and a long sharp bill, being designed to haunt marshes and pools, and feed upon whatever fish it can find therein. It is, however, a light unsubstantial bird, with nothing to protect it from enemies but its sharp bill. Herons are gregarious, and the lonely places where they live are called heronries. These explanations will introduce the following account of heron-hawking, from Blaine's "Encyclopædia of Rural Sports:"—

"The daily visitations of the heron to its feeding-places are watched by the falconers, who station themselves to the leeward or down wind of the heronry, so that the heron on his return must fly against the breeze, which gives a great advantage to its enemy. As soon as one is discovered on the return, a cast of falcons is let loose, who, catching sight of the quarry, rise in pursuit. The heron, instinctively aware that its life is at stake, prepares for the fray by disgorging the contents of its stomach to lighten the weight of the body. The coursing falcons ascend the airy vault in spiral gyration, by which the atmospheric resistance to their flight is lessened. These circlings, it has been observed, have frequently the curious effect of presenting the three birds as flying in different directions; whereas the real intentions of the two hawks are steadily directed to one point, which is that of contact with the heron, whose entire efforts are as steadily engaged in avoiding it. To effect this, the affrighted heron strenuously endeavours to rise above the hawks, who, however, by the superior power of wing, commonly succeed in getting the upper station, from which one presently makes its stoop; and happy it is for the poor heron if he can evade the blow, which he occasionally does, either by shifting his station, or by receiving the falcon on his sharp bill, which instantly transfixes it. This danger is, however, denied on authority, but we feel assured that it does occur. The second hawk, if the first fails, stoops in his turn; but the meditated blow of this also is frequently evaded like the former. The trio then still rising higher and higher, the sight becomes interesting in the extreme, and the spectators are scarcely less agitated than the feathered warriors above. At length another stoop takes place, and the fatal seizure is made by one hawk, while the other *binds* to his fellow, and all three quickly descend together, but not with a dangerous rapidity, as their powers of inflation and the action of their wings break the fall. It is now that the mounted horsemen make the best of their way to the assistance of their falcons, and their first efforts must be directed to secure the head of the heron, that the sharp beak may not take effect on one or both of them."

Pheasants are objects of this sport, but not to a great extent, on account of the inconvenience presented by the sylvan ground in which the sport must be practised. Partridge-hawking is found to be a more convenient sport. To quote the same authority—"The scene of practice is commonly on large fields or open tracts of country, where the horsemen and company generally can beat in line, and the attendant falconer or master, being well mounted, can ride forward and be ready to receive the quarry. Either pointers or spaniels are necessary, or both.

"The partridge being flushed, the hawk will stoop with astonishing rapidity, and seize on it; at which time neither horses, dogs, nor company, should press forward; on the contrary, they should permit the falconer only to advance, who, approaching the hawk with caution, must walk quietly round her, when, gently kneeling down with his arm extended, as though in the act of feeding the hawk, he should lay hold of the partridge, and at the same time place the hawk on his fist. This done, put on the hood, and reward the hawk with the head of the quarry, and if she be not intended to fly again, let her be fed immediately.

"A somewhat different method of partridge-hawking is practised in the latter part of the season, when the country is very bare, and when the partridges are often very wild, and lie indifferently even to the dog. In such cases it is recommended that the company 'draw up in line at fifty or sixty yards' distance from each other, and gallop across the plain with a hawk upon wing,' the falconer being in the centre of the line, that he may regulate the pace by the situation of the hawk. Sir John Sebright informs us that this method of partridge-hawking has afforded him more sport than any other, and that when the face of the country was so bare, and the birds so wild as to make it impossible to approach them in the usual way.

"Brook-hawking, as it is often termed, was much in vogue formerly. The practice was not, however, confined to brooks, but extended to rivers, sea-shores, moors, and ponds. It engaged, according to Blome, 'the jer-falcon, the haggard falcon, the jerkin, and the tassel gentle.' Waterfowl of every description were made prey of; but some particular objects, according with the training of the falcons, were particularly sought for. Dogs were employed to rouse the fowl, being led on by men who traversed the water's edge; while horsemen, with the hawks on their fists, were at hand to *cast off* one or more, according to the nature of the game. A heron or mallard would require two, while a widgeon or teal would probably engage only one."

Deer-hunting was another principal amusement of past times, but has now been abandoned in the form in which it used to be conducted. The species of animals chiefly hunted in England was the fallow-deer, a beautiful creature with stately horns or antlers, and of great speed in running. Fallow-deer are now closed up in parks, at least in Britain. The stag, red deer, or hart, whose female is called the hind, differs in size and in horns from the fallow-deer. He is much larger, and his horns are round, whereas in the fallow species they are broad and palmated. Red deer are now, we believe, the only objects of field sport in this country, and principally in the Highlands of Scotland, where they still exist in considerable numbers. No hounds, however, as in the chase in former ages, are employed, the hunter depending on his gun and his skill in approaching the animal noiselessly. This, which is called *deer-stalking*, is a sport requiring a vast deal of tact, knowledge of the animal's habits, and patience, as whole days are occasionally taken up in stealthily watching an opportunity for a shot. Such is the power of sight, scent, and hearing, that to approach unperceived on a plain is impossible. They must be approached down the wind, and from behind thickets or hillocks. A telescope is required in these difficult manœuvres. When it is impracticable to reach them in this artful manner, attendants drive them into gorges among the mountains, and the sportsman singles out an object for his gun as it passes his concealed station. A lively work on deer-stalking has lately been written by Mr. Scrope, to which we beg to refer those who are interested in the subject.

FOX-HUNTING.

The variety of fox most common in Britain is called the *cur fox*, which is of a brown colour, with generally some white on the breast and belly, and a light tip to the long bushy tail. Foxes go to *clicket* in winter, and cubs are produced in the latter end of March; they breed but once a year, and have from three to six young ones at a time. In his nature the fox is playful, but rapacious in his appetite, and his predominating characteristic is great craftiness. He usually fixes his abode on the border of a wood, at no great distance from a farm-house or village; he listens to the crowing of the cocks and the cries of the poultry; he scents them, and chooses the time of his attack with judgment; he conceals his road as well as his design; he slips forward with caution, sometimes even trailing his body, and seldom makes a fruitless expedition. He plans similar encroachments on the nests of birds, rabbit warrens, &c.; and, in a word, is so destructive to live-stock that it is absolutely necessary to take and kill him.

Fox-hunting on a proper scale requires to be conducted with the class of active horses termed hunters, a pack of fox-hounds to scent and run down the prey, and terriers to turn the animal from his hole, should he take to earth. A pack of hounds varies from twenty to thirty couples; but besides these, some hounds are always left undrafted into the field. The cost of a good pack is reckoned at from £1000 to £1200, and the annual expense of its keep and management as much. The huntsman, as the grand leader of the chase, is a functionary of no small importance; he is assisted by two whippers-in, who bring up and take charge of the hounds.

The fox being an early riser, and his scent lying best on the damp grass, he is hunted in early morning; and the first business on taking the field is to ride to and draw cover—that is, bring out the fox from his retreat. At the first sight, the view halloo is given by the huntsman, and all follow the sweeping track of the hounds. It is a rule in hunting never to get before the dogs, or to throw them out any way by a false signal; on the contrary, the great art is to keep them to the scent, and to aid their search. The run is considered the exhilarating part of the sport, and consists of a rapid chase through a broken or rough country, with the hounds in full cry. Then is the ardour of the chase shown; and it continues till the fox, by some clever manœuvre—such as tracking up a brook—throws the hounds off the scent, and the party is brought to check. The scent and track of the animal being again found, off all go once more in pursuit, but with generally frequent doubts of the result. "See," says Beckford, in his enthusiastic style, "where the hounds bend towards yonder furze brake; I wish he may have stopped there. Mind that old hound; how he dashes over the furze! I think he winds him! Hark! they halloo! Ay, there he goes! It is nearly over with him! Had the hounds caught view he must have died! He will hardly reach the cover. See how they gain upon him at every stroke! It is an admirable race; yet the cover saves him. Now be quiet, and he cannot escape us; we have the wind of the hounds, and cannot be better placed. How short he runs! He is now in the strongest part of the cover! What a crash! Every hound is in, and every hound is running for him! That was a quick turn! Again, another! He's put to his last shifts! Now mischief is at his heels, and death is not far off! Ha! they stop all at once; all silent, and yet no earth is open. Listen! Now they are at him again! Did you hear that hound catch him?—they overran the scent, and the fox had laid down behind him. Now reynard, look to yourself! How quick they all give their tongues! The terriers, too, are now yelping at him. How close *Vengeance* pursues!—how terribly she presses!—it is just up with him! What a crash they make; the whole wood resounds! That turn was very short!—There!—now!—ay, now they have him! Who-hoop!" The chase is over: Reynard is no more; and his *brush* or tail being cut off as a trophy by the huntsman, his unfortunate carcass is thrown to the hounds, and in a few moments destroyed, leaving scarcely a wreck behind.

HARE-HUNTING—COURSING.

Hares are hunted in much the same manner as foxes, the chief difference being that harriers are employed instead of hounds; both hunt by the scent. Of this branch of field sports, the writer of the excellent article on *Hunting*, in the "Encyclopædia Britannica," makes the following mention:—

"Hare hunting claims precedence of fox-hunting in the sporting chronology of Great Britain, and we believe of all other countries, inasmuch as a hare has always been esteemed excellent eating, and a fox the rankest of carrion. We gather from Xenophon that it was practised before his day, and he wrote fully three centuries before the Christian era, both hounds and nets being then used in the pursuit. Neither can we marvel at hare-hunting being the favourite diversion in all nations given to sporting, where the use of the horse in the field had not become common. But we will go a point farther than this, and assert, that how inferior soever may be the estimation in which hunting the hare is held in comparison with hunting the fox, no animal of the chase affords so much true hunting as she does, which was the opinion of the renowned Mr. Beckford

"The difficulty of finding a hare by the eye is well known. It is an art greatly facilitated by experience, although not one person in ten who attempts it succeeds. But here we recognise the hand that furnished her with such means for her security; as, from the delicacy of her flesh, she is the prey of every carnivorous animal, and her means of defence are confined only to flight. In going to her form, she consults the weather, especially the wind, lying always, when she can, with her head to face it. After harvest, hares are found in all situations; in stubble fields, hedge-rows, woods and brakes; but when the leaves fall, they prefer lying upon open ground, and particularly on a stale fallow, that is, one which has been some time ploughed; as likewise after frost, and towards the spring of the year. In furze or gorse, they lie so close as to allow themselves nearly to be trodden upon, rather than quit their form. The down or upland-breed hare shows best sport; that bred in a wet marshy district the worst, although the scent from the latter may be the strongest. If a hare, when not viewed away, runs slowly at first, it is generally a sign that she is an old one, and likely to afford sport; but hares never run so well as when they do not know where they are. Thus trapped hares turned out before hounds, almost invariably run straight on end, and generally till they can run no longer; and they generally go straight in a fog. The chase of the hare has been altered, and rendered less difficult in some degree, by the improvement of the hound used in it.

"The difference in the terms used in hare-hunting and fox-hunting is comprised in a few words:—Harriers are cast off in the morning; fox-hounds throw off. The hare is found by the quest or trail; the fox by the drag. The hare is on her form or seat; the fox in his kennel. The young hare is a leveret; a fox a year old is a cub. The view hollo of the hare is 'Gone away;' of a fox 'Tallyho.' The hare doubles in chase; the fox heads back, or is headed. The harrier is at fault; the fox-hound at check. The hare is pricked by the foot; the fox is balled or padded. The hare squats; the fox lies down, stops, or hangs in cover; the 'who hoop' signifies the death of each."

Hares are hunted with packs of generally twenty couples of harriers; but whatever number is employed, it is the established rule never to run in upon the hares as soon as discovered in their forms, but to allow them a little space before the dogs are set on. The hares, also, must not be pressed upon in the chase by the company, neither are the dogs, on losing scent, to be called on the right path; for this leads them to depend on the sight of the huntsman instead of their own nose. Leave the harriers pretty much to themselves.

Coursing is the chasing and taking of the hare by means of greyhounds, which hunt by the sight only. Among fox-hunters it is considered an inferior kind of sport, but many country gentlemen find in it an exhilarating recreation, and it is patronised by numerous coursing clubs. "There is," says Blaine, "even a philanthropic character about coursing almost unknown to other huntings. It may be said to offer a kind of refuge for the sporting destitute, for it holds out innocent recreation to those whose means or whose prudence will not allow them to risk either their neck after a fox or their wealth after a racer. Here the octogenarian, at once labouring under his increased years and his decreased energies, may solace himself with an epitome of former huntings; and farther, that the joys of this chase are within the reach of every state or stage of life."

The greyhound, whose form so eminently adapts him for competing with the hare in a race, requires to be well trained in the art of turning suddenly, and determinedly pursuing his game on a new line of pursuit. His eye should be clear and quick, and his wind good, to enable him to hold out to the last. Greyhounds are delicate in their nature, and require very careful treatment; their lodging must be dry and comfortable, and when taken out in a cold morning they must be held in leash with jackets on, ready to let slip. In any case, they are not uncoupled or let go till the hare has been seen and started. A single pair of dogs is generally sufficient for the sport; and betting often ensues as to the points in the course. There are numerous rules of ancient and modern date on the subject of coursing. The following, established by the Duke of Norfolk in Queen Elizabeth's reign, are yet held applicable:—

"The Feuterer, or person who lets loose the greyhounds, was to receive those that were matched to run together into his leash, as soon as he came into the field, and to follow next to the hare finder, or him that was to start the hare, until he came to the form, and no horse or footmen were to go before or on either side, but directly behind for the space of about forty yards.

"A hare was not to be coursed with more than a brace of greyhounds.

"The hare finder was to give the hare three 'sohos' before he put her from her form, to give notice to the dogs that they may attend her starting.

"The hare was to have twelve score yards law before the dogs were loosed, unless the small distance from the cover would not admit it without danger of immediately losing her.

"The dog that gave the first turn, and during the course, if there was neither cote, slip, nor wrench, won.

"A cote is when the greyhound goes endways by his fellow, and gives the hare a turn.

"A cote served for two turns, and two trippings or jerkins for a cote; if the hare did not turn quite about, she only wrenched, and two wrenches stand for a turn.

"If there were no cotes given between a brace of greyhounds, but that one of them served the other at turning, then he that gave the hare most turns won; and if one gave as many turns as the other, then he that bore the hare won. A 'go-by,' or bearing the hare, was equivalent to two turns.

"If neither dog turns the hare, he that led last to the cover won. If one dog turned the hare, served himself and turned her again, it was as much as a cote, for a cote was esteemed two turns.

"If all the course were equal, the dog that bore the hare won; if the hare was not borne, the cause was adjudged dead. If a dog fell in the course and yet performed his part, he might challenge the advantage of a turn more than he gave.

"If a dog turned the hare, served himself, and gave divers cotes, and yet in the end stood still in the field, the other dog, if he ran home to the cover, although he gave no turn, was adjudged the winner.

"If by accident a dog was rode over in his course, the course was void, and he that did the mischief was to make reparation for the damage. If a dog gave the first and last turn, and there was no other advantage between them, he that gave the odd turn won.

"He that came in first at the death, took up the hare, saved her from being torn, cherished the dogs, and cleansed their mouths from the wool, was adjudged to have the hare for his trouble.

"Those that were judges of the course were to give their decision before they departed out of the field."

SHOOTING—GROUSE—PARTRIDGES, &c.

The leading sports with dog and gun are the shooting of grouse, partridges, and pheasants, which differ in some respects from each other. The first thing to be attended to in either case is having a good fowling-piece or gun; and the second is to know how to use and clean it. Next, the sportsman must be provided with a dog trained to point the kind of game for which he is taken to the field; to take a dog accustomed to point partridges on a grouse-shooting excursion would be improper. The gunpowder employed should be kept very dry in a metal flask, and of proper strength and purity. Patent shot is now commonly used; it is of eight sorts, each numbered, and rises from 83 pellets to 620 pellets in the ounce. The more tender the birds, the smaller may be the pellets or drops. For grouse, shooters begin with No. 7, or 480 to the ounce; ducks require shot No. 4, or 105 to the ounce.

The following hints to a beginner in shooting are by Hawker and others:—"In raising the gun, let him remember that the moment it is brought up to the centre of the object, the trigger should be pulled, as the first sight is always unquestionably the best. Then send him out to practice at a card with powder, till he has got steady, and afterwards load his gun occasionally with shot, but never let the time of your making this addition be known to him; and the idea of it being perhaps impossible to strike his object will remove all anxiety, and he will soon become perfectly collected.

"The intermediate lesson of a few shots at small birds may be given; but this plan throughout must be adopted at game, and continued, in the first instance, till the pupil has quite divested himself of all tremor at the springing of a covey, and observed in the last, till most of his charges of shot have proved fatal to the birds. If he begins with both eyes open, he will save himself the trouble of learning to shoot so afterwards. An aim thus, from the right shoulder, comes to the same point as one taken with the left eye shut, and it is the most ready method of shooting quick. Be careful to remind him (as a beginner) to keep his gun moving, as follows:—before an object, crossing; full high for a bird rising up or flying away, very low; and between the ears of hares and rabbits running straight away. All this, of course, in proportion to the distance; and if we consider the velocity with which a bird flies, we shall rarely err by firing, when at forty yards, at least five or six inches before it. Till the pupil is *au fait* in all this, he will find great assistance from the sight, which he should have precisely on the intended point, when he fires. He will thus, by degrees, attain the art of killing his game in good style, which is to fix his eyes on the object, and fire the moment he has brought up the gun. He may then ultimately acquire the knack of killing snap shots, and bring down a November bird the moment it tops the stubble, or a rabbit popping into a furze-brake, with more certainty than he once used to shoot a young grouse in August or a partridge in September.

"Many begin with very quick shooting, and kill admirably well, but are often apt not to let their birds fly before they put up their gun, and therefore dreadfully mangle them, and, I have already observed, are not such every-day shots as those who attain their rapid execution on a slow and good principle.

"If a rival shooter (some stranger) races to get before you, push him hard for a long time, always letting him have rather the advantage, and then give him the double without his seeing you. Having done this, go quietly round (supposing you have been beating up wind); and on reaching the place where you began, work closely and steadily the whole of the ground or covert that you have both been racing over, and you will be sure to kill more game than he will, who is beating and shooting in haste, through fear of your getting up to him, and (if the wind should rise) driving the dispersed and consequently closest lying birds, to your beat as fast as he finds them.

"Beware of the muzzle of the gun being kept hanging downwards; when so carried, the shot is apt to force its way from the powder, especially in clean barrels. If it happens that a space of sixteen or eighteen inches is thus obtained, and the gun fired with its point below the horizon, it is ten to one but the barrel bursts. There are other perilous consequences besides those that generally accompany the disruption of a barrel, for the men, horses, and dogs are in perpetual danger of being shot when a gun is carried in the before-mentioned pendant manner.

"When a gun begins to exhibit symptoms of having done its work, the sooner a man discards it the better. An injured barrel or enfeebled lock may prove fatal to the owner or his associates. Accidents occur every day, and very lamentable consequences proceed, from a culpable neglect in retaining arms which should be declared unserviceable and disused."

Grouse Shooting.—This favourite field sport, as is well known, commences annually on the 12th of August, when thousands of persons adjourn to remote parts of the country to follow it, with all its toils and privations. Among the varieties of the game are numbered the cock of the wood or capercailze; the black cock, black game, or black grouse; the red grouse or moor-fowl; and the white grouse or ptarmigan. The moor-fowl are the most common, at least on the northern moors and hills. The birds being hatched in April, if the summer is dry, they will be pretty strong on the wing in August. The best weather for shooting is that which is dry and warm; wet makes them lie still on the ground. No one need attempt grouse shooting who is of delicate health, or not well trained by previous feeding or exercise. The labour of walking over heather is most toilsome, and the danger of colds from rain or wet feet considerable. The dress ought to be very strong, without any regard to fineness; stout shoes or quarter boots are indispensable.

The times of day best suited for grouse shooting are the morning and evening, when the birds are in quest of food; but few are able to reach their haunts till eight o'clock, when the sport commences. "To find the birds," says the author of "Wild Sports of the West," "when, satisfied with food, they leave the moor to bask in some favourite haunt, requires both patience and experience, and here the mountain-bred sportsman proves his superiority over the less practised shooter. The packs then lie closely, and occupy a small surface on some sunny brow or sheltered hollow. The best nosed dogs will pass within a few yards and not acknowledge them: and patient hunting, with every advantage of the wind, must be employed to enable the sportsman to find grouse at this dull hour. But if close and judicious hunting be necessary, the places to be beaten are comparatively few, and the sportman's eye readily detects the spot where the pack is sure to be discovered. He leaves the open feeding grounds for heathery knowes and sheltered valleys; and while the uninitiated wearies his dogs in vain over the hill-side, where the birds, hours before, might have been expected, the older sportsman profits by his experience, and seldom fails in discovering the dell or hillock where, in fancied security, the indolent pack is reposing."

Our most practical authority on this exciting topic is the "Oakleigh Shooting Guide:"*—"Grouse shooters should separate and range singly; they should have no noisy attendants. In wet weather one dog is sufficient; we advise rest from eleven till two. The flight of grouse is generally about half a mile. Their favourite haunts, when undisturbed, are those patches of ground where the young heather is most luxuriant. They avoid rocks, and bare places where the heather has been recently burnt; at any rate, they are not to be approached in such places. It is in young heather that grouse most frequently feed. They are seldom found in the very long thick heather that clothes some part of the hills, until driven there for shelter by shooters or others. It is early in the morning and towards evening that grouse are to be found in young heather. During the middle of the day the shooter should range the sunny side of the hill, and avoid plains.

"No species of shooting requires the aid of good dogs more than grouse shooting, and in no sport does so much annoyance result from the use of bad ones. The best dog, perhaps, for the moors, is a well-bred pointer, not more than five years old, which has been well tutored—young in years, but a veteran in experience. The setter is occasionally used with success, but we prefer the pointer. The latter has unquestionably the advantage when the moors are dry, as it not unfrequently happens that they are in August. If a setter cannot find water wherein to wet his feet every half hour, he will not be able to undergo much fatigue. Some sportsmen will hunt a couple of mute spaniels for grouse shooting in preference to any other team of dogs. Of course, when this method is pursued, the birds are never pointed, and the shooter must ever be on the look-out, for the game is generally sprung very near the gun."

Partridge Shooting.—Of partridges there are two kinds, the red and gray, the latter being that which is common in this country; the plumage is of a brown and ash colour, elegantly mixed with black; the tail is short, and the figure more plump than handsome. Partridges pair about the third week of February, and sometimes, after being paired, if the weather be severe, they all gather together and form a covey, and are then said to pack. They begin to lay in six weeks after pairing. The female lays her eggs on the ground, scraping together a few bents and decayed leaves into any small hollow. The young birds begin to appear about the first ten days in June, and the earliest will take the wing towards the latter end of that month. In dry seasons they are most numerous. So many are the enemies of the partridge, that it is believed never more than half of those produced come to perfection. The affection of both parents for their young is very remarkable; they lead them out in quest of food, shelter them with their wings, and resort to many tricks to lead supposed enemies away from their broods.

Partridge shooting commences, by law, on the 1st of September, when the birds are strong. In the course of this month, the short flights of the coveys, in tolerably well-preserved grounds, afford abundance of sport. In more open districts of country, where there is a wider range, partridge shooting requires more skill, and a steady pointer or setter. In shooting either at a flight of grouse or covey of partridges, select a bird on the outside, and fire at it alone; it is only over-hasty or ill-taught sportsmen who let fly indiscriminately at the centre of a group of birds.

Pheasant Shooting.—Pheasants are a species of birds allied to domestic fowls, and partake of some of their habits; no birds of the game kind possess such elegant plumage, and few are so large. They breed on the ground, and like partridges are fond of nestling in clover, but their chief resort is shrubberies or secluded spots in plantations. The pheasant and its brood, if undisturbed, remain in the stubbles and hedgerows some time after corn harvest; if molested they seek the woods and only issue thence to feed in the stubbles at morning and evening. Besides corn, the birds will live on wild berries, or any seeds they can pick up. As the cold weather comes on, they begin to fly up at sunset into trees, where they roost during the night.

"For shooting pheasants, it often becomes necessary

* This manual has been republished in an improved and handsome form in the volume entitled "The Rod and the Gun." A. and C. Black, Edinburgh.

to start very early in the morning, as they are apt to lie during the day in high covert, where it is almost impossible to shoot them till the leaf has fallen from the trees. We can never be at a loss in knowing where to go for pheasants, as we have only to send some one the previous evening, for the last hour before sunset, to watch the different barley or oat stubbles of a woodland country, and on these will be regularly displayed the whole contents of the neighbouring coverts. It then remains to be chosen which woods are the best calculated to shoot in; and when we begin beating them, it must be remembered to draw the springs, so as to intercept the birds from the old wood. If the coverts are wet, the hedgerows will be an excellent beginning, provided we here also attend well to getting between the birds and their places of security. If pheasants, when feeding, are approached by a man, they generally run into covert; but if they see a dog, they are apt to fly up.

"There are very few old sportsmen but are aware that this is by far the most sure method of killing pheasants, or any other game, when they are tolerably plentiful in covert; and although, to explore and beat several hundred acres of coppice, it becomes necessary to have a party with spaniels, yet on such expeditions we rarely hear of any one getting much game to his own share, except some sly old fellow, who has shirked from his companions to the end of the wood, where the pheasants, and particularly the cock birds, on hearing the approach of a rabble, are all running like a retreating army, and perhaps flying in his face faster than he can load and fire."

It is necessary, in pheasant-shooting, to use a short double-barrelled gun of wide bore, and large shot. Fire at not a greater distance than thirty yards, and only when the bird has risen clear of the bushes: aim is to be taken at the head; but if the pheasant is crossing your path, fire a little before the head, the rapid flight of the animal bringing it in contact with the shot. Towards November, this field sport may be united with woodcock shooting

GAME.

According to law, wild animals are no one's property but of these animals only certain kinds may be killed without a license. Those protected from indiscriminate slaughter are called *game*, and are deer of every species, foxes, hares, partridges, grouse, pheasants, woodcocks, snipes, &c. The wild animals not reckoned game are rabbits, rats, mice, crows, rooks, pigeons, sparrows, all kinds of sea-birds, &c.; any one may kill and appropriate these, provided it be in a highway, the sea-shore, or any other public ground. Game cannot be legally taken or killed in any form without a license procured from the competent officer of the crown, and a permission from the proprietor of the ground on which the game happens to be. To shoot or hunt without a license is called *poaching*: to shoot or hunt with a license, but without a permission, renders the person liable to an action for trespass. These game laws are relics of ancient laws instituted by the Anglo-Saxon and Norman sovereigns for protection of the royal forests; and though some of these provisions are useful, they are, generally speaking, a disgrace to the statute book, and ought to be simplified and amended.

ANGLING.

ANGLING is the art of alluring and capturing fish by means of a rod and line, to which a hooked bait of some kind is attached—an *angle*, as it were, being formed by the apparatus as held over the surface of the water. Either for profit or amusement, the practice of taking fish in this excusably crafty manner is of great antiquity, as we may learn from the mention made of it by the prophet Isaiah: "The fishers also shall mourn, and all they that cast angle in the brooks" (chap. xix., ver. 8). As well as fishing with nets, the practice has continued through all ages to the present time, and in almost all countries. In the British islands, it has long formed a favourite pastime among every class of society, lay and clerical, and to all presents many features of attraction. "It is," to use the words of Mr. Blaine, "far from dangerous or expensive, but on the contrary is productive of interest and amusement without any extraordinary sacrifice. Its *apparent* simplicity lures many into the practice; and as a trifling success elates the tyro and leads him on by its fascinations, so he pursues it, although he soon discovers that extreme nicety and precision, great patience, caution, and perseverance, are essential requisites to the attainment of proficiency in the art. Nevertheless, he still continues the pursuit; difficulty after difficulty is overcome; each succeeding year adds interest to the practice, which he continues with undiminished ardour to the latest period of his life. It is asserted, and we believe with truth, that there is not one among the field sports that takes so permanent a hold on the passions as this. It is no less remarkable for the variety it offers, for it presents itself under many forms, some of which are suited to the taste of every age, of every rank, and every variety of character and habit. The sedentary, the thoughtful, and the advanced in life, may watch the float as it slowly moves with the stream, without disturbance to the train of thought, or without any fatiguing exercise to their person. The active and volatile may throw afar the leaded bait for the pike, or may engage in the graceful evolutions of the fly-rod. Its seductions, therefore, prove universal, and it owns votaries of every age and station." As the sport is pursued on the banks of rivers or lakes, in the midst of purely natural scenery, and in weather which invites to out-of-door recreation, all conspires to render it in a peculiar manner delightful and healthful, when indulged in with judicious moderation.

No kind of amusement has been the object of such frequent description as angling. Hundreds of treatises have been written descriptive of the sport in all its departments, and with reference to all varieties of fish and the waters to which they resort. The first writer of note on the subject, and who has been acknowledged the great father of the angle, was Isaac Walton (born in Stafford, 1593, died 1683), who in the year 1653 gave to the world his "Complete Angler," a work afterwards enriched with additions by his friend Charles Cotton, and which till this day is esteemed not more for the correctness of its details than the singularly happy humour of its apologues, poetical pieces, and disquisitions. According to old Isaac, all recreations sink into insignificance in comparison with angling, which in almost every page he lauds for its moral qualities, and the happiness it is calculated to yield. "Will you hear," says he on one occasion, "the wish of an angler, and the commendation of his happy life, which he sings in verse:—

'Let me live harmlessly, and near the brink
  Of Trent or Avon have a dwelling-place,
Where I may see my quill or cork down sink
  With eager bite of perch, or bleak, or dace;
And on the world and my Creator think,
  Whilst some men strive ill-gotten goods to embrace,
And others spend their time in base excess
Of wine—or worse, in war and wantonness.

'Let them that list these pastimes still pursue,
  And on such pleasing fancies feed their fill,
So I the fields and meadows green may view,
  And daily by fresh rivers walk at will,
Among the daisies and the violets blue,
  Red hyacinth and yellow daffodil.
Purple narcissus, like the morning rays,
Pale gander-grass, and azure culver-keys.

'I count it higher pleasure to behold
  The stately compass of the lofty sky,
And in the midst thereof, like burning gold
  The flaming chariot of the world's great eye;
The watery clouds that in the air up-roll'd.
  With sundry kinds of painted colours fly;
And fair Aurora, lifting up her head,
Still blushing, rise from old Tithonus' bed

'The hills and mountains raised from the plains,
  The plains extended level with the ground;
The grounds divided into sundry veins.
  The veins enclosed with rivers running round;
These rivers, making way through nature's chains,
  With headlong course into the sea profound;
The raging sea, beneath the valleys low,
Where lakes, and rills, and rivulets do flow

'The lofty woods, the forests wide and long,
  Adorn'd with leaves and branches fresh and green,
In whose cool bowers the birds, with many a song,
  Do welcome with their choir the summer's queen;
The meadows fair, where Flora's gifts among
  Are intermix'd with verdant grass between;
The silver scaled fish, that softly swim
Within the sweet brook's crystal watery stream:

'All these, and many more of His creation
  That made the heavens, the angler oft doth see;
Taking therein no little delectation.
  To think how strange, how wonderful they be,
Framing thereof an inward contemplation
  To set his heart from other fancies free;
And whilst he looks on these with joyful eye,
His mind is rapt above the starry sky.'"

So much for the *poetry* of angling; we shall now speak of the practice of the art, beginning with a few observations on the

GENERAL CHARACTER OF FISH.

The fish which are the object of attention to the angler are all confined to fresh water, and are chiefly found in rivers or small brooks; some are found in lakes and ponds. All, except eels, have a pretty uniform character though differing in appearance and size. Their form is suitable, in a remarkable way, to give celerity and ease of motion—a small head swelling into a thick body, and tapering off towards the tail. Those designed for slower motion are more thick and lumpy in figure. The power of moving quickly, and of buoying themselves in the water, is very nicely provided for by their specific gravity which is nearly the same as the water in which they move; in other words, they are about the same heaviness as the water which they displace, and consequently they are almost destitute of any feeling of weight. On this account they are not in the slightest degree encumbered in their movements, and difficult to tire in their exertions.

The tail is the grand instrument of motion; it is a thin delicate membrane, whose smallest bending to and fro impels the body forward in any required course. The fins are principally required for balancing and regulating the movements of the fish; if any be cut off, the animal loses the power of keeping itself with the back fairly upwards; should it be deprived of the tail, the ability of moving forward is gone, and it lies a hulk at the mercy of its enemies. Not the least remarkable peculiarity in the economy of the fish is the existence of an air-bladder, by the dilatation or contraction of which it possesses the power of rising or sinking in the water, according as it feels inclined. It may be observed that fish, while in water, are constantly moving the gills, which is analogous to the art of breathing. The water sucked in by the mouth, and vented by the gills, contributes a minute portion of air, but enough to keep up the circulation of the blood and sustain life; if we were to tie up the gills, the fish would be immediately suffocated. The blood of fish is cold, being only about two degrees warmer than the water in which they live.

The senses of fish have engaged much attention from naturalists. Their quickest sense is that of sight; but they are destitute of the power of contracting the iris of the eye, so as to accommodate themselves to different degrees of light. In ordinary circumstances this is of no consequence, as the water diminishes the intensity of light, and the animal has the means of retiring to the bottom, or into holes, to escape the glare of the mid-day sun. It has been doubted if fish have any organs of hearing; but it is certain they do possess them, and hear to a limited extent. They are affected by any loud noise, though this may be partly ascribable to feeling the vibrations of the water. The taste of fish is allowed to be very blunt, if it exist at all; and so, likewise, is their smell. Whatever may be their deficiencies in these respects, they are provided with an appetite of boundless voracity.

"Every aquatic animal that has life," observes Daniel, "falls a victim to the indiscriminate voracity of one or other of the fishes. Insects, worms, or the spawn of other tenants of the waters, sustain the smaller tribes; which in their turn are pursued by millions larger and more rapacious. A few feed upon mud, aquatic plants, or grains of corn; but the far greater numbers subsist upon animal food alone; and of this they are so ravenous as not to spare those of their own kind. That there are vegetables in both fresh and salt waters admits of no doubt, and these may furnish food to particular fishes; but those sorts are few, perhaps no one kind can be pointed out that subsists entirely upon them; and although most fishes eat flies and terrestrial worms when they come in their way, yet in the immeasurable waste of waters surrounding this globe, the swarms of fishes are so immense that the subsistence to be derived from the above sources appears to be altogether disproportioned to their wants, and those of a smaller size seem to constitute the principal food of nearly all the fishes known to us. Charr kept in a pond, if scantily supplied, frequently devour their own young; other fish, that are arger, go in quest of more bulky prey, it matters not of what sort, whether of their own or of another species. If we turn our attention, in this argument, to sea-fish, those with the most capacious mouths pursue almost every thing that exists, and often meet each other in fierce opposition, when the fish which has the widest throat comes off with victory, and devours his antagonist.

"The voracious fishes differ widely from the predatory kinds of terrestrial animals; they are neither limited in their number nor solitary in their habits. Their rapacity is not confined to a few species, one region of the sea, or individual efforts. Almost the whole order is continually irritated by the cravings of an appetite which excites them to encounter every danger, and which, by its excess, often destroys that existence which it was intended to prolong. Innumerable shoals of one species pursue those of another through vast tracts of the ocean, from the vicinity of the pole to the equator. The cod pursues the whiting, which flies before it from the banks of Newfoundland to the southern coasts of Spain. The cachalot drives whole armies of herrings from the regions of the north, devouring at every instant thousands in the rear. Hence the life of every fish, from the smallest to the greatest, is but a continued scene of rapine; and every quarter of the immense deep presents one uniform picture of hostility, violence, and invasion.

"In these conflicts, occasioned by the voracity of the different kinds of fishes, the smaller classes must have long since fallen victims to the avidity of the larger, had not nature skilfully proportioned the means of their escape, their numbers, and their productive powers, to the extent and variety of the dangers to which they are unceasingly exposed. To supply the constant waste occasioned by their destruction in the unequal combat, they are not only more numerous and prolific than the larger species, but, by a happy instinct, are directed to seek for food and protection near the shore, where, from the shallowness of the water, their foes are unable to pursue them. These, however, yielding to the strong impulse of hunger, become plunderers in their turn, and revenge the injuries committed on their kind by destroying the spawn of the greater fishes, which they find floating upon the surface of the water.

"In what manner digestion, to such an amazing extent and rapidity, is carried on in the stomach of fishes, the inquiries of naturalists have at present been unable to ascertain. It so far exceeds every thing that can be effected either by trituration, the operation of heat, or of a dissolving fluid, that a celebrated physician (Dr. Hunter), after various experiments, was of opinion that none of these causes were equal to the effect, and that the digestive force in the cold maw of fishes is so great as to overturn the systems that have attempted to account for it on those principles; that by some power in the stomach yet unknown, which from all kinds of artificial maceration acts differently, the meat taken into the maw is often seen, although nearly digested, still to retain its original form; and whilst ready for a total dissolution, appears to the eye as yet untouched by the force of the stomach." It may be added, that although generally voracious, fish have a remarkably accommodating appetite, and will endure hunger a much longer period than most terrestrial animals.

Fishes are for the greater part oviparous, that is, produced by eggs or spawn, in the deposition of which a male and female fish are concerned. It is usual to call the male a *milt* or *milter*, and the female a *roe* or *rowaner*. The process of spawning, which takes place in secluded parts in the beds of rivers, is involved in considerable obscurity. The salmon, of which most is known, seeks the higher parts of rivers for spawning, and there the deposit is made. Mr. Halliday, in his communications to the House of Commons on this subject, describes the process as follows:—"When they proceed to the shallow waters, which is generally in the morning, or at twilight in the evening, they play round the ground, two of them together. When they begin to make the furrow, they work up the gravel rather against the stream, as a salmon cannot work with his head down the stream, for the water entering his gills in this manner would drown him. When they have made a furrow, they go to a little distance, the one to one side and the other to the other side of the furrow, and throw themselves on their sides when they come together, and rubbing against each other, they shed their spawn both into the furrow at once. They do not lay it all at once; on the contrary, it requires from about eight to twelve days for them to lay their stock of spawn, which being deposited, the bed is made and covered as they go along, both assisting in the operation."

Immediately after spawning, all fish are thin and poor, and not worth the trouble of catching. In about twenty days, if the circumstances be favourable, the eggs are hatched, and emit the young fry of fish. The number of young is in some cases enormous. Carp, perch, or roach, produce from 30,000 to 200,000 young; a herring from 20,000 to 36,000; a mackerel 400,000 to 500,000; and a cod between three and four millions. Of the young of any fish, however, comparatively few reach maturity, the greater proportion being devoured by enemies shortly after hatching. As if for the sake of mutual protection, most fish of a kind, as may be observed in the case of minnows and pars, associate together and swim in flocks.

That fishes are liable to diseases arising from variations of temperature and other causes, there is no reason to doubt; but few are ever seen dead in the water, there being too many scavengers of the deep to allow of this waste of food. In general the weak fall a prey to the strong before the period of natural death. It is understood that fishes possess a blunted nervous energy, which renders them almost insensible to any ordinary infliction; and so mean are their reflective faculties, that after escaping from a hook which has lacerated their palate, they will in the next minute catch at a similar bait, and be hooked a second time and drawn from the water. A number of years ago, two young gentlemen, while fishing in a lake in Dumfriesshire, having expended their stock of worms, had recourse to the expedient of picking out the eyes of the dead perch they had taken, and attaching them to their hooks—a bait which this fish is known to take as readily as any other; one of the perch caught in this manner struggled so much when taken out of the water, that the hook had no sooner been loosened from its mouth than it came in contact with one of its eyes, and actually tore it out. In the struggle, the fish slipped through the holder's fingers, and again escaped to its native element. The disappointed fisher still retaining the eye of the aquatic fugitive, adjusted it on the hook, and again committed his line to the waters. After a short interval, on pulling up the line he was astonished to find the identical perch that eluded his grasp a few minutes before, and which literally perished in swallowing its own eye.

Fishes are exposed not only to external foes, which it requires all their dexterity to elude, but to the torment of parasitical marauders in their own person. Besides creatures which make a lodgment in the intestines, various parasites fix themselves beneath the scales, in the mouth, and upon the gills. Salmon, perch, trout, and other fresh-water fish, are preyed upon in this manner by different species of lice; and as some of these parasites cannot live in salt water, it has been supposed that one of the reasons for the salmon migrating to the sea is to relieve itself from the lice (*lernea salmonea*) which have adhered to its gills. The trout louse, or *lernea truttæ*, is not unknown to trout fishers.

FISHING TACKLE.

The Rod.

This is the chief implement of the angler. It ought to be strong, but perfectly elastic, and bend, on being waved, through its upper half, but particularly at the small tapering point. The wood most suitable is hickory or ash, with yew for the upper part, to which a point of whalebone is attached. The size and strength must depend on the nature of the duty to which the rod is put. One for trout, perch, &c., ought to be from twelve to fifteen feet in length, and a salmon one from sixteen to twenty feet, besides being considerably stronger. Whatever be the length, it must be quite straight, and on all occasions bend back to its original straightness. If there be a single knot in the timber reject it, for it will certainly snap at the first severe pull or jerk. It should be varnished, to protect it from the action of the water. The rod is not all of one piece. For the sake of convenience, it is divided into four, or perhaps six pieces in the length. These pieces are usually joined by means of screws and verules; but if this be the plan of the rod offered to your choice, take care to see that these metal junctions do not impair the bending properties of the instrument, or render it too heavy. Rods of a plain kind made in the country are spliced with waxed threads, and these are generally more serviceable than the fine looking rods manufactured in cities. Listen to what John Young, of St. Boswells, (a village on the Tweed) says on this subject:—"To those who reside near the water, I would recommend a rod all of glued and tied joints as best in point of real use, and not so liable to break in the moment of action. Or, indeed, even for travelling, I would prefer tied joints, as wherever a person has time to stop to fish, though only for a day or two, he has at least five minutes to spare for tying his rod in a sufficient manner. Rods are often breaking at brass joints, and those who use them, instead of bringing in a back-load of fish, are constantly arriving home from the water, telling you, 'I've broke my rod!' Such sickening news may generally be prevented by tied joints."*

At the bottom of the rod where it is grasped by the hand, a brass reel or *pirn* is attached, and on this the line is wound. It should be simple in its mechanism, so as to allow of expeditious winding or unwinding. The line is conducted from the reel to the upper termination through small wire loops, in Scotland called *mylies*, which are fixed to the rod; these must be in an even line when the pieces of the rod are joined together, and be about a foot asunder. In *fashionable* rods, the mylies are small rings held by wires to the rod, and they conveniently fall flat when the rod is not in use. Good serviceable rods require no such elegance of design. The angler who is skilled in his art cares nothing for finery of apparatus, and will pull out dozens of fish in a day with an instrument which many would think not worth the carrying.

Lines.

These should be long, smooth, light, and flexible, and of a material which will not be easily injured by wet. These qualities are found in lines made of horse hair and gut, which we recommend in preference to any other. The part of the line which is wound on the reel, and goes along the rod, is called the *reel line*: and being designed to be let out only on occasions when a fish darts off with a hook in its mouth, it need not be so thin and light as the bulk of the portion termed the *casting line*. The reel line, which may be about thirty yards in length for ordinary trout fishing, is formed by spinning together horse hairs, so as to make a fine even cord. As it is troublesome to make, it should be purchased from a respectable dealer in fishing tackle. It should be from twelve to fifteen hairs in thickness, the hairs being white, fresh, and well cleaned. The line for salmon should contain from eighteen to twenty-four hairs, and extend to at least sixty yards in length.

The casting line, which is united by a loop to the reel line, may be also of horse hair, but of a smaller texture, and lighter in weight. It should be five lengths of hairs in extent, the uppermost length being eight hairs in thickness, and gradually diminishing the number to three or four in the lowest length. To the lower end of this casting line is added the *gut line*, which is the part that actually falls upon the water, and therefore requires to be very fine. It consists of a series of strong gut, and to it is attached the short lengths or casts of gut on which are the hooks. In some instances, the casting line is altogether made of gut, on which usually more dependence can be placed than on hair lines; if of gut, three threads are sufficient for the thickness.

On the article gut, Mr. Stoddart has the following observations:—"This article, originally imported from the east, and now brought in considerable quantities from Spain and Italy, is, as far as we have been able to learn, fabricated from the male silk-worm in a state of decomposition. The operation is principally conducted by children, and consists in removing the external slough of the worm with the fingers, elongating at the same time the gluey substance which composes its entrails. To do this properly requires some care and attention. Should the worm be kept too long, a hard crust forms itself over it, in destroying which the application of the nail is necessary; hence the gut becomes flattened, and loses much of its value. The sinews of herons and other birds are also manufactured in Spain into a sort of gut, and are much used, although unwittingly, by our salmon fishers. Worm-gut varies in length from nearly two feet and downwards. We have seen, however, an article very closely resembling it from the Archipelago, which measures at least a yard and a half. This is not to be confounded with sea-weed, although a vegetable fibre, and drawn out of a plant. It is much stronger and better suited for angling. The inhabitants of the Greek islands use it for catching mullet, and will often toss a fish some pounds' weight over their heads by a thread or two. We ourselves have found it excellent for the larger sorts of tackle. Animal gut is, however, more generally used, and better adapted for trouting. It ought to be small, round, and transparent, without any flaw or roughness. When worn or disordered, the application of a piece of Indian rubber will at once renovate it. In joining threads together for the purpose of making casts, the single knot properly drawn is quite sufficient. One should avoid clipping the useless extremities too closely in this operation, as in that case the knot is somewhat liable to give way. Gut, to keep well, should be moistened with fine oil, and stored in oiled paper."*

To these recommendations we may add, that lines of all kinds should be kept dry. On returning from a fishing excursion, draw out the line, and let it be thoroughly dried by waving in the air before being wound up or laid aside. When to be again used, look it over, giving it a gentle tug here and there to try its strength, and repair damaged parts. On coming to the water side, and just before throwing, allow the casting line to be wetted in the water, and this will at once give it smoothness and elasticity.

Hooks.

These are small instruments made of tempered steel, and of whatever size, they require to possess the qualities of lightness and great strength. They have been always

---

* "On River Angling for Salmon and Trout," by John Young, St. Boswells. Edinburgh: Blackwood and Sons. 1840.

* "The Art of Angling as practised in Scotland," by Thomas Tod Stoddart, Esq., author of the "Death Wake," and other poems. Edinburgh: W. and R. Chambers. 1835.

principally manufactured at two places—Kendal, in Westmoreland, and Limerick, in Ireland. The Kendal circular bends, as they are called, are reckoned the best hooks of a small size, while the Limerick hook is preferable for salmon. Many of the fish-hooks of ordinary English makers are worthless. Hooks range in size from about an inch and a half in length down to a quarter of an inch, with a proportional diminution of thickness. Some makers number them from No. 10, the smallest, to No. 20, the largest, while others number from 1, the largest, to 14, the smallest. The Limerick hooks are denoted by letters, commencing with A, and so on. In purchasing hooks, try their power of resistance by forcing the bend with the fingers, and urging the point against the thumb-nail. Hooks for fly-fishing should be thinner in the shank than those designed for bait. An angler should keep a small stock of hooks of various sorts, to be ready on all emergencies; with the tackle to which they are attached, they require to be kept very dry.

Landing Net—Gaff—Drag-Hook.

The *landing net* is considered in England a necessary implement for an angler, but in our opinion they must be poor hands at fishing who cannot drag a trout or any similar small fish from the water after hooking it without resorting to such a cumbrous apparatus. Perhaps it is found to be essential, in consequence of the feebleness of the rods and tackle usually employed. It consists of a small bag net stretched on a hoop at the extremity of a pole four or five feet in length. Mr. Blaine seems to think a landing net of first importance; and for the use of tyros in the art he gives the following directions:—"In fly-fishing, when the line is long, and there is not much space to step backward, or the reel clogged, it is necessary sometimes to lay hold of the line with one hand; but this should be done with great caution, and then only after the fish is well nigh spent, or one struggle may carry away line, hook, and fish. In all other cases avoid touching the line if possible; but having sufficiently played the fish, whether taken by bottom or by fly-fishing, bring him within reach of the landing net, and then carefully conduct or slide the net obliquely under the foreparts of his body, which, if the fish be completely exhausted, will fall into it; but if he has still sufficient vigour, it will be prudent rather to slide him over the net than the net under him. It must have occurred to every angler to have supposed a trout or salmon to be completely spent, who, the moment he has been touched by the net, or has even caught sight of the fisher, has sprung off with most annoying violence. Against such an accident it is prudent to be ever prepared by keeping the rod in an upright position, acting on a tightened line, but yet so disposed that it can run at liberty if required. When the head and shoulders of the fish are once fairly within the net, a slight turn of it will take in the whole body, and the net being then kept horizontally, will insure his safety; for with the head downwards, no efforts he can make will disengage him from the net; but if he be received tail foremost, as is sometimes done in deep waters, from overhanging banks, &c., beware of his plunges."*

The *gaff* is another aid to landing fish, and is employed in cases in which the landing net would be too small. It is used chiefly for landing salmon, and consists of a peculiarly-shaped hook at the end of a staff. When the salmon flounders about and incommodes the fisher, he is expected to secure the animal, and prevent it from breaking his line and rod by hooking it with the gaff at the gills, the tail, or any part he can conveniently reach.

The *drag-hook* is an implement with three bent prongs, or hooks, with a long cord line attached. It is used for casting into rivers to clear away any object at the bottom upon which the hook is caught. We pity the angler who attempts fishing in weedy puddles requiring such a clearer of hindrances.

Angler's Pocket-book, &c.

The angler's equipment is completed by the addition of a basket for holding his fish, which is slung on the back by a shoulder-belt; also pocket-book for holding hooks and other trifles; and a round flat tin box for his fly-casts. Many carry their supply of fly-casts wound round their hat, and some keep them within the leaves of their pocket-book. This pocket-book, which is the storehouse of all kinds of odds and ends—we have seen a good one made out of an old pocket almanac—should have two or three pockets for holding an assortment of hooks, silk thread, stuff for making flies, gut, wax, small cord, fly-nippers, scissors, &c.—all to be used in case of breakage of tackle or rod, or any other accident.

In fishing for perch, gudgeons, bream, &c., a small float is often used. Floats are made of cork, quill, and other materials; and a choice, according to circumstances, can be added to the contents of the pocket-book.

Dress.—All finery is worse than useless. Fish are easily scared with the appearance of any light or showy object on the banks. Let the angler, therefore, dress himself in a plain dull-coloured suit, with a hat equally sober in its aspect, and let him use only strong shoes or boots, which will not be injured by water.

Baits.

A bait is any substance put upon a hook to act as a lure to the fish; and when used, the baited hook is dropped into and allowed to sink in the water, instead of being kept near or upon the surface, as in the case of fishing with fly. The materials, living and dead, used for bait are very numerous; but the leading kinds are worms, maggots, minnows, insects, and salmon roe. The hook employed in either case is tied by the shank to the gut with waxed silk, and the preparation is therefore not at all difficult. When dressed to the gut, it is called bait or worm-tackle.

Worms used for bait are of various sorts; but that which is most commonly employed is the lob or garden worm, a long reddish-coloured reptile found in abundance in many gardens, grass-plots, and in any rich old soil. They may be dug up with a spade, or caught crawling from their holes at twilight, and particularly after heavy showers. "He who seeks them," says Daniel, "must move cautiously without noise, or they will quickly retreat into the earth; draw them gently out of their holes without nipping; those that sever in taking must be thrown away, as they will soon become putrid, and infect the others; when as many are collected as are wanted, having plenty of good moss freed from dirt, dip it into clean water, and wring it nearly dry; put it into an earthen pot proportioned to the quantity of worms, laying it regular, and forcing it down with the hands; strew the worms on the surface, after dipping them in clear cold water to rid them of the soil that may adhere to them; such as are not injured will soon bury themselves in the moss, and those that do not must the next morning be picked off as useless; they must be inspected every three or four days, the dead ones removed and have fresh moss, or that wherein they have been kept well washed and picked, and the water squeezed out at least once a week; they must be so placed summer and winter as to be safe from the extremity of the weather at both seasons. In a week's time they will be fit for use; and upon the angler coming home from fishing, he will return from his worm-bag into the pot those which he has not used. By observing the above care fully, they may be kept a month in summer, particularly by now and then giving them, drop by drop upon the moss, a small quantity of new milk and the yolk of an egg well beaten together, and warmed so as to thicken

* Encyclopædia of Rural Sports.

it; but when a stock of lob worms is meant to be retained for a considerable length of time, a large vessel must be filled half or three-quarters full of good mould, in the middle of which is to be placed some moss or old coarse linen cloths, hopsack, or rags wetted; in hot, dry weather, clean water must be sprinkled upon the earth with a watering-pot, so as to keep them moist but not wet; they may thus be preserved as long as is requisite; and a week before angling, what are wanted may be drawn from the store, and put into moss to scour themselves." Another worm, which is found in dunghills, called the *brandling*, from its striped appearance, forms a good bait, but it is seldom used.

Maggots.—These larvæ of insects, as is well known, are found on fly-blown meat or any putrid animal substances; very fine ones are procured from game in a *high* condition. Daniel calls these creatures *gentles*, and describes them as of great virtue in certain kinds of fishing:—"Gentles," he observes, "may be procured almost at any time at the tallow-chandlers, and should be kept in oatmeal and bran, as bran by itself is too dry. Those who live in or near London may buy them in proper condition for the day on which they wish to use them; but for the accommodation of those who reside in the country, remote from such convenience, the best modes of breeding them will be here mentioned, in order to prevent disappointments. Coarse fish, such as *chub* and *roach*, may be laid in an earthen pot in the shade, and will soon be fly-blown; when the gentles are of the proper size (but not before), put some oatmeal and bran to them, and in two days they will be well scoured and fit to fish with; in about four more they become hard, assume a pale red colour, and soon after change to flies; the red ones should not be thrown away, as frequently roach and dace take these with a white one, in preference to all other baits. Some have recommended a piece of liver suspended by a stick over a barrel of clay, into which the gentles fall and cleanse themselves; but clay will not scour them, and, besides, they fall from the liver before they have attained their full size. The before-mentioned is a less disgusting plan; for a short time after oatmeal and bran are put to the gentles, the fish in which they are bred will be found perfect skeletons, and may be thrown away; however, if they are to be bred from liver, it should be scarified deeply in many parts, and then hung up and nearly covered over, as in that way the flies will blow it better than when wholly exposed; in two or three days the gentles will be seen alive; the liver is then to be put into an earthen pan, and there remain until the first brood are of full growth; a sufficient quantity of fine sand and bran, (letting the liver remain) is then to be put into the pan, and in a few days they will come from the flesh, and scour themselves in it: the liver should then be hung across the pan, and the latter brood will soon drop out and be fit for use; and by thus breeding them in October, and keeping them a little warmer than those bred in the summer, until they arrive at their full growth, and afterwards putting them in the same pan into a dampish vault, they may be preserved for winter fishing. Those bred in summer, but for the bran and sand, would soon sink into a dormant state; the skins take on a blackish-red, full of white matter, and shortly after become flies; those produced in autumn, from whatever substance, will continue in this state all the winter, provided they can shelter themselves under the surface of the earth in fields, gardens, &c., and in the warm weather of the ensuing spring they change into flies, thus preserving their kind from year to year. Gentles are so universal and so alluring a bait, that the angler should never be unprovided with them. Trouts have been taken with them in clear water, when they have refused all kinds of worms and artificial flies."

Caddis, or *cad-bait*, is another kind of larvæ, inhabiting pieces of straw, or adhering to bits of stick or sand at the sides of rivers. Daniel has some interesting observations on this species of bait:—"The several kinds of cadews in their nympha or maggot state, thus house themselves: one sort in straw, thence called straw-worms; others in two or more parallel sticks, creeping at the bottom of brooks; a third in a small bundle of pieces of rushes, duck-weed, &c., glued together, therewith they float on the surface, and can row themselves about the water with the help of their feet; both these are called cad-bait. It is a curious faculty that these creatures possess of gathering such bodies as are fittest for their purpose, and then so glueing them together, some to be heavier than water, that the animal may remain at bottom where its food is, and others to be so buoyant as to float, and there collect its sustenance; these houses are coarse, and show no outward art, but are within well tunnelled, and have a tough hard paste, into which the hinder part of the maggot is so fixed that its cell can be drawn after it without danger of leaving it behind, and it can also thrust out its body to reach the needful supplies, or withdraw into its covering for protection and safety.

"These insects inhabit pits, ponds, low running rivers, or ditches, in cases of different forms, and composed of various materials; some of them enclosed in a very rough shell, found among weeds in standing waters, are generally tinged green; others are bigger than a gentle, and of a yellowish hue, with a black head; they are an excellent bait, and are found in most plenty in gravelly and stony rivulets, and by the sides of streams, in large rivers among stones.

"To collect them, turn up the stones, and the best will adhere to them; when the quantity wanted is obtained put them into a linen bag for five or six days, dip them, together with the bag, into water once a day, and hang them up; they will then turn yellow, become tough, and fitter for angling than when first got from the brook. If meant to be kept long, they must be put into a thick woollen bag, with some of the moist gravel or sand from the same rivulet whence they are taken; they must be wetted twice a day, but oftener in very hot weather; when you carry them abroad, fill the bag with water, and holding the mouth of it close, let the water run from them; in this way they may be kept three weeks. Another way of preserving them is by placing them in an earthen pot full of river water, with some of the gravel they were bred in at the bottom; but the preceding method is preferable. Some use bait pans of different sizes for insects, the tops punched full of holes, not so large as to admit of their escaping when placed in the river, which not only keeps them cool, but supplies them with aliment in the fresh water; some keep them in moss in a woollen bag on a damp floor, taking care that the bag retains a proper moisture. Another mode of preserving caddis, and also grasshoppers, caterpillars, oak-worms, or natural flies, is to take the green withy bark from a bough six or seven inches round, and about a foot in length; turn both ends into the form of a hoop, and fasten them with a large needle and thread; stop up the bottom with cork, and bore it with a [illegible] full of holes with a red-hot wire; tie over it a colewort leaf, and lay it in the grass every night. In this manner caddis may be preserved until they turn to flies. When grasshoppers are to be preserved in the case, some grass must be put into it.

"In angling with caddis, the line, when all out, should be as long as the rod, for three lengths next the hook, of single hairs, with the smallest float, and the least weight of lead that the swiftness of the stream will allow to sink; and that may be aided by avoiding the violence of the current, and angling in the returns of a stream, or in the eddies between two; which are also the most likely places wherein to kill fish, either at the top or bottom. The caddis may be at times, with very good effect, joined to a worm, and sometimes to an artificial fly, to cover the point of a hook, and also two or three together may be put in upon the hook; but it is always to be angled with at the bottom, especially when by itself, with the finest tackle, and at all seasons is a most holding bait for trout and grayling."

Minnow bait.—Minnows are a small fish, from an inch to two inches in length; they swim in flocks, and may be captured by a hoop-net on the end of a staff, or more simply by a crooked pin baited with a small worm. Anglers generally hire a boy to catch a quantity of them. The tackles used for minnow bait are various in their formation; some are single hooks; others a pair of hooks dressed back to back; and a third kind are a series of pairs, one above another. We cannot do better than give Mr. Stoddart's description of these deadly instruments, and the mode of baiting them. He alludes to Kendal hooks:—

"The most simple, and in some places the most deadly, is a common single bait hook. This we insert through the back of the minnow, and drawing it out, run below the gill, allowing the barb to protrude from the mouth; we then tie up the tail along the gut, either with a piece of silk thread, or more expeditiously with the gut itself, hitched over the part. This is angled with in the same manner as the worm, allowing plenty of time for the fish to gorge. A tackle similar to it may be used in standing pools or lochs. Here, however, the shank of the hook (a long one) is loaded, and the bait allowed to descend rapidly towards the bottom. Large cautious fish are sometimes taken by this method of angling. Of all minnow tackles, that with swivels is the commonest and most agreeable to employ. There are many ways of constructing it. Two of these we shall mention as preferable to all others. One is simply a large hook, No. 11, fastened to good round gut with two smaller ones, No. 7, tied back to back above, and looped in the dressing, so as to slide along, and shorten or lengthen the tackle to the dimensions of the bait. In using it, enter the lowermost hook through the mouth, and bring it out near the tail of the minnow; insert one of the hooks on the slider through its lips, noticing that the fish be slightly curved so as to spin properly. The other tackle is composed of six hooks, No. 7, dressed in pairs, and is angled with only when the trout are in a taking mood. Two or more swivels are required for both of these contrivances—the lowermost fastened about two feet or so above the bait. Leaden pellets may also be used, but many think them unnecessary. Some anglers attach behind the whole apparatus an extra hook, No. 12 or 13, dressed upon a hog's bristle, which, should the trout miss the minnow, is apt to catch him, when retiring, by the middle or other part of the body. This is a superfluity, and, like many superfluities, does more harm than good, alarming the fish without securing them. Tackle for trolling with par or small trout ought to be constructed on the same principles as the minnow tackle; only the hooks should be larger and dressed upon gimp instead of gut. Snap-hooks, also, are in use for this kind of angling. Small silk cord oiled will be found the best trolling-line."

Insects.—The insects used for baits are grasshoppers, crickets, day-flies, spring-flies, May-flies, humble bees, and various others. The ephemeræ, or those fragile creatures that live but for a day or even a few hours, and therefore called day-flies, are found sporting by the low banks of rivers in warm weather, and form a taking bait for trout and some other fish.

Salmon Roe.—The efficient use of this as a bait is a modern discovery, and has added largely to the angler's means of capturing the fishy tribes. The roe is taken from a salmon a fortnight before spawning, at which time it is best for the purpose. Some prepare it for use by salting it a little, and drying it to a state in which it will keep; others cure it with sugar instead of salt. Blaine recommends the following as a method by which it may be kept good for two years in a cool situation:—"A pound of spawn is immersed in water as hot as the hands can bear it, and is then picked from membranous films, &c. It is now to be rinsed with cold water, and hung up to drain for twenty-four hours, after which put to it two ounces of rock or bay salt, and a quarter of an ounce of saltpetre, and again hang it up for twenty-four hours more. Now spread it on a dish, and gently dry it before the fire or in the sun, and when it becomes stiff pot it down. We should, however, recommend that the potting be not in one mass, but, like the shrimp paste sold at the fish-sauce shops, that it be divided into small pots, pouring over each some melted suet, by which method a pot can be opened when wanted, instead of disturbing the general store. It forms an additional security to cover each over with a moistened skin or bladder. Trout roe is also said to make a good bait, but we have no personal experience of its efficacy; in fact, we never tried it; but it has been so strongly recommended, that it would be but fair to give credence to its value until numerous trials have proclaimed it as totally inert.

"To bait with salmon roe, first put on the hook (which should be sized according to the fish intended to be tried for) a mass which shall fill up the hollow of the bend and hide the steel. On the point put two or more firm large grains of it, both to conceal the snare and tempt the fish. In this way it is said to be principally a winter and a spring bait, but we know no reason why it may not be advantageously used at other times, for spawn of some kind is almost always to be found."

Pastes made of shrimps, of cheese, of bread crumbs mixed with honey, and of other materials, are also employed, according to the fancy of the angler, and the nature of waters and sport he intends to pursue; our limited space, however, obliges us to refer those who are curious in the subject of baits to the Encyclopædia of Blaine, where there is a vast body of highly interesting matter on angling. Those who are disinclined to prepare roe and pastes, or have not the means of doing so, may be supplied by the principal dealers in fishing-tackle.

Artificial Flies.

Hooks dressed up so as to bear something like a resemblance to actual live flies, are by far the most important lures employed by the angler. The principal materials employed in dressing are light portions of cock's hackle or other feathers, to form wings, the fur of a hare's ear or some other substance to make the body and waxed silk thread by which the whole is tied in an artful manner on the shank of the hook. A whole sheet might easily be filled with descriptions of artificial flies suitable to different fish, waters, and seasons; but the bulk of what has been written by Walton, Daniel, and many others, is now considered superfluous, experienced fishers having arrived at the conclusion that fishes in general are such eager and heedless fools as to be satisfied with a very limited choice of deceptions. The author of the article *Angling*, in the "Encyclopædia Britannica,"* has some clever remarks on this branch of the art:—

"As simulation," says he, "consists in the adoption or affectation of what is not, while dissimulation consists in the careful concealment of what really is—the one being a positive, the other a negative act—so the great object of the fly-fisher is to dissimulate in such a manner as to prevent his expected prey from detecting the artificial nature of his lure, without troubling himself by a vain effort to simulate or assume with his fly the appearance of any individual or specific form of insect life.

* Republished in the handsome volume, "The Rod and the Gun." A. and C. Black, Edinburgh.

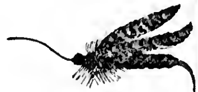
There is, in truth, little or no connection between the art of angling and the science of entomology; and therefore the success of the angler, in by far the greater proportion of cases, does not depend on the resemblance which subsists between his artificial fly and the natural insect. This statement is no doubt greatly at variance with the expressed principles of all who have deemed fishing worthy of consideration, from the days of Isaiah and Theocritus, to those of Carrol and Bainbridge. But we are not the less decidedly of opinion, that in nine instances out of ten a fish seizes upon an artificial fly as upon an insect or moving creature *sui generis*, and not on account of its exact and successful resemblance to any accustomed and familiar object.

"If it is not so, let us request to be informed upon what principle of imitative art the different varieties of salmon-fly can be supposed to bear the most distant resemblance to any species of dragon-fly, to imitate which we are frequently told they are intended? Certainly no perceptible similarity in form or aspect exists between them, all the species of dragon-fly, with the exception of one or two of the sub-genus Calepterix, being characterized by clear lace-like pellucid wings, entirely unadorned by those fantastic gaudy colours, borrowed from the peacock and other 'birds of gayest plume,' which are made to distinguish the supposed resemblance. Besides, the finest salmon-fishing is frequently in mild weather during the cooler seasons of the year, in autumn and early spring, several months either before or after any dragon-fly has become visible on the face of the waters, as it is a summer insect, and rarely makes its appearance in the perfect state until the month of June. If they bear no resemblance to each other in form or colour, how much more unlike must they seem when, instead of being swept like lightning down the current, as a real one would be, the artificial fly is seen crossing and recrossing every stream and torrent with the agility of an otter and the strength of an alligator! Or darting with regular jerks, and often many inches under water, up smooth continuous flows, where all the dragon-flies on earth, with St. George to boot, could not maintain their place a single second! Now, as it is demonstrable that the artificial fly generally used for salmon bears no resemblance except in size to any living one—that the only tribe which, from their respective dimensions, it may be supposed to represent does not exist in the winged state during the period when the imitation is most generally and most successfully practised—and if they did, that their habits and natural powers totally disenable them from being at any time seen under such circumstances as would give a colour to the supposition of the one being ever mistaken for the other—may we not fairly conclude that, in this instance at least, the fish proceed upon other grounds, and are deceived by an appearance of life and motion, rather than by a specific resemblance to any thing which they had previously been in the habit of capturing? What natural insect do the large flies, at which sea-trout rise so readily, resemble? These, as well as gilse and salmon, frequently take the lure far within the bounds of the salt-water market; and yet naturalists know that no such thing as a salt-water fly exists, or at least has ever been discovered by their researches. Indeed, no true insect inhabits the sea. What species are imitated by the palmer, or by three-fourths of the dressed flies in common use? An artificial fly can, at the best, be considered only as the representative of a natural one which has been drowned, as it is impossible to imitate the dancing or hovering flight of the real insect over the surface of the stream; and even with that restricted idea of its resemblance to nature, the likeness must be scarcely perceptible, owing to the difference of motion and the great variety of directions in which the angler drags his flies, according to the nature and special localities of the current, and the prevailing direction of the wind.

"We are therefore of opinion that all or a great proportion of what has been so ofte, and sometimes so well said about the great variety of flies necessary to an angler—about the necessity of changing his tackle according to each particular month throughout the season—about one fly being adapted solely to the morning another to noonday, and a third to the evening—and about every river having its own particular flies, &c., is, if not altogether erroneous, at least greatly exaggerated and misconceived. That determinate relations exist between flies of a certain colour and particular conditions of a river, is, we doubt not, true; but these are rather connected with angling as an artificial science, and have but little to do with any analogous relations in nature. The great object, by whatever means to be accomplished, is to render the fly deceptive; and this, from the very nature of things, is continually effected by fishing with flies which differ in colour and appearance from those which prevail upon the water; because, in truth, as we shall afterwards have occasion to show, none else can be purchased or procured. Even admitting for a moment the theory of representation, when a particular fly prevails upon a river, an artificial one in imitation of it will never resemble it so closely as to appear the same to those below (that is, the fish); on the contrary, a certain degree of resemblance, without any thing like an exact similitude, will only render the finny tribe the more cautious through suspicion, while a different shape and colour, by exciting no minute or invidious comparisons, might probably be swallowed without examination. Indeed, it seems sufficiently plain that where means of comparison are allowed, and where exact imitation is at the same time impossible, it is much better to have recourse to a general idea than to an awkward and bungling individual representation."

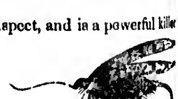
Mr. Stoddard, one of our most experienced anglers, entertains a similar opinion:—"The colours of water and sky," he observes, "are the only indicators which can lead us to select the most killing hook, and even these are often deceptive. We have fished in one stream where dark, and, in the next, where red flies took the lead. There is no trusting to the fancy in certain places. On Tweed, we have seen it veer about, like the wind, in one moment, without a note of preparation. Most rivers, however, are more steady; and when the water is of a moderate size, may be relied on with at most two sorts of flies all the year round. For ourselves, our maximum in every Scottish stream is reduced to only four descriptions of artificial flies, with one or other of which we engage to catch trout over all the kingdom. Knowledge and practice have convinced us of the needlessness of storing up endless and perplexing varieties, which some do, to look knowing and scientific."

The following, according to these and other trustworthy authorities, form a very serviceable set of lures for fly-fishing;—First, there is a fly which has been called *the professor*, after Professor Wilson of Edinburgh. The wings are formed of a mottled brown feather, taken from the mallard or wild drake, the body being composed of yellow flos silk, rather long, and wound about close to the head with a fine red or black hackle. This simulated fly has a tight clever aspect, and is a powerful killer.



The Professor.

Second, a fly which differs from the above only by being a little shorter, more thick, and with a body made of pale green instead of yellow silk. Green worsted may be used.



Fly with Green body.

Rough Hackle.

Third, a rough powerful hackle, with wings of white and black marked feather, a bristling body of dark-green wound about with gray or mottled hackle, to which is given a pointed tail.

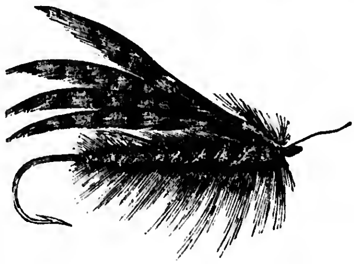
Fourth, a fly of a sombre cast, the wings formed of woodcock, snipe, or lark feather, and the body of hare's ear, darker or lighter, according to fancy.

Fifth, a fly with wings of the starling or fieldfare, and having a body made of mouse or water-rat fur.

Sixth, a plain hackle, black or red, without wings, and commonly called *palmer*.

Seventh, a red hackle, with wings of the starling, and a body formed of light-red mohair, and a red cock's hackle.

To these may be added any other variety of fly that the fancy suggests as being suitable to the time or place of fishing. Flies for salmon-fishing must be of a much more large and powerful kind, as representing insects



Salmon Fly.

of larger proportions. In the adjoining figure, a specimen is given of a powerful spring lure, with wings of variegated turkey feather, a body of orange camlet, mixed with mohair, and a brown cock's hackle. A thread of gold may be wound round the body for summer fishing. We refer to the work, the "Rod and the Gun," for further information on salmon-flies, which in all cases require to be dressed on double gut.

From dealers in fishing-tackle all sorts of artificial flies may be obtained at a reasonable advance upon the raw material; persons, however, who intend to make themselves masters of the art of angling, should not be dependent on tradesmen for their supplies, but learn to dress hooks for themselves. Mr. Stoddart offers the following explicit directions on fly-dressing:—

"Our materials for the making up of flies are as follow:—Hooks, and small round gut; a pair of brass nippers for twisting hackles; a point for dividing the wings; a pair of fine scissors; orange, yellow, and green silk thread of all sizes; good cobblers' wax enclosed in a piece of soft leather; a hare's ear; some brown wild-drake teal, and pheasant feathers; the fur of a mouse, squirrel, and water-rat; a few wings of lark, snipe, landrail, and starling; and lastly, red and black hackles, taken from the neck and head of an old cock at Christmas; these should be fully formed and free from softness. Plovers' herls, and those of the peacock, are used by some, yet, we deem them superfluous, as also tinsel, except for large flies.

Commencing your operations, the first step is to lay out the intended wings and body before you; wax your silk, and applying one end of it to the gut and hook together, wrap them both round four or five times, commencing a little below the end of the shank, and proceeding downwards; you then fasten, by drawing the disengaged end of the thread through under the last turn of the wrapping. Work the silk upwards to where you commenced, then take your wings, which are still unseparated, and lay them along your hook, so that their extremity or tips shall reach its curve; twirl the thread twice round the upper part, which lies along the shank top; then, taking it under, press firm, and clip off the unnecessary portion of the feather; divide with your point or penknife, so as to form the two wings; take up the silk betwixt them, and wrapping again around at the head, bring it back crosswise; then lift your hackle, and lay the root of it down along your hook; whip the thread over, as far as your first fastening; seize the top of the hackle with your nippers, and whirl it round in the same manner; fasten and lengthen the body to your liking with fresh floss silk; fasten once more, and your fly is made. This last fastening ought, in our opinion, to be the same as that used in arming bait-hooks, for which we quote Hawkin's directions:—'When you are in about four turns of the bend of the hook, take the shank between the fore-finger and thumb of the left hand, and place the silk close by it, holding them both tight, and leaving the end to hang down; then draw the other part of the silk into a large loop, and with your right hand turning backwards, continue the whipping for four turns, and draw the end of the silk (which has all this while hung down under the root of your left thumb) close, and twitch it off.' When the body of your fly is required to be of hare's ear or mouse skin, pull out a small quantity of the fur, and lay it along the silk, after the wings are formed; twist together, and then wrap as if the thread were bare, and fasten as above. In making flies, keep all tight, guard against heavy wings and much dubbing; the fibres of your hackle ought to be short and lie near the head of the fly; they are intended to resemble legs, which in the real insect are always so placed. Such is our method of fly-dressing, commendable both for its simplicity and expedition. It differs, we find, somewhat from that generally practised, being in a manner self-taught, and not encumbered with any unnecessary display."

Having now described the various parts of the angler's apparatus, and the lures which he generally employs, we proceed to show how he is to practise his craft when fully equipped for the purpose

PRACTICE OF ANGLING.

There are two distinct kinds of angling—bait-fishing and fly-fishing, and these are variously practised according to the depth or nature of the water, or the fish that are to be caught.

Bait-Fishing.

This kind of angling is practised to great extent in the Thames, the Lea, and other deep and somewhat dull rivers of England. The fish usually sought for in these waters are gudgeon, dace, roach, bream, chub, barbel, tench, carp, perch, and pike; all are sometimes taken by fly, but a bait of worms, gentles, roe, or some other material, is commonly employed. The angler, in these rivers, usually stands on the shore while fishing, but in some instances he fishes from a punt, or small flat-bottomed boat, in which his chief occupation is to sit watching his float, and pulling in his line when a fish appears to be hooked. Among the apparatus of this order of deep-water fishers, a plummet and line is carried, in order to sound the depth of the river, which having ascertained, the angler puts his float upon the line, at that point which will allow the bait to trail on the bottom, while the float swims on the surface.

The first thing the bait-fisher has to learn is the art a baiting his hooks. Taking the hook in his right hand and the bait between his fingers in the left, let him enter the hook at the head of the worm, and carry it through the animal to near the tail, covering the entire hook and its tying. The worm should be broken or mangled as little as possible; and the more life-like it appears, the greater the probability of its proving an effectual lure. There must not, however, be too much spare worm left dangling from the hook, otherwise the fish will keep nibbling it away without biting at the bait bodily, and taking it into its mouth, the thing which the angler desires.

In throwing the line with bait, take care not to splash the water, but let the bait fall gently on the surface, and sink slowly in the water, to the required depth. After sinking, the rod and line should be very slowly moved in a direction against the stream, or in some other way to give motion to the bait, which the fish perceiving to glide through the water will hasten to seize upon.

Occasionally the angler will *feel* a nibble, but he must not be in a hurry to *strike*, that is, to draw the fish from the water. Perhaps it is no more than a nibble, and it is well to allow the fish time to get the hook in his mouth. If drawn too quickly, you may actually pull away the hook after it is half gulped. Experience and dexterity are required in this ticklish part of the craft. As a general rule, do not strike till the line has been distinctly tugged; then strike by a slow side motion at first, then a more quick jerk, so as to cause the hook to catch in the jaws of the animal. Supposing the fish to be hooked, do not draw it violently out of the water as if in a transport of delight, but wind up part of your loose line if necessary, and holding up your rod, retire gradually backward, by which the fish may be landed on the shore. A good fisher does not lay aside his rod to take a fish from the hook, unless it be of great size, requiring two hands; if small, hold the rod in the right hand while you catch the fish with the left; unhook it carefully, place it in the basket, put on a new bait, and once more proceed to your sport.

The *gudgeon*, a fine large fish of the trout shape, affords a favourite amusement to anglers in the Lea, a river near London, and also in the Thames. Blaine thus speaks of this branch of angling:—"Fishing for gudgeons in the Thames is usually practised by means of a punt, which is fixed across the stream part of the river just above a tolerably sharp scower, running over a fine gravelly bottom, free from weeds, at depths varying from five to eight or ten feet. As the eddy is greater generally, and the water deeper in these scowers than in those of the Lea, so the tackle used is commonly somewhat stronger, and a fine gut line is more frequently met with there than one of single hair. Fine tackle, however, in a good hand, is to be always preferred; and we have seen many hundred dozens of gudgeons taken in the sharpest currents of this river also with a single hair only for the two bottom links. Punt fishing for gudgeon in the Thames is a delightful amusement, particularly to the luxurious angler who is not inclined to take much trouble. The scenery, the quietude and safety from interruption, the cleanliness of the practice, where the bait is put on the hook by the attendant fisherman, and where even the prize it gains is removed by the same hand, all tend to make it epicurean in the extreme. But the thorough-bred fisher is soon tired with it after this method, for the very reason that there is actually too much luxury in it to constitute true sporting, which must of necessity present some labour to keep up the attention, and some difficulty to enhance the value of the prey. In the Thames, so many as fifty dozen of gudgeons have been taken in a day; but in the Lea seldom half that number are caught. Yet the Lea angler has the best scope for his sport, for he can commence it in March, whereas in all that part of the Thames within the liberties of the city of London, it must not be attempted until the beginning of June, at which time the gudgeons have spawned, and continue for some time afterwards inferior in point of their gastronomic worth. Gudgeon fishing seems to have varied little from the ancient practice, and the angler who has aught of the antiquarian about him, will be amused probably at the close parallel between the present method and the gudgeon-fishing of early times, as it is described by John Davors or John Dennys, Esq., for it is a disputed point to which of these worthies the 'Secrets of Angling,' in which it is contained, owes its birth. Walton ascribes it to Davers, and gives the name at full length in the fifth edition of 'The Complete Angler:'—

> "Loe, in a little boat where one doth stand,
> That to a willow bough the while is tied,
> And with a pole doth stir, and raise the sand,
> Whereat the gentle streame doth softly slide;
> And then with slender line and rod in hand,
> The eager bite not long he doth abide.
> Well loaded is his line, his hooke but small,
> A good big cork to bear the stream with all.
>
> "His bait the least red worme that may be found,
> And at the bottome it doth alwayes lie;
> Whereat the greedy gudgion bites so sound,
> That hooke and all he swalloweth by and by.
> See how he strikes, and pulls them up as round,
> As if new store the place did still supply;
> And when the bit doth die, or bad doth prove,
> Then to another place he doth remove."

The *roach* is a thick fish deep from the back to the belly; it inhabits the bottom of deep rivers or lakes, and is usually reckoned so incautious and silly as to be called the water sheep: nevertheless, it is not taken without some degree of skill. It is angled for by means of bait sunk to within a few inches of the bottom. The fish may be attracted by throwing in some crumbs of bread. It is caught in the Thames some time after the end of August. The baits used are gentles, red paste, and boiled malt or wheat; one grain of the latter is sufficient. Great attention is required to strike quick when the bait is taken. Dace and tench are angled for much in the same manner. Carp is angled for in stagnant waters from February to September, and the baits are worms, larvæ, grain, and pastes. The perch also inhabits dull waters, and is a short unshapely fish, soft in the flesh, and seldom worth cooking. It is so eager to bite that little skill is required in pulling out a whole fry; the baits employed for it are worms, insects, and minnows.

Pike-Fishing.

The pike is a voracious fish, and may very appropriately be termed the fresh-water shark; it does not confine itself to feed on worms, insects, fish, and frogs, but will devour water-rats and young ducks, and attack much larger animals. All small fish are terrified at the approach of this marauder, which, if permitted, would soon clear a pond of all its finny tribes. "Pike," says Daniel, "love a still, shady, and unfrequented water, with a sandy, clayey, or chalky bottom (arriving at a larger size in pools than rivers); and from May to the beginning of October, they usually place themselves among or near flags, bulrushes, and water-docks, and particularly under the *ranunculus aquaticus* when in flower, and which floats on the surface; they will sometimes be found in the termination of sharp currents; from March to the end of May they resort to back waters that have direct communication with the main stream; as winter approaches they retire into the deeps, under clay-banks, bushes impending over the water, stumps and roots of trees, piles of bridges, and flood-gates. They spawn in March or April, according to the coldness or warmth of the weather, quitting the rivers for the creeks and ditches communicating with them, and there dropping their ova in the grass and reeds; in ponds they choose the weeds upon the shallows for depositing it; ducks and other wild fowl eagerly devour the spawn, and by them it is transported to other waters. The appearance of the pike in ponds where none were ever put, has been deemed as extraordinary as its asserted longevity; it is, however, easily accounted for upon the well-known principles of the generation of fishes. If a heron has devoured their ova, and afterwards ejected them while feeding in one of these ponds, it is highly probable that they may be produced from this original, in the same way as the seeds of plants are known to be disseminated.

"Pike are in season from May to February (the female fish are to be preferred), are bold biters, afford the angler good sport, and may be fished for all the year; but the best months (especially for trolling) are February, before the weeds shoot, and October when they are rotted; the latter is to be preferred, as the pike are fattened by their feed during the summer; and from the lowness of the waters, their harbours are easily discovered."

The same author thus describes the method of trolling for pike:—"For trolling, the rod should be twelve or fourteen feet long; but a strong top for this fishing, with a ring at the end for the line to run through, may be fitted to a fly or general rod; there should be one ring upon each joint to conduct the line, which is better than a greater number (and these rings must be set on straight, that it may run freely, so that no sudden check after the bait is taken prevent the pike from gorging it): the line should be of silk, with a swivel at the end to receive the armed wire or gimp, and at least thirty yards long, wound upon a winch or reel fixed to the butt end of the rod. Hooks for trolling, called dead gorges, and other sorts for trolling, snap, and trimmer, and fishing-needles, are to be bought at every shop where fishing-tackle is sold. In the choice of the first let them not be too large, nor their temper injured by the lead on the shanks, nor the points stand too proud; and although usually sold on wire, it is recommended to cut off the wire about an inch from the lead, and with double silk well waxed, fasten about a foot of good gimp to the wire, with a noose at the other end of the gimp large enough to admit the bait to pass through, to hang it upon the line. The best baits are gudgeons or dace of a middling size; put the baiting needle in at the mouth, and out at the middle of the tail, drawing the gimp and hook after it, fixing the point of the hook near the eye of the fish tie the tail to the gimp, which will not only keep it in a proper position, but prevent the tail from catching against weeds and roots in the water; thus baited, the hook is to be fastened to the line, and dropt gently in the water near the sides of the river, across the water, or where it is likely pike resort; keep the bait in constant motion, sometimes letting it sink near the bottom, and gradually raising it. The angler need not make more than two or three trials in a place, for if a pike be there, he will within that time bite if he means to do so. When the bait is taken, if at a depth too great to see, it will easily be ascertained by the line being drawn tight, and by some resistance; let the pike have what line he chooses, it will be soon known when he has reached his harbour by his not drawing more; allow from five to ten minutes for his gorging the bait; wind up the line gently until the pike is seen (which he will permit though he has not gorged); should the bait be across his mouth, give more time; but if he has swallowed, manage him with a gentle hand, keeping him, however, from roots and stumps, which he will try to fasten the line upon; in clear water veer out line until he is sufficiently tired, and a landing-net can be used; but by no means, however apparently exhausted, attempt to lift him out with the rod and line only; for the moment he quits the water he will open his mouth, and from his own weight, tear the hook from his stomach and the fish will be lost to the angler, although it must inevitably perish. In trolling, the bait should never be thrown too far; in small rivers the opposite bank may be fished with ease; and the violence of its fall upon the water, in extensive throws, soon spoils the bait, by rubbing off its scales, and alarms the pike instead of enticing him. Pike are to be allured by a large bait, but a small one is more certain to take them; never suffer weeds to hang upon the hook or bait when recast into the water, and which cannot touch the surface too softly. Always prefer a rough wind, and when the stream is clear, for trolling; pike never bite in white water after rain, &c. If a pike goes slowly up the stream after taking the bait, it is said to be a signal of a good fish."

Mr. Stoddart's methods of angling for pike here deserve notice:—"In rod angling for pike, we adopt three methods, employing the gorge tackle, the swivel tackle, and the fly. Our gorge-hook is double brazed, and armed upon brass wire. A par or small trout inverted is the usual bait. We insert the wire of our tackle through the fish, bringing the upper end of it out at the tail, and allowing the two barbs of the hook to protrude from its mouth. In angling, we both throw and drop the bait, as the nature of the water demends, moving it slowly towards the surface. When a pike seizes it, there is at first no perceptible tug; one feels as if he heard the shutting of a pair of jaws on the bait; and if you can manage to see your fish, you will observe him holding your trout by the middle, as if crushing the life out of it. Keep a tight line, but do not pull or strike. Too much resistance places your intended victim on his guard; a little, however, sharpens his appetite. After a few seconds, the pike will begin to move towards his den, still grasping your bait between his teeth, and intending to bolt it immediately. Let out line with your hand from the reel; and now he is fixed, and darts off like a tiger, shaking his chain, and with open mouth tossing himself out of the water at thirty yards' distance—the worst is over, and he turns revengefully towards the shore; wind up—ha! he is out again, and again he makes for the shallows; but the monster is exhausted and moves heavily; lead him with caution to the edge, lay down your rod, and lift him upon the bank. In order to disengage your hook from the entrails of this formidable fish, the gills should be forced open, and a knife introduced for the purpose, taking care previously to thrust it through the spine-bone of your victim, and so prevent the possibility of your catching a Tartar. Unfasten your hook from the wire before drawing the latter through the mouth of the pike, as otherwise it is again apt to catch among the teeth, from which it may be somewhat difficult to extricate it, without incurring a few scratches.

"Should a fish, after having bitten, abandon your gorge-hook, try him with a running bait upon swivels, and let this be a fresh trout of a smaller size than your other, and fixed upon a gimp tackle with the tail downwards, as in minnow fishing. See that it spins judiciously; and when the pike rises, let him turn with the bait before you strike. River pike, it may be remarked, seldom play so well as those in lochs. They push generally below the banks, instead of striking across, and look out for old stumps upon which to entangle and break your line. One ought, therefore to make quick sport with such rascals—running them down upon level banks in a twinkling, and before they are able to get under weigh.

"The third method of angling for pike is with a fly—a kind of fishing not much in use, but still on some waters very deadly. The pike-fly should be large and gaudy, fabricated of divers feathers and tinsels to resemble the king-fisher or a huge dragon-fly. Use it in a strong warm wind, upon water from six to two feet deep, and near weeds. You will kill with it fish of various sizes, from ten inches in length and upwards: very heavy ones, however, refuse to take it, on account, probably, of the exertion necessary in order to come to the surface. We have always noticed that the biggest pike are caught during close sultry weather with a ground bait, and at those times when trout refuse food altogether. Also at night, with set lines, in the summer months, when they leave the weeds and bulrushes in quest of food.

"Although the pike is often nice and suspicious in places where trout abound, still, when provoked, he becomes bold and unwary, treating your presence as no constraint upon his temper and appetites. He will follow the bait to your very feet, and should it escape him, will retire a yard or two, waiting eagerly for its reappearance. When angry he erects his fins in a remarkable manner, as the lion doth his mane or the porcupine his quills; moreover, the pike appears careless of pain, if, indeed, fishes in general feel it to any great degree. We have actually landed one of these fish, cooped him alive in our creel, and when by some negligence of ours, he made his escape into the water, have succeeded a second time in securing him. On another occasion, we remember having a part of our tackle, consisting of a large double gorge-hook, dressed upon brass wire, carried off by a pike; and yet, upon renewing it, the aggressor returned to the charge and was taken. The former hook we discovered gorged by him in such a manner as must, we thought, not only have suffocated any other animal, but done so by the medium of the most exquisite internal agony.

"Great injury has of late years been done by the transference of the pike to many of our best trouting lochs, where a single individual has been known to consume nearly its own weight of fish daily. This was the case on Loch Turit, near Creiff, where the trout, formerly abundant, are now greatly reduced by the hostile and merciless depredations of their natural enemy. The pike at table is reckoned by some a coarse dry fish, and so in general they are; yet to our knowledge, in certain lochs, for instance that of the Lowes, in Selkirkshire, they almost rival the turbot, and should be cooked somewhat in a similar manner. They are none the worse for being kept a few days, especially if of any size. A good eating pike ought to weigh at least from five to twelve pounds—the smaller ones being without exception bad."

Trout-Fishing.

The trout is of different species and varieties, as the common trout, the gillaroo or gizzard trout of Ireland, the bull-trout, and the salmon-trout. The shape is handsome; the flesh firm and sweet, and coloured pink or white, according to species and feeding-ground; and the weight varies from half a pound to four or five pounds. In one or other of its varieties, the trout is a universally-known fish in temperate climates; its favourite haunts are clear running rivers; and there, both in England and Scotland, it affords a favourite object of sport to the skilful angler. Sometimes bait is employed, but the fly is more common. In some cases the bait and fly must be tried alternately in one day, as the fish is capricious, and requires to be tempted in all kinds of ways. The season most favourable for trout-fishing is spring and early summer.

Trout-fishing with bait.—"Trout," says Blaine, "begin to take a bait on or near the ground early in the year, and before March will readily take most bottom baits all day long in favourable weather; but as the summer advances, it is only very early or very late in the day that they will take a bait near the ground, they being at the intermediate hours more disposed to rise to the surface for winged insects. In March and April use the worm in the forenoon, and a fly or minnow, according to the state of the water, the rest of the day, in the swiftest and sharpest currents, provided the day be warm and bright, and in the deeps early and late; but if the water be discoloured or very thick, try the gravelly shallows near the sides and tails of streams, with a worm only, to run on the bottom with one large shot a foot at least from it. When there is a small *fresh*, or the water is clearing off, and is of a dark brownish colour, first use the worm, which should be a well-scoured brandling, cast in as a fly at the head of the stream, and move it gently towards you, still letting it go down with the current so as to keep it a little under water; the line should be rather short, with no lead upon it, and the hook fine; then try the minnow, and as the water clears, the artificial flies should be tried. In fishing for trout with the worm, use running-tackle, and employ a strong line, but let its strength consist in the excellence of its material rather than its bulk, to which end the hook should be small, the gut fine, the shotting fine also, and let the whippings be well concealed, for in bright water trout are singularly wary and suspicious. In some few instances a float is indispensable, and when such is the case, let that likewise be as light and fine as the water will allow."

A short line and quick striking are recommended by Mr. Stoddart, who says the line "ought always to be kept at its full stretch, and moved in a half circle with the angler. It requires some degree of perception to know the exact instant when the fish first seizes your bait; it does so with such softness, and with no likeness of a tug, as one is apt to imagine; nay, it merely closes its jaws upon the hook, as a gaping oyster would do upon one's finger, then is your opportunity for striking; if you neglect it, you allow the trout its more leisurely process of nibbling, and its chances of escape. In striking with the short line, do it sharply, and never against the current, but rather with it, in a diagonal direction, and not too high. The reason of this advice is obvious, for all fish feed with their heads pointing up the stream—kindly giving you the choice of pulling the hook into or out of their mouths; the latter of which purposes you accomplish, to a dead certainty, by striking against the current. This whip-jack manner of bait-fishing is very deadly with an experienced hand. The long-line anglers make nothing of their method comparatively: and yet, among clear waters, and where fish are few, or bite shyly, patience and a long line will carry the day. Remarkably fine gut ought to be used by all ground anglers, whatever be the practice. Trout are a suspicious, distrustful set, and three in general slink off for one that nibbles, terrified, no doubt, by those singular accompaniments of your worm, a line and hook.

"To all bait-fishers Scotland affords excellent sport; her rivers run so strongly, and are maintained by so many sources in the shape of mountain burns. These romantic streamlets abound in trout; every stone shelters its inhabitant, and the meanest pool is peopled with numbers. Burn fish, however, are generally of a small size; they seldom exceed a pound in weight, except in the spawning season, when larger ones ascend from broader streams, or lochs at a distance. Still, the taking of them is a pleasant pastime, especially when they bite eagerly at your worm, as they do during rain and in discoloured water. At such times, you have only to drop your bait without art, and the fish will manage its own ruin. Worms are taken greedily at night and early in the morning; also, when the sun is very powerful, at mid-day. Akin to this sort of angling is roe-fishing, concerning which we remark, that in autumn it is the most fatal method of capturing trout, and is growing much into practice in the south of Scotland."

The same enthusiastic brother of the angle next proceeds to treat of minnow fishing, which he says is by far the pleasantest mode of capturing trout, next to angling with the fly:—"If you wish to engage in this pleasant sport, provide your minnows by means of a small drag-net or hook. Select those of a moderate size, and which shine whitest. They may be salted, but are best perfectly fresh. The tail of a small trout or par is no bad substitute, if minnows cannot be had. Our only reason for preferring the fresh to the salted minnow is, that by its silvery appearance and more rational form it better attracts the fish; at the same time, it is well known that a trout loves a salt bait, and will repeat its attack upon a minnow of that description, while it refuses to do so upon one newly taken. Fish in rapid streams, also in deep discoloured pools, and during a smart curl. Manage the minnow as you would your fly, throwing it down and across as far as you are able; bring it towards you about six inches or more below the surface, spinning rapidly by the aid of several swivels. When a fish rises, give him time before you strike; let him turn and gorge the bait, then strike sharply, and he is yours; all fly-fishers are apt to strike too soon, and miss the fish.

"Trout seize a minnow by the middle, or near the head, and you generally hook them on the upper hooks. In rivers where numbers of minnows are found, you must angle with the very smallest, not above an inch in length, and use a proportionate tackle. The trout in such waters love delicate tid-bits, and are absurdly nice in their feeding. Artificial minnows are sometimes employed by anglers, but generally fail, except in muddy waters and lochs. Mother-of-pearl makes the best imitation—there is a virtue in it which few fish can resist."

"Trolling with par for large trout," he continues, "is a glorious pastime, especially on a Highland loch circled with mountain scenery—the craft of nature by incantation wrought, when the morning stars sang together. It needs intellect to enjoy it well, and a poet's heart to know its luxury. Take with you some choice and idle spirit, a rower he must be, that can manage your airy shallop as the winds do a weathercock—can chant a ballad of yore, of ladye and chieftain, and pranksome elf and kelpie wild—can speak to the echoes and to yourself, cheering you with wit and wisdom, and admiring your science and skill; and the gorgeous fish you are playing, twenty fathom off, with a strong and steady hand, your heart 'high fluttering the while, like woman's when she loves.'

"Tackle for trolling should be dressed upon tried gimp. Bait as you do with a minnow: use a strong rod, heavy lead, and a long line of oiled cord wound upon an easy reel. Choose a sunny day, with a stiffish breeze, and troll near but not among the weediest parts of the loch. Plant yourself at the boat stern, and get rowed gently at the rate of three miles an hour, letting out from twenty to thirty yards of line between you and your bait. Trout from six to nine pounds' weight cause the best sport when hooked; a larger one seldom leaps or makes any violent exertion to escape; he swims sullenly, and at ease, regarding the angler with a sort of sovereign contempt. You must row after him, and turn him if you can before he gets among weeds; never slack your line for an instant, and look well about you. Land as soon as you are able, and play him from the shore. Your companion will assist you at the death.

"So much for the different kinds of bait-fishing practised in Scotland. We esteem it folly to talk of the less popular baits used by the *virtuosi*—of frogs, grubs, and leeches, water-rats, and mice—all of which animals trout will devour. It might be asked, may fish not be taken with any thing? They have been known to swallow money, rings, and many other marvels; nevertheless they seem to have no pleasure in snapping at the bait of the unskilful angler, and refuse to die under his hands."

Trout fly-fishing.

This, after all, is the true angling, all other efforts at taking fish being either somewhat childish or murderous. A long flexible rod, fine lines, and appropriate flies are the necessary equipment; and the best time for making the attempt is on a dark lowering day, at any rate not in bright sunshine. If the moon has shone brightly the previous night, it will have prevented the trouts from feeding freely, and they will accordingly bite more readily when tempted with the artificial fly. Great skill and nicety are required in throwing the fly line. Mr. Stoddart gives the following directions how to proceed:—

"Your rod and tackle being ready, the wind in your favour down the river, draw out with your left hand a few yards of line from your reel, dip the top of your rod in the water, and with a rapid jerk you will lengthen as you wish that part you intend for throwing. A thirteen foot wand will cast from six to seven fathoms of line. With a large double-handed rod you may manage a much greater length. Always, if you can, angle from a distance. Trout see you when you least imagine, and skulk off without your notice. Noise they care little about; you may talk and stamp like a madman without frightening them, but give them a glimpse of your person, and they won't stay to take another. Some icthyologists attribute to them an acute sense of hearing; this we are disposed to question; for how happens it that the most obstreperous rattling of stones, when wading, causes no alarm, although conveyed to them through the medium of water, a good conductor of sounds? We remember angling one still night by St. Mary's Loch, when our movements were heard distinctly by some shepherds from the distance of a mile, and yet the fish rose eagerly at our very feet, following our fly to the shallowest parts of the margin—a fact which, if it does not prove the obtusity of hearing, at any rate renders it a matter of little consequence to the angler.

"It requires some art to throw a long line. The beginner should commence with a short one, and without flies, lengthening it gradually as he improves. The best method of casting is to bring the rod slowly over the right or left shoulder, and with a turn of the wrist make the line circle behind you, then, after a pause, fetch it forward again in the same manner, and your flies will descend softly upon the water. All jerks are apt to whip off your hooks or crack your gut. A fly-fisher may use two, three, or four flies on his casts, according to pleasure. When angling with small hooks, we adopt the medium number. Large ones ought to be fished with in pairs, and well separated. In throwing the cast, the lowermost or trail-fly should be made to alight foremost; its fall ought to be almost imperceptible; it should come down on the water like a gossamer, followed by the droppers. The moment a fly touches the surface, it is ten times more apt to raise a fish than during the act of drawing it along. At no time are we stanch advocates for the system of leading our hooks either against or across a stream; our method is rather to shake them over it for a moment and then repeat the throw. A trout will discover your fly at the distance of several yards, if feeding, and will dart at it like lightning. Always, if you can, fish with the wind, and do not concern yourself, as some do, from what quarter it comes. In spring, no doubt, a south-west breeze is preferable to all others; yet we have seen even easterly winds not the worst on many waters, especially during summer months, when the natural fly is apt to become over plenty.

"Trout will sometimes take in the most unlikely weathers, so that the angler should not despair at any time

Hunger causes them to feed at least once in the twenty-four hours, and generally much oftener. If the wind blows down the river, commence at the pool head, and fish every inch of good water; you may pass over the very rough and very shallow parts, also those which are absolutely dead calm, and clear, unless you see fish rising in them, when, should your tackle be light, there is no harm in taking a throw or two. Dead water, however, when rippled or discoloured, may be angled in with great success. When you raise a good trout, strike slowly, or hardly at all; only continue the motion of your hand without slacking it; the fish, if large, will hook itself. Small trout and par may be whipped in with rapidity: it is folly to play or use ceremony with such trifles. Should the fish miss your fly altogether, give him another chance, and a third if that will not do; a touch of your barb, however, will sharpen his wits, so as to prevent him from again rising. He prefers flies without stings. When you hook a trout, if you can, turn his head with the stream, and take him rapidly down. Thus you will exhaust him in the shortest time, whereas, by hauling against the current, you allow him to swim freely in his natural direction, and also exert three times more strength upon your tackle than is really needful. A good-sized fish, handled in this foolish manner, can never be taken; it is impossible to tire him out, and the strongest line will give way to his resistance. When your victim is exhausted, draw him gently ashore upon the nearest channel, or most level part of the margin. He will come in sideways, and generally lie motionless for a few seconds, during which time you will be able to run forward and seize him. Beware of catching hold of your line until he is properly banked. Many a famous trout have we seen lost by this inadvertence on the part of anglers, who think so to save time and labour. One should remember how the spring of the rod is thus removed, and how there remains no proper curb to the strength of the fish, which easily breaks a single gut, or tears itself from a sharp hook, and wishes the astonished angler better sport further on."

The practice of double-rod fly-fishing for trout or for salmon is a murderous kind of sport, and should be prohibited by law. A line stretched between two rods, and hung with flies, is taken down the stream by two individuals on its opposite sides, so that every part of the water is gone over, and every feeding trout raised. By this plan large numbers are caught, but many also are wounded, and escape to pine away for months at the bottom, unable either to feed or spawn.

Salmon-Fishing.

This may be described as a gigantic trout-fishing, the principle of alluring and capturing being the same, but all the tackle requiring to be stronger, and a greater degree of physical power being necessarily called into operation. The salmon has a peculiar habit very likely to upset the calculations of beginners; it consists of the ugly practice of running off at a violent speed as soon as he feels himself hooked, darting up the stream, throwing himself several times out of the water, and generally in the end hastening into some sheltered haunt where he expects to be safe. Great tact is necessary on these occasions, first to give line, and then to keep him from burying himself in some unapproachable nook.

With respect to the minutiæ of the art, both in throwing and striking, the recommendations of Mr. Younger of St. Boswells are well worthy of attention:- "I recommend a beginner," says he, "to practise throwing the line on a broad smooth pool, where he can see that it is delivered out properly, and falls lightly, without splashing. In such a case the practitioner will perceive something which he cannot easily account for: and that is, that after he has even attained a great degree of perfection in the art, he will not be able to distinguish how it happens that in one throw his long line will proceed direct out, his fly alighting first on the water; in another throw the middle of his line will fall first, while the farther part, still obedient to the general impulse, will proceed out the full length, the fly falling the last on the surface. This last throw is not so good as the former, for this reason, that the main current having caught the middle of his line first, carries it too quickly down, leaving the fly lagging, to form an awkward curve, as, before it comes over above the fish, the fly should lie on the water, so as to have the appearance of flying at an angle against the current. And the angler should so manage his rod that, while he lets his line float round at its full length, yet to cause his fly to come as slowly as possible over the main spot. In this case the salmon will sometimes rise at once, rather before you expect him, but more generally will follow the fly to the eddy, or edge of the deep, where, if on examination he feel disposed to seize the hook, he has it before you perceive a head, fin, or tail above the surface. Indeed, before you perceive the web of his tail he generally has the hook in his jaw a foot below water, as in descending he goes, like other divers, head foremost."

Having managed to place the fly over the desired spot, our authority continues—"He will make no perceptible motion to keep his fly on the surface (except on a sluggish pool), but let it sink a little, depending on feeling rather than on sight; and though apparently keeping no pull on his line, yet all the while able to detect the touch of a minnow. On a *boil*, or rather appearance of a fish, he pulls up his line, not twitchingly but actively, steps a yard or two back, rests a minute to let the fish resume his lair and attention, and perhaps feels inclined to alter his fly, before he annoy and disgust or alarm his fish, to a shade darker or a size smaller, when he will most probably come up and seize it in earnest. Should he not rise again, or rise and pass it thrice, leave him quietly alone for the present, and return to try him some time afterwards. On taking the fly, the fish means to return with it to his precise select *spot* of lair, on rock, stone, or gravel, at the bottom; and the fine angler, holding him gently, often, in the first instance, allows him to do so, but soon, too surely feeling his awkward predicament, he bolts off 'indignant of the guile.' Then is the time when the fisher is attentive; with the butt end of his rod resting on his thigh or groin, he keeps the top nearly erect, never allowing it to fall below the proper angle of forty-five degrees, as relative to the situation of the fish, as in this position the elasticity of the rod never allows the line to slacken in the least degree for a single instant, however the fish may shake, flounce, jerk, or plunge. With two or three fingers and the thumb of his left hand the angler holds his rod while the wheel-line runs out, regulated by the first or first and second fingers, relieved or assisted, as occasion may suggest, by the right hand, when it can be spared from its necessary occupation of rolling up the wheel-line, as the fish settles a little or returns inwards. In this manner the fish is allowed to run right out, up, down, or across, as he may choose. But if in an outright dash of thirty or fifty yards aslant, ending in an outward bound fling above water, the inexperienced angler should feel flustered, which he is very likely to do, and by some involuntary twitch of the running line let the top of his rod be pulled down to a level with his own head, then the tug of the last plunge will assuredly break his hook or line, or tear the hook from the mouth of the fish. Or, what is as bad, a sudden jerk or turn of the fish will give the line a momentary slackening, when the hook's hold, already so strained as to have widened its incision, will fall out, and your fish is gone for ever."

Now is the critical moment for the salmon-fisher, who must keep up his rod and give line. "The fish will then," continues John, "allow himself to be led at ease to the angler's side of the river, like a bridegroom to the altar, when, on finding the water shallowing, he will again make another desperate effort, probably a new dash into the middle current; but too much exhausted to resist the still continued pull upon him, he will soon again fall into the shallow, where, on a sight of his enemy, he is again alarmed into a new effort, and again exhausted by turning his outward-bound head down with the water, again and again, and again, as if the parties were in the amusement of forming circles, until his own last efforts to keep swimming are made subservient to the cautious angler in moving him by degrees into the shallow, where, half dry, he must, like all the strong, at last yield to his fate, and fall panting on his side, while the line rolled up to within rod length, which is to be held with its top landwards, without slackening, and the fisher seizing him with the fore finger and thumb of his right hand across by the root of the tail (which is by far the surest method of seizure), lifts or rather slides him out head foremost over gravel and grass, and in mercy fells him with a blow on the back of the neck.

"After going through this process with a twenty-two pounder (and the process would be the same with a forty-four), the writer can aver, that he does not conceive that from the moment he has hooked such until he was laid on the grass, he ever for an instant had three ounces of more or less pull on the fish; for in all circumstances of run, regularity of pull is the sure test of true skill and final success. Indeed, I have seen many a fine fish laid on the dry gravel when the hold of the hook in the lip of his mouth was so slight as to be smaller than the steel of the hook—so much for equal pull and cautious management in the run. And, in short, a man is never a master angler so long as a desire to have his hooked fish to land excites in his feelings the least agitation, as the matter should be managed with that cool philosophical ease of mind which is alike above the paltry calculations of loss and gain and the common ridicule, which often tends to stir up a degree of childish fretfulness. This perfect ease is absolutely necessary to first-rate excellence and ultimate success."

Leistering is the name usually given to a murderous kind of sport pursued by salmon fishers in Scotland. Armed with *leisters*, or spears with three-barbed prongs, a set of fishers proceed to the river's bank, and there attract the fish by the glare of torches held over the water by members of the party. When a salmon is discovered, one selects it as his prey, and by a cool but rapid blow transfixes it with his spear. In many cases, the fish cannot be secured or landed without plunging into the water, but this usually forms no obstacle, and several men may be seen floundering in the depths of the stream while shouts and confusion prevail among the spectators on the banks. Sir Walter Scott, in his novel of *Guy Mannering*, has presented a vivid picture of this species of sport, which is still pursued on the Tweed and its tributaries, but mostly by parties of rude marauders who are regardless of law, and kill vast numbers of fish during "close time," or when the rivers are legally shut—from about the middle of October till February.

THE PAR.

The par is a small fish, which is found in great abundance in almost all rivers which are clear, and have a free communication with the sea. It varies in size, of course, according to its age, but seldom reaches a greater length than six inches, and is usually found below that magnitude. It is silvery in appearance, and marked by peculiar blueish bars or marks along the body; while a more nicely-forked tail, and one regular row of scarlet spots along the sides in place of two or three, aid further in distinguishing the par from the trout, the fish which it most resembles.

Of the actual character of the par, whether it is an independent species, or the fry of salmon, there has been a long-continued controversy. Many naturalists were inclined to hold it as a kind of mule, or creature betwixt the trout and salmon breeds. The dispute, however, may be said to have been terminated recently by Mr. Shaw of Drumlanrig, whose lengthened and ably conducted experiments establish the par to be the natural produce or fry of the salmon. In a memoir communicated to the Royal Society of Edinburgh, Mr. Shaw mentions that his first experiment on the subject consisted in the removal of a number of pars from their native stream to a pond, when he found that all of them assumed the perfect appearance of *salmon fry* or *smolts*, at the end of periods of time proportioned to their bulk when placed in the pond. He also satisfied himself that the change from the state of par to that of smolt, which is marked by the appearance of a covering of silvery scales over the blue bars, always takes place at the age of *two years*; and that then, for the first time, the metamorphosed fry take their departure for the sea.

But it was objected to these experiments, that Mr. Shaw might have mistaken young salmon for pars in the first instance, so rendering his conclusions of no weight. To settle all disputes, he began his experiments with the *ova* or *eggs* of the salmon, first constructing ponds for their reception. These ponds, three in number, he protected by falls, pipes, and gratings, in such a manner as to seclude them in a perfect manner from all interference on the part of any other fishes whatsoever. Having provided a proper net, Mr. Shaw was successful in capturing a pair of adult salmon, male and female, while engaged in depositing their spawn. By expressing a portion of the ova from the female, and of the milt from her companion, he had it in his power to transfer fertilized ova to his ponds on the 2[illegible]th of January, 1837. "On the 21st of March, fifty-four days afterwards, the embryo fish were visible to the naked eye. On the 7th of May they had burst the envelop, and were to be found among the shingle of the stream. It is this brood which I have now had an opportunity of watching continuously for a length of time."

Mr. Shaw's descriptions of the brood, read to the Royal Society, and accompanied with specimens, will best show the general scope of the results. At the age of forty days after the exclusion from the egg, the symmetry of the young fish's form was but imperfectly developed. "After the lapse of two months (7th July) the shape was found to be materially improved, and to exhibit in miniature much of the form and proportions of a mature fish. At the age of four months (7th September) the characteristic marks of the *par* were clearly developed. Two months later (six months old, 7th November) an accession both of size and strength was apparent, and on comparing the pond specimens with the par of the river, no marked difference was perceptible. The average length at this time was three inches.

"During the winter months, the general temperature of the rivers is so low, and the consequent deficiency of insect food so great, that the whole of the Scottish salmonidæ which inhabit the fresh waters during that season are well known to lose rather than gain in point of condition. The same rule holds in regard to the young salmon in the experimental ponds, although not to the same degree, they having maintained comparatively a superior condition throughout the winter to those found in the river of a corresponding age and size. The temperature of the ponds, averaging about 40 degrees during the winter, not only keeps the young fishes which occupy them in a more active condition, but the insects themselves are also more abroad, and thus afford a convenient supply of food not to be obtained by those at that time in the river, the average temperature of which, in ordinary winters, barely exceeds 34 degrees. I shall now refer more specially to the specimens before the Society

"Number six is a specimen from pond number one, of the age of nine months, taken in the middle of February, 1838. It exhibits little or no particular accession of size or condition to that of number five, but may serve to show the general appearance of the several broods of the young salmon in my possession at the age of nine months.

"Number seven is a specimen twelve months old, taken from pond number one, on the 10th May, 1838. It is much improved in condition, as well as in external appearance, in comparison to that taken in February, and has exchanged its dusky autumnal and winter coating for that which may be called its summer dress. It measures about three and three quarter inches in length, and is denominated, along with those of a corresponding age and size in the river, the *May Par*. Immediately after the migration of the two-year-old par (which the latter always effect about the beginning of May, under the name of salmon-fry), there is no other par, besides such as have been recently hatched, to be found in the river, save those which correspond with this specimen, which is the *Pink* of the river Hodder, alluded to by Mr. Yarrell. As the summer advances, they increase in size, and are actually the little fish which afford the angler in salmon rivers so much light amusement with the rod, during the months of August, September, and October. They remain over the second winter in the river, during which period the males shed their milt, and are found continuing their kind along with the female adult salmon, although still bearing all the external markings of the par, as I shall afterwards more particularly mention. Number eight is a specimen eighteen months old, taken from pond number one, on the 14th November, 1838. It measures six inches in length, and has now attained that stage when all the external characteristic markings of the par are strikingly developed, and, in point of health and condition, cannot be exceeded by any taken from the river. All the males, at the age of eighteen months, of the several broods in my possession, last autumn (1838) attained a most important corroborative stage, namely, that of showing a breeding state, by having matured the milt, which could be made to flow freely from their bodies by the slightest pressure of the hand. The females of the same broods, however, although in equal health and condition, did not exhibit a corresponding appearance in regard to the maturing of roe. The male and female pars in the river, of a similar age, are found respectively in precisely a corresponding state, which may surely be admitted as most important evidence in support of the fact that all these individuals are, in truth, specifically the same.

"Number nine is a specimen two years old, taken from pond number one, on the 20th May, 1839, *after having assumed the migratory dress*. The commencement of the change, which was perfected by the whole of the broods about the same time, was first observable about the middle of the previous April, by the caudal, pectoral, and dorsal fins assuming a dusky margin, while, at the same time, the whole of the fish exhibited symptoms of a silvery exterior, as well as an increased elegance of form. The specimen in question, so recently par, exhibits a very perfect example of the salmon fry or smolt."*

These experiments, conducted in an unexceptionable way, were confirmed by other observations. Being satisfied that the par never migrated to the sea until the age of two years had been attained, and the change from par to smolt had taken place, Mr. Shaw watched to discover the descending shoals. He was successful on three occasions. "The first of these was in the first week of May, 1831. I was able deliberately to inspect them as the several shoals arrived behind the sluices of a salmon cruive; and while they yet remained in the water, and were swimming in a particular direction, indistinct transverse lateral bars might still be seen; but as they changed their position, these became as it were lost in the silvery lustre. I also examined many of them in the hand, and could there also, by holding them at a certain angle in relation to the eye, produce the barred appearance; but when the fish were held with their broad side directly opposed to view, the character alluded to could not be seen. Its actual existence, however, could be easily proved by removing the deciduous silvery scales, when the barred markings became apparent, and, of course, continued so to whatever light exposed. The third opportunity to which I shall here refer occurred in May, 1836, at which time, as I have stated, I compared a few of the descending smolts with those which (having been two years in my possession as par) had, in the confinement of the pond, assumed the corresponding silvery aspect of the salmon fry. The river during this month being remarkably low, I was thus enabled to ascertain more accurately the time during which they continued to migrate, which I found to be nearly throughout the whole of the month, but more especially in the course of the second week, in which the shoals were both larger and more frequent in their successive arrivals. Their external aspect was the same as that of the former shoals, and the average length, as usual, from six to seven inches."

To conclude this subject, it may be added that pars are never found where salmon do not exist; and that large pars are always found to disappear when smolts disappear; being, indeed, as Mr. Shaw shows, the same animals slightly changed. Other points in the history of the par are fully elucidated by Mr. Shaw, whose memoir the disciple of Walton would do well to consult.

Pars are caught by the rod and fly, or with worm-bait, in the same manner as trouts; and fishing for them forms a common and amusing sport to the juvenile anglers in our Scottish rivers.

FISH PONDS

Artificial ponds for the rearing of fish and supplying them when wanted for the table, were common in ancient times. The luxurious Romans possessed such preserves, and we learn that one belonging to Lucullus sold after his decease for upwards of £24,000. Comparatively little has been done in modern times in the way of establishing artificial ponds, and those which exist are chiefly to be found in noblemen's preserves. Yet artificial fish ponds may, with little or no trouble, be made to yield a large and regular supply of fish, and may be constructed at a most insignificant expense in any piece of low-lying waste ground intersected by a rivulet of pure water.

The fish most suitable for ponds are trout, carp, tench, perch, and minnows. Eels also thrive in ponds, and, what has frequently been a matter of surprise, these animals sometimes find their way to ponds of their own accord, without actual transfer. It is extremely probable that the spawn or young of eels and other fish is gobbled up and vented by birds in appropriate localities; there is at least no other rational means of accounting for the spontaneous stocking of remote fish ponds and lakes.

The size of a pond may be from one to twenty acres; but a piece of water of from two to three acres is considered the most convenient dimensions. Of whatever size, the pond must not be overstocked, and it must not be left too long unfished. Fish ponds, to be on the most effective scale, should be in a series of two or three, the water running from the one to the other. This will allow means for periodical cleaning, if required, and for having a choice of fish. Some remarks of Daniel may here be introduced:—"In ponds so situated as to have communication with each other, never put into the upper of them either a pike, a bream, or a roach; the spawn

* One or two of each of the three broods assumed the migratory or smolt dress at the age of twelve months.

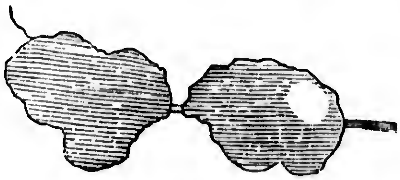
will get through the gratings, and by that means all the lower ponds will unexpectedly swarm with them. The pike will destroy the fry of the carp and tench, and the two latter will consume all the food which should be the subsistence of both parents and progeny. Pike, bream, and roach should, therefore, on no account be ever put into the first or highest of a succession of ponds." He continues—"Some have recommended, in raising carp, to have three ponds. One wherein the fish are to spawn (which is mostly from May to July), and in which they should continue during the summer and ensuing winter. A second for the convenience of nursing up the young fry, into which they should be put at the end of March, or early in April following, choosing a calm but not sunny day for their removal, and being careful to prevent their being destroyed when coming to the sides of their new habitation. In this pond they may remain two years, and become four, five, or six inches long. The third or main pond is for the reception of those that are so grown as to measure a foot or more in length, including their heads and tails.

"The proportions advised for the stocking these different ponds are—for the first sort, per acre, 'three or four male, and six or eight female carps, those of five, six, or seven years old, in good health, with full scale, and fine full eyes and a long body, without any blemish or wound,' are to be preferred. The pond must be previously cleaned of all sorts of voracious fishes and other animals, as 'perch, pike, eels, and trout; the water beetle, and also the frogs; the newts or lizards;' have a warm and open exposure with soft water, and all kinds of water-fowl kept from it. For the nursing pond a thousand or twelve hundred carp may be not more than sufficient for an acre; and for the main pond one to every square of fifteen feet is the allowed space, as their growth depends greatly on the room and quantity of food."

Our friend Mr. Stoddart likewise treats of fish ponds, but mainly in reference to Scotland, where the fish must be of the hardier kinds—perch, pike, and trout. In either case, the transfer of the fish to the ponds may be made with little difficulty. On being caught with a hoop-net, place them in large jars of water, and cart them to their new habitation; if this be inconvenient, they may be carried in wet moss or straw. All fish bear carriage best in winter, and better during the night than during the day.

"Ponds intended solely for perch do not require to be made large; they should slope gradually down towards the middle, from a depth of six inches to one of five or six feet. Water weeds ought not to be greatly encouraged. A series or chain of small basins, at different elevations, is preferable to a single large reservoir for this fish. These basins should be connected by a sluice and flood-gate, so that one may be readily emptied into another for the mutual convenience of cleaning and repairing. Also, the uppermost ought to be shallower than those below, and more exposed to the sun, so as to serve for a nursery and breeding-pond. Bream live well with perch in a warm situation; they are not, however, obtained readily in Scotland. Perch ponds should be let off and paved with channel stones every four or five years; many allow them to remain fallow for some months, and others sow them with grass and oats, a conceit laboriously encouraged by whimsy and theoretical writers of bygone days."

The following engraving represents a pair of perch ponds; *a* is the upper or breeding pond; *b*, the lower



pond; *c*, a covered sluice with movable gratings; *d*, the sluice with outlet; and *e*, the small feeder.

"The pike-pond," proceeds our authority, "if for breeding and fattening to some extent, ought to be large, covering from eight to twenty acres; its mean depth six or seven feet. One end, however, should be much shallower, and sown with bulrushes or other water-plants. Previous to stocking it with this fish, a sub-stock of perch or trout should by all means be introduced; otherwise, without a great supply of such sustenance, pike will not only become thin and ill-tasted, but quarrel and devour each other. To facilitate a steady supply of perch, small tanks should be constructed alongside of the leading preserve, with connecting sluices and flood-gates, so as to expel, when necessary, a shoal of live food."

Our author next treats of trout ponds:—"Choose from six to twenty acres, less or more, of an oval shape, but indented with small bays. Cast a long trench through the middle, from head to foot, noticing that you can readily divert along it the stream just mentioned, which stream is intended as a spawning place, seeing that trout never shed their roe in dead water. Let this trench deepen gradually as the ground descends; so that at the intended foot of the pond it should sink nearly three yards, while the upper part thereof is kept shallow. Dig from either side of your trench, keeping its slope and level until within four fathoms of the intended margin of the fish pond. When this is done, turn your attention to what is called the dam-head, at the outlet or lowest part of the pond. From it continue your trench for a short distance in the form of a paved sluice. Build stones, grass-sods, and clay, along the bank on each side, if needful, and drive in a few piles to strengthen it. Then set a flood-gate at the out-let, and another to serve as a check in case of accident, three yards farther down, where your paved sluice terminates. A few cart-loads of coarse channel, not from the sea, ought to be emptied over the earthy parts of your pond, which otherwise are apt to get covered with weeds, or else to encourage eels, the marked enemies of trout in all stages. After this is done, let loose your stream and form your preserve, introducing trout of about six inches in length, eight or ten to every acre. Raise also at the head a small nursery of minnows, connecting it by distinct sluices both with the pond and its feeder. These are favourite food of trout, and fatten them at a quick rate."

To these remarks it may be added that little care need be taken to fetch apparently fine breeds of any species of fish from a great distance, as what seem poor fish at the period of transfer will greatly improve by good pond feeding, and the easy unharassed life which they enjoy.

GYMNASTIC EXERCISES—OUT-OF-DOOR RECREATIONS.

Cricket.

A DESIRE for indulging in active sports and exercises has evidently been given to youth for the admirable purpose of promoting bodily health and strength, at a period of life when mental occupation or sedentary employment would not only have been unfitting, but positively injurious. Instead, therefore, of railing at the boisterous pastimes of boyhood, ridiculous as they may sometimes appear, we ought to view them, so long as kept within the bounds of moderation, as consistent with a great providential design in creation, and worthy of our warmest approval and encouragement. Impressed with these considerations of the value of youthful recreations, particularly those carried on in the open air, we should by all means afford reasonable scope for all the usual and harmless sports in which young persons are pleased to indulge; we should say to parents, let the boy have his marbles, ball, nine-pins, and bat; and the girl her doll, skipping-rope, and hoop, besides any other toys which would call their respective faculties into harmonious exercise. But an indulgence in physical recreations and general amusements is not to terminate with the period of youth. In advanced and middle life, it is of the greatest importance to health to relieve the tasked brain, to soothe and compensate the drudgery of our current labours, and to bring into exercise those parts of our muscular frame and intellect which professional duty has left unoccupied. To young men, especially, whose frame requires regular and bracing exercise, those out-of-door recreations which afford a certain degree of amusement are indispensable; and to them the contents of the present sheet are more particularly submitted. Our object will be to point out what sports may with propriety be indulged in, suitable to the different seasons of the year, and how they may be pursued with advantage to health and other circumstances.

GYMNASTIC EXERCISES.

Gymnastics are those exercises of the body and limbs which tend to invigorate and develop their powers.* In an ordinary course of living, without due regard to rules for promoting bodily strength, the frame becomes relaxed, the muscles are soft, the circulation of the blood languid, the bones and joints debilitated, and the stomach weakened and dainty. To avert as far as possible these imperfections, gymnastics ought to form a part of education in youth, when the joints and muscles are flexible, and time is permitted for the various kinds of exercises.

Precaution.—It has not been unusual of late years to conduct the gymnastics of schools on an improper scale, by impelling young persons of comparatively feeble frames to undertake feats and exercises which have been at variance with the bodily organization, or at least highly dangerous and of no practical value. A caution is necessary on this subject. "The best guide we can have," observes Dr. Andrew Combe, in a work on physiology, "is to follow the footsteps of nature, whether it is in harmony with the mode of action assigned by the Creator to the parts which are to perform it. If it be so, we may proceed with perfect confidence that it will not only improve the health, but add to the freedom, elegance, precision, and strength of our movements; whereas, if it be opposed to the obvious intention of the Creator, we may rest assured that no good can accrue from it. If, for example, we examine the various attitudes and motions of the body which occur in fencing, dancing, swimming, shuttlecock playing, and some of the better class of gymnastic exercises, we find that they are not less graceful and beneficial to the young who engage in them, than pleasing to those by whom they are witnessed—just because they are in perfect harmony with nature, or, in other words, with the structure and mode of action of the joints, ligaments, and muscles by which they are executed. But it is far otherwise with some of the anomalous exercises which were at one time so fashionable, and which are not yet extinct in schools and gymnasia, and which seem to have for their chief object the conversion of future men and women into foresters, firemen, or savages, rather than into beings who are to continue to have the use of stairs, ladders, carriages, steam-boats, and the other conveniences of civilized life. It is no doubt a good thing for a boy to be able to climb up a perpendicular pole or a slippery rope, when no other means present themselves of attaining an important object at its upper end; and it is an equally good thing for a young lady to be able to sustain her own weight hanging by one or both hands, when there is no possibility of resting her feet on terra firma; and where boys and girls are strong enough to take pleasure in such amusements, there is no great reason to hinder them, provided they are impelled to them, not by emulation or any secondary motive which may lead to over-exertion, but by the pure love of the exercise itself. In all ordinary circumstances, those only who are vigorously constituted will attempt them, and, if left to themselves, will be sure to desist before any harm can be done. But the case is entirely altered when such extraordinary evolutions are not only encouraged but taught to all indiscriminately, whether they are strong or weak, resolute or timid. We have only to reflect for a moment on the structure of the shoulder joint, and on the sphere of action of the muscles surrounding it, to perceive at once that the position of the one and the strain upon the other caused by the exercises alluded to, are so forced and unnatural as to exclude the possibility of the Creator having intended either to be practised, except upon occasions of urgent necessity, and to discover how preposterous it is therefore to make them a subject of general instruction. Nay, the very violence of the effort required to sustain the body when hanging by the hands, is far beyond that moderate exertion which adds to nutrition and to strength, and in delicate subjects it may even induce relaxation and stretching of the ligaments and blood-vessels, and thus, as in the case of the young men at Cambridge, lay the foundation for future and fatal disease. The same

* The term *gymnastic* is from a Greek word signifying *naked*—the athletæ or young persons who practised bodily exercises in the public arena or gymnasium of ancient Greece, being nearly in a state of nudity. The more gentle kind of gymnastics for females are termed *calisthenics* from words signifying elegant or graceful exercises.

remarks apply to a common practice of making the pupils slide down an inclined plane, resting on the hands alone, by which unnatural effort the shoulders are pushed half way up the neck, and the wrists, arms, and chest severely tried. But in these and other similar evolutions, it requires only to look at the dragging and distortion which they produce, and which form such a painful contrast to the ease and grace of all natural motions and attitudes, to perceive that they are out of the order of nature, and that neither health nor elegance can result from them. In the selection of exercises for the young, then, we should not be misled by a vain desire of surmounting difficulties and performing feats at the serious risk of inducing aneurism or rupture, but rather endeavour to strengthen the body by active amusements, which shall call the social and moral feelings and intellect into play at the same time, and by the practice of such gymnastic evolutions only as tend to improve and give tone to the natural action of the moving powers. And in endeavouring to attain this object, we should be always careful to avoid great fatigue, and to modify the kind, degree, and duration of the exercise, so as to produce the desired results of increased nutrition and strength; and to remember that the point of which these results are to be obtained, is not the same in any two individuals, and can be discovered only by experience and careful observation."

With the precaution suggested by these observations, the following gymnastic exercises may be pursued:—

General Directions.

The exercises are best performed in an open court or piece of ground, firm below, but without any stones to injure the feet or person; a grass plot is the most suitable. The fittings are a climbing stand, vaulting bar, leaping poles, &c. The dress of the gymnast is to consist of easy-fitting trousers, and encircled with a belt or girth. The belt should pass round the loins, and not be too tight. The performances should be in the forenoon, or at least before any heavy meal.

Positions and Motions.

The body must be drilled in the art of standing and throwing out the limbs. In standing properly, the person should be erect, the head held up, and the face looking straight forward; the shoulders are to be square, with the chest fully exposed, so as slightly to curve the back; the legs closed; the heels in a line, and closed; the toes turned out; the arms hanging straight down; the elbows held in to the body; the hands open to the front; the little finger touching the legs; and the thumb flat to the forefinger. When perfected in the art of standing in this position, which is called *attention*, as shown in fig. 1, the next thing is to be taught to march or walk, as in the case of a soldier on drill, the feet being alternately thrown out, and both brought together into position, at the order to halt.

Fig. 1.

The pupil next learns to bend the body and extend the arms. The first exercise of this kind is to carry the hands to the front, the fingers lightly touching at the points; now raise the arms, the hands still together, till they are held over the head, as in fig. 2.

Fig. 2.

The second motion is to learn to hold the arms out in front, the tips of the fingers touching, and returning to the position of fig. 1: this is to be done repeatedly. The third is to extend the hands separately, and raise them over the respective shoulders, the fingers pointing upwards. The fourth motion is to keep the arms and legs straight, and to bend the body forward, with the head down and the tips of the fingers towards the ground. This somewhat difficult motion is represented in fig. 3.

Fig. 3.

A fifth motion is to resume the position of attention, allowing the arms to fall freely to their place, but still without bending the legs. These motions are trying to the pupil, and should be done gradually; the great object is to exercise the muscles bit by bit, and perfection is not desirable at first. Then follow other motions, as throwing the arms out in opposite directions, swinging the arms, &c. In these, it is of importance to exercise the left hand and arm fully more than the right, in order to make them as active and strong.

Indian Club Exercises.

The pupil having advanced in simple personal exercises, is supposed to be somewhat strengthened; and to further the operation, he proceeds to the Indian club exercises. The main object is to expand the chest, and increase the power of the arms. For this end, some sedentary persons regularly exercise themselves with dumb-bells; that is, heavy pieces of metal, one being held in each hand. The club exercise is an improvement on that of the dumb-bells. The club bears a resemblance to the bat for cricket, and varies in weight from two to twelve pounds. One is used in each hand. The following, according to Torrens, are the regulation-exercises now adopted in the army:—

"The recruit being placed in the position of attention, with a club in each hand pointing downwards, as in fig. 4, must be exercised as follows:—

Fig. 4.

"*First Part.*—1. At the word *one*, the club in the right hand is slowly carried round the head, until the hand arrives in a perpendicular line above the shoulder, with the large end of the club pointing in a diagonal direction to the rear; 2. The club in the left hand is raised in a similar manner, and carried over that in the right hand till it reaches a corresponding position; 3. The hands are carried slowly to the right and left, until they become in a true horizontal line with the shoulders, the large ends of the clubs still remaining to the rear; 4. The hands are brought slowly to the first position. Care must be taken that the recruit does not stand with a hollow back during this and the succeeding practice.

"*Second Part.*—1. Raise both hands to the front, approaching them close together, in horizontal line with the shoulders, the clubs being held perpendicular, with the large ends upwards; 2. With the body well poised forward, separate the hands, and carry them to the right and left line with the shoulders, the large ends of the clubs remaining upwards; 3. With the head well kept up, let the clubs turn over till they point in a diagonal direction to the rear, the hands still remaining out in a line with the shoulders; 4. With the arms extended, drop them slowly to the first position.

Fig. 5

"*Third Part.*—1. The club in the right hand is circled round upon the *right* of the body for a few revolutions of the circle, or until the word *halt* is given; 2. The one in the left hand is used in the same manner on the *left* of the body, until the word *halt* is given, when the recruit will remain perfectly steady in the first position; 3. With the body rather leaning forward, circle both clubs at the same time, on the right and left of the body, until ordered to halt."

Leaping.—Vaulting.

The simplest kind of leaping is that of jumping on level ground from one point to another, with or without a run. The run accumulates power in the person, or momentum, and enables a person to leap considerably farther than without such an aid. "In all kinds of leaping," observes Walker, in his "Manly Exercises," "it is of great importance to draw in and retain the breath at the moment of the greatest effort, as it gives the chest more solidity to support the rest of the members, impels the blood into the muscular parts, and increases their strength. The hands, also, should be shut, and the arms pendant. The extent of the leap in height, or horizontally, is proportioned to the power employed and the practice acquired. As it is performed with facility only in proportion to the strength exerted, and the elasticity and suppleness of the articulations and muscles of the lower extremities, much exercise is necessary to attain that degree of perfection which lessens all obstacles, and supplies the means of clearing them without danger. Lightness and firmness are the qualities necessary for leaping; every thing should be done to acquire these two qualifications, for without them leaping is neither graceful nor safe." Pupils begin by leaping short distances and no great height, and as they become expert, the feat is increased. To regulate the exercise, a leaping stand is employed; it consists of two movable posts, about six feet high, having, above eighteen inches from the ground, holes bored through them, at the distance of an inch from each other; a rope stretched across from pins, and held tight by sand-bags, is the bar to be leaped over.

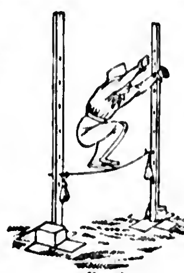


Fig. 6.

In leaping *without* a run, hold the legs and feet closed, bend the knees well up, hold forward the head, and throw out the hands, as in fig. 6. Skill in throwing forward the body with a jerk, thus doubled up, is only acquired by experience. Let great care be taken to descend with an inclination forward, and to fall on the fore part of the feet, so as to touch the ground lightly, and by the spring of the feet and limbs, to deaden the shock.

In leaping *with* a run, the run preceding the leap should never exceed ten paces; the rise into the air to take place at a distance from the cord equal to half the height of the chord from the ground. Skill should be attained in leaping from either foot, or from the spring of both feet. It is considered a good leap when five feet are cleared; a first-rate one is five and a half; and an extraordinary one six feet; few, however, ever reach more than four feet.

What is gained in height is lost in distance. To make a long leap, therefore, it is not necessary to go high. The measurement of long leaps is by marks on level and soft ground, and he who clears the greatest number of marks is the most proficient. As in high leaping, the body must be inclined forward, and the spring made from the balls to the toes. To clear twelve feet without a run is considered a good leap. With a run of ten to fifteen paces, increased in velocity as the runner approaches the springing point, a leap may be performed of fourteen or fifteen feet. In this running leap, it is best to spring from the foot in which there is most proficiency, and to rise to a moderate height from the ground; too low a spring defeats the desired end.

Leaping from a high to a low situation is another useful exercise. To acquire proficiency in it, begin with moderate heights, and learn to fall softly on the balls of the toes, or fore-part of the feet. If the fall be upon the heels, the whole body may be jarred, and the legs stove. Keep the body compact in the descent, with the hands well forward, so that, when alighting, the person will spring lightly up from a crooked posture.

Vaulting is that kind of leaping in which the body is helped forward by a momentary leaning on an object by the hands. The art of vaulting may prove useful in many circumstances in life, as, for instance, in getting quickly over a paling, fence, or gate to elude danger. Exercises are performed with vaulting bars, of which an illustration is given in fig. 7; they are of various heights, and some are shaped like a horse with a saddle.

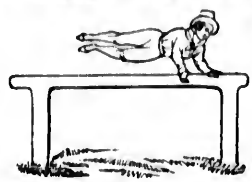

Fig. 7.

Vaulting is performed with or without a run. The spring, as usual is from the toes; and resting the hands on the bar, the legs are raised, and by a jerk pitched over to the other side. The pupil is to learn to vault in this manner, either towards the left or right. When perfect in the exercise, he learns to vault straight forward over the bar, between his hands, in which feat very great skill is necessary in doubling up the body during the spring. The methods of vaulting on and off horse-blocks are innumerable.

Leaping with a pole is a combination of simple leaping and vaulting, and is also a most useful and an elegant accomplishment. The pole should be smooth, light, and from seven to ten feet long. Held in the hands, as represented in fig. 8, the left hand below and the right above, the pole is planted with its lower point on the ground, and by a spring from the left foot, the body is impelled through the air to the desired distance.

Fig. 8.

In performing this exercise, the pupil must learn not to lean too much on the pole, and not to keep too close to it. The knack of pole-leaping is, like all other kinds, dependent on the spring of the feet, and the presence of mind in throwing the body forward lightly and gracefully. The best plan is to begin with short leaps across ditches, and to increase the distance afterwards. When the method of springing from a fixed situation is acquired, proceed to advanced practice by making a run, a quick plant of the pole, and a spring to a considerable distance, as across a brook of twelve or fifteen feet in width.

The next step is to learn to vault over a high object by means of the pole. Two posts and a cross cord, as in fig. 9, are usually employed in this exercise. The leap is taken by a run, and "upon this run," observes Walker, "principally depend the facility and success of the leap. As the spring can take place only with one foot, and as this must arrive correctly at the springing place, it is necessary that the order of the steps should be arranged so as to effect this object. The fixing of the pole in the ground and the spring must take place at the same instant,

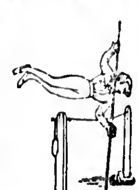

Fig. 9.

because by that means the upper and lower members operate together; no power is lost, and the swing is performed with the greatest facility. The leaper must carefully observe that the spring of the foot, and the plant of the pole, are in the direction of the preparatory run."

Carrying Weights.

A regular course of gymnastics embraces the art of lifting and carrying weights; but lessons in these exercises must be conducted with much caution, and only when the body has been otherwise well disciplined.

In lifting a weight, power is best exercised by doubling the body, as if about to sit down; the hands then grasp the ring of the weight placed between the feet, and the body gradually straightening, the arms rise with it and lift what is in the hands. By this means the whole force of the body is exerted, and no part more than another.

Loads of any kind are most advantageously borne on the back and shoulders, with the body erect. The arrangement of knapsacks on the backs of soldiers is on this plan, the weight depending from each shoulder, and not hanging too low. The more close the load is to the shoulder, the shorter is the lever, and the less the pull on the point of resistance.

A man exercises his power of draught with the greatest advantage by pulling a rope over his shoulder, for in this case he throws forward the weight of his person, and he acts both by muscular energy and weight. The least advantageous exercise of his power is to carry a load up a ladder; for he has to carry up his own weight as well as the load which is on his shoulders.

Running—Walking.

The art of walking with ease, firmness, and grace, forms a necessary part of gymnastic or drill exercises. Few persons walk well naturally; the constraint of dress, distortion from labour, or bad habits of some kind generally contributing to give a slounge to the figure, and an awkwardness to all the motions.

To walk gracefully, the body must be erect, but not stiff, and the head held up in such a posture that the eyes are directed forward. The tendency of untaught walkers is to look towards the ground near the feet; and some persons appear always as if admiring their shoe-ties. The eyes should not thus be cast downward, neither should the chest bend forward to throw out the back, making what are termed "round shoulders;" on the contrary, the whole person must hold itself up, as if not afraid to look the world in the face, and the chest by all means be allowed to expand. At the same time, every thing like strutting or pomposity must be carefully avoided. An easy, firm, and erect posture, are alone desirable. In walking, it is necessary to bear in mind that the locomotion is to be performed entirely by the legs. Awkward persons rock from side to side, helping forward each leg alternately by advancing the haunches. This is not only ungraceful but fatiguing. Let the legs alone advance, bearing up the body. In setting down the feet, let the outer edge of the heel first touch the ground, and the sole of the foot bear and project the weight of the body. The length of step is of course to be determined by the length of limb. Efforts at taking long steps, out of proportion to the power of motion, are always ungraceful. Reckoning from heel to heel, or toe to toe, the length of a military step at drill march is thirty inches, which is considerably more than the length of ordinary steps in walking. The length of step at a moderate pace, of a man five feet nine inches high, is usually twenty-four inches; and this will be found a convenient length to acquire the habit of using.

The motion of the arms to and fro, in cadence with the movements of the legs, greatly helps the locomotion, and is advantageous in exercising the muscles of the shoulders and expanding the chest. The motions of the arms, however, should be on a moderate scale, the hands not swinging through a greater space than eight or nine inches before and behind the leg. The practice of working forward the shoulders and swinging the arms at a great rate is most odious. It may be added, that the art of comporting the hands, keeping them down, or from middling with the person, is one very necessary in polite behaviour, and should be acquired by all young persons, before bad habits are confirmed.

Running is a rapid leaping kind of walk, the leap being from each foot alternately, and the motion being promoted by throwing forward the weight of the person. The following are Walker's definitions of running, which we illustrate by fig. 10:—"The upper part of the body is slightly inclined forward; the head slightly thrown backward, to counteract the gravity forward; the breast is freely projected; the shoulders are steady, to give a fixed point to the auxiliary muscles of respiration; the upper parts of the arms are kept near the sides; the elbows are bent, and each forms an acute angle; the hands are shut, with the nails turned inwards; and the whole arms move but slightly, in order that the muscles of respiration on the chest may be as little as possible disturbed, and follow only the impulse communicated by other parts. There exists, in fact, during the whole time of running, a strong and permanent contraction of the muscles of the shoulder and arm, which, though very violent, is less serviceable to the extended movements than to keep the chest immovable, toward which the arms are brought close, the flexors and adductors of which are especially contracted.

Fig. 10.

"At every step the knees are stretched out, the legs kept as straight as possible, the feet almost graze the ground, the tread is neither with the mere balls of the toes nor with the whole sole of the foot, and the spring is made rapidly from one foot to the other, so that they pass each other with great velocity.

"Speed, and still more duration in running, are in proportion to the development of the lungs, and consequently the volume of oxygen and blood which they can combine in their parenchyma at each respiratory movement. Thus, of two men, one having the abdominal members developed, and the other possessing good lungs, the former will run with the greatest speed for a short distance; but if the distance be considerable, he will soon be gained upon by the latter. A runner, after performing a certain space, is seized with a difficulty of breathing, long before the repetition of the contractions has produced fatigue in the abdominal members. To excel, therefore, in running, requires, like walking and dancing, a peculiar exercise. As the muscular contractions depend, for the principle of excitement, on the respiration, the chest should be firmly fixed, so as both to facilitate this and to serve as a point of support for the efforts of the lower members. The best runners are those who have the *best wind*, and keep the breast dilated for the longest time.

"During the whole time of running, long inspirations and slow expirations are of the greatest importance; and young persons cannot be too early accustomed to them. To facilitate respiration towards the end of the race, the upper part of the body may be leant a little forward. Running should cease as soon as the breath becomes very short, and a strong perspiration takes place."

Exercises in running should commence with very moderate distances, and for short periods of time; and great or fatiguing feats are only to be attempted after the body and lungs are strengthened by training.

TRAINING.

The method of training in modern times for pedestrian feats and other laborious undertakings, does not differ materially from that pursued by the ancient Greeks. The great object is to increase the muscular strength, and to improve the free action of the lungs or wind of the person subjected to the process. The means adopted to accomplish the end in view is evacuation, to cleanse the stomach and intestines; sweating, to take off the superfluous fat and humours; daily exercise, to strengthen the muscles and system generally; and a peculiar regimen to invigorate the body. And to this we add the use of the tepid bath, to remove impurities and promote a healthy action to the skin. We present the following graphic account of the process of training, from "Walker's Manly Exercises:"—

"The most effectual process for training appears to be that practised by Captain Barclay, which has not only been sanctioned by professional men, but has met with the unqualified approbation of amateurs. We are here, therefore, almost entirely indebted to it for details. According to this method, the pedestrian, who may be supposed in tolerable condition, enters upon his training with a regular course of physic, which consists of three doses. Glauber's salts are generally preferred; and from one ounce and a half to two ounces are taken each time, with an interval of four days between each dose. After having gone through the course of physic, he commences his regular exercise, which is gradually increased as he proceeds in the training.

"When the object in view is the accomplishment of a pedestrian match, his regular exercise may be from twenty to twenty-four miles a day. He must rise at five in the morning, run half a mile at the top of his speed up hill, and then walk six miles at a moderate pace, coming in about seven to breakfast, which should consist of beef-steaks or mutton-chops under-done, with stale bread and old beer. After breakfast, he must again walk six miles at a moderate pace, and at twelve lie down in bed, without his clothes, for half an hour. On getting up, he must walk four miles, and return by four to dinner, which should also be beef-steaks or mutton chops, with bread and beer, as at breakfast. Immediately after dinner, he must resume his exercise, by running half a mile at the top of his speed, and walking six miles at a moderate pace. He takes no more exercise for that day, but retires to bed about eight; and next morning he proceeds in the same manner.

"Animal diet, it will be observed, is, according to this system, alone prescribed, and beef and mutton are preferred. All fat and greasy substances are prohibited, as they induce bile, and consequently injure the stomach. The lean of meat contains more nourishment than the fat; and in every case the most substantial food is preferable to any other kind. Fresh meat is the most wholesome and nourishing. Salt, spiceries, and all kinds of seasonings, with the exception of vinegar, are prohibited. The lean, then, of fat beef cooked in steaks, with very little salt, is the best; and it should be rather under-done than otherwise. Mutton, being reckoned easy of digestion, may be occasionally given, to vary the diet and gratify the taste. The legs of fowls are also esteemed.

"It is preferable to have the meat broiled, as much of its nutritive quality is lost by roasting or boiling. It ought to be dressed so as to remain tender and juicy; for it is by these means that it will be easily digested, and afford most nourishment. Biscuit and stale bread are the only preparations of vegetable matter which are permitted to be given; and every thing inducing flatulency must be carefully avoided. In general, the quantity of aliment is not limited by the trainer, but left entirely to the discretion of the pedestrian, whose appetite should regulate him in this respect.

"With respect to liquors, they must be always taken cold; and home-brewed beer, old but not bottled, is the best. A little red wine, however, may be given to those who are not fond of malt liquor; but never more than half a pint after dinner. It is an established rule to avoid liquids as much as possible; and no more liquor of any kind is allowed to be taken than is requisite to quench the thirst.

"After having gone on in this regular course for three or four weeks, the pedestrian must take a four mile sweat, which is produced by running four miles in flannel at the top of his speed. Immediately on returning, a hot liquor is prescribed, in order to promote the perspiration; and of this he must drink one English pint. It is termed the sweating liquor, and is composed of one ounce of carraway seed, half an ounce of coriander seed, one ounce of root-liquorice, and half an ounce of sugar-candy, mixed with two bottles of cider, and boiled down to one-half. He is then put to bed in his flannels, and being covered with six or eight pair of blankets and a feather-bed, must remain in this state from twenty-five to thirty minutes, when he is taken out, and rubbed perfectly dry. Being then well wrapt in his greatcoat, he walks out gently for two miles, and returns to breakfast, which, on such occasions, should consist of a roasted fowl. He afterwards proceeds with his usual exercise.

"These sweats are continued weekly till within a few days of the performance of the match; or, in other words he must undergo three or four of these operations. If the stomach of the pedestrian be foul, an emetic or two must be given about a week before the conclusion of the training. He is now supposed to be in the highest condition.

"Besides his usual or regular exercise, a person under training ought to employ himself in the intervals in every kind of exertion which tends to activity, such as golf, cricket, bowls, throwing quoits, &c., so that, during the whole day, both body and mind may be constantly occupied. Although the chief parts of the system depend upon sweating, exercise, and feeding, yet the object to be attained by the pedestrian would be defeated, if these were not adjusted each to the other, and to his constitution. The trainer, before he proceeds to apply his theory, should make himself acquainted with the constitution and habits of his patient, that he may be able to judge how far he can with safety carry on the different parts of the process. The nature of the patient's disposition should also be known, that every cause of irritation may be avoided; for, as it requires great patience and perseverance to undergo training, every expedient to soothe and encourage the mind should be adopted.

"The skilful trainer will, moreover, constantly study the progress of his art, by observing the effect of its processes, separately and in combination. If a man retain his health and spirits during the process, improve in wind and increase in strength, it is certain that the object aimed at will be obtained; but if otherwise, it is to be apprehended that some defect exists, through the unskilfulness or mismanagement of the trainer, which ought instantly to be remedied by such alterations as the circumstances of the case may demand. It is evident, therefore, that in many instances the trainer must be guided by his judgment, and that no fixed rules of management can, with absolute certainty, be depended upon for producing an invariable and determinate result. In general, however, it may be calculated that the known rules are adequate to the purpose, if the pedestrian strictly adhere to them, and the trainer bestow a moderate degree of attention to his state and condition during the progress of training.

"It is impossible to fix any precise period for the completion of the training process, as it depends upon the previous condition of the pedestrian; but from two to three months, in most cases, will be sufficient, especially if he is in tolerable condition at the commencement, and possessed of sufficient perseverance and courage to submit cheerfully to the privations and hardships to which he must unavoidably be subjected. The criterion by which it may be known whether a man is in good condition—or, what is the same thing, whether he has been properly trained—is the state of the skin, which becomes smooth, elastic, and well coloured, or transparent. The flesh is also firm, and the person trained feels himself light and full of spirits. In the progress of the training, his condition may also be ascertained by the effect of the sweats, which cease to reduce his weight, and by the manner in which he performs one mile at the top of his speed. It is as difficult to run a mile at the top of one's speed as to walk a hundred; and therefore, if he performs this short distance well, it may be concluded that his condition is perfect, or that he has derived all the advantages which can possibly result from the training process."

PEDESTRIAN FEATS.

Prepared by training, and acting under certain precautions as to food and rest, a person may perform very surprising feats of pedestrianism. He may, for instance, completely out-travel a horse, by walking for days continuously from thirty to forty miles, and yet be as fresh at the end of his journey as at the beginning. Without preparatory training, however, the most fatal injuries may be committed in attempting pedestrian feats. We must offer some precautionary advices on this subject.

Advices to Young Men on Walking Excursions.

Young men who break away from regular, and perhaps sedentary, employment, to take a walking excursion of a few days in the country, often commit such grievous errors as mar their enjoyments, and deprive themselves of all the benefit they had calculated upon as the proper result of an exemption from ordinary duty. With soft and relaxed frames, they, in many instances, address themselves to walk such a distance each day as only could be conveniently walked by a person accustomed to such tasks. Accordingly, by the end of the second day at farthest, their feet are all over blisters, their strength is completely exhausted, and their whole system is in a fever of nervous agitation, the consequence of enormous voluntarily incurred suffering. The next morning, perhaps, sees them a little recovered, and, with their small stock of renewed strength, soaped stockings, and a vigorous resolution, they set out upon the third day's travel, which probably concludes by leaving them in a worse state than before. There is no time, however, to wait for a perfect recovery; so they travel on, and probably complete their excursion in a miserable dragging fashion, glad to get over the country without enjoying it, so that they only have the prospect of being again speedily at home and at rest.

This is the unavoidable consequence of ignorance and want of reflection. The excursion might have been a source of pleasure instead of pain, and might have added considerably to the youth's stock of ideas, instead of leaving him disgusted with the country and with nature, if he had only proceeded upon right principles. He ought to know that the body, after being long under the influence of a sedentary profession, or of ordinary city life, is not in a state fit for undertaking great fatigue. When soldiers, after being a considerable time in garrison, are about to undertake a long march, they usually are led out to take short walks each day for about a week beforehand, every day's walk lengthening a little, until they become fitted for the serious task. This they call being *beat into a march*. It is a practice founded on right physiological principles, and worthy of being followed by every individual in like circumstances. In the walks of the first two or three days, young pedestrians should not set themselves to any certain number of miles, but only walk as far as they feel their strength will agreeably carry them. Thus they will gradually acquire power, instead of losing it, and in the long run become good walkers, enjoying the country, moreover, as they go along, and leaving off with an increased love of nature, and a disposition to have another such walk at the first opportunity.

Young travellers, and old ones too, often make a great mistake with regard to eating. They suppose that, having much fatigue to undergo, they ought to eat a great deal; and the excitement of novelty, and the tempting and unusual food presented at inns, enable them to carry out this idea into practice. In a few days, however, they find themselves unaccountably unwell. This is the consequence of simple over-eating, for in travelling there is no need for more food than usual. Food is also taken at wrong times, and of wrong kinds. It is not uncommon for young pedestrians to walk ten or twelve miles before breakfast, not so much for any economy of time or money, as under the impression that they will have a capital appetite at the end of their walk. As they go along, they delight themselves with reflections as to how they will astonish the waiters, how fresh relays of eggs will be called for, and rolls vanish like morning dreams. Alas! when they have walked their dozen miles, their frames are in a state the most unsuited for the receipt of a full meal; and if they are *able* to eat largely, it will be the worse for them after. The whole aim here is the very reverse of what it ought to be. A very full meal should never be taken on a pedestrian excursion, and that simply for the reason that there is no time to digest a very full meal. A breakfast or dinner during a walking excursion, when only a little time can be allowed for rest afterwards, should be light. Whether light or heavy, the longer the rest afterwards the better—that is, of course, within a reasonable limit. Certainly the rest should not be less than three quarters of an hour; and if a heavy meal have been taken, half an hour longer will be required at the very least.

Many young travellers have the prudence to fare slightly during their day's walk, but, on getting to their inn in the evening, they make all up, as they think, by taking a great composite meal—dinner, tea, and supper, rolled into one. If, as often happens, this be taken pretty late, the tea keeps them awake half the night, by virtue of its exciting power. But it may act injuriously in another way. When much of it is taken in proportion to the solids, it prevents digestion. The gastric juice, it must be understood, requires that what is submitted to it should possess a certain solidity. It is for this reason that nature has so arranged, in the case of sucking infants, that the milk curdles immediately after being taken, the gastric juice being thereby enabled to catch hold of it. When a young man, after exhausting his energies by a long walk, fills his stomach with a great *blashy* meal, he commits one of the greatest of imprudences. The gastric juice gets mixed and confounded with the mass, and several hours will elapse before any progress whatever be made in digestion. Many is the sleepless night endured on this account on summer excursions. It is obviously necessary that, if tea is to be taken at all at a late hour, it should be weak, and in quantity strictly proportioned to the solids taken at the same time. Weak coffee, however, ought always to be preferred to tea, if to be taken near bedtime, as its exciting power is much less.

The rules here laid down are all of them grounded on natural principles, which will be found more particularly explained in physiological works—Those, for instance, of Dr. Combe, which are by far the most intelligibly written, at the same time that they are even more philo sophical than most others. By attending to such rules, a rural excursion may be made very delightful, and may have the best effects on both body and mind, while neglect of them as certainly must entail pain and disappointment.

Captain Barclay's Feats of Walking.

Captain R. Barclay Allardice, of Ury, an enthusiastic cultivator of manly sports, is well known as having some years ago performed various remarkable feats of pedestrianism, and his mode of walking is well worthy of notice. Pierce Egan thus writes of his performances:—"His style of walking is to bend forward the body and throw its weight on the knees. His step is short, and his feet are raised only a few inches from the ground. Any person trying this plan will find his pace quickened, and he will walk with more ease to himself, and be better able to endure the fatigue of a long journey, than by walking perfectly erect, which throws too much of the weight of the body on the ankle-joints. He always uses thick-soled shoes and lambs'-wool stockings, which preserve the feet from injury."

We have not space to conclude an account of the various extraordinary feats performed by this able pedestrian, and shall only notice his famous match with Mr. Webster, in October, 1808. "The captain engaged himself to go on foot a thousand miles in a thousand successive hours, at the rate of a mile in each and every hour, for a bet of one thousand guineas, to be performed at Newmarket heath, and to start on the following first of June. In the intermediate time, the captain was in training by Mr. Smith, of Owston, in Yorkshire. He started on his match at twelve o'clock at night on Thursday, the 1st of June, in good health and high spirits. His dress, from the commencement, varied with the weather. Sometimes he wore a flannel jacket, sometimes a loose gray coat, with strong shoes, and two pair of coarse stockings, the outer pair boot-stockings, without feet, to keep his legs dry. He walked in a sort of lounging gait, without any apparent extraordinary exertion, scarcely raising his feet two inches above the ground. During a great part of the time the weather was very rainy, but he felt no inconvenience from it; indeed, wet weather was favourable to his exertions; as, during dry weather, he found it necessary to have a water-cart to go over the ground to keep it cool, and prevent it becoming too hard. Towards the conclusion of the performance, it was said, the captain suffered much from spasmodic affection of his legs, so that he could not walk a mile in less than twenty minutes; he, however ate and drank well, and bets were two to one and five to two on his completing his journey within the time prescribed. About eight days before he finished, the sinews of his right leg became much better, and he continued to pursue his task in high spirits, and consequently bets were ten to one in his favour in London, at Tattersall's, and other sporting circles.

"On Wednesday, July the 12th, Captain Barclay completed his arduous undertaking. He had till four P. M. to finish his task, but he performed the last mile by a quarter of an hour after three in perfect ease and great spirit, amidst an immense crowd of spectators. The influx of company had so much increased on Sunday, that it was recommended that the ground should be roped in. To this, however, Captain Barclay objected, saying, that he did not like such parade. The crowd, however, became so great on Monday, and he had experienced so much interruption, that he was prevailed upon to allow this precaution to be taken. For the last two days he appeared in higher spirits, and performed his last mile with apparently more ease, and in a shorter time, than he had done for some days past.

"With the change of weather he had thrown off his loose greatcoat, which he wore during the rainy period, and walked in a flannel jacket. He also put on shoes thicker than any which he had used in the previous part of his performance. When asked how he meant to act after he had finished his feat, he said he should that night take a good sound sleep, but that he must have himself awaked twice or thrice in the night to avoid the danger of a too sudden transition from almost constant exertion to a state of long repose. One hundred guineas to one, and, indeed, any odds whatever, were offered on Wednesday morning; but so strong was the confidence in his success, that no bets could be obtained. The multitude who resorted to the scene of action, in the course of the concluding days, was unprecedented. Not a bed could be procured on Tuesday night at Newmarket, Cambridge, Bury, or any of the towns or villages in the vicinity, and every horse and vehicle was engaged. Among the nobility and gentry who witnessed the conclusion of this extraordinary performance, were the Dukes of Argyle and St. Albans; Earls Grosvenor, Besborough, and Jersey; Lords Foley and Somerville; Sir John Lade, Sir F. Standish, &c., &c. The aggregate of the bets is supposed to have amounted to £100,000. Upon the whole, Captain Barclay must be viewed as a most extraordinary man, and shows the extent of vigour that the human frame derives from exercise."

OUT-OF-DOOR RECREATIONS.

SWIMMING.

The art of swimming is so exceedingly useful, not only as a bracing summer exercise, but as a means of preserving life when accidentally plunged into the water, that it should be acquired by every young person. It may be performed either in the sea or in rivers; but the sea is preferable, as salt water is of greater specific gravity than fresh, and has the greater power of buoying up the body. Whether in fresh or salt water, however, the body is lighter, bulk for bulk, than the mass of liquid displaced, and consequently will float if a small aid be given by the impulsion of the hands. It is also important to observe, that the more the body is immersed in the water, the more easily is it sustained. Thus, if only the face is left above the surface, the buoyancy will be much greater than if the whole head or the head and hands were exposed. When persons unskilled in swimming are plunged into the water, as, for instance, by the upsetting of a boat, they ought, for the reasons now mentioned, not to struggle, splutter, and hold the hands up, but remain tranquil, with as little above water as possible; draw in the breath so as to fill the lungs, and sustain themselves by a paddling motion with the hands.

Practical Directions for Swimming.

The best season for bathing in the sea or rivers is summer and autumn, and the time of day most preferable is the morning before breakfast; the next best time is before dinner. Immediately after dinner, or when the stomach is full, is injurious. A person, also, should never bathe twice in one day, or continue in the water more than twenty minutes at one time. To avoid the danger of propelling the blood to the head, by stepping suddenly into cold water, always wet the head first. Bathing is best performed when entirely naked; but if this be unsuitable, short drawers may be used.

Young persons or others unskilled in swimming should not on any account go beyond the depth of breast-high, till they are able to buoy themselves up freely. They can commence their lessons in swimming by throwing themselves forward, and trying what will be the effect of a throwing out of hands and feet, keeping only the head above the surface. Some persons tie corks or bladders about their neck or breast, but this we discommend as dangerous. A preferable plan of learning to swim is to receive the aid of a person skilled in the art, who will help to buoy up the learner with his hand, and withdraw his assistance gradually. In ordinary circumstances, however, any young person may acquire the art himself.

The learner having thrown himself forward, he must draw his head back, elevate his chin clear of the surface, project his breast, hollow his back, and be firm and collected. Fear must be entirely thrown aside. Instead of putting down the hands, as if to grope for something, which is a very common error, throw the hands boldly forward, and strike out with them. The plan of doing this is first to bring the hands together, with the fingers close, and the thumbs closed to the forefingers; then strike out with the palms undermost and slightly hollowed. The hands must not touch the surface in striking, but make a sweep level with the breast, and as far out as possible. Next, they are to be drawn back with a rapid movement; in this retraction, the elbows are to be bent and the hands drooping downwards, so that as little obstacle as possible may be presented to the water. The hands being brought together as before, they are to be struck out in the same manner; and so on.

The hands furnish only half the means of advancing. The other half are the legs, which must be sent out behind with a jerk to their full extent, the soles pushing against the water. The position of the swimmer in the water is indicated in the adjoining cut, fig. 11, in which

Fig. 11.

it will be seen that the body slopes from the neck to the feet. To advance properly, and secure regular buoyancy, the hands and feet must act alternately, the arms descending while the legs are rising, and the arms rising while the legs are descending.

Besides regulating the action of the hands and feet, the swimmer must regulate his breathing. The breath is to be inhaled when the body is rising by the descent of the hands, and when the mouth is clearly above the ruffle of the water. This fills the chest with air at the moment most advantageous to do so. The breath is to be expended at the next impulse forward by the legs. Some persons, in learning to swim, acquire the habit of *breasting*, or rising high out of the water at every stroke of their arms; this mode of swimming is not only ungraceful but fatiguing; a good and tasteful swimmer advances smoothly through the water, with a moderate rise, and at a moderate and steady rate of speed.

There are various fanciful modes of swimming; one of these is swimming with the back downwards, as represented in fig. 12. In this case the head is more immersed than in ordinary swimming, and consequently less labour is required to buoy up the body. The method employed is to lie gently back in the water, with the hands on the thighs, and to strike out the legs as in front swimming. By swimming on the back little progress is made; and it is chiefly useful as a relief to the arms.

Fig. 12.

Another means of relieving the fatigue of swimming is to float on the back with a very gentle motion of the legs, in the position represented in fig. 13. The arms are extended, the chin and mouth elevated higher than the forehead; and the water is to be agitated as little as possible, so as not to enter the mouth.

Fig. 13.

Swimming with one arm is sometimes useful. To perform this feat, the head should be held more backward than usual; the swimmer hold himself more erect; the legs and arm must be exercised pretty quickly; and with force the hand should be struck out against the body, and so brought down before, the arm extended its full length for every stroke. The swimmer must, however, be very careful to keep his breast inflated, as this mode of swimming requires more than ordinary dexterity. Should the swimmer draw in his breast imprudently, when his arms are raised, he would immediately sink to the bottom.

Diving is the art of descending rapidly in the water, and requires to be done with address. The best method consists in drawing in the breath, placing the two hands together as a cut-water in front, and then to plunge head foremost, causing the forehead to receive the force of the fall. In taking the water, the eyes, for safety, should be shut; but they may be opened when beneath the surface, when the body assumes the swimming attitude. Swimming below the water is so exceedingly easy that it requires no directions.

Mr. Frost, in his small work on "Scientific Swimming," presents the following practical rules for sportive swimming:—"To spin with ease, the person should be somewhat buoyant; the breast must be well inflated, and the attitude may be that of sitting with the feet crossed. It is effected by embracing the water with each hand, alternately, on the same side. In order to turn to the right, the water must be embraced with each hand, alternately, on the right side; and to turn to the left, on the left side. . This action causes a circular or spinning movement, which increases in velocity as it is continued. Of all the playful ways of swimming he ever knew, the author considers this to be the most curious. He has seen boys sportively rolling along the stream, and conceived it very much to resemble the juvenile amusement, on a summer day, of rolling down a declivity. The stream is the most favourable situation for rolling, as it very much assists the turn. To achieve this, the person must lay himself straight across the current; he must inflate his breast, and hold his head very backward; his legs may either lie together or be crossed; he must exercise his hands in the same manner as in spinning. By this alternate action of the hands, with the assistance of the stream, some persons will roll along in a pleasing and extraordinary manner." He then mentions quadruped swimming; but neither the posture nor action is agreeable.

In some cases cramp takes place in the water, and the swimmer requires to be prepared for its attacks. The following directions by Walker, acted upon with due self-possession, comprise all that need be said on this subject:—

"As to cramp, those chiefly are liable to it who plunge into the water when they are heated, who remain in it till they are benumbed with cold, or who exhaust themselves with violent exercise. Persons subject to this affection must be careful with regard to the selection or the place where they bathe, if they are not sufficiently skilful in swimming to vary their attitudes, and dispense instantly with the use of the limb attacked by cramp. Even when this does occur, the skilful swimmer knows how to reach the shore by the aid of the limbs which are unaffected, while the uninstructed one is liable to be drowned.

"If attacked in this way in the leg, the swimmer must strike out the limb with all his strength, thrusting the heel downward and drawing the toes upward, notwithstanding the momentary pain it may occasion; or he may immediately turn flat on his back, and jerk out the affected limb in the air, taking care not to elevate it so high as greatly to disturb the balance of the body. If this does not succeed, he must paddle ashore with his hands, or keep himself afloat by their aid, until assistance reach him. Should he even be unable to float on his back, he must put himself in the upright position, and keep his head above the surface by merely striking the water downward with his hands at the hips, without any assistance from the legs."

SKATING.

This is a highly exhilarating and healthful out-of-door pastime in winter, when rivers and ponds are frozen, and offer a clear surface of ice. The art of skating consists in poising the body on a sharp ridge of iron beneath the sole of the foot, and advancing on the ice in that position, one foot relieving another. As a very slender base will support any mass of matter kept in motion, skating is by no means a difficult art, and requires only courage, quickness of eye, and delicacy of taste, to render the performances elegant.

A skate is a well-known apparatus of wood and iron, with straps and buckles to attach it to the foot. The skate for each foot must be alike. The iron should not be deeper than three quarters of an inch, and smooth or flat along its under edge; only boys' skates should be grooved, to take better hold of the ice. The iron should be a quarter of an inch thick. The edges should be smooth, free from rust, and sharply ground.

Practical Directions for Skating.

We beg to offer the following directions to the young skater, chiefly from the work of Mr. Walker:—

"Either very rough or very smooth ice should be avoided. The person who for the first time attempts to skate must not trust to a stick. He may make a friend's hand his support, if he require one; but that should be soon relinquished in order to balance himself. He will probably scramble about for a half an hour or so, till he begins to find out where the edge of his skate is. The beginner must be fearless, but not violent, nor even in a hurry. He should not let his feet get far apart, and keep his heels still nearer together. He must keep the ankle of the foot on the ice quite firm; not attempting to gain the edge of the skate by bending it, because the right mode of getting to either edge is by the inclination of the whole body in the direction required; and this inclination should be made fearlessly and decisively.

"The leg which is on the ice should be kept perfectly straight; for though the knee must be somewhat bent at the time of striking, it must be straightened as quickly as possible, without any jerk. The leg which is off the ice should also be kept straight, though not stiff, having an easy but slight play, the toe pointing downwards, and the heel within from six to twelve inches of the other.

"The learner must not look down at the ice, nor at his feet to see how they perform. He may at first incline his body a little forward, for safety, but hold his head up, and see where he goes; his person erect, and his face rather elevated than otherwise.

"When once off, he must bring both feet up together, and strike again, as soon as he finds himself steady enough, rarely allowing both feet to be on the ice together. The position of the arms should be easy and varied, one being always more raised than the other; this elevation being alternate, and the change corresponding with that of his legs; that is, the right arm being raised as the right leg is put down, and *vice versa*, so that the arm and leg of the same side may not be raised together.

"The face must be always turned in the direction of the line intended to be described. Hence in backward skating, the head will be inclined much over the shoulder; in forward skating, but slightly. All sudden and violent action must be avoided. Stopping may be caused by slightly bending the knees, drawing the feet together, inclining the body forward, and pressing on the heels. It may also be caused by turning short to the right or left, the foot on the side to which we turn being rather more advanced, and supporting part of the weight.

"The first attempt of the beginner is to walk, and this walk shortly becomes a sliding gait, done entirely on the inside edge of the skate.

"The first impulse is to be gained by pressing the inside edge of one skate against the ice, and advancing with the opposite foot. To effect this, the beginner must bring his feet nearly together, turn the left somewhat out, place the right a little in advance, and at right angles with it, lean forward with the right shoulder, and at the same time move the right foot onwards, and press sharply, or strike the ice with the inside edge of the left skate—care being taken instantly to throw the weight on the right foot. While thus in motion, the skater must bring up the left foot nearly to a level with the other, and may for the present proceed a short way on both feet.

"He must next place the left foot in advance in its turn, bring the left shoulder forward, inclining to that side, strike from the inside edge of the right skate, and proceed as before.

"Finally, this motion has only to be repeated on each foot alternately, gradually keeping the foot from which he struck longer off the ice, till he has gained sufficient command of himself to keep it off altogether, and is able to strike directly from one to the other, without at any time having them both on the ice together. This must be practised till he has gained some degree of firmness and power, and a command of his balance."

Thus accomplished in the rudiments of the art, the skater may proceed to learn the *forward roll*, which is the first step towards figure skating. "The impulse is gained in the same manner as for the ordinary run; but to get on the outside edge of the right foot, the moment that foot is in motion, the skater must advance the left shoulder, throw the right arm back, look over the right shoulder, and incline the whole person boldly and decisively on that side, keeping the left foot suspended behind. As he proceeds, he must bring the left foot past the inside of the right with a slight jerk, which produces an opposing balance of the body; the right foot must quickly press, first on the outside of the heel, then on the inside, or its toe; the left foot must be placed down in front before it is removed more than about eight or ten inches from the other foot; and by striking outside to the left, giving at the same moment a strong push with the inside of the right toe, the skater passes from right to left, inclining to the left side in the same manner as he did to the right. He then continues to change from left to right, and from right to left, in the same manner. At first he should not remain long upon one leg, nor scruple occasionally to put the other down to assist; and throughout he must keep himself erect, leaning most on the heel."

Having attained this proficiency, there will be little difficulty in describing any figure, formed by a combination of circles or semicircles. The figure 8 is a favourite among clever skaters, and also the figure 3, both forward and reversed.

Skating on ice of doubtful strength is accompanied with great danger, as in an instant the skater may find himself sunk to the neck in water, and be drowned before assistance can be rendered. Much of this danger may be obviated by wearing a *safety-cape*, which is a loose cape inflated with air, the invention of a member of the Edinburgh skating club. We recommend every skater to use by all means a cape of this kind while pursuing his amusement on the ice.

CURLING.

Curling is a game of great antiquity and popularity in the southern and western parts of Scotland. It is a winter game, played on the ice; and where the rivers and ponds are frozen, usually supersedes all other out-of-door amusements. As the ice requires to be much thicker than for skating, it is usual to form ponds so shallow that the whole water in them becomes a frozen mass capable of bearing up any weight.

The game is played by a party forming rival sides, each individual being possessed of a circular hard stone, of about nine inches in diameter, flat and smooth on the under side, and, on the upper, having a handle fixed to the stone. Each player is likewise armed with a broom to sweep the ice, in order to accelerate the progress of the stones; and his feet are ordinarily furnished with trampets, or crampets, which help to steady him in taking his aim. A large long open space of ice, of from thirty to forty yards in length, and eight or nine feet across, called a *rink*, being cleared, and a mark or *tee* being made at each end to play to, the contest takes place by each person hurling or causing his stone to slide towards the opposite end of the rink. A certain number being the game, the object of each side is, which will have the greatest number of stones nearest the tee; and all play from end to end alternately, till this is ascertained. To hurl these stones with precision, in this species of sport, is exceedingly difficult; much depending on the keenness of the frost, the tone of the ice, and the truth of the stone. Sometimes the best and oldest players are baffled by beginners, simply by their curling-stones having taken a bias to one side or another; and frequently, after the best players have placed their stones in a cluster round the tee, one rapid shot from an antagonist will disperse the whole in all directions round. Occasionally it also happens that, in hurling, the stones come far short of the mark; but if they do not get beyond a line, called the *hogg score*, they are dragged aside, and are not counted. A more than usually extensive match is called a *bonspiel.*

Curling.

Such is a meagre outline of the game of curling, which, all over the west and south of Scotland during the keen frosty days of winter, engages all classes of persons in exciting sport. Parish contends against parish, county against county, club against club, in universal mirthful rivalry. At Edinburgh, where there are neither rivers nor ponds, the inhabitants resort for the amusement of curling, as well as skating, to the adjacent beautiful small lake at Duddingstone, lying at the south-eastern base of Arthur Seat. Here a most animated scene is exhibited during the period that the waters of the lake are frozen. Numbers of rinks are cleared, at which may be seen playing together persons in almost every shade of society—professors of the university, clergymen, private gentlemen, merchants, tradesmen, and artisans—all meeting on a common level, and engaged in the same spirit-stirring pursuit; for in curling there is no aristocracy of feeling, and so, for the time, a universal saturnalia prevails. The game of curling is eulogized by more than one Scottish poet, particularly by Grahame who thus commences a description of the sport:—

> "Now rival parishes and shrievedoms keep
> On upland lochs, the long-expected tryst,
> To play their yearly bonspiel. Aged men,
> Smit with the eagerness of youth, are there,
> While love of conquest lights their beamless eyes,
> New-nerves their arms, and makes them young once more."

In Mr. M'Diarmid's "Sketches of Nature," we find the following spirited account of this delightful winter game:—

"The time is not distant when the game of curling was little known out of Scotland, or even within it, benorth the Forth. But the taste for this manly sport has increased greatly of late years; and in various parts of England, as well as America, the broom and the channel-stone are put in requisition with the same regularity that winter comes round.

"In the whole range of rural sports, I know nothing more exhilarating than a *spiel* on the ice, where the players are numerous and well-matched—the stakes a dinner of beef and greens—and the forfeit the honour of rival parishes. All around is blank and dreary—the snow-flake freezes as fast as it falls—the sun seems level with the horizon's verge—the hills make the spectator cold to look at them—and every thing, in one word, conspires to complete the picture of a winter's day. But the courage of men bent on the favourite amusement of curling, is not easily damped by the inclemency of the elements; on the contrary, their spirits seem to mount as the thermometer falls, and nothing pleases them more than a feeding storm, and, along with that, the prospect of a long lease at 'their roaring play.' Arrived at the scene of action, all is bustle and animation, till the stones have been distributed, assorted, claimed—rinks measured, tramps fastened, tees fixed, and the order of battle completely arranged; and as these preliminaries are speedily settled, to it the parties set with all the anxiety of those who contend for a much higher prize. Lots, perhaps, are cast for the first shot, and the greatest novice invited to deliver the first stone; and should his arm lack the proper pith, that instant a dozen brooms are raised to help the laggard over the *hogg score.* A second, a third, a fourth, succeeds, and so on, till the line stretches a tolerable length; and each man is warned by his respective friends to plant, if possible, an excellent guard—dislodge this stone and cover that—open up one port and close another—play soft or strong, outside or inside, as the occasion may require—and steer as closely by the signal broom as the mariner, when warned by similar devices, threads his watery way through sand-banks and shallows.

"As the animating sport deepens, it is amusing to contrast the bustle that obtains in one little spot with the stillness that broods over the external world; while the hills above are silent and dark, the shining lake below is instinct with life, and resounds with sounds of mirth and glee, which, borne along on the elastic air, invade the solemn loneliness that reigns around, till echo itself takes up the tale, and repeats in broken fragments the curler's vocabulary. At length, as the more veteran players advance to decide by their skill the fate of the *side*, the interest becomes intense, and gives rise to so many calculations of what is to be done and what avoided, such bustling to and fro, as must appear a perfect mystery to the uninitiated. The last wary shot hooms athwart the ice as if impelled by magic, and while every port, to an onlooker, seems closed, finds its way under the guidance of a powerful arm and steady eye, through passages rivalling the intricacy of the walls of Troy. Then fol low the shout of victory and the murmur of defeat, till the contest is renewed under the mingled emotions of hope and fear—the vanquished trusting that the tables will be turned, and the conquerors confident that they will remain the same. Speedily the eager players are marshalled, and the brooms put in requisition as before; again the stones boom away and away, meandering here, meeting there, and whirling from the collision like the urchin's top at school; again shot succeeds shot, and game follows game, until the conclusion of the *bonspiel*, or the approach of evening proclaims that it is time the sport should surcease, and the combatants wend their way to the nearest *clachan*, to enjoy their favourite feast of beef and greens. And now the scene changes entirely, though as the savoury viands load the board, all feel the effects of the keen mountain air, and make so good a use of their time while the opportunity serves, that the business of eating becomes nearly as noisy as the business of play; rounds of corn-beef, flagons of home-brewed, disappear with a rapidity that is truly astonishing, and of which no adequate conception can be formed by persons whose appetites were never whetted by a day on the ice."

Laws and Regulations for Curling.

In the year 1838 was instituted the Grand Caledonian Curling-Club, for the purpose of uniting all curlers into a "brotherhood of the rink," and of regulating the game by general laws, which it was hoped would be adopted by all local curling associations. From the Annual published by the club, we extract the following as the rules of the game:—

"1. The length of the rink shall be forty-two yards: any deviation occasioned by peculiar circumstances to be by mutual agreement of parties. When a game is begun, the rink is not to be lengthened nor shortened, unless by consent of the majority of players.

[It is advisable that rinks have double tees at each end, the one at least two yards behind the other, the whole four to be as nearly as possible in the same line. The stones are to be delivered from the outer tee, and played towards the inner; this saves the ice from being injured around the tee played up to.]

"2. The rink shall be changed in all cases when, from the springing of water, the majority of players cannot make up. Neither the winning nor losing party have right to object, as all contests must be decided on the fair and equitable principle of science, not of strength.

"3. The number of shots in a game, if not otherwise mutually fixed upon, shall be twenty-one.

[A game more frequently consists of thirteen shots, or even of seven, than of any others, when an hour or two's practice only is intended; but this is a matter of private arrangement.

In a bonspiel or match, when a considerable number of players appears on each side, the aggregate number of shots gained in a fixed time is not only as equitable a method, but affords amusement to all the rink to the conclusion, and ought to be universally adopted.]

"4. The hogs' score to be one-sixth part of the length of the rink from the tee. Every stone to be considered a hog which does not clear a square placed upon the score.

"5. Every rink to be composed of four players a side, each with two stones, unless otherwise mutually agreed upon. In no case shall the same individual or party play two stones in succession, and every player shall deliver both his stones alternately with an opponent, before any other of the same side or party play one.

"6. Parties to draw cuts which shall fill the ice at the first end; after which the winning party of the last end or game of that day's play shall do so. No stone to be counted which does not lie within seven feet from the tee, unless it be previously otherwise mutually agreed upon. In cases where each party has a stone equally near the tee, neither to be counted, and the winning party of the previous end is again to fill the ice. Measurements to be taken from the centre of the tee to that part of the stone which is nearest it.

"7. Each player to place his feet in such a manner as that, in delivering his stone, he shall bring it over the tee. A player stepping aside to take a brittle (or wick), or other shot, shall forfeit his stone for that end. A player, after delivering his last stone, shall not remain longer than to see his next opponent fit his tee, but shall take his place at the other end between the score and the previous player of his own party; and shall on no account remain to give directions to the next of his party who plays.

"8. If any player shall improperly speak to or interrupt another while in the act of delivering his stone, one shot shall be added to the score of the party so interrupted.

"9. The rotation of play adopted at the beginning must be observed through the whole game.

"10. All curling stones shall be of a circular shape. No stone must be changed throughout the game, unless it happen to be broken, and then the largest fragment to count, without any necessity of playing with it more. If a stone rolls and stops upon its side or top, it shall not be counted, but put off the ice. Should the handle quit the stone in the delivery, the player must keep hold of it, otherwise he will not be entitled to replay the shot.

"11. If a player plays out of turn, the stone so played may be stopped in its progress, and returned to the player. If the mistake shall not be discovered till the stone is again at rest, the opposite party shall have the option to add one to their score, and the game proceed in its original rotation, or to declare the end null and void.

"12. In double-soled stones, the side commenced with shall not, under forfeit of the match, be changed during the progress of the game.

[Double-soled stones are those in which the handle can be shifted from one side to another; one side being slightly concave for keen ice, and the other convex for dull ice.]

"13. The sweeping department to be under the exclusive control of the skipper. No sweeping to be allowed by any party till the stone has passed the hogs' score, except when snow is falling or drifting, in which case it shall be admissible to sweep from tee to tee. The player's party may sweep when the stone has passed the further hogs' score, his adversaries' when it has passed the tee. Sweeping to be always to one side. Previous to each direction being given, either party are entitled to sweep the rink clean.

"14. Parties, before beginning to play, to take different sides of the rink, which they are to keep throughout the game; and no player, on any pretence, to cross or go upon the middle of the rink. The skippers alone to stand about the tee. Their respective parties, according to their rotation of play, shall take their position down to the hogs' score.

"15. If in sweeping, or otherwise, a running stone be marred by any of the party to which it belongs, it shall be put off the ice. If by the adverse party, it shall be placed where the skipper of the party to whom it belongs shall direct. If marred by any other means, the player shall take his shot again. Should a stone at rest be accidentally displaced at any part of the end before the case provided for in rule 13 comes into operation, it shall be put as nearly as possible in its former position.

"16. Every player to come provided with a besom, to be ready to play when his turn comes, and not to take more than a reasonable time to throw his stones. Should he accidentally play a wrong stone, any of the players may stop it while running; but if not stopped till it is again at rest, it shall be replaced by the one which he ought to have played.

"17. No measuring of shots allowable previous to the termination of the end. Disputed shots to be determined by the skippers; or, if they disagree, by some neutral person mutually chosen by them, whose decision shall be final.

"18. Should any played stone be displaced before the last stone is thrown and at rest, by any of the party who are lying the shot, they shall forfeit the end; if by any of the losing party who have the stone yet to play, they shall be prevented from playing that stone, and have one point deducted from their score. The number of shots to be marked by the winners to be decided by the majority of the players, the offender not having a vote.

"19. The skippers shall have the exclusive regulation and direction of the game, and may play in what part of it they please: but having chosen their place at the beginning, they must retain it till the end of the game. The players may give their advice, but cannot control their director; nor are they upon any pretext to address themselves to the person about to play. Each skipper, when his own play comes, shall name one of his party to take charge for him. Every player to follow implicitly the direction given him.

"20. Should any question arise, the determination of which is not provided for by the words and spirit of the rules now established, it may be referred to the three nearest members of the representative committee, unconnected with the disputing parties, who shall form a district committee of reference, and whose decision shall be binding on all concerned till the annual general meeting of the representative committee, to whom either party may appeal the case."

CRICKET.

This is perhaps the best of all out-of-door sports for youth. It requires quickness of mind and eye, great agility of limb, and, properly conducted, is highly exhilarating and amusing. The game is played on an open well-shaven green, which is level and free from stones or shrubs; it should also be dry, and of sufficient dimensions to allow of a good blow to the ball and run—a square field of three or four acres is a good size. The apparatus required in the game consists of balls, bats, and wickets. The dress of the players should be light and easy—a white woollen jacket, cap, linen trousers, and shoes provided in the soles with points to prevent slipping in running; in London there are shoes made purposely for cricketing.

Cricket is played in two distinct forms; one is called *Single Wicket*, and the other *Double Wicket*. We shall first give an outline of Single Wicket.

Single Wicket.—This game is played by a number of persons, but generally *five* are on each party or side. Three straight rods or *stumps*, twenty-seven inches high, are stuck in a row in the ground; on the top of the stumps are laid two pieces of wood called the *bail*, and so placed that they will readily fall off if the stumps be hit by the ball. This apparatus is called the *wicket*. At the distance of four feet four inches in front of the wicket is a mark on the ground, called the *popping-crease*. In a straight line with the wicket is a mark on the ground called the *bowling-crease*, which is parallel to the popping-crease.

An individual taken from one party is appointed *bowler;* his duty is to bowl his ball towards the opposite wicket, which he does by a short run. An individual from the antagonist party is appointed *batter;* his duty is to stand with his bat placed with its tip on the ground at the popping-crease, and to oppose the progress of the ball, or to prevent it from knocking down his wicket. He must also endeavour to strike the ball smartly, so as to send it to a distance on the field. The field is in charge of the party to which the bowler belongs; these are termed *field-men* or *field-keepers*, and each has an appointed place from which he takes a peculiar designation: one is named the *leg-hit*, or *long stop*, another the *off-hit*, a third the *long field on*, a fourth the *long field off*. Their duties are to catch the ball when either struck or missed by the batter.

If the ball be missed by the batter, he remains at his wicket, and the ball is returned by the long stop to the bowler. If the ball be struck, and to such a distance that the batter thinks he could run to the bowling-crease, touching it with his bat, and return to his popping-crease, touching it also before the ball is returned and strikes the wicket, he does so, and if he perform this feat successfully, it is called *one run*, and counts one towards the game. Sometimes he strikes the ball to such a great distance that he can run to and fro twice, and this counts two; if three times, it counts three; and so on. These are termed *runs* or *notches*.

Should the bowler knock down the wicket, the batter retires, and this finishes his *inning*. His inning is also finished by the wicket being knocked down with a ball by any of the field-keepers, if he be off his ground. The inning may likewise be finished if the batter strikes the ball into the air, and it be caught by any of the batter's antagonists before it reaches the ground, and retained long enough to be thrown up again.

Double Wicket, which is considered the true game of cricket, is like two games of single wicket playing at one time, there being two wickets from which to bowl; also two batters, but only one ball. This game is played as above, with this difference, that the batter runs only to the opposite end, exchanging places with the other batter, who is of the same party. The number of persons engaged is properly eleven on each side. As in single wicket, the game is determined by the number of runs made in two innings by each player; the party gaining the greater number of runs being the victor.

Such is an outline of the two kinds of the game; but there are many minute differences in playing in different parts of England, which it would be tedious to describe. It has been conceded by general consent to follow, in case of dispute, the laws and regulations of the "Mary-le-bone Cricket Club," an association in London which has taken a leading part in this truly English sport. The following are the laws of the club:—

"Laws and Regulations of Single Wicket.

"1. When there shall be fewer than five players on a side, bounds shall be placed, at twenty-two yards each, in a line from the off and leg stump.

"2. The ball must be hit before the bounds to entitle the striker to a run; which run cannot be obtained unless he touch the bowling stump or crease in a line with it with his bat or some part of his person, or go beyond them; returning to the popping-crease, as at double wicket, according to the twenty-second law.

"3. When the striker shall hit the ball, one of his feet must be on the ground, and behind the popping-crease, otherwise the umpire shall call 'no hit.'

"4. When there shall be less than five players on a side, neither byes nor overthrows shall be allowed; nor shall the striker be caught out behind wicket, nor stumped out.

"5. The fieldsmen must return the ball, so that it shall cross the play between the wicket and the bowling stump, or between the bowling stump and the bounds. The striker may run till the ball be so returned.

"6. After the striker has made one run, he must touch the bowling stump and turn, before the ball shall cross the play, to entitle him to another.

"7. The striker shall be entitled to three runs for lost ball, and the same number for ball stopped with hat, with reference to the twenty-ninth and thirty-fourth law of double wicket.

"8. When there shall be more than four players on a side, there shall be no bounds. All hits, byes, and overthrows, will then be allowed.

"9. The bowler is subject to the same laws as at double wicket.

"10. Not more than one minute shall be allowed between each ball.

"Laws and regulations of Double Wicket.

"1. The ball must not weigh less than five ounces and a half, nor more than five ounces and three quarters. It must not measure less than nine inches, nor more than nine inches and one-eighth in circumference. At the beginning of each innings, either party may call for a new ball. (But in matches the same ball must go through the game.)

"2. The bat must not exceed four inches and one quarter in the widest part; it must not be more than thirty-eight inches in length.

"3. The stumps, three to each wicket, must be twenty-seven inches out of the ground, the bails eight in length; the stumps of sufficient thickness to prevent the ball from passing through.

"4. The bowling-crease must be in a line with the stumps, six feet eight inches in length; the stumps in the centre, with a return crease at each end towards the bowler, at right angles.

"5. The popping-crease must be four feet four inches from the wicket, and parallel to it; unlimited in length, but not shorter than the bowling-crease.

"6. The wickets must be pitched opposite to each other by the umpires, at a distance of twenty-two yards.

"7. It shall not be lawful for either party during a match, without the consent of the other, to alter the ground by rolling, watering, covering, mowing, or beating. This rule is not meant to prevent the striker from beating the ground with his bat near to the spot where he stands during the innings, nor to prevent the bowler from filling up holes with saw-dust, &c., when the ground shall be wet.

"8. After rain, the wickets may be changed, with the consent of both parties.

"9. The bowler shall deliver the ball with one foot behind the bowling-crease, and shall bowl four balls before he change wickets, which he shall be permitted to do once only in the same innings.

"10. The ball must be bowled. If it be thrown or jerked, or if the hand be above the shoulder in the delivery, the umpire must call 'no ball.' (This is not reckoned as one of the four balls.)

"11. The bowler may require the striker at the wicket from which he is bowling to stand on that side of it which he may direct.

"12. If the bowler toss the ball over the striker's head, or bowl it so wide that it shall be out of distance to be played at, the umpire (even though he attempt to hit) shall adjudge one run to the parties receiving the innings, either with or without an appeal from them, which shall be put down to the score of wide balls, and such ball shall not be reckoned as any of the four balls. When the umpire shall have called 'Wide ball' one run only shall be reckoned, and the ball shall be considered dead.

"13. If the bowler shall deliver a 'no ball,' the striker may play at it, and be allowed as many runs as he can get; and be shall not be put out except by running out. In the event of no run being obtained by any other means, then one run shall be scored.

"14. In the event of a change of bowling, no more than two balls shall be allowed for the sake of practice.

"15. If the bowler bowl one ball, he shall be obliged to bowl four.

"16. The striker is out if either of the balls be bowled off, or if a stump be bowled out of the ground.

"17. Or if the ball, from a stroke of the bat or hand below the wrist, be held before it touch the ground, although it be hugged to the body of the catcher.

"18. Or if in striking, or at any other time while the ball is in play, both his feet be over the popping-crease, and his wicket put down, except his bat be grounded within it.

"19. Or if in striking at the ball he hit down his wicket.

"20. Or if, under pretence of running or otherwise, either of the strikers prevent a ball from being caught, the striker of the ball is out.

"21. Or if the ball be struck, and he wilfully strike it again.

"22. Or if in running, the wicket be struck down by a throw or by the hand or arm (with ball in hand) before his bat (in hand) or some part of his person be grounded over his popping-crease. But if the bails be off, a stump must be struck out of the ground.

"23. Or if any part of the striker's dress knock down the wicket when striking.

"24. Or if the striker touch or take up the ball while in play unless at the request of the opposite party.

"25. Or if with any part of his person he stop the ball, which in the opinion of the umpire at the bowler's wicket shall have been delivered in a straight line to the striker's wicket, and would have hit it.

"26. If the players have crossed each other, he that runs for the wicket which is put down is out.

"27. A ball being caught, no run shall be reckoned.

"28. If a 'lost ball' be called, the striker shall be allowed six runs; but if more than six shall have been run before 'lost ball' shall have been called, then the striker shall have all which shall have been run.

"29 After the ball shall have been lodged and definitively settled in the wicket-keeper's or bowler's hand, it shall be considered dead. If, when the bowler is about to deliver the ball, the striker at his wicket shall go outside his popping-crease before such actual delivery, the said bowler may put him out.

"30. If the striker be hurt, he may retire from his wicket, and return to it at any time during that innings.

"31. If a striker be hurt, some other person may stand out for him, but not go in.

"32. No substitute in the field shall be allowed to bowl, keep wicket, stand at point, cover the point, or stop behind, in any case.

"33. If any fieldsman stop the ball with his hat, the ball shall be considered dead, and the opposite party shall add five runs to their score. If any be run, they shall have five in all.

"34. The ball having been hit, the striker may guard his wicket with his bat, or with any part of his body, except his hand; but the twenty-fourth law, by which he is forbidden to touch or take up the ball, may not be disobeyed.

"35. The wicket-keeper shall not take the ball for the purpose of stumping, until it has passed the wicket. He shall stand at a reasonable distance behind the wicket, and shall not move till the ball be out of the bowler's hand; he shall not by any noise incommode the striker; and if any part of his person be over or before the wicket, although the ball hit it, the striker shall not be out.

"36. The umpires shall not stand more than six yards from the wicket; they are sole judges of fair and unfair play, and all disputes shall be determined by them, each at his own wicket; but in case of a catch which the umpire at the wicket bowled from cannot see sufficiently to decide upon, he may apply to the other umpire, whose opinion shall be conclusive.

"37. The umpires in all matches shall pitch fair wickets, and the parties shall toss up for the choice of innings.

"38. They shall allow two minutes for the striker to come in, and fifteen minutes between each innings. When the umpire shall call 'play,' the party refusing to play shall lose the match.

"39. They are not to order a striker-out, unless appealed to by the adversaries.

"40. But if one of the bowler's feet be not entirely behind the bowling-crease, within the return-crease, when he shall deliver the ball, the umpire at his wicket, unasked, must call 'no ball.'

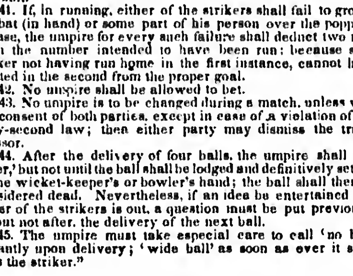
"41. If, in running, either of the strikers shall fail to ground his bat (in hand) or some part of his person over the popping-crease, the umpire for every such failure shall deduct two runs from the number intended to have been run: because such striker not having run home in the first instance, cannot have started in the second from the proper goal.

"42. No umpire shall be allowed to bet.

"43. No umpire is to be changed during a match, unless with the consent of both parties, except in case of a violation of the forty-second law; then either party may dismiss the transgressor.

"44. After the delivery of four balls, the umpire shall call 'over,' but not until the ball shall be lodged and definitively settled in the wicket-keeper's or bowler's hand; the ball shall then be considered dead. Nevertheless, if an idea be entertained that either of the strikers is out, a question must be put previously to, but not after, the delivery of the next ball.

"45. The umpire must take especial care to call 'no ball' instantly upon delivery; 'wide ball' as soon as ever it shall pass the striker."



Names of parties indicated by the figures—*, Strikers; 1 Bowler; 2, Wicket-keeper; 3, Long Stop; 4, Short Slip; 5, Long Slip; 6, Point; 7, Cover; 8, Middle Wicket; 9, Long Field, off side; 10, Long Field, on side; 11, Leg; O, Umpires; †† Scorers. This is the usual placing of the field-men, but Bowlers make such alterations as they deem best to oppose the Strikers.

The preceding diagram represents the field during a cricket match, with the proper position of the parties playing, also the technical names of these parties.

BOWLS.

Games with bowls are of great antiquity, and have existed in many different forms. That which has ultimately become the proper English game of bowling is performed with balls of fine hard wood on a smooth shoven lawn called a *bowling-green*. There are two parties, and each individual possesses a bowl. One of each party plays alternately. The object is to deliver the ball from the hand along the surface of the green, and in such a manner as to place it close by an appointed mark. The party which first gains the specified number of points, by being nearest the goal, is victor. The goal or object played to is a small ball called the *jack*. It is not fixed upon any particular spot, but is bowled by one of the party to a certain distance.

A bowling-green requires to be remarkably level, and kept closely shaved by the scythe. The length of space played in, called sometimes a *rink*, may be about thirty yards. The balls are not altogether spherical; they are spheroids, or flattish on two opposite sides. They are usually made of *lignum vitæ*, and are sometimes handsomely mounted with silver plates on the sides, bearing the names or arms of the owners. The size varies from about four to six inches in diameter.

A knowledge of the value of forces, which can be gained only by experience, is necessary in bowling; but a not less important requisite is a knowledge of the art of giving a bias to the bowl. A person skilled in this art will, by a peculiar pressure of the fingers in delivering his ball, cause it to roll in a kind of semicircle, so as to go with a sweep round the clusters of balls in front of the jack, and come to its place of rest close by the jack or goal.

The game is healthful and exhilarating, and, played in moderation, seems well adapted for the recreation of sedentary persons. In many towns in England and Scotland there are beautiful bowling-greens, the property of the citizens at large, or maintained by private clubs. In Glasgow there are several bowling clubs, and the following are a few of the regulations laid down for the game by a most respectable association in that city, namely, the "Wellcroft Bowling Club:"—

Regulations for Bowls.

"The game to consist of nine points, unless otherwise agreed; and the throwing of the jack and playing first to be decided by lot.

"If the jack is thrown into the ditch on any occasion after the first throw, the opposite party have the privilege of throwing it anew, and not afterwards moved if three feet clear of the ditch in front of the players. This rule not to apply to the side ditch, from which the jack must be sufficiently distant to allow both fore and back hand play.

"All players, when throwing their bowl, to have one foot on the aftermost white ball marked on the cloth; the position of the cloth not to be changed during an end; and if by accident removed from its situation, to be placed as near as possible to the same spot.

"A bowl touching the jack at any time during its course on the green, is what is called a toucher, and counts the same as any other bowl, though in the ditch.

"If the jack, or bowl after touching the jack, is run into the ditch, the place where either rests may be marked, the jack placed at the edge of the ditch, and both replaced when the end is played out.

"If the jack is *burned*, or displaced otherwise than by the effect of the play, the opposite party to have the option of playing out the end, or beginning it anew.

"When a bowl is burned, if belonging to the party guilty, it is to be put off the green; if belonging to the opposite party, to be replaced as near its original position as possible by the party to whom it belongs. If the jack is burned by a non-player, the end to be played over again.

"If a bowl is accidentally marred by an opponent, it shall be in the option of the party playing to let it rest, or play it over again: if it is marred wilfully by an opponent, it may be placed anywhere, at the pleasure of the player. If a bowl is marred in either case by the player's party, the opponents to have the same privilege.

"If a bowl (without touching the jack) rebounds from the ditch, it shall be put off the green; and if it has disturbed either jacs or bowls, they shall be replaced as near as possible by the opponent's party.

"After an end is played, neither jack nor bowls to be touched until the game is counted and all parties satisfied. And no measuring till the end is played.

"No player to change his bowls during the game; the party doing so loses the game."

GOLF.

The game of golf is believed to be peculiar to Scotland, though most likely derived from Germany; the term *golf* being from the German word *kolbe*, or the Dutch *kolf*, a club. The popular pronunciation of the Scotch word is *goff*, or *gowf*. Strutt, in his "Sports and Pastimes of the People of England," observes that "there are many games played with the ball, that require the assistance of a club or bat, and probably the most ancient among them is the pastime now distinguished by the name of goff. In the northern part of the kingdom goff is much practised. It answers to a rustic pastime of the Romans, which they played with a ball of leather stuffed with feathers, and the goff-ball is composed of the same materials to this day. In the reign of Edward III., the Latin name *cambuca* was applied to this pastime, and it derived the denomination, no doubt, from the crooked club or bat with which it was played."

It seems to be quite uncertain at what period the game of golf was introduced into Scotland; but it may be fairly presumed that this amusement, as well as football and archery, were practised to a considerable extent in the reign of our King James the First.

King Charles I. was much attached to the amusement of golfing, and, on his visit to Scotland in 1641, was engaged in it on Leith Links when intimation was given him of the rebellion in Ireland; whereupon he threw down his club, and returned in great agitation to Holyrood House. The Duke of York, afterwards James II., also delighted in the game.

Golf is played upon a large piece of open ground, covered with short herbage, but not necessarily level. It is considered that skill is best shown by playing over a surface on which there are certain irregularities or *hazards*. The grounds on which the game is played are called *links*, a term nearly equivalent to downs in England. The open downs of Blackheath, near Greenwich, seem a fair specimen of the kind of ground suitable for the sport, and there we believe it is now played. Bruntsfield Links, a common near Edinburgh, slope somewhat, and are irregular in form, but they afford a fine opportunity of showing skill in playing "up and down the green," a greater force being required in strokes in impelling the ball in one direction than in another.

Golf is entitled to be called a "respectable" game. It is played almost exclusively by gentlemen, and is conducted leisurely and without any appearance of boisterousness. A stranger would call it a spiritless sport, little better than walking. It possesses, however, the usual fascination of a game of skill and chance, and might appropriately be compared to billiards—the table being a green of a mile in length, the billiard rods clubs, the balls, instead of ivory, hard stuffed leather, and the pursee holes in the ground.

Golfs are formed of wood. The handle, which is straight, is generally about four and a half feet long, and made of ash or hickory. To the lower part of this stalk is united, by compact tying, a flattish curved end, which is the striking part; it is faced with horn, and to give force is loaded with lead. To give a hold to the hands, the upper extremity of the stalk is wrapped with a rind of cloth. In regular practice, players use several golfs. Each has his set of three, four, five, or even as many as ten, which is carried by an attendant boy called a *cadie;* and from this set the golf appropriate for the stroke is selected. Sometimes the ball lies fairly on the grass, at other times it may have got into a hollow, or behind a stone or bush, and an instrument best adapted for sending it forward, or lifting it from its *hazard* or awkward situation, is in requisition. One of the golfs is technically called the *spoon*, from its use in lifting the ball from hollows; another is called the *iron;* and so on.

The ball is small, being not more than an inch and a half in diameter; it is made of leather, stuffed almost as hard as a stone with feathers; the outside is smooth, and painted white. At Edinburgh and St. Andrews, the making of golfs and balls is a regular profession.

There are generally two players, one matched against the other. Each has his own ball. The game consists in driving the ball into certain holes made in the ground, which he who achieves in the fewest strokes obtains the victory. When four persons play, two of them are sometimes partners, and have but one ball, which they strike alternately. The holes are situated at the different ends and sides of the green, at irregular distances, and their number is optional. The usual number is five. A player must never touch his ball, unless in very particular circumstances, or when he takes it out of one of the holes. When commencing from a hole, the ball may be cogged up on the point of a dot of mud or turf, to allow of a commanding stroke; and this is called *teeing* the ball; but on all other occasions the ball must be struck or impelled by the golf from the place in which it happens to lie. Much depends on the first blow, and it should be given with great firmness of person and a good aim. Properly performed, the first stroke will send the ball two hundred yards, while at other times a blow in an awkward situation will advance it only a few feet. When the balls at length get near a hole, great skill is shown in *putting* or giving those delicate strokes which will not make the ball go beyond the hole, but if possible into it. A knowledge of the value of forces, the nature of the green, the influence of wind or weather, &c., is important in this and all other parts of the game, and is only to be gained by long experience.

At Edinburgh, Leith, Musselburgh, St. Andrews, Perth, and perhaps some other towns, there are associations or clubs of golfers, whose proceedings are governed by certain laws and regulations. The oldest in Edinburgh are the "Edinburgh Burgess" and "Bruntsfield Links" Golfing Societies. The Bruntsfield Links Society was instituted in 1761, and is limited to forty members, the uniform of which is declared "to be a red jacket with green velvet collar and badge, bearing the arms of the society; namely, vert two golf clubs in saltier, with heads in chief proper, between four golf-balls argent: motto in an escroll below the shield, *Inde Salus* (Thence Health). The affairs of the Society are managed by a captain, treasurer, secretary, and six councillors, elected annually. A gold medal, played for annually on the last Saturday of March, is retained by the winner for one year. A silver medal, played for annually on the last Saturday of September, is retained by the winner as his property. The following are the regulations prescribed by the society for playing the game:—

"1. No golfer, or cadie, to be allowed to dig tee within ten yards of the hole, and no ball to be teed nearer the hole than two club lengths, nor farther from it than four, unless by consent of parties, and the ball to be teed on the ground.

"2. Two or more parties meeting at the hole, the party who plays first to be allowed to play their second strokes before the succeeding party strikes off. But should the first party's ball be in a hazard, that party shall allow the second party to pass.

"3. Every hole must be played out with the same ball that is struck from the tee.

"4. All loose sticks, stones, filth, nuisance, or other movable impediments, may be removed, if within one club length of the ball; and in putting, all movable obstructions may be removed within four club lengths of the hole—the distance to be measured with the club which the party is to play with. In the event of a ball getting into a hole, or any other hazard, the party shall be allowed to take it out, and standing immediately behind the hazard, drop it over his shoulder, and play it, losing a stroke.

"5. No hole is gained unless the ball be holed (except by consent of parties), and a party losing his ball loses the hole.

"6. In case of doubt as to the ball belonging to either party, neither ball shall be lifted unless by consent of parties, and the ball farthest from the hole must be played first.

"7. If a ball be struck or moved by any one not of the party, it shall be brought back and played from where it was so struck or moved, the party previously dropping it over his shoulder.

"8. In a match of more than two players, if a ball be struck twice or oftener, successively by one player, that side of the match loses the hole.

"9. If a party play the adversary's ball, the adversary gains the hole.

"10. If a party personally, or by his cadie, stop or touch any ball of the match, the adversary gains the hole.

"11. If a ball stick fast into the ground, it may be loosened.

"12. In playing for prizes, no competition to be allowed unless the parties be dressed in the uniform of the society.

"13. In putting, the ball, if practicable, shall be played directly for the hole, but if the adversary's ball oppose the player, it shall be lawful to play upon it."

Enthusiastic and long-experienced cultivators of golf at Edinburgh have been known to perform some remarkable feats in their favourite sport. "Bets of a novel nature, which set the ordinary routine of the game entirely aside, are occasionally undertaken by the more athletic. An amusing and difficult feat, sometimes attempted from Bruntsfield Links, is that of driving the ball to the top of Arthur's Seat [a hill 800 feet high.] In this fatiguing undertaking, being a species of steeple-chase over hedges and ditches, the parties are usually followed by bottle-holders and other attendants, denoting the excessive exertion required. In 1798, bets were taken in the Burgess Golfing Society that no two members could be found capable of driving a ball over the spire of St. Giles's steeple. The late Mr. Sceales of Leith, and the present Mr. Smellie, printer, were selected to perform this formidable undertaking. They were allowed to use six balls each. The balls passed considerably higher than the weathercock, and were found nearly opposite the Advocate's Close. The bet was decided early in the morning, in case of accident, the parties taking their station at the south-east corner of the Parliament Square. The feat is described as one of easy performance. The required elevation was obtained by a barrel-stave suitably fixed; and the height of the steeple, which is one hundred and sixty-one feet, together with the distance from the base of the church, were found to be much less than a good stroke of the club."*

SHINTY—HURLING.

Shinty in Scotland, Hockey in England, and Hurling in Ireland, appear to be very much the same out-of-door sport. We shall describe shinty:—Two parties armed with sticks or clubs crooked at the lower extremity, and generally termed *gouffs* (golfs), throw down a little ball of wood, called a *shinty*, midway between two points, and the struggle is, which party will drive the ball to their "hail," as it is called, or the point allotted as their goal. It may be guessed by those who have never seen it, that there is smart smashing work at this game of shinty—most appropriately named so, seeing that the shins of the players are exposed to ticklish cracks from the clubs of their opponents when a lock takes place, and a dozen boys, perhaps, are struggling to get the ball out from among each other's feet. Hard though the ball be, and smart the strokes given, the activity and quick eyes of the players usually prevent any great injury from being received at shinty. By far the most serious mischief commonly resulting from it consists in the damage which it brings upon the neighbouring hawthorn hedges, which are sadly cut to pieces in order to provide clubs for the sport. The worst of it is that young hawthorn slips, with the root cut for the striking part, make by far the best clubs, and accordingly the evil done is radically ruinous to the unfortunate hedgerows.

Hurling is alluded to as follows by Mr. and Mrs. Hall, in their work on Ireland:—"The great game in Kerry, and indeed throughout the South, is the game of 'Hurley'—a game rather rare, although not unknown, in England. It is a fine manly exercise, with enough of danger to produce excitement, and is, indeed, *par excellence*, the game of the peasantry of Ireland. To be an expert hurler, a man must possess athletic powers of no ordinary character; he must have a quick eye, a ready hand, and a strong arm; he must be a good runner, a skilful wrestler, and withal patient as well as resolute. In some respects, it resembles cricket; but the rules and the form of the bats are altogether different; the bat of the cricketer being straight, and that of the hurler crooked.

"The forms of the game are these:—The players, sometimes to the number of fifty or sixty, being chosen for each side, they are arranged (usually barefoot) in two opposing ranks, with their hurleys crossed, to await the tossing up of the ball, the wickets or goals being previously fixed at the extremities of the hurling-green, which, from the nature of the play, is required to be a level extensive plain. Then there are two picked men chosen to keep the goal on each side, over whom the opposing party places equally tried men as a counterpoise; the duty of these goal-keepers being to arrest the ball in case of its near approach to that station, and return it back towards that of the opposite party, while those placed over them exert all their energies to drive it through the wicket. All preliminaries being adjusted, the leaders take their places in the centre. A person is chosen to throw up the ball, which is done as straight as possible, when the whole party, withdrawing their hurleys, stand with them elevated, to receive and strike it in its descent; now comes the crash of mimic war—hurleys rattle against hurleys—the ball is struck and re-struck, often for several minutes, without advancing much nearer to either goal; and when some one is lucky enough to get a clear 'puck' at it, it is sent flying over the field. It is now followed by the entire party at their utmost speed; the men grapple, wrestle, and toss each other with amazing agility, neither victor nor vanquished waiting to take breath, but following the course of the rolling and flying prize; the best runners watch each other, and keep almost shoulder to shoulder through the play, and the best wrestlers keep as close on them as possible, to arrest or impede their progress. The ball must not be taken from the ground by the hand; and the tact and skill shown in taking it on the point of the hurley, and running with it half the length of the field, and, when too closely pressed, striking it towards the goal, is a matter of astonishment to those who are but slightly acquainted with the play. At the goal is the chief brunt of the battle. The goal-keepers receive the prize, and are opposed by those set over them; the struggle is tremendous—every power of strength and skill is exerted; while the parties from opposite sides of the field run at full speed to support their men engaged in the conflict; then the tossing and straining are at their height, the men often lying in dozens side by side on the grass, while the ball is returned by some strong arm again, flying above their heads, towards the other goal. Thus, for hours, has the contention been carried on, and frequently the darkness of night arrests the game without giving victory to either side. It is often attended with dangerous and sometimes with fatal results.

"Matches are made sometimes between different lands or parishes, sometimes by barony against barony

* Biographical sketches of "Kay's Portraits."

and not unfrequently county against county; when the crack men' from the most distant parts are selected, and the interest excited is proportionably great. About half a century ago, there was a great match played in the Phœnix Park, Dublin, between the Munster men and the men of Leinster. It was got up by the then lord-lieutenant and other sporting noblemen, and was attended by all the nobility and gentry belonging to the vice-regal court, and the beauty and fashion of the Irish capital and its vicinity. The victory was contended for a long time with varied success; and at last it was decided in favour of the Munster men, by one of that party running with the ball on the point of his hurley, and striking it through the open windows of the vice-regal carriage, and by that manœuvre baffling the vigilance of the Leinster goalsmen, and driving it in triumph through the goal. This man is still living; his name is Mat. Healy, and he has been many years a resident in London. Between twenty-five and thirty years ago, there were several good matches played on Kennington Common, between the men of St. Giles's and those of the eastern parts of the metropolis; the affair being got up by the then notorious Lord Barrymore and other noblemen who led the sporting circles of the time."

FIVES—RACKETS—TENNIS.

The sport of striking a soft ball covered with leather against the wall, or throwing it upwards and catching it with the hand, seems to be of great antiquity, and in progress of time was regulated into the character of certain games. One of these, the most simple of the whole, is the striking of a ball against a wall, rebounding from which it falls with force on the ground, and in the rise is again struck in the same manner. The sustaining of this action for a specified number of times constitutes the game. In England it has been customary to call a game of this kind *fives*, from the ball being struck with the five fingers and palm of the hand. In Scotland it has for ages been called *cage* or *caitch* ball. James I., in his quaint production descriptive of what should constitute the education and recreations of a prince, refers to caitch ball. He remarks—"The exercises I would have you to use, although but moderately, not making a craft of them, are running, leaping, wrestling, fencing, dancing, and playing at the *caitch* or tennise, archerie, pallemalle and such like other fair and pleasant field sports."

Rackets is the same game as fives; but instead of striking the ball with the open hand it is struck by a racket, which is an implement held in the hand formed of a frame and catgut. It is played against a high and broad wall, even in surface, with a smooth stone or earthen ground, from which the ball will rise evenly to the hand. Two persons play the match, each striking the ball alternately, and each strikes it in such a way as that his adversary may not be able to return it. But the adversary is supple of limb and quick of eye, and darting to the spot on which the ball is about to fall, endeavours to strike it with his racket, and preserve it from rolling on the ground. He who does not return the ball, either loses a point (or, as it is termed, an *ace*) or has his *hand out*, that is, forfeits the situation in which he would be able to add to his score of the game. Neither fives nor rackets are now played to the extent that they formerly were. There are still, however, several courts laid out for these games in the metropolis; and nowhere are they played so well as in the court-yards of the Queen's Bench and Fleet prisons, where many of the inmates endeavour to kill time by this species of amusement.

Tennis is a game similar with ball; it is played with a racket, but instead of striking the ball against a wall, it is struck over a central net, on each side of which the players stand. The game, which was once fashionable we believe, is now scarcely ever practised.

TRAP-BALL.

This game, which is traceable as far back as the commencement of the fourteenth century, is played chiefly by boys. A wooden object, called a trap, resembling a shoe in shape, with a spring slip or tongue fastened in it by a joint, is laid on the ground. The ball is laid on one end of the spring; the other end is struck with a bat, and the ball rising is to be smartly struck. "It is usual," says Strutt, "in the present game of trap-ball, when properly played, to place two boundaries at a given distance from the trap, between which it is necessary for the ball to pass when it is struck by the batsman, for if it falls withoutside of either, he gives up his bat and is out; he is also out if he strikes the ball into the air and it is caught by one of his adversaries before it grounds; and again, if the ball, when returned by the opposing party, touches the trap, or rests within one bat's length of it; on the contrary, if none of these things happen, every stroke tells for one towards the striker's game." In some country parts of England trap-ball is a favourite sport of the rustic population.

FOOT-BALL.

Foot-ball is an old English sport, now little known in some parts of the country, but keenly played in others. It is played by means of a distended ox-bladder, tightly covered with dressed leather, and sewed up in a strong and secure way, so as to retain its full elasticity. This ball is thrown aloft in the air between two parties of players, equidistant from each other; on one side and the other there is a fixed point or line, called, as in the preceding case, the hail or hailing spot. The object, then, of each party is, by vigorous kicks to propel the ball to the hailing place behind their adversaries, on the attainment of which object the game is won. This game is less hazardous than shinty, and exercises fully both the strength and speed of the players. It is amazing how dexterous even very young boys become by continual practice at foot-ball; and skill in the application of a slight degree of force avails much more at this sport than greater strength unskilfully directed. The young men of the Scottish Border yet practise this game annually in various places; and few sights can be more exhilarating than to behold a strong body of them so employed, when the fleet foot of the shepherd vies for conquest with the vigour of the ploughmen, and health and enjoyment beam unequivocally from every countenance.

QUOITS.

Contests in throwing or pitching heavy pieces of metal were practised by the ancient Greeks at their great periodical assemblages for athletic exercises. The piece of metal thrown was called the *discus*, from its round form. The main object in these contests was the cultivation of strength of arm, and victory was gained more from the ability of throwing heavy weights to a distance than from skill in attaining a particular mark.

From these ancient practices, first pursued by the Greeks and then by the Romans, the game of quoits, or coits, appears to have been derived. The quoit is a circular plate of iron perforated in the middle, or, more properly, a flattish iron ring, concave on one side and convex on the other, the concave or hollow side being undermost in throwing; and a notch being in the edge for the finger to press upon in delivering the throw. Quoits are of different sizes, to suit the different tastes and powers of players. "To play this game," says Strutt, "an iron pin, called a nob, is driven into the ground within a few inches of the top; and at the distance of eighteen, twenty, or more yards (for the distance is optional), a second pin of iron is also made fast in a

similar manner; two or more persons, as four, six, eight, or more, at pleasure—who, divided into two equal parties, are to contend for the victory—stand at one of the iron marks and throw an equal number of quoits at the other [the quoit being delivered from the hand by an upward and forward pitch with a steady aim at the pin, near which it should sink with its sharp edge in the turf]; the nearest of them to the hob are reckoned towards the game. But the determination is discriminately made: for instance, if a quoit belonging to A lies nearest to the hob, and a quoit belonging to B the second, A can claim but one towards the game, though all his other quoits lie nearer to the mark than all the other quoits of B; because one quoit of B being the second nearest to the hob, *cuts out*, as it is called, all behind it; if no such quoit had interfered, then A would have reckoned all his as one each. Having cast all their quoits, the candidates walk to the opposite end and determine the state of the play; then, taking their stand there, throw their quoits back again, and continue to do so alternately as long as the game remains undecided." The dress in quoiting should be loose and easy, with no restraint from braces.

In some of the rural districts of England horseshoes used to be employed as quoits; and in some parts of Scotland the quoits consist of round flat stones, games with which are called the "penny-stanes."

IN-DOOR AMUSEMENTS.

CHESS.

It has been justly observed, that among all the in-door amusements invented by man for the employment of the idle or the relief of the studious, chess stands pre-eminent. It is the most refined and ingenious of all games, and possesses a charm which has rendered it a favourite of the greatest characters, whether kings, warriors, or philosophers. As an amusement, it possesses an advantage as great as it is singular: being highly interesting in itself, and played with leisure, it requires no inducement of gain, and in consequence is rarely played for money. The glory of conquest is allowed to form a sufficient attraction.

Chess is of unknown origin and antiquity. Some writers have ascribed its invention to the Greeks, some to the Hindoos, others to the Chinese, and a fourth class to the Persians. There can be little doubt that it originated in the east, and at a very remote period of history; and it is certain that it has been known in Hindostan and adjacent regions for at least two thousand years. From the Persians it was introduced by the Arabians into Spain; thence it found its way to France; and was made known in England during the reign of William the Conqueror.

The name of the game, and also the names of the pieces with which it is played, have undergone many mutations in travelling from country to country; nevertheless, in the present terms which we employ, the semblance of the original eastern appellations may be seen. In Hindostan it possesses the Sanscrit name of *Chaturanga*, which imports the four members of an army—elephants, horses, chariots, and foot-soldiers; the game being a scene of mimic warfare, in which these elements respectively act a peculiar part. The Persians corrupted the Sanscrit word into *chatrang*, which the Arabians softened into *shatranj*; from that appellation it passed into *scacchi*, *echecs*, and finally chess. By the French it is called *echecs*, and a chess board they term *echiquier*.

According to the modern European arrangement, the idea of elephants, horses, chariots, and foot-soldiers has been abandoned, and there have been substituted a king, queen, bishops, knights, castles or rooks, and pawns, forming six distinct classes of pieces. The term *bishop* is only English, being a substitution for elephant. The knights represent the horse-soldiers. The term *rook* is from the eastern word *rokh*, a hero, and represents an armed chariot or fortification; the English give the piece the form of a castle. The pawns are the foot-soldiers, the name being from *peon*, an attendant.

The chess pieces made in India or China for sale to wealthy Europeans are sometimes made of solid ivory, five or six inches high, and are exceedingly beautiful, no degree of labour being spared in the carving. The king and queen are seated on elephants, under a canopy; the bishops are camels, with archers as their riders; the knights are on horseback; the castles are elephants, with castles on their backs filled with warriors; and the pawns are soldiers, one a sergeant, another a drummer, another a fifer, and the rest ordinary fighting men.

In England the pieces are usually made of bone or boxwood, with more or less taste, and from a low to a high price. The following is a representation of their common form.

Pawn. *Rook.* *Knight.* *Bishop.* *Queen.* *King*

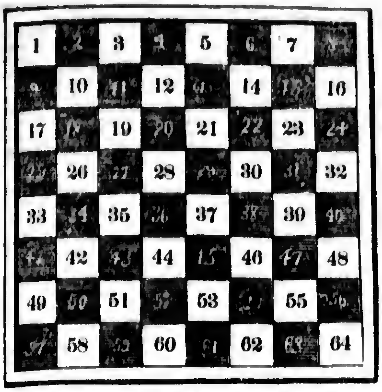
Chess Men and Board.

There are two sets of pieces, of different colours; one is usually white, and another red. A set consists of sixteen pieces, so that the entire number with which the game is played is thirty-two pieces. A set includes one king, one queen, two bishops, two knights, two rooks or castles, and eight pawns. Two parties play, each having a set of a different colour.

The game is played on a square board, divided into sixty-four squares, checkered black and white, as represented in the following figure. The *numbers* which are here shown on the squares do not exist on the chess-board; we have only marked them thus in order to illustrate the subjoined explanations of the method of playing the game.

In beginning to play the game, the first thing is to set the board. This is done by placing it before you, with a white square in the right hand corner. As the players sit opposite each other at a table on which the board is placed, each has a white square on his right.

Next, place the men in their appointed places. Let us suppose it is the white set of men. On the white corner square marked 64 place a rook or castle, and on the black corner, 57, place the other rook; on the black



square, 63, place a knight, and on the white square, 58, place the other knight; on the white square, 62, place a bishop, and on the black square, 59, place the other bishop; on the black square 61, place the king, and on the white square 60, place the queen. This completes the first row, in which the king and queen stand supported on each side by their officers. The second row, marked 49, 50, 51, 52, 53, 54, 55, 56, is filled entirely with the eight pawns, which thus form a front guard to the pieces behind.

The red or dark set of pieces are placed in precisely the same order—a castle on 1 and 8, a knight on 2 and 7, a bishop on 3 and 6, the queen on 4, and the king on 5. It is a rule of the game that the queen must be placed at first on a square of her own colour—the white queen on a white square, and the dark queen on a dark square. The pieces and pawns on the side and front of each king and queen take their names from them; as king's bishop, king's knight; queen's bishop, queen's knight; king's pawn, &c.

When properly placed, four rows of squares are left unoccupied in the middle of the board, and these form a space on which the early evolutions of the men take place.

The Moves.

It is a leading peculiarity of chess that each class of pieces has its own peculiar value and style of moving; some can move one way and some another, a system very different from that of the ordinary movements on a draught board.

A *pawn* moves only one square at a time, in a straight line forward, and takes the enemy diagonally. On being first moved, however, a pawn has the power of advancing either one square or two, as the player thinks fit, unless the square over which he leaps is commanded by a hostile pawn; so that if he were to rest on that square instead of leaping over it, he might be captured. In such a case, the adverse pawn has the option of taking him, and placing himself on the square leaped over. A pawn cannot move backwards; but on getting to the further side of the board, upon the first line of the enemy, which is styled *going to queen*, he may be changed for any one of the pieces lost in the course of the game, and the piece chosen must be placed on the square at which the pawn has arrived. If not exchanged, he remains idle. The power of taking diagonally, possessed by a pawn, differs from that of all other pieces, who take in the direction in which they move: after every capture he continues to go forward as before. The king's bishop's pawn is reckoned the most valuable.

A *knight* moves obliquely, either backward or forward, upon every third square, including the square on which he stood; from black to white, or white to black, over the heads of the men, which no other piece is permitted to do. For example, a knight may leap from 36 to 19, 21, 26, 30, 42, 46, 51, or 53, passing over pieces in the intermediate squares. This property of leaping renders the knight particularly useful at the beginning of a game, as he can be brought into the enemy's ranks, and retire, notwithstanding any blockade; and should he check a king, without being himself liable to be taken, the king must remove, and cannot afterwards castle.

The *bishop* moves only diagonally over any number of squares as far as they are open, forward or backward, but always on the colour he is first placed on. He can take at any distance when the road is open. For example, the bishop may move from 29 to 2, 8, 56, or 57. The king's bishop is usually considered the better one, as he can check the king on his original square, which the queen's bishop cannot.

The *rook* moves backward, forward, or sidewise, and as far as the squares are open. He is viewed as not very useful at the beginning of a game, but is particularly so towards the conclusion, by possessing the power of giving *checkmate* with the king alone, which neither the bishop nor knight can do.

The *queen* is the best piece on the board. She unites the powers of the bishop and rook, and her moves are therefore unlimited, provided the squares are open in her line of motion. As an example, she may be moved from 37 to 1, 5, 16, 23, 40, 58, 61, 64, or any other number in the direction of these, so that the squares are not blocked up. The preservation of the queen is always a matter of great importance in the game.

The *king* moves only one square at a time, but in any direction, either forward or backward, sideways or diagonally. But once in a game, he can move two squares to the right or left, which is termed castling. He can take any of the enemy's men in any square adjoining to him, provided he does not place himself in check. This *check* is a peculiarity in his condition. He has the privilege of never being taken; but this can scarcely be considered a benefit, since it only means that he must not move into or continue in a situation of danger. To be in such a situation, and liable to be captured if he were an ordinary piece, is called being in *check*. On the avoidance of this perilous situation the whole game depends; for the instant the king is checkmated, without the means of moving into a place of safety, the game is at an end. The adversary has the victory.*

To the foregoing account of the moves and powers of the respective pieces, may be added the following explanation of terms:—

Castling.—This, as above hinted at, is allowed once in the course of a game: it consists in moving the king to the second square to the right or left of that where he originally stood, and placing the castle or rook on the square over which he leaped. Castling is a means adopted to secure the king from attack; but it is not allowable—1. When the king or the rook with which you would castle has already been moved; 2. When the king is in check; 3. When the king would require to pass over a square in which he would be checked; and 4. When the king has a piece between himself and the rook.

Check.—When the king is in a situation that, were he an inferior piece, he would be taken, notice is given by the adversary, by saying the word "*check*," and the player

* In a battle between the French and English, in the year 1117, an English knight seizing the bridle of Louis le Gros, and crying to his comrades, "The king is taken!" the prince struck him to the ground with his sword, saying, "Ne sçais tu pas qu' aux echecs on ne prend pas le roi?" (Dost thou not know that at chess the king is never taken?) The meaning of which is, that at the game of chess, when the king is reduced to that pass that there is no way for him to escape, the game ends; because the royal piece is not to be exposed to an imaginary affront.—*Philidor on Chess.*

must adopt some means of removing him from this position.

Double check is when the king is in check by two pieces at once. He may emancipate himself from single or double check—1. By capturing the piece which is attacking him, either by himself or one of his party—and this is only available in double check, if one of the pieces does not guard the other; 2. By interposing a piece between him and the attacking piece; and 3. By removing to another square, of which no hostile piece has the command.

Checkmate is when no means of escape or conquest is available; the king is then said to be checkmated, and the game terminates. One king cannot give check to another, as it would place him in a similar situation. The term checkmate is said to be a corruption of the eastern words *chah-mat* (the king is dead).

Stale-mate (from *stall*, a place of fixture) is applied to the condition of the king when he is compelled to remain in his place, by being surrounded in such a manner by his own or his adversary's pieces that he could not move without going into check, and has at the same time no means of moving other pieces. The game is then considered *drawn*, that is, not won by either party.

Laws of Chess.

The game commences by the two parties determining by lot, or concession, which shall have the first move. After this, the moves are taken alternately, one piece at a time. The principle of advance is to push forward the men gradually against those of the enemy, each party calculating beforehand what will be the effect of any particular move. The following are old established laws in reference to playing:—

1. If you touch your man you must play it, except it would expose your king to check, in which case you can only move the king, if it be practicable.

2. As long as you retain a hold of your man, you are at liberty to place him where you think proper, though you may have him set down on a square.

3. If you have removed your hand from a man, he must remain where he is.

4. If you touch one of your adversary's men, he may insist on your taking it, if you can, and when you cannot, then you must move your king, provided the move do not put him in check.

5. If you make a false move, by accident or otherwise, your adversary can oblige you to move the king; but if he plays without having noticed the false move, it cannot be recalled.

6. If your adversary challenge you with a check, while in reality the king is not in check, and you move your king or any other man in consequence, you may retract it if you discover the error before he has made his next move.

7. You are not to give check to your adversary's king, when, by doing so, you would expose your own king to check.

8. If your adversary give check, but without giving the usual warning of "check," you are not obliged to notice it till he does; but if he discover that he should have done so on his next move, and then warn you, each must retract his move, and the king be removed out of check or protected.

9. After your king or rook has moved, you cannot castle.

10. In each fresh game the players have the first move alternately; but if a player give the advantage of a piece, that is, agrees to start with one piece less than his antagonist, he who gives the advantage has the first move.

Hoyle's Rules for Chess.*

1. Move your pawns before your pieces, and afterwards bring out the pieces to support them: therefore the king's, queen's, and bishop's pawns should be the first played, in order to open the game well.

2. Do not therefore play out any of your pieces early in the game, because you thereby lose moves, in case your adversary can, by playing a pawn, make them retire, and he also opens his game at the same time; especially avoid playing your queen out, till your game is tolerably well opened.

3. Avoid giving useless checks, and never give any unless to gain some advantage, because you may lose the move, if the adversary can either take or drive your piece away.

4. Never crowd your game by having too many pieces together, so as to prevent your men advancing or retreating, as occasion may require.

5. If your game should be crowded, endeavour to free it by exchanges of pieces or pawns, and castle your king as soon as convenient; afterwards bring out your pieces, and attack the adversary where weakest.

6. When the adversary plays out his pieces before his pawns, attack them as soon as you can with your pawns, by which you may crowd his game, and make him lose moves.

7. Never attack the adversary's king without a sufficient force; and if he attack yours, and you cannot retaliate, offer exchanges; and should he retire when you present a piece to exchange, he may lose a move. It may also be sometimes expedient to act in this manner, in case of other attacks.

8. Play your men in guard of one another, so that if any be taken, the enemy may also be captured, by that which guarded yours, and endeavour to have as many guards to your piece as your adversary advances others upon; and, if possible, let them be of less value than those he assails with. When you cannot well support your piece, see if by attacking one of his that is better, or as good, you may not thereby save yours.

9. Never attack but when well prepared, for thereby you open your adversary's game, and prepare him to pour in a strong attack upon you, as soon as your weaker one is over.

10. Never play till you have examined whether you are free from danger by your adversary's last move, nor offer to attack till you have considered what harm he would be able to do you by his next moves, in consequence of yours.

11. When your attack is in a prosperous way, never be diverted from it by taking any piece, or other seeming advantage, your adversary may purposely throw in your way, with the intent that, by your taking the bait, he might gain a move which would make your design miscarry.

12. When, in pursuing a well-laid attack, you find it necessary to force your adversary's defence, with the loss of some pieces, if, upon counting as many moves forward as you can, you find a prospect of success, sacrifice a piece or two to gain your end: these bold attempts make the finest games.

13. Never let your queen stand so before the king as that your adversary, by bringing forward a rook or a bishop, might check your king if she were not there; for you could hardly save her, or perhaps at best must sacrifice her for an inferior piece; as, for example place the white king on 61, the queen on 53, the black king on 4, and the rook on 16; which last, if moved to 13, must be taken by the white queen, who in return would be taken by the black king, because the white queen could not otherwise be moved without putting the king on check to the black rook.

14. Let not your adversary's knight fork your king and queen, or king and rook, or queen and rook, or your two rooks, at the same time; for in the two first cases, the king being forced to go out of check, the queen or the rook must be lost; and in the two last, a rook must be lost, at best, for a worse piece. Place the white queen on 5, the rook on 7, and a black knight on 37. The latter piece, if moved to 22, will fork both the queen and rook, and consequently one of them must be lost for the knight.

15. Take care that no guarded pawn of your adversary's fork two of your pieces; knights and rooks are particularly liable to this mode of attack; also guard against either a check by discovery or a stale-mate.

16. When the kings have castled on different sides of the board, attack with the pawn you have on that side where the adversary has castled, advancing the pieces, especially the queen and rooks, to support them; and if the adversary's king have three pawns on a line in front, he should not stir them till forced to it.

17. Endeavour to have a move in ambuscade; that is, place the queen, bishop, or rook, behind a pawn or a piece in such a manner as that, upon playing that pawn or piece, you discover a check upon your adversary's king, and consequently may often get a piece or some other advantage by it. Suppose the black king on 6, a white bishop on 41, and a pawn on 34, by moving the pawn to 26, a check by the white bishop is discovered upon the black king.

18. Never guard an inferior piece or pawn with a better, if you can do it with a pawn, because that better piece may in such a case be, as it were, out of play.

19. A pawn pushed on and well supported often costs the adversary a piece; but one separate from the others is seldom of any value. And whenever you have gained a pawn or other advantage, and are not in danger of losing the move thereby, make as frequent exchanges as you can.

20. If each player have three pawns upon the board, and no piece, and you have a pawn on one side of the board, and the other two on the other side, and your adversary's three are opposite to your two, march with your king to take his pawns; and if he move to support them, go on to queen with your single pawn; and if he attempt to hinder it, take his pawns, and push yours to queen: that is, to move a pawn into the adversary's back row, in order to make a queen.

21. At the latter end of the game each party having only three or four pawns on different sides of the board, the kings are to endeavour to gain the move, in order to win the game: for example, the white king placed on 54, and the black king on 37, white would gain the move by playing to 53, or black to 38, and in both cases the adverse king would be prevented from advancing.

22. When the adversary has no more than his king and one pawn on the board, and you a king only, you can never lose that game if you bring and keep your king opposite to your adversary's, when he is immediately either before or on one side of his pawn, and only one square between the kings. This must, then, be a stale mate or drawn game.

23. Never cover a check with a piece that a pawn pushed upon it may take, for fear of only getting that pawn for it; put a black rook on 7, and a pawn on 40; the white king on 63, and a knight on 61: the white king being on a check to the rook, if the check be covered by moving the white knight to 56, the black pawn could then be moved to 48, and take the knight.

24. Do not crowd your adversary's king with your pieces, or you inadvertently give a stale-mate, which is a drawn game.

25. Do not be too much afraid of losing a rook for an inferior

* Hoyle is a very old author, and his works on chess and other games are well known: they are now found in all forms, abridged or altered to suit modern players.

piece; though a rook is better than any other except the queen, yet it seldom comes into play, so as to operate, until the end of the game; and it is generally better to have a worse piece in play than a superior out.

26. When you have moved a piece which your adversary drives away with a pawn, that is a bad move, your enemy gaining a double advantage. At this nice game no move can be indifferent. Though the first move may not be much between equally good players, yet the loss of one or two more, after the first, makes the game almost irretrievable; but if you can recover the move or the attack (for they both go together), you are in a fair way of winning.

27. If ever your game be such that you have scarce any thing to play, you have either brought out your piece wrong, or, what is worse, not at all: for if you have brought them out right, you must have variety enough.

28. Do not be much afraid of doubling a pawn: two in a direct line are not disadvantageous when surrounded by three or four others; three together are strong (as three white pawns on 28, 35, and 37); but four (as 44 in addition) that make a square, with the help of other pieces, well managed form an invincible strength, and probably may produce you a queen: on the contrary, two pawns, with an interval between (as on 35 and 37), are no better than one: and if you should have three over each other in a line (as 26, 34, and 42), your game cannot be in a worse situation.

29. When a piece is so attacked that it is difficult to save it, give it up, and endeavour to annoy your enemy in another place; for it often happens, that whilst your adversary is pursuing a piece, you either get a pawn or two, or such a situation as ends in his destruction.

30. Supposing your queen and another piece are attacked at the same time, and by removing your queen you must lose the piece, if you can get two pieces in exchange for her, rather do that than retire, for the difference is more than the worth of a queen; besides, you preserve your situation, which is often better than a piece; when the attack and defence are thoroughly formed, if he who plays first be obliged to retire by the person who defends, that generally ends in the loss of the game on the side of him who attacks.

31. Do not aim at exchanges without reason; a good player will take advantage of it to spoil your situation and mend his own; but when you are strongest, especially by a piece, and have not an immediate check-mate in view, then every time you exchange your advantage increases. Again, when you have played a piece, and your adversary opposes one to you, exchange directly, for he wants to remove you: prevent him, and do not lose the move.

32. Every now and then examine your game, and then take your measures accordingly.

33. At the latter end of the game, especially when both queens are off the board, the kings are capital pieces; do not let your king be idle; it is by his means generally you must get the move and the victory.

34. As the queen, rooks, and bishops, operate at a distance, it is not always necessary in your attack to have them near your adversary's king; they do better at a distance, as they cannot be driven away.

35. When there is a piece you can take, and that cannot escape, do not hurry; see where you can make a good move elsewhere, and take the piece at leisure.

36. It is not always right to take your adversary's pawn with your king, for very often it happens to be a safeguard and protection to him. Place a black rook on 5, with a pawn on 45, and the white king on 53, and he will be sheltered by the black pawn from the attack of the rook.

Recommendations as to some of the foregoing Rules.

1. Whether you play the open or close game, bring out all your pieces into play before you begin the attack; for if you do not, and your adversary should, you will always attack or be attacked at a great disadvantage; this is so essential, that you had better forego an advantage than deviate from it; and no person can ever play well who does not strictly practise this. In order to bring out your pieces properly, push on your pawns first, and support them with your pieces, by which your game will not be crowded, and all your pieces will be at liberty to play and assist each other, and so co-operate towards obtaining your end; and either in your attack or defence, bring them out so as not to be driven back again.

2. When you have brought out all your pieces, which you will have done well if you have your choice on which side to castle, then consider thoroughly your own and adversary's game, and not only resolve where to castle, but likewise to attack where you appear strongest and your enemy weakest. By this it is possible you will be able to break through your adversary's game, in which some pieces must be exchanged. Now, pause again, and survey both games attentively, and do not let your impetuosity hurry you on too far; at this critical juncture (especially if you still find your adversary very strong) rally your men, and put them in good order for a second or third attack, still keeping them close and connected, so as to be of use to each other. For want of this method, and a little coolness, an almost sure victory is often snatched out of a player's hands, and a total overthrow ensues.

3. At the last period of the game, observe where your pawns are strongest, best connected, and nearest to queen: likewise mind how your adversary's pawns are disposed, and compare these things together; and if you can get to queen before him, proceed without hesitation; if not, hurry on with your king to prevent him. I speak now as supposing all the higher pieces are gone; if not, they are to attend your pawns, and likewise to prevent your adversary from going to queen.—*See Hoyle, Jones, &c.*

To these rules and recommendations we add the following advice:—Conduct your game with coolness, take time to consider the chances for and against in moving, and do not give up the contest till all hope is gone of retrieval. An anecdote has been told of two gentlemen playing at chess, one of whom found his game so hopeless that he declared himself beat; when an onlooker of more skill said he would undertake to win the game for him by three moves, without the possibility of being counteracted. The offer was accepted, and the game at once retrieved and won. As this is a particularly instructive incident, we shall state the positions of the pieces on the board in reference to the numbers of the squares on the diagram.

The black rook was at 9, the black knight at 18, the black bishop at 20, the black king at 22, the black rook at 40, black pawns at 25, 26, 30, 35, and 36, and the black queen at 42. The white king was at 7, the white rooks at 61 and 63; the white knight at 47, and a white pawn at 38. The white has the move. The white knight at 47 gives check at 32; the black rook at 40 takes it. The white rook at 63 gives check at 23; the black king takes it. The white rook at 61 gives checkmate at 21. Thus, the white, by a few dexterous moves, completely paralyzes the adversary, and wins the game.

By writing an account of moves, it is possible for adversaries to carry on games at chess though at a great distance from each other. Thus, chess clubs in London are known to carry on matches with clubs in Edinburgh or Paris, or even with a club in India. Games of this kind sometimes last for years

The Morals of Chess, by Dr. Franklin.

The game of chess is not merely an idle amusement; several very valuable qualities of the mind, useful in the course of human life, are to be acquired or strengthened by it, so as to become habits, ready on all occasions; for life is a kind of chess, in which we have often points to gain, and competitors or adversaries to contend with, and in which there is a vast variety of good and ill events that are, in some degree, the effects of prudence or the want of it.

By playing at chess, then, we may learn,

1. *Foresight*, which looks a little into futurity, and considers the consequences that may attend an action; for it is continually occurring to the player, "If I move this piece, what will be the advantage or disadvantage of my new situation, what use can my adversary make of it to annoy me? What other moves can I make to support it, and to defend myself from his attacks?"

2. *Circumspection*, which surveys the whole chess-board, or scene of action; the relation of the several pieces, and their situations; the dangers they are respectively and repeatedly exposed to; the several possibilities of their aiding each other; the probabilities that the adversary may make this or that move, and attack this or the other piece; and what different means can be used to avoid his stroke, or turn its consequences against him.

3. *Caution*, not to make our moves too hastily. This habit is best acquired by observing strictly the laws of the game, such as, "If you touch a piece, you must move it somewhere; if you set it down, you must let it stand." And it is therefore best that these rules should be observed, as the game thereby becomes more the image of human life, and particularly of war; in which, if you have incautiously put yourself into a bad and dangerous position, you cannot obtain your enemy's leave to withdraw your troops and place them more securely, but you must abide all the consequences of your rashness.

And, lastly, we learn by chess the habit of *not being discouraged by present bad appearances in the state of our affairs*, the habit of *hoping for a favourable change*, and that of *persevering in the search of resources.* The game is so full of events, there is such a variety of turns in it, the fortune of it is so liable to sudden vicissitudes, and one so frequently, after long contemplation, discovers the means of extricating one's self from a supposed insurmountable difficulty, that we are encouraged to continue the contest to the last, in hopes of victory from our own skill, or at least of giving a stale-mate, by the negligence of our adversary; and whoever considers, what in chess he often sees instances of, that success is apt to produce presumption and its consequent inattention, by which more is afterwards lost than was gained by the preceding advantage, while misfortunes produce more care and attention, by which the loss may be recovered, will learn not to be too much discouraged by any present success of his adversary, nor to despair of final good fortune upon every little check he receives in the pursuit of it.

That we may, therefore, be induced more frequently to choose this beneficial amusement in preference to others which are not attended with the same advantages, every circumstance which may increase the pleasure of it should be regarded; and every action or word that is unfair, disrespectful, or that in any way may give uneasiness, should be avoided, as contrary to the immediate intention of all parties, which is to pass the time agreeably.

Therefore, 1. If it is agreed to play according to the strict rules, then those rules are to be exactly observed by both parties, and should not be insisted on for one side while deviated from by the other; for this is not equitable.

2. If it is agreed not to observe the rules exactly, but one party demands indulgences, he should then be as willing to allow them to the other.

3. No false move should ever be made to extricate yourself out of a difficulty or to gain an advantage; for there can be no pleasure in playing with a person once detected in such unfair practices.

4. If your adversary is long in playing, you ought not to hurry him, or express any uneasiness at his delay. You should not sing, nor whistle, nor look at your watch, nor take up a book to read, nor make a tapping with your feet on the floor or with your fingers upon the table, nor do any thing that may distract his attention; for all these things displease, and they do not show your skill in playing, but your craftiness or your rudeness.

5. You ought not to endeavour to amuse and deceive your adversary, by pretending to have made bad moves, and saying that you have now lost the game, in order to make him secure and careless, and inattentive to your schemes; for this is fraud and deceit, not skill in the game.

6. You must not, when you have gained a victory, use any triumphing or insulting expression, nor show too much of the pleasure you feel; but endeavour to console your adversary, and make him less dissatisfied with himself, by every kind and civil expression that may be used with truth, such as, "You understand the game better than I, but you were a little inattentive;" or, "You had the best of the game, but something happened to divert your thoughts, and that turned it in my favour."

7. If you are a spectator while others play, observe the most perfect silence; for if you give advice you offend both parties—him against whom you gave it, because it may cause the loss of his game; him in whose favour you gave it, because, though it be good, and he follows it, he loses the pleasure he might have had if you had permitted him to think until that had occurred to himself. Even after a move or moves, you must not, by replacing the pieces, show how they might have been placed better; for that displeases, and may occasion disputes or doubts about their true situation. All talking to the players lessens or diverts their attention, and is therefore unpleasing. Nor should you give the least hint to either party by any kind of noise or motion; if you do, you are unworthy to be a spectator. Should you have a mind to exercise or show your judgment, do it in playing your own game, when you have an opportunity, not in criticising, or meddling with, or counselling the play of others.

Lastly, if the game is not to be played rigorously according to the rules as afore-mentioned, then moderate your desire for victory over your adversary, and be pleased with one over yourself. Snatch not eagerly at every advantage offered by his unskilfulness or inattention; but point out to him kindly, that by such a move he places or leaves a piece exposed and unsupported; that by another he will put his king in a dangerous situation, &c. By this generous civility (so opposite to the unfairness before forbidden) you may, indeed, happen to lose the game to your opponent, but you will win what is better, his esteem, his respect, and his affection, together with the silent approbation and good-will of impartial spectators.

When a vanquished player is guilty of an untruth to cover his disgrace, as "I have not played so long—his method of opening the game confused me—the men were of unusual size," &c., all such apologies (to call them no worse) must lower him in a wise person's eyes, both as a man and as a chess-player; and who will not suspect that he who endeavours to shelter himself under such untruths in trifling matters, is no very sturdy moralist in affairs of greater consequence, where his fame and honour are at stake? A man of proper pride would scorn to account for being beaten by one of these excuses, even were it true; because they all at the moment have the appearance of being untrue.

DRAUGHTS.

Draughts is a game with a checkered board and men, of much less antiquity than chess, and is perhaps to be considered a degenerate descendant of that noble sport. In France it is called *les dames*, from having been a favourite game with the ladies; and in Scotland, this signification is preserved in the term *dam-brod*, the name universally applied by the common people to the draught board.

Draughts is played on a chess-board, or a board checkered precisely in the same manner, with thirty-two white and thirty-two black squares. The board, however, is placed before the players differently; in chess there must be a white square in the right-hand corner, but in draughts the right-hand corner must be black (that is, supposing you to play on the white squares).

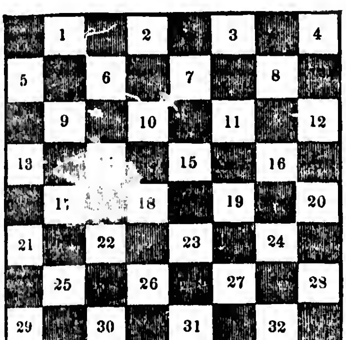
The game is played by two persons, who sit opposite to each other. Each party has a set of twelve men, the colour of the two being different for the sake of distinction. The men are generally round and flat pieces of wood; one set white, and another black: those of the neatest kind are turned out of boxwood and ebony.

The men may be placed either on the white or black squares, but the whole must be put on one colour only. It is customary in England to place all upon the white, and to have, as above, a black square on the right. In Scotland the black are played upon, when there is consequently a white square to the right. We go upon the supposition that the play is upon the white squares, and have numbered them in the annexed figure accordingly.

The movements in draughts are very simple: a man can move only one square at a time, and diagonally, never straight forward or sideways. If an enemy's man stand in the way, no move can take place, unless there be a vacant square beyond, into which the piece can be ated In this case the man leaped over is taken; he is removed from the board.

The grand object of the game, then, is to clear the board of the enemy's men, or to hem them in so that they cannot move; and which ever party does so first gains the victory. As no piece can move more than one step diagonally at a time, there can be no taking till the two antagonists come to close quarters; and the pushing them incautiously into each other's neighbourhood is the principal art of the game.

When the men on either side have cleared their way by taking, or found an open path to the opposite side of the board, they become invested with a new power of movement: by reaching the first row of squares on the opposite side, the piece is entitled to be *crowned*, which is done by placing a man on the top of it. Thus crowned, the man may move backwards, but always diagonally, and one square at a time, as before. This power of moving and taking either forwards or backwards, renders it of consequence to get men crowned; and if two or three on each side gain this honour, the game becomes more interesting, and may speedily be determined. The following is a representation of a draught board, numbered for the sake of illustration, and placed as it should be in playing.



Draught-Board.

Immediately after crowning, great art is shown in blocking up one or more of your adversary's men, by the aid of which to accomplish a series of decisive moves. For instance, supposing you have detained your adversary's piece at 4, while he has others situated on 25 and 26—and supposing you have pieces on 12 and 19, with a crowned man at 14, you may, by giving him your 12 and 19, exchange two pieces for three, which is commonly equivalent to winning the game. Again, supposing you have pieces on 13, 22, 30, and a crowned one on 26, and your adversary a piece on 5, with others scattered in the direction of 16, 8, 7, you may, by successively pushing before him your pieces on 13 and 22, gain a formidable exchange.

In beginning to play, much depends on having the first move; and the rule is, that in playing several games each party takes the first move alternately.

If a player touch one of his men he must play it. If a player omit to take a man when it is in his power to do so, his adversary can *huff*, or *blow*, him; that is, either take the man or insist upon his own man being taken. The practice is at once to lift the man which ought to have taken yours.

We present the following as an example of playing a game in which white loses. The letters N C F, T, at the head of the columns, signify Number, Colour, From, To:—

N	C	F	T	N	C	F	T
1	B	11	15	28	W	30	25
2	W	22	18	29	B	29	22
3	B	15	22	30	W	26	17
4	W	25	18	31	B	11	15
5	B	8	11	32	W	20	10
6	W	29	25	33	B	15	18
7	B	4	8	34	W	24	12
8	W	25	22	35	B	18	27
9	B	12	16	36	W	31	24
10	W	24	20	37	B	14	18
11	B	10	15	38	W	16	11
12	W	27	24	39	B	7	16
13	B	16	19	40	W	20	11
14	W	23	16	41	B	18	23
15	B	15	19	42	W	11	8
16	W	24	15	43	B	23	27
17	B	0	14	44	W	8	4
18	W	18	9	45	B	27	31
10	B	11	25	46	W	4	8
20	W	32	27	47	B	31	27
21	B	5	14	48	W	24	20
22	W	27	23	49	B	27	23
23	B	6	10	50	W	8	11
24	W	16	12	51	B	23	18
25	B	8	11	52	W	11	8
26	W	28	24	53	B	18	15
27	B	25	29	&c.	W	loses.	

It is not considered fair for any bystander to advise what motions should be taken, or for a player to wait longer than five minutes between each move. The draught player, therefore, must on all occasions act with much more promptitude and decision than in the case of chess. In short, draughts is a very ticklish game. A single false step may lead to irretrievable ruin; and it is only after long experience in figuring in the mind what would be the result of particular movements that proficiency is attained.

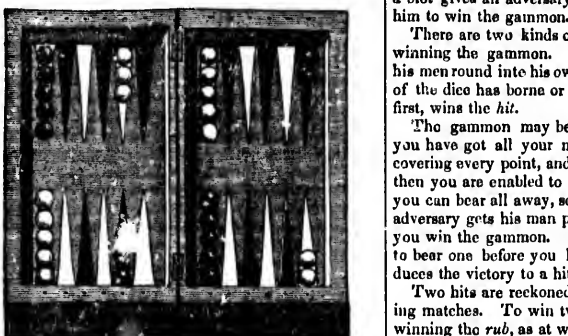
BACKGAMMON.

Backgammon is the modern name of a game of considerable antiquity in England, where it was formerly known by the appellation of "the tables." The words *back-gammon* have been ascribed to the Welsh tongue, in which they are said to signify *little-battle;* but Strutt, with greater plausibility, traces the term to the Saxon "*bac* and *gamen*, that is, back-game; so denominated because the performance consists in the two players bringing their men back from their antagonist's tables into their own; or, because the pieces are sometimes taken up, and obliged to go back; that is, re-enter at the table they came from." Whatever be the etymology of the term, the game has been long established in the country; and, as a fireside amusement of a decorous and exciting nature, is a favourite among clergymen, squires, farmers, and retired professional persons.

Backgammon is played with an apparatus consisting of a board or tables, men or pieces, dice, and dice-boxes. The introduction of dice into the game, and their constant use in determining moves, makes backgammon essentially a game of chance, and therefore brings two players of unequal talents nearer a level than other diversions in which skill is the sole or predominant element.

The backgammon board consists of two parts or tables, generally united by a hinge in the middle, by which they can be shut up as a box. Each table possesses twelve points, six at each end. These points are coloured white and black alternately; but this variation of colour has no reference to the game, and is only done to make the points more easily counted.

The game is played by two parties, and with 30 pieces or men: each party has 15 men, one set of 15 being black and the other white. In beginning the game, the men are placed on certain points on the tables, as shown in the subjoined figure.



B

The Backgammon Table.

The game is played with two dice and two dice-boxes. The dice are common to both; but each party uses his own dice-box, and the throws are alternate.

Each die is a perfect cube, marked on its sides with dots from 1 to 6. The 1 is called *ace*, the two *deuce*, the three *tre* or *trois*, the four *quatre*, the five *cinque*, and the six *size*. At every throw the two dice are employed; consequently a person may throw from two up to twelve; that is, two *aces* up to two *sizes*.

If a player throw *doublets*, or both dice of one number, double the number of dots is reckoned; thus, by a throw of two aces, the player does not count two, but four.

These numbers thrown or accidentally turned up by the dice, bear a reference to the points on the tables. In order to understand this connection between the dice and the men, the learner must observe how the men are placed on the points, and the rules by which their shifting from one to another is governed.

The tables are here spread out as if two partners were seated and about to begin to play. The party owning the white men is seated at W, and the party owning the black men at B. We shall call one party White and another Black. White counts round from the ace point of Black, and Black counts round from the ace point of White. These ace points are respectively seen to have two men upon them in opposite corners of the same table.

The grand object of the game is for each party to get all his men played round into the table containing the aces, removing them from point to point agreeable to the throws of the dice.

In throwing, the number upon each die turned up may be reckoned by itself, or collectively, with the number on the other die. Thus, if quatre be thrown by one die and size by the other, a man can be advanced four points and another six points, or one man can be advanced ten points, always providing that a point is open to suit this movement to it. No point can be moved to, if covered by two men belonging to the adversary. If covered by only one man, which is called a *blot*, then that man can be hit, and be removed from the point, and placed on the bar between the tables, his place being taken by the man who has won it.

The removal of a man to the bars throws a player considerably behind in the game, because the man must remain out of the play till the dice turn up a number corresponding to one open point on the adversary's table. Being fortunate enough to get an open point by this means, the man must be entered and wrought round from thence, as in the case of others in the set to which he belongs. The frequent occurrence of this hitting of a blot gives an adversary a great advantage, and allows him to win the gammon.

There are two kinds of victory, winning the hit and winning the gammon. The party who has played all his men round into his own table, and by fortunate throws of the dice has borne or played the men off the points first, wins the *hit*.

The gammon may be explained as follows:—When you have got all your men round to your own table, covering every point, and your adversary has a man out, then you are enabled to *bear* or lift your men away. If you can bear all away, so as to clear your table before the adversary gets his man placed by a throw on your table, you win the gammon. If the adversary has been able to bear one before you have borne all your men, it reduces the victory to a hit.

Two hits are reckoned equal to one gammon in playing matches. To win two games out of three is called winning the *rub*, as at whist.

Hoyle's Directions for Bearing Men.

If a player has taken up two of the adversary's men, and happens to have two, three, or more points made in his own tables, he should spread his men, that he either may take a new point in his tables, or be ready to hit the man which the adversary may happen to enter. If he finds, upon the adversary's entering, that the game is upon a par, or that the advantage is on his own side, he should take the adversary's man up whenever he can, it being 25 to 11 that he is not hit: except when he is playing for a single hit only; then, if playing the throw otherwise gives him a better chance for it, he ought to do it.

It being 5 to 1 against his being hit with double dice, he should never be deterred from taking up any one man of the adversary's.

If he has taken up one of the adversary's men, and should happen to have five points in his own tables, and forced to leave a blot out of his tables, he should endeavour to leave it upon doublets preferable to any other chance, because in that case the odds are 35 to 1 that he is not hit; whereas it is only 17 to 1 but he is hit upon any other chance.

When the adversary is very forward, a player should never move a man from his own quatre, trios, or deuce points, thinking to bear that man from the point where he put it, as nothing but high doublets can give him any chance for the hit. Instead of playing an ace or a deuce from any of those points, he should play them from his own size or highest points; so that throwing two fives or two fours, his size and cinque points being eased, would be a considerable advantage to him; whereas had they been loaded, he must have been obliged to play otherwise.

It is the interest of the adversary to take up the player as soon as he enters. The blot should be left upon the adversary's lowest point; that is to say, upon his deuce point rather than upon his trois point; or upon his trois point rather than upon his quatre point; or upon his quatre point preferable to his cinque point, for a reason before mentioned; all the men the adversary plays upon his trois or his deuce points are deemed lost, being greatly out of play; so that those men not having it in their power to make his cinque point, and his game being crowded in one place and open in another, the adversary must be greatly annoyed by the player.

If the player has two of the adversary's men in his tables, he has a better chance for a hit than if he had more, provided his game is forwarder than that of his antagonist; for if he had three or more of the adversary's men in his tables, he would stand a worse chance to be hit.

When a player is running to save the gammon, if he should have two men upon his ace point, and several men abroad, although he should lose one point or two in putting his men into his tables, it is his interest to leave a man upon the adversary's ace point, because it will prevent his adversary from bearing his men to the greatest advantage, and at the same time the player will have a chance of the adversary's making a blot, which he may chance to hit. However, if a player finds, upon a throw, that he has a probability of saving his gammon, he should never wait for a blot, as the odds are greatly against his hitting it, but should embrace that opportunity.

BILLIARDS.

This sport may be said to combine the principles of bowls, golf, and some other games in which objects are impelled from the hand. Whether the game was invented in France or England is not clearly ascertained; but as it is mentioned by Shakspeare, it is at least as old in this country as the sixteenth century. In the present day, it is pursued in every civilized country, but principally by the higher or leisurely classes of society. In France, it is much more common than in England, where its character has suffered materially by the game having been made the subject of large gambling speculations. It is unfortunate that such should be the case, for no game is to be considered so purely scientific: it is *dynamics*, or certain laws of motion, put into practical operation; the hits are concussions of the balls exhibiting some of the finest examples of divergent forces.

Billiards is played with a table, certain kinds of rods, and balls. The table varies in size, that in most common use being from eight to twelve feet long, and from four and a half to six feet in width. Whatever be its dimensions, it requires to be perfectly level and smooth. It is ordinarily made of small pieces of wood joined together, so as to avoid warping, and these being brought to a dead level by planing, the surface is covered with fine green cloth. All round is a ledge two to three inches high, and stuffed as a cushion. The table is furnished with six pockets, one at each of the four corners, and one on each side at the middle. The mouths of these pockets or purses are level with the surface, so as to allow the balls to glide easily into them.

The balls are of ivory, about an inch and a half in diameter. Two are white, and one is red. One of the white is distinguished by a spot. There are usually two players; he who owns the plain ball is called *Plain*, and he who owns the spotted ball is termed *Spot*. The red ball belongs to neither, but is aimed at by both.

The rods or bills used by the players are of two kinds, and different lengths to suit different players. The ordinary kind of rod is called a *cue*. It is long and smooth, with one end thick and heavy, and the other more slender. The other kind of rod is termed a *mace*; it has a club-like extremity, and is much less frequently used. Almost all players employ cues of the length which suits them.

In playing, the left hand is rested with the palm undermost on the table. The palm is hollowed, and the thumb close to the forefinger is raised up to form a bridge or rest for the cue. The hand is to be at the distance of about six inches from the ball. The cue is lightly held in the right hand, the thick end uppermost, the blow being struck with the small extremity. Thus held, in a free but firm manner, and resting on the channel between the forefinger and thumb, the cue is given a sharp run forward so as to hit the ball in the required direction, and with that exact degree of force which will make it perform the desired feat. To prevent slipping, the point of the cue is generally chalked.

The table is laid out as follows for play:—At the distance of about a foot from one end, in the centre of the table, is a small dot or mark in the cloth, on which the red ball is placed. At a similar distance from the other, which we shall call the upper end of the table, a line is made across by a chalked string; and in the middle of this line there is a mark on which the white ball of a player is to be struck from.

The leading principle in the sport is for a player to impel his white ball against the red ball, and drive them into a pocket or pockets; or to perform a still greater feat of striking the red ball, the adversary's ball, and his own ball, into pockets. It must be understood that nothing is gained by a player striking his own ball direct into a pocket; anybody could do that, and there would be no science in it. The merit consists in impelling balls against each other, at such an exact angle that one or both may be pocketed; and the skill displayed in this is often very surprising.

In setting out in a game, the first stroke or lead is determined by lot. This is called *stringing* for the lead. Each player hits his ball from the *string* or line, and he who causes it to rebound from the bottom cushion and come back nearest to the upper cushion, has the lead and the choice of the balls.

The first player begins by striking his ball from the string against the red ball, as already mentioned; and if he pockets the balls, he scores a certain number and begins again. So long as he pockets, the adversary does not get a stroke. If the player miss, the adversary takes his turn. Both now play alternately, hitting the balls where they chance to lie; but when one pockets, he starts afresh by striking from the string.

A person in attendance *scores* or keeps reckoning of the play. He does this by means of two indices moving round a figured circle, and when one is gained he turns the index accordingly. Technically, he is told to score one for Plain or one for Spot.

Hitherto we have spoken of billiards as one game, but it is necessary to explain that at least twelve different games may be played. We shall notice the two following as those in common use.

Winning and Losing Game.

This is played by two persons, and twenty-one points are the game. The following are Hoyle's regulations for playing it:—

1. The game commences, as usual, with stringing for the lead, as well as the choice of balls. The ball in stringing to be placed within the circle, and the striker must stand within the corners of the table. The ball which rebounds from the bottom cushion, and comes nearest to the cushion within the baulk, takes the lead, and has the choice of balls.

2. If the adversary to the first person who has strung for the lead should cause his ball to touch the other, he loses the lead thereby.

3. When a player holds the ball in stringing or leading, his lead is forfeited.

4. If a ball is followed by either mace or cue beyond the middle hole, it is no lead; the adversary, of course, may force him to renew his lead.

5. After every losing hazard, the ball is to be replaced within the nails or spots, and within the ring.

6. The place for the red ball is on the lowest of the two spots at the bottom of the table.

7. The red ball being holed or forced over the table, is placed immediately on the lowest of the two spots; the present player is, besides, compelled to see it thus replaced, else he cannot score any points while it is off the spot; the stroke, of course, is foul.

8. When the player misses his adversary's ball, he loses one; but should he at the same time pocket his own ball, he then loses three besides the lead.

9. The adversary's ball, and the red ball also, being struck by a player.

10. When the striker, after making a hazard or carambole, accidentally forces his own or either of the other balls over the table, he loses all the advantages he has gained besides the lead.

11. When a ball is accidentally forced over the table, the striker loses the lead.

12. To strike your adversary's ball and the red one too, you score two; this is called a carom or carambole.

13 To hole the adversary's or the white ball, you score two. To hole the red ball you score three.

14. When the striker holes his own ball off his adversary's

he scores two points; but if he holes his ball off the red, he scores three. But if he holes both the red and his adversary's balls, he scores five. If the player holes the red and his own ball, he scores six.

15. If the striker holes his own and his antagonist's ball, he scores four.

16. When the striker plays at the white ball, and should hole the red after that, and his own ball besides, he scores five—two for holing the white and three for the red.

17. When the striker playing on the red ball first, should pocket his own as well as his adversary's ball, he scores five points; three for holing off the red, and two for holing his own.

18. If the player holes his adversary's ball, his own, and the red, he scores seven points; namely, two for holing off the white, two for the adversary's holing, and three for holing the red ball.

19. Should the striker hole his own ball off the red, and hole the red and his adversary's too at the same stroke, he scores eight points thus: three for holing himself off the red, three for the red itself, and two for holing his adversary.

*** All the above games, commencing with the thirteenth, are scored without the carambolea; the following are those in which the carambolea occur:—

20. When a carambole is made, and the adversary's ball is pocketed, four are scored; namely, two for the carambole, and two for the white.

21. If the striker pockets the red ball after making a carambole, he scores five; two for the carambole, and three for the red.

22. If the striker should hole both his adversary's and the red ball, after having caramboled, he scores seven; two for the carambole, two for the white, and three for the red ball.

23. When a carambole is made by striking the white ball first, and the striker's ball should be holed by the same stroke, four points are gained.

24. When the striker makes a carambole by striking the red ball first, and should hole his own ball at the same time, he gains five points; three for the red losing hazard, and two for the carambole.

25. If in playing at the white ball first you should make a carambole, and hole your own and adversary's ball at the same time, you score six points; namely, two for each white hazard, and two for the carambole.

26. The striker wins seven points when he caramboles off the red ball, and holes his own and his adversary's ball; namely, two for the carom, two for the white, and three for the red hazard.

27. When the player caramboles by playing first at the white, and should also hole his own and the red, he scores seven points: namely, two for the carom, two for the white losing hazard, and three for the red winning hazard.

28. When the player caramboles by hitting the red ball first, and also holes his own and the red, he scores eight; namely, two for the carom, three for the red winning hazard, and three for the red losing hazard.

29. Should a player carambole on the white ball first, and then hole his own ball and his opponent's, and the red ball besides, he then scores nine; thus, two for the carom, two for each white, and three for the red hazard.

30. If a carambole is done by striking the red ball first, and at the same stroke the player holes his own ball, the red ball, and his adversary's too, he gains ten points, upon the principle of the preceding rule.

31. When your adversary's ball is off the table, and the other two balls are upon the line or inside of the stringing nails at the leading end of the table, it is named being within the baulk. The player, therefore, striking from the ring, must make his ball rebound from the opposite cushion, so as to hit one of the balls within the baulk; if he misses, he loses a point.

32. Now and then it occurs that after the red ball has been forced over the table or holed, one of the white balls has so taken up the place of the red ball, that it cannot be replaced in its proper situation without touching it. In such, the marker holds the red ball in his hand, while the player strikes at his opponent's ball.

33. And directly after the stroke, replaces it on the proper spot, in order that it may not prevent a carambole from being made.

34. When the striker plays a wrong ball, it is reckoned a foul stroke.

35. When the player is about to strike at or play with the wrong ball, none in the room can with propriety discover it to him, his partner excepted, if they are playing a double match.

36. When the player, after making a carom or a hazard, should, either with his hand, cue, or mace, move either of the balls remaining on the table, the stroke is foul.

37. If the striker should play with the wrong ball, and this erroneous play should not be discovered by his opponent, the marker is obliged to score, and he is a winner of all the points he has gained by the stroke.

38. None can move or touch a ball without permission of the adversary.

39. Sometimes a ball happens to be changed in the course of the game, and it cannot be ascertained by which player; in that case, the balls must be used as they then are, and the game so played out.

40. It is a foul stroke when the striker, in the act of playing, should happen to touch his ball twice.

41. Sometimes the player accidentally touches or moves his ball, without intending to strike. In that case he loses no point, but his ball may be replaced as it originally stood.

42. When a striker's adversary or spectator impedes the player's stroke by accident or design, he has a right to renew his stroke.

43. Should a player, in the act of striking, hit his ball, and cause his cue or his mace to go over it or past it, he forfeits a point.

44. No striker can play upon a running ball; such stroke is foul.

45. An accidental stroke is to be considered good if attended with the proper effect, though, by missing the cue, &c., it is not intended as such.

46. Should a striker, in attempting to play, not hit his ball at all, it is no stroke, and he is to try again.

47. Should the striker or his adversary, in the act of playing, move by accident or design the opponent's white or red ball from the place it occupied on the table, the stroke is foul.

48. When the striker's ball and either of the other balls are so close as to touch each other, and in striking at the former, either of the latter is moved from its place, the stroke is foul.

49. Whoever stops a running ball in any way loses the lead, if the opponent does not like the situation of the ball he has to play at next time.

50. It may happen that a striker, after having made a carambole or a hazard, interrupts, by accident, the course of his own ball; in this case he scores nothing, as the stroke is foul.

51. Should a player impede the course of his own ball, after having made a miss, and it is running towards the hole, and it is so thought also by the marker, he loses three points.

52. To stop, retain, or impede the adversary in the act of striking, is deemed foul.

53. Should a player in any way interrupt, stop, or drive his adversary's ball out of its course when running towards a pocket, he forfeits three points.

54. Even blowing upon a ball whilst running makes a stroke foul; and should the striker's ball be making its way towards a hole, and he blow upon it, he loses two points by such act.

55. If a mace or cue is thrown upon the table during a stroke, it is baulking the striker, and the stroke is considered foul.

56. No play is deemed correct when both feet are off the ground.

57. If the table is struck when a ball is running, the stroke is deemed foul.

58. A player leaving a game unfinished loses that game.

59. Some tables are so uneven that they give way toward the pockets. In case a ball should go to the brink of a hole, and after there resting for a few seconds, should drop into it, such tells for nothing; and the ball must be again placed on the brink before the adversary strikes again; and should it fall into the hole again the moment the striker has played his ball, so as to frustrate the intended success of his stroke, the striker's and his opponent's balls must be placed as they were originally, and the strokes played over again.

60. When a player's mace or cue should touch both balls in the act of striking, the stroke is foul; and if noticed by his opponent, nothing is gained on the points made by the stroke; and the opponent may, if he pleases, part the balls also.

61. Those who agree to play with the cue must do so during the whole of the match; but if no conditions of this sort have been made, the player may change as he pleases. No player can, without permission of the adversary, break his agreement.

62. If a foul stroke is made, the adversary may either part the balls and play from the ring, or, if the balls should be favourably placed for himself, permit the striker to score the points he had gained, which the marker is bound to do in all cases where the balls are not broken.

63. All agreements are specially binding. For instance, those who agree to play with the cue point and point, cannot use the butt without permission; but they may use the long cue: and the same with those who agree to play with the butt only.

64. A striker wins, and the marker is obliged to score all the points he gains, by unfair strokes, if the adversary neglects to detect them.

65. He who offers to part the balls, and the adversary agreeing to the same, the offerer loses the lead by such proposal.

66. None (unless they belong to a four match) have a right to comment on a stroke, whether fair or foul, until asked; and in the above case, none but the player and his partner can ask it.

67. When disputes arise between the players, the marker alone decides, and there is no appeal from his decision. But, it may occur, he might have been inattentive to the stroke; in that case, he is to collect the sense of the disinterested part of the company; namely, those who have no bets on the stroke; and their decision is to be final.

The White Game.

Two players are engaged as above, and the striking is alternate. The general principle is, that you win if you pocket the red ball or your adversary's ball, but invariably lose if by any means you hole your own ball. The number of points in the game is twelve. The following are Hoyle's regulations:—

1. In beginning, string for the lead, and the choice of balls, if you please.

2. When a person strings for the lead, he must stand within the limits of the corner of the table, and also must not place his ball beyond the stringing nails or spots; and he who brings his ball nearest the cushion wins the lead.

3. If after the first person has strung for the lead, and his adversary who follows him should make his ball touch the other, he loses the lead.

4. Should the player hole his own ball either in stringing or lending, he loses the lead.

5. Should the leader follow his ball with either mace or cue past the middle hole, it is no lead; and if his adversary chooses, he may make him lead again.

6. The striker who plays at the lead must stand with both his feet within the limits of the corner of the table and must not place his ball beyond the stringing nails or spo[illegible] nd his adversary (only) is bound to see that he stands and [illegible] fair, else the striker wins all the points he made by that stroke.

7. When a hazard has been lost in either of the corner holes, the leader is obliged (if his adversary requires it) to lead from the end of the table where the hazard was lost; but if the hazard was lost in either of the middle holes, it is at the leader's option to lead from either end of the table he pleases.

8. If the striker misses his adversary's ball, he loses one point; and if, by the said stroke, his ball should go into a hole, over the table, or on a cushion, he loses three points: namely, one for missing the ball, and two for holing it, &c., and he loses the lead.

9. If the striker holes his adversary's ball, or forces it over the table, or on a cushion, he loses two points.

10. If the striker holes his own ball, or forces it over the table, or on a cushion, he loses two points.

11. If the striker holes both balls, or forces them over the table, or on a cushion, he loses two points.

12. No one has a right to take up his ball without permission from his adversary.

13. If the striker, by accident, should touch or move his own ball, not intending to make a stroke, it is deemed as an accident; and his adversary, if he requires it, may put the ball back in the place where it stood.

14. If the striker forces his adversary's ball over the table, and his adversary should chance to stop it, so as to make it come on the table again, the striker nevertheless wins two points.

15. When the striker forces his own ball over the table, and his adversary should chance to stop it, so as to make it come on the table again, the striker loses nothing by the stroke, and he hath the lead; because his adversary ought not to stand in the way, or near the table.

16. If the striker misses the ball, and forces it over the table, and it should be stopped by his adversary, as before mentioned, he loses one point, and has the lead if he chooses.

17. If the striker, in playing from a cushion or otherwise, by touching the ball, makes his mace or cue go over or past it, he loses one point; and if his adversary requires it, he may put the ball back, and may make him pass the ball.

18. If the striker in attempting to make a stroke, doth not touch his ball, it is no stroke; and he must try again to make a stroke.

19. If, when the balls are near each other, and the striker by accident should make his ball touch the other ball, it is nevertheless a stroke, though not intended as such.

20. If the striker who plays his stroke should make his adversary's ball go so near the brink of a hole as to be judged to stand still, and afterwards should fall into it, the striker wins nothing; and the ball must be put on the same brink where it stood, for his adversary to play from the next stroke.

N. B.—There is no occasion for challenging the ball if it stops, as some imagine.

21. If the striker's ball should stand on the brink or edge of a hole, and if, in playing it off, he should make the ball go in, he loses three points.

22. If a ball should stand on the brink or on the edge of a hole, and it should fall into the hole before or when the striker has delivered his ball from his mace or cue, so as to have no chance for his stroke, in that case the striker and his adversary's balls must be placed in the same position, or as near as possible thereto, and the striker must play again.

23. The striker is obliged to pass his adversary's ball, more especially if he misses the ball on purpose; and his adversary may, if he chooses, oblige him to place the ball where it stood, and play until he has passed.

24. If the striker plays both balls from his mace or cue, so that they touch at the same time, it is deemed a foul stroke; and if it is discovered by his adversary, and a dispute should arise thereon, he has an undoubted right to appeal to the disinterested company then present: and if determined by the majority of the disinterested company, and the marker, if needful, to be a foul stroke, then it is at his adversary's option (if not holed) either to play at the ball or take the lead. But if, by the above-mentioned stroke, his adversary doth not discover it to be a foul stroke, then the striker may reckon all the points he made by the said stroke, and the marker is obliged to mark them.

25. No person has a right to discover to the player whether the stroke is fair or foul, until it is asked.

26. If by a foul stroke the striker should hole his adversary's ball, he [illegible] the lead.

27. I[illegible] foul stroke the striker holes his own or both balls, or forces [illegible] own or both balls over the table, or on a cushion, he loses two points.

28. If the striker plays on a ball when it is running or moving, it is deemed as a foul stroke.

29. If the striker plays with both feet off the ground, without the permission of his adversary, it is deemed a foul stroke.

30. If the striker plays with a wrong ball he loses the lead, if his adversary requires it.

31. If the ball should be changed in a hazard or on a game, and it is not known by which party, the hazard must be played out by each party with their different balls, and then changed.

32. If the striker plays with his adversary's ball, and holes or forces the balls he played at over the table, &c., it is deemed a foul stroke.

33. If the striker plays with his adversary's ball, and holes or forces the ball he played with over the table, &c., he loses two points; and if he missed the ball, three points.

[illegible] If the striker plays with his adversary's ball, and misses it, he loses one point: and if his adversary discovers that he hath played with the wrong ball, he may part the balls, and take the lead if he pleases.

35. In all the before-mentioned cases of the striker's playing with the wrong ball (if discovered), his adversary must play with the ball the striker played at throughout the hazard, or part the balls and take the lead.

36. Whoever stops a ball when running with hand, stick, or otherwise, loses the lead, if his adversary does not like the ball, he has to play at the next stroke.

37. Whoever retains his adversary's stick when playing, it is deemed foul.

38. If the striker stops or puts his own ball out of its course when running towards either of the holes, and if adjudged by the marker and the disinterested company then present to be going into a pocket, if he missed the ball he loses one point, and, if going into a hole by the same stroke, three points.

39. If the striker stops or puts his adversary's ball out of the course when running towards or into a hole, or puts his adversary's ball into a hole, it is deemed a foul stroke.

N. B.—If the adversary doth the same as in the foregoing rules, he is subjected to the same penalties as the striker.

40. He who shakes the table when the ball is running makes it a foul stroke.

41. He who throws his stick upon the table, so as apparently to be of any detriment to his adversary, makes it a foul stroke.

42. He who blows on the ball when running makes it foul. And if his own ball was running towards or near the hole, he loses two points.

43. He who leaves the game before it is finished, and will not play it out, loses the game.

44. Any person may change his mace or cue in playing, unless otherwise previously agreed on.

45. When two persons are at play, and no particular terms of agreement have been made, neither party has a right to object to either mace or cue being played with in the said game.

46. When the parties agree to play mace against cue, the mace player hath no right to use a cue, nor has the cue player any right to use a mace during the game or match, without permission from his adversary.

47. When a person agrees to play with the cue, he must play every ball within his reach with the point thereof; and if he agrees to play with the butt of the cue, he has no right to play with the point thereof, without permission from his adversary.

48. When the parties agree to play point and point of the cue, neither of them has a right to use a butt during the game or match, without permission, &c., but they have a right to play with the point of a long cue over a mace, &c.

49. When the parties agree to play all point with the same cue, they have no right to use any other during the game or match.

50. Whoever proposes to part the balls, and his adversary agrees to it, the proposer thereof loses the lead.

51. Two missings do not make a hazard, unless it is previously agreed on to the contrary.

52. In all cases, the betters are to abide by the players on the determination of the hazard, or on the game; and the betters have a right to demand their money when their game is over, to prevent disputes.

53. Every person ought to be very attentive, and listen for the stroke, before he opens the door of a billiard-room.

54. The striker has a right to command his adversary not to stand facing him, nor near him, so as to annoy or molest him in the stroke.

55. Each party is to attend to his own game, and not to ask if his adversary's ball be close?—if he touches his ball?—if he can go round the ball?—nor any question of the like tendency; nor is any one to be set right, if going to play with the wrong ball.

56. When four persons play, the game is fifteen in number, and each p[illegible] has a right to consult with and direct his partner in any [illegible] respecting the game, &c., and the party who makes two missings before the hazard is made, is out, and it is his partner's turn to play; but if, after the two missings have been made by the party, his adversary should hole a ball, so as to make a hazard, the stroke following the said two missings have been made, yet the party who did not make the two missings is to play, as he cannot be supposed to be out who has not made a stroke.

BAGATELLE.

The large and inconvenient size of billiard-tables has led to the introduction of bagatelle-tables—*bagatelle* being the French word for any thing trifling. A bagatelle-table is usually about five feet long and eighteen inches broad; it is lined with cloth, and a game is performed on it with balls and a cue or mace. The balls are small ivory spheres, and the sport very much consists in striking one or more into holes at one end of the board. To perform this and other feats, some skill and experience are required, and the sport is far from unamusing in a cheerful parlour circle. Of late years, bagatelle-tables have become very common in the houses of the middle classes of society; they possess the recommendation of being purchaseable at a small expense.

GAMES WITH CARDS.

Playing cards are small oblong pieces of pasteboard, on which divers figures are impressed in two principal colours, red and black. Fifty-two cards form a *pack*, or complete set for playing any game. The pack consists of four *suits* or kinds of cards, thirteen in each, distinguishable by their respective marks. The suits are *hearts*, *diamonds*, *clubs*, and *spades*. Hearts and diamonds are red; clubs and spades are black. The thirteen in each suit consist of ten cards, distinguishable by spots, from one to ten; and three cards, ordinarily called *court cards*, from being impressed with certain figures having a semblance of court costume—one of these is the *king*, another the *queen*, and a third the *knave*, or *jack*.

Of the origin of playing-cards, and the signification of their respective markings, there has been no small controversy among antiquaries. The general opinion has been that cards were invented about the year 1392, for the purpose of amusing Charles VI. of France, at the time he was afflicted with a mental depression or derangement. But it has been ascertained that, in 1387, John I., king of Castile, issued an edict forbidding the playing of cards in his dominions; and from this, as well as from some of the names given to the cards, it is extremely probable that playing-cards were known in Europe as early as about the middle of the fourteenth century. At first, the outlines of the figures on the cards were made by stamps, and afterwards filled up by the hand; but soon after the invention of engraving on blocks, the devices were produced by wood, and sufficiently finished, so that the impressions did not require any assistance from the pencil.

The names—hearts, diamonds, spades, and clubs—which the English give to the cards, appear to be in a great measure a corruption of the original Spanish and French appellations, or a misapplication of terms to the original symbols. We find the following account given of the design and names of the cards in the work of an anonymous writer:—

"The inventor proposed, by the figures of the four suits, or colours, as the French call them, to represent the four states or classes of men in the kingdom.

"By the *Cœurs* (hearts) are meant the *gens de chœur*, choir men, or ecclesiastics; and therefore the Spaniards, who certainly received the use of cards from the French, have *copas*, or chalices, instead of hearts.

"The nobility or prime military part of the kingdom are represented by the ends or points of lances or pikes, and our ignorance of the meaning or resemblance of the figure induced us to call them spades. The Spaniards have *espadas* (swords) in lieu of pikes, which is of similar import.

"By diamonds are designed the order of citizens, merchants, and tradesmen, *carreux* (square stone tiles or the like). The Spaniards have a coin, *dineros*, which answers to it; and the Dutch call the French word *carreux*, *stieneen*, stones and diamonds, from the form.

"*Trefle*, the trefoil leaf, or clover grass (corruptly called clubs), alludes to the husbandmen and peasants. How this suit came to be called clubs, is not explained, unless, borrowing the game from the Spaniards, who have *bastos* (staves or clubs) instead of the trefoil, we gave the Spanish signification to the French figure.

"The history of the four kings, which the French in drollery sometimes call the cards, is *David*, *Alexander*, *Cæsar*, and *Charles* (which names were then, and still are on the French cards). These respectable names represent the four celebrated monarchies of the Jews, Greeks, Romans, and Franks, under Charlemagne.

"By the queens are intended *Argine*, *Esther*, *Judith*, and *Pallas* (names retained in the French cards), typical of birth, piety, fortitude, and wisdom, the qualifications residing in each person. Argine is an anagram for *regina* (queen by descent).

"By the knaves were designed the servants to knights (for knave originally meant only servant; and in an old translation of the Bible, St. Paul is called the knave of Christ); but French pages and valets, now indiscriminately used by various orders of persons, were formerly only allowed to persons of quality; esquires (*escuiers*), shield or armour bearers.

"Others fancy that the knights themselves were designed by those cards, because *Hogier* and *Lahire*, two names on the French cards, were famous knights at the time cards were supposed to be invented."

With the entire pack of fifty-two cards, or with only a portion of it, there have been innumerable games, and there are so still; to notice the whole of these, however would occupy too much of our space, and we propose to confine our explanations to what are considered respectable and harmlessly amusing games.

WHIST.

All games at cards, in our opinion, are insignificant in comparison with *whist*, which is believed to take its name from an old exclamation to keep silence; it must, at least, be conducted noiselessly, and with extreme attention. The whole structure of the game is ingenious, and a result of just calculation. Its rules have all been carefully studied, and there seems to be a sufficient reason why each has been instituted. The game is a happy blending of skill and chance; skill being the most important element, and chance only accessary, in order to impart a due relish or piquancy to the sport, and deprive highly-skilled players of being always certain of the victory.

Whist is played by four persons, two forming a party or side. The four sit at a square table, one on each side, partners being opposite to each other. The table should be covered with cloth, to permit an easy lifting of the cards. Before commencing the game, a pack of cards is laid on the table, the faces undermost. The parties then *cut* for partners; that is, they leave it to chance to determine who shall be partners. This is done by each person lifting or *cutting* a portion of the cards from the heap or pack, and the two who have the highest cards play together.

The *value* of the cards is as follows:—As already stated, there are four suits, each suit consisting of thirteen cards, ten being common, and three being court cards. The card in each suit which has but one mark is called the *ace*; and this ace is the highest in value in all cases except in cutting for partners, when it is the lowest. The next highest is the king, the next the queen, the next the knave; then the ten, nine, eight, and so on down to the two, or *deuce*, which is the lowest. In playing whist, one suite is of higher value than any of the other three; but which suit shall possess this temporary distinction depends on chance in dealing out the cards; the last card dealt out is turned up, and the suite to which it belongs is called *trumps*;* trumps, then, is the suite of the highest value. In the course of a game, the trump suit may of course vary at every deal.

The *cutting* of the pack, as above mentioned, determines who are to be partners, and at the same time determines who is to *deal*. The rule is, that he who had the lowest card in cutting is the dealer. This person *shuffles* the cards; that is, mixes them in any way he thinks proper, always keeping the backs towards him. Having done this, his adversary is entitled to shuffle the cards also; indeed, each person has a right to shuffle them, but this is seldom done. Being duly shuffled, the pack is laid on the table (always back uppermost) before the *youngest hand*, or the person sitting to the right hand of the dealer; and he cuts it, by lifting off a portion and laying it down. The dealer now puts the lower portion on the top of the portion laid off, and is prepared for dealing.

* The term *trump* is believed to be a corruption of *triumph* meaning the triumphant card.

Dealing must be neatly performed; the dealer holding the pack in his left hand, lifts off the top cards with the right, and distributes them, one to each, all round. He begins with the person on his left, who is called the *elder hand*, then the person opposite, then the youngest hand, and then himself. He thus goes thirteen rounds, the last card which he holds in his hand falling to his own share. This last card he turns up, and it determines the suit to be trumps. The dealer, therefore, has at least always one trump in his hand, but this advantage is supposed to be neutralized by the adversaries having a knowledge of one of his cards. The trump card lies on the table exposed till the first trick is played. Any exposure of a card in dealing, by real or pretended accident, is strictly provided against. The following are Hoyle's

Rules for dealing.

If a card is turned up in dealing, the adverse party may call a new deal if they think proper; but if either of them has been the cause of turning up such card, then the dealer has the option.

If a card is faced in the deal, there must be a fresh deal, unless it happens to be the last card.

It is the duty of every person who plays to see that he has thirteen cards. If any one happens to have only twelve, and does not find it out till several tricks are played, and that the rest have their right number, the deal stands good, and the person who played with the twelve cards is to be punished for each revoke, provided he has made any. But if any of the rest of the players should happen to have fourteen cards, in that case the deal is lost.

The dealer should leave his trump card upon the table till it is his turn to play; and after he has mixed it with his other cards, no one has a right to demand what card was turned up, but may ask what suit is trumps: in consequence of this law, the dealer cannot name a wrong card, which otherwise he might have done.

None of the players may take up or look at the cards while they are dealing out; when this is the case, the dealer, if he should happen to misdeal, has a right to deal again, unless it arises from his partner's fault: and if a card is turned up in dealing, no new deal can be called, unless the partner was the cause of it.

If any person deals, and, instead of turning up the trump, he puts the trump card upon the rest of his cards, with the face downwards, he loses his deal.

Playing the Game.

The cards being all dealt, each takes up his hand, which he must scrupulously prevent any of his antagonists or his partner from seeing. The cards should be ranged like a fan in the left hand, so that its holder can see all his cards at a glance. It is advisable, for the sake of order and convenience, to arrange the cards in the hand, all of a suite together. Each having his cards sorted, the game commences by the elder hand, or person on the left of the dealer, laying down a card. The person on his left follows, and so on to the dealer, who lays down last.

The principle of playing is as follows:—Whatever suit the first card is of, that suit must, if possible, be followed by each party round; but if one party has not a card of that suit, he can lay down one of any other suit. Should he do so, and afterwards lay down a card of the suit which he appeared to be deficient of, he has committed a *revoke*, and a penalty is exacted in loss of three tricks. It is necessary, for the sake of fair play, to be very rigorous in punishing a revoke.

The four cards laid down in a round is called a *trick*. The trick is won in various ways. The card of the highest value wins. For example, if the first player lays down a deuce of spades, the second a three of spades, the third a four of spades, and the fourth a five of spades, this last person wins; his party gains a trick. But should one of the players not have a spade in his hand, and lays down a deuce of the suit which happens to be trumps, that card wins. No matter how high in value the cards laid down are, the trick is always won by a trump card, though it were only a deuce. If several trump cards be laid down, or all be trumps, then the highest trump card wins. The ace of trumps is the highest card.

When the trick is played, it is lifted by the person who wins, and placed beside him in a heap on the table, back uppermost; and he continues to take up all other tricks his party wins. Thus, one on each side collects and reckons the tricks.

Whoever wins the trick becomes elder hand, and plays first in next round; and so on each winner plays first till all the cards are played out.

A pack produces thirteen tricks, but none is counted till after six. For instance, if one party wins four tricks, they do not count; and the other party which has nine tricks counts three. Should one party gain all the tricks, it counts seven.

The ace, king, queen, and knave of trumps, are called *honours*. These have a peculiar value in reckoning towards the game. Should each person hold one honour, honours do not count: but should two partners hold three honours between them, they score two points; when they hold four, they score four points.

The game consists of ten *points*, and these may be gained by tricks and by honours. Should a party make six tricks and hold four honours, it has won the game at one deal. It will therefore be perceived that honours, the possession of which is a matter of mere chance, exert a powerful influence in gaining the victory over an adversary.

Only at one time in the game do honours not count; this is when the party is at nine; the odd point to make up to ten being only gained by tricks. When a party is at eight, and the first trick has been played, one of that party, who holds two honours, may ask his partner if he has one honour; and if he says he has, the three honours are at once shown, which concludes the game. There are rules for calling honours, which we subjoin.

In the course of playing the game, no one must drop the slightest hint how he wishes his partner to play, or make any other observation calculated to mislead or direct. Neither may any one, before his partner has played, inform him that he has or has not won the trick; even the attempt to take up a trick, though won, before the last partner has played, is deemed very improper.

All parties must play by their own perceptions of what would be most judicious. There is only one exception to the rule of keeping silence, which is in the case of a revoke. If a person happens not to follow suit, or trump a suit, the partner is at liberty to inquire of him whether he is sure he has none of that suit in his hand. This indulgence must have arisen from the severe penalties annexed to revoking, which affects the partners equally, and is now universally admitted.

The great knack in playing whist is to *remember what is out*, and hence, by the play of both partner and adversaries, to have a shrewd guess of what each holds in his hand. A primary rule is to follow a partner's lead, as it is presumed that no one, in playing first, is without a good reason for tabling a particular suit.

The term *finessing* signifies the attempt to gain advantage; thus, if you have the best and third best card of the suit led, you put on the third best, and run the risk of your adversary's having the second best; if he has not, which is two to one against him, you are then certain of gaining a trick.

A *loose card* is a card of no value, and consequently the most proper to throw away; it would be folly to lay a good card down, when it must clearly be taken by a better card already tabled.

A *sequence* is a succession of cards in the same suit as ace, king, queen, knave.

Tenace is possessing the first and third best cards, and being last player; you consequently conquer the adversary when that suit is played.

Scoring is the method of reckoning the points in a game. The reckoning is made by four counters or pieces of money; and the way in which these pieces are dis posed, shows the score. The following is the ordinary method of scoring:—

1	2	3	4	5	6	7	8	9
				0	0	00	000	0
0	00	000	0000	00	000	0	0	0
								0

Rules for Playing.

If a person plays out of his proper turn, or shows a card, it is in the option of either of his adversaries to call that card; that is, cause him to lay it down at any time in that deal, provided it does not make him revoke; or either of the adversaries may require of the person who ought to have led, the suit the said adversary may choose.

If a person supposes he has won the trick, and leads again before his partner has played, the adversary may oblige his partner to win it if he can.

If a person leads, and his partner plays before his turn, the adversary's partner may do the same.

If the ace or any other card of a suit is led, and the last player should happen to play out of his turn, whether his partner has any of the suit led or not, he is neither entitled to trump it nor to win the trick, provided you do not make him revoke.

If a revoke happens to be made, the adversaries may add three to their score, or take three tricks from the revoking party, or take down three from their score; and if up, notwithstanding the penalty, they must remain at nine: the revoke takes place of any other score of the game.

If any person revokes, and discovers it before the cards are turned, the adversary may call the highest or lowest of the suit led, or call the card then played, at any time when it does not cause a revoke.

No revoke can be claimed till the trick is turned and quitted, or the party who revoked, or his partner, has played again

If a revoke is claimed by any person, the adverse party are not to mix their cards, upon forfeiture of the revoke.

No person can claim a revoke after the cards are cut for a new deal.

If any person calls except at the point of eight, the adversaries may call a new deal, if they think proper.

After the trump card is turned up, no person must remind his partner to call, on penalty of losing one point.

No honours in the preceding deal can be set up after the trump card is turned up, unless they were before claimed.

If any person calls at eight, and his partner answers, and the adverse party have both thrown down their cards, and it appears that the parties calling have not the honours, the adversaries are entitled, if they please, to compel the play to go on, or to have a new deal.

If any person answers without having an honour, the adversary may consult and stand the deal or not.

If any person calls at eight, after he has played, it is in the option of the adverse party to call a new deal.

If any person separates a card from the rest, the adverse party may call it, provided he names it, and proves the separation; but if he calls a wrong card, he or his partner are liable for once to have the highest or lowest card called in any suit led during that deal.

If any person, supposing the game lost, throws his cards upon the table with their faces upwards, he may not take them up again, and the adverse party may call any of the cards when they think proper, provided they do not make the party revoke.

If any person is sure of winning every trick in his hand, he may show his cards, but he is then liable to have them called.

If any person omits playing to a trick, and it appears that he has one card more than the rest, it is in the option of the adversary to have a new deal.

Each person, in playing, ought to lay his card before him; and if any of the adversaries mix their cards with his, his partner may demand each person to lay his card before him, but not to inquire who played any particular card.

Hints to Learners.

1. Lead from your strong suit (or that with which you could make the most tricks), and be cautious how you change suits.
2. Lead through an honour when you have a good hand—that is, cause your adversary on the left to lay down a good honour, in order that it may be taken up if possible by your partner.
3. Lead through the strong suit of the left-hand adversary, unto the weak of him who is on the right; but not in trumps, unless you are strong in them.
4. Lead a trump, if you have four or five, or a strong hand; but not if weak.
5. Sequences are eligible leads, and begin with the highest.
6. Follow your partner's lead, but not your adversary's.
7. Do not lead from ace queen or ace knave.
8. Do not lead an ace unless you have the king.
9. Do not lead a thirteenth card unless trumps are out.
10. Do not trump a thirteenth card unless you are last player, or want the lead.
11. The third to play always to put on his best card.
12. When you are in doubt, win the trick.
13. When you lead small trumps, begin with the highest.
14. Do not trump out when your partner is likely to trump a suit.
15. Having only a few small trumps make them when you can.
16. Make your tricks early, and be cautious how you finesse.
17. Never neglect to make the odd trick when in your power.
18. Never force your adversary with your best card, unless you have the next best.
19. If you have only one card of any suit, and but two or three small trumps, lead the single card.
20. Always endeavour to keep a commanding card to bring in your strong suit.
21. When your partner leads, endeavour to keep the command in his hand.
22. Always keep the card you turned up as long as you conveniently can.
23. If your antagonists are eight, and you have no honour, play your best trump.
24. Always take care to reckon and amend the score at conclusion of each deal; and do not speak or attempt to converse unless between the deals.

A *rubber*, or rub, generally consists of three games. The parties who have two out of the three win the rub. If the same party gain the first and the second game, that concludes the rub, without playing the third.

A rubber also consists of five *points*. If a party wins the game before the adversary has scored five, he is said to have won a *double*, or two points. Two games won in this manner count four points, and consequently concludes the rubber, for which one point is also reckoned. When an adversary has scored five or more at the termination of a game, you have won only a *single*, which counts but as one point.

Whist is sometimes played by three persons, the fourth place being termed *dumby*. The cards for dumby are exposed on the table and played by one who undertakes to act as dumby's partner throughout. This method of playing very much destroys the interest of the game, and is never resorted to but in cases of necessity, when four persons cannot be had.

CRIBBAGE.

This game is played with the whole pack of cards, and by two, three, or four persons, as the case may be. When there are three, they play as individuals; when four, we play as partners, as in the case of whist. The value of the cards in cribbage is the same as in whist, but there are no trumps, excepting the knave of the suit turned up. There are different modes of playing according to the number of cards dealt; the number is generally five or six. The game consists of sixty-one points, and to keep score or reckoning, an apparatus called a cribbage-board is employed. This board possesses holes for the scoring of each party, and the scoring is effected by means of pegs. The party who is able to bring his peg into the last hole first wins the game.

The following is an explanation of terms generally used in the game:—

Crib, the cards laid out by each party; and whatever points are made by them, the dealer scores.

Pairs are two similar cards, as two aces or two kings. They reckon for two points, whether in hand or playing.

Pairs royal are three similar cards, and reckon for six points, whether in hand or playing.

Double pairs royal are four similar cards, and reckon for twelve points, whether in hand or playing. The points gained by pairs, pairs royal, and double pairs royal, in playing, are thus effected: your adversary having played a seven, and you another, constitutes a pair, and entitles you to score two points; your antagonist then playing a third seven, makes a pair royal, and he marks six; and your playing a fourth is a double pair royal, and entitles you to twelve points.

Fifteens.—Every fifteen reckons for two points, whether in hand or playing. In hand, they are formed either by two cards, such as a five and any tenth card, a six and a nine, a seven and an eight; or by three cards, as a two, a five, and an eight, &c. And in playing thus, if such cards are played as make together fifteen, the two points are to be scored towards the game.

Sequences are three or four, or more successive cards, and reckon for an equal number of points, either in hand or playing. In playing a sequence, it is of no consequence which card is thrown down first, as thus: your adversary playing an ace, you a five, he a three, you a two, then he a four, he counts five for the sequence.

Flush is when the cards are all of one suit, and reckons for as many points as cards, for a flush in the crib, the card turned up must be of the same suit as those in hand.

The go is gained by the player when no other number can be played under thirty-one, in which case he takes one; but if the number makes thirty-one, he takes two. The turn-up card accounts in with both hand and crib.

Regulations for Playing.

1. In dealing, the dealer may discover his own cards, if he pleases, but not those of his adversary. If he does, that adversary is entitled to mark two points, and call a fresh deal, if he pleases.

2. If the dealer gives his adversary too many cards, the adversary may score two points, and also demand another deal, provided he detects the error previous to his taking up his cards.

3. When any player is observed to have in his hand more than the proper number of cards, in that case the person who discovers it may mark four points to his game, and call a new deal, if he thinks proper.

4. If the dealer gives himself more cards than he is entitled to, the adversary may score two points to his game, and call a fresh deal, if he thinks proper: if he does not, he is entitled to draw the extra cards from the dealer's hands. If the non-dealer observes his adversary has more cards than are his due, after they are taken off the table, he may score four points to his game, and call a new deal.

5. If either party meddle with the cards from the time they are dealt until they are cut for the turn-up card, his adversary is entitled to score two points.

6. If any player scores more than he is entitled to, the other party has a right not only to put him back as many points as were so scored, but also to score the same number to his own game.

7. If either party touches even his own pegs unnecessarily, the adversary may score two points to his game.

8. If either party take out his front peg, he must place the same behind the other.

9. Either party scoring a less number of points than are his due, incurs no penalty.

10. Each player has a right to pack his own cards; and should he place them on the pack and omit scoring for them, whether hand or crib, he must not mark for them afterwards.

FIVE CARD CRIBBAGE.

Proper cribbage is played with five cards, and we shall give a description of it in reference to two persons.

After the dealer has been determined by cutting, as in whist, they are dealt one alternately, to the extent of five for each individual. The elder hand takes three points on the board. Each player then proceeds to lay out two of the five cards for the crib, which always belong to the dealer. In doing this, always recollect whose crib it is, as the cards which may advantage your own are almost invariably prejudicial to your game when given to your adversary. This done, the non-dealer cuts the remainder of the pack, and the dealer turns up the uppermost. This card, whatever it may be, is reckoned by each party in hand or crib. When it happens to be a knave, the dealer scores two points to his game.

After laying out and cutting as above mentioned, the eldest hand plays any card, which the other endeavours to pair, or to find one, the points of which, reckoned with the first, will make fifteen; then the non-dealer plays another card, trying to make a pair, or pair royal, and so on alternately till the points of the cards played make thirty-one, or the nearest possible number under that.

When the party whose turn it may be to play cannot produce a card that will make thirty-one, or come in under that number, he then says, "go," to his antagonist, who thereupon is to play any card he has that will come in to make thirty-one, if he can, and take two points, or to score one for the end hole; and besides, the last player has often opportunities to take pairs or sequences. Such cards as remain after this are not to be played; but each party having, during the play, scored his points gained, in the manner as hereafter directed, proceeds, the non-dealer first, then the dealer, to count and take for his hand and crib as follows, reckoning the cards every way they possibly can be varied, and always including the turned-up card:—

For every fifteen, two points; for every pair, or two of a sort, two points; for every pair royal, or three of a sort, six points; for every double pair royal, or four of a sort, twelve points; for every sequence of any sort, according to the number; for every flush, according to the number; for every knave or noddy of the same suit as was turned up, one point; but when turned up it is not to be reckoned again, nor is any thing to be taken for it when played.

Three cards of the same suit in hand entitle the holder to reckon that number, and five for the crib when the turned-up card happens to be of the same suit.

It is always highly necessary, in laying out cards for the crib, that every player should consider not only his own hand, but also whom the crib belongs to, and what is the state of the game; because what might be proper in one situation would be extremely imprudent in another.

If you should happen to possess a pair royal, be sure to lay out the other two cards for either your own or your adversary's crib, except you hold two fives with the pair royal; in that case, it would be extremely injudicious to lay them out for your adversary's crib, unless the cards you retain insure your game, or your adversary being so near home that the crib becomes of no importance.

It is generally right to flush your cards in hand whenever you can, as it may assist your own crib or baulk your opponent's.

Endeavour always to retain a sequence in your hand, and particularly if it is a flush.

Always lay out close cards, such as a three and four, a five and six, for your own crib, unless it breaks your hand.

As there is one card more to count in the crib at five card cribbage than there is in hand, be sure to pay great attention to the crib, as the probability of reckoning more points for the crib than hand is five to four.

For your own crib, always lay out two cards of the same suit, in preference to two of different suits, as this will give you the chance of a flush in the crib.

Never lay out cards of the same suit for your adversary's crib.

Endeavour always to baulk your opponent's crib. The best cards for this purpose are a king and an ace, a six, a seven, an eight, a nine, or a ten; or a queen with an ace, a six, a seven, an eight, or a nine; or any cards not likely to form a sequence.

A king is generally esteemed the greater baulk; as, from its being the highest card in the pack, no higher one can come in to form a sequence.

Never lay out a knave for your adversary's crib, when you can possibly avoid it, as it is only three to one but the card turned up is of the same suit, by which he will obtain a point.

Even though you should hold a pair royal, never lay out for your adversary's crib a two and three, a five and six, a seven and eight, or a five and any tenth card. Whenever you hold such cards observe the state of your game, and particularly if it is nearly ended, whether your adversary is nearly out, or within a moderate show, and it is your deal. When this is the case you must retain such cards as will, in playing, prevent your adversary from making pairs or sequences, &c., and enable you to win the end-hole, which will often prevent your opponent from winning the game.

THREE AND FOUR HAND CRIBBAGE

Three and *four* hand cribbage differs only from two hand in as far as the parties only put out one card each to the crib; and when thirty-one, or as nearly as can be, have been made, then the next eldest hand leads, and the players go on again, in rotation, with any remaining cards, till all are played out, before they proceed to show their hands and crib.

In three-hand cribbage, a triangular board is used, with three lines of holes to allow of each scoring his own game.

SIX CARD CRIBBAGE.

Six card cribbage bears so great a resemblance to five card, that any one playing the one well must play the other equally so. It consists of pairs, fifteens, sequences, flushes, &c., and the points are reckoned and marked precisely in the same manner; all the cards must be played out; that is, when either party has made the end hole, the remaining cards in hand must be played, scoring for the pairs or fifteens they may form. When last player, you should endeavour to retain close cards in hand, as they may enable you to acquire four points in playing.

The dealer is supposed to have some trifling advantage.

The dealer is entitled to expect twenty-five points by his hand, crib, and next hand. Thus, at his second deal, if his peg is in the twenty-fifth hole of the board, he has his complement of points; the same at his third deal, if he is within eleven points of the game.

If the non-dealer by his first hand attain the eleventh hole in the board, he will have the best of the game; for he is entitled to expect that he shall make his second deal with his front peg in the thirty-sixth hole, and by which he will probably win the game by his hand, crib, and next hand.

If you are dealer, and your adversary has above his complement of points, you must play your game accordingly. Thus, if you have good cards, try to make as many points as possible by pairing, fifteens, &c. On the contrary, if your cards are indifferent, you must play off, to prevent your adversary from obtaining points.

ALL-FOURS.

This is a game at cards played by two, three, or four persons, with a complete pack of cards. If four, there are two parties, two in each. We shall suppose only two individuals are playing:—

After the cards have been dealt by three at a time, six to each, the dealer turns up the next card as the trump. If your adversary be not satisfied with his hand, he says, "I beg." In this case, if you do not wish to run the risk of changing the trump, you say, "I give you one," and you allow him to score one towards his game. If your own hand be bad, you then deal out three more cards to each, and turn up anothe trump, which supersedes the former. The adversary may propose to take the chance of dealing three more cards to each, but this can be refused by the dealer, without any forfeiture.

The cards are then played, the elder hand leading, and the party taking up the tricks which he wins. You must either follow suit or trump, if you can.

Ten points make the game, and they are produced by *high*, which is the highest trump dealt; *low*, or the lowest trump dealt; *jack*, or knave of trumps; and *game*, the number of pips on the counting cards. The counting cards are as follows:—ace, four; king, three; queen, two, knave, one; and the ten, which reckons ten. This counting applies to all suits. If the jack be in your hand, secure it as quickly as possible; as, for instance, do not lose an opportunity of trumping with it; for if it fall into the adversary's hand, he reckons it to his game.

Should the card turned up be a knave, the dealer scores one point to his game. Knave of trumps in hand does not reckon, unless you make a trick with it; for if your adversary takes it with the ace, king, or queen, he scores it.

SPECULATION.

This is a round game at cards, the term *round* meaning that it can be played by a large party round a table. The number most suitable is from seven to thirteen.

The principle of the game is this: A *pool* is formed by the dealer putting two counters, and every other player putting one counter, into a dish or treasury in the middle of the table; and this store is paid to the person who holds the highest trump. Thus it is the object of every person to get the highest trump, and the effort to do so is the *speculation*, from which the game derives its name.

After being duly shuffled and cut, and the dealer determined, he deals three cards to each person, one at a time. These cards must be placed before each person, and no one is allowed to look at them until after the trump is turned. Having finished the deal, the next card determines the trump; this card may be *sold* either before or after being seen. When this speculation is concluded, by some person *purchasing* it with counters, or the dealer retaining it, if he thinks proper, the eldest hand turns his uppermost card, and if this be a superior trump to the one turned, he may also speculate. Each player does the same, till all the cards have been exposed, when the pool is given to the possessor of the highest trump.

LOO.

Loo is a game played by five or six people; and a pool is made by the dealer putting in five counters. He then deals five cards to each person, and turns up a trump. Whatever suit the trump may be, the knave of clubs, called *pam*, forms the chief. Those who are dissatisfied with their hands can throw up their cards, and demand fresh ones from the pack.

When the ace of trumps is played, it is usual to say, "Pam, be civil;" the holder of pam is then expected to let the ace pass.

When any person holds a flush of trumps with pam, this individual can sweep the pool before playing. Then there is a new deal.

The next best hand to the above is trumps only, and this sweeps the pool, if there be not a pam flush; and there is also a new deal.

The next best hand is that of a flush of other suits, which sweeps the pool; and there is also a new deal.

When any of these flushes occur, each person, excepting those who hold inferior flushes or pam, is *looed*, and has to pay five counters into the pool.

When none of these flushes occur, and those who wish have changed their cards, the game goes on as at whist, the highest card taking the trick.

When all the cards are played out, they will make but five tricks; and all the counters in the pool are divided between the holders of these tricks, every other person being looed, and obliged to pay five counters to the pool for next deal.

DANCING.

Dancing, as one of the most healthful and elegant in-door amusements, cannot be too highly recommended. Among a rude or dissolute people it may degenerate into something worthy of condemnation; but all the blessings of Providence are similarly liable to abuse, and it would be most unjust to condemn a cheerful domestic amusement, merely because it has at times been degraded into immoral purposes. By all physicians, dancing, when pursued in moderation, is recommended as highly conducive to health; and it may be truly said, that, allied with music, nothing is more calculated to purge the mind of melancholy, and put the whole temper into good humour.

Dancing is the poetry of motion. It must be performed with ease and grace, and always with a perfect regard for propriety of movement. As an art, it is taught by professed masters; and one of the leading rules given to the learner is to raise and lower himself gracefully on the elastic part of his feet, that is, the toes never to leap or come down on the whole sole or heels also to keep exact time to the music. Dancing is therefore a simple and elegant gliding on the toes, these bending more or less to accommodate the steps, and to prevent every thing like harshness of motion. The body should not be held stiffly, and the hands ought to hang down easily by the sides.

Dancing takes the form of several distinct kinds or series of movements, some quick and some slow, and some more complex than others. The most popular of the old-established dances are termed

Country Dances.

This class of dances takes its name from the French word *contre* (against), from being danced by two parties standing in a row opposite or against each other. The general principle is for each couple in succession to go down the middle of the rows and up again, with some other movements, till all have danced down and into their original places. It is a rule for the top couple to dance down twice, thus leaving the couple that was the second to be at the top. This finishes the dance. If the party wish to dance another dance, the second couple, now at the top, begins, and so on. Thus, each couple in the party has the opportunity of choosing any particular dance or tune they may wish. The choice is left to the lady. In general, a party in a country dance do not remain up for more than two dances, when the partners are changed, and new dances begin.

A country dance should not consist of more than twelve or fourteen couples, as it is fatiguing to dance with a greater number. In standing up, the lady should always be on the gentleman's right hand, if they turn their faces to the top of the room. This is a simple rule to determine on which side the ladies and gentlemen should respectively take their places.

The principal figures in country dances are,

1. *Hands across:* that is, the top lady takes the second gentleman by the right hand, and the top gentleman, at the same time, takes the second lady by the right hand, and all go a half-circle round; then all change hands and back again.

2. *Hands four round;* the two top couples join hands, forming a circle; dance half round and back again.

3. *Right and Left.*—In this the top lady gives her right hand to her partner, changing places with him; then her left hand to the person below her, changing places; her partner performs a similar movement, and both return to their places.

4. *Set and change sides.*—The lady takes hold of both hands of the lady below her, and sets, that is, dances for a short time without changing her situation; then both ladies pass to the gentlemen's side, while the gentlemen pass at their backs to the ladies' side; all again set, and return to their places.

5. *Pousette.*—This signifies that the two top couples respectively join hands, each couple dancing round the other.

6. *Down the middle.*—The top couple go down hand in hand and return, stopping one couple lower than they commenced.

7. *Casting off* is the lady going down behind the ladies, and the gentleman behind the gentlemen, and returning to their places.

There are English, Irish, and Scotch country dances; but we know of no distinction among them except the tunes. All vary less or more in their figures. In each, however, as already observed, the plan is followed of the first or top couple dancing with each following couple in succession to the bottom of the room; and as soon as a sufficient number of couples are disengaged at top, another couple commences, and so on through the whole party. The following is an outline of the figures in a few of the more popular country dances. It will be understood that we always refer to what each couple does in succession:—

Voulez vous danser, Mademoiselle.—Set and change sides, down the middle, up again, and pousette.

John of Paris.—Right and left, down the middle, up again, and pousette.

Captain Fleming.—Hands across, down the middle, up again, and hands four round.

The Honey-moon.—Hands three round on the ladies' side, then on the gentlemen's side, down the middle, up again, pousette, right and left.

The Triumph.—Down the middle and up again; then the lady down with the next gentleman; her partner follows: the two gentlemen now lead the lady up between them, taking hold of her hands by one hand, and joining their other hands over her head; pousette.

Petronella.—First couple move to the right into the middle, and set; to the right again, and set at the side; to the right again and set in the middle; to the right again to places; down the middle, up again, and pousette.

Caper Fey.—Top couple go down backs and up again; down the middle and up again; set, and turn corners, and reel on the sides.

The Legacy.—Hands three round on the ladies' side; then on the gentlemen's side; down the middle and up again; set in the middle, and turn with both hands.

Sir Roger de Coverley or *the Haymakers.*—Top lady and the bottom gentleman advance to the centre of the dance, turn with both hands, and back to their places; the first gentleman and bottom lady do the same; the top lady and bottom gentleman again advance, turn with the right hand, and back to places; then the top gentleman and bottom lady do the same; top lady and bottom gentleman advance and turn with left hand and back to places; the top gentleman and bottom lady do the same. The top lady and bottom gentleman advance, the gentleman bows and the lady curtsies; the top gentleman and bottom lady do the same. The top lady and bottom gentleman advance, and pass back to back; top gentleman and bottom lady do the same. The top couple turn, the lady to the right and the gentleman to the left; all the ladies following the lady, and all the gentlemen following the gentleman to the bottom of the room, where they meet their partners and lead up the centre of the room. The top couple then half pousette with each couple, till they reach the bottom of the dance.

Scotch Reels.

These are rapid and rather fatiguing, but not ungraceful dances. They are danced by three, four, five, or six persons; but four is best and most common. The foursome reel is danced very much according to fancy; the two couples commencing by placing themselves opposite each other, or in a line, with the two ladies in the middle, back to back. In whichever way the dance begins, the plan is for each person to perform the figure of eight by winding round the others, and setting to partners alternately. The music, of course, guides the time for the setting and the moving.

Highlanders dance reels with great agility, and are fond of introducing the steps ordinarily called the *Highland fling*, which is of the character of dancing on each foot alternately, and flinging the other in front and behind the leg which is dancing.

Quadrilles.

These are modern dances of French origin, comparatively tranquil in character, and very suitable for small domestic parties. They are danced by four couples or eight persons, a couple standing on each side of a square. The lady is always on the gentleman's right.

There are many sets of quadrilles, the figures in each varying from the others; but in by far the greater number of instances one set is adhered to, which is termed Payne's first set. This set, of which we present an outline, consists of four figures, and a finale. The couples at top and bottom first perform a figure; then it is performed by the others; and so on.

La Pantalon.—First right and left, set and turn partners; ladies chain, which is performed by the two ladies giving their right hands to each other, and changing places; then their left hands so the gentlemen, and turn round; and the same back again to places. Now, promenade (each couple holding hands crossed) to the opposite side; then half right and left back to places.

L'Ete.—The first lady and opposite gentleman advance and retire, dance to the right, then to the left, cross over, lady and gentleman changing places. Dance to the right and left, cross again to their own places, and turn their partners. The second lady and first gentleman do the same.

La Poule.—The first lady and opposite gentleman cross over, giving their right hands; back again, giving their left and then right to their partners, and set, forming a line; promenade to opposite places. The two who begin advance and retire; advance a second time; the lady curtsies and the gentleman bows, and return. The two couples advance and retire; half right and left to their original places.

La Trenise.—Ladies chain; set and turn partners; first couple advance and retire; advance again; the gentleman returns, leaving the lady on the left of the opposite gentleman; the two ladies pass or cross to the opposite side, changing to opposite corners, during which the gentleman passes between them, and sets. The ladies cross over again, and pass to opposite corners, while the gentleman returns to his place, and sets. The first couple set and turn. During these performances, the gentleman at the bottom of the dance stands still. The movement being finished, a similar figure is performed by himself and partner.

La Finale.—All eight dance or chasse across, changing places with their partners, and set at the corners; back again to places, and set. After this, *L'Ete* is danced, concluding with chasse across.

This finale is danced in another way. All eight promenade round the room to their own places. The first and second couple advance and retire; advance again, the gentlemen taking the opposite ladies, or exchanging partners. Ladies chain; advance and retire; advance again, reclaiming partners, and promenade. This is called the *gallopade* finale.

The preceding embraces nearly all dances usually performed in private parties and balls of an ordinary kind. In the higher class of assemblies, various foreign dances are introduced, such as waltzes, mazourkas, pas seuls, minuets, and gallopades; but of these it is unnecessary to offer any description, as they require careful training under a master.

FOREIGN COSTUMES.

Among the many subjects of just and natural curiosity in the history of mankind, there is none more distinctive and characteristic of a people than the peculiar costume in which they are attired. The various articles of clothing have, from the earliest ages, formed the principal manufactures of every country—skill and industry in which, carried to a certain extent, mark, beyond almost any other circumstance, the advance of a people in arts and civilization. The savage wraps himself in the skins of the animals upon whose flesh he feeds; and even the most inhospitable regions furnish not only their natives with such rude clothing, but also supply the most civilized world; for example, the Danes obtain from Greenland seal-skins and fur, the eiderdown for the couch of the luxurious noble, and whalebone to complete the wardrobe of the court beauty. The processes by which plain substances shorn from an animal or gathered from a plant are converted into magnificent robes of the most brilliant tints, involve some of the most striking points in the history of human invention. But the entire subject of costume is replete with interest, from the rude skin-coverings of the natives of the icy north and south, to the exquisite fineness and beauty of the fabrics of the east, and the elegance and economy of those of the west. Ingenuity is not, however, exclusively the work of civilization; for we find the wild Indians of both the Americas, the South-Sea islanders, the negroes and Hottentots of Africa, and the poor savages of the Polar Regions, all acquainted with the art of plaiting wood, grass, or seaweed; and some of them producing, merely by hand, textures which we, assisted by all the aid of machinery, can scarcely rival.

The earliest clothing was coats of skins, from which the transition was to woollen tissues, linens, cotton, and silk, in the various forms which fancy suggested. Linen was made at a very early period in Egypt, as we see from the cloth wrappers of mummies, which are all linen; and early in the present century, there were found at Sakkara two Egyptian tunics, in the form of a shirt, and supposed to be the "linen ephod" of Scripture.* The Egyptians also knew the art of colouring and preparing leather, of which, as well as papyrus, they made sandals, and subsequently shoes. It is uncertain whether cotton was known to the Egyptians; but the cotton plant is found wild both in the old and new world. Herodotus mentions it as indigenous in India; and cotton cloth has been found in ancient Peruvian tombs. The country of the Hindoos has always been distinguished in the art of weaving; and thence, through the medium of Egypt, ancient Rome is stated to have been supplied with fine India cottons; whilst the beauty and durability of the Indian colours were as celebrated among the Greeks and Romans as among ourselves. Silk also was manufactured in India in very early times. In fabricating articles for ornamenting the person, the Egyptians professed great skill: their gold mines were worked under the early Pharaohs; beads and other ornaments of glass are found on many mummies; whilst, at a very early date, the rich gems of the east were conveyed thither, for which Egypt gave in return its manufactures of fine linen, its robes, and its carpets. Such were the principal articles of costume in earliest use; and although few, they denote convenience and even costliness and magnificence in dress to have characterized civilization in its remotest ages.

* Notes to Pictorial Bible, Samuel, ch. ver. 18.

EUROPEAN COSTUMES.

The form of dress throughout the civilized nations of modern Europe is generally far from picturesque, and has been adopted more for personal convenience than external effect. While in eastern countries the garments are light, flowing, and graceful, in those of the west they are stiff and formal, and generally composed of materials which are alike substantial and durable.

Northern Nations.—Commencing our survey at *Lapland*, we find that the wandering tribes of that remote and inclement region use a dress either of the skins of reindeer, or of thick woollen cloth. The men generally wear a gray conical cap, with eight seams covered with strips of brown cloth, the cap itself reaching only to the tips of the ears; and they rarely have any thing round their necks except their long black hair. Their tunic or short coat is mostly of sheep-skin, with the wool inwards, next the skin, and over this is a similar garment of woollen or skins, with a stiff collar. Their pantaloons are of woollen, tapering to their half-boots; they wear no stockings, but straw and rushes are stuffed into the shoe around the foot and ankle; and their gloves are of skin, lined with cypress-grass. They have no pockets, but a small bag hangs about breast-high, and a leathern belt is worn round the waist. The Lapland women have a peculiar fancy for gaudy colours, with which they work their skin or cloth caps, and gowns; they have a girdle containing their needles, scissors, and thread, hanging at their sides, and they wear small brass trinkets, which they prize highly.

The Laplander.

The clothing of the *Icelanders* is not very dissimilar, being equally substantial and homely; the chief difference being, that hats of a peculiar form are used instead of caps, and jackets instead of pelisses. The ladies of Iceland have also some gaudy trappings. Many of them wear about the waist a silver massive girdle, with an ornament above it, fastened in front on a belt of richly-worked velvet. These silver ornaments, in design and execution, are equal to any thing of the kind which a jeweller in England could fabricate, although they are the work of the peasantry. But the most distinctive portion of Icelandic dress is a kind of turban of white linen, stiffened with pins to about twenty inches in height, and sometimes terminated with a tassel, and fastened to the head by a dark silk kerchief, which completely hides the hair. Sometimes, instead of the above head-dress, the women wear a closely-fitting helmet-shaped worked cloth-cap, with a snow-white muslin termination, curved over in front.

Russia.—Throughout Russia the dress of the higher ranks is now formed on the European model; but the burghers, merchants, and peasants, wear the national costume of Asiatic character. This consists of a conical or square high-crowned hat or cap, a long coarse coat reaching to the calves of the legs, and girdles, with a sash, in which the wearer carries his purse, and often his hatchet; a woollen cloth is wrapped round the legs instead of stockings, and the boots or shoes are made of the rind of the young linden, plaited; each pair is rarely worn more than five or six days, so that many millions of these shoes are annually consumed.

Some of the costumes of the Russian peasantry are strikingly picturesque. The holiday dresses of the females are very gay, the principal garment being a loose jacket of sky-blue silk, the sleeves lined with spotted fur, and hanging loose from the shoulders. Among the Tartar population, the women wear embroidered velvet jackets over showy petticoats, and the little national tippet of red or yellow silk, lined with fur; gaudy colours are in great request, and even the poorest persons have their kirtles showily trimmed. The men, too, wear coarse cloth more frequently than skins. Towards Tula, however, the women wear the most dashing costume; a flat-fronted head-dress of gold or silver embroidery; the legs are swathed in folds of white worsted, and the feet are lodged in sandals; and the principal robe is a white eastern tunic, girdled round the waist, but floating loose below, and left open at the bosom, to display the top of a short petticoat trimmed with red; so that, "in gay tiara and flaunting robe, the maidens of Riazan strut about with all the dignity of tragic queens."*

The costume of the Cossack is gay. At home the Don Cossack wears a blue jacket lined with silk and edged with gold-lace, silk vest and girdle, ample white trousers, and a large cap of black wool, with a red bag floating behind. The women wear open silk tunics, white trousers, and yellow boots. The soldiers dress in a short Polish jacket, wide dark-blue trousers, and a huge sheep-skin cap.

The dress of *Swedes*, *Norwegians*, and *Danes*, is now similar to the costume of central Europe, but generally sober in tone and precise in fashion. As everywhere else, the costume of the humbler class of women is much gayer than that of the men. This is very observable at Stockholm, where a variety is displayed very different from the general monotony of northern attire. The boatwomen wear huge muslin caps, a bright scarlet boddice, a striped apron of blue, black, or red, over a grayish petticoat, thick stockings of flaming red, and "the largest and most marvellous shoes in the world," with birch-wood soles several inches thick, heavily shod with iron, and a round lump in the *middle*. But the Sunday full dress of the women is still more gaudy. A long kerchief is rolled round the hair like a turban, but with a loose end, and the long white robe, of thick cloth edged with red, thrown open at the girdle, and the lower corners pinned at the leg behind the petticoat, also of bright colours and ample dimensions—all give the wearer an Asiatic appearance among the blue skirts and homely linsey-woolsey of the general population. The holiday costume of the mountain maids of Norway is also pretty. They wear short loose scarlet or green cloth spensers, embroidered at the edges, and trimmed with shining buttons, and hanging over a coarse dark petticoat: the poorest women, however, wear a shapeless gown or sack of blue woollen, strapped tight up to the arm-pits.

Germany.—Advancing southwards to Germany and the Netherlands, the costume of the people is generally found to be modernized and reduced to that condition in which it is found in London and Paris. It is principally among certain classes of the fishing population, and the peasantry, that any striking peculiarity of costume exists.

In the mountainous territories of Austria, as in Styria, the national dress is, however, very picturesque. The women wear full short petticoats, with coloured boddices, tightly laced, and snow-white sleeves reaching to the elbows, and straw hats lined with green silk, and ornamented with flowers and feathers. The men usually wear a green hat, with a curious cockade of feathers, mixed with the hair of the chamois and the deer, and secured in the centre with gold tinsel, around which wave long red feathers: "green jackets, black chamois leather small-clothes, edged with green leather, striped stockings, and shoes tied with green ribbon, and a broad

* "Excursions in Russia."

leathern belt embroidered with green silk, complete the costume of a genuine mountaineer of Styria."* Among the peasantry of *Carniola*, too, may be seen some interesting primitive attire; as a short coarse linen tunic (which also serves as a shirt), confined by an untanned skin girdle, and sandals of the same rude material, and very wide small-clothes reaching only to the knee, but neither stockings nor hat.

In *Bohemia*, the general poverty of the peasants is apparent in their dress, which is rarely little better than tatters. The market at Prague, however, presents some picturesque costume; as the women wearing neatly trimmed jackets, ornamented boddices, and gayly-coloured petticoats and stockings, and head-dresses of kerchiefs fastened with large pins. The men wear very full small-clothes, ornamented jackets and vests, and broad-brimmed, low-crowned hats. The Moravian peasants of both sexes wear sheep-skin mantles in winter, but their summer dresses are of woollen and cotton of the gayest colours, the stockings and boddices being red, and the mantles blue or green; and the men wear a very short tunic, belted, tight pantaloons, and sandaled boots nearly to the knees, with a broad flapping hat, sometimes ornamented with bunches of gay ribbons. The materials of clothing are abundant in these countries; linen, including cambric, lawn, and tape, being the staple; and the woollen and cotton manufactures are very flourishing. The linens of Silesia, too, are the best in the world.

Prussia has little to distinguish it in the records of costumes from the other countries of Germany. From its capital, the fashionable embroidery known as *Berlin-work*, dates from the commencement of the present century; but this is mostly employed as ornamental furniture. It may here be mentioned, that in needle-work Germany stands first, then Russia, England, France, America, &c., the three first names on the list being by far the largest consumers; and in Germany, many ladies of rank add to their pin-money by executing needle-work for the warehouses.

Bavaria presents very beautiful and tasteful costumes. In the streets of Munich, on holidays, a washerwoman may be seen wearing a silver tiara, a blue satin brocade boddice, and a skirt and apron of worked muslin; and a waiting-maid will display a silver head-dress, and a gown, the whole of which, above the ceinture, is entirely of silver and gold; and these brilliant ornaments form the distinctive national costume of the pretty women of Munich. In the environs of the city, the men wear round blue jackets, tight black breeches, and white stockings; red waistcoats, with silver sugar-loaf buttons, outside which are worn braces gayly embroidered, or made of painted velvet: the leathern belts are also embroidered; and in the large round hats are worn artificial flowers. The women no longer wear the short petticoats of the mountaineer; and, instead of the broad-brimmed hat, is worn a cap of gold tinsel, projecting in fantastic forms, or a silver head-dress, forming a tiara in front; the boddice is of blue, red, or gold brocade, the skirt of smart-coloured cotton, and the apron of flowered muslin. Elsewhere in Bavaria, as in the mountainous districts, the peasants wear broad-brimmed hats, and coats of sylvan green. But the national costume must be sought in the provinces, where the Saxons wear "the stiff old-fashioned costumes which one still sees among the most primitive inhabitants of Germany. The women, like their Hungarian neighbours, wear long boots and thick woollen petticoats, their dress much resembling that which the 'broom-girls' have made familiar to our streets—a full cloth petticoat, stomacher buttoned or laced in front, and a closely-fitting cap; the unmarried girls wearing a long braid of flaxen hair down the back, with a small-crowned but broad-brimmed straw hat."† The men wear picturesque cocked hats, long antique coats, breeches, and large buckles in their shoes. Elsewhere, as in Lusatia, the women, who rank among the handsomest in the empire, set off their blond hair and rosy complexions with black velvet caps, and wear blue aprons flowered with white, red stockings, with green cloaks, and a hundred-folded petticoat terminating at the knee. Near Leipsic, the male peasants wear large loose breeches and tight jackets; and the women are distinguished by long pointed caps terminated with a tassel. The chief peculiarity in the costume of the peasantry in Darmstadt and adjoining districts on the Upper Rhine, is the wearing of cocked or broad-brimmed hats, which give even the youngest men an air of antiquity.

Small cloth caps are almost universally worn by the men throughout the towns of Germany; they are made of cloth, with low crowns, with small projections over the eyes, and have now become the common travelling cap in Europe.

In *Holland* and *Flanders* there is now little to remark in the costume. The fashion of wearing voluminous garments is abandoned, and the ordinary attire is universal. We stil find, however, the fish-women of Scheveling wearing large skuttle-shaped bonnets, and the women of the middle classes in Brussels covering their heads with black silk scarfs—a relic of Spanish manners. Throughout Holland and Belgium, the traveller rarely meets man, woman, or child in rags; neither are any seen barefooted. The shoes universally worn by children of the lower ranks are wooden *sabots*; these, formed out of a single piece of wood, and pointed like a canoe, are procurable at the easy charge of sixpence per pair. At the great annual fairs held in Holland, a few remarkable costumes make their appearance, from remote corners of the country. The most gay of these is the head-dress of the girls of North Friesland, which consists of a glittering plate of gold, bent and shaped to the head, and is of great value; they are also all decorated with fanciful gold ear-rings, twisted like a ram's horn, and pointing outwards from the face.

In *Switzerland* and the *Tyrol*, the population is generally dressed in plain apparel; but in certain quarters, and particularly on holidays, a picturesqueness of costume is far from uncommon among females. In the canton of Berne, the old-fashioned and peculiar costume of women is tasteful. Around the neck, and falling down on the breast, is worn a collar of black velvet, ornamented with gold beads, and which is held in its place by steel or silver chains passing beneath the arms. The head-dress consists of projecting pieces of black lace. In the cantons of Vaud and Friburg, the large chip bonnets of the women are a striking feature in the dress.

In the cantons of Thurgovia and Argovia, the male costume is very singular, the breeches being in the Turkish style, very large, and tied in just below the knee; the waistcoat is red, and remarkably long, as is also the large flapped coat. At Appenzel, the modern invention of braces is not yet adopted; the dress is a scanty jacket and short breeches, with a preposterous interval between the two garments. The canton of Grissons is said to derive its name from the gray colour of the men's dresses; but at present their coats and pantaloons are almost universally blue.

In the *Tyrol*, national costume appears to be more closely adhered to than in any other country of Europe except Spain, and perhaps Hungary. The peasantry strangely wear stockings without feet to them, tight black breeches, and leathern girdles with knives stuck in them; the hat tapers to the crown, whence hang on one side silk bands and tassels, generally green, and the blue smock-frock is tastefully worked, and worn not only by the peasantry, but by gentlemen. The men, too, wear flowers in their breasts, as well as in the

* "Germany and the Germans." † Paget's "Hungary."

hi der part of their hats. Th: aged wome.: wear huge white or red worsted caps, of sugar-loaf shape, and weighing six or seven pounds, and their dresses appear hooped, from often consisting of no fewer than ten petticoats. The young peasant women have round beaver hats, petticoats of rainbow hues, lace aprons, boddices with frills at the elbows, and figured blue and scarlet worsted stockings, which are sometimes worn in such enormous folds and plaits as to render the ankle as thick as the waist of a Parisian lady. The younger the women are, the fewer the number of petticoats they wear. The varieties of costume are best witnessed at the fairs, where may be seen the peasantry of almost all the Tyrolean valleys: "the ten-petticoated women (observes Inglis), with their great tapering white and red worsted caps: the black-breeched, white-stockinged, and girdled peasantry of the inn; and the bare-kneed peasant of the mountains; the men of Botzen, and its vale, with their broad-brimmed hats; the women of Meran, with their green cloth hats turned up at one side; and the peasant of the Italian Tyrol, with his less national costume and darker countenance."

Hungary.—Among the peasantry of Hungary the costumes still in use are remarkably picturesque, and trace their origin to that period when the country was a Roman province. One of the most characteristic articles of Hungarian costume is the *bunda*, or hairy cloak, made without a collar, and of sheep skins, with the long wool in its natural state, the leathern or skin side being ornamented with cords and flowers worked in coloured silks, and the cape being a black Transylvanian lamb-skin. To the Hungarian shepherd the bunda is his house, his bed, and all; for he wears it alike in all seasons and at all times. His under-dress is loose linen drawers, short shirt, and sometimes a gayly embroidered waistcoat or jacket, long boots or sandals, and a v..y broad-brimmed

Hungarians.

varnished hat, below which hangs two wide plaits of hair. The turned-up brim serves for a drinking cup, and around his neck hangs a bag to hold provisions.

T[illegible] peasants are mostly gayly dressed—the women in bright blue petticoats deeply edged with red, and neatly folded white handkerchiefs on their heads; and the men in tight blue pantaloons, embroidered jackets, and broad hats ornamented with artificial flowers. But almost every village in the mountainous countries has its peculiar costume; a white skirt, red and blue boddice, and white worsted boots, are common among the females, all of whom wear a little white cap at the back of the head. The men usually wear white cloth pantaloons embroidered with black, short woollen boots slit at the sides, and a dark short cloak or coat with sleeves, embroidered with red or light-green lace

In the mining countries, the women wear their short sheep-skin coats fastened in front with a silver chain and clasp, and ornamented with large silver filigree buttons, and high-heeled red, yellow, or black boots, reaching to the knees. The dress of the men is similarly ornamented with silver, and in "the good old times" the heels of their boots were shod with silver. The peasantry of these districts wear thick white pantaloons sandaled at the ankles, and a short-sleeved cloak lined with fur, and braided and fastened with a silver band; and the hat is wider than any part of the wearer's body.*

France must be viewed as the great fountain of European costume both in past and present times. However backward in many points, the French people, along with their neighbours, the Italians, naturally possess those qualities which lead to advancement in the fine arts, and the improvement of modes of dressing suitable to a civilized condition. England, the great competitor of France, as will be noticed at length in a succeeding sheet, has done little to alter or improve costume. In all ages its fashions have been mostly imitations of those first adopted in Italy or Paris. Hats, coats, nether garments, pantaloons, gloves, buckles, periwigs, stays, bonnets, &c., in all their varying shapes, are of French origin; and advanced as England is in refinement, till this hour it draws its fashions periodically from those current in the circles around the French court.

In speaking of French costume, it is always necessary to remember that the term applies only to the costume prevalent in Paris, and among the higher and middle classes in the country. Of that costume, the *species* of which other modern costumes are but the *varieties*, it is unnecessary here to speak, as it will be noticed in the article British Costumes. What we have to remark upon on the present occasion, are the costumes of a peculiar nature still lingering in the French provinces.

The most striking provincial costume in France is the head-dress of the women in Normandy. It is usually a kind of cap made of starched muslin, from half a yard to a yard in height, ornamented with long lace lappets called *coquilles;* the hair is braided in front, and gathered up in a mass behind. These caps have a very pretty effect, and are called *cauchoises, marmottes,* and *pierrots*, according to their height and form. The rest of the dress consists of a red, blue, or black corset, large wooden shoes, black stockings, and full scarlet woollen petticoat, and apron of different hues; pockets are worn outside; and occasionally the colour of the costume is still further diversified by a checkered handkerchief and white apron. Even on Sundays or feast-days, bonnets are seldom to be seen; but round the neck are suspended large silver or gilt ornaments, usually crosses or hearts, whilst long gold ear-rings drop from either side of their head, and their shoes frequently glitter with enormous paste buckles. In Lower Normandy the dress is nearly the same, with the exception of the cap, which is low and flat in the crown. In the former costume, the lover of antiquarian research will easily trace a resemblance to the attire of the women of England in the fifteenth and sixteenth centuries. In the adjoining province of Picardy, the head-dresses are equally antique. In Brittany, an old-fashioned style of

Women of Normandy.

* Paget's "Hungary and Transylvania," vol. i., p. 390.

dress prevails to a large extent; the hair of the peasant girls is fine and abundant, and is disposed of at fairs for large sums, to dealers who attend for the purpose.

In some parts of France, as in the neighbourhood of Lyons, the peasant women wear a flat, round black hat of cloth or velvet, and not unlike that worn in some parts of Switzerland; and a common article of male dress throughout the country is a *blouse* of blue stuff, like a wagoner's frock, buckled at the waist, and embroidered in white at the wrists and collar.

The female costume in La Vendee is thus noticed by Mr. Trollope:—"The women were dressed in short gowns of striped woollen stuff of various colours, chiefly red, yellow, and blue, with very high waists and tight sleeves. The gown ceases some inches above the ankle, and permits the exhibition of a pair of white ornamented linen stockings, knitted by the fair wearer's own hands, from flaxen yarn of her own spinning. A bright-coloured cotton handkerchief, manufactured at the neighbouring town of Chollet, in the department of Maine-et-Loire, is spread over her shoulders, and its ends secured in front within the bosom of her gown, in such fashion as to leave no portion of the neck or bosom uncovered. The sabot is, in this part of the country, an article of the peasant's costume, on which very great care is bestowed. They are small and slight, cut very low in the front, so as to show a great part of the foot, and shaped with as much care as a fashionable London artist could employ on the form of a pair of boots. They are, moreover, always painted black, in order the better to set off the white stocking. A good deal of lace is often displayed about their caps; and the 'barbes' of the coiffure, as they are termed, which are long strips of cotton, linen, or sometimes muslin, about six inches broad, falling on each side of the face, upon the shoulders, are frequently trimmed all round with it. The girls rarely hide their hair entirely here as they do in Brittany. It is for the most part beautifully black, and a specimen of it is generally seen in a broad band on each side of the forehead. This costume is very generally completed by a short black woollen cloak, made to keep open in front, and show the neat striped cotton apron beneath it."

Italy.—Throughout the Italian peninsula there is a remarkable variety of costume pertaining to different districts and professions. The garments, however, are more picturesque than cleanly; and rags and nakedness are everywhere conspicuous, more particularly in the Neapolitan territory. The dress of the bandits who frequent the Apennines consists of little more than a patched overall, cloak, and slouched hat; but the costume of their chief is a piece of studied coxcombery: upon the glossy curled hair is placed a cloth cap with a gold tassel hanging to the shoulders; around the throat is twisted a gaudy silk handkerchief, and the mustachios are carefully trimmed; the jacket is short, of cloth, or even velvet, and decorated with several rows of gilt filigree buttons; the breeches are tightly fitted and curiously braided; and in a broad particoloured sash are placed two silver-hilted pistols, and a sheathed knife mounted in ivory, elaborately carved; whilst a small carbine of handsome workmanship is slung across the shoulder, and sometimes the legs are sandaled with ribbons; and a high-crowned beaver hat, richly plumed, is worn over the cloth cap. The head-dress of the female peasantry is very striking. Sometimes, upon a long tasseled cap, is placed a little straw hat decked with red ribbons, or the straw hat is worn with a very broad brim. In Tuscany the women wear black beaver hats with high crowns and stiff black feathers, with streaming ribbons on holidays. But more characteristic is the square-topped muslin head-dress, like a university cap, with its embroidered drapery falling behind gracefully to the waist.

Rome offers a great variety of costume—in the dark sheep-skin dresses, shaggy goat-skin aprons, and ribboned hats of the carters, and the pretty square white muslin head-dress and scarlet boddice, laced with blue ribbons, of the peasant girl. But a more finished specimen of a Roman toilette includes a petticoat of delicate blue silk, with a brilliant scarlet boddice laced before and behind over a pure white chemisette, sleeves of silver tissue fastened with pink ribbons, and a shawl of embroidered muslin thrown over the shoulders; the black hair braided and hung in loops, with a silver bodkin and filigree flower, and over all a square of white muslin, trimmed with fine lace. The clerical habits contribute to the variety; you see the Franciscan friar in his brown or gray garment, with a cord girdle and sandaled feet; the Dominicans in white garments, with black cowls and girdles; the Carmelites entirely in white, even to their shoes and hats; the Jesuits all in black, with shovel hats; and other fraternities in black dresses and red crosses, violet robes and triangular hats, and red girdles and buttons on black garments; besides, the priests in black, the bishops in violet, and the cardinals entirely in fiery red, and the penitents enveloped in sackcloth, with only two holes for the eyes.

In Tuscany and Sardinia, the poorest females are rich in ornaments of pearl, coral, and gold; and the women and girls sit at their doors making "Leghorn bonnets." In Florence, the higher classes dress in the latest French fashion, except during the carnival, when the usual absurd and varied scene is exhibited, as in most other Italian cities. Part of the true costume of a Florentine *bourgeoise* is, however, a large broad-brimmed black hat of beaver or straw. Leghorn, however, presents greater variety than the Tuscan capital: here "many wear the oriental dress; priests, monks, and soldiers abound; mustachios, whiskers, and beards are seen in every variety; pretty female faces peep from beneath the bewitching *mezzaro* (shawl); the sunburnt tar mingles in the crowd; and the chained culprit, attired either in a rusty-red brown or a yellow habit, sweeps the streets, followed by his musket-bearing guard."* Throughout Tuscany, however, in costume we find no trace of the truly classic taste of its Etruscan masters.

At Naples, the most "open air" city in Europe, the poor are scantily dressed, but with picturesque effect; but children are sometimes seen in the streets with only a coarse shirt on, or even naked. The lazzaroni have gaudy holiday dresses, but some of them may be seen lying in the sunshine with merely white drawers, not reaching to the knee, such as are also worn by the fishermen. The restless Neapolitan crowd, with its grotesque popular exhibitions (including the national Punch), its groups of preaching, dancing, and story-telling, and its artisans at work in the open street, with the market-people from the environs in picturesque dresses—make up a scene of less interest for its costumes than for its other national characteristics. In the island of Procida, however, within a few miles of Naples, the females to this day wear the Greek costume, which, in that sequestered nook, has descended from their ancestors.

Spain.—Nothing strikes the traveller in Spain more forcibly than the character and diversity of costume among the people. Every province and class has its peculiarities, and so widely different from each other, that they almost appear to be inhabitants of two opposite hemispheres. It has been well observed, that "there exists as much difference between an inhabitant of Andalusia and one of Castile and Catalonia, as between an Englishman and a Russian;" and in no respect is this more evident than in dress.

Notwithstanding the general diversity of costume in

* Notes of a Ramble &c., by a Lover of the Picturesque

the provinces of Spain, of which the Catalonian, the Andalusian, and the Galician, are the most romantic and effective, yet the cloak is, after all, the most national feature; it is generally worn everywhere, and universally in Castile; and to the Spaniard, it seems his only garment for holiday and every day, for rain and sunshine, for winter and summer; the very children wear it; and are often encumbered with it at play; and so attached were the Spaniards in past ages to the cloak, that a minister of Charles III. was sacrificed to the popular clamour for attempting to cut down this article of dress to legal dimensions.

Spanish Peasantry.

Beneath the cloak is generally worn, in winter, a sheep or lamb-skin jacket, varying in price from four to forty dollars: in the summer this is replaced by a body-jacket, decorated with rows of small buttons or coins, and braided in various colours; round the waist is worn an immense bandana or shawl in the eastern fashion; the leather leggings are richly embroidered, and the hat is either high-crowned or oval, decorated with black velvet buttons, or trimming, with points.

The general female costume of Spain consists chiefly of a petticoat and a large mantilla or shawl, or a veil covering the upper part of the person; but this is rarely worn except at mass. The colour of the mantilla is black; it is of lace or silk, or both, and it is thrown over the head so as to display a large and costly comb. Neither bonnet nor ribbons are generally worn, although some ladies may be seen dressed in the French mode. The fan is carried by all females, from the lady in her carriage to the servant walking in the street; indeed, "a Spanish woman would be as likely to go out of doors without her shoes as without her fan." The neat stocking and small shoe are also much studied.

But the varieties of costume are almost endless: the Catalan wears a velvet jacket with silver buttons and long pantaloons; the Valencian loose breeches of linen, and a long sack unlike the full cloak; and the Castilian a black velvet cap, a black sheep-skin jacket, light breeches, a girdle, embroidered leather leggings, and stout nail-shod shoes. In the north is worn the red woollen cap, hanging down the back; in La Mancha the montero cap; and in the south the low-crowned hat, with a wide brim turned up. Among the eccentricities of costume, is the dressing of the hangman in green, from an ultra-Catholic aversion to the sacred colour of Mahomet.

The common mode of dress in Portugal is similar to that of Spain.

Greece.—The dress of the modern Greeks is a mixture of Turkish and Frank costume, with little to mark the classical origin of the people. The chief article of attire of the poorer Greeks is a capote, or large woollen garment, with a hood, shaggy with short threads of yarn; it is heavy when dry, but nearly insupportable when wet; it is as serviceable for home and bed to the wandering Greek as the *bunda* is to the Hungarian shepherd, and it is a perfect defence against cold and dew. All but the poor classes of Greeks, however, dress showily; and even a servant will expend every farthing of his wages in fine clothes. Thus, a physician's janissary may be seen in a rich robe of scarlet, his vest of blue velvet trimmed with gold lace, and in his silk girdle a brace of pistols embossed with silver; turban, short petticoats, and trousers of purest white, and gaiters or "leggings" of scarlet velvet, embroidered with gold; altogether, a costume that might suit a prince. The general dress consists of a short embroidered jacket, without collar, and with sleeves open from the elbow; an embroidered vest, a cotton shirt, a tunic of several folds, secured by a sash or shawl about the waist, and reaching to the knee; loose breeches or trousers, short socks, and slippers between sandals and shoes. In one corner of the sash, the common people carry their money, which the rich put into purses, and carry, with their handkerchiefs, watches, and snuff-boxes, in their bosoms. The head-dress is various: as the turban, *a la Turque;* the fur-cap, like a muff; the fez or tasseled cloth cap worn on one side; the plain caps of the peasantry; and skull-caps of velvet or gold, embroidered or tasseled. The young Greeks are the handsomest race in Europe; their long hair falls over their shoulders from under the cap; their embroidered jackets, vests, and buskins, their arms mounted with silver, and even jewels, and their white kilts, compose, on the whole, one of the most graceful and becoming costumes in the world.

The Greek.

The costume of the Greek female more closely resembles that of the Turks. She wears loose trousers of fine calico, embroidered with flowers, a closely-fitting vest, a jeweled zone about the waist, and a long-sleeved gown flowing off loosely behind, or a veil covering the body; and sometimes a rich pelisse trimmed with fur. Jewellery is worn to excess; and bracelets of gems, or strings of gold coins round the arm and neck, across the forehead, and in the hair, which the younger girls let fall down their backs and over their brows and cheeks. Little caps, similar to those of the men, are also worn by the females, studded with coins, but worn on one side of the crown, the girls wearing in them flowers, and the matrons heron-plumes or jewels. The young women often dye their hair auburn, and the old ladies red, with which colour the nails are also tinged. The females walk abroad in a robe of red or blue cloth and an ample muslin veil.

Turkey.—Although belonging to Europe, the Turks are properly an Asiatic people, and their garments, where their true national costume is preserved, are according to an eastern or Asiatic model. The outward Turkish garment is a long and loose robe; underneath is a wide vest bound with a sash; loose drawers, and a wide-sleeved shirt without wrist-bands. Slippers are worn abroad, but are left at the door on entering a house. This, with a turban, is the usual dress, though many classes have a different one, and an office is often denoted by a peculiar dress.

The Turk.

The turban was long the most characteristic feature of eastern dress: it was a cap surrounded by many folds of cloth or muslin, its form and ornaments not only distinguishing the rich from the poor, but distinguishing the various professions. The varieties of form were considerable, a barber of Constantinople having been known to arrange the drapery of a turban in sixty-six different fashions. The yatagan or sabre is invariably worn by the Turks.

The dress of the Turkish females has a general resemblance to that of the men, though a stiff cap is worn instead of a turban. When abroad, the women are closely veiled, but they unpin a corner of the muslin to enable them to eat sweetmeats and smoke the long *chibouk* or Turkish pipe; their white muslin turbans, too, are sprigged with gold, and decorated with red flowers; the hair is worn long, and plaited with embroidered gauze, knobs of gold, and spangles with diamonds and other gems.

A crowd in Constantinople was formerly a picturesque group; there was the graceful Effendi Turk with snow-white turban, jetty beard, sparkling and full eyes, long flowing caftan, scarlet trousers, yellow boots, rich Cashmere shawl round the waist, in which shone the gilded dagger; next was the gay but cunning-looking Greek, with short chin, black turban, enormous but short trousers, bare legs, and black shoes; then the grave Armenian, with his calpac of black felt balloon-like upon his head, his long Turkish robe, silver ink-horn in his girdle, and his feet in the crimson slipper or boot; next was the Jew, with his blue turban and slippers; and with these were seen the high taper calpac of the Tartar, the melon-shaped head-piece of the Nizam Djedid, the gray felt conical cap of the imaum and dervish, and occasionally the ungraceful hat of the Frank, with the bebuttoned and mean-looking costume of Europe.* Latterly, the costume of Turkey has been greatly infringed upon by the introduction of the Frankish dress.

ASIATIC COSTUMES.

Although the transit from Europe to Asia may be somewhat modified by our description of the journey still lying in the Turkish empire, the contrast of the oriental costume, but imperfectly adopted in one corner of Europe, soon becomes striking on entering Asia. Instead of our tight short clothes, we see long floating robes wrapped loosely round the body; the hat is displaced by a light turban, and sandals are worn instead of shoes. The oriental costume is simple, and, among the rich, of costly materials. India and China furnish abundance of silks and dyes, and the muslins of the former country are unrivalled, as are also the Asiatic wools, and the art of interweaving gold and silver with these fabrics; whilst the jewels and precious stones of their country enable the Asiatics to eclipse other nations in splendour of personal ornaments; whilst all over the east the beard is allowed to grow so as almost to be considered a feature of costume.

To notice the thousand varieties of fanciful costume prevailing in this vast continent, is altogether beyond our limits, and all we can do is to give a glance at those more strictly national.

Arabs.—The general dress of this interesting people is of a simple form. Their ordinary attire is a piece of linen over the shoulder, another round the middle, and a girdle, with a knife; sandals, sometimes of wood, merely covering the soles of the feet. Upon the coast, the whole dress consists of a napkin round the loins, and a kerchief fringed with silk on the head, the rest of the body being quite naked. Some wear only drawers and a shirt. This, however, is only the dress of the poorest classes; that of the rich resembles the Turkish costume, being loose and flowing. At Muskat, the inhabitants wear a carpet skull-cap and a white embroidered turban, a long white garment reaching to the ankles, a cloth girdle, and sandals of hide, with straps; and an Arab must be poor indeed if he has not a sabre hung over his shoulder, and a dagger by his side. The Muskat soldiers are distinguished by a circular shield of rhinoceros-hide, a foot and a half in diam[illegible] long thin sword, a dagger, and a pike from seven [illegible]n feet in length.

A captain of the Arab navy wears a blue check turban, bordered and fringed with red; a dark-green upper garment, with wide slashed sleeves, falls just below the knees, and beneath it is a wrapper of pink silk, the sleeves slashed with yellow satin, and secured about the waist with a girdle of cloth or silver, over which is worn a sword-belt and ornamented dagger. From half way below the knee the legs are bare; the feet are sandaled, the straps being fancifully ornamented; and the toe-nails, as well as those of the fingers, are stained reddish-yellow. Such is the costume of an Arab gentleman of the present day, and it has probably varied but little from the earliest times. Another picturesque dress is a large white turban, full white breeches, a frock buttoned straight upon the chest to the throat, girded above the loins, hanging half-way to the knee, and looped up on one side, the feet being sandaled. The Arab women of the same place (Muskat) shroud the greater part of their face with dominoes or hooded cloaks; their white long-sleeved gowns or robes reach half way below the knees; and they stain their eyelids dark, and their cheeks and hands yellow; or they wear a loose gauze robe over pantalettes fitting close at the ankles, which are ornamented, as among Jewish females of old, with silver bangles; the feet are cased in gay stockings and slippers, or they are bare, with rings on the toes; the short-sleeved spenser or jacket is tastefully bespangled and tinseled.*

A merchant of Jidda or Yemen wears a caftan or gown of silk, and a red scarf, and around the waist a Cashmere shawl, in which is fixed a long curved dagger; and sometimes the lower part of the face is muffled up in a woollen shawl. The rich also wear slippers. The profits from the pilgrimage enable the people of Mecca to dress very gaily; and from the Persian Gulf they obtain the finest pearls in the world.

But the most characteristic portion of the Arab costume is the head-dress, which is profusely ornamented, but has neither comfort, convenience, nor any adaptation to climate. A man of fashion will wear no fewer than fifteen caps piled one above another, the top one being embroidered with gold, and with a sentence of the Koran worked into it; around the whole is folded a muslin turban, with loose gold and silver-fringed ends. In the south, the turban is formed of a bordered square of silk, with a piece of India muslin coiled round it. The green turban, when worn by the head of an ancient tribe, denotes the highest dignity that can exist in Arabia. The poor wear only two caps; and the Bedouins, or wandering tribes, wear no caps, but only a hood in their cloaks, which are draped so as to keep off the cold and rain. The Arab sailors at Mocha and other ports of the Red Sea wear dark-flowing robes, and pale blue and red turbans of picturesque form. At Muskat, none except those of royal lineage may wear the turban above a prescribed height.

Persians.—The Persians are allowed to have once surpassed in pomp and show the other oriental nations; and this magnificence was nowhere more displayed than in the splendour of their attire and personal ornament. But this distinction now applies rather to the costliness of the materials of dress than to its colours; for however gayly the Persians may have dressed formerly, their present choice is confined to dark tints, as brown, olive, green, and blue.

The Persian dress has been considered effeminate, and not unreasonably so. The men wear very wide trousers, and a shirt extending below the hips, over the trousers; a tight-sleeved vest des[illegible] to the middle of the leg, and over all, a long ro[illegible]ing to the ankles, fitting tight as far as the hip[illegible]hen buttoned at the side, but flowing like [illegible] The sash around the waist is of flowered m[illegible]sh chintz, the common shaw

* Frankland's Travels to and from Constantinople.

* Dr. Rasch[illegible]er's Voyage round the World.

of the country, or a Cashmere shawl. It is eight yards long and one yard broad, and in it is stuck a dagger, without which, and a sabre, no Persian considers himself fully dressed; and these weapons are profusely jewelled. Great care is taken of the feet and legs: in winter, a thick woollen sock is worn, and the legs are bandaged with cloth; the slipper turns up at the toe, and has an iron heel an inch and a half in height. High-heeled boots are likewise worn; and it is customary to take off and leave at the door the slippers or boots before the wearer enters a room, this being done on account of the sacred character of the carpet. The head-dress is a black sheepskin cap, from a foot to a foot and a half in height, which was formerly encircled, turban fashion, with a shawl. They keep their head covered, a compliance with which etiquette has been troublesome to foreigners, who have thus been compelled to dine in their cocked hats and feathers. The Persians pay great attention to the hair and beard; the head is completely shaven except a small tuft on the crown, and two locks behind the ears; the beard is allowed to grow very large, and to spread about the ears and temples; the pride is to dye it a rich glossy black (which must be repeated once a fortnight), and then to adorn it with jewels.

Altogether, the Persians are fond of fine clothes, and will pay a liberal price for them. They prefer English manufactures to those of any other nation. English chintzes and broadcloths are much in demand; the latter for the outer garments of most respectable persons. The taste in colour varies much; one year blue and brown will be in favour, next year red and grey. The chintzes are invariably high coloured; but the patterns must be changed as often as in the Manchester market. Hence the British trade with Persia is considerable, although we have powerful competitors in the Russians and Americans.

Circassians.—In Circassia, where the distinctions of rank and birth lead the people to associate in septs or clans, the varieties and gradations of costume, as might be expected, are closely observed. The warlike spirit of the men likewise encourages this taste; their indulgence in dress never degenerates here, as in some other countries, into luxurious effeminacy, but fosters their chivalrous bearing and personal gallantry. The exquisite beauty of the women, and, above all, the active part which they take in the business of life, also ensure this attention to costume.

Circassian Lady.

A Circassian beauty, whose fine form and delicate complexion have almost exhausted eastern panegyric, is tall and well, though slightly shaped, and carries herself very erect, though somewhat ungracefully, from the practice of tightly compressing the loins from infancy, and thus giving an unseemly protrusion to the body and stiffness in walking. Her beauty is tenderly watched, her face being shaded from the sun, her feet protected by a wooden shoe, her hands by gloves, and her waist by a broad leathern girdle, fastened at an early age with clasps. Her costume is a bonnet or skull-cap of scarlet cloth, tasseled and covered with broad silver lace; a boddice of blue silk, with silver studs; a girdle with silver shell-shaped clasps; and beneath a petticoat of striped silk, loose Turkish trousers, from which peep her white and delicate feet, which, in-doors, are left uncovered, but ornamented pattens or morocco slippers are worn out of doors. The maiden is not veiled, whereas the married woman wears a veil and a piece of calico muffled to the nose. The hair is worn in braided tresses over the shoulders. Sewing, embroidery, and straw plaiting, are the occupations of all females above the rank of slaves

The male dress of the Circassian is the well-known Caucasian costume; the sheep-skin bonnet and collarless frock, with loose hanging sleeves, fitted closely to the body, fastened by loops in front. The trousers are wide above, and gathered tightly over the knee and calf, and covered to the middle of the leg with gayly-gartered galoches; the shoes are remarkably neat, of red morocco trimmed with silver, or of black leather or ox-hide, but they are without soles. On each breast is a row of ten cartridges; a rifle is slung over the shoulders, a pistol in the belt behind, a broad dagger in front, and a sabre at the side. The costume is uniform in its most trifling details and adjustment, so as to give a group of men the appearance of one family, except the calpac or bonnet, which is of lamb, sheep, or goat-skin, crisp and curly, long and shaggy, thick and bushy: the cloth of the dress is coarse, and of gray, straw, or brown colour. The winter garments are sheep-skin doublets, worn with the wool inwards under the tunic; a hood of stout frieze covering the calpac and shoulders; and a large cloak of thick brown felt.*

The costume of the mounted warrior is very picturesque; as a brown surtout silver-laced, sometimes open at the breast, and displaying a gleaming shirt of mail; black pantaloons, puce leggins, red shoes, sabre, bow, and quiver; and a white turban, with a red cap and long purple tassel. These coats of mail were doubtless introduced by the Egyptian Mamelukes, and we shall hereafter find them worn in the interior of Africa.

Tartars.—The wandering tribes of northern and middle Asia, consisting of Tartars, have little to boast of in the way of costly costume. The common dress is a cotton robe and drawers, sometimes trimmed with wool, and red is the favourite colour. Garments of skins are also worn; and a young Tartar has been known to have the fresh hide of a horse thrown over his naked body, and cut, fitted, and stitched into a dress in an hour or two, which only wanted to be tanned by continual wearing. The Calmucks have scarcely any clothing but a strip of cloth about the waist. The Mongols wear sheep-skin dresses, with the wool inwards, and the better classes furs. But the dress is nearly as various as the people. In the northern countries furs are much worn.

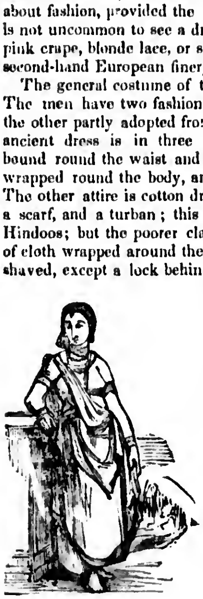
The warlike Toorkmans of the deserts between Balk and the Aral are a handsome race; they wear the *tilpak*, a square or conical black sheep-skin cap, which is far more becoming than a turban. They are very fond of bright-coloured clothes, and choose the lightest red, green and yellow, for their flowing pelisses. The head-dress of the ladies would grace an English ball-room; it consists of a lofty white turban, over which is thrown a red or white scarf that falls down to the waist; but they never veil. Ornaments are sometimes attached to the hair, which hangs in tresses. The other part of their costume consists of a long gown reaching to the ankle, and hiding both it and the waist, which are standard points of beauty in our country.

Siberia and Kamtschatka furnish rich and soft furs, which, however, are only worn by the higher classes, or exported for the wealthy of other countries. The most valuable fur is that of the weasel, called the *sable;* and next, the black fox. The dress of the poor Burettas, in Siberia, consists of a pelisse of dressed goat or sheep-skin, with the hair or wool worn inside or out-side, according to the season. It is mostly trimmed with common fur, and painted with black and red stripes about the neck and shoulders. The hair is worn in a long plait, hanging down the back from beneath a peaked shaggy goat-skin cap.†

* Abridged from "Longworth's Year in Circassia."
† Dobell's "Travels in Siberia," &c.

India.—The vast country of Hindostan presents innumerable circumstances favourable to the characteristics of costume; in its antiquity as the seat of oriental pomp, in the richness of its products, greater than those of any other country, ancient or modern, and in the variety of races and castes which distinguish its social state. These observations apply only to the natives of Hindostan, for no "Christian of European descent, however remote, ever wears a native dress. Rich Indo-British ladies, on the other hand, attire themselves in the latest and newest fashions of London and Paris, greatly to their disadvantage, since the Hindostanee costume is so much more becoming to the dark countenance and pliant figures of eastern beauties;"* those of an inferior class care less about fashion, provided the style be European, so that it is not uncommon to see a drummer's wife in blue satin, pink crape, blonde lace, or silver-lama dresses, and other second-hand European finery.

The general costume of the Hindoos is as follows:—The men have two fashions of dress, one very ancient, the other partly adopted from the Mohammedans. The ancient dress is in three pieces of cotton cloth, one bound round the waist and falling to the knee, another wrapped round the body, and the third round the head. The other attire is cotton drawers, a long robe tied with a scarf, and a turban; this is the regular dress of the Hindoos; but the poorer classes have often only a piece of cloth wrapped around the loins. The head is usually shaved, except a lock behind, and small mustachios are worn. The dress of the females is very elegant; the close part is a half-sleeved jacket, the remainder is a large piece of silk or cotton wrapped round the middle, falling gracefully below the ankle of one leg, while it gracefully displays a part of the other. The upper end crosses the breast, and is thrown forward again over the head or shoulder. The materials are generally cotton, but in some of the higher regions, the colder climate renders general the wearing of woollen cloth and even of furs. The clothes of the different classes differ mainly in degrees of fineness, the rank of the wearer being indicated by a profusion of jewels, embroidery, and gilding.



Hindostanee Woman.

The extreme ugliness of the dress adopted by the most refined nations of Europe, is nowhere more apparent than in British India, where it is contrasted with the flowing garments of the natives. The round sailor's jacket and tight trowsers, brought by the early factors from their ships, are worn to this day in India; and the men are clothed from head to foot in white cotton, in which the coxcomb can only distinguish himself by the quantity of the starch. The officers of the Indian army, when on duty, wear jackets of thin scarlet or blue Cashmere, China crape, or China silk; and young civilians sometimes appear in full dress swallow-tailed coats of China crape.

In India, dress is rarely varied; and accordingly few things surprise the natives more than the changes in European fashions. The dresses of the ladies, therefore, are plain, if not dowdy, in comparison with the gorgeous show of the Asiatic groups; and in warm weather bonnets are dispensed with, and the hair is worn in the plainest manner. There is not so great a variety of oriental costumes at Calcutta as might be expected; some of the Armenians appear in their national dress; a few Hindoo and Mohammedan gentlemen are clad in very picturesque attire; and a Chinese physician may be seen in an old tumble-down chariot. Some of the native shoes are very handsome, but can only be worn by foreign residents as slippers; the points are peaked and turned up, and the shoe itself of cloth or velvet, stiffened with embroidery. Most of the shoemakers of Calcutta are Chinese, who live in one wide street, and are always well dressed in the rich silk upper costume of their country.

Benares is celebrated for its rich displays of costume. A native noble wears a velvet turban, so richly embroidered as to resemble a cluster of precious stones; the vest and trowsers are of crimson and gold brocade, a Cashmere shawl is wound round the waist, a second shawl is thrown over the shoulder, and the belt of his scimitar, and the studs of his robe sparkle with diamonds. The costly gold and silver tissues of Benares are worn as gala-dresses by all the wealthy classes of Hindostan as robes or turbans; silver and gold lace are very cheap here; and the trinkets of Benares, as chains, necklaces, ear-rings, and bangles, are at once elegant and massive; pearls are much worn by the natives, and strings of the size of pigeons' eggs are frequently displayed round the necks of rich men; and diamonds are worn in similar profusion. The dress of the *nautch*, or singing and dancing girls, is very picturesque; it consists of gay silk trousers embroidered with silver; rich anklets strung with small bells; the toes covered with rings, and a silver chain across the foot; over the trousers is worn a petticoat of rich stuff, very full, and deeply trimmed and fringed with gold or silver; the vest is almost hidden by an immense veil of rich tissue, which crosses the bosom several times, and hangs, in broad end, at the front and at the back. The hands, arms, and neck, are covered with jewels, and in the hair are worn silver ribbons and bodkins. The ears are fringed with rings, and through the nose is worn a large gold wire ring, from which hang a pearl and two other precious gems.

Bombay, in its mixed population, presents several varieties of costume, as that of the wealthy Parsee, shown in the annexed cut, with collarless white muslin frock over scarlet silk trousers, long sharp toed slippers, and high purple or chocolate-coloured cap, figured with white flowers. A Parsee lady wears a tight satin spenser with short sleeves, embroidered and fringed with gold bells, and a satin mantle thrown round the body and over the head, like the Spanish mantilla; large pearls are worn in the ears, and emeralds in rings on the toes.

The Parsee.

The costume of the native islanders of Ceylon is attractive. The Cingalese women of rank wear, over coloured silks or satins, a white muslin robe embroidered with flowers and spangled with gold. The chemise has lace ruffles and trimming; and in the hair are worn gold and tortoise-shell combs, and pins set with gems. The men of the middle class wear muslin waistcoats and jackets, the women short shifts and petticoats of printed cotton. The poorer classes wear simply a thick fold of coarse muslin wrapped round their bodies. The poor Candian mountaineers go almost naked, but the higher classes are arrayed in superb tiss[illegible] and embroidered muslins, and a square cap or round turban co[illegible]ers the head. The Malabars wear gold ear-rings n[illegible] [illegible] foot in circumference set with large gems; but th[illegible] [illegible] by the women [illegible] much smaller. They wear a s[illegible] piece of muslin folded

---

* Miss Roberts's "Scenes and Characteristics of Hindostan."

round the waist, hanging below the knee, and gracefully thrown over the shoulder, so as to cover the body and leave the arms bare; and the hair is merely combed and turned up behind and before.

The manufactures of India furnish the most costly materials for clothing, and her mines yield the finest diamonds in the world, and other gems in abundance. Ceylon, too, furnishes pearls and chank-shells, much worn by the Hindoos. Cotton, the native material of India, is there worked into the most elegant forms: in Dacca, muslin* is made richer, softer, and more durable than elsewhere; and the calicoes,† ginghams, and chintzes of Coromandel are unrivalled, though almost excluded from the European market by cheap and close imitations. Silk is manufactured in taffetas, brocades, and embroidered tissues. The woollen fabrics of the northern provinces have been already mentioned.

China.—The most familiar representations of these extraordinary people and their quaint costumes, are to be seen upon their "china;" and Viscount Jocelyn‡ remarks, that "it is wonderful how correct they are in the main features." Here they are shown to be well clothed; and they are more completely so than the other nations in the south of Asia.

The extremes of heat and cold which characterize the climate of China at opposite seasons of the year, have led to a marked distinction between the summer and winter dress of the better classes. But the difference is principally in the cap, which in summer is of finally-woven bamboo, of conical shape, with a blue, white, or gilt ball at its point, whence falls, all around, silk or red horse-hair fringe. The winter cap is circular-crowned, and a broad brim, turned up all round, and faced with velvet or fur; at the top of the crown is likewise a ball, whence falls just over the dome a bunch of crimson silk. The changing of these caps with the season is of such importance as to be notified in an official gazette. A small skull-cap is commonly worn within doors in cold weather. The summer garment is a long loose gown of light silk, gauze, or linen; in full dress, worn with a silken girdle, to which are fastened the fan-case, tobacco-pouch, bag for flint and steel, and sometimes a sheathed knife and chop-sticks. In winter a large sleeved spenser is worn to the hips, over a dress of silk or crape, which reaches to the ankles. This spenser is of fur, silk, or broad-cloth, lined with skins; and the neck, which is bare in summer, is in winter covered with a collar of silk or fur. The loose dresses fold over to the right breast, where they are fastened by buttons and loops; and the button, by its shapes and sizes, denotes the rank of the wearer. In summer the breeches are loose; and in winter a pair of tight additional leggings are worn. Woven silk or cotton stockings are worn; and in winter boots of cloth, satin, or velvet, with white soles, by persons of certain rank. On state occasions the under dress is splendidly embroidered in silk and gold, and the caps are crimson, with various coloured balls. The fur dresses of the higher classes are expensive, and descend from father to son. Little linen is worn, and the body garment, sometimes of light silk, is very rarely changed.

Chinese Tradesman.

Nevertheless, the costumes of all ranks and orders about the imperial palace are observed at Pekin with as much precision as in any court of Europe. Fashion, too, has its votaries; a Chinese fop being dressed in costly crapes and silks, boots or shoes of black satin of Nankin, embroidered knee-caps, cap of exquisite cut, and button of neatest pattern, an English gold watch, a tooth-pick attached to a string of pearls, and a scented Nankin fan; and such a personage is attended by servants in silk dresses.

The head of the men is shaven, except at the top, whence the tail hangs after the Tartar custom; they have little beard; but the shaving of the head employs a great number of barbers; in mourning, however, the hair is allowed to grow.

The dress of the women is modest, and of exquisite silks and embroidery, of bright and permanent gloss and colour. Pink and green are favourite colours, but they are never worn by men. The ordinary dress is a large-sleeved robe over a longer garment, under which are loose trousers fastened at the ankle, and embroidered shoe, proverbially small, about four inches in length and two in breadth, the feet being barbarously compressed from infancy. Unmarried women wear the hair in long flowing tresses down the back; after marriage it is twisted up towards the back of the head, and ornamented with bodkins, flowers, and jewels; and at a certain age, a silk wrapper is worn round the head. Females of all ages daub their faces with red and white paint. They pass most of their time at home in music, drawing, or embroidery; and the handsome crape shawls taken to England are entirely the work of women.

Chinese Women.

The general material of the dresses of the peasantry is nankeen, dyed of various colours, black and blue being the most common. The men wear loose trousers tied round the waist, underneath a smock-frock. They protect the head from the sun by a very broad umbrella-shaped hat of bamboo slips, which in winter is exchanged for a felt cap; and in rainy weather they have a flax or reed cloak, from which the water runs as from a pent-house.* Shoes are rarely worn by the peasants, but some protect the feet with sandals of straw. The women wear on the forehead a velvet peak, adorned with a bead, and the hair combed back, and kept together by a loop of leather, and ivory and tortoise-shell bodkins. The girls wear their hair in long plaits, but after marriage it is twisted into a hard knob at the crown, and ornamented with artificial flowers; and even the poor peasant girls pique themselves on their small feet, which they deck with embroidery, whilst the rest of their dress is poor and mean; even the poorest market-women of Canton, though clad in rags, protrude their little bandaged feet into notice.

The uniform of the Chinese soldiers is loose trousers and jacket, often with "valour" inscribed on the back, and a coloured cloth wrapped round the head; some dresses are studded with brass knobs, to imitate armour, and the cuirasses and helmets are of polished steel, the latter bearing red and brown plumes; they appear al[l]

* Muslin is said to have been named from Mosul, formerly the capital of Mesopotamia, on the western bank of the Tigris, and one of the greatest entrepôts of eastern commerce.

‡ Six months in China.

* Dewer's "Chinese."

arms—matchlocks, bows and arrows, swords, shields, and quilted breastplates; but the paper helmets, wadded gowns, quilted petticoats, and clumsy satin boots of other troops, are most unmilitary.

The islands upon the coast of China offer a few peculiarities worth notice. At Macao, the Chinese servants wear full white breeches and leggings, blue gartered, and wooden-soled shoes; and the porters blue shirts, short trousers, and straw or glazed hats tied under the chin. The Tartar women, who row the passage-boats, wear a long blue Nankin frock over black waterproof trousers, and a handkerchief is bound diagonally over the head, and tied under the chin. The Chinese pilot is sheltered from the storm by a broad-brimmed hat made of palm-leaves, somewhat like the husbandman's. The Portuguese women of Macao wear loose figured calico gowns and scarfs over their heads; and if not taking the air in sedan chairs, are followed by a slave bearing an umbrella.

The dress of the Loo Choo islanders is graceful and picturesque: it consists of a loose coloured robe, generally of cotton, wide and long sleeved, with which is always worn round the middle a belt wrought with silk and gold flowers; the robes of grown persons are mostly plain, but those of the children are gaudily printed with flowers. In rainy or cold weather, a sort of thick blue cloth great-coat is worn by the chiefs only, and buttons in front over the robe. All ranks wear straw-soled and banded sandals; the upper classes have white cotton socks, buttoning at the outside, and having a place like the finger of a glove for the great toe. The hair is invariably pulled tight up all round into a compact knot with two pins, so as to conceal the crown of the head, which is shaved. On state occasions only, is worn a kind of turban, made by winding a broad band diagonally. The poorer classes tie a coloured cloth or handkerchief round the head, and wear a thin cotton body dress. The men wear no ornaments, nor are they tattooed; they all carry fans, to keep the sun from striking hot upon their skulls, and short tobacco-pipes and pouches in their girdles. The women are much neglected, and even restricted from using fans. The islanders of Hainan and Formosa wear scarcely any clothes; the natives of the latter are almost savage, and tattoo their skin like the rudest of the South-Sea Islanders.

The manufactures for clothing in China are not numerous. Silk is the staple of the empire, and the Chinese fabrics are still unrivalled in richness, though they are very little worn in Europe: it is, however, stated that the Chinese keep the best silks for themselves. Nankin cotton (which grows of the yellow colour we wear it) is not so worn by the Chinese, but dyed blue, black, and brown, when it is the general clothing; some cotton is, however, imported. Woollen garments appear to be only worn by persons of rank. The beautiful crape shawls have been mentioned. In fans, tortoise-shell, mother-of-pearl, and silver filigree ornaments, the Chinese artisans are only rivalled by their Japanese neighbours. Furs to a great amount are received in China from North America; that of the red fox is used for trimmings and linings of robes, and is variegated with the black fur of the paws.

Japan.—The characteristic intelligence of the Japanese is strongly marked in their dress, which they aim at rendering substantial and becoming, instead of indulging that passion for glitter and show which is evident in all the rest of Asia. Their principal garment is a [illegible] silk or cotton robe, large and loose like a bed-gown, and a girdle. Within doors, socks are the only covering of the feet; abroad are worn shoes, or rather soles, of rice straw, matting, or wood, mainly kept on by an upright pin or button, held between the two principal toes, which, for this purpose, project through the socks. The difficulty of lifting a foot thus shod in walking may account for the awkward gait ascribed to the Japanese. Upon entering any house, these shoes are taken off.

The head-dress constitutes the chief difference, in point of costume, between the sexes. The men shave the front and crown of the head, and draw the rest upwards, and tie it in a tuft upon the bald skull. But priests and physicians shave off all their hair; while surgeons retain all theirs, gathered into a knot at the top of the head. The women arrange their luxuriant hair into the form of a turban, and stick it full of pieces of fine tortoise-shell, so highly polished as to resemble gold. No jewellery or trinkets are worn. The face is painted red and white; the lips purple, with a golden glow; and the teeth of a Japanese married lady are blackened, and her eyebrows plucked out. Neither men nor women wear hats, except as a protection from rain, or when on a journey; a conical hat of plaited grass or oiled paper is then tied with a string upon the head; and the fishermen generally wear these hats. The fan serves as a guard from the sun, and it is to be seen in the hand or the girdle of every Japanese; and soldiers and priests are no more to be seen without their fans than fine ladies are. The uses of the fan are almost endless: dainties are handed upon it; the beggar holds out his fan for alms; the fan [illegible] it instead of a switch; the school-master for [illegible]; by the presentation of a fan, death is announced to the high-born criminal, his head being struck off at the moment that he stretches it towards the fan. There is great pride in wearing swords, and they are never laid aside. The higher orders wear two swords on the same side: the next in rank wear one.*

Vast numbers of rice-straw shoes are consumed by all classes. They cost, however, a mere trifle; and the pedestrian supplies himself with new shoes as he goes along; whilst the more provident man always carries two or three pair with him for use, throwing them away as they wear out. The consumption must thus be very great; for the Japanese travel in their own country more than perhaps any other nation.

East India Islanders.—The dress of the native population of the East India Archipelago partakes somewhat of the close-fitting European and the loose flowing Asiatic costume. The principal tribes are the Javanese and Malays.

The poorer classes of the Javans wear a handkerchief neatly tied about the head, tight drawers reaching to the knee, and a *saroug* or sash of bright-coloured calico thrown over the shoulder, or around the hips, whence it falls like a petticoat. The saroug is not unlike the Scottish Highlander's plaid, being a piece of parti-coloured cloth, six or eight feet long, and three or four feet wide, sewed together at the ends.† In rainy weather, a basin-shaped basket-hat is worn; but in clear weather, it is carried in the hand. A loose jacket is also worn. The Mohammedans wear a turban-like cap; but the other inhabitants have the head naked. A Javan prince copies his dress from the European settlers; he wears a dark cloth jacket, with gold-laced cuffs and collar, a cravat of the fashion of fifty years ago, the only native taste being a handkerchief on his head, and a saroug hanging about the lower limbs. The native court-dress is, however, a full robe wrapped about the waist, and falling over pantaloons, the upper part of the body entirely naked, long flowing hair, a flower-pot cap, and a straight sword and curved dagger in the waistband. The body is smeared with yellow, and richly ornamented with gold trinkets. The war-dress consists of a long-sleeved robe, pantaloons, close cap, sword, dagger, and long spear.

Sumatra has some rude races, who tattoo their skins, and otherwise resemble the South-Sea Islanders; and some few wear no clothing at all. Yet in this island is wrought gold and silver filigree, the only fine manufac-

† De Ruschenberger's Voyage round the World

ture in the Archipelago. The Bugis, the best-armed natives, make their own guns, spears, daggers, and swords; and their chiefs wear a chain shirt of plaited iron or copper wire. Of this tribe, with Malays, Javans, Chinese, "head-hunting" Dayaks, and a few Europeans, is the population of Borneo made up; and with the addition of East Indians, that of Singapore.

It will be seen that Asia possesses an abundance of the superb materials of dress, which, conjoined with the semi-barbaric condition of a great proportion of its inhabitants, and the consequent taste for glittering distinctions, renders this by far the most striking portion of the earth in the characteristics of costume.

AFRICAN COSTUMES.

Africa presents fewer distinctions of costume than either of the other great divisions of the globe. This may be in consequence of its population consisting, in the main, of Moors and Negroes. The former inheriting the industry of the original Arab invaders, display most taste in their dress; but that of the gay and hospitable negroes has considerable picturesqueness, although consisting of few and simple materials.

Moors, Arabs, Berebers.—These distinct classes form the population of the Barbary States, the wandering tribes being distinguished as Arabs, and the inhabitants of cities as Moors.

The better class of Tripolines have a long and a short dress; the former worn by elderly men and persons of great consequence, and the short worn generally. This consists of a tight waistcoat resembling a Guernsey frock; over it a gold-laced waistcoat, and a jacket with embroidered sleeves; these are confined at the waist by immense trousers of silk or cloth, and a broad belt of silk or gold; and over the jacket is worn an embroidered sleeveless waistcoat. The long dress consists of the two under waistcoats, and over them a long-sleeved gown, embroidered. Over both dresses, which are of the gayest colours, are worn Bornouse or woollen cloaks, bordered with gold lace. The turbans are various; those of Cashmere shawls are the most splendid; green can only be worn by the descendants of the prophet; and blue is confined to the Jews. The boots, shoes, and slippers, are of yellow morocco leather, the staple manufacture of the country. The women dress magnificently, wearing a silk skirt of many colours in stripes, highly embroidered waistcoat, silk trousers, and a large silk wrapper of gaudy colour, so put on as to form a petticoat, and hang over the head and shoulders, showing only one eye; a cap of cloth of gold is worn with many rich ornaments on the head; the eyelids are stained with antimony; much rouge is used; and the ear-rings, anklets, and bracelets, of gold and silver, are very massive. The dress of the Jewish women varies from the preceding chiefly in showing both eyes instead of one; they can wear only black or yellow slippers, and boots are prohibited. Altogether, the above is a most gorgeous costume.

Algiers presents a picturesque variety in its population of Moors, negroes, Jews, and Kabyles, or Berebers. The costume of the Moors consists of a loose head-dress, a shirt, large breeches, an embroidered jacket of coloured cloth, a large white outer mantle, and slippers; and in winter, stockings. In the streets, the poorer Moorish women are veiled, and look like phantoms; the richer Mooresses wear fine linen, bordered with silk; the hair is bound with blue silk ribbon; and over an embroidered silk-velvet jacket, with silk lace ruffles from the elbows to the fingers, and silk pantaloons to the knees, is worn an embroidered silk gown, like that of a European lady; morocco slippers, a veil, shawl, ear-rings, bracelets, armlets, and a necklace, complete this costume, which differs from ours principally in the absence of stockings and petticoat; and the gown is only worn occasionally. The children of the Moors are dressed exactly like their parents, the little girls wearing veils, and the boys turbans. Possibly the above admixture of European fashion may be one of the results of the colonization of Algiers by the French. The Jews generally dress like Europeans: their women wear a gilt wire cap, slanting a yard back from their heads, giving them, as Mr. Campbell tells us, "the appearance of dragon flies;" they strain their hair and eyebrows "to the frightful resemblance of a red cow's tail."* Their costume often presents the extremes of poverty and wealth; as a pair of ragged small-clothes, and a crimson-velvet and gold jacket, and embroidered silk sash. The Berebers cover themselves with a black woollen garment like a sack, which is made to last generally a whole life, and is never taken off; and the head-dress is a woollen cap, like a priest's cowl. The women dress much like the men; they tattoo their legs and arms, and stain their hands and nails, but never veil; and they delight in trinkets. Both sexes wear buskins, like those of the ancient Romans; and any one who repairs a cap which is wholly repudiated at Algiers is considered a fop.

The general costume of the Arabs is a large loose shirt and cotton trousers; sandals or red leather half-boots, laced; a red hanging cap, with a blue silk tassel; a woollen wrapper worn round the body, and thrown over the head, and hanging down the back; and the Bornouse mantle. The dress of the females differs but little from that of the men. The poorest class have only the wrapper or scarf, which is passed over the head and fastened at the waist, others have a woollen gown with short sleeves. The young women wear their hair in tresses, decorated with beads, coral, and a silver crescent, and they wear a large blue woollen turban; also silver ear and neck rings, and charms against disorders and misfortunes. All the women tattoo themselves, and stain their hands and nails, but they never dye their hair; they wear red laced boots, like the men. An Arab belle is almost covered with tattooed flowers, open hands, circles, the names of gods, and of her friends; and she often wears two or three pounds' weight of jewelry.

The countries of central Africa, explored by Denham, Clapperton, and Lander, present many interesting portraitures of costume. The principal garment is the tobe, a linen or cotton garment not unlike the surplice of an English clergyman in shape and volume; it hangs loosely over the person, and is suitable to a climate in which any kind of tight garment would be oppressive.

The costume of the negresses of Soudan is very remarkable, in the hair being stretched over a high pad, helmet-shaped, and the head bound with coral and other bead fillets; the neck-laces are of coral and gold, and the ear-rings very large; glass armlets and anklets are worn; and the upper and under shirts are blue and many-coloured stripes; and a whitish dress, braided pink, with blue waist and wristbands, and a yellow close cap, bound with red, make a very effective costume upon the dark negro person.

African Woman—Kingdom of Bornou.

The negroes of the Sheikh of Bornou may be noticed here: they wear coats of mail composed of iron chain, which cover them from the throat to the knees; some have helmets or skull-caps of the same metal, with chin-pieces; and their horses' heads are defended by plates of iron, brass or

* Letters from the South.

silver, with holes for the eyes. This armour, especially the skull-cap, is like that of the Parthians sculptured on the Trajan column, and subsequently adopted in the Roman army, and then introduced into Africa.

Negroes of Western Africa.—The clothing and ornaments of these people have great variety; different tribes, and people of the same tribe, indulging in a diversity. This passion for dress is not surprising, if we recollect that the negroes have all the requisites for beauty, save colour; and that the mineral wealth of their country enables its chiefs to indulge in barbaric magnificence, which is astounding to more civilized nations.

The poor negroes are content with a coarse cloth wrapper; but the rich wear robes of silk, velvet, and Indian chintz. Red mantles, gold and silver lace, ribbons, and veils, are much in request among the women; and bracelets, rings, and anklets, are worn in profusion. The hair, or rather wool, is as carefully dressed with palm-oil as the flowing locks in other countries, and is entwined with gold; and painting the face and tattooing are common. The general dress is a large-sleeved shirt reaching to the knees; and a high pointed cap is much worn. The Kroomen, on the Grain Coast, wear round their waists shawls and blue cloths, which they purchase at Sierra Leone.

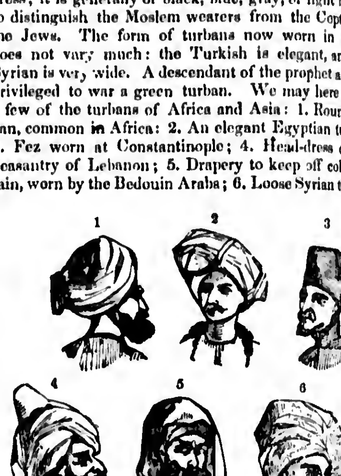
The Ashantees behind the Gold Coast, who are altogether a superior class, dress in barbaric splendour. The Ashantee cloths are of extravagant price, from the costly foreign silks which are unraveled to weave them; they are thrown over the shoulder like the Roman toga; a small silk fillet encircles the temples, and strings of gold beads, coins, and rings are worn round the neck, wrists, arms, and ankles; the sandals are of fine green, red, and white leather. Lumps of rock-gold hang from the left wrist, which are supported on the heads of boys; and wolves' and rams' heads, of cast-gold, as large as life, hang from the sword-handles. The warriors wear caps of eagles' feathers, and of pangolin and leopard skin, the tails hanging down behind; their corselets are of leopard skin, covered with gold cockle-shells, and stuck full of knives sheathed in gold and silver; and their cartouch-boxes, of elephant hide, are similarly ornamented; silk scarfs and horses' tails stream from their arms and waist-cloth; iron chains and collars dignify the most daring; and the sides of their faces and their arms are curiously painted in long white stripes, having the appearance of armour. Even the executioner wears on his breast a massive gold hatchet. The splendour of all Ashantee pageants is enhanced by large umbrellas or canopies of the most showy cloths or silks, crowned with emblems in gold.

Modern Egyptians.—Egypt has long been mainly occupied by Arabs, whose manners and customs are a combination of those which prevail most generally in the towns of Arabia, Syria, Northern Africa, and in a great degree, Turkey, whose characteristics of costume have already been sketched. Nevertheless, the Arab-Egyptians "are to be regarded as not less genuine Arabs than the townspeople of Arabia itself;"* and although their dress has points of resemblance to the costumes of all the countries referred to above, it will be found to possess great originality of character and interest.

The dress of the men of the middle and higher classes has remained almost the same during the lapse of centuries. It consists of a pair of full drawers, of linen or cotton, descending a little below the knees or to the ankles; a full-sleeved shirt of linen, cotton, or silk, over which, in cool weather, is worn a short vest of cloth or striped coloured silk or cotton, and a long vest of the latter materials descending to the ankles, and having full sleeves divided from or a little above the wrist. A coloured shawl or piece of white figured muslin is worn round this vest as a girdle; and the usual outer robe is a long cloth coat with or without sleeves. The turban consists of white muslin, or a Cashmere shawl wound round a close red cloth cap, with a dark blue silk tassel at the crown, beneath which is worn a close cotton cap. The head is shaved, except just at the crown, and mustachios and moderate beards are common. Socks are occasionally worn, but stockings are not in use: the shoes are of red morocco, pointed and turned up at the toes; and sometimes these are worn over yellow morocco shoes. In the girdle is worn a case-knife, a dagger, or a case for ink and pens. The pipe is generally carried; and the tobacco-pouch and handkerchief are crammed into the bosom of the outer vest.

The humbler classes wear drawers, and a full blue linen, cotton, or brown woollen gown, wide sleeved, and open from the neck to the waist, where is sometimes a white or red woollen girdle. The turban is of white, red, or yellow woollen, cotton, or muslin, round a white or brown felt cap. The poorest classes wear only this cap and the brown or blue gown, or merely a few rags. In cold weather, they sometimes wear coarse black or variously-striped woollen cloaks. A blue and white plaid is likewise worn over the shoulders or wrapped about the body. The shoes are of red or yellow morocco, or of sheep-skin.

The turban is the most distinctive article of Egyptian dress; it is generally of black, blue, gray, or light brown, to distinguish the Moslem wearers from the Copts and the Jews. The form of turbans now worn in Egypt does not vary much: the Turkish is elegant, and the Syrian is very wide. A descendant of the prophet alone is privileged to war a green turban. We may here notice a few of the turbans of Africa and Asia: 1. Round turban, common in Africa: 2. An elegant Egyptian turban; 3. Fez worn at Constantinople; 4. Head-dress of the peasantry of Lebanon; 5. Drapery to keep off cold and rain, worn by the Bedouin Arabs; 6. Loose Syrian turban.



Eastern Head-dresses.

The women of the middle and higher orders of Egypt dress elegantly; under their shirt, which is like the men's, they wear very wide trousers of silk, cotton, or muslin, coloured or white; and over them a long vest closely resembling that of the men. A shawl or embroidered handkerchief is put loosely round the waist as a girdle. The outer robe is of cloth, velvet, or silk, embroidered with gold or silk, and generally resembling that of the men; though, instead of this robe, a jacket is often worn. The head-dress consists of an under and upper cap, round which is tightly wound a kerchief of printed or painted muslin or crape, and to it is attached a muslin veil embroidered and spangled, and hanging from the back of the head to the ground. The hair is worn plaited or braided down the back, with attached

* Lane's Account of the Manners and Customs of the Modern Egyptians.

golden ornaments; and two tall locks hang down on each side of the face. Stockings or socks are rarely worn, but inner shoes of red or morocco, and over them yellow slippers, with high pointed toes; or wooden clogs, from four to nine inches in height, richly ornamented. Such is the in-door dress of the Egyptian ladies. When abroad, they wear over this dress a large loose silk gown of pink, rose, or violet colour; a sort of silk robe tied over the head (black for the married, and white for the unmarried), and a long white muslin face-veil, reaching from under the eyes nearly to the feet. Yellow morocco short boots or socks are worn under the yellow slippers. This dress resembles an unsightly disguise, though it displays the eyes, which are always the most beautiful feature of an Egyptian woman.

The poorer class of women wear trousers, a blue shirt, a coarse black face-veil, and a dark blue muslin or linen head veil. A very large blue, white, and red plaid wrapper is also worn by the middle class. The head-dress is a black silk kerchief, bordered red and yellow, and tied diagonally in a knot behind. The shoes are of red morocco, round toed; but in Upper Egypt shoes and the face-veil are rarely seen; and some of the poorest women of Cairo never conceal their faces. But the most common female dress in Egypt is merely a blue shirt and head-veil; and in Upper Egypt, some of the women envelope themselves in a dark brown woollen wrapper and head-veil, which, though dull, is picturesque. Mr. Lane tells us that "the women of Egypt deem it more incumbent upon them to cover the upper and back part of the head than the face, and more requisite to conceal the face than most other parts of the person." He adds, that he has seen in this country women but half covered with miserable rags, and others still nearer a state of nudity.

AMERICAN COSTUMES.

In all those portions of America, including Canada and the United States, which have been long possessed by an English race, the costumes of England and France prevail, any differences which exist being only of minor importance. Peculiarity of costume on the American continent has therefore to be sought for among the native Indian tribes, and among the descendants of Spanish or Portuguese settlers.

North American Indians.—The Indian savages, or red men of the forests and prairies of North America, occupying the vast region to the west of the Missouri, present

North American Indian.

the most interesting specimens of costume in the New World, enthusiastically described as "worthy the pencils of Raphael or Hogarth." The condition of these extraordinary people is, indeed, highly favourable to the distinctions of dress; they are divided into tribes (of whom great numbers are warriors), which are much less broken than the feudalism of those countries of Europe in which costumes are most strongly marked.

The general dress of these tribes consists of a skin shirt, a robe of hide, leggings, and mocassins, and equipments and decorations in great variety. The fashion of long hair is almost universal; but, contrary to European usage, the women are not permitted to indulge in this taste. The length of the hair of a chief (who received his name and office in consequence) is stated to have measured ten feet six inches.

In the costliness and elegance of their costumes the Blackfeet and the Crows are, perhaps, unrivalled. The materials of their dresses are nearly the same; but there is a distinctive mode in each tribe of stitching or ornamenting with porcupine quills, which are the principal decorations of all their fine dresses. The attire of a chief of the Blackfeet consists of a shirt or tunic of deer skins, the seams embroidered with porcupine quills, and fringed with the locks of the hair of victims slain by the chief in battle. The leggings are of the same material and trimming, as are also the mocassins. Over all is worn a robe of young buffalo-skin with the hair on, the inside being garnished with porcupine quills and rude representations of battles. A long pipe, bow and quiver, lance and shield, complete his equipments. He is almost always on his horse's back: and thus armed and equipped, his appearance is very picturesque. A Crow sometimes wears a magnificent crest, or head-dress, made of the quills of the war-eagle and ermine skins; and his horse is covered with a many-coloured net terminating with a crupper, embossed and fringed with beautiful shells and porcupine quills. Necklaces of bears' claws and otter-skin, and ornamented tobacco sacks and belts, are too numerous to describe. The medicine bag is also an important article of costume; it is formed of the skins of animals, of birds, or of reptiles, variously decorated, and always stuffed with grass or moss, and generally without drugs or medicines in them, as they are religiously closed and sealed, and carried as a sort of protection throughout life. The scalps (from the crown or centre of the head) of enemies are preserved as records of a warrior's prowess, and their locks used as trimming. Sometimes a war-knife and buffalo horns are worn upon the head, which is shaven; and the shield and spear are decorated with feathers. In short, nothing can exceed the picturesque variety of these aboriginal costumes, or the vanity of their wearers.

The women wear long loose robes or wrappers of skin, and carry their children strapped to a kind of frame at their backs. The snow-shoe must not be forgotten; it is about three feet long and one foot wide in the broadest part, and its frame is filled with a network of twisted deer-skin, strengthened with sticks placed crosswise; the foot is confined to the shoe by skin strings, though to walk well in these shoes requires as much practice as to navigate a canoe.

Mexicans.—The European dress is common in Mexico, and has long been worn by the higher classes: the people are fond of change; for it is related that a traveller having left a book of London fashions at Xalapa for a few months, on his return found an entire revolution in female dress, founded upon the English model. Still, many picturesque dresses are seen in Mexico, in great measure the introduction of the Spaniards, whose celebrity in the annals of European costume will doubtless be remembered by the reader.

The national riding-dress is of all the most curious, and is enormously expensive. The back and quarters of the horse are covered with stamped and gilt leather, fringed with tags of brass, iron, or silver, which jingle at every step. The saddle, which is large, is superbly embroidered with silk, gold, and silver, and the pummel inlaid with these metals; the bridle has large silver ornaments; and an Arabic bit. The horseman is attired with corresponding richness. His *sombrero*, a low-crowned hat, with a brim six inches wide, is broadly edged with gold or silver lace; his jacket, of cloth or printed calico, is likewise embroidered with gold or silk, or trimmed with fur; his breeches are generally pea-green or azure, open at the knee, and terminating in two points below it, and they are thickly studded down the side with large silver buttons. Next is the riding-cloak, often of velvet, and embroidered with gold. But the boots are the pride of a true Mexican cavalier; they are formed of deer-skin, well tanned and soft, stamped with figures, and bound round the legs with coloured garters below the knees. At the ankle commences the shoe, which, at the top, spreads out six inches, like a scallop-shell. The spurs, of silver, are very heavy, and have rowels three or four inches in diameter, and often a bell attached to the side.

The costume of a muleteer is likewise very striking: the jacket, of embossed russet leather, has silver buttons; the overalls, of the same material, are cut so as to be the length of the foot, and are sustained by a red silk sash above the waist, allowing the shirt to appear between it and the jacket; a pair of huge silver spurs rattle at the heels, and a long straight sword hangs from the waist.

The ladies generally wear black, but on holidays the colours are very gay; shawls are worn over the head like the *mantilla*; and the country ladies wear a profusion of spangles; and they are as proud of a neat shoe and a small foot as the females of Spain. Few ladies appear in public on foot, but in enormous coaches, in full evening costume, smoking cigars. The milliners of Mexico are so many brawny mustachioed men, who may be seen in the shops making flowers and dresses and trimming caps. Next door, women may be seen on their knees grinding chocolate; but in all semi-barbarous nations the hardest labour falls to the women's share.

Colombians.—The Colombian costume is chiefly borrowed from the mother country. The Spanish mantle, or a wide cloak which envelopes the whole person, is the usual attire. But in the streets of Bogota a female may be seen smoking her cigar, and wearing a handsome broad beaver hat, pearl necklace, many rings, and a rich black mantle, ornamented with bugles, but walking without shoes or stockings. The ladies of rank, however, are proud of their pretty feet and small ankles, which are always set off by handsome silk stockings and very neat shoes. Like the women of Spain, they walk with grace and dignity, and are equally coquettish and playful with their fans. A black or blue cloth mantilla, and a small conical black beaver hat, and black silk gown, were formerly the walking dress; but large French bonnets, with artificial flowers and gay silk gowns and neckerchiefs, are now much worn; and the walking evening dress is a pretty straw hat, with artificial flowers; a warm Norwich shawl, and chintz or cotton gowns of British manufacture. Pearls, emeralds (the largest in the world), gold chains, and crosses, and very large pendant gold and pearl-drop ear-rings, are worn in profusion. The women of the middle class generally wear an embroidered scarlet petticoat, a white boddice, with frills and ribbons, and a parti-coloured cotton band; the hair is plaited, and adorned with artificial flowers. The dress of the men is Spanish, with jack-boots and long silver spurs; and a cloak made of rushes, a large straw hat, and bark sandals, are much worn in travelling.

Of the native Indian tribes of this territory, the Carribees are the finest race; the head is shaven, except a tuft on the crown; both sexes paint themselves, and wear only a band or wrapper of blue cloth; they are of a reddish copper colour, and, with their picturesque drapery, resemble bronze statues. The women oat barouary ornament their infants by raising the flesh in alternate stripes from the ankle to the hip. The Chaymans, another tribe, only wear clothes out-of-doors, and then a light cotton gown.

Peruvians.—Peru presents many interesting peculiarities of costume, owing to the various races of its population. The Indians, or native Peruvians, in their male dress, remind Mr. Templeton of the peasantry of Connaught; they wear coarse brown frieze breeches open at the knees, a vest falling in strips round the waist, where it is confined by a cord, and a sort of loose cloak; shirts are seldom worn; the legs are bare, with the exception of low hide sandals; and the hat resembles Don Quixote's helmet, without the niche in it. The women wear a short petticoat, and a scarf round the shoulders, fastened with a large silver pin or a spoon. The Cholas, of Indian and Spanish descent, are very fond of dress and ornament; the girls wear a petticoat containing from twelve to fourteen yards of rich velvet or satin, trimmed with ribbons and gay flowers, a scarf over the shoulders, and a narrow-brimmed black hat, like that of the Welsh women, or a broad hat, with a little lace, silk, or velvet-festooned curtain attached to it. They wear gold and silver ornaments and jewels in profusion.

The women of Lima wear a very unique costume, consisting of a closely-fitting petticoat of velvet, satin, or stuff, with a waistband and buckle; fringe, lace, spangles, or flowers on the lower part, and elegant silk stockings and satin shoes; the *manto*, or hood, of thin crimped silk, is drawn round the waist, and then turned over the back of the head, and enveloping all the upper part of the person except one eye, thus completely disguising the wearer. The ladies of Lima sit on horseback like men; the dress is then European, with a large shawl over the head, and a Manilla grass hat above all, and huge gold or silver spurs on their satin shoes.

The Peruvian ladies are fast adopting the French fashions, and many *marchandes des modes* are established in the large towns; but the Spanish fan is still retained; the mantilla may also be seen, and the long veil falling down the back. The hair is very luxuriant, and universally prized, so that a poor peasant girl has been known to refuse £7 or £8 for her weaving tresses. The shoe of the Indian city dame strongly contrasts with the hide-sandal of the peasant; sometimes a pair costs ten dollars; the heel spreads like a fan, and is adorned with shreds of cloth, spangles, and gold and silver tissue.

The Peruvian male costume has little worth notice; and it would be better for the men of Peru if the women only took the lead in dress. The Tucumano wears trousers, and a large figured shawl over his shirt, with a very broad-brimmed conical-crowned hat tied under the chin. The Indian merchant has embroidered breeches and jacket, a rich fringed mantle over the left shoulder, and a helmet-shaped ornamented cap. But the Peruvian gentlemen mostly dress in the English fashion, and our goods are preferred to either French or German manufactures.

The cloak of the country, or the *poncho*, is an oblong square garment, with a hole in the centre for the head; it is made of cloth or silk and *vicuna* wool of very tasteful colours; it is worn constantly by the men, but only by ladies when on horseback. Mr. Temple* describes a pair of light summer boots made without seam or stitch, of the skin of the hind legs of a horse, and dried ready for wear in a week—"easy as a glove."

Chilians, &c.—Among the changes produced in Chili by free trade, is the general substitution of the English for the Spanish-American costume; and the principal

* Travels in Peru and Potosi.

peculiarities of costume remain among hunters, guachos, and other half-wild denizens of the country.

The equipment of a rich guacho chief at Paraguay is truly magnificent: his Peruvian *poncho* is superbly embroidered on a white ground; his jacket is of fine India cloth; his waistcoat embroidered white satin, with gold buttons; his short collar and front are of fine French cambric, richly tamboured his breeches are of black velvet, with gold buttons, and open at the knees; and from under the knee-bands are seen the fringed and worked extremities of a pair of drawers of fine Paraguay cloth, and ample as a Turkoman's trousers, and just showing a pair of brown *vicuna* wool stockings; while his skin boots fit the feet and ankle as a French glove fits the hand; the tops are turned over like buskins, and to the heels are attached large silver spurs. His large hat is of Peruvian straw, with a black velvet band; and around his waist is a rich crimson silk sash, which serves as riding-belt, braces, and girdle for a huge silver-handled knife in a morocco sheath. His horse is alike gorgeously caparisoned: the saddle, bridle, and reins being silver mounted, and the stirrups elaborately wrought out of at least ten lbs. of virgin silver.* In fine, nothing more splendid than this horse and rider can be found in South America.

At Buenos Ayres and Mendoza, British manufactures are much in request. In the latter town the men wear blue and white round jackets; and the women are only seen in *dishabille* during the day, but in the evening they promenade completely equipped in the costume of London or Paris.

Brazilians.—The vast region of Brazil presents a few traces of its original Indian barbarism, the natives having never been incorporated with the European settlers, but having retired before them into the depths of the forests. Here some of the tribes paint themselves frightfully, and by hanging pieces of wood to their ears, stretch them till they hang down to the shoulders; and the under lip is similarly extended. A scanty portion of clothing has been borrowed from the Portuguese colonists, whose costume was generally adopted in the towns, until, by the free intercourse of Brazil with England, our fashions of dress were assumed by the Brazilians, as well as our furniture and domestic habits. Within two years from their introduction in 1818, English goods made their way, and women might be seen dressed in silks, who, a year previous, would have worn Lisbon printed cottons and thick cloths, and have gone to church stockingless and slipshod. The mineral wealth of Brazil has ensured so ample a supply of clothing from other countries, that manufactures have made less progress here than in any other of the South American colonies; and the only important fabrics are gold and silver articles, which are very beautifully wrought.

Rio Janeiro is almost a European town in dress as well as style of building, though its crowd of half-naked blacks and mulattoes soon destroys the illusion. St. Salvador is a gayer city; and here the French style of dress is much followed, but the official costume is more native. Thus we find the Secretary of State, a half-Indian, mounted on a mule, and dressed in white cotton; his jacket faced with red, and leggings with ponderous spurs; his hat is broad-brimmed and glazed, and has a gold lace-band; his sash is yellow; a gold epaulette graces his right shoulder, and a huge long sword hangs by his side, while his dagger is fastened to his right knee.

In the provinces, sandals with loops and ankle-rings were the Brazilian shoes long after the introduction of English manufactures; and when a native took to wearing a shirt and drawers, a long bed-gown and slippers, he oddly thought himself a gentleman, and entitled to respect accordingly. To this day the arts of life appear to be unknown in some villages, where the natives are bare from the waist upwards, and the children wear no clothes whatever. Even at Rio the extremes of mankind are collected, and the slave population merely wear a waist-cloth.

Brazilian.

At Pernambuco, the benefits of its large cotton-trade are evident; white and coloured muslins alternate with silks and satins; and the men, who formerly wore full-dress suits of black, gold buckles, and cocked hats, now wear Nankin pantaloons, half-boots, and round hats; and even the sedan-chairs and their bearers are improved The costume of the Sertanejos, the graziers of the interior, is partly aboriginal; his pantaloons or leggings, jacket, and hat, are of brown undressed leather; a tanned goat-skin tied over his breast; slippers confined by straps, and iron spurs upon his naked heels. He carries on horseback a change of clothes in a piece of red baize, with tinder, tobacco, and pipe, and a knife in his girdle. The Sertanejos women merely wear a chemise and petticoat within doors, and shoes and a white head-cloth when they leave home. Before the direct trade with England, the coarse cotton cloth of the country was worn by both sexes; and then a dress of English or Portuguese common printed cotton cost from two to three guineas!

The preceding engraving represents a Brazilian sugar-planter. He is well clothed and armed, and his horse is superbly caparisoned; the mountings are silver; and such a saddle as is here represented, when made of morocco leather and green velvet, silver-mounted, sometimes costs one hundred guineas. He travels, with his wife, in rude state, the lady being borne by negroes in an embroidered hammock, and attended by a female on foot.

It may be mentioned, that jewels and gems are worn profusely in Brazil; yet, although it is the land of the diamond, the splendid beetles of the country are worn as brooches. The coronation attire is magnificent. The crown, except the green velvet cap and the band of gold, seems one mass of diamonds; the ruff is of Spanish lace; and the green velvet robe, embroidered with gold, has, in place of the ermine in other regal attire, a dress cape of the bright yellow feathers of the toucan, which was part of the dress of the ancient caciques of the country. The imperial under-dress is of white satin, embroidered with gold, high military boots, gold spurs, and a diamond-hilted sword. At court the nobility wear the costumes of their ancestors centuries since; and in the national museum are preserved the superb feather coronets, dresses, and ornaments of the aboriginal chiefs.*

AUSTRALASIAN COSTUMES.

The costume of the English settlers in the Australian continent and islands is, as may be supposed, purely European, the London fashions being regularly transmitted thither. The only peculiarity of costume is among the native tribes, who, placed at a low condition in savage life, are dressed in the most primitive and barbarous style.

The clothing of the men of certain tribes consists of a skin cloak worn like a robe over the shoulders, and fastened round the neck, the fur part being turned inside in wet weather. Around the waist is worn a belt, not unlike an officer's sash, made of opossum fur; and attached to it are flaps of opossum skin cut in stripes, and worn before and behind; and a skin purse and tobacco pouch are carried in this belt. The jet-black hair is worn long, and well greased; but some tribes tie it to the top of the head with bunches of reeds and cockatoo feathers; and they wear the beard. The skin is tattooed in stripes, more especially among the natives of the south, which renders them terrific in appearance.

The women also wear opossum skin-cloaks; and they have one or two nets, in which they carry at their back an infant child, and burdens generally. Their hair is shorter and more curly than that of the men, and is occasionally ornamented with kangaroo teeth, affixed to their locks by wax, so as to dangle all round their heads. Both sexes are very fond of ornament, for which purpose they thickly coat their skin with fish-oil, and on high occasions smear their faces with red and white earth; on their bodies are traced the forms of birds and beasts, and the jaw-bones of fish and the tails of dogs are favourite decorations; and through the nose is often worn a feather or piece of bone. They carry spears, clubs, and other weapons, in great variety.

New Zealanders.—The natives of New Zealand, considered by Dr. Laing to be of Asiatic origin, are physically and intellectually superior to the New Hollanders, although they are yet essentially a savage people. Their personal appearance is very fine; their mean complexion is that of a European gipsy; but their faces are much disfigured by tattooing. Their chiefs have fine athletic forms; and their mat cloak tied over the right shoulder, and descending to the ankles, brings to the mind of a classical beholder the Roman toga; whilst their towering stature and perfect symmetry give even more than Roman dignity to the illusion. The young women, too, are graceful, and have expressive eyes and a profusion of long silky hair.

No two persons are tattooed exactly alike; it is generally commenced on the lips, then on the cheeks, and progress is made alike in embellishment and age. Tattooing is no sign of rank, for slaves get marked as much as chiefs; but every tribe has distinctive insignia. It is considered a mark of beauty; and some of the young natives have their bodies marked over with small dots, resembling the blue spots in a Guernsey frock. The most valued article of dress is the *pui*, a sort of cloak formed of the skins of dogs, the furs cut lengthwise, and sewed alternately white, brown, or black, to a strong matting. These garments are sent to the principal chiefs as presents. The common native mat is made of flax, scraped with the mussel-shell. Another mat is made of silken flax, interwoven with blue, red, and green baize, purchased of the Europeans: it is worked with sampler-like borders of elegant design. This is a handsome summer dress; but for warmth and comfort, the English blanket is in universal repute.

The mats are worn over the shoulders, tied across the breast; and around the waist is a similar mat, fastened with a belt. Spear-grass and sedgy cloaks are worn in wet weather. The women affect less handsome apparel than the men, but they are fond of ornament. Red ochre and shark-oil are the cosmetics used from head to foot. Both sexes wear in the ears paroquet-skins, bones, cloth, beads, teeth of friends, enemies, dogs, pigs, &c., and are generally garnished with sealing-wax: armlets, ringlets, necklets, and anklets, and fancy wood combs are worn, and nose ornaments by the men. The hair on gala-days is worn in a topknot, with sea-fowl flowers; and various paints are used.

English female garments are already much in request; and the men may be seen strutting about in a cast-off cloth jacket; and this passion has been indulged by the missionaries and colonists from England. It has been well observed—"True it is, till their European costume shall become complete (and perhaps even then), they will look more noble in their mat-cloaks; but no barbarous country was ever civilized till the people had adopted the costume of their conquerors; and the expensive and complicated dress of refinement and fashion is the taste that will lead the savage to industry and the arts of peace—not the head-dress of plastered hair and the garment made from the cloth-tree."*

New Zealand Family.

The engraving represents a family of New Zealanders, two of whom wear the fine coloured silken flax-mats and the third the blanket robe.

* Murray's Encyclopædia of Geography.

BRITISH COSTUMES.

BRITISH AND ROMAN PERIODS.

The original inhabitants of the British isles were of Celtic descent, and are believed to have brought with them the Thracian custom of *tattooing* their bodies, by squeezing certain coloured juices into figures made with the points of needles. Hence they must have resembled in appearance the tattooed islanders of the South Seas; and although personal distinction may have been the leading object of this species of ornament, it appears to have been generally adopted by barbarous half-clad tribes. Among the Southern or Belgic Britons, at the time when Julius Cæsar landed in the country (55 B. C.), the arts connected with clothing had made some advance; but in the more northern parts, the practice of living half naked, with painted and tattooed bodies, was common, and remained till a much latter period than in the south. Such fanciful decorations are supposed to have given name to the nation of Picts, from the Latin word *picti* (painted); but other authorities refer the term to different origins.

Pict.

The Roman dress does not appear to have been adopted until towards the close of the first century, when the better classes of Southern and Eastern Britain exchanged the *braccæ* for the Roman tunic, reaching to the knee, and the *toga* or mantle.

In the dress of the women there was but little change. They appear in two tunics, the one reaching to the ankles, and the other has short sleeves, and reaches about half-way down the thigh; or they resemble a round gown, or bed-gown and petticoat, though the latter, distinct from body and sleeves, is not considered to be ancient. This tunic was called in British *gwn*, and hence our word *gown*; of which we still see specimens of short dimensions worn by women of the humble classes in England, Scotland, and Wales.

ANGLO-SAXON AND DANISH PERIODS.

Whatever traces of costume may have been left in Britain by the Romans, they disappeared soon after the arrival of the Saxons in 449, who introduced fashions of apparel from northern Germany, which were copied by the Romanized British, and continued with no material change for several centuries.

The common dress of the males of the eighth century consisted, as we find, of linen shirts; tunics, or a kind of surcoat; cloaks fastened on the breast or shoulders with brooches; short drawers, met by hose, over which were worn bands of cloth, linen, or leather, in diagonal crossings. Leather sandals were worn by the early Anglo-Saxons: but afterwards the shoe became common; it was very simple, and well contrived for comfort, being open down the instep, and there, by a thong passed through holes on each side of the slit, drawn tight round the feet like a purse. A felt or woollen cap, called *hæt* (hence our modern word hat), was worn by the higher classes of Anglo-Saxons; but it is generally believed that the serfs or lower orders were without any other covering for the head than what nature had given them.

Although Sir Walter Scott, with the natural modesty of genius, disclaims pretensions to complete accuracy in the costume of the characters in his historical romances, the following portrait of Gurth, the Saxon swineherd, in "Ivanhoe," is nearly correct: "His garment was of the simplest form imaginable, being a close jacket with sleeves, composed of the tanned skin of some animal, in which the hair had been originally left, but which had been worn off in so many places that it would have been difficult to distinguish from the patches that remained to what creature the fur had belonged. This primeval vestment reached from the throat to the knee, and served at once all the purposes of body-clothing.

Gurth.—Saxon.

There was no wider opening at the collar than was necessary to admit the passage of the head, from which it may be inferred that it was put on by slipping it over the head and shoulders in the manner of a modern shirt or ancient hauberk. Sandals, bound with thongs made of boar's hide, protected the feet; and a sort of roll of thin leather was bound artificially round the legs, and, ascending above the calf, left the knees bare, like those of a Scottish Highlander. To make the jacket sit more closely to the body, it was gathered at the middle by a broad leathern belt, secured by a brass buckle, to one side of which was attached a sort of scrip, and to the other a ram's horn, accoutred with a mouth piece for the purpose of blowing. In the same belt was stuck one of those long, broad, sharp-pointed, and two-edged knives which were fabricated in the neighbourhood, and bore even at this early period the name of a Sheffield whittle The man had no covering upon his head, which was only defended by his own thick hair matted and twisted together. One part of his dress only remains, but it is too remarkable to be suppressed; it was a brass ring resembling a dog's collar, but without any opening, and soldered fast around his neck; so loose as to form no impediment to his breathing, yet so tight as to be incapable of being removed, excepting by the use of the file. On this singular gorget was engraved in Saxon characters—'Gurth. the son of Beowulf, is the born thrall of Cedric of Rotherwood.' "

The Anglo-Saxon females wore under-tunics, with sleeves; another inner garment, the linen kirtle; and over these the long full gown, with loose sleeves. The head-dress is a hood or veil, which, falling down before, was wrapped round the neck and breast; and this was the only head-covering of the women when abroad. The hair was carefully dressed, and golden head-bands, half-circles, neck-bands, and bracelets were worn; with ear-rings, necklaces, crosses, and jewelled ornaments too numerous to describe. The hose and shoes resembled those worn by the men. The long sleeves of the gown or the mantle, drawn over the hands, served as gloves, which were not worn before the eleventh century. All classes used on their cheeks a red cosmetic, so that the art of painting the face is not a creature of refinement. The general colours of the dresses were red, blue, and green, sometimes embroidered in patterns; and gold tissue and cloth of gold were worn by princesses and nuns; and the latter embroidered robes, sandals, tunics, vests, cloaks, and veils of enormous cost—for pearls and precious jewels were interwrought with the materials, and sometimes three years were spent in working one garment; and their dresses were often lined with sable, beaver, and fox furs, or the skins of lambs or cats.

The Danes originally wore the dresses of sailors, the general colour of which was black; but when enriched by piracy, they soon became wearers of scarlet, purple, and fine linen, and in England outshone the Saxons; they were effeminately gay in their dress, and the length and beauty of their hair. The Anglo-Danish kings appear principally to have worn a red habit, embroidered with gold, and a purple robe; and their mantles were richly embroidered with gold and pearls. Upon a manuscript of the reign of Canute, he is, however, represented in a Saxon dress, the mantle being richly ornamented with cords or ribbons, and tassels; and he wears shoes and stockings with embroidered tops. His body, when discovered in Winchester Cathedral in the year 1766, was decorated with gold and silver bands, and a richly jewelled ring; bracelets were worn by all persons of rank, and invariably buried with them. Canute's queen wore the tunic, mantle, and long veil. The materials of the Danish dresses were cloths, silks, or velvets, procured either from Spain or the Mediterranean, by plundering the Moors.

From the Danish Invasion to the Norman Conquest there were few changes in costume, if we except the imitation of Norman-French fashions in the reign of the Confessor, by shortening the tunics, clipping the hair, and shaving the beard, but leaving the upper lip unshorn. Tattooing was practised even to this time, although it had been forbidden by a law passed in the eighth century.

ELEVENTH TILL FOURTEENTH CENTURY.

The Norman Conquest introduced a greater degree of taste and splendour into British costume; but the dress of the common order of people remained long of a comparatively rude fashion, partly from the effect of caste and sumptuary laws, which prevented any decided change. As time advanced, the materials of dress improved, but the cut was little different, and, till this day, we have a sample of the Anglo-Saxon tunic in the *smock-frock*, a species of overall linen shirt, very generally worn by the peasantry of England. The *blouse*, a linen shirt of blue instead of white, which is now universally worn by workmen in France, Switzerland, the Low Countries, and part of Germany, had an equally early origin.

In the reign of Rufus many costly changes were made in dress; the tunics were lengthened, and the undergarments even trailed upon the ground. The sleeves were also drawn over the whole hand, although gloves were worn, at least by the higher classes. The cloth mantles were lined with rich furs; and one lined with black sables and white spots cost £100. Extravagantly peaked-toed boots and shoes were worn; and a court coxcomb, who caused the points of his shoes to curl like a ram's horn, received the name of *De Cornibus*, or with the horns. The hair, which had been shorn from the back of the head as well as the face by the Norman-French, was now again worn long; and the courtiers in Stephen's reign even wore artificial hair, so that wigs may date from the twelfth century. The long beard also reappeared in the reign of Henry I.

The monumental effigies of Henry II. and his queen Eleanor, and Richard I. and his queen Berengaria, in the abbey of *Fontevraud*, Normandy, are undoubted examples of the regal costume of the latter half of the twelfth century, inasmuch as they represented the sovereigns sculptured in their habits, as if they still lay in state. The robes of the two kings are two tunics (the upper called a *Dalmatica*), with rich waist-belts, and over them mantles superbly embroidered; that of Henry being fastened by a *fibula* or brooch on the right shoulder, and that of Richard fastened upon the breast. The gloves are jewelled on the back of the hand, and the boots have spurs without rowels; both monarchs wear their crowns, although that of Henry is much mutilated. These royal habits represent also the costume of the nobles at the same period. Henry introduced the fashion of indenting the borders of dresses, and the short cloak of Anjou, whence he was called Court Manteau (curt or short-mantle). A mantle of Richard is also described as nearly covered with solid silver half-moons and orbs.

In the course of the thirteenth century, the sumptuousness of apparel increased; rich silks woven with gold, embroidered and fringed, and French velvets, were much used; and a rich stuff manufactured in the Cyclades was made into a dalmatica or super-tunic, called Cyclas, which was worn by both sexes. The furs of ermines, martens, squirrels, the vair, and the minevair or minever, were added to the list of furs for winter garments.

The general male dress consisted of the cyclas just mentioned; and the tunic open as high as the waist, to show the drawers; with chausses or stockings. The principal novelty is the super-totus, or over-all, worn like the mantle or cloak, and consisting of a kind of large-sleeved shirt, with a capuchon. Long-toed shoes and boots were resumed, with embroidery and colours. The caps or bonnets, and hats, now resemble our modern beaver.

The female costume differed in fashion and name, rather than in form, from those of the twelfth century. The veils were of gold tissue or superbly embroidered silk, and over them was worn a diadem, circlet, or garland, or a cap-like coronet, by persons of rank, and sometimes a round hat. The head-dresses were very numerous: the wimple covered the head and shoulders, and was fastened under the chin; and the hair was worn in a net or caul of gold thread, which continued in fashion for the next two centuries. A very ugly kind of wimple called the gorget, appeared in the thirteenth century; it was a neck-covering, poked up by pins above the ears. The long robe was also worn trailing on the ground; the cloth stockings were embroidered with gold; and trinkets of gold, as buckles, rings, earrings, and chaplets, and jewels, were much worn; and sometimes flowers, fresh from the garden or field, were entwined round the head as a relief to artificial decoration. In this century, too, we first meet with the surcol, which Strutt calls a corset, boddice, or stays, worn over the rest of the dress, which enlarged in the skirt, and spread into a train; it was made high in the neck and had long tight sleeves.

The dress of the working-classes may be supposed to have been improved about this period by the introduction of the worsted manufacture; it is stated to have been brought to the country by a colony of Flemings, who, in the reign of Henry II. settled at *Worsted*, a village in Norfolk, and hence the name of the fabric.*

We now come to the fourteenth century, in which Edward III. and his queen Philippa led the fashion in apparel. As seen from the effigy on his tomb, the costume of Edward is characterized by its dignified simplicity. The dalmatica is low in the neck, falls in straight folds to the feet, and is open in front nearly half its height, being embroidered at the edges of the aperture; the sleeves of the under tunic have at each wrist a row of buttons, a fashion of the reign of Henry III.; the mantle, embroidered at the edges, is worn over the shoulders, and confined by a jewelled band across the breast; the shoes or buskins are also embroidered, and the hair and beard are patriarchal; the crown has been removed or lost.

* See note to Hallam's History of the Middle Ages.

The effigy of Queen Philippa, also at Westminster, is equally distinguished by its simplicity; the skirt is long and full, the boddice closely fitting, the waist-belt jewelled, and the mantle ornamented on the shoulders, and confined by a diagonal band across the breast; and upon the head is a low crown, jewelled, and from it depends a kind of draped ornament half way down the check. The costume of the nobles in this reign was, however, far less simple than that of the sovereign. In place of the long robe and tunic was worn a close-fitting body-garment (jupon) superbly embroidered, reaching to the middle of the thigh, and confined across the hips by a splendid belt; from the sleeves of this garment hung long slips of cloth, called *tirippes* (tippets), and over the whole was occasionally worn a long mantle fastened by buttons upon the right shoulder. This dress was, however, the extreme of foppery. The caps were of various shapes, and among them we find the knight's *chapeau*, nearly in the form now used in heraldry. Beaver hats are also worn; but the greatest novelty was a single feather in the front of the cap. The golden chaplets, by the addition of leaves, now assumed the form of coronets. The gay tournaments of this period led to the introduction of many costly foreign fashions; so that, in 1363, expensive dress, beyond the income or rank of the wearer, was forbidden by law; furs of ermine, and pearl ornaments (except for head-dress), were forbidden to all but the royal family and the wealthiest nobles; cloths of gold and silver were permitted only to the next in fortune; and persons of small income were forbidden to wear silks, embroidery, or trinkets.* But the ladies dressed still more sumptuously, as in the engraving, where the gown fits close in the boddice, and the train is so long in the front as to be held up, and thus display the embroidered under-dress; the sleeveless jacket worn over the gown is also embroidered and trimmed with fur; the hair is worn long, and the cap is low, and resembles a coronet. Tippets from short sleeves, and the jupon, were also worn by ladies as well as by gentlemen; and both sexes wore daggers stuck through pouches in their rich girdles. The particoloured tunics worn by the ladies at tournaments were likewise very striking, and greatly encouraged the fopperies of the time. One of the additions to the military costume of this period was the knight's cap and crest.†

Lady of 14th century.

In this reign mourning habits appear to have been first worn, the colours being black and brown.

The reign of Richard II. must have been the high carnival of coxcombery. The sovereign himself, according to Holinshed, had a coat or robe which cost 30,000 merks. Particoloured dresses were universally worn, and even the hose were of two colours, so as to render the term, *a pair*, inapplicable: the colours of the king and his court were white and red. Men and women alike wore hoods set with jewels; and their tippets were jagged, and reached to the heels; and the long-peaked shoes, called *crackowes* (from Cracow, in Poland), were fastened to the knees with gold and silver chains. The engraving shows a gentleman of this period, with shoes and hose all in one, the mantle cut into the shape of leaves at the edges, a belt and pouch, and a fantastically-turbaned head-covering. Chaucer has left us the costume of several ranks at this period: his squire wears a short gown, "with sleeves long and wide;" his yeoman "a coat and hood of grene;" his merchant many colours, with a forked beard, and a "Flaunderish bever hat," and clasped boots; the reeve or steward a long surcoat and rusty sword, his beard and head shaven and shorn; the miller wore a white coat and blue hood, a sword and buckler, and red cloth holiday-hose; and the hats, caps, and bonnets of all classes were very fantastical. Knives, ornamented with silver, and purses, were worn by most classes in their girdles; and shoulder-belts, with bells, were a mark of rank. Liveries are also now mentioned as worn by substantial artisans as well as by menial servants; but the ploughman appears only in a tabard or sleeveless coat, and the mechanic in a tunic. The hair was worn long and curled, and the beard forked.

Gentleman of 14th Century.

In the female costume of this reign the fantastic particoloured dresses were retained, with the embroidered jupons and kirtles, hip-kirdles, and long tippets from the elbow; and the *surcol* or external corset, faced with fur, and terminating in a train sometimes so long as to be carried over the arm, or shorter, opened up the side, and bordered with ermine. The gowns, mantles, and other garments, were emblazoned with arms, or they bore sentimental mottoes; and the royal badge of a white hart, chained, was much worn at tournaments and jousts. The head-dress continued as in the preceding reign. The attire of the carpenter's wife in the "Canterbury Tales," with a silk girdle and head-fillet, and brooch, indicates the condition of this class of females.

FIFTEENTH CENTURY.

Whatever may have been the foppery of the thirteenth and fourteenth centuries, they appear to have been exceeded by the absurdities of costume in the fifteenth century, when it was difficult by dress to distinguish one sex from the other. These fantasies were mostly borrowed from France, whose fashions now began exclusively to guide the taste of the English, and have continued to do so until the present time.

The effigy of Henry IV. is remarkably splendid, the upper tunic, girdle, and mantle being embroidered at the edges, and the latter connected by a richly-jewelled band across the chest, besides cords and tassels. The beard and mustachios are worn, but the poll is shaven; the

* Few enactments have been more erroneous in principle, or in operation more detrimental to national prosperity, than the sumptuary laws, by which, in the earlier ages of our history, the legislature so vainly, and, it may be added, so unjustly endeavoured to prevent the various ranks of men from enjoying the fruits of their industry or of their patrimonial possessions. "There is hardly," says Mr. M'Culloch, "a single article among those that are now reckoned most indispensable to existence which has not been denounced, at its introduction, as a useless superfluity, or being in some way injurious. Few articles of clothing are at present considered more indispensable than shirts; but there are instances on record of individuals being put in the pillory for presuming to wear so expensive and unnecessary a luxury!" Mr. Hallam observes, that the sumptuary laws, enacted in France and England during the fourteenth century by the governments, to restrain the extravagance of their subjects, may well justify the severe indignation which Adam Smith has poured upon all such interference with private expenditure. "The kings of France and England were undoubtedly more egregious spendthrifts than any others in their dominions, and contributed far more, by their love of pageantry, to excite a taste for dissipation in their people, than by their ordinances to repress it."

† The origin of the "Prince of Wales' Feathers" (a triple ostrich plume) was long referred to the Black Prince adopting them from the helmet of the king of Bohemia; next, they were stated to have been assumed from that monarch's banner; but there is still greater reason to believe the plume to have been but a fanciful badge chosen when feathers were first used as heraldic crests upon helmets.

crown is supposed to be an imitation of the magnificent "Harry Crown," broken up and pawned by Henry V. Early in this reign, too, the sumptuary laws were revived not only as to materials but fashions; so that garments, cut or slashed in devices, were forbidden, but with little effect. In this reign appeared the collar of SS (or Esses), which Meyrick considers to have been taken from the initial letter of Henry's motto, "Souveraine." The annexed engraving represents a gentleman of this reign in shortened tunic, buttoned in front, with girdle, large flapping sleeves, tight hose, peaked shoes, and head-cloth, with long end hanging over the left shoulder, and tucked in the girdle. The next cut shows a labourer of the same period in the ordinary woollen dress, with hood and tippet, hose, and leather boots laced in front. The female costume in this reign differed from that of the preceding principally in a kerchief or veil covering the head-dress, and assuming a square form.

Gentleman of 15th century.

Labourer of 15th century.

In the short reign of Henry V., there were few changes in the civil costume: cloaks of scarlet cloth or camlet, and pieces of fur, are novel outer garments. Feathers were worn in the helmets, and the bascinet took the shape of the head behind: for the jupon or surcoat was substituted a skirt of horizontal steel bands, and large sleeves of cloth or silk were worn over the armour, and the two-handed sword now first appeared.

The confused costume in the reign of Henry VI. baffles classification, more especially the odd-shaped caps, hats, and bonnets, in which a single feather was sometimes worn. The boots or galoches, reaching half way up the thigh, the short boots or buskins, and the high-fronted shoes, had very long toes, which, in the next reign, reached half a foot. The state robes were lined and trimmed with furs or had only caps or collars of ermine, with bars according to the rank of the wearer. The mantle of the Order of the Garter about this period was first made of velvet, and lined with white damask or satin. Silk was worn over armour, and the *salade* or *sallet* head-piece, projecting behind, was introduced; and the armour was richly ornamented. Gowns, with long and heavy trains, continued to be worn by ladies, whose most fantastic change was the heart-shaped head-dress of great size:* turbans of the Turkish form were also worn.

Edward IV. on his seal, wears a tunic, dalmatica, and mantle, deep ermine cape, and high-arched or imperial crown. The civil costume was very absurd; and jackets and doublets were worn so short as to call forth a law in 1463 ordering them to be lengthened behind; the sleeves were slit, so as to show the fine white linen shirt, and the shoulders were padded; the men wore their hair very long, and their bonnets either very high or covering simply the crown; the hose were tight, and the boots and shoes of all patterns and lengths. Gold chains were generally worn; and even boys strutted in velvet, silk, and satin. All this extravagance was attempted to be checked by law, but with little effect. In armour, the principal novelty was the halbert. In the female costume, trains of gowns were partially discontinued for broad fur or velvet borders, and the silk girdles widened, and were more richly ornamented. The boddice, laced in front over a stomacher, now first appeared. But the greatest eccentricity was the lofty steeple head-dress, shown in the annexed portrait; this consisted of a roll of linen covered with fine lawn, which hung to the ground, or was mostly tucked under the arm.* Caps, with large wings or lappets on each side, were also much worn at this period.

Lady of 15th century.

Richard III., according to his wardrober's books, was a right royal fop, for we find him wearing a blue cloth-of-gold doublet and stomacher, "wrought with netts and pyne-apples," and crimson and purple-velvet robes, embroidered and furred, and crimson satin hose, and tissue cloth-of-gold shoes, at his coronation. The nobles in this reign had their hose tied by points to the doublet, which was sometimes worn open, but laced like a boddice; and over it was worn a long or short gown, the former hanging loose, and the latter plaited before and behind, and girded about the waist; and both gown and doublet were slashed. The general head-dress was a closely-fitting cap or *bonet* (bonnet), with a single feather in it; and scarlet hats and hoods were worn. The boots had very long-pointed toes, and reached to the middle of the thigh.

In this reign plate-armour reached its highest perfection; it was elaborately ornamented and inlaid with gold, and, with the arms, it bore religious and other mottoes; and the knee and elbow pieces were fan-shaped, and curiously wrought. Richard wore his crown of ornament in the field of Bosworth, as Henry V. had done at Agincourt. The mode of putting on a suit of armour may be here described: the knight commenced with his feet, and proceeded thus:—"1, His sabatyns, or steel shoes; 2, the greaves, or shin-pieces; 3, the cuisses, or thigh-pieces; 4, the breech of mail; 5, the tuilettes, or overlapping pieces under the waist; 6, the cuirass, or breastplate; 7, the covers for the arms, or vambraces; 8, the rerebraces, or covering for the remaining part of the arm or shoulder; 9, the gauntlets; 10, then the dagger was put on; 11, the short sword; 12, the cloak, which was worn over the armour; 13, the bascinet; 14, the long sword; 15, the pernonbel, held in the left hand; 16, the shield."† The knight was then armed *cap-à-pié*.

In the female costume, the chief novelty is a head-dress of embroidered stuff or gold net, projecting from the back of the head, and a stiffened kerchief over it, spreading out like wings.

Hitherto, the authorities for costume have been illuminated manuscripts, tapestry, and monumental effigies,

* It is related that Isabella of Bavaria, Queen of Charles VI. of France, carried this fashion to such an extent as to have the doorways of the palace of Vincennes altered to admit ladies when in full dress; but we think, with M. Planché, that the above anecdote, if authentic, relates to the steeple head-dress, to be mentioned presently.

* This extraordinary head-dress resembles the *tantoora* worn at the present time in Syria. M. Planché considers that the peasantry of Normandy "to this day wear the identical steeple caps with the butterfly wings, that, 300 years ago, towered upon the heads of the gentle dames of London and Paris."—*History of British Costume*, p. 207.

† Sir Samuel Meyrick.

in which there is often perplexing indistinctness. At this period painting comes to our aid; and the portraits by Holbein are the best illustrations of the costume of the two succeeding reigns, the minute execution of this great painter being well shown in the embroidered dresses of his time. Of Henry VII., however, we find a portrait of earlier date than Holbein's time, from a beautiful painting on vellum, in which the king wears a richly-embroidered doublet, with a jewelled border, low in the neck, beneath a large mantle with a fur cape; the gold neck-chain is massive; the hair is in long ringlets, surmounted by a close cap, with wing-like projections at the sides.* The male costume of the wealthier classes in this reign consisted of a fine shirt of long lawn, embroidered with silk round the collar and wristbands; and such a shirt, that belonged to the eldest born son of Henry VII., is in the possession of M. Gage, F. S. A. The sleeves of the doublet were slashed at the elbow, as in the reign of Edward IV.; or they were in two or more pieces, fastened at the shoulders and elbows with laces or points, through which the shirt protruded. The doublet was laced over a stomacher and petticoat, the male costume thus resembling that of the females in name as well as form. The outer garment was a long coat or gown, with loose hanging sleeves, and a broad turn-over collar of velvet or fur. The long hose were differently coloured in the upper and lower portions, and in the former slashed or puffed; the shoes were absurdly long and broad-toed, and high boots were worn for riding. In the head coverings there was great variety. The hoods were abandoned to official habits, and instead were worn broad felt hats or caps, and bonnets of velvet or fur profusely decked with ostrich feathers; or the large plumed cap was slung at the back, and a smaller cap of velvet or gold net worn on the head. The knave of our playing cards has a cap peculiar to this period: the hair was worn as long as in the reign of Henry I.

At the latter part of this century military costume had reached the highest degree of splendour of which it was capable; and the disuse of the surcoat, and the transfer of its armorial emblazonry, in relief or engraving, to the polished steel, had introduced great variety of decoration. Every visiter to the Tower of London must remember the famous suit of armour which unquestionably belonged to Henry VII.; and nothing can exceed its superb beauty, covered as it is with engraving, and accompanied by a complete harness of steel for the charger on which it is mounted. The puckered skirts appear no longer in cloth or velvet but in steel; *pauldrons* of the same material protect the shoulders; the whole frame is impervious to the lance point; and the plumed helmet completes the panoply: besides the long sword, the thin-bladed dagger of the time hangs sheathed at the girdle, on the right side. The disuse of the surcoat in this reign was doubtless to show the splendid armour, which was not only ribbed and engraved, but fluted. The halberd became the common weapon; and the hand-gun or cannon, by the addition of a rude lock with a cock, borrowed from the cross-bow, became the *arc-a-bouche* or *arquebus*.

In these distracted times party-colours were worn. Thus, the family colours of the House of Lancaster were white and red; those of York, purple and blue; and those of Tudor, white and green. Buttons also bore partizan figures; and in 1833 there were found, in excavating for the New Hungerford Market, in London, two linked cloak-buttons of silver, one bearing a bust with a diadem, and a bandeau of roses, the robe fastened with a rose brooch or jewel, and on each side of the bust a rose springing up; whence these buttons are presumed to have been made and worn in honour of Elizabeth of York, whose union with Henry VII. terminated the Wars of the Roses.

The female costume of the reign of Henry VII. is distinguished by the square cut of the boddice in the neck, and embroidered and jewelled stomachers, belts, and girdles hanging in front nearly to the feet; the sleeves were large and full, and when confined at the wrist, resembled "the bishops' sleeves" imitated in England, from the French, a few years since. These sleeves were slashed, divided, and joined like those of the men. The head-dresses were close caps and cauls, from beneath which the hair hung down to the waist; and several kinds of capuchons were worn. In the dress of the humbler classes we find mentioned a "furred flocket and gray russet rocket," "kirtle bristow red," "blanket hose," "Lincoln green," &c.

At the close of this century the mourning habits had become so sumptuous as to be limited by law; the principle article being a barb or veil, used at funerals, which was tied on above the chin by duchesses and countesses, and lower by all other ranks.

Throughout the above period the principal material of the clothing of the middle classes must have been abundant; for in the reign of Edward III., our woollen manufacture almost rivalled that of the Flemings, and our exports to the continent were very large; there appears however, to have been little or no linen made at this period in England.

SIXTEENTH CENTURY.

Few changes of costume occur in this century until after the accession of Henry VIII., when the petticoat was laid aside; and as fashion delights in extremes, there was substituted the tight hose, or *trouses*, closely resembling the Norman chausses. The costume of Henry and of the noblemen and gentlemen of his time, appears to have been a jacket or doublet, with full skirts, and sleeves to the wrist, with ruffs or ruffles, and over it a short but full coat or cloak, with large hanging sleeves, and a wide fur collar; stockings and broad-toed shoes; and a large-brimmed cap edged with ostrich feather. Henry's wardrobe comprised coats of every length, and among them occurs the *cassock*, of German origin, short in the waist, and reaching to the knee, having sleeves to the elbow, and thence showing the shirt: this garment was ornamented with strips or borders of cloth, silk or velvet, of different colours, or of gold lace or embroidery, and gold buttons. Hall, the chronicler, describes several of Henry's superb dresses, and among them a *frocke*, or coat of velvet, embroidered all over with gold of damask, the sleeves and breest cut and lined with cloth of gold, and tied together "with great buttons of diamonds, rubies, and orient pearls." The cloaks and mantles were of corresponding magnificence. The shirts were pinched or plaited, and embroidered with gold, silver, or silk. The term *hose* continued to be applied to the entire vestment, from the waist to the feet, throughout this century: the material is more distinctly stated, for Henry wore knit silk, as well as cloth hose; the precise period of the separation of the hose into breeches and stockings is not so clear as the derivation of the latter term from the "*stockying* of hose," "that is, adding the lower part that covered the legs and feet to that which was fastened by points to the doublet,"* and was called the *stocks*. The shoes and buskins were of the German fashion, very broad at the toes, and of velvet and satin, slashed and puffed. The hats, caps, and bonnets, were of almost endless forms. We find in Henry's wardrobe accounts hats of green velvet, and caps of orange, yellow, and green; his favourite bonnet, and, indeed, that of the time, is seen in the portraits of Henry, by Holbein. The Milan caps and

* Engraved from "the Sutherland Clarendon," as the frontispiece to M. Planché's "History of British Costume."

* Planché's History of British Costume, p. 256.

bonnets, of cloth or velvet, were worn placed on the side of the head, profusely ornamented with feathers. The bonnet with an embattled border was also worn; but the chaperon or hood was almost confined to official personages. The cardinal's hat may be mentioned here: it was of a red colour, low, circular-crowned, and had a much broader brim than is represented in sculpture.

Henry passed sumptuary laws, directing that cloth of gold and tissue should be used only for dukes and marquisses, and that purple should be kept for the royal family. Earls might use embroidery, and commoners of distinction silks and velvets; and it was even thought necessary to restrict the commonalty and serving-men to cloth of a certain price, and lamb's fur, and to forbid them wearing any ornaments, or even buttons, save the badge of their lord or master. The king likewise forbade his courtiers wearing long hair, according to the general fashion, and made them poll their heads, which led to the introduction of the peruke. This change rendered short hair fashionable; and as the king grew corpulent, the doublet and breeches were puffed out and wadded by his courtiers and attendants, to make them as bulky as himself.

One of the principal events of this reign, illustrative of costume, was the famous Tournament of the Field of Cloth of Gold, at which Henry VIII. and Francis I., and their suites, vied more in splendour of attire than in prowess of arms; and the splendour of their dresses has almost exhausted the descriptive powers of Hall, who has minutely chronicled this "most magnificent spectacle that Europe ever beheld." Its mighty artificer was Wolsey, who was most gorgeously habited, his very shoes gleaming with diamonds, and the crimson velvet saddle-cloth of his horse glittering with burnished gold. The brilliancy of the armour, and the elaborate beauty of the costume of the queens and courtly dames, well became this sunset of chivalry, at which even citizens and city wives disported their richest silks and their heaviest chains.

With the female costume of this reign we are familiarized by the portraits of Henry's queens, who appear to have been sumptuously attired in cloth of gold, brocade, velvet, and other costly materials; and they wore diamonds, gold neck-chains, and girdles, and jewelled ornaments in profusion. The gowns of the nobility were open in front to the waist, so as to show the petticoat; and above was worn a waistcoat similar to that of the men, superbly embroidered. Another novelty was the partlet, covering the neck and throat like a habit shirt. It was made of lawn, embroidered with gold. The ladies' sleeves, like those of the men's dresses, were distinct from the gown or waistcoat, to which they were tagged. They were mostly of satin, quilted and variegated with gold, and had buttons of pearls and gold at the wrist. This fashion must have added greatly to the variety of the costume, for several pairs of sleeves might be worn in turn with the same body-dress. The masques in this reign were very splendid; and in the report of the dresses worn at one of them, are mentioned "demy sleeves, naked down from the elbows," which M. Planché considers to have been "the first appearance of bare arms since the time of the ancient Britons." Gloves were not unknown, for Henry left a pair to one of the executors of his will. They were sometimes finely perfumed, and brought from Spain and Italy as presents. In this and the preceding reign the head-dresses assumed a different character, having long lappets or ear-pieces hanging down below the shoulders, and when made of velvet studded with pearls, jewels, and gold, they were truly superb. Three-cornered caps of minever were also worn throughout the reign; and the close-fitting cap reaching to the ears, and known as "Mary Queen of Scots' cap," was first worn about this period. The ladies' hunting-dress differed but little from the riding-habit of the present day; across it was usually slung, from the right shoulder to the left side, a horn resembling a bugle.

In this reign *pins* were first brought from France, and used by Catherine Howard, before which time the different parts of the dress were kept together by ribbons and loopholes, laces with points and tags, clasps, hooks-and-eyes, and skewers of brass, silver, and gold; but the poorer classes used the natural thorn for the above purpose.

The dress of the middle ranks in this reign may be seen in prints of the time: plain russet coats, and white kersey sloppes, or breeches, with stockings of the same pieces, were the ordinary suit; and the London apprentices wore blue cloaks in summer, and gowns of the same colour in winter, as badges of servitude; for this appears to have been the age of domestic distinctions—the relics of the feudalism of the middle ages. The women wore sheep, russet, or long woollen gowns, worsted kirtles (hereafter called *petticoats*), and white caps and aprons; and milk-white underlinen came into general wear. The engraving shows a man and woman in the ordinary dress of this period.

Man and Woman of 16th century.

The principal novelty of the reigns of Edward VI. and Mary was the flat round bonnet or cap, of plain velvet or cloth, worn on one side of the head, and decorated with a jewel and single ostrich feather. The bonnet itself is preserved in the caps worn at the present day by the boys of Christ's Hospital; and their blue coat and yellow stockings are such as were worn by the London apprentices at the date of the foundation of the hospital by the youthful Edward. The gown of the wealthier classes was furred with sables in front and round the broad sleeves. Philip, on his marriage with Mary, brought into England a richer style of dress for the men, particularly the close ruff; the doublet, which fitted exactly under the chin, and the short Spanish cloak—all of which remained for a considerable time in fashion. The preposterously large stocks, or trunk hose, continued to be worn, but the broad-toed shoes were discarded. The armour continued nearly the same as in the preceding reign. To female costume the chief addition was the *fardingale*, an immense hooped petticoat, introduced from Spain under Queen Mary. The entire dress was worn very close, so as to conceal the person as much as possible.

Queen Elizabeth's fondness for dress is proverbial, and she is stated to have left three thousand different habits in her wardrobe. This great number is explained by the royal affectation of wearing by turns the costume of all the nations of Europe, which may be traced to the use of foreign materials made up by foreigners. Bohun in his character of Elizabeth, tells us that "when she appeared in public she was richly adorned with the most valuable clothes, set off again with much gold and jewels of inestimable value; and on such occasions she ever wore high shoes, that she might seem taller than indeed she was. The first day of the Parliament she would appear in a robe embroidered with pearls." Hentzner gives a less flattering portrait of the queen, in her 65th year: "Her face oblong, fair, but wrinkled. She had in her ears two pearls, with drops; she wore false hair, and that red, and upon her head she had a small crown. She was dressed in white silk, bordered with pearls of the size of beans, and over it a mantle of black silk, shot with silver threads. Her train was very long. Instead of a chain she had an oblong collar of gold and jewels."

But the glory of the Elizabethan era of female costume, as well as its most remarkable characteristic in the sixteenth century, was the *ruff* of plaited linen or cambric, which took the place of the partlet, and rose from the front of the shoulders behind the head nearly to its full height: from the bosom descended a huge stomacher, on each side of which projected the immense fardingale. In this characteristic costume Elizabeth went to St. Paul's Cathedral to return thanks for the defeat of the Spanish Armada; though, besides the magnificent ruff, the queen wore a mantle with a large wing-like collar, her hair intertwined with pearls, large pendant jewels on the neck, and a superb lattice-work of pearls over the entire dress.

But the ruff must be further noticed: no sooner had its material been changed from Holland to lawn or cambric, than a difficulty arose as to starching or stiffening it, instead of the clumsy mode of supporting it by poking-sticks of ivory, wood, or gilt metal. At length the art of starching was brought from Flanders, and taught in London for a fee of four or five pounds. The fashion next lay in the colour of the starch, of which there were five varieties. Stubbs assailed these "spiders' webbs" of ruffs, some of which were "clogged with gold, silver, or silk lace," and "speckled and sparkled with the sun, the moon, and the stars," and either pinned up to the ears, or hanging over the shoulders like flags or windmill sails. The same writer describes the gowns of silk, velvet, *grograin*, taffeta, or fine cloth; of "fashions changing with the moon," with sleeves trailing on the ground, or "cast over the shoulder like cows' tails," or short sleeves tied with "love knots" of ribbon.

Stockings, which we find mentioned as foreign rarities in the wardrobe accounts of Henry VIII. and Edward VI., became common of home manufacture in the reign of Elizabeth. In the third year, a pair of black knit silk stockings made in England was presented to her majesty, who was so pleased with the article that she would never after wear cloth hose. This resolution has been attributed to Elizabeth's desire to encourage English manufactures by her own example, and may be taken as some set-off to her extreme fondness for foreign materials and fashions of dress. Soon after this, a city apprentice having borrowed a pair of knit worsted stockings brought from Mantua, made a pair like them, which he presented to the Earl of Pembroke; and these are the first worsted stockings known to have been knit in England. Mary Queen of Scots, at her execution, wore stockings of blue worsted, clocked and topped with silver, and under them another pair of white; and the stockings of this time generally consisted of silk, jarnsey, worsted, crewel, fine yarn, thread, or cloth, of all colours, and with clocks, open seams, &c. The invention of the stocking-frame, by Lee, at Calverton, near Nottingham, in 1599, must have brought stockings into general use: he or his brother is said to have worked for Queen Elizabeth; but he was driven by the jealousy of the other stocking manufacturers into France, where he died of a broken heart—an end by no means uncommon in the lives of inventors. The garters of this period were very costly, sometimes of gold and silver, and £4 or £5 a pair; they are presumed to have been worn by ladies since the time of Edward II., but they must not be confounded with the leg bandages of an earlier date. The ladies wore "corked shoes, prisnets, pantoffles, or slippers," which raised them two inches or more from the ground: they were made of black, white, green, or yellow velvet, or Spanish and English leather, embroidered with gold, silver or silk, and shaped after the right and left foot, like the Anglo-Saxon sandal. The Elizabethan head-dresses were French hoods, hats, caps, kerchiefs, cauls of net-wire, and lattice caps, the latter, as well as an ermine bonnet, being forbidden by law to all but "gentlewomen born, having arms." In Elizabeth's jewel-box is a long list of wigs, or rather head-dresses, among which are cauls of hair set with seed-pearl and gold buttons. The hair was curled, frizzled, and crisped, and under-propped with pins and wires into the most fantastic forms. The finger-rings, ear-rings, bracelets, and other jewelry, were very splendid: velvet masks and pocket looking-glasses were carried by fashionables, with fans of ostrich feathers set in gold, silver, or ivory handles, the latter introduced from Italy, and used by both sexes.

The male costume in Elizabeth's reign was the large trunk hose, long-waisted doublet, short-cloak, hat, band and feather, shoes with roses, and the large ruff; but the great breeches, "stuffed with hair like woolsacks," after the separation of the hose into this garment and stockings, appear to have been worn throughout the reign: they were made of silk, velvet, satin, and damask. The doublets were still more costly, and quilted and stuffed, "slashed, jagged, pinched, and laced;"* and over these were worn coats and jerkins in as many varieties as there are days in the year. The cloaks were of the Spanish, French, and Dutch cuts, of cloth, silk velvet, and taffeta of all colours, trimmed with gold, silver and silk-lace and glass bugles, inside and outside equally superb. The stockings, shoes, slippers, and ruffs, resembled those of the ladies. Nor must the rapier, or tuck, be forgotten; and some coxcombs, having introduced this long sword with a high ruff, approaching the royal standard, the queen became jealous, and appointed officers to break those rapiers and clip those ruffs which were beyond a certain length and height. Hats first became common in this reign: they were of all shapes, but the most curious was the steeple-crowned; others were flat and broad, like the battlements of a house; and others with round crowns, and bands of all colours, and ornamented with huge feathers, and brooches, clasps, and jewels of great value. These hats were of velvet, taffeta, or sarsenet, beaver hats being then very expensive, and "fetched from beyond sea." Caps of wool were worn not by choice but compulsion, by a law passed "in behalf of the trade of cappers;" and this led to feuds among the wearers of black and blue caps. The numerous fashions of wearing the hair were assailed by Stubbs, who, after saying there are no finer fellows under the sun than barbers, speaks of the French, Spanish, Dutch, and Italian cuts, new and old cuts, gentlemen's, common, court, and country cuts.

Elizabeth's passion for dress was fully imitated by her courtiers, as preserved to us in the pages of historians and on the canvas of painters. The best portrait of the gallant Raleigh represents him in a white satin doublet embroidered with pearls; and his dress in the Tower was a velvet cap, laced, and a rich gown and trunk-hose. His plush cloak is preserved in the well-known anecdote of his throwing it off for the queen to walk on.

In taking leave of the British costume of the sixteenth century, we may observe that its splendour was almost entirely borrowed from France, "that country which has since given laws in dress to nearly all Europe."

SEVENTEENTH CENTURY.

The changes of costume in this century were not so much in forms as in fashions of habits. The male dress continued nearly the same as in the latter portion of

* This doublet formed a point in front, hanging over the girdle; and, allowing for a little caricature, "is to this day," says M. Planché, "the body-dress of our old and inestimable friend Punch, whose wardrobe, of Italian origin, dates as nearly as possible from this identical period."—*History British Costume.*

Elizabeth's reign. Under James I. it was somewhat more decidedly Spanish, and was chiefly worn of black, with large trunk hose, Spanish rapier, a hat with a conical crown, and a band with a jewel, the better to show which feathers seem to have been discarded. The trunk, breeches, and doublets, appear to have been increased in size from the timid disposition of the sovereign, who had his garments additionally quilted for fear of stilettos. James, in his *braveties*, dressed immoderately, though only in keeping with the sumptuous style of the furniture and house-decoration of the period; and in some instances he scarcely left his nobles the means of "keeping up appearances." Henry, Prince of Wales, must have drawn largely from his father's privy purse, for we find his wardrobe purchases in one year to have been thirty-eight suits of velvet and satin, crimson, green, carnation, orange, and watchet, ash and liver-colour, black and tawny, pink, rose, hair, and deer colour, laid over with Naples silk, gold parchment, silver and "gollowne" lace; the cost of all which was considerably above £2000, then no trifling sum: he had also thirteen cloaks, at the rate of £50 each; gloves wrought with gold and silver at £3 a pair; stockings at £3: and every-day garters at £4, 10s. And we find the weak-minded James encouraging his son's prodigality by sending to him at Madrid "the mirroure of France, the fellow of the Portugal dyamont," which the king wished him to wear alone in his hat, with a little black feather. To his favourite, George Villiers, Duke of Buckingham, who accompanied Prince Henry to Spain, James also sent "a faire table dyamont," with a "faire pearle" hung to it. Buckingham was also "imprisoned in jewels," and wore diamonds as a nobleman of the last century did paste buttons; he had also diamond hat-bands, cockades, and ear-rings; and his hat-feather, sword, girdle, and spurs, were set with this precious gem; and one of his court suits was estimated to be worth £80,000. In these times, therefore, the common phrase of "a man's wearing his estate upon his back" could scarcely have been an exaggeration; and there is no poetical license in John Taylor's censure of the prodigals who

> "Wear a farm in shoe-strings edged with gold,
> And spangled garters worth a copyhold;
> A hose and doublet which a lordship cost;
> A gaudy cloak three manors' price almost;
> A beaver band and feather for the head,
> Prized as the church's tythe, the poor man's bread."

Instead of the ruff was now sometimes worn a starched collar or band, plain, and edged with lace. Late in the reign the jackets or doublets were shortened, and the breeches reduced in size, and fastened in large bows at the knees; the well-stockinged leg was admired, and the hat worn low in the crown, and with broad brim, as seen in portraits of the date 1619. Beards and whiskers had become almost universal in the reign of Elizabeth; but in that of James, the former was sometimes worn trimmed to a point, hanging down at the division of the ruff.

In the female costume there was little change. The huge fardingale continued to be worn by the nobility; a strong passion for foreign lace was introduced; pearls were the favourite jewels, and the ruff maintained its sway, so as to be anathematized from the pulpit; and the fancies of female costume were glanced at in a sermon preached before the king at Whitehall in 1607–8, as "her French, her Spanish, and her foolish fashions; her plumes, her fannes, and a silken vizard, with a ruff like a sail, yea, a ruff like a *rainbow*, with a feather in her cap like a flag in her top, to tell which way the wind will blow."

Experience had scarcely convinced the military world of the inefficacy of steel harness to resist the death-shot of the arquebuss and musket, when James I. wittily said he could not but "greatly praise armour, as it not only protected the wearer, but also prevented him from injuring any other person." The warriors of his time, however, began to discover that it lacked the best part of these qualities. They first laid aside the jambes, or steel boots, then the shield, and next the covering for the arms. When the cavalry disused the lance, the cuisses were no longer worn to guard against its thrust; and the stout leathern or buff coat hung down from beneath the body armour to the knees, and supplied the place of the discarded steel. In the portrait of Henry, Prince of Wales, the armour is worn only to the waist, and the trunk is covered with wide loose straps, through which appears the rich silk or velvet.

We now approach the best era of costume in England; for whatever may have been the merits of certain garments worn in previous reigns, the entire dress in that of Charles I. is unrivalled for picturesqueness and elegant taste. At this we shall not be surprised, if we recollect that it was copied from the habit of Spain, the most becoming of all European costumes. Early in this reign, however, the motley fashion of the time of James I. prevailed; and the Savoy neck-chain, the ruff and cuffs of Flanders, the Naples hat with the Roman hatband and Florentine agate, the Milan sword, and the cloak of Geneva set with Brabant buttons, gloves from Madrid, &c., were the characteristics of the beau of 1629. The ruff had almost universally given place to the falling band; and collars of rich point-lace, large and hanging down on the shoulders, held by a cord and tassel at the neck, and called *Vandyke*, from its being the most sriking part of the dress in which Vandyke at this time painted portraits.

The principal habits were vests and cloaks of velvet, or silk damask, short trousered breeches terminating in stuffed rolls and fringes and points, and very rich boots, with large projecting lace tops. A dress of Charles is thus described: a falling band, green doublet (from the arm-pits to the shoulders wide and loose), zig-zag turned-up ruffles, long green breeches (like a Dutchman's) tied below the knee with yellow ribbons, red stockings, green shoe-roses, and a short red cloak lined with blue, with a star on the shoulder; the king sometimes wore a large cravat, and at other times a long falling band with tassels. The cavaliers were genuine successors of Edward's knights, not less in costume than in high chivalrous bearing. Their dress consisted of a doublet of velvet, silk, or satin, with large loose sleeves slashed and embroidered; Vandyke collar and band, and short embroidered cloak worn on one shoulder; the long breeches, fringed and pointed, met the ruffled tops of the boots; the embroidered sword-belt was worn over the right shoulder, and in it was hung a Spanish rapier; and in the flapping beaver hat was worn a plume of feathers confined by a jewel. A buff coat or jerkin was often worn as a better defence than the doublet, which is sometimes covered. The engraving represents a citizen of this period more plainly attired. In this reign the hair was worn long, and the mustachios and pointed beard formed a triangle about the mouth, as was witnessed not many years since upon opening the coffin of Charles I. at Windsor, when the severed head of the king was found with the pointed beard perfect. Charles is painted by Vandyke with a jewel in one ear only; at Bath is preserved the pocket-handkerchief

Citizen in the time of Charles I.

by him at the time of his execution; it is of very fine white cambric, marked with the imperial crown and the initials C. R. Oliver Cromwell is described by an eye-witness, in 1640, as "very ordinarily apparelled" in an ill-made plain cloth suit; his linen plain, and not very clean, and his sword stuck close to his side. At this time the men usually wore long vests and cloaks of dark colours, with plain collars called falling bands or turn-overs.

Charles is believed to have generally used armour; but the helmet was deprived of its visor; and before the middle of the seventeenth century, nothing remained of the ancient harness but the open cap and cuirass; and some regiments of cavalry thus armed were thence called Cuirassiers.

The female costume of this period was rather elegant than splendid. Gowns with close bodies and tight sleeves were worn, though the fardingale was retained; with a gorget ruff standing up about the neck like a fan. French hoods were still worn, though with little distinction as to rank. The hair was worn in small curls, and the hoods, of all colours, fastened under the chin with curious effect. Ear-rings, necklaces, and bracelets, were much worn; but the Puritans forbade the females to wear lace, jewels, or even braided hair; and they retained the close hood and high-crowned hat.

Towards the close of the reign of Charles I., the cumbrous fardingale disappeared, with the yellow starched ruff and band. Yellow starch had, however, become unfashionable since Mrs. Turner, the physician's widow, went to the gallows with a yellow ruff round her neck, to be hung for her share in the poisoning of Sir Thomas Overbury (Mrs. Turner having introduced yellow starch from France). These tasteless fashions having disappeared, the female dress became very elegant, with its rich full skirt and sleeves, and falling collar edged with rich lace, and the hair worn in graceful ringlets; but these vanities were condemned by the Puritan party.

With the restoration of Charles II. came certain tasteless innovations upon the elegant Vandyke costume of the time of Charles I., which were the first resemblance to the coats and waistcoats of the present day. Thus, our most picturesque attire lasted little more than a quarter of a century. Its decline was gradual, its chivalric character soon degenerated into grotesqueness, which in its turn changed to stark meanness. Early in the reign of Charles II. the doublet was much shortened, and worn open in front, where, and at the waistband, the rich shirt was shown; and the loose sleeves and breeches were decked with ribbons and points, and from the knee-bands hung long lace ruffles. At the wrists, too, ruffles were worn; but the lace collar was shorn of its points, designated to this day Vandyke. The cloak was retained upon the left shoulder, and the high-crowned and plumed hat remained for a short time; but the crown of the hat was soon lowered.

The petticoat breeches were another absurdity; although ornamented with ribbons at the sides, the lining strangely appeared below the breeches, and was tied at the knees; to match which, the sleeves of the doublet only reached to the elbows, and from under them bulged the ruffled sleeves of the shirt, both being ornamented with ribbons. Meanwhile, the skirt of the doublet had been lengthened from above the waist nearly to the knees, and had buttons and button-holes in its entire length, thus becoming a coat, and so named in an inventory of 1679; wherein, also, are the items of waistcoat, breeches, pantaloons, drawers, and trousers, being the earliest mention of these articles. Stockings of various kinds were common, and "the lower ends of stockings are understood as socks. Instead of the lace collar was worn the long square-ended cravat, of the same material, from Brussels and Flanders.

The female costume, as if to compensate for the tasteless additions to that of the men, retained much of its elegance in Charles's reign; indeed, from this time, "the stronger sex" appear to have left the art of dress to the ladies. The portraits of the beauties of the court of Charles II., in Windsor Castle and Hampton Court Palace, are familiar illustrations, in which we see only a pearl necklace upon the bosom, and the hair falling in luxuriant ringlets from beneath a string of pearls. The gowns are of the richest satin, low in the bosom, and have long trains, so that the wearers could not "stir to the next room without a page or two to hold them up." The annexed engraving shows a citizen's wife performing this office herself.

Citizen's wife in the time of Charles II.

In the gossiping diary of Pepys (from 1659 to 1669) we obt[illegible]veral glimpses of the costume of the early part of [illegible] Pepys venerated the fine clothes of either sex [illegible] perhaps inherited from his father's shop-bo[illegible]etches Charles's queen looking "mighty pretty [illegible]te laced waistcoate and a crimson short pettico[illegible]air dressed *a la negligence;*" Lady Castlema[illegible]ellow plume in her hat; and Mrs. Stewart "[illegible]t cocked, and a red plume and excellent taille." He tells us, too, of his wife's jewels, "increased by the ring she hath made lately as my valentine's gift this year; a Turkey stone set with diamonds; and with this and what she had, she reckons that she hath above £150 worth of jewels of one kind or other." His catalogue of coats, cloaks, breeches, and stockings, is curious to the antiquary. In 1660–61, casting his roundhead, he appeared for the first time in the dress of a cavalier, with coat and sword; then a new lace-band; a new scallop, very fine; "shaggy purple gown, with gold buttons and loop-line; a black cloth suit, with white linings under all, to appear under the breeches;" and a fine camlet cloak. Upon launching his coach, he gave his servants a serge livery of green, lined with red: his wife was "extraordinary fine, with her flowered tabby gown that she had made two years ago, now laced exceeding pretty; and indeed was fine all over." He put on his new suit, and so anon they went through the town, with their "new liveries of serge, and the horses' manes and tails tied with red ribbons, and the standards then gilt with varnish, and all clean, and green reines, that people did look mightily upon us." Elsewhere, we find him thus generous to a relative: "I did give my wife's brother 10s. and a coat that I had by me, a close-bodied, light-coloured cloth coat, with a gold edging in each seam, that was the lace of my wife's best pettycoat that she had when I married. He is going into Holland to seek his fortune." Then he chronicles a shepherd's "woollen knit stockings, of two colours mixed," and the king's having no "handkerchers, and but three bands to his neck," the grooms of the bedchamber having taken all the royal linen for their quarter's fees. But a more important note is his minute account of the plan of Charles II. to introduce *a national dress never to be altered*, and which was taken from that of Poland; and it was worn experimentally by the king and his courtiers, and consisted of "a long cassocke close to the body, of black cloth, and pinked with white silk under it, and a coat over it, and the legs ruffled with black riband like a pigeon's leg." Pepys thought this "a very fine and handsome garment; but the king laid aside the pinking, as it made the wearers look too much like magpies." Dryden says these long vests "did become our English gravity;" but they soon gave way before doublets, and hose, and other importations of the Duke of Grammont. Then the diarist describes a new play, in which the

queens Elizabeth and Mary appear dressed in the costumes of the age. He gives us some curious accounts of "young pretty ladies dressed like men, in velvet coats, caps (hats), and ribbons, with laced bands * * * the ladies of honour dressed in their riding garbs, with coats, and doublets, and deep skirts, just for all the world like mine; and doublets buttoned up the breast, with periwigs and with hats; so that only for a long petticoat dragging under their men's coats, nobody would take them for women." Evelyn also mentions "the queene in her cavalier riding-habit, hat and feather, and horseman's coat." Evelyn, too, tells us that our modern paper folding fans, much less picturesque than the feathered fans of earlier date, were introduced by the Jesuits from Japan and China. Trifling as these notes may appear, they illustrate manners and customs, minute information on which will fruitlessly be sought in the broad path of history.

Passing to the reigns of James II. and William III., we find few noticeable novelties in costume. The coats were often of velvet, without collars, with large hanging sleeves, and button-holes of gold embroidery. The petticoat breeches were exchanged for the close-fitting garments tied below the knee, and therefore called knee-breeches; the broad-brimmed hats were turned up on two sides, and edged with feathers or ribbons; the fashion lay in the rich long lace cravat and embroidered waistcoat, the band was now narrowed, so as to resemble that worn at the present time by clergymen. The periwig was worn still longer than hitherto, hanging down in front, or flowing upon the shoulders, though the colour was altered from black to suit the complexion; and combing these wigs was a piece of gallantry, for which purpose a comb was carried, whence the origin of our present pocket-comb: and at court, in the walks of Kensington, the Mall of St. James's, or the boxes of the theatre, the beaux turned their wig curls over their fingers whilst in conversation; the effect of these wigs flowing over the cuirass will be seen in the portrait of the great Duke of Marlborough.

The female costume was unchanged in the reign of James II.; but it became less luxuriant and more formal in the time of William and Mary, in accordance with Dutch taste. The waists were much lengthened with velvet stomachers, covered with jewels, so as to conceal the bosom, hitherto unsparingly exposed; the sleeve was made tight, and trimmed with lace lappets or ruffles, and long gloves were worn, so as entirely to cover the arm; but the skirts were worn long, full, and flounced; the hair, instead of flowing in ringlets, was gathered up, and strained over a toupee of silk or cotton wool, carried up so high as to be called a tower, covered with a lace scarf or veil that hung in front below the bosom; but this head-dress gradually shrunk into a caul with two lappets, known as a "mob." False locks and curls, set on wires to make them stand out, were also worn. Before the Revolution, the citizens' wives dressed with becoming plainness, and gentlewomen wore serge gowns, which, after 1788, were rejected by chambermaids. The increase of rich clothes and jewels was great, and there were one hundred coaches to one kept formerly, all denoting the improving wealth of the country.

A few of the fashions and peculiarities of this century may be summed up in conclusion. From the reign of James I., the ladies appear to have dressed their hair in better taste than previously, in curls on each side of the face, and braided in a knot at the back of the head, where it was often ornamented with jewels or pearls, or a single feather. It was next worn in long locks flowing below the shoulders; and the love-lock, ornamented with ribbon and twisted pearls, was worn on one side. From the reign of Charles II. to that of Queen Anne, long hair was much prized, and was often sold by women of inferior fortune to be made into periwigs. About this time the *fontange* or top-knot, so called from Mademoiselle de Fontange, who first wore it, was driven out of fashion by the fanatical spirit of the time. Hair powder was also introduced from France in this century: it was worn of various colours, an absurdity only discontinued at the close of the last century. Of the fashion of hats we shall afterwards speak.

Under the house of Stuart, the shoe-rose yielded to the shoe-string, the beaux wearing them of silk tagged with silver, and the humbler classes wore laces of plain silk, or even leather thongs—the latter still to be met with in rural life. Shoe-buckles, in size and shape resembling the horse-bean, were introduced at the Revolution; flimsy Spanish leather boots, with spurs, were also fashionable, and beaux went in them to balls.

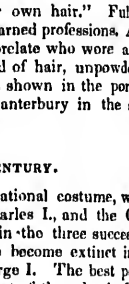
Ostrich and peacock feathers were variously worn in hats, and twigs of yew for mourning. Before the reign of Charles I., the high-crowned hat began to be less worn; and that monarch, in his escape, is described as disguised, and wearing "a very greasy old gray steeple-crowned hat, with the brim turned up, without lining or hat-band." The brim of the hat, however, continued to be worn broad, and when much worn, was called "slouched." It was worn till the end of the century, but with first one flap turned up before or behind, then two flaps; and the third flap being turned up, the cocked hat was complete.

Towards the close of the century, wigs became fashionable, together with false hair, "a custom contrary to our forefathers, who wore their own hair." Full-bottomed wigs were worn by the learned professions. Archbishop Tillotson was the first prelate who wore a wig, which resembled a natural head of hair, unpowdered: the changes in clerical wigs are shown in the portraits of successive archbishops of Canterbury in the state-dining room of Lambeth Palace.

EIGHTEENTH CENTURY.

The picturesqueness of our national costume, which was perfect in the reign of Charles I., and the Commonwealth, gradually declined in the three succeeding reigns, and may be said to have become extinct in the reigns of Queen Anne and George I. The best period of our costume was, therefore, that of the school of portrait painting in England, led by Vandyke, when the fine arts were highly esteemed in the English court, and a good taste began to prevail in the nation.

It has already been seen how a fanciful fashion of attire began to dwindle into the tameness of modern costume in the reign of Charles II., a change which the efforts of that gay monarch could not avert. The alterations were of French origin. Louis XIV., whose general taste was unimpeachable, introduced a new and far from elegant fashion of dress, which the celebrity of his court and other circumstances caused to be extensively copied in foreign countries. About the reign of Queen Anne, this new French fashion had been embraced by courtiers, physicians, and other professional persons in England, also the higher order of gentry; and in the following reigns of George I. and II., it became universal.



Gentleman of 1750.

This dress of the old English gentleman, as it afterwards came to be called, consisted at first, during Queen Anne's reign, of a periwig in formal curls, partly contained in a silk bag on the shoulder; a small cocked hat, full bottomed coat, short breeches, blue or scarlet stockings drawn over the knee and square-toed shoes, with small buckles and high red heels. And this formal costume, relieved only by lace cuffs, ruffles, and neckcloth, and gold or silver clocks in the stockings, remained unmodified through three quarters of the century. The engraving shews a gentleman of the year 1750, and reminds us that the snuff-box, first carried in the reign of James II., continued indispensable for the fine gentleman.

The origin of the cocked-hat has been explained. In the middle of the century it was considered a mark of gentility, and a distinction from the humbler orders, who wore round hats. But the varieties of the native cocked-hat being exhausted, a larger one, named Kevenhuller, was imported from Germany; and early in the reign of George III. (1762), hats were worn, upon an average, six inches and three-fifths broad in the brim, and cocked between Quaker and Kevenhuller. Some had their hats open before like a church-spout or a tin flour-scale; some wore them rather sharper, like the nose of a greyhound; and an account states—"We can distinguish by the taste of the hat the mode of the wearer's mind. There is the military cock and the mercantile cock; and while the beaux of St. James's wear their hats under their arms, the beaux of Moorfields wear theirs diagonally over their left or right eye; sailors wear the sides of their hats uniformly tucked down to the crown, and look as if they carried a triangular apple pasty upon their heads. Some wear their hats with the corners, which should come over their foreheads in a direct line, pointed into the air; those are the Gawkies. Others do not above half cover their heads, which is owing to the shallowness of their crowns."* Cocked-hats, richly trimmed with gold-lace and ostrich-feathers, occur in Hogarth's pictures, which, indeed, will furnish a better idea of the entire costume from 1727 to 1760 than many pages of description; and the portraits by Sir Joshua Reynolds will supply the dress of the next forty years.

The fashions of wigs were as various as those of hats. A peruke and a plaited and tied tail were called a Ramillies, from the famous battle of that name. The tie-wig became the fashion, from the celebrated Lord Bolingbroke going to court with his wig tied up, upon which Queen Mary observed that he would "soon come to court in his night cap," a royal rebuke which established a fashion. In 1764, wigs went out of wear, and the wig-makers of London petitioned George III. to compel gentlemen to wear wigs by law, for the benefit of their trade! The fashion of wearing powder in the hair, however, came to the wig-makers' relief; and the wig decreased in size as the century rolled onward. In the present day, formal wigs are almost confined to the heads of prelates and law officers; and the latter, to get rid of the powder nuisance, wear wigs made of other materials than hair, as the metal platina. Wigs are, however, much worn, from the greater prevalence of baldness than formerly; but their perfection now consists in bearing so close a resemblance to the natural or living hair as to avoid detection. The side curls were originally worn by postilions, to maintain their resemblance to boys.

Towards the middle of the reign of George III., the male dress took the form of the court suit worn at the present day; the breeches having, from the year 1760, been worn over the knees, fastened by buckles or strings. The coats of the eighteenth century were of velvet, silk, or satin, as well as broadcloth, and their colours very fanciful. Hogarth's favourite colour was sky-blue; Reynolds's, deep crimson and violet; and Goldsmith rejoiced in plum-colour. About 1790, cloth became the general wear; the waistcoat being of the costlier materials, and embroidered, and sometimes the breeches. The court dresses were of velvet or satin, with steel, jewel, or paste-buttons; the wig had a silk bag; and the jewelled or steel-cut hilted sword has been retained through the mutations of the last hundred and forty years.* Buckles were worn at the knees and in the shoes till the close of the last century; and the large square plaited buckle was the *ton* until 1791, when shoe-strings became general; though the Prince of Wales and his household endeavoured, by wearing buckles, to retain the fashion.

Lady in the time of George II.

The female costume of the eighteenth century was as formal and tasteless as that of the men. The most odious piece of attire introduced in the early part of the century was the large whalebone petticoat, which degenerated into the hoop petticoat, and made a lady to appear as if standing in an inverted tub. In the reigns of George I. and II., loose gowns, called *sacques*, and hooded silk cloaks, were worn, and a very small muff, such as have been lately revived. This costume is shown in the annexed portrait of a lady of George II.'s time. Ornamental aprons were also worn, as at the present day, with the watch, necklace, and the fan, which was sometimes from twelve to eighteen inches in length, and beautifully made. Gay sings:

> "The fan shall flutter in all female hands,
> And various fashions learn from various lands.
> For this shall elephants their ivory shed.
> And polish'd sticks the waving engines spread:
> His clouded mail the tortoise shall resign,
> And round the rivet pearly circles shine.
> On this shall Indians all their art employ,
> And with bright colours stain the gaudy toy;
> Their pains shall here in wildest fancies flow;
> Their dress, their customs, their religion show.
> * * *
> Gay France shall make the fan her artists' care,
> And with the costly trinket arm the fair."

Spanish broadcloth, trimmed with gold-lace, was used for ladies' dresses in the reign of George I.; and furbelowed scarfs were worn from the duchess to the peasant.

The flowing coif, or rather veil, of the finest linen, fastened on the head, and falling behind, prevailed under Queen Anne, until the towering head-dress was restored; and this being again disused, the hair was worn in curls down the back. Hoods of all colours and fashions on horseback and at the opera, were worn; the projecting fontange again appears, pointed like a steeple, with long crape streamers, their feathers piled up with flowers in stages; and even figures of four-wheeled carriages were head ornaments. Periwigs were also worn by the ladies; and the head was sometimes made up of pins, paste, and pomatum, so as to *keep* for a month. Queen Ann had the good sense not to disfigure her chestnut locks with powder; but it was generally worn till 1793, when Queen Charlotte and the princesses discarded it.

Caps may next be noticed: they were at first small frilled or puffed; then the French night-cap covering the cheeks; the Ranelagh mob-cap, copied from the head-kerchiefs of market-women; the Mary Queen of Scots' cap, of black gauze, edged with French beads; the fly-cap, like a butterfly, edged with garnets, topazes, or brilliants; and Goldsmith's "Cousin Hannah's cap," a few bits of cambric and flowers of painted paper stuck on one side of the head. Calashes, like the head of a cabriolet, were next appended to the head-dress. A flat straw or silk hat, of small size, and trimmed with ribbons,

* London Chronicle, quoted in M. Repton's paper on Hats, in the Archæologia.

* The Marquis of Westminster occasionally wears a court-sword, on the hilt of which is, we believe, set the celebrated Nassuck diamond, sold, in 1837, for £7200, though originally valued at £30,000.

was worn upon the crown of the head; and a large round gipsy straw hat fastened by ribbons under the chin. The bonnet, in early times generally made of velvet, cloth, and silk, was in the eighteenth century changed to straw. Gay mentions a new straw hat lined with green, about 1724, but it was then comparatively rare; for the simple art of plaiting straws together to make bonnets was only practised to any considerable extent about sixty years since; it now employs upwards of 200,000 females in England—Dunstable, in Bedfordshire producing the best plait. In our time English straw has been superseded by Leghorn plait, which having declined in fashion, our own straw, silk, and velvet, have been substituted as materials for bonnets; and our home manufactures must have been materially benefited by the change.

NINETEENTH CENTURY.

The formalities of the eighteenth century received a terrible blow at the French Revolution; and in the ten years from 1790 to 1800 a more complete change was effected in dress by the spontaneous action of the people than had taken place at any previous period in a century. The change began in France, partly to mark a contempt for old court usages, and partly in imitation of certain classes of persons in England, whose costume the French mistook for that of the nation generally. This new French dress was introduced by the party who were styled the Sans Culottes. It consisted of a round hat, a short coat, a light waistcoat, and pantaloons; a handkerchief was tied loosely round the neck, with the ends long and hanging down, and showing the shirt collar above; the hair was cut short, without powder, *à la Titus*, and the shoes were tied with strings.

The comparatively simple form of dress of the Sans Culottes found many admirers in England, and soon became common among young men; the change from antique fashions was also greatly helped by the imposition of a tax on the use of hair-powder, which was henceforth generally abandoned. Pantaloons which fitted closely to the leg remained in very common use by those persons who had adopted them, till about the year 1814, when the wearing of trousers, already introduced into the army, became fashionable. Still, many elderly persons held out in knee-breeches against all innovations, and till the present day (1842) an aged gentleman may occasionally be seen clinging to this eighteenth-century piece of dress. The general use of white neckcloths continued, notwithstanding the introduction of the standing collar, till the reign of George IV., when this monarch's taste for wearing a black silk kerchief or stock, and also the use of black stocks in the army, caused a remarkably quick abandonment of white neckcloths, and the adoption of black instead. The year 1825, or thereabouts, was the era of this signal improvement in costume.

While these leading changes were effecting, other alterations of a less conspicuous nature were from time to time taking place. The disbanding of the army after the piece of 1815 led to various transformations besides those we have mentioned. While pantaloons were the fashionable dress, it became customary to wear Hessian boots; these, which had originated among the Hessian troops, were without tops, and were worn with small silk tassels dangling from a cut in front; being drawn over the lower part of the pantaloons, they had a neat appearance, but the keeping of them clean formed a torment that prevented their universal use. When trousers were introduced from the practice of the army, the use of Wellington boots to go beneath them also became common.*

Referring to the era of 1815 to 1825, as that in which trousers, Wellington boots, and black neckcloths or stocks came into vogue, we may place the introduction of the surtout in the same period of history. From the time when the collarless and broad-skirted coat had disappeared about the commencement of the century, the fashion of coats had changed in various ways, till the above-named era, when the loose frock-coat or surtout was added to the list of garments. We remember of seeing French military officers, when in undress, wearing frock-coats as early as 1811; it is probable, therefore, that the modern surtout is only a variety of the loose military great-coat brought from the continent by the British army; however it originated, it may be allowed to be one of the greatest improvements in the style of dress which has yet occurred in the nineteenth century.

WELSH COSTUME.

The Welsh, as a relic of an ancient Celtic people, possess remarkably few external traits of their original. They have, like the Irish, become Anglicised in costume, and we should in vain search amongst them for the *breacan* or checkered clothing of their Scythian ancestry. The general material of dress is home-made, or at least a common kind of woollen cloth, and flannel. Blue is the general colour of attire. The women wear close-fitting jackets, and dark brown or striped linsey-woolsey petticoats. The most remarkable part of the Welsh costume is the hat worn by the women. All females, in parts of the country not modernized, wear round black hats, like those of men; and this fashion is supported to a small extent by ladies of the higher rank. This use of the hat is not Celtic: the fashion is derived from England, and is only two or three centuries old.

IRISH COSTUME

The Irish at an early period wore the same Celtic fashion of attire as was preserved till recent times in the Scottish Highlands; but, as in Wales, every thing of the kind disappeared as the country became Anglicised. The primitive species of attire, including coloured mantles, kirtles, and other fanciful garments, remained in use till the sixteenth century, when laws were passed by Henry VIII. enjoining the use of caps, cloaks, coats, doublets, and hose, of English cut, but of Irish or any other materials.

The general dress in Ireland, at the present day, rarely varies from that in England. There are, however, some interesting peculiarities of costume amongst the peasantry of the southern and western counties. In Kerry, says Mr. Crofton Croker, "the inhabitants of one barony are easily distinguished by their peculiar dress from those of another; the greatcoat is there worn in the fashion of a mantle, fastened by one button under the chin, and the sleeves hanging down unoccupied by the arms." In the county of Limerick the men's dress is invariably grey, produced by a mixture of black and white wool, without dyeing. In the eastern parts of the county of Cork, light blue is predominant; in the western parts, and in the county of Kerry, light or powder blue; and nearly the same peculiarity extends to female dress. In the eastern baronies of the county of Cork and county of Limerick, cloaks of the brightest red are seen. In the west of Kerry and Cork, dark blue and gray prevail.

A brown stuff gown and green petticoat is the popular female costume, with stockings of the brightest blue; stockings are seldom seen, and shoes are scarcely ever worn except on the Sabbath and other holidays. Silver buckles and cloak clasps are much prized, and are handed down from mother to daughter. Bonnets are quite unknown; but the high-cauled mob cap is sometimes worn under the hood. The *fadakeen*, or little hood, is also a favourite head-dress, and is formed by a kerchief

* It is proper to mention that trousers had, for the previous fifteen or twenty years, been used by boys, and were perhaps from them adopted by the army. Previous to the French Revolution, the dress of boys was almost the same as that of men.

ully folded round the head, and tied in a knot under the chin.

The general costume of the male peasantry is well known for its oddity. A round black hat or *caubeen*, round which perhaps is bound a rope of straw; the rough short coat; the corduroy small clothes, open at the knees, the buttons and strings enjoying a sinecure "for convayience;" the gray stockings most likely hanging loose on the legs; and the short black pipe stuck in the side of the mouth, which is ever ready for a joke. Such is Pat in ordinary costume; but frequently he may be seen with a freeze greatcoat over all—and this cumbrous garment, like the mantle worn by females, seems to be used when there is no plea for its use on the score of weather. Mr. and Mrs. Hall, in their beautiful work on Ireland, thus speaks of the female cloak:—

"The Irish cloak forms very graceful drapery; the material falls well and folds well. It is usually large enough to envelop the whole person; and the hood is frequently drawn forward to shield the face of the wearer from sun, rain, or wind. Yet we would fain see its general use dispensed with. A female in the lower ranks of life cares but little for the other portions of her dress if she has 'a good cloak;' and certainly her ordinary appearance would be more thought of, if the huge 'cover-slut' were not always at hand to hide dilapidations in her other garments. 'Oh, then, I'm not fit to be seen; wouldn't I better tidy myself a bit?—but aisy! sure when I throw on my cloak no one will know what I am,' is a so frequent observation; and away they go, shrouded from head to foot in this woollen hide-all. It is true that the climate is damp, that it is cold, and that the cloak commonly performs a double office, being used as a blanket by night as well as a covering by day. But woollen retains the damp; and this fact, together with the certainty that it imbibes and retains all unwholesome infections, and is seldom or never washed, are serious arguments against it, picturesque though it is. The peasant Irish have so few comforts, that we would far rather add to than take from their small store; but we conceive the 'cost of a cloak' could be more advantageously laid out."

The materials of the dress of the Irish peasantry are chiefly the native wool, worked rudely up into frieze or linsey, druggets, and flannels, for they seldom can afford to wear the linen they fabricate. Unfortunately, the bulk of the Irish have little idea of tidiness either in households or attire. Taking things too easily, as respects exterior marks of decency, they allow their clothing to fall into disrepair, and finally ruin; consequently, their dress is generally more picturesque than neat, and it often seems a problem how they get into it. We are glad to observe, however, that this heedlessness is in course of removal, and that the dress is everywhere improving.

SCOTTISH COSTUMES.

At the present day, Scotland cannot be said to possess any national costume which distinguishes the bulk of the people from their fellow-subjects in South Britain; and however much the fact may surprise the artists and dramatists of England, it is very certain that the inhabitants of Edinburgh, Glasgow, and other cities and towns in Scotland, are dressed in precisely the same fashion of garments as is now seen in the streets of London, Paris, Brussels, or the capital of any other civilized country.

This general resemblance of Scottish costume to that of England has existed since about the reign of James I., when foreign manners and fashions were introduced among the higher classes of society, and thence forced their way into ranks of professional men, traders, and ultimately the people at large. Previous to the era we mention, the dress of the Scotch, both those of the Highlands and Lowlands, was distinguished by parti-colours, woven in checks, according to taste or ancient usage. By the Celtic race in the Highlands, this species of variegating cloth with colours was called *Breacan*, which signifies spotted, and by the Teutonic population of the Lowlands it received the name of *Tartan*, a word whose origin has defied the researches of etymologists, but which it is not unlikely may have been derived from the ancient Tartar races, who used a similar kind of colouring in their attire. Whatever be the origin of the term, all doubt as to the antiquity and almost universal use of the thing meant is at an end.

"When the soldiers of Catherine [Empress of Russia] opened the vast tumuli which are scattered over the great desert between the Tobal and the Irtish, among other memorials of a high antiquity they discovered a small bronze figure of a mounted Tartar, apparently an image of one of those tutelary deities still in common use among the Calmucs and Mongols. The head was represented in the small conical bonnet once universally worn from Thibet to St. Kilda, *still* continued in China and Albania, and not extinct among the Highlanders until the beginning of the eighteenth century. The body was covered by a *checkered tunic*, engraved in cross lines, evidently indicating a parti-coloured garment; and the whole figure might have passed unnoticed among the earliest Highland grave-stones, or the remote Islesmen in the year 1715. By the traditions of the surrounding tribes, the tumuli where the bronze was found are said to cover the remains of Tartars killed in the battles between Tamerlane and the Calmucs, whose descendants at this day wear vestments checkered in various colours, resembling the character of tartan. The Turks, another race of the same stock, are still attached to the same habit; and hence the wandering Turkish pedlars in England frequently wear a gown of *Highland tartan*, from its conformity to their ancient taste. But not only among the Calmucs and Walgusians remains this remnant of an earlier period, separated by distance and by language; it is found lingering in various quarters of the world, and various degrees of civilization. Among the Tuscans, the Neapolitans, the Albanians, and the Basques, broad striped stuffs and silks retain the common elements of its colouring. In Wales, the petticoat of the women still preserves a tradition of their ancient *breacan;* and that of the Malo-Russians and Don-Cossacks exhibit unequivocal tartan. It is of checkered cloth, in various colours, *both of the warp and the woof*, generally red, green, and black, and so exactly resembling the Scottish patterns that it might be mistaken for the manufacture of a Scottish loom. These coincidences are strong evidence of an ancient universality, once prevalent through a large portion of mankind, and of which the tartan of Scotland is only one of the last remnants, preserved by the remote solitude and the tenacious habits of an aboriginal people, secluded from the revolutions of the world and the modifications of society."*

We do not find that tartan cloth, or indeed cloth of any kind, had been worn by the Lowlanders of Saxon or Teutonic origin in the shape of philibegs or kilts, that ancient fashion of attire being for ages previously confined to the Highland clans. That tartan, however, was at one time as much in use for other garments in the Lowlands as Highlands, is distinctly proved by the following extract from the "Vestiarium Scoticum" (1560–1570), already quoted. We slightly modernize the orthography, to render the language intelligible to English readers:—

* "Vestiarium Scoticum:" from the manuscript formerly in the Library of the Scots College at Douay, with an Introduction and Notes, by John Sobieski Stuart. Edinburgh: William Tait. 1842. The above extract is from the learned introduction of Mr Stuart.

"For sameikle as in thir present tymes been seen dyvers uncuthe chaunges in the auld Scottysh fassoun, and men do now effect foreign and straunge fantasies, radder nor sic holsom use and order as cumeth of their ain native guise, and has been usit be our forbeirs in the auld tyme, for nowe all do tak pryd to buske them in heich crounit hattis, Frenche cloukis, Englishe hudes, lang pyket schune, and udder sic lyk uncuthe braveries, the whilk was unknawen till our ancestors of gude femen, wha was contentit to gang with ane bonnet of Kelshewblew, and ane mantel or plaid lyk as affore tym was usit be ther faderis begone; with ane pair of rouch rowlyns [buskins] or hemands of hartshyd, as was much usit be our umquhile lorde and soverine King James of nobil memorye; for he had ever besydes thae of his awin colouris, twa or three plaidis of divers kyndes in his wardrobe, whilk he usit in his jornayes when that he wald not be knawen openlye."

Tartan, for clothing, disappeared in the Lowlands in the course of the seventeeth century; but even as late as the beginning of the eighteenth century, parti-coloured plaids were pretty generally worn; and young women were in the habit of using a "tartan screen," that is, a small plaid of variegated colours. In the fine old Scottish song, "Wat ye wha I met yestreen,' the *screen* of tartan is alluded to in the following characteristic manner:—

"Wat ye wha I met yestreen,
Coming doun the street, my joe,
My mistress in her *tartan screen*,
Sae bonnie, blythe, and sweet, my joe."

The tartan screen, which was worn in the fashion of a covering for the head and shoulders, so as to combine in some measure the properties of a modern bonnet and shawl, was formed of costly materials; the ladies of the higher classes employing silk, and those of inferior station fine worsted, the colours in each case being remarkably brilliant. Being often employed with a degree of real or affected modesty to conceal a part of the features, it may be said to have performed the office of a veil to Scottish maidens; and hence its appellation of *screen*. Against such "vanities" the pulpit in these times often railed, and, as we suppose, with the usual results. The plaids of the men were of coarser materials, and were used only as mantles as a defence against the weather; yet, if we are to believe Ramsay, they were not untasteful in their colouring: in the "Gentle Shepherd," he makes one of his shepherds speak of

"A *tartan plaid* spun o' gude haslock woo,
Scarlet and green the sets, the borders blue,
Wi' spraings like gowd and silver cross'd wi' black."

Whatever may have been the character of the tartan employed for the plaids of the Lowlanders, and the general garments, including the philibeg of the Highlanders, towards the middle of the eighteenth century, it was very much obliterated in the year 1747, when all kinds of tartan, and also the ancient costume of the Highlanders, were, with a view to break the spirit of the clans, formally proscribed by law. The following is the provision in the act of Parliament on the subject:—

"That from and after the 1st day of August, 1747, no man nor boy, within that part of Great Britain called Scotland, other than such as shall be employed as officers and soldiers in his majesty's forces, shall, on any pretence whatever, wear or put on the clothes commonly called Highland clothes; that is to say, the plaid, philibeg, or little kilt, trowse, shoulder belts, or any part whatsoever of what peculiarly belongs to the Highland garb; and that no tartan or parti-coloured plaid or stuff shall be used for great-coats or for upper coats; and if any such person shall presume, after the said first day, to wear or put on the aforesaid garments, or any part of them, every such person offending, being convicted by the oath of one or more credible witnesses before any court of justiciary, 'shall suffer imprisonment, without bail, during the space of six months;' and being convicted for a second offence, shall be transported to any of his majesty's plantations beyond seas, there to remain the space of seven years."

This contemptible law was repealed in the year 1782; but before that time the tartan and the "garb of old Gaul" had been generally abandoned, except among Highland regiments, and it is chiefly copies from their attire that have guided modern attempts at reviving the costume.

Highland Costume.—Originally the costume of the Highlanders resembled that of other Celtic tribes, and consisted of little else than a woollen garment of variegated colours wrapped round the body and loins, with a portion hanging down to cover the upper part of the legs. In progress of time this rude fashion was superseded by a distinct piece of cloth forming a philibeg or kilt, while another piece was thrown loosely as a mantle or plaid over the body and shoulders. In either case the cloth was variegated in conformity with the prescribed *breacan* or symbol of the clan; and hence the tartan was sometimes called *cath-dath*, or battle colours, in token of forming a distinction of clans in the field of battle.

According to the author of the "Vestiarium Scoticum," the following, in the reign of James VI., was the list of chief and subordinate clans, each possessing its own tartan; among these clans, it will be observed, are included certain Lowland families or houses, who had also adopted the same kind of cognisance.

Clan Stewart—six colours, chiefly red, checked with green, purple, black, white, and yellow.
Prince of Rothsay—three colours, checked with green and white.
Royal Stewart—chiefly white, checked with green, red, purple, and black.
Macdonald of the Isles—chiefly green, checked with black, purple, red, and white.
Ranald—chiefly green, checked with black, purple, red and white.
Macgregor—chiefly red, checked with green and white.
Ross—chiefly red, checked with green and purple.
Macduff—chiefly red, checked with green, black, and purple.
Macpherson—equal portions of black and white, with small lines of red and yellow.
Graht—chiefly red, with checks of green and purple.
Monro—chiefly red, checked with black and white.
Macleod—chiefly yellow, checked with black and red.
Campbell—chiefly green, checked with black, purple, yellow, and white.
Sutherland—chiefly green, with black, purple, red, and white.
Cameron—chiefly red, checked with green and yellow.
Macneil—chiefly green, with purple, black, white, and red.
Macfarlane—very dark, being chiefly black checked with white.
Maclachlan—chiefly yellow, with checks of brown.
Gillean or Maclean—chiefly green, checked with black and white.
Mackenzie—nearly equal portions of green and purple, checked with black, white, and red.
Fraser—chiefly red, checked with purple, green, and white.
Menzies—equal portions of red and white.
Chisholm—chiefly red, checked with purple, green, and white.
Buchanan—chiefly red and white, with small black stripes.
Lamont—chiefly green, checked with black, purple, and white.

Macdougall—chiefly red, checked with black, purple, and green.
Mackintyre—chiefly green, checked with purple, red, and white.
Robertson—chiefly red, checked with purple and green.
Macnab—chiefly red, checked with crimson, green, and black.
Mackinnon—chiefly red, checked with green, black, and white.
Mackintosh—chiefly red, checked with green, black, and white.
Farquharson—chiefly green, with purple, black, red, and yellow.
Gun—chiefly green, checked with black and red.
Macarthur—chiefly green, checked with black and yellow.
Mackay—chiefly a bluish purple, with black and red checks.
Macqueen—nearly equal portions of red and black, with yellow.
Bruce—chiefly red, with green, yellow, and white.
Douglas—very dark, being equal checks of black and slate colour.
Crawford—equal portions of red and green, with white.
Ruthven—chiefly red, with purple and green.
Montgomery—chiefly light green, checked with purple.
Hamilton—chiefly red, with purple and white.
Wemyss—chiefly red, checked with black, white, and green.
Comyn—chiefly red, with green, black, and white.
Sinclair—chiefly green, checked with black, purple, red, and white.
Dunbar—chiefly red, checked with green and black.
Leslie—chiefly red, checked with purple, black, and yellow.
Lauder—chiefly green, with purple, black, and red.
Cunningham—chiefly red, with black, purple, and white.
Lindsay—chiefly red, with purple and green.
Hay—chiefly red, with green, yellow, white, and black.
Dundas—chiefly green, with purple, black, and red.
Ogilvie—chiefly green, beautifully checked with purple, black, yellow, and red.
Oliphant—equal portions of green and purple, with black and white.
Seton—chiefly red, with small lines of green, black, purple, and white.
Ramsay—chiefly red, with black squares checkered with white.
Erskine—red and green.
Wallace—red and black, checkered with yellow.
Brodie—chiefly red, with black and yellow.
Barclay—chiefly light green and purple, checkered with red.
Murray—chiefly green, checkered with black, purple, and red.
Urquhart—chiefly green, with black, purple, white, and red.
Rose—chiefly red, with small checks of purple, green and white.
Colquhoun—green, purple, black, red, and white.
Drummond—chiefly red, with green and dark red.
Forbes—chiefly green, with black, red, and yellow.
Scott—chiefly red, with green, red, and black.
Armstrong—chiefly green, with black, purple, and red.
Gordon—chiefly green, with purple, black, and yellow.
Cranstoun—yellowish-green, with purple and red.
Graham—chiefly green, with black checks.
Maxwell—chiefly red, with green and black.
Home—dark purple, with black, red, and green.
Johnston—chiefly green, with purple, black, and yellow.
Ker—chiefly red, with black and green.

To this list the names of other Scottish families who have adopted a peculiar set of tartan as a cognisance would be added, and probably the entire number of tartans now fabricated for indiscriminate sale is not fewer than a hundred. One of the most commonly used patterns of tartan is that adopted by the 42d regiment—dark-green, checkered with purple. Some of what are called fancy tartans are gaudy, but not in good harmony or contrast of colour.

As modernized and improved by the Highland regiments, the "belted plaid," worn as the philibeg or small kilt, with a separate drapery depending from the shoulder in imitation of the ancient garb, is one of the most picturesque and graceful costumes to be seen in any part of the world; and although it leaves the leg bare at and a short way above the knee, we are assured that it is by no means too meagre an attire for cold weather. A gentleman in Edinburgh informs us that he never catches cold when dressed in the kilt and hunting among his native Highland hills; but that he is always unwell after returning to town and donning the dress of the Lowlanders. Anciently, the Gael wore no shoes or garments for the legs. The feet were only on occasions covered with pieces of hide, tied with a thong, called *brogs*, which, though slender, were very lasting, and were well suited for walking or running on heathy mountains. The introduction of shoes, and also hose, formed from the same tartan cloth as the kilt, is comparatively modern. The hose of the common men in the Highland regiments are still not knitted or wove like stockings, but cut from the web and sewed.

It appears that even in ancient times the Celtic tribes did not always wear the loose garments we have described; but that they also, or at least some of them, wore the *triughas* or *trius*, a species of vestment "formed of tartan cloth, nicely fitted to the shape, and fringed down the leg. They were sometimes merely striped, and were fastened by a belt around the loins, with a square piece of cloth hanging down before. It required considerable skill to make the trius. The measure was a stick, in length one cubit, divided into one finger and a half. There is preserved a Gaelic saying respecting this garment, by which we are given to understand that there were two full nails to the small of the leg, eleven from the haunch to the heel, and three to the breech, a measure inapplicable to few well made men."*

The coat in which the upper part of the body and arms of the Highlanders are now invested, is of course quite modern, having come into use when the old form of the plaid dress was laid aside. Made, as it usually is, with short skirts and small round buttons, it cannot be considered in harmony with the rest of the attire; but it is nevertheless convenient, and could not well be improved.

The bonnet has for ages been a part of the Highland costume, as it was formerly also of the Lowlanders, and, we may add, the English previous to the introduction of felt hats. The *haet* of the Anglo-Saxons must have been little else than a thick woollen cap or bonnet. "In England, it was ordained, in 1571, that every person above seven years of age should wear, on Sundays and holidays, a cap of wool knit, thickened and dressed in the country by cappers, under the penalty of 3s. 4d. for every day's neglect; lords, knights, gentlemen of twenty marks' lands, such as have borne offices of worship, gentlewomen, ladies, and wards being excepted."†

The English gave up bonnets sooner than the Scotch; and ultimately the cry that "the blue bonnets had come over the border," was equivalent to saying that a party of Scotch marauders had entered England on one of their usual hostile excursions. The Highlanders, with whom the bonnet has remained longest as a part of ordi-

* "The Scottish Gael." By James Logan. 2 vols. London 1831.
† Logan's "Scottish Gael."

nary dress, have adopted very many shapes and modes of ornamenting their head-gear. The heavy plume of black feathers used in the army is quite modern, and in exceedingly bad taste, besides being totally unconformable to the idea of a primitive and light costume. The true bonnet of the Highlands is small, either round or peaked in front, dark blue or gray in colour, and without any tartan or checkering. In fancy dress, as for example in the adjoining cut, the bonnet is somewhat larger, and occasionally has a band of tartan. Highland chiefs were distinguished by three pinion feathers of the native eagle stuck in the bonnet; and those who enjoyed the rank of gentlemen were entitled to wear a single feather. It was customary also for the members of each clan to wear in the bonnet a peculiar badge formed of some native shrub. Authorities differ as to the precise shrubs worn for this purpose. According to Logan, the Buchanans used a sprig of bilberry; the Camerons, crowberry; the Campbells, fir-clubmoss; the Forbses, broom; Frasers, yew; Macleods, juniper; Robertsons, fine-leaved heath, &c.

The full dress of Highland chiefs and gentlemen has always been liberally ornamented with sword, baldrick, dirk, large brooches, buckles, shot pouch, and purse. The purse or sporan is a most important part of the costume: it is formed of the skin of a wild animal with the hair on, and tied to the waist by a band, hangs down in front, so as to fall easily upon the lap, and not incommode the legs in walking. It is usually ornamented with silver tags or tassels, and a flap covering the mouth of the purse is sometimes decorated with the vizard of a fox. "In many cases," says Logan, "the purse is composed of leather, like a modern reticule. It is formed into several distinct pockets, in which the Gael carried their money, watch, &c., and sometimes also their shot; but anciently they bore a similar wallet or builg at the right side, for the shot, or for a quantity of meal or other provision. This was termed *dorlach*, and was the knapsack of the Highland soldier; and small as that of the present military is, among the Gael it was still more portable. 'Those of the English who visited our camp,' says an author quoted by Jameson, 'did gaze with admiration upon those supple fellows, the Highlanders, with their plaids, targets [shields], and dorlachs.' The purse admits of much ornament, but according to my taste, when too large, it hides the beauty of the kilt."

After a period of indifference to the preservation of this beautiful national costume, there has latterly sprung up a better tone of feeling on the subject, both among Lowlanders and Highlanders. Encouraged by prizes liberally awarded by the Caledonian Society of London, a public exhibition takes place triennially at Edinburgh, at which there is a competition of skill in playing the Highland bagpipes, dancing, &c., and taste in dressing in proper holiday costume. A hundred or more men generally attend from all parts of the Highlands in their respective clan tartans; and the exhibition as a surviving relic of manners and customs the most ancient in the world, is one of the most interesting which can be witnessed. The last exhibition was in the summer of 1841.

In conclusion, with respect to the ancient Highland dress, it is proper to mention that it is upon the who[le] little worn in the present day in the Highlands, in[to] which the modern garb of jackets and trousers of pla[in] woollen cloth has been generally introduced, and [is] worn on all ordinary occasions. In short, except as [a] fancy costume, it is seldom seen anywhere in Scotlan[d].

Lowland Costume.—As already observed, the costu[me] of the Lowland Scotch is at the present day the same [as] that which has for ages been common in England an[d] France. Among the peasantry, however, in unsophisti[-]cated districts of the country, there remains a few trai[ts] of a past state of things. The Lowland small far[mer] of eighty years since was dressed in strong woolle[n] clothing, perhaps home-made of a gray or light-blue colour, the legs below the knee being enveloped in coarse gray stockings. The Anglo-Saxon smock shirt does not appear ever to have been used in Scotland, where the garments both of men and women were for the most part of woollen or plaiden. The hat eighty years since was rare. The class of peasants we allude to still wore the blue bonnet, which differed, however, from the Highland bonnet in shape; it was flat like a bannock, drooping on the neck or projecting over the countenance, and was ornamented o[n] the top with a small tuft or cherry of red worsted. I[f] to this humble attire we add a gray woollen plaid, wor[n] when the weather or old age required such a means o[f] protection, and place in the hand a snuff-*mull*, or box i[n] the form of a crooked horn, we have a complete pictu[re] of the Lowland Scot in full costume, as he existed abo[ut] the year 1760. As late as thirty years since, we remem[-]ber of seeing many such; and even yet they have n[ot] entirely disappeared.

While the flat blue bonnet has generally given way [to] the modern hat, or only survived in the degenerate for[m] of a small round Kilmarnock bonnet worn pretty gene[-]rally by carters, ploughmen, and boys of the humbl[er] rank, the gray checked plaid has withstood all innova[-]tions. This garment, which is still universally wor[n] by shepherds and other persons in rural districts of t[he] country, may be viewed as the only relic of the ancie[nt] variegated attire of the Lowland Scotch. The checke[r-]ing is very simple, consisting only of small cro[ss] bars of white and black, and the general effect [is] gray. The plaid is made longer than broad, to enab[le] the wearer to wrap one end round his body and shou[l-]ders, and allow the other to hang gracefully down th[e] back. The right arm is generally left disengaged. Th[e] very general use of this simple kind of plaid has led [to] frequent reference in the lyrical pieces of the Scotti[sh] bards; thus Burns, in his usually descriptive languag[e] says in one of his songs:—

> "I'll tak my *plaid* and out I'll steal,
> And ower the hills to Nannie O."

The only other variety of costume worthy of noti[ce] in connection with the Lowlands of Scotland, is that of [a] remarkable community of fishers on the coast of the Fi[rth] of Forth, near Edinburgh. At Newhaven, a villa[ge] westward from Leith, and at Fisherrow, a suburb [of] Musselburgh, these fishers have from time immemori[al] possessed a monopoly of supplying the metropolit[an] market with their perishable wares, procured often at [no] small personal risk on the bosom of the adjacent fi[rth]. The dress of the males differs little from that of [...]

women generally, and the peculiarities we have to mention are confined entirely to the women, married and unmarried, whose exclusive and cheerfully performed duty it is to sell the fish in the markets and streets of Edinburgh. These *fishwives*, as they are termed, are of an exceedingly robust frame and constitution, and usually carry loads of from one to two hundred weight upon their backs, in creels or willow baskets, and evince a masculine degree of strength which is not unaccompanied by manners equally masculine. These singular Amazons dress themselves in a style which, if coarse, must also not be uncostly. They are unable to wear any head-dress, excepting a plain muslin cap or *mutch*, and on the front of this is loosely placed a coloured kerchief, to lessen the pressure of a broad belt which crosses the forehead and must be slipped over the head every time they set down their merchandise. They usually wear a voluminous mass of petticoats, with a jerkin of blue cloth, and several fine napkins enclosing the neck and bosom. Their numerous petticoats are of different qualities and colours, but generally striped red, or yellow, or blue; and it is customary while two or three hang down to the calf of the leg, to have as many more bundled up over the haunches, so as to give a singularly bulky and sturdy appearance to the figure. Thirty or forty years ago, they wore no shoes or stockings, but cannot now be impeached with that defect, so often imputed to Scottish women by travellers. The *cries* of the fishwives are well known to visiters of Edinburgh as being musical, and far from unpleasing. It has been conjectured that the fisher community to which they belong, and which admits of no mixture from other departments of the population, is descended from a colony of settlers from the coast of the Netherlands; but of this there is no evidence, and their names and language do not materially differ from what are common in other parts of Mid-Lothian

TIME—CHRONOLOGY—TIME MEASURERS.

SPACES OF TIME.

Time is the general relation of events and successive existences to each other—a thing of duration, involving the past, the present, and the future. It is very obvious that for the measurement of time we can have no standard of the same tangible nature with a pound, a yard, or a pint measure. We must have recourse to the lapse of time involved in some continued or reiterated *motion*, as to which we have all the proof possible in the nature of the thing, that, on the whole, it requires the same period of time for its recurrence on one occasion as on every other. Such motions, as the measure of periods or portions of time not less in duration than a single day, are those of the rotation of the earth on its axis, the revolution of the moon round the earth, and that of the earth and moon round the sun. Of such as shall constitute the measure of periods less in duration than a single day, or day and night, there are no explicit natural standards; and hence the utility and necessity of mechanism of human invention, the motions of which, mathematically adjusted and numbered, shall measure and record such briefer and more arbitrary periods of time as those we term seconds, minutes, and hours.

In accordance, therefore, with what is the common practice of mankind in applying such a scale of time to the general routine and purposes of life, especially in its more civilized condition, we propose to treat here, briefly, of the measurement of time by days, months, years, and cycles, considered with special reference to their respective natural and artificial subdivisions and accumulations.

DAYS AND HOURS.

The day is that portion of time which elapses while the earth turns once completely round on its axis—each half of its circumference passing, alternately, through the light of the sun on the one hand, and through the darkness of the starry heavens on the other—thus producing, to those carried around with it, the succession of day and night, and the apparent phenomenon of a diurnal revolution of the sun from one point in the illuminated atmosphere back again to the same point, or nearly so.

The succession of day and night would undoubtedly constitute the first great natural period reckoned by the human race—involving, as it does, not only the most familiar and most strikingly contrasted phenomena within the bounds of man's experience, but phenomena peculiarly adapted to the great necessities of his nature—those of vigilance and sleep. Yet the precise point at which the day should be held to begin and terminate must have been a matter much less easily settled; and accordingly we find, that while amongst ancient nations—the Babylonians, Persians, Syrians, Greeks, and almost all the nations of Asia—the day began at sunrise, and was held to last throughout the whole of the ensuing daylight and darkness (an arrangement better adapted to countries near the tropics than elsewhere, as the sun there rises more nearly about the same time throughout the year); the Jews, Turks, Austrians, and others, with some of the Italians and Germans, have begun their day about sunset; the Arabians theirs at noon, as do astronomers and navigators of all nations; the ancient Egyptians, and most of the modern Europeans and Americans, on the other hand, as well as the modern Chinese, beginning theirs at midnight, which is evidently the most convenient plan, since it throws all the waking and active part of the day under one date.

The subdivision of the day into morning, forenoon, mid-day, afternoon, evening, and night, is natural, though somewhat indefinite, and may be conceived to have always been more or less marked by man, even in his rudest state, and at all events the ancient Chaldeans, Syrians, Persians, Indians, Jews, and Romans, divided the day and the night into four parts; but there is nothing obvious in the natural changes or motions of the sun, moon, earth, or stars, which could point out the division of days into hours, hours into minutes, or minutes into seconds. These divisions are entirely artificial and arbitrary, unless, indeed, we conceive the second to represent that minutest portion of time which, to the human mind, constitutes its natural unit or rudiment, as particles constitute the units of a mass; but even seconds have been subdivided into thirds, and still it is evident that, after all, these are no more the minutest elements of time than are what our chemists term molecules the minutest elements of masses.

In the civilized part of the world, it is now customary to divide the day, and reckon the minuter portions of time, by instruments to be afterwards described, in seconds, sixty of which constitute a minute; in minutes, sixty of which constitute an hour; and in hours, twenty-four of which constitute a day. Most nations have these instruments marked for only twelve hours, the computation being twofold, like the day itself; but the Italians, Bohemians, and Poles, run them on from the first to the twenty-fourth—from one o'clock to twenty-four o'clock. The Chinese, on the other hand, divide the day into twelve hours only, each being, therefore, twice the length of ours. In the decimal system adopted by the French, the day was divided into ten hours.

The length of time which elapses while any given point on the earth's surface passes from a similar point in the starry firmament and returns to the same point, is called the sidereal day, and is found, when measured by the motions of the ordinary instruments invented for the purpose of pointing out its subdivisions—namely, time-keepers—to consist of, or be equal to, 23 hours, 56 minutes, 3 seconds, and (to be still more exact, as astronomers require to be) 4 thirds—a third being the sixtieth part of a second. But although the distance of any fixed star in the firmament is so immense that the whole orbit of the earth is but as it were a point itself in comparison, and the motion of the earth in that orbit therefore cannot alter or affect the length of the sidereal day to any appreciable extent, it is otherwise with the solar or natural day, which is that portion of time elapsing between the arrival of the sun at the meridian, or mid-day, on two consecutive days. The main length of this period of time is 24 hours, nearly 3 minutes 56 seconds on the average being required, in consequence of the earth's motion in its orbit, to bring the sun up to the same meridian on every successive day. The present inclination of the plane of the earth's equator to the plane of its orbit, however, which is diminishing, though with extreme slowness, and the unequal rapidity of the motion of the earth in its orbit, which is also diminishing as slowly, with the diminution of the eccentricity of the orbit, really cause the solar or natural days to be of unequal length: so that, though averaging 24 hours each, they sometimes fall short and sometimes exceed that average. It is the former of these causes, too, which gives rise to the difference in the relative length of night and day, according to the seasons of the year.

MONTHS AND WEEKS.

After the day, the next distinct natural measure or division of time marked out by the heavenly bodies, in their time-keeping revolutions, is the month. The lunar month is a period during which the moon revolves once round the earth, and is equal to 29 days, 12 hours, 44 minutes, 3 seconds. The solar month is the period during which the sun appears to pass through a twelfth part of his annual course, or through one of the twelve arbitrary signs of the zodiac, and is equal to 30 days, 10 hours, 30 minutes: it is not so distinctly pointed out by nature as the lunar month. The month came ultimately to be disconnected from the lunar and terrestrial revolutions, as will be afterwards more particularly noticed, and civil or calendar months, accommodated to the year, were substituted; these also, as well as the names given to them in their annual order, will fall to be noticed while treating of the year itself and its subdivisions.

The subdivision of the month into weeks of seven days is very ancient, having, from the most remote period of history, been in use among the Hindoos and other nations in the East, including the Chaldeans and Jews. According to an early practice, the days of the week in various countries received names from planets with which they were imagined to be connected, or from certain deities reverenced by Pagan nations. Thus the French, at the present day, following the practice of the Romans, name the days from Mercury, Jupiter, Venus, &c., while the English adopt Saxon appellations derived from the deities of northern Europe, and from the Sun and Moon. Hence our term Sunday is from the Sun; Monday, the Moon; Tuesday, Tuesco; Wednesday, Woden; Thursday, Thor; Friday, Friga; and Saturday, Seater. (See article SUPERSTITIONS.)

YEARS AND SEASONS.

The year, properly so called, or the solar or astronomical year, is that portion of time which elapses while the sun passes through the twelve signs of the zodiac, or rather while the earth revolves once completely round the sun in its orbit; and while, from the parallelism of the axis of the earth's rotation to itself, combined with its inclination to the axis of the orbit, each hemisphere is turned alternately, once toward and once from the sun; thus constituting, at least in the extra-tropical regions, the distinction between summer and winter.

It would undoubtedly be this marked alternating distinction which would first lead the attention of every rude but progressing nation not inhabiting tropical countries to calculate their time by years, for in these would even the most savage nation feel an interest analogous to that with which they had come to contemplate the alternating distinction between day and night. The spring and autumn, too, would soon be stamped with the impress of their sensibilities as natural periods, respectively, of hope and fruition. But it is rather remarkable that the only distinctions in the seasons made by the most ancient nations known were those of summer and winter, as if these had been so extreme as to absorb all other distinctions.

The distinction of the seasons would soon be found to depend upon the alternate approach and departure, or elevation and depression, of the sun in the heavens at stated and regularly recurring intervals; but the exact division of time into solar years could not have been effected till astronomy had made some progress; when it would immediately appear, in the endeavours at length made to measure the year by revolutions of the moon, that as an exact number of days, or times of the earth's rotation, is not contained in "a moon," or lunar month, so an exact number of moons, or even of days, is not contained in a year, or revolution of the seasons. Such observations as these led to methods of accumulating the one period to the other; or, in other words, to the

ADJUSTMENT OF THE CALENDAR.

The Chaldeans, Egyptians, and Indians, and indeed almost all the nations of antiquity, originally estimated the year, or the periodical return of summer and winter, by 12 lunations; a period equal to 354 days, 8 hours, 48 minutes, 36 seconds. But the solar year is equal to 365 days, 5 hours, 48 minutes, 49 seconds; or 10 days, 21 hours, 13 seconds longer than the lunar year, an excess named the *epact:* and accordingly the seasons were found rapidly to deviate from the particular months to which they at first correspond; so that, in 34 years, the summer months would have become the winter ones, had not this enormous aberration been corrected by the addition or intercalation of a few odd days at certain intervals. Thus was the calendar first adjusted, and the solar year estimated to consist of 12 months, comprehending 365 days. But no account was taken of the odd hours, until their accumulation forced them into notice; and a nearer approximation to the exact measurement of a year was made about 45 years before the birth of Christ, when Julius Cæsar, being led by Sosigenes, an astronomer of his time, to believe the error to consist of exactly 6 hours in the year, ordained that these should be set aside, and accumulated for four years, when, of course, they would amount to a day of 24 hours, to be accordingly added to every fourth year. This was done by doubling or repeating the 24th of February; and, in order to commence aright, he ordained the first to be a "year of confusion," made up of 15 months, so as to cover the 90 days which had been then lost. The "Julian style" and the "Julian era" were then commenced; and so practically useful and comparatively perfect was this mode of time-reckoning, that it prevailed generally amongst Christian nations, and remained undisturbed till the renewed accumulation of the remaining error, of 11 minutes or so, had amounted, in 1582 years after the birth of Christ, to 10 complete days; the vernal equinox falling on the 11th instead of the 21st of March, as it did at the time of the council of Nice, 325 years after the birth of Christ. This shifting of days had caused great disturbances, by unfixing the times of the celebration of Easter, and hence of all the other movable feasts. And, accordingly, Pope Gregory XIII., after deep study and calculation, ordained that 10 days should be deducted from the year 1582, by calling what, according to the old calendar, would have been reckoned the 5th of October, the 15th of October, 1582. In Spain, Portugal, and part of Italy, the pope was exactly obeyed. In France the change took place in the same year, by calling the 10th the 20th of December. In the Low Countries the change was from the 15th December to the 25th, but was resisted by the Protestant part of the community till the year 1700. The Catholic nations in general adopted the *style* ordained by their sovereign pontiff, but the Protestants were then too much inflamed against Catholicism in all its relations to receive even a purely scientific improvement from such hands. The Lutherans of Germany, Switzerland, and, as already mentioned, of the Low Countries, at length gave way in 1700, when it had become necessary to omit *eleven* instead of ten days. A bill to this effect had been brought before the Parliament of England in 1585, but does not appear to have gone beyond a second reading in the House of Lords. It was not till 1751, and after great inconvenience had been experienced for nearly two centuries, from the difference of the reckoning, that an act was passed (24 Geo. II., 1751) for equalizing the style in Great Britain and Ireland with that used in other countries of Europe. It was enacted, in the first place, that eleven days should be omitted after the 2d of September, 1752, so that the ensuing day should be the 14th; and, in order to counteract a certain minute overplus of time, that "the years 1800, 1900, 2100, 2200, 2300, or any other hundredth year of our Lord which shall happen in time to come, except only every fourth hundredth year of our Lord whereof the year 2000 shall be the first, shall not be considered as leap years." A similar change was about the same time made in Sweden and Tuscany; and Russia is now the only country which adheres to the *old style*; an adherence which renders it necessary, when a letter is thence addressed to a person in another country, that the date should be given thus:—April $\frac{1}{13}$ or $\frac{\text{June 26}}{\text{July 9}}$; for it will be observed, the year 1800 not being considered by us as leap-year, has interjected another (or twelfth) day between old and new style.

The twelve calendar or civil months were so arranged by Julius Cæsar, while reforming the calendar, that the odd months—the first, third, fifth, and so on, should contain 31 days, and the even numbers 30 days, except in the case of February, which was to have 30 only in what has been improperly termed leap-year, while on other years it was assigned 29 days only; a number which it retained till Augustus Cæsar deprived it of another day.

The commencement of the year, till a comparatively very recent period was the subject of no general rule The Athenians commenced it in June, the Macedonians in September, the Romans first in March, and afterwards in January, the Persians on 11th August, the Mexicans on 23d February, the Mohammedans in July, and astronomers at the vernal equinox. Amongst Christians, Christmas day, the day of the Circumcision, the 1st of January, the day of the Conception, the 15th of March, and Easter day, have all been used at various times, and by various nations as the initial day of the year. Christmas day was the ecclesiastical beginning of the year till Pope Gregory XIII., on reforming the calendar, ordered it, in 1582, to begin thenceforward on the 1st of January. In France and England the same practice commenced about the same time; but, in the latter country, it was not till 1752 that legal writs and instruments ceased to consider the 25th of March, as the beginning of the year. In Scotland, New Year's day was altered both for historical and legal purposes, from the 25th of March to the 1st of January, by a proclamation of King James VI., in the year 1600. The English plan was found exceedingly inconvenient; for when it was necessary to express a date between the 1st of January, which was the commencement of the historical year, and the 25th of March, which opened the legal one, error and confusion were sure to occur, unless it were given in the following awkward fashion—January 30, 1648-9, or 164$\frac{8}{9}$. Even this was apt to lead to mistakes; and it is perhaps, even to this day, a matter of doubt with some intelligent persons whether the execution of Charles I., of which the above is the usual appearance of the date, occurred in the year 1648 or 1649; it in reality occurred in the year which, by our present uniform mode of reckoning, would be called 1649.

The present mode of reckoning time has experienced no interruption, in its leading features, for many years, except under the French republic. In September, 1793, the French nation having resolved that the foundation of their new system of government should form their era, instead of the birth of Christ, whose religion they had in a great measure shaken off, resolved also that a calendar should be adopted on what were termed philosophical principles. The Convention, therefore, having decreed, on the 24th November, 1793, that the common era should be abolished in all civil affairs, and that the new French era should commence from the foundation of the republic, namely, on the 22d September, 1792, on the day of the true autumnal equinox, ordained that each year henceforth should begin at the midnight of the day on which the true autumnal equinox falls. This year they divided into twelve months of thirty days each, to which they give descriptive names, as follow:—from the 22d of September to the 21st of October was Vendémiaire (Vintage Month); to the 20th November was Brumaire (Foggy Month): to the 20th December was Frimaire (Sleety Month;) this completed the autumn quarter; to the 19th January was Nivose (Snowy Month); to the 18th February was Pluviose (Rainy Month); to the 20th March was Ventose (Windy Month); which completed the winter quarter; to the 19th April was Germinal (Budding Month), to the 19th May was Floreal (Flowery Month); to the 18th June was Prairial (Pasture Month); here ended the spring quarter; to the 18th July was Messidor (Harvest Month); to the 17th August was Fervidor or Thermidor (Hot Month); to the 16th of September was Fructidor (Fruit Month), which terminated the period of summer. In ordinary years there are five extra days, namely, from the 17th to the 21st of our September, inclusive; these the French called *Jours Complementaires*, or *Sanscullotides*, and held as festivals; the first being dedicated to Virtue, the second to Genius, the third to Labour, the fourth to Opinion, and the fifth to Rewards. At the end of every four years, forming what they called a Franciade, occurred a leap-year, which gave a sixth complementary day, styled *La Jour de la Revolution*, and employed in renewing the national oath to live free or die. The *week*, though not exclusively a Christian or Jewish period of time, they also abjured. The thirty days of the month were divided into three parts of ten days each, called *Decades*; of which the first nine (called Primidi, Duodi, Tridi, Quartidi, Quintidi, Sextidi, Septidi, Octidi, Nonidi) were working or common days, while the tenth, styled Decadi, was observed as a kind of Sabbath, though not exactly in the Jewish sense of the word. The French, however, in indicating any particular day, either by word or writing, generally mentioned only the number of the day of the month. The Republican Calendar was first used on the 26th of November, 1793, and was discontinued on the 31st of December, 1805, when the calendar used throughout the rest of Europe was resumed.

CYCLES.

A cycle is a perpetual round or circulating period of time, on the completion of which certain phenomena return in the same order, the end being thus, as it were, brought back to the beginning. Under such a definition, the common practice of accumulating years into centuries has, of course, no title to be classed; it is merely an arithmetical computation, like the equally common mode of counting by tens—forming, indeed, part of the same system.

The *Solar Cycle* is a period of 28 years, during which the day of the month, in every succeeding year, falls on a different day of the week from the first, till the cycle is completed; when the days of the month and week meet as at first, one cycle corresponding to another. By this cycle, which has no relation to the sun's course, we find "the Dominical letters," or those letters among the first seven in the alphabet (used to represent the days of the week) which point out the days of the month on which the Sundays fall during each year of the cycle. If there were 364 days in the year, the Sundays would happen every year on the same days of the month; if 365 exactly, every 7th year; but because the additional fractional period contained in the year makes an alteration of a day in every 4th year, the cycle extends to four times seven, or 28 years.

The first solar cycle in the Christian era having begun 9 years before the commencement of that era, to discover what year of the cycle the year 1842 forms, we must add 9, and divide the sum 1851 by 28, the period of the cycle, and the quotient 66 is the number of solar cycles that have passed during that era, the remaining 3 being the year of the cycle corresponding to 1842.

The *Lunar Cycle*, also called the "Golden Number," from its having been written in letters of gold by the Greeks, and the "Metonic Cycle," from its having been discovered by Meton, an Athenian astronomer, is a period of 19 years, at the end of which the phases of the moon occur on the same days of the civil month as in a previous lunar cycle, and within an hour and a half of the same precise moment of time.

The first lunar cycle in the Christian era having begun one year before the commencement of that era, to discover what year of the cycle 1842 forms, we must add 1, and divide the sum 1843 by 19, the period of the cycle, and the quotient 97 is the number of lunar cycles that have passed during that era: there being no remainder, the golden number is completed in 1842; or that year forms the last in the cycle.

The *Dionysian Period* is a combination of the solar and lunar cycles, forming, by the multiplication of 28 by 19, a period of 532 years, at the expiration of which it is again new moon on the same days of the week and month as before: chronological events are compared and tested by such a calculation.

The *Indiction* may here also be noticed; though, were it not for severing it from the other cycles with which it is connected in the Julian period, it might perhaps more properly appear under the head of epochs and eras. This was a Roman period of 15 years, the first of which commenced in the year 312 after the birth of Christ. It was appointed merely for the regulation of certain payments by the subjects of the empire; but it came to be observed by the Greek church and the Venetian senate, as well as the court of Rome.

The *Julian Period* is a combination of the solar and lunar cycles with the Indiction; the respective periods of 28, 19, and 15 years being multiplied by each other, and the product 7980 years, being what is called the Julian Period, during which there cannot be two years having the same numbers for the three cycles; but at the termination of this period they return in the former order.

The year 1842 is the 6555th of the Julian period; hence it began about 700 years previous to the date vulgarly assigned to the creation of the world, and has been used instead of that era, to obviate the disputes of chronologers, and to reconcile their systems; for all agree as to the year in which the Julian period began.

The *Precession of the Equinoxes*, on the supposition that the motion on which it depends is uniform, is a cycle of 25,920 years, during which the points whereat the sun crosses the equator at the equinoxes retrograde along the whole circle of the ecliptic, and return to their former position. The present rate of this motion, which depends on the solar and lunar attraction of the quantity of matter heaped up along the region of the equator, is 50 seconds of a degree yearly, or a whole degree in 76 years.

Sir Isaac Newton endeavoured to fix the period of the Argonautic expedition by this cycle, and it has given rise to some curious and interesting speculations regarding the period when the signs of the zodiac were invented.

The *Ecliptical Cycle* is an unknown period of time during which the angle between the ecliptic and the equator, or the obliquity of the ecliptic, has completed all its changes. The present rate of the diminution of the obliquity is estimated at about 48 seconds of a degree every century. The extent of this change on either hand, like the length of the period in which it is accomplished, is at present unknown, though astronomers, founding on elements with regard to which there admittedly exists "great uncertainty," suppose the extent of the "oscillation" to be very limited. The degrees of ecliptical obliquity at present existing in the *different* planets, however, so far as known, vary from a state in which it almost vanishes in the entire coincidence of the ecliptic with the equator, as in Jupiter, to one in which it is almost "wide as the poles asunder," as in Uranus. The ascertainment of the extent of this movement, in the case of the earth, is of great practical importance, especially in geological chronology. The changes of the seasons are occasioned by the obliquity of the ecliptic, being more or less extreme according to the greater or less degree or extent of that obliquity; and, from certain recent discoveries in geology, which seem to imply the former increase of these extremes, coincidently with the former increase of the obliquity of the ecliptic, it appears highly probable that the hiththe hopeless problem of a *geological chronology*, in its most comprehensive sense, by a "conversion of astronomical into geological periods"—a problem proposed a few years since as the subject of a prize essay by the Royal Society of London—will receive its complete solution from the movements of this great ecliptical pendulum.

CHRONOLOGY.

The subject to which we have here found it advantageous to limit the use of the term Chronology, as more or less involving the occurrence of events in the world's history, may be divided into the two following branches:—

EPOCHS AND ERAS.

The principal difficulty which must have presented itself to nations desirous of preserving the memory of events, as they might occur, in their annals, from day to day, from month to month, and from year to year, and for long periods of years, would be to obtain a starting point from which to number these days, months, years, and periods of years; and as no very marked astronomical event (unless, perhaps, eclipses) could render one of these starting points preferable to another, such starting points came practically and generally to consist, in early times, when nations had little mutual intercourse, of some event, important or known, perhaps, only to the nation dating from it. This event would form *an epoch*, so named from a Greek word signifying to stop. The enumeration and series of years computed from an epoch is called an *era*; and accordingly of epochs and eras there have been almost as many as there have been of nations. As the eras of ancient nations, however, have become obsolete, it would be useless, as it is here impossible, to enumerate all that we know of, or even any great number of them. But we shall notice a few of the most important in the mean time, reserving the names of all the other principal eras to be afterwards presented together in a tabular form.

The *Era of the Olympiads* is the first on record, and it also became the most celebrated of the ancient methods of computing lengthened periods of time. It took its rise among the Greeks, 776 years before the birth of Christ. Public games had been instituted at Olympia, a city in Elis, which took place every fifth year, at the recurrence of the full moon after the summer solstice, namely, about the beginning of our July. As this festival made a great impression on the public mind, the people began to reckon by Olympiads, or recurrences of the Olympic games, an Olympiad comprising four years. The computation by Olympiads ceased after the 364th Olympiad in the 440th year after the birth of Christ, as usually computed, though the epoch of the birth of Christ is not a point of time exactly fixed. The Greeks lately adopted a new era, called

The *Era of Seleucus*, or the *Seleucidæ*, sometimes also called the era of Alexandria. This era commenced twelve years after the death of Alexander the Great, at the first conquest, by Seleucus Nicator, of that part of the west which afterwards formed the immense empire of Syria. This era has also prevailed, and still exists, amongst the people inhabiting the Levant. The Jews reckoned by it till the 15th century of the Christian era, when they substituted the supposed era of the Creation, to be afterwards noticed; and they still begin their year according to it, in the months of September or October.

The *Roman Era* was reckoned by the Romans from the epoch of the foundation of their famous city Rome, an epoch now precisely ascertained to have corresponded to the 753d year before the birth of Christ. The computation of time by the Roman era ceased in the sixth century of the Christian era.

The *Christian Era*, of which we now live in the eighteen hundred and forty-second year, was not adopted as a mode of time-reckoning immediately after the commencement of Christianity. That religion existed long in a very obscure way; and the date of the birth of its founder did not, for several centuries, become a sufficiently important event in the eyes of enlightened nations to cause them to make it an era. The era of the Olympiads, the Roman era, the era of Seleucus, and the dates of ecclesiastical councils, and other events then considered of importance, were the common modes of reckoning, and continued partially to be so till a period less remote than many people suppose. Even in Italy and its celebrated capital, Rome, which became the chief seat of Christianity at a very early period, this era was not used till the sixth century. It was introduced into France in the seventh, but not fully established till the eighth. In Spain, though occasionally adopted in the eleventh, it was not uniformly used in public instruments till after the middle of the fourteenth, nor in Portugal till about the year 1415. Now, however, all nations professing Christianity have abandoned other eras, and confined themselves to this; using the Latin words *Anno Domini*, "the year of our Lord," or their initial letters, A. D., to distinguish it; while for all dates previous to the generally received epoch of the era, the words *Anno ante Christum*, "the year before Christ," their abbreviation, A. A. C., or even more usually the letters B. C., signifying "before Christ," are used.

The *Era of the Hegira* commences at the epoch of the flight of Mohammed from Mecca to Medina, which took place on the 16th day of July, A. D. 622. The Mohammedan year is regulated by this event, and hence it is used by the Turks, Arabs, and other Mohammedans, comprising a large portion of the modern population of the world.

The *Mundane Era*, or era of the creation of the world, has been the subject of much controversy. No less than 300 different opinions, according to Kennedy, in his "Scriptural Chronology," have been entertained regarding the period which elapsed between the creation and the incarnation. Some have made it 3616 years; others 6484. From the creation to the deluge, the computation of the Hebrew text makes a lapse of 1656 years; the Samaritan version only 1307; the Septuagint 2262. No ancient chronologist attempted to fix the epoch of the creation: some conceived it impious to do so. In modern times, the impiety has been supposed to lie all the other way. But some enlightened commentators have been bold enough to return to the ancient orthodox idea, so far, at least, as to maintain that the Scriptural epoch of the creation is indefinite, being merely cursorily alluded to in the words, "In the beginning God created the heavens and the earth." Geologists, in general, also adopt this wide interpretation. In the authorized version of the Bible, however, the chronology usually given places the epoch of the creation in the year 4004, B. C. Thus, A. D. 1 is A. M. 4004; the letters A. M. being used as an abbreviation of *Anno Mundi*—"year of the world."

TABULAR CHRONOLOGY.

Under this head the leading events, phenomena, or facts, recorded in history, are arranged in the order of time in which they have occurred—that is, in chronological order.

BEFORE CHRIST.

Twilight of history previous to B. C. 3000. But fabulous or doubtful till about 1200, or the period of the Trojan war. Homer lived at about 1000 B. C. Fall of Assyrian empire, 900.

800.—Chaldeans in Mesopotamia—Reckoning by Olympiads, 777. New Assyrian empire—Rome founded, 753 (according to Newton, 627). Æthiopians in Egypt—Syracuse—End of kingdom of Israel—Babylonian Assyrian empire—Epoch of era of Nabonassar, 747. Grecian colonies in Italy.

700.—Draco in Athens—Nebuchadnezzar—Invasion of Upper Asia by Scythians, 635. Zoroaster in Persia.

600.—Babylonish Captivity, 588. Cyrus, king of Persia, conquered the Medians, 546. Pythagoras flourished, 539. Cyrus took Babylon, 538. Return of Jews, 536. Pindar, 518. Parmenides—Heraclitus—Anaxagoras, 500.

500.—Sophocles, 495. Tribunes and Ædiles at Rome, 493. Herodotus born, 484. Euripides, 480. Thucydides, 471. Athenian ascendancy, 477. Socrates born, 468. Zeno, 464. Xenophon born, 444. Isocrates born, 436. Metonic cycle began, 432. Peloponnesian war began—Hippocrates flourished, 431. Plato born, 429. Aristophanes flourished, 427. Diogenes born, 413. Athens taken, 404. Retreat of 10,000 Greeks, 401.

400.—Aristotle born, 384. Demosthenes, 382. Lacedæmonians expelled from Thebes, 379. Epaminondas—Thebans in Greece (till 362), 371. Prætors at Rome, 365. Alexander the Great born—Dionysius expelled from Syracuse by Dion—Theopompus flourished, 356. Menander born, 342. Epicurus, 341. Macedonian ascendancy, 338. Thebes destroyed by Alexander, 335. Persia invaded, 334. Syria and Egypt conquered, 332. Death of Alexander—His empire divided, 323. Ptolemy carried 100,000 Jews into Egypt, 320. Alexis flourished, 310. Restoration of Thebes, 315. Seleucus in Babylon—Era of Seleucus began, 312. Sun-dials in Rome—Time divided into hours, 308. Athenian democracy restored, 307. Ptolemy took Lybia, Egypt, and Palestine; Cassander took Macedonia; Lysimachus took Thrace and Bithynia; and Seleucus took Syria with most of Upper Asia, all about this period.

300.—Chrysippus born, 280. Gauls driven out of invaded Greece into Asia—Zeno of Citium, Strato, and Epicurus flourished, 278. Silver first coined at Rome, 269. First Punic war, 265. Regulus put to death, 250. Antiochus the Great, king of Syria—Second Punic war—Hannibal passed the Alps, 218. He defeated the Romans at Thrasymene, 217; at Cannæ, 216. Archimedes's screw invented—Archimedes killed, 212. Polybius born, 206. Plautus flourished, 204. Hannibal defeated by Scipio at Zama, 202. First Macedonian war, 201.

1829.—York Minster injured by fire, 2d February. Pope Leo XII. died, 10th February, and was succeeded by Pius VIII. Duel between the Duke of Wellington and Earl Winchelsea. Protocol of Britain, France, and Russia, arranging government, boundaries, &c., of Greece. Catholic emancipation bill carried in House of Lords, 10th April.

1830.—French expedition against Algiers set sail 25th April (city taken 5th July). George IV. died, and William IV. proclaimed, 26th June. The three fatal ordinances issued at Paris to overthrow the charter, 25th July. A coup d'etat violently demanded by the ultras. Stern resistance of the Parisians during three days, 28th, 29th, and 30th July. Flight of Charles X.; abdicated in favour of Duke de Bourdeaux, 2d August. Louis Philippe, Duke of Orleans, declared by Chamber of Deputies king, 7th August. Liverpool and Manchester railway opened, 15th September. National guards re-established. Revolution in Belgium; Dutch rule overthrown and Belgium declared independent, 4th October. Grey ministry formed, 22d November. Polish revolution began at Warsaw, 29th November. Recognition of Belgic independence by allied powers. Polignac and other French ministers tried; the ministers condemned to perpetual imprisonment, and Polignac to civil death.

1831.—Cholera appeared at St. Petersburg, 12th January. Gregory XVI. Pope, 9th February. Reform bill introduced into British Parliament by Lord John Russell, 1st March; frustrated in committee. Parliament dissolved. Carried in new House of Commons, 22d September; rejected by the Peers, 7th October. Riots at Bristol. Great meetings of reformers. Leopold accepted the crown of Belgium. Warsaw surrendered to the Russians. Cholera appeared in England, [illegible] ember.

1832.—Cholera in Edinburgh, 6th February [illegible] ondon, 16th. British reform bill again frustrated in House of Lords. Resignation of ministers, 7th May. Duke of Wellington attempted to form an administration; failed. Earl Grey recalled, 18th May. Reform bill passed. Otho of Bavaria king of Greece. Insurrection at Paris. Don Pedro landed at Oporto 9th July. Civil war for possession of Portugal. Cheap periodical publications of a respectable character began this year: Chambers's Edinburgh Journal, Feb. 4; Penny Magazine, March 31.

1833.—First reformed British Parliament. Bill passed in British Parliament for abolition of slavery in West Indies. Lisbon surrendered to Don Pedro. Opening of China trade in Britain. Donna Maria recognised as queen of Portugal by Britain. Death of Ferdinand VII., king of Spain. Return of Captain Ross from North Seas, after an absence of four years.

1834.—Hostilities in Spain between the adherents of Don Carlos and those of the Queen. Earl Grey resigned, 10th July, and was succeeded by Lord Melbourne. Great dinner to Earl Grey at Edinburgh. Lord Melbourne dismissed by William IV., after being five months in office, and Sir Robert Peel called to the premiership. Dissolution of British Parliament.

1835.—New election and meeting of British Parliament. British ministers defeated on question of Speakership, 19th February. Resignation of Sir Robert Peel. Lord Melbourne recalled, 18th April. English municipal reform act passed, 7th September. Captain Back's return from Arctic land expedition. First election of English town councils under reform, 25th December.

1836.—Ferdinand Augustus, Duke of Saxe Coburg, married by proxy to Donna Maria, queen of Portugal, 1st January. Madame Maria Lætitia Bonaparte, mother of Napoleon, died at Rome, 2d February (born 24th August, 1750). Revolution at Lisbon; constitution of 1820 accepted by Donna Maria. Parliament of Lower Canada opened by Earl Gosford, and dissolved as refractory. Charles X. died at Goritz, in Hungary, 6th November. Balloon voyage from London to Nassau on the continent, in 18 hours, 7th November. Prince Polignac released and exiled, 23d November.

1837.—General Espartero successful in Spain. Princess Victoria, on the 24th May, attained the age of 18, the period of majority by act of Parliament. All the American banks suspended specie payments; very extensive failures. William IV. died, aged 72, after a memorable reign of 7 years. Queen Victoria proclaimed, 22d June. Duke of Cumberland entered Hanover (27th June) as king by salique law, in place of William IV. Grand Junction railway from Birmingham to Liverpool and Manchester railway, opened in July. Railway from Paris to St. Germain, opened 26th August. Riots at Montreal. Carolina American steamer attacked and burnt by Canadians on United States territory, 20th December.

1838.—Sir Francis Head repelled Canadian insurgents under Dr. Mackenzie at Toronto, 5th January. Royal Exchange, London, burnt 10th January. Earl of Durham sent to Canada as Governor-General and High Commissioner, 16th January. Prince Talleyrand, the celebrated French diplomatist, died 17th May. The "Great Western" steamer, the first that ever crossed the Atlantic, arrived at New York from Bristol in fifteen days, on 17th June. Coronation of Queen Victoria, 28th June. Spain still distracted by civil war. The number of newspapers put into the London Post-office on 2d July for provincial circulation was 175,000. Slavery abolished in East Indies. Railway from Ghent to Ostend, opened 2d September—from Paris to St. Cloud, 6th September. Emperor of Austria crowned with iron crown of Lombardy, 6th September. London and Birmingham railway opened throughout, 17th September. Railway from Potsdam to Berlin, opened 29th October. Disturbances in Canada suppressed, 17th November. British troops entered Affghanistan, as auxiliaries of the legitimate king of Cabool, Shah Soojah, against the usurping chief, Dost Mahomed.

1839.—Melbourne ministry resigned, 7th May. Railway from London to Croydon, opened 1st June. Hostilities between Ibrahim Pasha for Mehemet Ali, viceroy of Egypt, and the Sultan, 10th June. Railway from London into the eastern counties opened to Romford, 18th June. Sultan Mahmoud II. died, and his son Abdul Medjid proclaimed, 27th June. The five powers interfered between the Porte and Mehemet Ali, 16th July. Ghiznee taken by the British in India—Dost Mahomed defeated, and Shah Soojah enthroned in Cabool, 20th July. Railway from Paris to Versailles, opened 2d August. Flight of Don Carlos—Peace in Spain, 25th August. Chartist attack on Newport; Frost, an ex-magistrate, and others, apprehended, 4th November. Queen Victoria announced to the Privy-Council her intention to marry Prince Albert of Saxe-Cobourg Gotha, 23d November. Frost and others found guilty of high treason; sentence commuted to transportation for life, 31st December.

1840.—The Chinese emperor issued an edict prohibiting all commerce with the British "barbarians." Penny postage, 10th January. Treaty of commerce between Turkey and Sweden, 23d January. Marriage of Queen Victoria to Prince Albert solemnized, 10th February. Insurrection of Syrian mountaineers against Pasha of Egypt, 7th June. Oxford, a pot-boy attempted to shoot Queen Victoria, 10th June. Prince Louis

Napoleon landed at Boulogne in a steamer with 40 or 50 followers to overturn the French government, and was arrested, 6th August. Convention between Turkey, Austria, Prussia, Russia, and England, for settlement of Eastern question, ratified 15th August. Fortification of Paris by walls, &c., ordered by government, 20th August. Louis Napoleon sentenced to perpetual imprisonment, 6th October. Voluntary abdication of king of Holland, who retired into private life, 7th October. Abdication of Queen Regent of Spain, 12th October; Espartero made Regent. Blockade of all Egyptian and Syrian sea-ports announced in London Gazette, 13th October; suspended till 20th November. Another unsuccessful attempt to assassinate Louis Philippe, 15th October. Capture of Sidon and Acre by allied troops, November 5 and 6. Princess Royal born 21st November. Mehemet Ali agreed to terms of allies; namely, to evacuate Syria, restore Turkish fleet, and receive Egypt as hereditary fief of the Porte, 27th November. Total abstainers from spirituous liquors, or tee-totallers in Ireland, estimated by Father Mathew at 3,300,000. Remains of Napoleon Bonaparte deposited with great pomp in Hotel des Invalides, Paris, 15th December.

1841.—Union of Canadas proclaimed at Montreal, 10th Feb. General Harrison, President of United States, died 4th April, and succeeded 5th, by Mr. Tyler, Vice-President. President, Atlantic steamer, missing, 11th April, and never since heard of. Espartero declared, by Spanish chambers, regent during minority of queen, 12th April. Sir Henry Pottinger sent out to China. Canton taken, but ransomed by Chinese for $6,000,000. Great Western railway from London to Bristol opened throughout, 30th June; cost £5,000,000. Statue of Napoleon placed on column of Grande Armée at Boulogne: fêtes in celebration of the event, 13th to 18th August. Conference of clergy at Manchester for repeal of corn-laws: 650 ministers present. Parliament re-assembled, 19th August. Dreadful destitution in Paisley. Melbourne ministry resigned, 30th August. Railway from Cologne to Aix-la-Chapelle, and other continental lines, opened. Attempt to assassinate a son of Louis Philippe, 13th September. London and Brighton railway opened, 21st September. Dublin, 25th October, Daniel O'Connell was elected Lord Mayor. Birth of Prince of Wales, 9th November.

TIME-KEEPERS.

Reference has already been made to article Astronomy, for an account of the most primitive and natural, as well as the most perfect time-keepers. Our attention here, therefore, must be confined to those artificial machines which have been invented chiefly for the purpose of adding to the convenience of these, by dividing the unit of astronomical time-keeping, namely, the day, into fractional parts, termed hours, minutes, and seconds; there being no such convenient and desirable measurement obvious in nature. Yet long before the invention of any artificial machine, the interval between sunrise and sunset was really divided, with no little accuracy, even among the rudest nations, simply by the shortening, turning, and lengthening of the shadows of trees, rocks and mountains; and it was this primitive mode of dividing the day which no doubt naturally suggested the first idea of

SUN-DIALS.

The most ancient artificial time-keeper of which we have any historical notice is the sun-dial of king Ahaz, who lived about 742 years before the birth of Christ. The first sun-dial constructed on mathematical principles, however, was probably one placed near the temple of Quirinus at Rome, B. C. 293. The Romans, at this time, were not aware that a dial made for Rome is not suited to other places. The ancients used hemispherical dial-plates, and placed the radius which throws the shade in the direction of the north polar star. The dial-plates now in use are flat, with the style or gnomon, the edge of the shadow of which determines the hour-line, running in the plane of the meridian, and hence, also, due north and south; while its sloping edge forms an angle with the horizon equal to the latitude of the place in which the dial is situated, and hence parallel to the earth's axis. Although a sun-dial may certainly be adjusted so as to point out the time of day within a few minutes, it is needless here to dwell farther on the details of an instrument now of little use. The most perfect of sun-dials being only available in sunshine, and not at all through the night (in which, by the way, moon-dials are sometimes used), they were partly superseded, even at a very remote period, by

CLEPSYDRÆ AND SAND-GLASSES.

It has been thought that the regular motion of the dropping of water, and the simpler forms of clepsydræ, or water-clocks, were used for the measurement of time even previous to the invention of sun-dials. They certainly were known in very remote antiquity, and were used in various parts of Asia and Europe; in China, India, Chaldea, Egypt, Italy, and Greece; into the last of which countries they were introduced by Plato. Julius Cæsar found them even in Britain. It was by them that he discovered some of the nights to be shorter or longer in this country than in Italy, which is nearer the equator, or line of equal days and nights. The Romans themselves had clepsydræ 100 years before Cæsar's invasion; and it is supposed that the Phœnicians had introduced them into Britain through Cornwall, where they traded for tin. The clepsydra, invented by Ctesibius of Alexandria, B. C. 145, consisted of a jar containing water, which slowly escaped by a hole at the bottom, while the oar of a miniature boat on the surface, as it sank with the fall of the water, pointed out the hours, which were marked on the side of the jar. It is even alleged that toothed wheels were applied to clepsydræ by Ctesibius. Such instruments, however, though brought to great perfection in the ninth and tenth centuries, and, indeed, still used in India, have never been made to measure time with great accuracy, the water always dropping more slowly as its quantity and weight diminish.

The running of sand through a tube was another obvious species of regular motion, very analogous to the running or dropping of water; and accordingly the hour glass, still in use in this and other countries, was also a very early invention. It was known, if not first made, in Alexandria, B. C. 140.

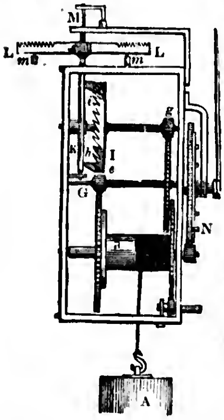
PLANETARIUMS OR ORRERIES.

It is rather a curious circumstance, that, long before the invention of clocks or watches, artificial machines, imitative of the motions of the sun, moon, and planets, the natural time-keepers, were constructed by the ancients.

Of the planetariums of modern times, the first in England was one made for Lord Orrery, whose name has since been given to such machines. The talented and self-taught astronomer, Ferguson, who was originally a poor Scottish herd-boy, made several orreries, and used chronometers to keep them in motion. But though the accuracy with which wheels and pinions can be made to represent different revolutions is beautifully illustrated by the best of these machines, they can give no just conception of the relative size, distance, or velocity of the planets, or hence of the periods of their revolution; and in this respect, therefore, they are mere philosophical toys, as will be at once perceived by reference to article Astronomy, in which an accurate representation of one is given, together with a method, first suggested by the celebrated astronomer, Sir John Herschel, of pointing out the actual sizes, distances, &c., of the various bodies in the solar system in relation to each other

CLOCKS.

The strong hold which the planetary motions appear to have taken on the minds of our forefathers, as the great antitypes of all true time-keepers, is also curiously manifested in the fact, that even when a more detailed measurement of time became necessary, in the intellectual progress of nations, these motions still continued to be represented, so that the very first clock of which we have any perfectly authentic account—that, namely, invented by Wallingford, Abbot of St. Albans, in 1326 not only showed the hours, but the apparent motion of the sun, the changes of the moon, the ebb and flow of the tides, &c. This, however, was by no means the first clock ever constructed; instruments with weights, wheels, pinions, and a balance, for the measurement of time, having been long previously known, though by whom invented appears to be a subject of much controversy. Doubtless they required more than the intellect of a single mind. Be this as it may, the most ancient clock of which we have any description, is that of Henry Vic or De Wyck, a German, erected in the tower of the palace of Charles V., king of France, in 1379; and rude and imperfect as it was, the analogy of modern invention, especially in watches, would lead us to think that it must have been the fruit of several centuries of thought and improvement.



A portrait of this parent of modern time-keepers may be interesting to our readers; and from its comparative simplicity, will be well adapted as a ground-work for further explanation of the mechanism of clocks and watches in their more complex and intricate forms. It will, moreover, show the general mode of construction adopted in the fourteenth century, including the balance with weights instead of a pendulum, by which the motion was then regulated.

General Movement and Regulation of Clock-work.

Without requiring to enter into any very minute detail of the manner in which motion in a clock or watch is successfully communicated from one toothed wheel G or I, or pinion *e* or *g*, to another, which, indeed, would in some instances only tend to perplex the mind of the general reader, it will be readily understood that the weight A below the clock-work, wound up by a cord on the cylinder B, in its constant tendency to fall to the ground, will cause the cylinder to turn round on its axis as it falls, and as the cord uncoils; and thus one toothed wheel or pinion will set another in motion, till the movement be communicated to the crown wheel, escapement wheel, or wheel of rencounter, I, the teeth of which so act on the two small levers or pallets, *ih*, projecting from and forming part of the suspended upright spindle or vertical axis, KM, on which is fixed the regulator or balance, LL, that an alternating or vibratory instead of a circular motion of the balance itself will be the result. The rotatory motion of the wheel-work, in short, will be converted into a vibratory motion by the alternate catching of the levers by the teeth of the crown or escapement wheel, and their alternate escape or 'scapement from them: this, or something always similar, is the cause of the constant ticking of a clock or watch.

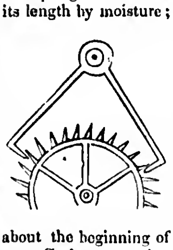
Now, it will at once appear manifest that a heavy weight, such as that here represented, operating on a few wheels thus arranged, unless it have some counteractive weight or other check to modify and balance its operation, will rapidly run down even to the ground, if the height of the clock-work and the length of the cord attached to the cylinder permit it, causing the wheels to rotate, the balance to vibrate, and the hands to revolve on the face of the clock, with similar rapidity, increasing every moment till the weight be fairly run down. It is this rapid motion of the wheel-work which begins in a *modern* clock whenever the *pendulum* is taken away while the weights are still attached to the cylinders; and the rapid ticking then heard is the uncounteracted operation of the crown wheel, moved by the falling weight upon a piece of mechanism similar in purpose to the levers and spindle in the above figure. To prevent this rapid unwinding of the clock-work, then, and to adjust it to the more deliberate measurement of time, we have, in De Wyck's clock, the balance, *loaded with two weights*, *m m*; and the farther these are removed from the axis or spindle, KM, the more heavily will they resist and counteract the escapement of the levers and the rapidity of the rotation of the escapement wheel, till the clock be brought to go neither too quick nor too slow; when, of course, it would be improper to remove them further towards the ends of the balance, as the clock would then go too slow for correct time-keeping.

Pendulum and Escapement.

What the balance and the weights attached to it in De Wyck's clock were to clocks of an ancient date, the pendulum is, in general, to modern clocks; the oscillations of the pendulum, and the vibrations of the balance, being completely analogous in purpose and effect, both being kept up or sustained by the "escapement," while both require, or, as it were, demand, by the law of gravity, a certain time for their performance; and thus, by reaction, check and equalize the exercise of those very powers and movements by which they are kept in play. The measurement of time being thus regulated by the oscillations of the balance or the pendulum, this part of the mechanism of a clock, including the escapement, is of primary interest and importance; and we shall find this also to be the case in the numerous contrivances, chiefly by English artists, to effect the same object to the best advantage in the still more delicate and ingenious mechanism of watches. We may here also remark, that, so invaluable is the principle of *regulation*, whether by oscillation or rotation, and so generally and extensively useful in other respects, that, from the smoke-jack to the steam-engine, has it, in one form or other, been called into practical operation.

Galileo, the great astronomer, when a student at Pisa, happened to discover, while engaged in the cathedral there—not in meditating on the imposing ceremonial of the Catholic church, which was then in progress, but in what, to many a good Catholic, would undoubtedly have seemed the vacant, idle, and profane contemplation of the lamps which swung from the roof—that the oscillations of a pendulum, whether great or small, are performed in equal times in each pendulum—an important fact, the truth of which he tested, not by the beats of his watch (for no such instrument then existed), but by the beats of a natural time-keeper to which we have not yet alluded—namely, the pulse. He afterwards discovered, what was ultimately demonstrated by Newton, that "the shorter the pendulum the less is the time of its vibration;" or, in other words, that the number of oscillations performed by a pendulum in a given time depends on its length, four times the length producing twice the number of oscillations. A pendulum, the length of which, from the point of suspension to the centre of the weight attached to its lower extremity, is 39 inches and 2 tenths, will oscillate once precisely every second in the latitude of London; not in any other latitude, however, as has been found by experience; the number of oscillations with the same length of pendulum diminishing towards the equator, where oscillations equal in length to 2 minutes 15 seconds a day will be lost; while, on the other hand, they will increase towards the poles, where a proportional number of oscillations will be gained. Thus the pendulum of a clock, made and adjusted to time in London, requires to be lengthened if taken nearer to the poles, or shortened if taken towards the equator.*

The first use which Galileo, then a medical student, made of his valuable discovery was to ascertain the rate and variations of the pulse; and its application to clock-work was an afterthought. It is even denied that he did more than suggest such an application; or, as has been also alleged, that at all events his son put his suggestion into execution; and accordingly the merit of the invention of pendulum clocks is very generally attributed to Huygens, a learned Dutchman, about 1657. This celebrated philosopher, in adapting the pendulum to the mechanism previously invented, had little more to do than simply to add a new wheel to the movement, so as to enable him to place the crown wheel and spindle in a horizontal instead of a perpendicular position, that the lower arm of the balance—then, of course, perpendicular, instead of horizontal, as in De Wyck's clock—might be extended, as it were, downwards, and thus, in fact, be converted into a pendulum. The principle thus adopted, however, from the peculiar action of the levers and spindle, required a light pendulum and great arcs of oscillation; and the consequence was, as Mr. Thompson, a recent popular author, tritely remarks, that "Huygens' clock governed the pendulum, whereas the pendulum ought to govern the clock." About ten years afterwards, the celebrated Dr. Hook invented a better method, which was introduced by Clement, a London clockmaker, in 1680, and enabled a less maintaining power to carry a heavier pendulum, which, also making smaller swings or arcs, was less resisted by the air, and therefore performed its motion with greater regularity. This was called the anchor escapement, and it is still in use, together with the practice to which it gave rise of suspending the pendulum by a thin flexible spring instead of a cord, which was liable to change its length by moisture; an evil, however, perhaps fully equalled by the variation of the elasticity of the spring by heat and cold. The seconds pendulum, with the anchor escapement, was called the *royal* pendulum. As this plan, however, was found to cause a reaction or retrograde movement of the wheels, and has hence been called the *recoil* escapement, a further improvement was made about the beginning of the eighteenth century by George Graham, another English artist, who invented the repose or dead escapement.



The wheels are kept by this escapement in a state of repose or rest during the whole oscillation of the pendulum, except at the moment when it receives its impulse from the crown-wheel. Requiring smaller arcs, too, even than before, the oscillations are made in more equal times. A still more perfect modification of the escapement is the free or detached, but it is more difficult to execute. The half-dead escapement, also, has been introduced as a mean between the dead escapement, an increase of power with which causes a clock to lose time, and the recoil escapement, with which a similar increase of power causes one to gain. For the purposes of ordinary clocks, this mode of escapement has been found to answer very well.

Compensation Pendulums.

Pendulum rods, which are usually made of metal, though sometimes of wood, especially in church clocks, were next found to vary in length by variations of temperature, according to that law of nature by which every body increases in volume or in actual size by heat, and diminishes or contracts by cold. The inevitable consequence of the influence of such variations on the length of the pendulum will at once be seen, from what has been already said, to be an increase of the number of its oscillations in a given time while in cold temperatures, and hence shorter than its mean length, as in winter, or even at night or in cold situations; and a diminution of them while in warm temperatures, and hence longer, as in summer, or even during the day, or in warm situations: and a pendulum with a metal rod will cause a clock to vary several seconds in a day from such changes alone. To insure, therefore, a still greater accuracy and uniformity in the measurement of time than had previously been obtained, various ingenious but simple devices have been put into practice, wherein the very cause of the inaccuracy has been made subservient to the end desired. And here the talent of the artist Graham again displayed itself, and led the way to every other modification of the primitive *idea*, however dissimilar in detail, and whether applicable to pendulums or balances, to clocks or watches. Indeed, the first method of "compensation" adopted for pendulums has, with some little improvement, ultimately superseded all its more recent modifications. This method Graham called "the mercurial compensation," and it consists simply of a tube or cylindrical glass jar containing quicksilver or mercury, and attached to the lower end of a steel rod in the arc of its oscillation. As the steel rod lengthens by heat, the mercury expands in volume and rises in the tube; while, as the rod shortens by cold, it contracts, and sinks or falls. Thus the arc of oscillation remains ever at the same distance from the point of suspension or upper extremity of the pendulum; or, in other words, the pendulum, in fact, remains ever of the same length. Graham also conceived the notion of another compound pendulum, composed of different metals so arranged as to compensate each other by their *difference* of expansion or contraction. This modification of the idea of a compensating pendulum was more fully developed by John Harrison, another celebrated artist, who in 1726 invented the gridiron pendulum, composed of five rods of steel and four of brass, so arranged that the rods which expand the most raise the weight at the bottom of the pendulum, as much as the rods which expand the least depress it. Unfortunately, however, this compensation changes, as all metals do, not continuously and gradually, under the influence of heat or cold, but by jerks. The mercurial pendulum, therefore, under certain improvements by Thomas Reid, a talented Edinburgh artist, and by others, has of late been frequently resumed; and it has been found that time-keepers provided with this pendulum and a dead escapement do not vary, on the average, more than a quarter of a second daily—a degree of accuracy wonderful, indeed, when contrasted with the fact, that down to the middle of the sixteenth century clocks were incapable of going nearer to accurate time than about 40 minutes within the 24 hours, and were nevertheless held

* The discovery of this fact, when cleared of the effects of difference of temperature on the length of the pendulum, served to *demonstrate* that the earth is in rotation on an axis passing through the poles; and that its form is that which must result to a fluid or molten mass from precisely such a line and measure of rotation: namely, not a perfect sphere or circular globe, but a spheroid or orange-shaped mass, flattened at the poles and protuberant at the equator. This it did on the natural law of centripetal and centrifugal forces, or forces tending to and from a centre; whence it follows, that bodies are attracted more and more, or become heavier, as they approach the centre of attraction, and that they are repelled more and more, or become positively lighter, not only as they recede from that centre, but also as they approach and enter into the vortex of rotation, or the centrifugal force, which must of course be in the region of the equator. The surface of the earth towards the poles, therefore, was thus proved to be nearer the centre, or, in other words, flatter, the pendulum descending with more weight and rapidity of oscillation there than elsewhere; and a surplus difference remained to be accounted for by the centrifugal force, strongest towards the equator.

to be precision itself compared with all other methods of measuring time then known.*

Other Improvements.

While improvements were effecting in the escapement and pendulum of clocks, the ingenuity of artists was not confined to these alone. Till the beginning of the 16th century clocks were of great bulk, and only fit for turrets or large buildings; and although after this period they were made small enough to be introduced into apartments, there could be no such thing as a really portable clock, far less a watch, till weights and pendulums were got rid of altogether. The substitution of a main-spring for a weight, therefore, constituted a great era in horology, or the science of time-keeping; and this took place about the middle of the sixteenth century, and was shortly afterwards followed by the invention of the fusee, a very necessary appendage to the main-spring. But as these inventions completely altered the form and principles of horological machines, and, together with that of the spiral escapement spring and other improvements, which soon followed that of the pendulum, rather constitute peculiar features of the watch than of the clock (although they were mostly applied at first only to portable time-pieces of the nature of clocks, in which they are, indeed, still used), we shall reserve the explanation of these ingenious pieces of mechanism till we come to treat of watches. Meantime, there is another part of the works of a clock which requires to be here noticed.

Mechanism for Striking the Hours.

It is not known when the alarm or when the striking mechanism of the clock was first applied. The alarm was adopted for the use of the Romish priesthood, to arouse them to their morning devotions. The first striking clock probably announced the hour by a single blow, as they still do, to avoid noise, in most if not all of the Scottish churches. In De Wyck's clock, the wheel N, with its projecting pins, served to discharge the striking part, which it has not been thought necessary to illustrate. Like other old clocks, it locked against an interrupted hoop, fixed on what was called the hoop-wheel; and the 11 notches on the edge of the plate-wheel determined the hours, or particular number of blows which the hammer should give. During the seventeenth century, there existed a great taste for striking clocks, and hence a great variety of them. Several of Tompion's not only struck the quarters on 8 bells, but also the hour after each quarter; at 12 o'clock, 44 blows were struck; and between 12 and 1, no less than 113! Many struck the hour twice, like that of St. Clement Danes, in the Strand, London, first on a large bell and then on a small one. Others, again, were invented so as to tell the hours with the least possible noise, also by the aid of two bells, each blow on the small one indicating 5 hours.

The striking part of a clock is rather a peculiar and intricate piece of mechanism. In ordinary clocks the impelling power is a weight similar to that which moves the time-measuring mechanism itself; but the pressure of this weight on the striking machinery is only permitted to come into play at the stated periods, in course of the workings of the time-keeping apparatus, namely, at the completion of every hour; when the minute-wheel, which revolves once in an hour, and carries the minute-hand of the clock along with it, brings it into action by the temporary release of a catch or detent, permitting the weight wound up on the cylinder of the striking apparatus to run down for a little, in doing which the hammer is forced into action, so as to strike the bell. Whether the strokes shall be one or many, is determined principally by two pieces of mechanism, one called a *snail*, from its form or outline, with 12 steps, and the other a *rack*, with 12 teeth; but the intricate action of the whole it would be in vain here to attempt to explain. Suffice it to say, that the time during which the striking weight is *allowed* to descend varies according to the turning of the 12 steps of the snail on its axis, and the position of the 12 teeth of the rack, at different hours of the day, being sometimes only long enough to permit one blow to be given by the hammer on the bell, and at another time long enough for 12 such blows. The lifting piece of the rack-hook, in some clocks, may be raised by pulling a string attached to a small additional piece of mechanism, and thus the clock is made to repeat the hour last struck at any time required—an addition useful through the night, or to the blind. The modes, however, by which clocks as well as watches have been made repeaters have been very various. Repeating-clocks were first invented by Barlow, an English clergyman, and executed by Tompion in 1676. Some have been made to repeat both hours and quarters at any time, and to indicate the time by blows which might be felt but not heard. The size and weight of some church-bells are enormous. The great bell of St. Pauls, London, weighs between 11,000 and 12,000 pounds. Great Tom of Lincoln, though smaller than St. Pauls is heavier still, being fully 12,000 pounds; and Great Tom of Oxford, the largest in England, weighs 17,000 pounds. But these are all insignificant when compared with some of the Russian bells, which weigh from 50,000 to even 432,000 pounds! All bells are made chiefly of a compound of copper and tin cast in moulds in bell-foundries.

Curious Clocks.

Various and ingenious, as well as often highly curious, have been the forms and purposes displayed in the construction of clocks, even from their earlier epochs down to the present day. We have already instanced some of an ancient date which pointed out the motions of the sun and moon, the ebb and flow of the tides, &c. Others of a more fanciful description followed. The famous cathedral clock of Strasburg was formed previous to 1580; and besides many other curious details, had the four quarters of the hour struck by four figures, emblematical of the distinguishing periods of human life. The first was struck by a child with an apple, the second by a youth with an arrow, the third by a man with a bludgeon or staff, and the fourth by an old man with a crutch; these were followed up by Death himself, who struck the hour at last. Other ancient clocks displayed

* Before quitting the subject of pendulums, it is worthy of remark that their mutual action or sympathy, while oscillating near each other on the same wall, so long as they are mutually connected by a rail or shelf common to both, so long as the cases of the clocks to which they belong are either fixed to each other or standing on the same flooring plank, is a very singular phenomenon, observed by Huygens, Ellicot, De Luc, Reid, and many other artists. One pendulum will even stop another, it is said, in such circumstances, and will again cause it to resume its vibrations till it stop, alternately, itself. It has also been found that two clocks with pendulums of nearly equal length and power, or weight, though differing in their measurement of time while apart, will so vibrate in unison when thus connected, as to keep time together with the most surprising accuracy, till they are again separated, or till the plank connecting them be sawn asunder. This singular but not altogether unaccountable influence appears to be not unlike that sympathy of sound between two musical instruments tuned in unison, wherein, when a chord of one is struck, the other, placed in a proper situation, though untouched, responds or echoes back the sounds at first called forth. And as in the combinations of certain medical substances, or in various other combinations, the general result of all the elements is obtained as a steady mean to be depended on, without the special failure, fault, or disadvantage of any one element in the combination, accuracy of time keeping, of a remarkable kind, might readily be obtained by this singular mode of bringing out, by a combination of pendulum clocks, an average rate of motion. "It is the opinion of an eminent foreign artist," says Reid, the author of a standard article on clock and watch-making in the new edition of the "Encyclopædia Britannica," afterwards enlarged and separately republished, "that a few clocks placed in this way would communicate the motion of their pendulums to each other, till they came all at last to beat at the same instant;" an opinion in which Reid himself expresses his entire concurrence

processions of saints, with obeisance to the virgin and child, &c.; and scarcely a town of any importance was without some curiosity of this sort peculiar to itself. Many curious clocks were invented in the seventeenth century, among which were a variety measuring time, or at least moved, by balls running down inclined planes, swallowed up by and traversing the bodies of brazen serpents, or descending in metallic grooves, to be again thrown up by Archimedean screws; some were made to go by their own weight, descending inclined planes, and thus avoiding the casualties to which main-springs and weight lines are liable; others, by means of springs, were even made to ascend such planes. One was simply and ingeniously hung like a lamp from the ceiling, and was kept going by its own descent, the winding up consisting merely of pushing it again towards the ceiling. In another, the dial formed the brim of a plate, filled with water, in which swam a tortoise, turning marvellously with the hour, and ever pointing towards it—by magnetic attraction, as every one would now readily conceive; and this favourite idea was varied by many other simple contrivances. Within the last few years, not a little wonder of a similar kind, we recollect, was excited by a puzzle-clock, with an hour-hand proceeding from the centre of a crystal dial-plate, perfectly transparent, and moving without any visible connection with mechanism. In this case a piece of glass itself, rotating in the interior of the dial, constituted the requisite mechanism. The illumination of clocks was a favourite idea in the seventeenth and eighteenth centuries; and little more than twenty years since this plan was adopted for public clocks. It was first applied in Glasgow, where one clock is lighted (though very imperfectly) from without, as two others are, through translucent dials, from within. A somewhat better system of lighting is adopted in Edinburgh; and in London, the pure brilliancy of the Bude light has recently contributed to the improvement of this very useful practice. A clock was made by George III. which registered the daily fluctuations of the barometer by means of a pencil floating on the surface of the mercury, and made to traverse a circular card divided into 365 parts by radii lines, and turned on its centre by the clock once a year. The fluctuations of the wind were proposed by Sir Christopher Wren to be registered on a similar principle—an idea which has been recently revived. A curious time-keeping method of insuring the presence and attention of night-watchmen has been successfully tried of late years at Derby, and we believe elsewhere in England. It consists of a clock with pins projecting round the dial, which can only be pushed inwards at a certain interval, when the watchman's presence and attention are required to unlock the case and do so, otherwise his neglect and the exact quarter of an hour at which he was absent is shown by "the telltale." Among other recent inventions is a lock-clock, to prevent bankers' safes, &c., from being opened except at stated intervals. The greatest novelty, however, in the art of clock-making, is the electro-magnetic regulation of clocks, by which the dials of all the clocks in a town, or even in different towns, may be made simultaneously, and, as it were, by sympathy, to indicate the same moment of time.

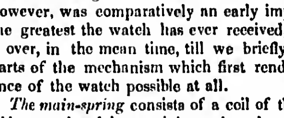
WATCHES.

Clocks and watches are certainly among the most perfect, as, in the civilized world, they are the most indispensable, machines ever produced by human ingenuity. "To become a good watchmaker," says Berthoud, "it is necessary to be an arithmetician, in order to find the revolution of each wheel; a geometrician, to determine the curve of the teeth; a mechanician, to find the forces that must be applied; and an artist, to be able to put it to execution the principles and rules which these sciences prescribe. He must know how fluids resist bodies in motion; the effects of heat and cold on different metals; and, in addition to these acquirements, he must be endowed by nature with a happy genius." No one who has not closely attended to the matter, can conceive the difficulty which has been experienced even in dividing circles for the wheels of a watch into the requisite number of rigorously equal parts, and in "pitching" them in, or adjusting them one with another. All the resources of art shown by Ramsden, Troughton, and other eminent mathematical instrument makers, have been here called into requisition. And as to the delicacy of touch and adjustment necessary in the mere regulation of the mechanism, after being thus accurately made and "pitched in," some slight idea may be formed from the fact, which we give in the words of Mr. Thomson, that "a second (a mere pulsation) is divided into four or five parts, marked by the vibrations of a watch-balance, and each of these divisions is frequently required to be lessened an exact 2880th part of its momentary duration!" England has great honour in having advanced the art of watch-making to its present high condition.

Main-spring and Fusee.

The invention of the main-spring in place of the weight was the first pre-requisite in the formation of the watch. But although the main-spring was applied as the maintaining power to time-pieces of a very imperfect description, called watches, about the middle of the sixteenth century, and although the balance had, in such instruments as these, assumed its present form of a vibrating ring, with the greatest weight, of course, accumulated round a circumference, it was not until the spiral hair-spring was applied to the balance, some time after the invention of the pendulum, as a substitute in clocks for the balance itself, that a comparatively useless machine was converted into a time-measurer nearly as accurate, even in its ordinary form, as the pendulum clock. Though the invention of the balance-spring, however, was comparatively an early improvement, and the greatest the watch has ever received, we must pass it over, in the mean time, till we briefly describe those parts of the mechanism which first rendered the existence of the watch possible at all.

The main-spring consists of a coil of thin elastic steel ribbon, enclosed in a miniature barrel or "drum," to the inner side of which the outer end of the coil is fixed, while the inner is fixed to an axis at the centre of the drum, and round which it may be wound or twisted, so as, by its elasticity and recoil, to cause the drum to make as many revolutions as it makes turns itself while it unwinds. Here, then, we have the main power which sets the whole mechanism of the watch in motion. But it is evident that this power, if thus at once applied to the wheels, would cause them to move with less and less rapidity as it became uncoiled, and as its springing power, of course, became exhausted; so that, unless the wheels were so constructed that only the middle turns were required to be in action, and not those in which it is at its greatest or its least power, a force sufficiently equal even for ordinary purposes could not be thus obtained. French spring clocks, strange to say, are still in general made on this defective principle; but English watches and spring-clocks are supplied with a "fusee," which corrects the inequalities of the main-spring with a simplicity only equalled by its ingenuity.

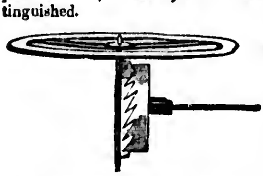


The fusee is a cone with a spiral groove, attached to the side of the first wheel of the watch, and connected with the barrel or drum containing the main-spring by a chain, hooked, at its ends, to both. The figure to the right in the above cut, is the fusee; that to the left is the drum.

In winding a watch, the key is placed on the axis of the fusee, and the chain is wound off the barrel on to the cone of the fusee. When fully so wound, the spring is at its greatest power of recoil; but the chain being then round the smallest part of the cone, the influence of the spring on the wheels is at its least amount; while, just as the power of the spring relaxes and diminishes, the cone enlarges, and its lever influence hence increases. The fusee, in short, is a variable lever, worked by the main-spring, with more purchase when it has less power, and with less purchase when it has more power. It is a very beautiful contrivance, completely answering the intended purpose, when properly made. By means of a spring contained in the interior of the fusee-wheel, the watch is maintained in motion, while the fusee itself is turned by the watch-key in winding up the main-spring. This is called *the going fusee*. When the watch or spring-clock has no fusee at all (and in very flat watches no fusee *can* be introduced), the barrel is immediately attached to the first wheel. In every case, however, the power of the spring is conveyed through the wheels by nearly the same arrangement in all watches and clocks to

The Escapement.

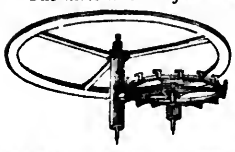
On the peculiar construction of this part of the mechanism, so as best to keep up the vibrations of the balance, the superiority of one watch over another principally depends; though much, of course, also depends on the skill of the workman, and the quality of his materials, in the construction of *every* part of so delicate a machine. The escapement, however, according to its peculiar form, is that by which the watch is chiefly distinguished.



The *vertical watch* is so named from its old vertical escapement.

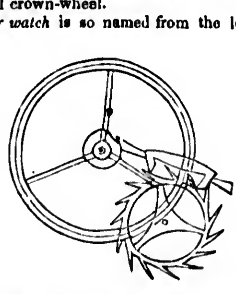
This particular mode of escapement is still made in common watches, though found not to produce a sufficient accuracy.

The *horizontal or cylinder watch* is so named from the horizontal escapement of Graham, introduced in the beginning of last century.

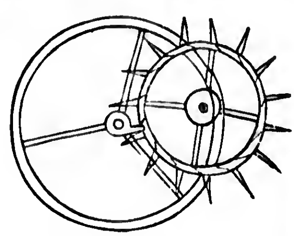


In this mode of escapement the impulse is given to a hollow cut in the cylindrical axis of the balance, by teeth of a peculiar form projecting from a horizontal crown-wheel.

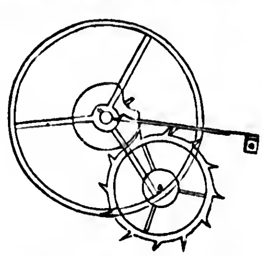
The *lever watch* is so named from the lever escapement of Mudge, in which the impulse is given to the balance by a lever attached to anchor pallets.



The *duplex watch* is so named from the duplex escapement of Hooke, perfected by Tyrer, in which the impulse is given by a double wheel.



The *detached watch* is so named from the detached escapement of Berthoud, improved by Arnold and Earnshaw, in which the vibrations of the balance are free or detached from the influence of the crown-wheel unless at the instant when it receives its impulse and unlocking, the wheels standing still till then.



This mode of escapement, which requires no oil, forms a peculiar feature of the chronometer or marine time-keeper.

On the respective merits of these different kinds of watches a few useful hints will be afterwards given. There are many other escapements, but those only now pointed out are in general use.

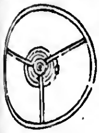
Balance and Balance-Spring.

These are the only other parts of the mechanism of the watch of which it is necessary here to treat.

The balance, as may be seen from the representation of it in connection with the different escapements just noticed, is a wheel finely poised on its axis; the pivot holes in which it turns being frequently, in chronometers and clocks, as well as in watches, jewelled, or made of small rubies, diamonds, &c., as those of other of the wheels also are, for the sake of durability. The natural effect of an impulse given to such a wheel would be a complete rotation on its axis. This, however, as we have already seen, is convertible, by various escapements, into a vibratory motion. But as in clocks the pendulum was found to be a most invaluable adjunct, absorbing, as it were, in its own more or less extended oscillation, every inequality in the rotation of the wheel-work, or the vibration of the balance, something of precisely the same nature for watch escapements was the great desideratum when the balance-spring or hair-spring was invented; and, from this analogy, it even acquired the name of the pendulum-spring—improperly so, however, as Reid remarks, especially as there is a pendulum-spring of another description altogether.*

* This little instrument, the hair-spring, is no less remarkable for the extreme delicacy of its construction, than for the great value which it shows the possibility of giving to a piece of steel of exceedingly small and insignificant appearance

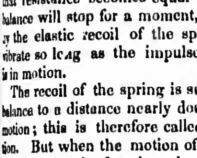
Simple and obvious as the suggestion of the regulative influence of a spring, applied to the vibrating mechanism of the watch balance in place of either weight or pendulum, may now appear, especially after the idea of the main-spring, as a substitute for the maintaining weight, had been suggested, this has been held to be a crowning invention in the mechanism of the watch; and the honour of its first suggestion has been claimed by no less than three very eminent men—by Dr. Hooke, by Abbe Hautefeuille, a Frenchman, and by Huygens, the Dutch astronomer. It was ultimately proved, that although Huygens had applied for a patent at Paris in 1674, Hautefeuille had done so several years before; while Hooke had made a similar application in England in 1658. To Hooke, therefore, must be attributed the first idea of the balance-spring.



In its application to the balance of a watch, one of the extremities of the spring is fastened to a point independent of the balance, while the other is attached near its axis.

When the balance is at rest, the spring is inclined neither way, this position being called the point of rest; but when the impulse is given to the balance by the crown-wheel of the escapement, it is clear that now a rotatory motion of the balance cannot take place, even though there should be nothing in the form of the escapement to prevent it; the balance will now only move round so far as the impulse given is able to overcome the elastic resistance of the spring; and when that resistance becomes equal to the impulse given, the balance will stop for a moment, and then be driven back by the elastic recoil of the spring, continuing thus to vibrate so long as the impulse is repeated or the watch is in motion.

The recoil of the spring is sufficient to drive back the balance to a distance nearly double the length of its first motion; this is therefore called the long arc of vibration. But when the motion of the balance is free, with a certain length of spring, the *long* arc of vibration is made in less time than the short one, to which the impulse is given; with a spring of greater length the principle is reversed; whence it was concluded by Le Roy and Berthoud, that equality of time or *isochronism*, in unequal vibrations, could be more easily obtained by lengthening the spring than by tapering it. In principle, too, the stronger and shorter the spring, the quicker will be its vibrations. Thus, effects of an extremely varied description can be produced on the motions of a watch by the slightest difference of length and taper in a hair-spring. And it is thus that the correctness of the time-keeping is essentially dependent on the principle adopted in the formation of this apparently most insignificant little appendage. So much is this the case, that, if the hair-spring be isochronal in a free or detached escapement, the time shown will be the same, notwithstanding changes in the motion of the wheels, or even in the power of the main-spring. In England, where time-keepers have been brought to their greatest perfection, it is considered that isochronism is most easily obtainable by using the cylindrical helical spring, which is applied to all marine chronometers.



manual labour. Four thousand hair-springs scarcely weigh more than a single ounce, but cost often more than £1000. "The chisel of the sculptor," as Mr. Thompson justly remarks, "may add immense value to a block of marble, and the cameo may become of great price from the labour bestowed, but art offers no example wherein the cost of the material is so greatly enhanced by human skill as in the balance-spring."

One of the most recent improvements in watches, or rather in chronometers, has been invented and patented by Mr. Dent, of London, and consists in coating the balance and balance-spring with gold by the electro-metallurgic process (see article on Electricity), by which means they are secured from rust. Another invention of the same gentleman is that of balance or hair-springs made of *glass*, which, singular to say, appear decidedly preferable to those of steel, their principal disadvantage being the difficulty of making them with certainty or accuracy.

Compensation.

But let a watch be ever so perfect—in the correction of the inequalities of its main-spring by a fusee mathematically adjusted to it, in the formation, and the position or pitching in of all its wheels and pinions, in the principle and execution of its escapement, and even in the accuracy with which its hair-spring vibrates in equal times—still it will vary in the time it indicates *on every change of temperature*, however slight, unless it be *compensated*.

From what we have already stated in treating of the compensation pendulum in clocks, the intelligent reader will readily appreciate the difficulties to be here overcome, and will probably conclude, that as in clocks the compensation has been effected by means of the pendulum, so in watches it must have been effected by means of the balance-spring or balance: such is the fact; but as there was no room here, and indeed no analogous opportunity, for the introduction of mercury, the idea of compensation by virtue of the different degrees of expansion in different metals, as in the gridiron pendulum, was the only one that remained to be entertained; and here also the ingenuity of human invention has indeed triumphed; and the method of making compound balances for watches has been justly considered one of the most curious of our metalline manufactures. When completed, the compensation balance consists of a double or compound rim or ring, the outer part of which is of brass, and the inner of steel, to which the brass is added while in a molten state. The opposite sides of this ring are united by a steel bar, the whole of the steel part, indeed, being filed out of one piece of metal. One half of the ring is then cut or filed away at one side of the bar, and the other half at the other side, as represented in the figure last above given; and the balance is loaded either with small screws, as in that figure, or with sliding weights on each half of the ring, in order to regulate the rate of the chronometer or watch. The compensation, then, is thus effected: An increase of temperature *diminishes* the elastic force of the hair-spring, which would cause the machine to *lose* time; but the same degree of heat expands the outer or brazen part of the ring of the balance more than it does the inner or steel part—brass expanding more than steel by heat, and contracting more by cold—and so, not being able to separate, a curvature of the whole arm of the ring *inwards* ensues, which lessens the inertia or checking weight of the balance; so that the hair-spring now *requires* less force to influence it to the same degree as before; and thus its *loss* of power is *compensated*. On the other hand, cold *increases* the elastic force of the hair-spring, which would cause the machine to *gain* time; but the brass contracting more than the steel, curves the arm outwards, and increases the inertia, or resistance of the balance, allowing the spring no more influence over it now than it had before. The screws are turned in or out, or the place of the sliding weights adjusted, by experiments on the rate of the machine; so that if an increase of temperature causes it to gain time, or a decrease to lose, the screws must be turned outwards, or the weights moved farther from the ends of the arms; if the contrary be the case, then of course the contrary changes must be made.

The compensation curb is another instrument for cor recting variations in the rate of going from variations in temperature. It limits or extends the length of movement in the hair-spring itself, by a self-moving action, also caused by a difference in the effect of change of temperature on two different metals, and is called a curb, from the name of a small piece of mechanism which operates similarly on the balance-spring in regulating a watch by hand.

CHRONOMETERS.

The term *chronometer* is, properly speaking, applicable to all time-keepers, but it is now more usually applied to marine time-keepers only, which are machines of a size between watches and clocks. Some watches, however, made like chronometers in every respect but in size, are called pocket chronometers. But neither of these are any thing else than merely such time-keepers as combine all those chief excellencies in horological invention just described, including compensation balance, cylindrical spring, detached escapement, &c., so as to constitute the most accurate time-measurer possible; the purpose of marine chronometers being to discover the longitude at sea; for it is only necessary to ascertain the exact difference in time between two places on different meridians, in order to determine their difference of longitude, or distance eastward or westward of each other. Reverting to what has been already said on this subject in the first article of the present series, the general reader will at once perceive that, so soon as a time-keeper could be made that would keep time with perfect accuracy, such an instrument, set to the time of any sea-port, for instance, in Britain—whose precise meridian or longitude was known—and carried abroad in a vessel sailing thence, would afford the means of ascertaining the longitude at sea, by simply observing the instant that the sun reached his meridian there, when of course it would be mid-day, or 12 o'clock noon; and at the same time observing the difference between this time and that shown by the time-keeper, which would necessarily be different if the longitude was different—the amount of the difference giving him his longitude, on the calculation that 15 degrees east or west make *one hour* of time, or 15 geographical miles *one minute*. If, for example, the time-keeper had been set to time at the meridian of Greenwich observatory [where, in fact, chronometers are now usually adjusted, and where a signal hoisted every day on the instant that 12 o'clock strikes, or rather on the instant that the sun arrives at the meridian there, proclaims the true time of day, on that meridian, to all the mariners in sight of it, that they may be able, without trouble or mistake, to adjust their chronometers accordingly], and if it was but 11 o'clock on the time-keeper thus set, while it was, of course, 12 o'clock or mid-day at the time and place where the meridian was taken at sea, then that place must have been in longitude 15 degrees *west* of the meridian of Greenwich; if, on the other hand, it was one o'clock instead of 11 at that moment, the longitude must have been 15 degrees *east*, not west, of the meridian of Greenwich. By knowing also the time when any particular star passed the meridian at Greenwich, the navigator, in a similar manner, could calculate his longitude by an observation of the same star at sea. Lunar observations, eclipses, or any other of the celestial phenomena, might be made use of on similar principles.

It was a clear perception of the fact, that the longitude might thus be at any time determined, could time-keepers be made to measure time with accuracy, that led Sir Isaac Newton and others to recommend to government the offer of a public reward for the accomplishment of so desirable an object; and it was the hope of reaping the splendid reward of £20,000, which government accordingly did offer, that formed the very main-spring to all those high exertions of horological ingenuity which led to the final success of John Harrison, after an unwearied labour of forty years—a success which, in turn, resulted in the present highly advanced state of horology, the perfection of which, as a most scientific art, is perhaps only paralleled by the perfection of astronomy as a cognate science deeply indebted to it, and indeed to which it is as indispensable, in almost every respect, to the present condition of society.

USEFUL HINTS.

For the attainment of habits of punctuality, for the regulation of the usual routine of business and of every day life, for the morning's timely arousement, and the evening's sufficient repose, and for other and innumerable purposes of convenience, necessity, and pleasure—much, in reality, often depends on the judicious selection of a time-keeper. And even the character of a young man has been known to be much influenced by the quality of his watch, the possessor of an accurate time-keeper becoming ambitious to emulate its excellence, and thus gradually acquiring habits remarkable for punctuality. It is therefore to be regretted—even though in many cases a very indifferent time-keeper may be thought all that is required for general purposes—that no efficient instruction can be given to the inexperienced, especially towards the selection of a watch, as none but a workman possessing the highest knowledge of his art is capable of forming a correct opinion of its relative merits. The hints given by a skilful and practical artist himself, however, who has had years of the most attentive and constant experience, cannot but be deemed invaluable; and as such, we would especially recommend a popular little volume, recently issued by Messrs. Boone of New Bond Street, namely, "Thomson's Time and Time-Keepers," for the useful as well as pleasing and interesting instruction, to the inexperienced in horology, with which it is stored. A work such as this is a novelty, opening up the rather abstruse science of horology to the general reader, much in the same way in which the highly popular works of Professor Nichol have opened up the more sublime and still more abstruse science of astronomy.

Among many valuable hints for the proper selection of time-keepers contained in Mr. Thomson's little volume, we shall take the liberty of briefly instancing the following; and first of clocks:—These, in general, measure time more accurately than watches, especially eight-day weight or long-clocks, which are also cheapest. Long and heavy pendulums are to be preferred. The pendulum should occupy the whole available length of the case, except in regulators, or in pendulums beating seconds. A light pendulum shows a clock to be badly constructed, or deficient in power. Steel rods are better than brass, well-seasoned and varnished wood than steel, and compensation-rods than either. The clock should be steadily fixed to the wall, or firmly placed on three feet sufficiently far apart, so that the mechanism may be uninfluenced by the oscillations of the pendulum. Clocks are regulated by lengthening the pendulum to make them lose, and by shortening it to make them gain; this is very generally done by turning a nut or screw *below* the weight or *bob* of the pendulum, *to the right to gain, or to the left to lose*; or, if the screw is *above* the weight, the rule is *reversed*. Many French clocks, and a few of English ones, are liable to derangement in striking, unless the hands are moved rapidly *forward*. The hands of English clocks, in general, may be turned either way without injury, and the same with a watch, unless it has an alarm. An intelligent careful man may be safely trusted with the cleaning or repairing of clocks, while a diversity of talent and experience is necessary to qualify him for the manipulation of watches. "The possessor of a good picture would doubtless inquire into the ability of the artist before he intrusted him to retouch it; and this caution is equally necessary for a watch, as many of the best construction have sustained irreparable injury from the hands of unskilful workmen. Even watches (which are by far the greatest number) require the aid of better hands than those which constructed them." A clever artist may enable even a bad watch to perform tolerably well. Watches should ordinarily be cleaned every second or third year; small, flat, or complicated ones oftener. All require care in handling. They should be regularly wound as nearly at the same hour as possible: and while being wound, should be held steadily in the hand, so as to have no circular motion themselves. When hung up let the watch have support, and be perfectly at rest; or when laid horizontally, let it be placed on a soft substance for more general support, otherwise the motion of the balance will degenerate a pendulous motion of the watch, causing much variation in time. Should a watch vary by heat or cold, as when worn or not worn in the pocket, the hands may be set to time; but the regulator should not be altered, if set to the ordinary temperature of the season. Compensation-watches, if properly constructed, do not so vary. A trial even of a year or two is no proof of the substantial worth of a watch. Dealers themselves may be deceived. A duplex watch may be very bad, while a vertical one may be very good, so that workmanship is as important as principle. Many low priced and bad watches have eight or even ten holes jewelled, while many good and costly ones have but four: a hole can be jewelled for three shillings. "The high sounding description, the handsome exterior, the offered trial, and enticing cheapness, are effective baits to the short-sighted." External ornament forms but a small item of expense, and the prices therefore will, in general, point out the comparative qualities of the work in the shop of an artist of known integrity and ability. The large thick old watch is less absurd than some recently made little nicker than half a crown [or even much smaller, as in the latest and rarest novelty among the beautiful and ingenious Genevese watches, one of which recently seen at Geneva by one of the editors of the present series of papers, was about the size of a shilling]. The lever watch is capable of great accuracy, and is preferable to the vertical, though the principle of the latter is more generally understood and more easily repaired; lever watches, however, are neither expensive to repair nor liable to derangement. The horizontal or cylinder-watch is liable to great tear and wear, but performs with considerable accuracy. The duplex watch, with a compensation balance, when well constructed, and treated with ordinary care, will keep time with the greatest accuracy, but being delicate, it does not stand violent exercise; a bad duplex watch is most expensive to repair. The detached watch, the escapement of which is the only one used in marine chronometers, is the most perfect, but requires care. Repeaters are expensive to repair as well as to purchase, but may be as accurate as others. Watches showing seconds are often useful, and, if well made, are neither expensive nor easily deranged. A watch may be handsome, yet bad, but a good watch is seldom unsightly. The spring for shutting the shells is not so good as the snap; it often allows dust to penetrate to the works. The covers of hunting-watches will not protect the glass when the hunters are very flat. The extreme accuracy of marine chronometers is partly produced by their being kept constantly in a horizontal position. They are only required to show *equal* time; whether they gain or lose is of no consequence, provided they are regular, and *keep* their known rate.

KEY TO THE CALENDAR.

JANUARY.

JANUARY and February are said to have been added to the list of months by the second Roman king, Numa Pompilius, in the year before Christ 672. The name of the former month is unquestionably from Janus, the god of the year of the Roman mythology, to whom the first day was sacred, and in whose honour it was celebrated with riotous feastings and givings of presents. We learn from Ovid's Fasti, that a Roman workman did not spend the Kalends or 1st of January entirely in debauchery: he wrought a little at his trade, for the sake of luck throughout the year.

1. *Circumcision.*—A festival of the Romish Church, from about the year 487, and of the Church of England since 1550, in honour of the circumcision of Christ. The banks and public offices are shut on this day. As first day of the year, it is celebrated throughout the modern Christian world with festive rejoicings, too often approaching or exceeding the bounds of propriety. In England, till a period not very remote, it was customary to usher in the year by drinking spiced liquor from the *Wassail Bowl*, so called from the Anglo-Saxon *Waes-hael* (Be healthy), the toast used on the occasion. The custom without the name still exists in Scotland. It was also customary on this day to give and receive gifts, originally with the superstitious design of securing good fortune for the year, and afterwards for affection and to promote good neighbourhood. Even the kings of England accepted presents from their courtiers on this morning. The 1st of January, under the name of *Le jour de l'an*, continues in France to be distinguished by a universal system of present-giving, in which the royal family partakes. It has been calculated that sweetmeats to the value of £20,000 are sold in Paris on this day.

6. The *Epiphany*, a festival in honour of the manifestation of the infant Jesus to the three wise men of the East, who came to worship him. It began to be celebrated in 813. This continues to be observed as a festival in the English Church, and is marked by the shutting of many of the public offices. The popular name for the festival is *Twelfth Day*, with reference to its occurring twelve days after Christmas. Twelfth Day, and more particularly Twelfth Night, are distinguished by joyful observances. It is a tradition of the Romish Church, that the three wise men were kings, and many sets of names have been furnished for them, Caspar, Melchior, and Balthazar, being the set best known: their remains were said to have been recovered in the fourth century by the empress Helena, and the skulls are still shown, under circumstances of great pomp and ceremony, in the great church at Cologne. Perhaps it is owing to this idea of the regal rank of the wise men, that a custom has existed from early ages throughout Europe, of choosing a person to act as king on Epiphany. In England, this custom has blossomed out a little. Both a king and queen were chosen. It was done by placing beans in a large cake. The cake was divided among the company and whoever of the male sex got a bean was king, whoever of the female sex queen. Latterly, other characters

have been added, and these were expressed on slips of paper. The Twelfth Night cake continues to be eaten by merry companies, and the characters of king, queen, &c., being drawn in that manner, are supported amidst much jocularity till midnight. There is reason to suppose that the custom of choosing a king is also connected with ancient heathen rites, as in Rome a king of the Saturnalia was chosen by beans. Twelfth cake in England is generally covered with hardened white sugar and many little ornaments, and its abundant appearance in the windows of bakers and confectioners on this day never fails to arrest the attention of strangers. In Scotland, there is not the least trace of either a religious or popular observance of Twelfth Day.

Till the reign of George III., it was customary at court on Twelfth Night to hold a public assembly for playing the game of basset, in which the king and royal family took part, the winnings being for the benefit of the groom-porter, an officer who on those days had an especial charge of the games of chance played in the palace, at which he acted as umpire.

The day after Twelfth Day was a popular rustic festival, under the mock name of *St. Distaff's* or *Rock Day*. (Rock is the appellation of a quantity of lint put upon a distaff.) It seems to have been a sort of farewell to the festivities of Christmas.

18. *Septuagesima Sunday.*—[It is necessary here to mention that the Movable Feasts and Holy-Days of the church are nearly all regulated by Easter—that is, so long before or after Easter. Easter, the great festival of the church, is itself movable. According to canonical regulations, Easter-day is always the first Sunday after the full moon which happens upon, or next after, the 21st day of March; and if the full moon happens upon a Sunday, Easter Sunday is the Sunday after. The first of these movable feasts is Septuagesima Sunday, which occurs on January 18th, when Easter Sunday is on March 22d. In this place, we propose setting down the movable feasts on the earliest days on which they ever occur; and Septuagesima Sunday is therefore put under January 18th. All the rest will follow in order, as in the calendar for a year on which they occur on the earliest possible day.] Quadragesima is an ancient name of Lent, as meaning the forty day's fast. The first Sunday in Lent hence got the name of Quadragesima. Early in the seventh century, Pope Gregory appointed three Sundays of preparation for Lent, and assuming a decimal reckoning for convenience, they were respectively called, reckoning backwards, Quinquagesima, Sexagesima, and Septuagesima.

21. *St. Agnes's Day*, a festival of the church of Rome. The annals of canonization present no image of greater sweetness and purity than St. Agnes. She is described as a very young and spotless maid, who suffered martyrdom in the tenth persecution under Dioclesian, in the year 306. A few days after her death, her parents going to make the offerings of at[illegible] at her tomb, beheld a vision of angels, amidst which [illegible] their daughter, with a snow-white lamb by her [illegible]fore usual[illegible] represented with a lamb [illegible]ter. Perhaps this legend has been partly founded on the resemblance of the name Agnes to *Agnus*, Latin for *a lamb*, for jingles of sound often led to more important ideas in the middle ages. At Rome, on St. Agnes's Day, during mass, and while the Agnus is saying, two lambs, as white as snow, and covered with finery, are brought in and laid upon the altar. Their fleeces are afterwards shorn and converted into palls, which are highly valued.

Throughout the Christian world, and in England as much as elsewhere, it was customary for young women, on St. Agnes's Eve, to endeavour to divine who should be their husbands. This was called *fasting St. Agnes's Fast*. The proper rite was to take a row of pins, and pull them out one after another, saying a pater-noster, and sticking one pin in the sleeve. Then, going to rest without food, their dreams were expected to present the image of the future husband. In Keates's poem, entitled "The Eve of St. Agnes," the custom is thus alluded to:—

> They told her how upon St. Agnes' Eve,
> Young virgins might have visions of delight,
> And soft adornings from their loves receive,
> Upon the honied middle of the night,
> If ceremonies due they did aright;
> As, supperless to bed they must retire
> And couch supine their beauties, lily-white,
> Nor look behind, nor sideways, but require
> Of heaven with upward eyes for all that they desire.

25.—*Sexagesima Sunday*; eight weeks before Easter.

Conversion of St. Paul.—A festival of the Romish and English churches, and, in London, a holiday at the public offices, excepting the Excise, Stamps, and Customs. The populace in former times thought this day prophetic as to the weather of the year:—

> If St. Paul's day be fair and clear,
> It doth betide a happy year;
> If blust'ring winds do blow aloft,
> Then wars will trouble our realm full oft;
> A[illegible] ance to snow and rain,
> Th[illegible] all sorts of grain.

In Germany, when the day proved foul, the common people used to drag the images of St. Paul and St. Urban in disgrace to duck them in the river.

30. *The Martyrdom of King Charles I.*—A holiday of the English Church, in whose behalf Charles is held to have lost his life; observed by the closing of all the public offices, except the Stamps, Excise, and Customs. A motion in the House of Commons in 1772, to repeal so much of the act of 12th Charles II., cap. 30, as relates to the ordering of the 30th of January to be kept as a day of fasting and humiliation, was lost by 125 against 97. The sheet in which the head of Charles was received upon the scaffold, presenting large black stains from his blood, together with his watch, are preserved at Ashburnham Church in the county of Sussex, having been given at the time to his friend Lord Ashburnham. The cap, of laced satin, which he wore on the scaffold, and which he directed to be sent to his friend the Laird of Carmichael in Scotland, passed through the hands of that gentleman's descendants, the Earls of Hyndford, and is now the property of Robert Logan, Esq., residing at New Lanark.

Natural History.—January, in our climate, is the coldest month of the year, on an average; for in some years February and March are both colder. The store of heat acquired in summer is now completely dissipated, and the sun has not yet attained sufficient power to replace it. In the central parts of the Island of Great Britain, the general average of the thermometer this month is 37 degrees. Vegetation is nearly at a stand during January. Our ancestors thought it necessary that it should be a severe month, for the sake of the rest of the year. This mode of judging, however, is not confirmed by modern experience; for a mild winter is often followed by a warm summer. A few flowers, as the crocus, mezereon, and polyanthus, are occasionally seen to blossom in the latter part of January; and about the same time (in England) the hedge-sparrow, thrush, and wren, begin to pipe.

FEBRUARY.

The establishment of February as the second month of the year by Numa Pompilius has already been mentioned. According to Ovid in his "Fasti," a curious record of Roman customs, all objects which were thought to have the effect of moral purgation in the religious ceremonials of that people were called Februa. Ceremonials of this kind took place at this season; hence the name of the month. The vanity of Augustus is said to have been the cause of this month being so much shortened. The arrangement of Julius Cæsar seems to have contemplated an alternation of months of thirty with those of thirty-one days. August was one of thirty days; but when Augustus gave it his name, he could not endure that it should be one of the shorter class, and therefore gave it an additional day, at the expense of February, already one of that class. Our Saxon ancestors called February *sprout kale*, from the sprouting of the cabbage, still called kale in Scotland.

1. *Quinquagesima Sunday*: seven weeks before Easter: called also Shrove Sunday.

2. *Candlemas Day*, or the Purification of the Virgin, a festival of the Church of Rome, and holiday in the English Church. It is said to have been founded upon Roman rites in which candles were carried. The early fathers of the Church held it in commemoration of the attendance of Mary in the Temple, forty days after child-birth, as commanded by the law; and it was their custom on this day to bless candles and distribute them among the people, by whom they were carried in solemn procession. The saying of Simeon respecting the infant Christ in the Temple, that he would be a *light* to lighten the Gentiles, probably supplied an excuse for adopting the candle-bearing procession of the heathen, whose external religious practices the founders of the Romish Church made a practice of imitating, in order to take advantage of the habits of the people. Apparently, in consequence of the celebration of Mary's purification by candle-bearing, it became customary for women to carry candles with them when, after child-birth, they wanted to be *churched*. It was to this custom that William the Conqueror referred in his famous remark on a jest of the king of France. The latter, on hearing that William seemed too fat and unwieldy to take the field, said, "Methinks the king of England lies long in child-bed." "When I am churched," said William, "there will be a thousand lights in France." And he made good his boast.

Candlemas Day is a holiday at the public offices, excepting the Stamps, Excises, and Customs. It is called a Grand Day in the Inns of Court, a Gaudy Day at the two universities, and a Collar Day at St. James's, being one of the three great holidays, during the terms, on which all legal and official business is suspended.

There is an ancient superstitious notion, universal in Europe, that if Candlemas be a sunshiny day, the winter is not half finished. The Germans say—The badger peeps out of his hole on Candlemas Day, and if he finds snow he walks abroad; if he sees the sun shining, he draws back again into his hole. It is an ancient custom in Scotland for scholars on this day to make presents of money to their masters, and to enjoy it as a holiday.

3. *St. Blaise's Day*.—St. Blaise, who has the honour of a place in the church of England calendar, was a bishop of Sebaste in Armenia, and suffered martyrdom in 316. He is the patron saint of the craft of woolcombers, and his name was once considered potent in curing sore throats. At Bradford there is still a septennial procession of the wool trade upon his day. Formerly, it was celebrated extensively by fires lighted on hills, and this is still done in Scotland on the previous evening, under the name of the Candlemas Blaze, the resemblance of the name Blaise to blaze having apparently suggested the practice.

Shrove Tuesday.—According to the plan already laid down, we place Shrove Tuesday upon this day of the month of February. As the day before the commencement of Lent, it has been from an early age celebrated throughout Christian Europe by feasting and merry-making of such an extravagant nature, as to appear designed to impart a disgust with all such indulgences, in order to make the subsequent mortifications less felt. It is the concluding day of the time of Carnival, which in various Catholic countries is of greater or less extent, but celebrated with most distinction at Venice and Rome. Carnival is obviously a term from *caro* and *vale*, as meaning a farewell to flesh, this article of food being unused during the whole of Lent. In these two Italian cities, and partially in many others, the Carnival is distinguished by shows, masquerades, races, and a variety of other amusements. The people may be said to live for several days in public. The wealthier classes parade about in their carriages, from which they pelt each other with sweetmeats. Whim and folly are tolerated in their utmost extent, so that only there be nothing said or done to burlesque ecclesiastical dignitaries. In Germany, the masqueings and mummings of the time of carnival, called there *Faschings*, are said to have given birth to the dramatic literature of the country.

The main distinction of Shrove Tuesday, in the early times of our own history, was the eating of pancakes made with eggs [illegible]. The people indulged in games at football, at which there was generally much license; also in the barbarous sport of *throwing at cocks*. In the latter case, the animal being tied by a short string to a peg, men threw sticks at it in succession, till an end was put to its miseries and its life at once. Cockfights were also common on this day, not only amongst the rustics, but at the public schools, the masters condescending to receive the defeated and slain cocks as a perquisite. The festive and mirthful observances of Shrove Tuesday are now much decayed; but the eating of pancakes or fritters still continues.

4. *Ash Wednesday*, the first day of Lent, a holiday of the Church of England, observed by the closing of all the public offices, excepting the Stamps, Excise, and Customs. The palms or substitute branches, consecrated and used on palm Sunday of one year, were kept till the present season of another, when they were burnt, and their ashes blessed by the priests and sprinkled on the heads of the people; hence the name given to the day. The sprinkling of ashes was performed with many ceremonies and great devotion. On this day, also, persons convicted of notorious sin were put to open penance. In England it is still a season for the saying of the "commination" in the prayer-book, by which the doers of certain kinds of wickedness are cursed.

8. *First Sunday in Lent*.—The Wednesday, Friday, and Saturday after this Sunday are called Ember Days, and the week in which they occur Ember Week. On Ember days, our forefathers ate no bread but what was baken in a simple and primitive fashion under hot ashes; hence the name. The other Ember Days of the year are the Wednesdays, Fridays, and Saturdays after the Feast of Pentecost, Holyrood Day (Sept. 14), and St. Lucia's Day (Dec. 15).

14. *St. Valentine's Day*.—St. Valentine was a priest of Rome, martyred in the third century, but he seems to have had no connection with the notions and practices to which his day has since been given up. This, it is scarcely necessary to say, is a day thought to be especially devoted to the business of Cupid and Hymen. Possibly, its being about the season when the birds choose their mates is the cause. Antiquaries have also pointed out that the Lupercalia, feasts of ancient Rome in honour of Pan and Juno, were held at this time, and that amongst the ceremonies was a game in which young persons of the opposite sexes chose each other jocularly by lot.

St. Valentine's Day is now almost everywhere a degenerated festival, the only observance of any note consisting in the sending anonymous letters, by way of practical joke, and this confined very much to the humbler classes. The approach of the day is heralded by the appearance in the printsellers' shop windows of vast numbers of missives calculated for use on this occasion, each generally consisting of a single sheet of paper on the first page of which is seen some ridiculous coloured caricature of the male or female figure, with a few burlesque verses below. More rarely, the print is of a sentimental kind, such as a view of Hymen's altar, with a pair undergoing an initiation into wedded happiness before it, while Cupid flutters above, and hearts transfixed with his darts decorate the corners. These are paltry frivolities compared with the observances of St. Valentine's day at no remote period. Ridiculous letters were then unknown; and if letters of any kind were sent, they contained only a courteous profession of attachment from some young man to some young maiden, honied with a few compliments to her various perfections, and expressive of a hope that his love might meet with return. But the true proper ceremony of St. Valentine's Day was the drawing of a kind of lottery, followed by ceremonies not much unlike what is generally called the game of forfeits. Misson, a learned traveller of the early part of the last century, gives apparently a correct account of the principal ceremonial of the day. "On the eve of St. Valentine's Day," he says, "the young folks in England and Scotland, by a very ancient custom, celebrate a little festival. An equal number of maids and bachelors get together; each writes his or her true or some feigned name upon separate billets, which they roll up, and draw by way of lots, the maids taking the men's billets, and the men the maids'; so that each of the young men lights upon a girl that he calls his *valentine*, and each of the girls upon a young man whom she calls hers. By this means each has two valentines; but the man sticks faster to the valentine that is fallen to him than to the valentine to whom he is fallen. Fortune having thus divided the company into so many couples, the valentines give balls and treats to their mistresses, wear their billets several days upon their bosoms or sleeves, and this little sport often ends in love."

In the various jesting ceremonies of the day, there always seems to have been a disposition to believe that the person drawn as a valentine had some considerable likelihood of becoming the associate of the party in wedlock. At least, we may suppose that this idea would be gladly and easily arrived at, where the party so drawn was at all eligible from other considerations. The common people seem to have imagined that an influence was inherent in the day, which rendered in some degree binding the lot or chance by which any youth or maid was now led to fix attention on a person of the opposite sex. It was supposed, for instance, that the first unmarried person of the other sex whom one met on St. Valentine's morning in walking abroad, was a destined wife or husband.

15. *Second Sunday in Lent.*

22. *Third Sunday in Lent.*

24. *St. Matthias the Apostle.*—A festival of the Church of England. St. Matthias was chosen by lot after the Crucifixion, in place of the traitor Judas (Acts i. 23).

Natural History.—The popular voice allots a course of snow, rain, and their hybrid sleet, to this month, and considers it necessary that such should be its features, in order that all the powers of humidity may be exhausted before the commencement of March, when an opposite kind of weather is looked for. It is indeed true that frost followed by regular thaw, and that succeeded by the sharp winds of March, bring the ground into the most favourable state for ploughing.

The general average of the thermometer is 39 degrees; that of different years varies from 30 to 42. The snowdrop and crocus are the chief ornaments of our flower-borders at this season. The primrose will also flower, and the hepatica come forth in some strength. In England, the raven and rook build their nests; the house-pigeon has young; the ringdove coos, the goldfinch sings, and thrushes pair. In Scotland, the notes of the thrush and blackbird give token of the approach of spring.

MARCH.

March, which with the ancients ranked the first month of the year, was named in honour of Mars, the supposed father of the founder of Rome. Our Anglo-Saxon ancestors called it *Lenct Monath*, that is, Lent or Spring Month.

1. *Mid Lent Sunday.*—A holiday of the Church of England. It was considered as incumbent upon all true Christians on this day to pay a visit, if possible, to their mother church, or church of their native parish, and there make some small offering. The epistle for the day accordingly contains an appropriate allusion, *Hierosolyma mater omnium*, Jerusalem the mother of all (Gal. iv. 21). And it was customary on the same day for people to visit their parents, carrying with them some gift, and receiving the parental blessing in return, together with a mess of furmety—that is, a porridge composed of whole grains of wheat, boiled in milk, and sweetened and spiced. This practice was called "going a mothering," and the day was sometimes called *Mothering Sunday*. The festival is supposed, with all its observances, to have taken its rise in the heathen festival of the Hilaria, celebrated by the ancient Romans in honour of the mother of the gods, on the ides of March.

St. David's Day.—The interest attached to this saint and his day is confined to the Welsh, whose patron saint St. David is considered. The most rational accounts of St. David represent him as Archbishop of Menevy (since, from him, called St. David's) in the sixth century. He is said to have been the illegitimate son of a prince of Cardigan, and uncle of the famous, but more than half fabulous, King Arthur. Learning, and more particularly asceticism, the great sources of promotion in those days, raised him to high esteem and ecclesiastical rank, and gave him the reputation of a power to perform miracles. At a synod called at Brevy in Cardigan, in 519, in consequence of the Pelagian Heresy, he made an eloquent and convincing display against the erroneous doctrines, which were therefore condemned. He died in 544, at an advanced age, and was buried in the church of St. Andrew, but in 962 his remains were transferred to Glastonbury Abbey.

While the Welsh venerate the memory of St. David, they are unacquainted with our idea of him as their patron saint, a notion which has sprung up in consequence of the popular fiction of the Seven Champions of Christendom. They observe the 1st of March as the anniversary of his death. On this day, all true Welshmen, whether in their own country or far removed from it, make it a point of conscience to wear a leek in their hats, and this custom is alluded to in writings of considerable antiquity. How the leek has become connected with St. David and the affections of Welshmen, is not ascertained. The most probable story is, that at a great battle between the Welsh and Saxons in the sixth century, the former, by advice of St. David, adorned their hats with leeks, for the sake of distinction from their enemies, taking the herb from a neighbouring field, where they grew in abundance. The victory gained by the Welsh being partly attributed to this cause, the leek was ever after held in veneration, and associated with the name of St. David. "The most honourable and loyal society of Ancient Britons," instituted in London 1714, and who support a school in the metropolis for the support and education of poor Welsh children, have an annual procession on St. David's Day, on which occasion each member wears a representation of the leek in his hat, the marshals in front being decorated in like manner. In the household expenses of the Princess Mary, in 1544, is a gift of fifteen shillings among the yeomen of the king's guard for bringing a *leek* to her grace on St. David's Day.

8. The *Fifth Sunday in Lent*.—It was popularly distinguished as *Care* or *Carling Sunday*, terms which appear to be of a very dubious import. The peasantry and yeomanry used to steep peas and afterwards parch them, and then, frying them with butter, made a feast of them on the afternoon of this day. It is thought not unlikely that the custom bore some reference to the superstitious notions which the ancients entertained respecting beans, as containing the souls of the departed. The peas, as eaten in the north of England, were called *carlings*. We may presume that the day took its name from this word, *carling* being in time softened into *Care*. It figures in an old rhyme which enumerates the Sundays of Lent by popular appellations—

"Tid, Mid, and Misera.
Carling, Palm, and good Pace-day."

The three first words are supposed to have been derived from the beginnings of certain psalms—thus, *Te deum*, *Mi deus*, *Miserere* mei.

15. *Palm Sunday*, called in the English Prayer-book the Sunday next before Easter; also sometimes called Passion Sunday, as being the commencement of Passion Week, or the week celebrative of the sufferings or passion of our Lord. It is a festival of great antiquity and a partly joyous character, as more particularly commemorating the brilliant though short-lived popularity of the reception which Christ met with on entering Jerusalem, immediately before his passion. On this day, in Catholic countries, the priests bless branches of palm, or or some other tree, which are then carried in procession, in memory of those strewed before Christ at his entrance into the holy city. The procession is as splendid as circumstances will admit of: and after it is done, the boughs used are burnt, and their ashes preserved, that they may be laid on the heads of the people next Ash Wednesday, with the priest's blessing.

After the Reformation, 1536, Henry VIII. declared the carrying of palms on this day to be one of those ceremonies not to be contemned or dropped. The custom was kept up by the clergy till the reign of Edward VI., when it was left to the voluntary observance of the people. Fuller, who wrote in the ensuing age, speaks of it respectfully, as "in memory of the receiving of Christ into Hierusalem a little before his death, and that we may have the same desire to receive him into our hearts." It has continued down to a recent period, if not to the present day, to be customary in many parts of England to go *a palming* on the Saturday before Palm Sunday; that is, young persons go to the woods for slips of widow, which seems to be the tree chiefly employed in England as a substitute for the palm, on which account it often receives the latter name. They return with slips in their hats or button-holes, or a sprig in their mouths, bearing the branches in their hands. Not many years ago, one stall-woman in Covent-Garden market supplied the article to a few customers, many of whom, perhaps, scarcely knew what it meant. Slips of the willow, with its velvety buds, are still stuck up in some rural parish churches in England.

17. *St. Patrick's Day*, a high festival of the Romish Church. The interest attached to this saint and his day is, however, chiefly confined to the Irish, whose patron saint he is considered; though that term, as in the case of St. David, is of modern and English origin. The Irish venerate St. Patrick as the person who introduced Christianity into their country. He is said to have been born at Kilpatrick, near Dunbarton in Scotland, and to have first visited Ireland as a boy and a prisoner. Afterwards travelling into Gaul and Italy, and growing up as a learned priest, he was commissioned by Pope Celestine to convert the Irish, a task which he immediately commenced, and carried into effect with unexampled ardour and perseverance. He travelled throughout the whole of Ireland, preaching everywhere to the barbarous people, whom he baptized in multitudes. He also ordained clergy to preside over them, gave alms to the poor, made presents to the kings, founded monasteries, and, in short, established the Christian religion and a full apparatus for its support in Ireland. Monkish annals and popular tradition attribute to him an immense number of miracles, most of which have probably no basis in fact. He died in 432, at Down in Ulster, and was there buried.

As the Welsh are solicitous to display the leek on St. David's Day, so are the Irish to show the *shamrock* on that of St. Patrick. The shamrock is a bunch of trefoil, a species of grass. It is associated with St. Patrick and his day in consequence, as popular story goes, of the saint having made a very adroit use of the plant in his first preaching immediately after landing. The people being staggered by the doctrine of the Trinity, and disposed to show some violence to him, he took up a trefoil growing by his side, and illustrated the point by showing its three blades growing on one stalk; whereupon they were immediately convinced, and became converts. In Dublin, St. Patrick's Day is, or was lately, a scene of festivity and mirth unparalleled. "From the highest to the lowest, all seem inspired by the saint's beneficence. At day-break, flags fly from the steeples, and the bells ring out incessant peals till midnight. The rich bestow their benevolence on the poor, and the poor bestow their blessings on the rich, on each other, and on the blessed St. Patrick. The 'green immortal' shamrock is in every hat. Sports of manly exercise, exhibit the capabilities of the celebrated shilelah. Priestly care soothes querulousness; laughter drowns casualty; lasses dance with lads; old women run about to share cups of consolation with each other; and by the union of wit, humour, and frolic, this miraculous day is prolonged till after the dawn of next morning."*

19. *Maundy Thursday*, called also Shere Thursday, the day before Good Friday. Its name of Shere Thursday appears to have arisen from the practice which the priests had of shearing their hair on this day, to make themselves as trim as possible for Easter. The other name is more doubtful, but seems most probably to have been derived from *maund*, an old English word for a basket, in consequence of the distribution of gifts on this day in baskets—the word *maundy* used by old authors for alms or gifts being apparently derived in its turn from the practice of this day. The religious customs of the day consisted in works of humility and in conferring gifts on the poor. The object seems to have been to commemorate, or imitate, the humility of Christ in washing the feet of his disciples—the giving of maundies being an additional good work. Cardinal Wolsey, at Peterborough Abbey, in 1530, "made his maund in our lady's chapel, having fifty-nine poor men whose feet he washed and kissed; and after he had wiped them, he gave every of the said poor men twelve pence in money, three ells of good canvas to make them shirts, a pair of new shoes, a cast of red herrings, and three white herrings; and one of these had two shillings"—the number of the poor men being probably in correspondence with the years of his age. Even royalty condescended to this practice. The king of England was accustomed on Maundy Thursday to have brought before him as many poor men as he was years old, whose feet he washed with his own hands, after which his majesty's maunds, consisting of meat, clothes, and money, were distributed among them. Queen Elizabeth, when in her

* Hone's Every-day Book.

thirty-ninth year, performed this ceremony at her palace of Greenwich, on which occasion she was attended by thirty-nine ladies and gentlewomen. Thirty-nine poor persons being assembled, their feet were first washed by the yeomen of the laundry with warm water and sweet herbs, afterwards by the sub-almoner, and finally by the queen herself, kneeling; these various persons, the yeomen, the sub-almoner, and the queen, after washing each foot, marked it with the sign of the cross above the toes, and then kissed it. Cloths, victuals, and money, were then distributed. This strange ceremonial, in which the highest was for a moment brought beneath the lowest, was last performed in its full extent by James II. King William left the washing to his almoner; and such was the arrangement for many years afterwards. "Thursday, April 15, [1731], being Maundy Thursday, there was distributed at the Banqueting House, Whitehall, to forty-eight poor men and forty-eight poor women (the king [George II.]'s age being forty-eight), boiled beef and shoulders of mutton, and small bowls of ale, which is called dinner; after that large wooden platters of fish and loaves, viz. undressed, one large old ling, and one large dried cod; twelve red herrings and twelve white herrings, and four half-quarter loaves. Each person had one platter of this provision; after which were distributed to them shoes, stockings, linen and woollen cloth, and leathern bags, with one penny, twopenny, threepenny, and fourpenny pieces of silver and shillings—to each about four pounds in value. His Grace the Lord Archbishop of York, Lord High Almoner, performed the annual ceremony of washing the feet of a certain number of poor in the Royal Chapel, Whitehall, which was formerly done by the kings themselves, in imitation of our Saviour's pattern of humility." For a considerable number of years, the washing of the feet has been entirely given up; and since the beginning of the reign of Queen Victoria, an additional sum of money has been given in lieu of provisions.

20. *Good Friday.*—This day, as the presumed anniversary of the Crucifixion, has for ages been solemnly observed throughout Christian Europe, the only exceptions being in Presbyterian countries, such as Scotland. In Catholic times, the observances of the day in England were of the same character with those which are still maintained in many parts of the continent. It is still a solemn festival of the Church of England, and the only one besides Christmas which is honoured by a general suspension of business. Strict church-of-England people abstain from all kind of animal food, even from cream to tea; such, we are informed by Boswell, was the custom of Dr. Johnson. The churches are well attended, and it is considered proper to appear there in black clothes.

Among the usages of this day was a strange ceremony of creeping to the cross, which even the king was not exempt from performing. The king also distributed rings at Westminster Abbey for the cure of the cramp. The ceremonious burying of a crucifix, as representing the burial of Christ, is calculated to give less surprise. It is still in some measure kept up in the service of the *Tenebræ*, performed in St. Peter's at Rome. It was also customary at great churches to have a small building in the form of a tomb, in which the host was this day deposited, by way of representing the burial of Christ. In England, and perhaps also in other countries, eggs and bacon were the kinds of food appropriate to Good Friday. The eggs laid on this day were thought to have the power of extinguishing any fire into which they might be thrown. In modern times, the only species of viands connected with the day is the well-known hot cross bun, a small spiced cake, marked with the figure of a cross, and sold not only in baker's shops, but by persons traversing the streets with baskets.

In London, as well as in almost every other considerable town in England, the first sound heard on the morning of Good Friday is the cry of "Hot Cross Buns!" uttered by great numbers of people of an humble order, who parade the streets with baskets containing a plentiful stock of the article, wrapped up in flannel and linen to keep it warm. The cry, which is rather musical, is strictly—

> Hot cross buns—
> One a penny, buns—two a penny, buns
> One a penny, two a penny—hot cross buns.

Hucksters of all kinds, and many persons who attempt no traffic at any other time, enter into the business of supplying buns on Good Friday morning. They make a stir on the streets, which lasts till church time, and it is resumed in the afternoon. About a century ago, there was a baker's shop at Chelsea, so famous for its manufacture of excellent buns that crowds of waiting customers clustered under its porch during a great part of the day. The buns were brought up from the oven on small black tin trays, and so given out to the people. The king himself had stopped at the door to purchase hot cross buns, and hence the shop took the name of the Royal Bun-House. As always happens in London when any thing original and successful is struck out, the royal bun-house soon obtained a rival, and was obliged to advertise as the Old Original Royal Bun-house. The wars of these two houses, like those of York and Lancaster, have long since been hushed to rest, and we find it stated in a recent work* that neither of them is now distinguished for this article above the other bakers' shops of Chelsea.

In old times, Good Friday was distinguished in London by a sermon preached at *Paul's Cross* (a wooden pulpit placed on stone steps, and surmounted by a cross, which stood till the time of the civil war, in the open air, near the north-east corner of St. Paul's Cathedral). The sermon was generally on the subject of Christ's passion. Connected with it, two or three others were preached on Monday, Tuesday, and Wednesday, in Easter week, at the Spital in Spitalfields, where the Lord Mayor and all the most eminent persons in London generally attended. The "Spital sermons" are still kept up, but take place in St. Bride's Church.

21. *Easter Eve.*—In Catholic times, it was customary to put out all fires on this day, and light them anew from flint. The priest blessed the new fire, and a brand from it was thought to be an effectual protection against thunder-strokes. A large wax taper, called the Paschal Taper, was also blessed and lighted beside the representative sepulchre above-mentioned, and there a vigil was kept till morning. The taper used on one of these occasions in Westminster Abbey church was 300 pounds in weight.

22. *Easter Day*, a solemn festival in celebration of the Resurrection. The word used by us is from the Saxon *oster* (rising). Easter is observed with much ceremonial, not only throughout Catholic Europe, and in the countries where the Greek Church is established, but in Turkey and the Mohammedan countries along the coast of Africa. The festival is an engraftment upon the Jewish Passover, the name of which (*pascha*) is still applied to it in almost every country besides England. The Catholic observances of Easter are of an elaborate character. At Rome, the Pope is carried in state to perform high mass in St. Peter's, from the balcony of which he afterwards blesses the people assembled in the piazza below—perhaps one of the most imposing religious spectacles which the world anywhere presents. In England, before the Reformation, the Catholic observances of Easter were as fully enacted as in any other country. Early in the morning, a sort of theatrical representation of the Resurrection was performed in the churches, t-

* Hone's Every-day Book, i. 404.

priests coming to the little sepulchre where, on Good Friday, they had deposited the host, which they now brought forth with great rejoicings, as emblematical of the rising of the Saviour. In the course of the day, the clergy had a game at ball in the church, a custom of which it is now difficult to believe that it ever could have existed.

At present, in large seats of population, Easter Sunday is distinguished by little besides the few peculiarities of the service, and the custom of going to church in attire as gay as possible. But in rural districts there still exist a few vestiges of old superstitions and customs connected with the day. It was once a general belief, and probably still is so in a few out-of-the-way places, that on Easter morning the sun danced or played immediately after his rising. People rose early and went into the fields to see this supposed phenomenon.

The viands appropriate to Easter Day in the old times were, first and above all, eggs, then bacon, tansey pudding, and bread and cheese. The origin of the connection of eggs with Easter is lost in the mists of remote antiquity. They are as rife at this day in Russia as in England. There it is customary to go about with a quantity, and to give one to each friend one meets, saying, "Jesus Christ is risen," to which the other replies, "Yes, he is risen," or, "It is so of a truth." The Pope formerly blessed eggs to be distributed throughout the Christian world for use on Easter day. In Germany, instead of the egg itself, the people offer a print of it, with some lines inscribed. Formerly, the king of England had hundreds prepared to give to his household: in a roll of the expenses of Edward I., there occurs, in the accounts of Easter Sunday, in the eighteenth year of his reign, "Four hundred and a half of eggs, eighteenpence." The custom is supposed to have been originally Jewish.

At this day, the Easter eggs used in England are boiled hard in water containing a dye, so that they come out coloured. The boys take these eggs and make a kind of game, either by throwing them to a distance on the green sward—he who throws oftenest without breaking his eggs being the victor—or hitting them against each other in their respective hands, in which case the owner of the hardiest or last surviving egg gains the day.

It was customary to have a gammon of bacon on this day, and to eat it all up, in signification of abhorrence of Judaism. The tansey seems to have been introduced into Easter feasts, as a successor to the bitter herbs used by the Jews at the Passover. It was usually presented well sugared.

It was a custom in the thirteenth century to seize all ecclesiastics found walking abroad between Easter and Pentecost, and make them purchase their liberty with money. This was an acting of the seizure of the apostles after Christ's passion. We have still what appears to be a relic of this fashion in a custom which exists in various parts of England. A band of young men go abroad, and whatever female they meet they take hold of her, and pull off her shoes, which are only returned to her upon her paying some trifling forfeit. In Durham, it is done by boys, who, on meeting any woman, accost her with, "Pay for your shoes, if you please." The trifling sums which they thus collect are spent in a feast at night. At Ripon, celebrated for its manufacture of spurs, travellers riding through the town are stripped of those articles, which in like manner they have to redeem. On Easter Monday, the women make a return by going abroad in groups, and causing the men to redeem their shoes.

"Lifting at Easter" is another old custom, which may be presumed to have originated in a design of dramatizing the events connected with Christ's passion. It consisted in hoisting individuals up into the air, either in a chair or otherwise, until they relieved themselves by a forfeit. A curious record makes us aware that, on Easter Day, in the eighteenth year of the reign of Edward I., seven ladies of the queen's household went into the king's chamber, and *lifted him*, for which fourteen pounds appears to have been disbursed as a forfeit. The men lifted the women on Easter Monday, and the women claimed the privilege of lifting the men on the ensuing day. Three hoists were always given, attended by loud huzzas.

23. *Easter Monday.*—This and the ensuing day are holidays of the church. The week commencing with Easter, and called thence Easter week, is a season of festivity, and the earlier days of it after Easter itself, are in London devoted by the working-classes to recreation and amusement, which they chiefly seek for at Greenwich fair, and in excursions to taverns near town.

25. The *Annunciation of our Lady*, a festival of the Church of England. It is commonly called in England *Lady Day*, as an abridgment of the Day of our Blessed Lady. This festival is in celebration of the incarnation of Christ, or the announcement by the Holy Ghost to Mary that she should bear the Son of God. The Annunciation is observed as a holiday at all the public offices, excepting the Stamps, Excise, and Customs. It is a gaudy day in the Romish Church. In Catholic countries, the service of this day resounds with "Hail, Mary!" uttered in a strain of the highest enthusiasm. The 25th of March is held as a quarter-day for many commercial purposes in England.

29. The first Sunday after Easter, called *Low Sunday*, because it is Easter day repeated, with the church-service somewhat abridged or *lowered* in the ceremony from the pomp of the festival the Sunday before.

Natural History.—March is eminently a spring month, and the season more particularly devoted to sowing. Its general character, as far as the extreme uncertainty of our climate warrants us to speak, is dryness. The frosts of winter, followed by the sharp dry winds of this month, have the effect of pulverizing the soil, and fitting it for the reception of the seed. The value of the weather appropriate to March is expressed in the saying, "A peck of March dust is worth a king's ransom." This month is also expected to undergo a change between its beginning and its end. The English say, "March comes in like a lion, and goes out like a lamb;" the Scotch version of the same idea is, "March comes in with an adder's head, and goes out with a peacock's tail." The general average temperature of March (41 degrees) is so little above that of February, as to make the greater dryness appear to arise in but a small degree from heat. There is in March a general bursting of the trees into leaf, of the meadows into flower, and partly, it may be added, of the birds into song. It is the season for planting gardens as well as sowing the fields, although there are few which may not be deferred for a little longer without disadvantage.

APRIL.

The Romans gave this month the name of *Aprilis*, from *aperio*, because it was the season when things *opened*. By the Saxons it was called Ostre month, probably from the same word from which Easter is supposed to have been derived. The Dutch and Germans call it Gras month.

1. *All Fool's Day.*—From a very early age, this day has been considered as one set apart for the exercise of all kinds of mirthful folly and practical joking: the term given to it we may hold as a travestie of the festival of All Saints' Day. The custom of playing off little tricks on this day, whereby ridicule may be fixed upon unguarded individuals, appears to be universal through-

out Europe. In France, one thus imposed upon is called *Un poisson d'Avril* (an April fish). In England, such a person is called an April fool; in Scotland, a gowk. Gowk is the Scotch for the cuckoo, and also signifies a foolish person, being in fact from the same root with the English word gawky. The favourite jest in Britain is to send one upon an errand for something grossly nonsensical, as for pigeon's milk, or the history of Adam's grandfather, or to make appointments which are not to be kept, or to call to a passer-by that his latchet is unloosed, or that there is a spot of mud upon his face. When he falls into the snare, the term April fool or gowk is applied with a shout of laughter. It is very remarkable that the Hindoos practise precisely similar tricks on the 31st of March, when they have what is called the Huli festival.

7 The fifteenth day after Easter is marked by an old English festival, to which the inexplicable term *Hock Day* is applied. The custom peculiar to the day consisted in the men and women of rural districts going out the road with ropes, and intercepting passengers jocularly, and raising money from them, to be bestowed, it may well be presumed, in pious uses.

23. *St. George's Day* in the Romish calendar. St. George is held as the tutelar or patron saint of England. He is said to have been a native of Cappadocia; and it is tolerably certain that he was held in great veneration by the Greeks in the fourth century. Throughout the countries once constituting the Lower Empire, in the Crimea, and in Tartary, he has for ages been worshipped, in the former countries, as a saint, in the latter as a deity. By all he is invariably represented as a man on horseback, spearing a dragon. With a regard, apparently, to his military character, our Edward III. adopted his name as his war-cry, and his figure as a badge in connection with the order of the garter; thus originated the association of St. George with England, since in many respects so conspicuous. It is remarkable that in Russia St. George is as much a favourite saint as he is in England. The sovereigns of that country have borne his emblem from a time previous to Edward III. The derivation of Russian Christianity from the Greek Church suggests a ready explanation of this fact. The English do not mark the day of their national saint with any of those observances which give St. David's and St. Patrick's days so peculiar a character; but it was customary at no distant period for people of fashion to wear a blue coat on this day, in honour of St. George.

25. *St. Mark the Evangelist's Day*, a holiday of the Church of England. It was once customary to bless the fruits of the earth on this day; hence, perhaps, a notion amongst the peasantry, that to plough or do any other work on St. Mark's day will be apt to bring down divine wrath. The eve of St. Mark was distinguished by some superstitious ceremonies. Maidens met to make the *dumb cake*. This was done by a number not exceeding three, and it was to be done in silence. At twelve o'clock, the cake being prepared, each broke off a piece and ate it; then walked backwards to her sleeping-room. It was thought that those who were to be married would hear a noise as of a man approaching. Those who heard nothing were to remain unmarried. Watching the church porch was another practice of this eve. A man went fasting and took his station there before midnight. It was thought that, during the hour between twelve and one, he would see the spirits of all who were to die in the parish during the ensuing year walk into church, in the order in which they were to die, those who were to perish by violence making gesticulations appropriate to the peculiar modes of their death. There were similar superstitions regarding the eve of St. John (June 24); which see.

26. *Rogation Sunday*.—The Sunday before Ascension is always so called. The three days immediately following are also called Rogation Days. The Archbishop of Vienne in Dauphiné, about the year 469, caused the litanies or supplications to be said on those days for deliverance from earthquakes, by which his city had been much injured. The days were thence called Rogation (that is, supplication) days. They were distinguished by great processions of ecclesiastics throughout the bounds of their districts.

30. *Ascension Day*, or *Holy Thursday*, a holiday of the Church of England, observed by the shutting of most of the public offices. This festival, which invariably occurs on the fortieth day after Easter, is designed to celebrate the ascension of Christ into heaven It was once distinguished by great festivities. On this day, also, there was a custom of the parish schoolmaster going with his pupils round the bounds of the parish, the pupils carrying peeled willow wands wherewith they struck the boundaries. This was an expedient for keeping those boundaries in memory, in an age when more accurate means of attaining the same end did not exist.

Natural History.—Mild weather, with genial showers, is the character usually given to April; but in modern times, the weather is often the reverse of this, being dry, with cold winds. On the average, indeed, there is more north wind and *less rain* this month than in any other. The progressive advance of temperature from winter towards summer is very apparent this month, the general average height of the thermometer being 46 degrees. This month is the usual seed-time for barley. In the gardens it is the busiest time of the year for seed-sowing.

MAY.

Among the Romans, this was the *mensis maiorum*, or month dedicated to the elder persons of their community, while the next was the *mensis juniorum*, or month of the younger people. Thus, most probably, arose the names of May and June. Others suppose that May would derive its name from Maia, the mother of Mercury, who was worshipped on the first day; but it is not impossible that Maia and her day were afterthoughts, when the real origin of the name of May was out of mind. The Saxons are said to have given this month the strange-looking name of Trimilchi, because they then began to milk their cows three times a day. The Romans believed it to be unlucky to marry in May.

1. *St. Philip and St. James the Less*, a holiday of the Church of England.

As a popular festival, under the name of *May Day*, this day has been celebrated from time immemorial. The celebration must, doubtless, have been prompted by nature herself: the time of the young flower and leaf, and of all the promise which August fulfils, could not but impress the minds of the simplest people, and dispose them to joyful demonstrations in word and act. The sun, as the immediate author of the glories of the season, was now worshipped by the Celtic nations under the name of Baal; hence the festival of *beltein*, still faintly observed in Ireland and the Highlands of Scotland. Even in Ayrshire, they kindled Baal's fire in the evening of May-day, till about the year 1790. The Romans held games called Floralia, at which there was great display of flowers, and where women danced, if we are to believe Juvenal, only too enthusiastically. The May-day jollities of modern Europe seem to be directly descended from the Floralia.

In England, we have to go back a couple of hundred years for the complete May-day; since then it has gradually declined, and now it is almost extinct. When it was fully observed, the business of the day began with the day itself, that is to say, at midnight. We have the authority of Shakspeare, that with the populace of England it was impossible to sleep on May morning. Immediately after twelve had struck, they were all astir, wishing each other a merry May, as they still, at the same hour on the 1st of January, wish each other a happy new year. They then went forth, with music and the blowing of horns, to some neighbouring wood, where they employed themselves in breaking down and gathering branches. These they brought back at an early hour, and planted over their doors, so that by daylight the whole village looked quite a bower. The citizens of London went a-Maying in this fashion, notwithstanding their comparative distance from woods. They went marshalled in parishes, or in unions of two or three parishes; their mayor and aldermen went also; and we read of Henry VIII. and Queen Catherine riding from Greenwich to Shooter's Hill, attended by lords and ladies, to join in the sport. In some places, the Mayors brought home a garland suspended from a pole, round which they danced. In others, and this was a more general custom, there was an established May-pole for the village, which it was their business to dress up with flowers and flags, and dance around throughout all the latter part of the day. A May-pole was as tall as the mast of a sloop of fifty tons, painted with spiral stripes of black and white, and properly fixed in a frame to keep it erect. Here lads and lasses danced in a joyful ring for hours to the sounds of a viol, and masquers personating Robin Hood, Little John, Maid Marian, and others of the celebrated Sherwood company of outlaws, as well as morris-dancers, performed their still more merry pranks. May-poles, as tending to encourage levity of deportment, were condemned by the Puritans in Elizabeth's time; James I. supported them in his Book of Sports; they were altogether suppressed during the time of the Commonwealth, but got up again at the Restoration. Now, change of manners has done that which ordinances of Parliament could not do. This object, so interwoven with our national poetical literature, is all but rooted out of the land.

A certain superstitious feeling attached to May-day. The dew of that morning was considered as a cosmetic of the highest efficacy; and women, especially young women, who are never unwilling to improve in this respect, used to go abroad before sunrise to gather it. To this day there is a resort of the fair sex every May morning to Arthur's Seat, near Edinburgh, for the purpose of washing their faces with the dew. Mr. Pepys, in his diary, gravely tells us of his wife going to Woolwich for a little air, and to gather May-dew, "which Mrs. Turner hath taught her is the only thing in the world to wash her face with." Scott, in his "Discovery of Witchcraft," speaks of a sprig of hawthorn gathered on May-day, and hung in the entry to a house, as a presumed preservative against all malign influences. There was also a practice of making fools on May-day, similar to what obtains on the first of the preceding month. The deluded were called *May-goslings*. It was held unlucky to marry in May, a notion which, as already mentioned, existed among the Romans. It still exists in Scotland, where very few marriages take place in May, the higher classes being equally superstitious on the subject with the lower.

In London, as has been said, May-day was once as much observed as it was in any rural district. There were several May-poles throughout the city, particularly one near the bottom of Catherine Street in the Strand, which, rather oddly, became in its latter days a support for a large telescope at Wanstead in Essex, the property of the Royal Society. The milkmaids were amongst the last conspicuous celebraters of the day. They used to dress themselves in holiday guise on this morning, and come in bands with fiddles, whereto they danced, attended by a strange-looking pyramidal pile, covered with pewter plates, ribbons, and streamers, either borne by a man upon his head, or by two men upon a hand-barrow: this was called their *garland*. The young chimney-sweepers also made this a peculiar festival, coming forth into the streets in fantastic dresses, and making all sorts of unearthly noises with their shovels and brushes. The benevolent Mrs. Montagu, one of the first of the class of literary ladies in England, gave these home slaves an annual dinner on this day, in order, we presume, to aid a little in reconciling them to existence. In London, May-day still remains the great festival of the sweeps, and much finery and many vagaries are exhibited on the occasion.

The Robin Hood games and morris-dancers, by which this day was distinguished till the Reformation, appear, from many scattered notices of them, to have been entertainments full of interest to the common people. Robin has been alternatively styled in at least one document as the King of May, while Maid Marian seems to have been held as the Queen. The various scattered particulars respecting these festivities, which make but dry reading by themselves, have been wrought up to some advantage by Mr. Strutt in his "Queen Hoo Hall," where he describes May-day as celebrated by the servants and dependants of an English baron of the fifteenth century.

3. *The Invention of the Cross*, a festival of the Romish Church, designed to commemorate the finding of the cross upon which Jesus had suffered, by St. Helena. The festival is shortly called *Rood Day*.

10. *Whit-Sunday*, a festival of the Church of England, designed to commemorate the descent of the Holy Spirit upon the apostles on the day of Pentecost. In Catholic countries, on this day, while the people are assembled in church, pigeons are suspended above, and wafers, cakes, oak leaves, and other things, are made to shower down upon the altar—all this as a dramatic representation of the miracle.

11. *Whit-Monday*.—A festival of the Church of England, as is

12. *Whit-Tuesday*.—These three days together are called Whitsuntide. It forms a term, for which the 15th of May is fixed. The Wednesday, Friday, and Saturday of this week are Ember Days, and the week is consequently an Ember Week. (*See 8th February*.) This also was a period of festivity among our ancestors. They now had what they called the *Whitsun Ale*, which consisted in a meeting of householders with their families at the church, after service, to partake of a feast provided by the churchwardens, at which the young danced and played at games, while the seniors looked on. In the days before the poor were supported by rates, a collection was made on this occasion, usually found sufficient to provide for them. The Whitsun Ale is now degenerated, where it exists at all, into a merry-making at a barn. Whitsunday and Martinmas terms (May 15 and November 11) are those alone regarded for the leasing of all kinds of property, paying of rents, and engaging of servants, in Scotland.

17. *Trinity Sunday*, a festival of the Church of England, which always takes place eight weeks after Easter.

21. *Corpus Christi*, a festival of the Romish Church, always held on the Thursday after Trinity Sunday. It celebrates the doctrine of transubstantiation. In all Roman Catholic countries it is observed with music, lights, flowers strewed in the street, rich tapestries hung upon the walls, and processions and plays representing Scripture subjects.

29. *Restoration Day*, a holiday of the Church of England to celebrate the restoration of monarchy in the person of Charles II., May 29, 1660, after its suppression for the preceding twelve years. The populace at one time wore oak leaves in their hats on this day, with reference to the concealment of Charles in the Royal Oak, while skulking after the battle of Worcester, 1651.

Natural History.—May is a month of the best reputation—indeed a general favourite in imagination; but it often balks the hopes of its worshippers. In favourable seasons, it presents many beautiful appearances, as herbage and foliage of the brightest green, a profusion of natural flowers, soft and genial skies, fishes leaping, swallows twittering, bees humming, the cuckoo repeating her note, and the corn coming into blade. But these appearances are often prevented or much clouded by cold east winds, most destructive to the fruit blossom. The greater prevalence of this wind during May than in any other, seems to be chiefly the cause of the well-known injunction, "Change not a clout till May be out." The general average temperature is about 51 degrees. We are now arrived at the latest period of seed-time. In the most backward parts of the country, barley is still sown, and the seeds of some of the tenderer garden plants are committed to the earth. The ash, last-budding of the trees, comes into leaf in the latter part of the month.

JUNE.

The probable origin of the name of this has been explained at the same time with that of May.

11. *St. Barnabas the Apostle*, a holiday of the Church of England. In the days of old style, the 11th of June was the longest day of the year—hence an ancient rhyme—

> Barnaby bright.
> The longest day and the shortest night.

15. *St. Vitus's Day*.—St. Vitus was a Sicilian martyr. From him, though for what reason is unknown, is named a well-known nervous affection of the limbs, proceeding from a disordered state of the visceral system. It was a popular belief that rain on this day indicated rain for thirty days thereafter.

24. *St. John's Day*, the Nativity of St. John the Baptist, a holiday of the Church of England. The *Eve of St. John*, variously called *Midsummer Eve*, was formerly a time of high observance amongst the English, as it still is in Catholic countries. Bonfires were everywhere lighted, round which the people danced with joyful demonstrations, occasionally leaping through the flame. A certain number of citizens formed a watch, which perambulated the streets all night. It was also believed that, on this eve, by fasting, waking, pulling certain herbs, and going through certain ceremonies, it was possible to obtain an insight into futurity on some important points. *Fasting St. John's Fast* was a great feat of young women a century or two ago. There was also a custom of holding vigil in the church-porch, precisely the same as described under St. Mark's Day (April 25).

29. *St. Peter's Day*, a high festival of the Romish Church, and a holiday of the Church of England. It is celebrated at Rome with illuminations and magnificent ceremonials. In England, till a recent period, the bonfires and watchings of St. John's Eve were also customary on the eve of this festival.

Natural History.—In the central parts of our island, this is in general a dry coldish summer month. The days, however, are at the longest; and though June ranks only third highest as to temperature, drought or evaporation reaches the extreme point. June here resembles the May of more southern climes. The foliage being now quite fresh and fully expanded, and the verdure of the pastures and corn fields being also at the best, the face of nature appears to the greatest advantage. Towards the end of the month we meet with a near coincidence of four stages of vegetation—the earing of wheat, the flowering of the rose, the ripening of strawberries, and the commencement of hay harvest. The general average of the thermometer is 57 degrees. In the course of the month we have the flowering a great number of fine perennials and shrubs, so that the gardens are usually in great glory. It is also the time when weeds give the gardener the greatest trouble.

JULY.

This, being at first the fifth month of the Roman year, was called Quintilis. It became the seventh in consequence of the reform of the calendar by Julius Cæsar, in whose honour, as he was born in it, Augustus gave it the present name.

3. The day fixed in the calendars as the first of the *Dog-Days*, the last being the 11th of August. The dog-days precede and follow the heliacal rising of the star Sirius (in the constellation of the Greater Dog) in the morning, which in Pliny's time was on the 18th of July. The extreme heat of this season of the year, although to us palpably the effect of the continued high position of the sun, was connected by the ancients with the appearance of this star in the morning. They considered the dog-star as raging, and gave the time the appellation of the Dog-Days. The liability of dogs to rabies in consequence of the heat of the season was connected with the same star, though there was nothing but accident in the collusion; and they butchered these animals without mercy. At Argos, there was a festival expressly instituted *for the killing of dogs* during this season. By the precession of the equinoxes, the heliacal rising of Sirius in the morning has been changed to the latter end of August, and in a few thousand years more it will take place in the depth of winter.

4. *The Translation of St. Martin Bullion*, noticed as a festival in the Church of England calendar, though not observed. There is an old saying, not heretofore in print, "If the deer rise up dry and lie down dry on St. Bullion's Day, it is a sign there will be a good gose har'st;" meaning, apparently, that dry weather at this season is favourable to the crops.

St. Ulric's Day.—On this day, in ancient Catholic times, the people brought fish to the altar to obtain the favour of St. Ulric, and one sat there selling the same back to the public for the benefit of the Church.

7. *The Translation of St. Thomas à Becket*, noticed as a festival in the Church of England calendar.

15. *St. Swithin's Day*—remarkable on account of a well-known popular notion, that if it rain on this day, there will be more or less rain for forty days to come. St. Swithin lived just a thousand years ago. He was an eminently pious and learned bishop of Winchester, and priest to King Egbert. He was the deviser and originator of tithes in England. The story runs that, being buried by his own request in the churchyard of the cathedral, the priests a hundred years after felt desirous of giving him greater honour, and commenced the work of translating his remains into the interior. This was on the 15th of July. They were stopped in their work by a heavy fall of rain; neither could they resume their duty next day, for the heavy rain still continued. In short, this rain lasted forty days, by which time the priests became convinced that it was designed to stop them in a work which, though well meant on their part, was ill taken on that of the saint; and they gave up the point. Ever since then, it has been held as a maxim, that if there be rain on St. Swithin's Day (the 15th of July), there will be rain for the forty ensuing days. In a scientific work on the climate of London, it is acknowledged that, "in a majority of our summers, a showery period, which with some latitude as to time and local circumstances, may be admitted to constitute daily rain for forty days, does come on about the time indicated by this tradition—not that any long space before is often so dry as to mark distinctly its commencement."

20. *St. Margaret's Day*.—This day figures in the Church of England calendar. St. Margaret was a holy Italian virgin, martyred in 278. She seems to have been the Christian Lucina: formerly, at Paris, there was a flocking to church on this day of all women who were

pregnant or thought they might be so in the course of the year.

25. *St. James the Apostle*, a holiday of the Church of England. In Catholic times, it was customary for the priests on this day to bless the apples. On St. James's Day, but according to old style (7th August, new style), oysters appeared in London, and there is a popular notion that he who eats oysters on that day will never want money for the rest of the year.

Natural History.—July is the warmest month of the year, the general average temperature being 61 degrees. With us it may be accounted the most important, as its temperature in a good measure regulates the ripening of the crop, that is to say, determines whether it shall be early or late; and in our climate this for the most part may be reckoned a criterion of its value. Flora is in her glory this month. The greatest display of flowers in the whole year takes place in the course of July in our climate. The list includes all the hardy annuals and a great many others. At the same time all our small fruit are in abundance, cherries and strawberries in the beginning being followed by currants, gooseberries, and raspberries, in all their varieties. In the early part of the month barley and oats come into ear, and sometimes in very forward seasons a little barley is cut before the end of July; but very rarely any other kind of grain is ready for the sickle before August. A great part of the produce of the garden comes to perfection, such as early cabbage, cauliflower, turnips, peas, beans, lettuce, &c. Early potatoes also make their appearance, but are not mature till next month.

AUGUST.

In early Roman times this month was called Sextilis, as being the sixth of the year. The Julian arrangement made it the eighth. It acquired the name *Augustus*, in honour of the second of the Cæsars, to whom it had been a fortunate period, he having in it assumed his first consulship, celebrated three triumphs, subdued Egypt, received the oath of allegiance of the legions that occupied the Janiculum, and terminated the civil wars of Rome. As already mentioned, being dissatisfied with its being a month of thirty days, he took a day from February to make it one of the longer class, like that of his uncle Julius. At the same time, September and November were each deprived of a day, which was added in the one case to October, and in the other to December.

1. *Lammas Day*, called also the *Gule of August*. It is now only remarkable as a day of term for some purposes. It was probably one of the great festival days of our heathen ancestors; and it is worthy of observation that it occurs exactly three months after another of these—Beltane. Cromac, Bishop of Cashel in the tenth century, records that in his time four great fires were lighted up on the four great festivals of the Druids, namely, in February, May, August, and November: probably Beltane and Lammas were two of these. Lammas seems to have been held as a day of thanksgiving for the new fruits of the earth. It was observed with bread of new wheat; and there was a custom in some places at no distant period for tenants to be bound to bring in wheat of the new crop to their lord on or before this day. The most rational explanation of the word is that which derives it from the Saxon *Hlaf-Masse* (loaf-mass, or the loaf-festival), the *f* being in time softened away on account of the difficulty of pronouncing it before *m*. Till the middle of the last century, the shepherds in various parts of Scotland were accustomed to hold festive meetings on Lammas day, on the tops of conspicuous hills, turf towers and benches having been previously constructed for the purpose. The Gule of August is probably from the Celtic *Cul* or *Gul* (a festive anniversary). The early Christian priesthood, finding this word in ogue, Latinised it into Gula, which means throat. This, taken in connection with its being the day of the festival of St. Peter ad Vincula (instituted in honour of a relic of St. Peter's chains), seems to have suggested to them to make up a story of the daughter of the tribune Quirinus having been cured of a disorder in the throat by kissing the said relic on the day of its festival. And the Celtic *Gul* (an adversary) has thus been the remote cause of a Christian festival being instituted to *Gula* (the throat), and held on the day of St. Peter's Chains.

15. *The Assumption of the Blessed Virgin*, a grand festival of the Romish Church, and a day noted in the calendar of the Church of England. It was instituted in 813, to celebrate the ascension of the Virgin into heaven. In Catholic countries, this day is marked by splendid ceremonies and processions.

24. *St. Bartholomew's Day* a holiday of the Church of England. Bartholomew was an apostle, but there is no scriptural account of his labours or death. The legend of the Romish Church represents him as preaching in the Indies, and concluding his life by being flayed alive by order of a brother of the king of Armenia. In memory of his death, it was customary at our monastic institutions, in the middle ages, to distribute small knives amongst the people. The day has a horrible celebrity in connection with the massacre of the Protestants at Paris in 1572.

Natural History.—The mean average heat of this month (60 degrees) approaches so near that of July, that a warm dry August often compensates for a low temperature in the preceding month. In the beginning of August, we have often the heaviest rain of the whole year, termed in Scotland the Lammas Flood. July and August, always our warmest, are often our wettest months. Southerly and westerly winds have now the ascendency, but in the case of very heavy rain the wind usually falls. Harvest, in the average, commences about the middle of this month, but in late seasons not till the very end. The order of ripening of our cereal grains is—barley, wheat, oats. The earliest of our larger fruit begin to ripen this month—apples and pears, but hardly plumbs. The latter and more tender exotic annuals now come into flower, such as the amaranths, xeranthemum, zinnia, jacobea, China asters, &c.; also the gigantic biennial shepherd's club, which sows itself, and the also gigantic annual sunflower. St. John's wort, monkshood, flox, also flower about this time.

SEPTEMBER.

This was the seventh month in the Roman year before the Julian reform of the calendar. The two first syllables of the name are thus readily accounted for; the last, which also figures at the end of the names of the three following months, is an ancient particle of doubtful signification.

1. *St. Giles's Day.*—This saint's day figures in the Church of England calendar. A native of Greece, he travelled into France in 715, and became abbot of Nismes. He literally obeyed the scriptural injunction by settling his patrimony for the benefit of the poor, and on one occasion gave his coat to a sick mendicant, who was cured miraculously by putting it on. St. Giles has thus become the patron saint of beggars and cripples. St. Giles's Church, Cripplegate, London, and the High Church in Edinburgh, are dedicated to him; and he is the patron saint of the Scottish capital, as far as it can be said to have one.

8. *The Nativity of the Blessed Virgin*, a grand festival of the Romish Church, and still retained in the Church of England calendar. This festival has been held in honour of the Virgin, with matins masses, homilies, collects, processions, and other ceremonies for upwards of a thousand years. According to the Catholic writers,

a religious contemplative, every year upon the 8th of September, heard most sweet music in heaven, with great rejoicings of angels. Once he asked one of them the cause, and was told that upon that day was celebrated in heaven the nativity of the mother of God. The birthday of the Virgin being thus miraculously communicated to mankind, Pope Servius instituted a festival to hold it in honour.

14. *Holy Rood Day*, or the day of the Exaltation of the Holy Cross, a festival of the Romish Church, still retained in the Church of England calendar. It celebrates the miraculous appearance of a cross in the heavens to the emperor Constantine. The Wednesday, Friday, and Saturday after Holy Rood Day, are Ember Days, and the Week in which they occur consequently an Ember Week.

21. *St. Matthew the Apostle*, a festival of the Church of England.

29. *The Festival of St. Michael and all the Holy Angels*; shortly, *Michaelmas Day*, a grand festival of the Romish and English churches. St. Michael is singled out for particular mention as being the chief of angels, or archangel. The theological character of Michael is obscure. Suffice it here to quote the remark of Whatley, in his exposition of the book of Common Prayer, that "the feast of St. Michael and all Angels is observed, that the people may know what benefits are derived from the ministry of angels."

Michaelmas, besides being one of the quarter days in England for the payment of rents and wages, has been distinguished from an early period in that and other countries as the time for the annual election of corporation officers, magistrates, and other civil guardians of the peace. It has been suggested that the selection of the day for this purpose might arise from "the old opinion of tutelar spirits, who have, or are thought to have, the particular charge of certain bodies of men, or districts of country, as also that every man had his guardian angel, who attends him from the cradle to the grave, from the moment of his coming in to the moment of his going out of life."

It is an ancient and extensively prevalent custom to have a goose for dinner on Michaelmas day. Queen Elizabeth is said to have been eating her Michaelmas goose when she received intelligence of the defeat of the Spanish Armada. Very curious and recondite origins have been assigned to this custom, but it seems to have arisen simply from the goose being at its best immediately after it has had the range of the reaped harvest fields.

Natural History.—This is often the finest month of the year; yet as with other portions of our seasons, it is not to be depended on. In temperature (the general average is 55 degrees) it ranks between May and June, yet the first three weeks are often as warm as any part of the summer; but there is usually a sensible falling off in the latter part. In Scotland the bulk of the harvest work of the season is usually effected during this month. It is likewise the time when large fruit comes to perfection. The flower borders have still a gay appearance, the latest exotic annuals only beginning to flower at this time. The dahlia, a magnificent flower of recent introduction, appears in all its grandeur during September. It has been remarked that at no other season is the house-fly so numerous.

OCTOBER.

As already explained, October has its name from having been the eighth month of the Roman year before the Julian reform of the calendar. In the time of the emperor Domitian it was called Domitianus, in his honour; but after his death that name was abandoned by general consent, from a wish to sink the memory of so execrable a tyrant. The Saxons called October *Wyna'-monat* (wine month), from its being the time when wines were annually brought into Germany (none being then made in that country).

2. The festival of the *Holy Angel Guardians* in the Romish Church.

9. The day of *St. Dennis*, the patron saint of France. St. Dennis was put to death, with some companions, in the year 272, upon an eminence near Paris, since called from that circumstance Montmartre (*Mons Martyrum*). According to the legend, his head had no sooner been cut off, than the body rose, and taking up the head, walked with it two miles. Portraits of St. Dennis, carrying his head in his hand, abound in old prayer-books.

18. The day of *St. Luke the Evangelist*, a festival of the Church of England. This day was appointed to be St. Luke's festival in the twelfth century.

St. Luke was usually represented in the act of writing, with an ox by his side, having wings and large horns. The natural habit of this animal in ruminating upon its food, caused it to be selected as an emblem of meditation, appropriate to this evangelist. At Charlton, a village near Blackheath, about eight miles from London, a fair is held on St. Luke's Day, and at this fair there was kept up until a very recent period a curious custom originating evidently in the emblem of St. Luke. People came to this fair masked; the men generally wore women's clothes; and many bore horns upon their heads. It was a scene of wild riot and confusion. The booths had horns of various animals, gilt and otherwise, for sale, and even the gingerbread was marked with that figure. "Horns! Horns!" was the universal cry. The gentry used to come in multitudes to see the sports of this occasion. Some fragments of a stained-glass representation of St. Luke and his horned companion still exist in a window of the parish church.

25. *The festival of St. Crispin and St. Crispinian.* The name of St. Crispin is in the Church of England calendar. Crispin and Crispinian are said to have been two Roman youths of good birth, brothers, who, in the third century, went as Christian missionaries to France, and preached for some time at Soissons. In imitation of St. Paul, they supported themselves by working at the trade of the shoemaker during the night, while they preached during the day. They were successful in converting the people to Christianity, until arrested in their course by Rictius Varus, governor under the emperor Maximian Herculeus. Butler, in his "Lives of the Saints," says: "They were victorious over this most inhuman judge by the patience and constancy with which they bore the most cruel torments, and finished their course by the sword about the year 287." The two young martyrs were of course canonized, and a splendid church was built to their honour at Soissons, in the sixth century. The shoemaker craft throughout the whole Christian world have from an early period regarded Crispin and Crispinian as their patron saints, but particularly the first. They often celebrate the day set apart for these saints in the calendar, with processions, in which Crispin, Crispinian, an Indian prince, and some other personages whom tradition has associated with their history, are represented in splendid antique dresses. Sometimes a coronation of Crispin is part of this ceremony, for there is a notion that he was a royal personage, and hence we find the shoemakers, in Scotland at least, assuming for their arms a leather knife, surmounted by a crown, and styling themselves "the royal craft." Whether they celebrate the day by procession or not, they are sure to distinguish it by giving themselves up for the time to jollity.

28. The day of *St. Simon and St. Jude*, a festival of the English Church. Simon, usually surnamed the Canaanite, remained with the other apostles till after Pentecost

it has been surmised that he visited Britain, and there suffered martyrdom. Jude, otherwise called Thaddeus, and thought to have been a son of Joseph by a former wife, is said to have suffered martyrdom in Persia.

On this day, formerly, it was considered proper to indue winter vestments. It was always expected to be rainy. A character in an old play called the *Roaring Girl*, says, "As well as I know 'twill rain upon Simon and Jude's Day." In another production of the Elizabethan stage, some one exclaims, "Now a continual Simon and Jude's rain beat all your feathers as flat down as pancakes." Perhaps there is some connection between this notion and the emblem assigned to the day in old calendars, namely, a ship, which seems to have been adopted in consideration of Simon and Jude having been fishermen.

Natural History.—During this month, the average temperature of which is 49¼ degrees, there are usually decided symptoms of the approach of winter; yet the weather of the month is often of a steady and agreeable character. Bare harvest fields, some of which are in the course of being ploughed for winter wheat, form a conspicuous feature of external nature. The foliage of the trees become changed from green into a variety of tints, which gives the woods a beautiful appearance, and is generally admired, although felt to betoken that they are soon to be stripped of their summer honours. The migratory birds assemble, and commence their annual flight to more genial climes—the swallow to the shores of Africa, the nightingale to Lower Egypt, and the puffin and some others either to Africa or to Spain. Towards the end of the month, if high winds prevail, the trees are a good deal bared. In the gardens less decline is to be remarked. The flower-borders still have a gay appearance; the hollyhock, dahlia, and some other flowers, being yet in good condition. This is the time of the laying up of potatoes. In England, it was the favourite time for brewing, on account of the equable temperature; and *October* is a secondary name for the yeoman's brown beverage. In this month the gossamer has a striking appearance, floating like an aërial veil over the fields, and meshing the passing traveller.

NOVEMBER.

November obtained its name from being the ninth month in the Roman year, before the reform effected by Cæsar. Our Saxon ancestors called it *wint-monat* (wind month).

1. *All Saints' Day*, a festival of the Romish and English churches—otherwise called *All Hallow Day*. The evening of the 31st October is called All Hallow Even, or Hallow E'en, as being the vigil or eve of All Hallow Day. Hallow-tide is a comprehensive name for both days. The Romish Church designed this day to be held in honour of all those saints who had not particular days appointed for them.

It does not appear that All Saints' Day or its Eve, was ever marked by very particular observance in the Catholic Church. Nevertheless, there is scarcely any time more distinguished by the common people throughout the British islands than All Hallow Eve or Hallowe'en. This is probably owing to the fact of November 1st having been one of the four great festivals of our Pagan ancestors. The 1st of February, the 1st of May, and the first of August were the other three; the antient names of the two latter are still in vogue—Beltane and Lammas. These four days were celebrated by the kindling of fires in conspicuous places, and performing certain ceremonies. The fires of Beltane and Lammas have already been spoken of; it is probable that those of the February festival are kept up in the *Candlemas blaze*, with a slight change of day. Fires were kindled in Wales, Ireland, the Scottish Highlands, and even in England, on the 1st of November, until a very recent period; and the custom may still be kept up in some remote places.

Pennant states as follows:—"In North Wales there is a custom upon All Saints' Eve of making a great fire called *Coel Coeth*. Every family, about an hour in the night, makes a great bonfire in the most conspicuous place near the house, and when it is almost extinguished, every one throws a white stone into the ashes, having first marked it; then having said their prayers turning round the fire, they go to bed. In the morning, as soon as they are up, they come to search out the stones, and if any of them are found wanting, they have a notion that the person who threw it in will die before he sees another All Hallow Eve." The Welsh also practise many of those rites for divining the future, which are so prevalent on Hallowe'en in other parts of the United Kingdom. It is mentioned by another writer that they dance round and jump through the bonfires, and at the conclusion always run away "to escape the black short tailed sow."

General Vallancey states that the Irish have now generally substituted a candle illumination for the fire of the 1st of November.

The Rev. Mr. Shaw, in his "History of Moray," written in the latter part of the last century, speaks of the Hallow Eve fire being still kindled in Buchan. In the "Statistical Account of Scotland," published at the close of the century, the same fire is spoken of as kept up in various parts of the Highlands. In the parish of Callendar for instance, "On All Saints' Eve, they set up bonfires in every village. When the bonfire is consumed, the ashes are carefully collected in the form of a circle. There is a stone put in, near the circumference, for every person of the several families interested in the bonfire: and whatever stone is moved out of its place, or injured before the next morning, the person represented by that stone is devoted, or *fey*, and is supposed not to live twelve months from that day." How strange thus to find a superstitious custom of this nature existing in a form so nearly identical in Wales and Perthshire.

Several writers in the Gentleman's Magazine, in the latter part of the last century, speak of Hallow Eve fires being still kindled in various parts of England, chiefly by persons of the Catholic persuasion. The practice seems to have been to carry about a quantity of burning stuff, under the name of *tinley* or *tindle*.

These ceremonies appear to be among the earliest connected with the 1st of November. They are, or have recently been, everywhere prevalent throughout these islands. As they are obviously of a Pagan character, we conclude that the notability of this season is of older date than the introduction of Christianity, and that its character as All Saints' Day has comparatively little affected the popular mind.

We have notices from both Perthshire and Ireland of the 1st of November being partly regarded as the proper time for returning thanks for the realized fruits of the earth. The Irish, in this regard, called it *La Mas Ubhal*, that is, the day of the apple fruit, and celebrated it with a drink or mess composed of bruised roasted apples among ale or milk. This drink in time acquired the strange appellation of *lamb's wool*, a corruption, apparently, of the name of the day in the Celtic language.

Ringing of bells was one of the modes of celebrating Hallowmas in England in the days of our ancestors. It was a Roman Catholic practice, being designed in some way to favour the souls of departed Christians. For this reason Queen Elizabeth prohibited it.

It was also a custom of our Catholic forefathers to have a cake baken on this eve for every member of the family, as a *soul mass cake* or *soul cake*. It was composed of oatmeal, and seeded; and pasties and furmety were incidental to the same evening. In families of good condition, a quantity were baken and set up on a board, like the shew-bread in old pictures in the Bible, to be given to visiters, or distributed among the poor. There was a ryhme for the occasion—"A soul cake! a soul cake! Have mercy on all Christian souls for a soul cake!" People went from parish to parish *a-souling*, as they called it, that is, begging in a kind of chant for soul-cakes, or any thing to make them merry on this eve. It is very curious to find that a century and a half ago the inhabitants of St. Kilda, so far removed from all other parts of Britain, had a custom of baking a large triangular cake, furrowed on the edges, on All Saints' Night.

Essentially connected with all these customs are those better known ones which Burns has so well and so faithfully described in his poem of *Halloween*. All over the British islands, the festive and fortune-telling practices of this evening are very nearly the same. As some proof of this, passages from an English, Irish, and Scottish poet may be presented side by side:—

Two hazel-nuts I threw into the flame,
And to each nut I gave a sweetheart's name:
This with the loudest bounce me sore amazed,
That in a flame of brightest colour blazed;
As blazed the nut, so may thy passion grow,
For 'twas thy nut that did so brightly glow.
The Spell, by Gay.

These glowing nuts are emblems true
Of what in human life we view:
The ill-matched couple fret and fume,
And thus in strife themselves consume;
Or from each other wildly start,
And with a noise for ever part.
But see the happy, happy pair,
Of genuine love and truth sincere;
With mutual fondness, while they burn,
Still to each other kindly turn;
And as the vital sparks decay,
Together gently sink away:
Till life's fierce ordeal being past,
Their mingled ashes rest at last.
Nuts-Burning, All Hallowe'e, by Charles Graydon.

Jean slips in twa wi' tentie ee,
Wha 'twas she wadna tell
But this is Jock and this is me,
She says into hersel';
He bleezed owre her, and she owre him,
As they wad ne'er mair part,
Till fuff! he started up the lum,
And Jean had e'en a sair heart
To see't that night.
—Halloween, by Burns.

Nuts, besides being thus used for divination, are cracked and eaten; and hence, in the north of England, All Hallow Eve is often called *Nut-crack Night*. Apples are also extensively eaten, this consumpt of fruit having probably some reference to the heathen character of the day, as that of thanksgiving for the produce of the season. The fortune-telling customs described by Burns, besides the above, are—for the girls to pull stalks from a corn-stalk, and ascertain, from the presence or absence of the top pickle, an interesting point in their moral history—for a solitary female to go to a kiln, and throwing a blue clue into the pot to wind it, expecting that ere finished it will be held back, when, by inquiring who holds, a response will be obtained disclosing the name of the future husband—to eat an apple at a looking-glass, expecting to see a vision of the future husband peeping over the shoulder—to sow hemp-seed in the yard, saying, "Hemp-seed, I saw thee, hemp-seed, I saw thee, and her that is to be my true love come after me and draw thee," expecting that, on looking over the shoulder, a vision will be obtained of the future spouse in the act of pulling grown hemp—to win three wechts o' naething in the barn, expecting to see a like vision—to fathom a barley-stack thrice, expecting at the last to embrace your mistress—to dip a shirt sleeve in a rivulet at the meeting point of the lands of three proprietors, and then hang it by the fire to dry, trusting to see such a visionary person come in and turn the other side—to pull stalks of deceased cabbages, blindfolded, without choice, and augur, from their straightness or crookedness, the figure of the future spouse, from the earth which clings to the root, the fortune she will bring, and from the taste of the heart, her temper—finally, to set three dishes on the floor, one empty, one with clean, and one with foul water, and cause the company to approach them blindfolded and dip in a hand; when he who dips in the empty one is expected to remain unmarried, he who dips in the foul one to marry to a widow, and he who dips in the clean one to marry a female not hitherto married. The whole of these rites are as familiar to the Welsh, Irish, and Northumbrian, as to the Ayrshire peasantry. Many of them are also practised in England on St. John's Eve, the 23d of June.

Hallowe'en is still observed, but the more daring rites are generally given up. Meetings of young persons take place, and a plentiful store of nuts and apples being provided, a few simple amusements are practised. The experiment of the burning nuts, to test the duration of love or friendship, is still a favourite. Ducking for apples is another. A tub being provided, nearly full of water, and the fruit thrown in, the young people endeavour to seize an apple with their teeth—a task of much more difficulty than might be supposed, and which generally puts the dress and tresses of fair experimentalists into considerable disorder. The baffled efforts of the various parties raise, of course, shouts of laughter. Or a cross stick is suspended by a string from the ceiling, with a short burning candle on one end and an apple on the other. While it swings rapidly round, lads and lasses, with their hands tied, endeavour to catch the apple with their teeth, but generally suffer a good deal from the candle before they succeed in their object. Here, also, failure is a source of infinite amusement. It is rather remarkable that Burns has not introduced into his poem any notice of these sports, which, like the others, are prevalent over the whole of her Majesty's home dominions. It may not be out of place here to remark, that the jest of the apple and candle is nearly the same as that of the quintain, a favourite sport of our ancestors, commonly practised in summer. The quintain was a heroic figure of wood, on a vertical pivot, used as a butt for the practice of tilting. In this case it had a cross board, one end of which was broad, while the other was furnished with a heavy bag of sand. The trick was, to come tilt against the broad end, and escape receiving a knock-down blow from the sand-bag.

2. *All-Souls' Day*, or the *Commemoration of the Faithful Departed.*—A very solemn festival of the Romish Church, which has masses and ceremonies appropriate to the occasion, designed in favour of the souls of all the dead. "Odillon, Abbot of Cluny, in the ninth century, first enjoined the ceremony of praying for the dead on this day in his own monastery; and the like practice was partially adopted by other religious houses until the year 998, when it was established as a general festival throughout the western churches. To mark the pre-eminent importance of this festival, if it happened on a Sunday, it was not postponed to the Monday, as was the case with other such solemnities, but kept on the Saturday, *in order that the church might the sooner aid the suffering souls*; and that the dead might have every benefit from the pious exertions of the living, the remembrance of this ordinance was kept up by persons dressed in black, who went round the different towns, ringing a loud and dismal-toned bell at the corner of each street, every Sunday evening during the month, and calling upon the inhabitants to remember the deceased suffering the expiatory flames of Purgatory, and to join in prayers for the repose of their souls."*

5. The anniversary of the discovery of the Gunpowder

* "Brady's Clavis Calendaria."

Plot in 1605, and of the landing of King William III. in 1688; observed in the British dominions as a holiday, and celebrated by the Church of England by a form of prayer with thanksgiving. There is also a popular celebration of this day. From an early hour, the boys go about collecting materials for a bonfire, or money wherewith to purchase them. In some, perhaps most places, they carried with them a frightful figure composed of an old suit of clothes stuffed with straw, to represent Guy Fawkes. They called on the passengers and householders to "remember Guy," or shouted some balderdash rhymes. In the evening, the bonfire is lighted with Guy Fawkes in the middle of it, amidst tumultuous merriment. The firing of guns as a token of rejoicing, we are glad to say, is now discontinued on this day, and we trust the other absurd usages will soon likewise disappear.

11. *St. Martin's Day*, or *Martinmas*, in the Church of England calendar. Popularly, this is one of the most remarkable days of the year, especially in Scotland, where Whitsunday and *Martinmas* are the two great terms for leases and engagement of servants, the latter being that at which the occupation of farms usually commences. Formerly, it was a quarterly term day in England: a payment of corn at Martinmas occurs in the Doomsday Survey. On the continent, from an early age, the day has been distinguished convivially; and this apparently for two reasons, namely, that now the people first tasted the wines of the season, and killed the animals required to be salted for their winter provisions. The entrails of these animals, prepared as sausages, or blood-puddings, became the subject of an immediate feast, while the rest of the meat was salted and set aside. In some countries, also, the goose, which is elsewhere enjoyed at Michaelmas, was now presented. The killing of beeves at Martinmas for winter provision was formerly universal in northern Europe, in consequence of there being no means of keeping them alive in winter; since the improvement of husbandry in some countries, the custom has been given up, and fresh meat used all the year round. The feasting upon the entrails was equally universal. So much was all this associated with Martinmas, that in Scotland a beeve killed at that time was called a *mart* or *mairt*. In the old book of laws attributed (erroneously) to David I. of Scotland, it is provided that "the fleshours sall serve the burgesses all the time of the slauchter of *Mairts*." In Northumberland, also, a Martinmas bullock is called a *mart*. Tusser, in his curious metrical treatise on husbandry, written in the time of Henry VIII., says—

> When Easter comes, who knows not than
> That veal and bacon is the man?
> And *Martinmas beef* doth bear good tack,
> When country folks do dainties lack.

Bishop Hall, in his Satires, written in the time of James I., mentions

> —— Dried flitches of some smoked beeve,
> Hanged on a writhen wythe since *Martin's eve*.

It appears that the contents of the puddings, as made in England, were composed of blood, suet, and groats; and there was an enigmatical proverb thence arising, that "blood without groats was nothing," meaning that birth without fortune was of little value. Down to near the end of the last century there was not a family above the poorest condition in the rural districts of Scotland which had not a *mart*, or a share in one, and salted meat was the only food of the kind used in winter; now, there is no such practice known, except as a matter of tradition.

Martin, in whose honour this festival was at first instituted, is said to have been born in Lower Hungary about 316, and to have originally been a soldier. After a number of miraculous adventures, he settled as a hermit in the hollow of a rock near Tours in the south of France, where he was greatly venerated. He died bishop of Tours in 397. When a few fine days occurred about this time of the year, they were called *St. Martin's summer*.

23. *St. Clement's Day*, in the Church of England calendar. Clement is spoken of by St. Paul as one of his fellow-labourers. Monkish imagination has supplied him with a history and a martyrdom. He is said to have been thrown into the sea with an anchor fixed about his neck. An anchor is therefore assigned to him as an emblem: of this the metropolis presents a conspicuous memorial in the anchor which forms the vane of the church of St. Clement Danes, in the Strand. St. Clement is held as the patron saint of the blacksmiths. It was formerly customary for boys, and the lower class of people generally, to go about on this day begging for liquor, wherewith they made a regale at night. Hence, in a certain class of old almanacs, the day was signified by the figure of a pot.

29. This is one of the days on which *Advent* may commence. Advent [literally, the Coming] is a term applied from an early period of ecclesiastical history to the four weeks preceding Christmas, which were observed with penance and devotion, in reference to the approaching birth of Christ. There are four Sundays in Advent, the first of which is always the nearest Sunday to St. Andrew's Day (November 30).

30. *St. Andrew's Day.*—The festival day of this saint is retained in the Church of England calendar. St. Andrew was one of the apostles. His history, as related by the Catholic writers, represents him as martyred in the year 66 at Patræ in Greece, upon a cross of the form of the letter X, which accordingly is still recognised as St. Andrew's Cross. A supposed relic of this cross, carried to Brussels in the middle ages, caused its figure to be adopted as a badge for the knights of the Golden Fleece. Some relics of the apostle himself are said to have been carried by a Greek devotee named St. Regulus, to Scotland, where they were placed in a church built at a place which subsequently became distinguished by the name of St. Andrews. St. Andrews became the seat of the Scottish primacy; and from this cause probably it was that St. Andrew was in time considered as the patron saint of Scotland. In that country, however, there is scarcely any observance of this day in any manner; it is only when Scotsmen are abroad, and have occasion to select a day for an annual convivial meeting, that St. Andrew's Day comes into notice. There used to be a procession of Scotsmen on this day in London, with singed sheeps' heads borne before them. It is remarkable that St. Andrew is also a tutelar saint of the Russians, probably in consequence of the Greek locality of his martyrdom. There is an ancient and widely prevalent custom connected with St. Andrew's day, to which Luther has adverted. Maidens, on the eve of this day, stripped themselves, and sought to learn what sort of husbands they were to have by praying in these terms—"Oh, St. Andrew, cause that I obtain a good pious husband; to-night show me the figure of the man who will take me to wife."

Natural History.—In this month the business of vegetation experiences its death. The trees are now thoroughly stripped of their foliage. It is reputed as a gloomy month; but the temperature is sometimes agreeable in the earlier part of it, and its average for the whole term is 43 degrees. A considerable number of plants remain in flower throughout November. The gloom of the month is said to have a depressing effect on the spirits of the English nation; let those who are liable to such influences lay to heart the following remarks of Johnson in the "Idler:"—"The distinction of seasons is produced only by imagination acting upon luxury. To temperance every day is bright, and every hour is propitious to diligence. He that resolutely excites his faculties, or exerts his virtues, will soon make himself superior to the seasons, and may set at defiance the morning mist and the evening damp, the blasts of the east and the clouds of the south. Instead of looking for spring with anxious and caring mind, enjoy the present day; there are pleasures even in November."

DECEMBER.

So called as being originally the *tenth* of the Roman year. Our Anglo-Saxon ancestors called December *winta monat*, that is winter month; but, after becoming acquainted with Christianity, this name was changed into *heligh monat*, or holy month, with reference to the celebration of the nativity on its twenty-fifth day.

6. *St. Nicholas's Day.*—Retained in the Church of England calendar. St. Nicholas was Archbishop of Myra, in Greece, A. D. 342. He is regarded as the patron saint of children and of mariners, probably in consequence of his benevolent zeal in the protection of orphans and stranded seamen. Churches built near the sea are in many instances dedicated to St. Nicholas. He is also said to have shown much kind interest in the fate of young women, sometimes secretly throwing purses into the chamber-windows of those who lacked dowries. Hence has arisen a custom prevalent over a large part of the Christian world. On his eve, presents are hid in the shoes of those to whom any one wishes to give a pleasing surprise; and these, being found in the morning, are jocularly said to be gifts from St. Nicholas.

St. Nicholas is also considered as the tutelar saint of scholars, or clerks, and of robbers. The fraternity of parish-clerks have thought themselves entitled by their name to adopt him as their patron. How robbers should have come to be called St. Nicholas's clerks, or St. Nicholas's knights, it is not easy to see, unless it were from the coincidence of his name with one of the slang appellations of the devil.

Throughout the middle ages, there was a universal custom of electing a kind of mock bishop on St. Nicholas's Day. A boy, possibly taken from among the choristers, was chosen by his associates as bishop, arrayed in suitable vestments, and endued with appropriate powers, which he enjoyed for some days. The infant prelate was led along in a gay procession, blessing the grinning multitude as he went, and he was even allowed to sing mass and to mount the pulpit and preach. Edward I., in his way to Scotland, in 1299, heard vespers by a boy bishop at the chapel of Heton, near Newcastle. The boy bishop at Salisbury is said to have had the power of disposing of any prebends that fell vacant during his term of office; and one who died at that time had a monument in the cathedral, representing him in his episcopal robes. Mr. Wharton is of opinion that we see some faint traces of the rise of dramatic entertainments in the strange mummeries connected with the election of the Boy Bishop.

8. *The Conception of the Blessed Virgin*, in the Romish and English calendars.

11. The fourteen days from this to Christmas Eve were called the *Halcyon Days*, and supposed to be, in their calm and tranquil character, an exception from the season. The term, which is now a regular adjective in our language, is derived from the bird king-fisher or halcyon, which, from the days of Aristotle at least, has been the subject of a curious superstition. The ancients supposed that it built its nest on the ocean, and brought forth its young at the winter solstice. To account for the preservation of the nest and young amidst the severity of the season, they imagined that the bird had a power of lulling the raging of the waves during the period of incubation; and this power was believed to reside in its song.

13. *St. Lucia's Day*—Retained in the Church of England calendar. St. Lucia was a young lady of Syracuse, who obtained a high character for a devout and charitable life, and died in the year 304. The last of the four series of Ember Days commences on the Wednesday following this festival.

16. *O Sapientia.*—This day is so marked in the church calendar, probably from an anthem sung on this day in the Romish Church, beginning, "O sapientia quæ ex ore altissimi prodidisti," &c.

21. *St. Thomas the Apostle*, a festival of the English Church. It was customary in England for women to go *a-gooding* on St. Thomas's Day; that is, they went about begging money, and presenting in return sprigs of palm and bunches of primroses, probably with a view to the decoration of their houses against Christmas.

25. *Christmas Day*, observed from an early period as the nativity of our Lord, and celebrated not only by the religious ceremonies from which the name of the day is partly taken, but by popular festivities of the most joyful kind. In England, Christmas is held by the church as a solemn festival, and distinguished by the complete cessation of business—an honour paid to no other day besides Good Friday. But within the last hundred years, the festivities once appropriate to the day have much fallen off. These at one time lasted with more or less brilliancy till Candlemas, and with great spirit till Twelfth Day; but now a meeting in the evening, little different from a common dinner party, though sure to be marked by a roast and plum-pudding, and pretty generally followed by a game at cards, is all that distinguishes Christmas in most families.

In former times, the celebration of Christmas began in the latter part of the previous day—Christmas Eve. The house was first decked with holly, ivy, and other evergreens. Candles of an uncommon size were then lighted under the name of Christmas Candles; an enormous log, called the Yule Clog, or Christmas Block, was laid upon the fire: the people sat round regaling themselves with beer. In the course of the night, small parties of songsters went about from house to house, or through the streets, singing what were called Christmas Carols—simple popular ditties full of joyful allusions to the great gift from God to man in the Redeemer. A mass was commenced in the churches at midnight, a custom still kept up in the Catholic Church. At one period, the people had a custom of wassailing the fruit trees on this evening; that is, they took a wassail bowl, threw a toast from it to the tree, and sung a song, expecting thus to secure a good crop of fruit the next season. It was thought that, during the night, all water was for a short time changed into wine, and that bread baked on this eve would never become mouldy. These notions are essentially foolish, but as they are all well-meant adorations of the simple spirit of the people, they should not be hastily condemned.

The carols were more generally sung in the morning of Christmas Day. A contributor to the "Gentleman's Magazine," in 1811, describing the manner in which Christmas is celebrated in the North Riding of Yorkshire, says: "About six o'clock on Christmas Day I was awakened by a sweet singing under my window; surprised at a visit so early and unexpected, I arose, and looking out of the window, I beheld six young women and four men welcoming, with sweet music, the blessed morn." It may scarcely be imagined how delightfully at such a moment would fall upon the half-slumbering ear such strains as the following:—

God rest you, merry gentlemen,
Let nothing you dismay,
For Jesus Christ our Saviour
Was born upon this day,
To save us all from Satan's power,
When we were gone astray.
Oh tidings of comfort and joy,
For Jesus Christ our Saviour
Was born on Christmas Day.

In Bethlehem in Jewry
  This blessed babe was born,
And laid upon a manger
  Upon this blessed morn;
The which his mother Mary
  Nothing did take in scorn.
    Oh tidings, &c.

Christmas carols are among the oldest of English songs. A collection of them was printed by Wynkyn de Worde in 1521. They are still printed on single sheets, which are sold by chapmen or dealers in cheap literature. There is also more than one modern collection of these curious productions of former ages.

The religious service of Christmas Day receives but a small share of attention from old writers. In fact, the day was chiefly distinguished by the popular festivities. Its grand feature was a feast, of great abundance, and at which a few particular dishes regularly appeared, above all, plum-porridge and mince-pie. In every great hall, whether of a man of rank or of a great corporation, there was a boar's head ushered in by minstrelsy. It was customary for the rich and noble to treat their humble dependants, and to meet with them on terms of equality, as considering that all men are regarded alike by the religion of him whose natal day they were celebrating. A sort of license prevailed. A branch of the mistletoe being hung up in the hall or over the doorway, the youths were understood to have a right to kiss any maiden whom they could inveigle under it. At York, the freedom of the time was so extreme, that there were regular proclamations allowing women of evil repute and gamblers to come to the city and walk about openly for a certain number of days. It was also customary to elect a person as *Lord of Misrule*, who went about taking the lead in every kind of extravagant sport and merriment which the wit of man could devise. The election and functions of this personage were perhaps the most singular part of the festival. According to Stow, "at the feast of Christmas, there was in the king's house, wherever he lodged, a Lord of Misrule, or Master of merry Disports, and the like had ye in the house of every Nobleman of honour or good worship, were he spiritual or temporal. The Mayor of London, and either of the Sheriffs, had their several Lords of Misrule, ever contending, without quarrel or offence, who should make the rarest pastime to delight the beholders. These lords, beginning their rule at Allhallond Eve, continued the same till the morrow after the Feast of the Purification, commonly called Candlemas Day: in which space there were fine and subtle disguisings, masks, and mummeries, with playing at Cards for Counters, Nayles, and Points in every House, more for pastimes than for gaine."

The management of the plays usually acted at Christmas in the halls of colleges and law societies, fell to the care of the Lord of Misrule. The particular functionary elected in the inns of court in London, after exercising all the duties and going through the parade of royalty for a fortnight, at an expense of a couple of thousand pounds, was knighted at Whitehall by the real sovereign of the land.

In Scotland, before the Reformation, the religious houses had a similar officer for the Christmas revels, called the *Abbot of Unreason*, whose particular functions are graphically pourtrayed by Scott in his novel of "The Abbott." The custom was suppressed by statute in 1555.

26. *St. Stephen's Day*, observed as a festival of the Church of England. There was formerly a widely prevalent dogma that it was good to bleed horses about this time of the year, and St. Stephen's Day was that chosen by most people for this purpose. On this day, also, blessings were implored upon pastures.

27. *St. John the Evangelist's Day*, observed as a festival by the Church of England. Because John drank poison, without dying in consequence, it was supposed that those who put their trust in him were safe from all injury from that cause.

28. *Childermas* or *Holy Innocent's Day*, observed by the Church of Rome with masses for the children killed by Herod. It was considered unlucky to marry, or to begin any work, on Childermas Day. The learned Gregory says, "It hath been a custom, and yet is elsewhere, to whip up the children upon Innocent's Day morning, that the memory of Herod's murder might stick the closer, and in a moderate proportion to act over the 'crueltie again in kinde.'"

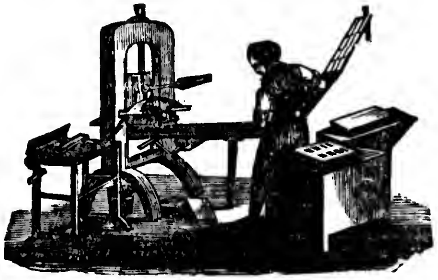
31. The last day of the year is called in Scotland *Hogmanay*, a word which has fruitlessly exercised the wits of the etymologists. The Scottish people, overlooking Christmas in obedience to the behests of their religious teachers, have transferred the merriment of the season to Hogmanay and New Year's Day, which they accordingly abandon to all kinds of festivity. Handsel Monday, or the first Monday of the year, is also an occasion of festivity. On Hogmanay, the children in small towns perambulate among the neighbours of the better class, crying at their doors, "Hogmanay!" or sometimes the following rhyme:—

Hogmanay, trollolay,
Gie's of your white bread and none of your gray;

in obedience to which call, they are served each with an oaten cake. In the evening, there are merry makings, which are always prolonged to twelve o'clock, which has no sooner struck than all start up excitedly, and wish each other a happy new year. Small venturous parties take a kettle with hot ale posset, called "a het pint," and go to the houses of their friends, to wish them a happy new year. Whoever comes first, is called in that house "the First Foot," and it is deemed necessary on such occasions to offer the inmates both a piece of cake and a sip from the posset kettle, otherwise they would not be lucky throughout the year. This is called "*First-Footing*." Next day, all people go about among all other people's houses; presents are given among relations; and dinner-parties close the evening. Formerly, the first Monday of the year was also much observed as a festive day, and time for giving presents, from which latter circumstance it was called *Handsel Monday*. The Handsel Monday, old style, is still, in some rural districts, the chief feast day of the season. On the evenings of Christmas, Hogmanay, New Year's Day, and Handsel Monday, parties of young men and boys went about disguised in old shirts and paper vizards, singing at the various houses for a small guerdon. These *guizarts*, as they were called, also acted a rustic kind of drama, in which the adventures of two rival knights, and the feats of a doctor, were conspicuous. Almost everywhere in Scotland the festive and frolicsome observances of the New Year tide have much declined.

Natural History.—December is the darkest, but not the coldest month of the year: the general average temperature is 40 degrees. The deciduous trees are now completely stripped of their foliage, and the ground often shows a snowy covering, although it is rarely that there is much strong ice in December. Amidst the general desolation, the pines and other evergreens form an agreeable resting-place for the eye. The rose also continues to blow during this month. Formerly, the Glastonbury thorn was a great wonder in England, being supposed to blow regularly on Christmas Day. The monks of the abbey there represented it as the staff of Joseph of Arimathea, which, being inserted by him in the ground, had miraculously sprouted out into a living tree. But it seems to have been only a member of a certain species of thorn well known in the east for blowing in the depth of winter.

PRINTING—ENGRAVING—LITHOGRAPHY



ORIGIN AND HISTORY OF PRINTING.

PRINTING is the art of producing impressions from characters or figures, movable and immovable, on paper or any other substance. There are several distinct branches of this important art—the printing of books with movable types, the printing of engraved copper and steel plates, and the taking of impressions from stone, called lithography. Our object, in the first place, is to describe the art of printing books or sheets with movable types, generally called *letterpress printing*, and which may undoubtedly be esteemed the greatest of all human inventions.

The art of printing is of comparatively modern origin: four hundred years have not yet elapsed since the first book was issued from the press; yet we have proofs that the principles upon which it was ultimately developed existed amongst the ancient Chaldean nations. Entire and undecayed bricks of the famed city and tower of Babylon have been found stamped with various symbolical figures and hieroglyphic characters. In this, however, as in every similar relic of antiquity, the object which stamped the figures was in one block or piece, and therefore could be employed only for one distinct subject. This, though a kind of printing, was totally useless for the propagation of literature, on account both of its expensiveness and tediousness. The Chinese are the only existing people who still pursue this rude mode of printing by stamping paper with blocks of wood. The work which they intend to be printed is in the first place carefully written upon sheets of thin transparent paper; each of these sheets is glued, with the face downwards, upon a thin tablet of hard wood; and the engraver then, with proper instruments, cuts away the wood in all those parts on which nothing is traced; thus leaving the transcribed characters in *relief*, and ready for printing. In this way, as many tablets are necessary as there are written pages. No press is used; but when the ink is laid on, and the paper carefully placed above it, a brush is passed over with the proper degree of pressure. The Chinese chronicles state that the above mode of printing was discovered in China about fifty years before the Christian era, and the art of paper-making about 145 years afterwards; previous to which period, all their writings were transcribed or printed in volumes of silk cut into leaves of proper dimensions.

It is a somewhat curious circumstance, that amongst the first attempts at printing by means of wood-engraving, which can be traced to have been made in Europe, was the making of playing-cards for the amusement of Charles VI. of France. This was towards the latter end of the fourteenth century. Thereafter came prints from wood-blocks of human figures, single or in groups; the earliest existing specimen of which is in the possession of Earl Spencer, and dated 1423. It is by an unknown artist. These prints were at first without any text, or letterpress, as it is modernly termed; but after the ground-work of the art had been completed, its rise towards perfection was almost unparalleled in rapidity. Its professors composed historical subjects with a text or explanation subjoined. The pages were placed in pairs facing each other; and as only one side of the leaf was impressed, the blank pages came also opposite one another; which, being pasted together, gave the whole the appearance of a book printed in the modern fashion.

The next step in the science of typography was that of forming every letter or character of the alphabet separately, so as to be capable of re-arrangement, and forming in succession the pages of a work, thereby avoiding the interminable labour of cutting new blocks of types for every page. It is exceedingly remarkable, that this most important and yet simple idea should not have occurred to the Romans; and what renders it the more surprising, is the fact, which we learn from Virgil, that brands, with the letters of the owner's name, were in use in his time for the purpose of marking cattle. The credit of the discovery was reserved for a German, John Guttenberg (or Guttemberg), who accomplished this important improvement about the year 1438. As this man was the first great improver of typography, to the study of which he exclusively devoted his whole time and attention, a short sketch of his life will only be a part of the history of the art. Guttenberg, who is supposed to have been born at Mayence, or Mentz, in the beginning of the fifteenth century, settled at Strasburg about the year 1424. In 1435, he entered into partnership with Andrew Drozhennis (or Dritzehen), John Riff, and Andrew Heelmon, citizens of Strasburg, binding himself thereby to disclose certain important secrets connected with the art of printing, by which they would attain opulence. The workshop was in the house of Dritzehen, who, dying shortly after the work was commenced, Guttenberg immediately sent his servant, Lawrence Bieldich, to Nicholas, the brother of the deceased, and requested that no person might be admitted into the workshop, lest the secret should be discovered, and the *forms* (or fastened-together types) stolen. But they had already disappeared; and this fraud, as well as the claims of Nicholas Dritzehen to succeed to his brother's share, produced a lawsuit among the surviving partners. Five witnesses were examined; and from the evidence of Bieldich, Guttenberg's servant, it was incontrovertibly proved that Guttenberg was the first who practised the art of printing with movable types, and that, on the death of Andrew Dritzehen, he had expressly ordered the forms to be broken up, and the characters dispersed, lest any one should discover his secret. The result of this lawsuit, which occurred in 1439, was a dissolution of partnership; and Guttenberg, after having exhausted his means in the effort, proceeded, in 1445-6, to his native city of Mentz, where he resumed his typographic labours. Being ambitious of making his extraordinary invention known, and of value to himself, but being at the same time deficient in the means, he opened his mind to a wealthy goldsmith and worker in precious metals, named John Fust or Faust, and prevailed on him to advance large sums of money in order to make further and more complete trials of the art. Guttenberg being thus associated with Fust, the first regular printing establishment was begun, and the business of printing carried on in a style corresponding to the infancy of the art. After many smaller essays with respect to the capabilities of his press and movable types, Guttenberg had the hardihood to attempt an edition of the Bible, which he succeeded in printing complete, between the years 1450 and 1455. This celebrated Bible, which was the first important specimen of the art of printing, and which, judging from what it has led to, we should certainly esteem as the most extraordinary and praiseworthy of human productions, was executed with cut-metal types, on six hundred and thirty-seven leaves; and, from a copy still in existence in the Royal Library of Berlin, some of them appear to have been printed on vellum. The work was printed in the Latin language.

The execution of this, the first printed Bible—which has justly conferred undying honours on the illustrious Guttenberg, was, most unfortunately, the immediate cause of his ruin. The expenses incident to carrying on a fatiguing and elaborate process of workmanship, for a period of five years, being much more considerable than what were originally contemplated by Fust, he instituted a suit against poor Guttenberg, who, in consequence of the decision against him, was obliged to pay interest, and also a part of the capital that had been advanced. This suit was followed by a dissolution of partnership; and the whole of Guttenberg's apparatus fell into the hands of John Fust, who, from being the ostensible agent in the business of printing, and from the wonder expressed by the vulgar in seeing printed sheets, soon acquired the name of a magician, or one in compact with the devil, and under this character, with the appellation of Dr. Faustus, he has for ages enjoyed an evil notoriety.

Besides the above-mentioned Bible, some other specimens of the work of Guttenberg have been discovered to be in existence. One in particular, which is worthy of notice, was found some years ago among a bundle of old papers in the archives of Mayence. It is an almanac for the year 1457, which served as wrapper for a register of accounts that year. This, says Hansard, would most likely be printed towards the close of 1456, and may consequently be deemed the most ancient specimen of typographic printing extant, with a *certain* date. That Guttenberg was a person of refined taste in the execution of his works, is sufficiently obvious. Adopting a very ancient custom, common in the written copies of the Scriptures and the missals of the church, he used a large ornamental letter at the commencement of books and chapters, finely embellished, and surrounded with a variety of figures as in a frame. The initial letter of the first psalm thus forms a beautiful specimen of the art of printing in its early progress. It is richly ornamented with foliage, flowers, a bird, and a greyhound, and is still more beautiful from being printed in a pale blue colour, while the embellishments are red, and of a transparent appearance. What became of Guttenberg immediately after the unsuccessful termination of his lawsuit with Fust, is not well known. Like the illustrious discoverer of the great Western Continent, he seems to have retired almost broken-hearted from the world, and to have spent most of the remainder of his days in obscurity. It is ascertained, however, that in the year 1465 he received an annual pension from the Elector Adolphus, but that he only enjoyed this small compensation for his extraordinary invention during three years, and died in the month of February, 1468.

It long formed a subject of contention amongst antiquaries and Bibliomaniacs, by what means Guttenberg formed his types, but it is now pretty clearly ascertained that they were at first all individually cut by the hand. The mode of *casting* types in moulds has been very generally, and seemingly correctly, assigned to Guttenberg's successor, Shœffer. This individual was an industrious young man of inventive genius, an apprentice with Faust, who took him into partnership immediately after his rupture with Guttenberg, and who is supposed to have been initiated into the mysteries of the art by the latter. The first joint publication of Faust and Schœffer was a beautiful edition of the Psalms, which came out only about eighteen months after their going into partnership. Along with it appeared a declaration by them, claiming the merit of inventing the cut-metal types with which it was printed; but this pretension was evidently false; and, in fact, it afterwards appeared that the book had been four years in the press, and must, consequently, have been chiefly executed by Guttenberg. It is worthy of notice that the above publication was the very first to which the date, printer's name, and place of publication, were affixed.

To Schœffer, however, as said before, must be awarded the honour of completing Guttenberg's invention, by discovering the method of casting the characters in a *matrix*. In an account of Schœffer, given by Jo. Frid. Faustus of Aschaffenburg, from papers preserved in his family, we are informed that the artist privately prepared matrices for the whole alphabet, and showed the letters cast from them to his master Faust, who was so well pleased that he gave his daughter, Christina, to him in marriage. Faust and Schœffer concealed the new improvement, by administering an oath of secrecy to all whom they intrusted, till the year 1462, when, by the dispersion of their servants into different countries at the sacking of Mentz, by the Archbishop Adolphus, the Invention was publicly divulged, and the art was spread throughout Europe.

EARLY PROGRESS OF PRINTING.

Haerlem and Strasburgh were the first places to which the art of printing was transplanted from Mentz, and this at so early a date, that each of these places has its respective advocates as being the birth-place of it. From Haerlem, it passed into Rome in 1466, where its first professors were Conrad Sweinheim and Arnold Pannartz, who introduced the present Roman type in the following year, in printing Cicero's *Epistolæ Familiares*. The Gothic character, from which our own *black-letter* was derived, was the next which was employed by the ancient printers; after which, in 1476, the first set of Greek characters was cast by the Italians—whether at Venice, Milan, or Florence, is a disputed point. In 1488, however, all previous attempts at the Greek character were eclipsed by a splendid edition of Homer's works, published at the last-named place, in folio, and printed by Demetrius, a native of Crete. The first book in the Hebrew character was an edition of the Pentateuch, printed in 1482; the whole Bible, including the New Testament, not being executed till 1488. This was done at Soncino, a small town in the Duchy of Milan.

In 1467, printing was set up in the city of Tours; at Routhlingen and Venice in 1469; and, it is believed, at the same time in Paris. This city was the tenth town in Europe in which the printing-press was established;

it was set up by Ulrich Gering, a native of the Canton of Lucerne, in the house of the Sorbonne, and in the year 1469. This Gering had been taught the art by Elias Helie von Lauffen, who introduced it into Switzerland, and he commenced the operations of the Lucerne press, by publishing Marchesini's Biblical Lexicon Mamotrectus sive Primicerius, in the year 1470. The first work which issued from Gering's press, at the Sorbonne, was the Epistolæ Gasparini Pergamensis; it was also published in the year 1470. Gering continued his labours until 1508, and died on the 23d of August 1510, bequeathing very considerable property for the benefit of young scholars and the poor of Paris. Strasburg was the next town which had the advantage of a press, and soon afterwards Lyons—the one in 1471, the other in 1473. It was introduced into Russia about the year 1560.

About the year 1496, the letter which we now call *Italic* was invented by Aldus Manutius, a Roman by birth, who set up the business of a printer in Venice. At first, Manutius used his Italic, or Venetian, as he called it, for the printing of entire volumes; but this was not generally approved of by typographers, and after a short period, Italic was employed only for particular words, prefaces, and introductions. Latterly, it has been the practice to use Italic only in very particular cases, as its constant requisition indicates a poor style of literary composition.

PRINTING IN ENGLAND.

The early history of printing in England is obscure. The credit of introducing the art into that country was long believed to be due to Mr. William Caxton, a mercer and citizen of London, who, during his travels abroad, and his residence for many years in Holland, Flanders, and Germany, had thoroughly informed himself of the process, and upon his return, was induced, by the encouragement of many men of wealth and rank, to set up a press in Westminster Abbey, about the year 1471. Such was the tradition amongst writers, and it is still generally believed. Its groundlessness was ascertained about the time of the Restoration, when a little book, which previously had been little thought of, fell under the notice of the curious, as bearing date at Oxford in the year 1468, being three years antecedent to the presumed commencement of Caxton's labours. This book, copies of which are yet extant, is a small quarto of forty-one leaves, entitled "Exposicio Sancti Jeronimi in Symbolum Apostolorum ad Papum Laurentium." At the same time (1664), a work was published by a Mr. Atkins of London, entitled "Original and Growth of Printing in England;" in which an account is given of an ancient chronicle, said to have been found in the archbishop's palace at Lambeth, containing the particulars attending the first introduction of the art. By the latter, it would appear that it took place during the reign of Henry VI., under the auspices of Thomas Bourchiers, Archbishop of Canterbury, who sent R. Tournour, master of the robes, and William Caxton, merchant, to Haerlem, who persuaded an under workman, named Corsellis, to come to England and set up a press at Oxford. The manuscript mentions, that the transaction cost King Henry 1500 merks. But a single press was soon found insufficient for England; upon which the king set up another at St. Alban's, and a third at Westminster; the last being placed under the charge of William Caxton, in the year 1471.

It would be useless for us here to enter into the merits of the question concerning the authenticity of the above-mentioned chronicle, which at one time divided the literary world to a violent degree. We shall only observe, that the result of the disputation appears to be this:—The existence of the book before named establishes beyond a doubt that books were printed at Oxford by Corsellis several years before Caxton set his press to work at Westminster, and therefore that that city has the honour of having been the first seat of the art in England; but Caxton was the first who introduced the printing with *moulded metal types*, the works by his predecessor having been executed merely with wooden ones. It is by our early writers not having attended sufficiently to this line of demarcation between the two stages of the art, that the misunderstanding has, as far as we can judge after much careful investigation, solely arisen.

After the art of printing had been thus introduced into Oxford and Westminster, it spread to St. Alban's, Cambridge, Tavistock, Worcester, Canterbury, Ipswich, &c., in almost all cases by the encouragement of the churchmen of these places, and generally with the view of printing works of piety. About the year 1500, or probably somewhat earlier, Pynson was, by patent of Henry VII., invested with the office of king's printer, which may be regarded as the first instance of an appointment of this nature. At the close of the fifteenth and the commencement of the sixteenth century, London possessed a number of printers, but none whose name has been so celebrated as that of Wynken de Worde, a foreigner, who had been instructed under Caxton. He improved the art considerably, and was the first printer in England who introduced the Roman letter—all previous printing, and much of a later date, being in the black or German letter.

Although at first countenanced by the clergy, the art of printing was soon looked upon with extreme jealousy by the church, which at length discovered that this invention was but too certainly calculated to revolutionize the whole fabric of society. The earliest efforts of the art, as we have seen, were directed to the multiplication of the Bible; but for a period of sixty or seventy years from the date of the invention, all the copies of the Scriptures which were printed were in the Latin or some other classic language, not understood by the people. But now a new era commenced. Certain printers began to issue the Bible in the English tongue, translated from the original, and this gave mighty offence to the church, or Romish hierarchy.

In 1526, Richard Grafton, a gentleman of liberal education, having adopted the profession of printing, issued an edition of the New Testament in the English language, which drew down the wrath of the then Bishop of London. A proclamation was issued by this prelate prohibiting its use. "Understanding (says this document) that many children of iniquitie, maintayners of Luther's sect, blynded through extreame wickedness, wandrying from the way of truth, and the catholic fayth, craftely have translated the New Testament into our English tongue, entermedlying therewith many heretical articles and erroneous opinions, pernicious and offensive, seducying the simple people,' &c. The proclamation goes on to order all copies of the said New Testament to be brought to the bishop's vicar-general, to be burnt, under pain of excommunication, and incurring the suspicion of heresy. It does not appear that the fulminations of the bishop were of much effect. The New Testament having been readily purchased, it led to the publication, in 1535, of the whole Bible in the English language, into which it was translated by Miles Coverdale. But this noble undertaking was accomplished abroad. In 1539, England had the honour of producing an edition of the Bible in the English tongue, under the auspices of Cranmer and Henry VIII., the work being executed by Grafton and Edward Whitechurch.

The progress of the art in England, after its first rush into notoriety, was remarkably slow. In the sixteenth century, it was interrupted by the broils consequent on the Reformation, and in the seventeenth century by the still greater harassments of the civil war, and the gloomy religious spirit which prevailed up till the Restoration. This last event was even unfavourable to it, by introducing a general licentiousness and contempt for any solid and respectable literature. At this period there was an act of parliament still in force, preventing more than twenty printers to practise their art in the kingdom. "At the fire of London in 1666, the booksellers dwelling about St. Paul's lost an immense stock of books in quires, amounting, according to Evelyn, to £200,000, which they were accustomed to stow in the vaults in the metropolitan cathedral, and of other neighbouring churches. At that time the people were beginning to read again, and to think; and as new capital naturally rushed in to replace the consumed stock of books, there was considerable activity once more in printing. The laws regulating the number of printers soon after fell into disuse, as they had long fallen into contempt. We have before us a catalogue (the first compiled in this country) of 'all the books printed in England since the dreadful fire, 1666, to the end of Trinity term, 1680,' which catalogue is continued to 1685, year by year. A great many—we may fairly say one-half—of those books are single sermons and tracts.

"The whole number of books printed during the fourteen years from 1666 to 1680, we ascertain, by counting, was 3550, of which 947 were divinity, 420 law, and 153 physic—so that two-fifths of the whole were professional books; 297 were school-books; and 353 on objects of geography and navigation, including maps. Taking the average of these fourteen years, the total number of works produced yearly was 253; but deducting the reprints, pamphlets, single sermons, and maps, we may fairly assume that the yearly average of new books was much under 100. Of the number of copies constituting an edition, we have no record; we apprehend it must have been small, for the price of a book, as far as we can ascertain it, was considerable.

"Roger North, speaking of those booksellers of his day who had the nack of getting up volumes on temporary matters, says, 'They crack their brains to find out selling subjects, and keep hirelings in garrets, on hard meat, to write and correct by the grate; so puff up an *octavo* to a sufficient thickness, and there is *six shillings* current for an hour and a half's reading.' In a catalogue, with prices, printed twenty-two years after the one we have just noticed, we find that the ordinary cost of an octavo was *five shillings*."*

After the Revolution of 1688, the business of printing rapidly increased, by the demands for sheets of intelligence or news, as well as for a better class of literary productions. In the reign of Queen Anne, printing was increased still further by the issue of the Guardian, Spectator, and other literary sheets; and in 1731, it received considerable impetus by the establishment of the Gentleman's Magazine, being the first of the class of larger periodicals.

Printing was introduced into Scotland, and begun in Edinburgh, during the year 1507, only thirty years after Caxton had brought it into England. Since that period it has continued to be pursued with success in the Scottish metropolis, and, within the last thirty years, has there become the most distinguished craft in the city. Printing was not known in Ireland till about the year 155., when a book in black-letter was issued from a press in Dublin; but till the year 1700, very little printing was executed in Ireland, and even since that period, the country has acquired no celebrity whatever in this department of the arts, although possessing some respectable printing establishments.

PROGRESS ON THE CONTINENT AND IN AMERICA.

The progress of printing on the Continent of Europe has been remarkably slow. Unless in the free states of Germany, where the art is pursued to an incalculable extent, the profession of the printer is almost everywhere under the severest restrictions, and little can be published without coming first under the scrutiny of censors appointed by the governments. The art is carried on in Paris perhaps with a greater degree of freedom than usual in other continental capitals, and from the presses in that city some exceedingly elegant works have been issued. But at Paris, as everywhere else, there is a general inferiority in the mechanism of the printing-office, when compared with that now in use in England and Scotland, except in those cases in which the presses employed have been imported from Great Britain.

While the art of printing has been by slow degrees creeping through the despotically governed states of Europe, and establishing itself at isolated spots in Oriental countries, everywhere creating distrust, and nowhere allowed to be exercised with perfect freedom, it has readily taken root and flourished among the civilized inhabitants of North America. The first printing-press established in the American colonies was one set up at Cambridge, in Massachusetts, in the year 1638, the era of the foundation of Harvard College of that place. It was only established by the exertions and joint contributions of different individuals in Europe and America; and there is no doubt that the mechanism and types were imported from England. The first work which issued from this press was the Freeman's Call, and the second the Almanack for New England, both in 1639; the first book printed was the New England version of the Psalms, an octavo volume of 300 pages. In 1676, books began to be printed at Boston; in 1686, printing became known in Philadelphia; and, in 1693, in New York. In the year 1700, there were only four printing-presses in the colonies. Since that period, and especially since the revolution, which removed every thing like a censorship of the press, the number of printing-presses has greatly increased. The mechanism of the press has likewise been much improved in that country; and the Americans have copied the patent steam-press of Cowper of London, and now possess machines of this description. In 1800, the number of presses had increased to 300; in 1830, they amounted to 1200; and we learn that they are still increasing in number and extending their influence. A few years ago, the Cherokees, one of the tribes of native Indians, set up a press, and commenced a newspaper—a circumstance which may be regarded as an extraordinary proof of the growth of knowledge in America.

We shall now proceed to a description of the art in its various branches, though without entering into the more minute, and what would be tiresome, details of the profession.

OF THE TYPES.

Printers in early times made the letters which they used, but, in process of time, the necessity for a division of labour created the distinct trade of a manufacturer of types, and it is only in rare instances in the present day that printers supply their own letter. The preparation of types requires much delicacy and skill. The first step in the process is the cutting of a punch or die, resembling the required letter. The punch is of hardened steel, with the figure of the letter cut, the reverse way, upon its point. On this die being finished, it is struck into a piece of copper, about an inch and a quarter long, one-eighth of an inch deep, and of a width proportionate to the size of the type to be cast. This copper, being so impressed with the representation of the letter, is called the matrix. The matrix is now fixed into a small instrument or frame, called the mould, which is composed of two parts. The external surface is of wood, the internal of steel. At the top is a shelving orifice, into which the metal is poured. The space within is of the size of the required body of the letter, and

* Penny Magazine.

is made exceedingly true. The melted metal, being poured into this space, sinks down to the bottom into the matrix, and instantly cooling, the mould is made to open with the instantaneous movement of a spring, and the type is cast out by the workman. This process of casting types is executed with great celerity. Of course, every separate letter in the alphabet, every figure, point, or mark, must have its own punch and matrix. In casting types, the founder stands at a table, and has beside him a small furnace and pot of heated metal, which he lifts with a small ladle. Type metal is a compound of lead and regulus of antimony, the latter giving hardness to the composition. The proper proportions of these metals is regulated by the size of the type, a greater quantity of antimony being employed for small than large letters.

When the type is cast from the mould, it is in a rough state, and as soon as a heap has accumulated on the caster's table, they are removed by a boy, who breaks off the superfluous tag of metal hanging at the end of each type. From the breaking-off boy the types are removed to another place, where a boy is constantly engaged in rubbing or smoothing their edges upon a stone. Being now tolerably well cleaned, they are next removed to a table, and set up in long lines upon a frame, where they are polished and made ready for use. Whatever be the size of the types, they are all made of a uniform height, and must be perfectly true in their angles, otherwise it would be quite impossible to lock them together. A single irregular type would most likely derange a whole page. The height of a type is, or ought to be, exactly one inch; but founders, much to their discredit, do not act with uniformity in this particular, the letters of some founders being higher than those of others. But all the types of one class of any founder are always uniform in size and height; and to preserve their individuality, all the letters, points, &c. belonging to one class, are distinguished by one or more notches or nicks on the body of the type, which notches range evenly when the types are set. These nicks, as we shall immediately see, are also exceedingly useful in guiding the compositor. Types are likewise all equally grooved in the bottom to make them stand steadily.

The varieties of size of types in the present day amount to forty or fifty, enlarging by a progressive scale from the minutest used in printing pocket Bibles, to the largest which is seen in posting-bills on the streets. Printers have distinct names for each size of letter, and use about twelve sizes in different descriptions of book-work; the smallest is called *Diamond*, and then follow, in gradation upwards, *Pearl*, *Ruby*, *Nonpareil*, *Minion*, *Brevier* (the type with which this sheet is printed), *Bourgeois*, *Long Primer*, *Small Pica*, *Pica*, and *English*. The larger sizes generally take their names thus—*Two-line Pica*, *Two-line English*, *Four*, *Six*, *Eight*, or *Ten-line Pica*, &c. Other nations have adopted different designations for their letters, principally from the names of their inventors; for instance, the French entitle Small Pica, *Philosophie*, from the first maker of the letter. Some of these classes of letters have derived their names from having been first employed in the printing of the prayers in the Romish church. Thus, *Pica*, from the service of the mass, termed *Pica*, or *Pie*, from the glaring contrast between the black and white on the page—*Primer*, from *Primarius*, the book of prayers to the Virgin—*Brevier*, from *Breviary*—*Canon*, from the *canons* of the church, &c.

All kinds of type are sold by weight by the founders, the price varying in amount according to the size of the letter. The smallest size, *Diamond*, costs about 12s. per pound; *Brevier*, about 3s. 6d.; *English*, about 2s.; and so in proportion for all intermediate sizes. Expensive as types thus are, their prices will not appear too high considering the immense outlay in cutting the punches and the general manufacture. In the *Diamond* size, 2800 go to a single pound weight of the letter *i*, and of the thinnest *space* about 5000.

A complete assortment of types is called a *Fount*, which may be regulated to any extent. Every type-founder has a scale showing the proportional quantity of each letter required for a fount; and a peculiar scale is required for every language. For the English language, the following is a type-founder's scale for the small letters of a fount of types of a particular size and weight:—

a	8500	h	6400	o	8000	v	1200
b	1600	i	8000	p	1700	w	2000
c	3000	j	400	q	500	x	400
d	4400	k	800	r	6200	y	2000
e	12000	l	4000	s	8000	z	200
f	2500	m	3000	t	9000		
g	1700	n	8000	u	3400		

It will be seen from this scale that the letter *e* is used much more frequently than any other character.

Types are nowhere manufactured so well as in Great Britain, and for their elegance and regularity of form, they have been much indebted to the late William Caslon, letter-founder, in London. Mr. Caslon was originally an engraver of ornamental devices on the barrels of fire-arms, and a maker of bookbinders' tools. The neatness with which he executed his work brought him into notice, and he was appointed to cut a fount of Arabic letters for an edition of the New Testament. This occurred about the year 1720, and from this period he entered on a successful career as a letter-founder. Hitherto the types used in England had been mostly imported from Holland; but Caslon's letters, by their decided superiority over those of all competitors at home and abroad, soon put a stop to the importation of foreign types, and were held in such estimation, as to be frequently sent to continental countries. From 1720 till 1780, few books were printed in England with the types of any other than this foundery, which still continues in existence in London.

The ingenuity and success of Caslon meet with a parallel in the case of the late Mr. Alexander Wilson, type-founder, in Glasgow. This person, by a strong effort of perseverance under difficulties, began to cut punches for types at his native town, St. Andrews, about the year 1740, and there opened a letter-foundery—the first established in Scotland—in company with an equally enterprising individual named Bain. In 1744, Messrs. Wilson and Bain removed with their foundery to the neighbourhood of Glasgow, where it long flourished. The types produced by Mr. Wilson were exceedingly neat, and even elegant, and became the real foundation of the fame of the Messrs. Foulis, printers, whose editions of the Classics were printed from them. Branches of the Glasgow letter-foundery were afterwards established in the English and Scottish capitals. In Edinburgh, besides the foundery of the Messrs. Wilson, grandsons of the first of the name, the principal establishment of the kind is that of Messrs. Miller and Company, whose types we consider as standing in the first class in respect of neatness, beauty, and regularity. They are largely employed in the printing of Bibles, newspapers, and other works in which a small type is required.

The large letters used in posting and hand-bills are manufactured chiefly at Sheffield. In this kind of types very great improvements have also been made in recent times; and the varieties are becoming yearly more numerous and varied in character. The letter used in printing in North America is made principally at New York and Philadelphia; and the style of both typography and presswork in that country is rapidly improving, and now competing with the products of the English press. The type used in this edition of CHAMBERS'S INFORMATION FOR THE PEOPLE, was cast in the foundry of L. Johnson & Co., Philadelphia.

COMPOSING.

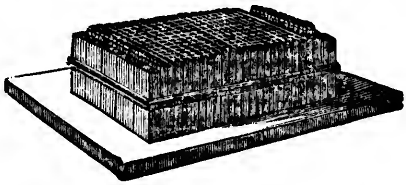
All the types in use in the printing-office are sorted in *cases*, or shallow boxes, with divisions. There are two kinds of cases—the *upper* and *lower case*; the latter lying nearest the compositor upon the frame for their support. In the upper case are placed all the capitals, small capitals, accented letters, figures, and characters used as references to notes. In the lower case lie all the small letters, points, and spaces to place between the words. In the lower, no alphabetical arrangement is preserved; each letter has a larger or smaller box allotted to it, according as it is more or less frequently required; and all those letters most in request are placed at the nearest convenient distance to the compositor. By this ingenious and irregular division of the lower case, much time is saved to the compositor, who requires no label to direct him to the spot where lies the particular letter he wants. To a stranger in a printing-office, nothing appears so remarkable as the rapidity with which the compositor does his work; but habit very soon leads the hand rapidly and mechanically to the letter required. When Italic letters have to be introduced, they are taken from a separate pair of cases of the same fount.

The process of composing and forming types into pages may now be adverted to. Placing the copy or manuscript before him on the upper case, and standing in front of the lower case, the compositor holds in his left hand what is termed a composing-stick. Sometimes this instrument is of wood, with a certain space cut in it of a particular width; but more commonly it is made of iron or brass, with a movable side, which, by means of a screw, may be regulated to any width of line. In either case the composing-stick is made perfectly true and square. One by one the compositor lifts and puts the letters of each word and sentence, and appropriate points, into his stick, securing each with the thumb of his left hand, and placing them side by side from left to right along the line. When he places a letter in the stick, he does not require to look whether he is placing it with the face in its proper position. His object is accomplished by looking at what is called the *nick*, which

must be placed outwards in his composing-stick. (See adjoining representation of a type.) This is one of those beautiful contrivances for saving labour which experience has introduced into every art, and which are as valuable for diminishing the cost of production as the more elaborate inventions of machinery. When he arrives at the end of his line, the compositor has a task to perform in which the carefulness of the workman is greatly exhibited. The first letter and the last must be at the extremities of the line: there must be no spaces left in some instances, and no crowding in others, as we see in the best manuscript. Each metal type is of a constant thickness, as far as regards that particular size of letter; though all the letters are not of the same thickness. The adjustments, therefore, to complete the line with a word, or at any rate with a syllable, must be made by varying the thickness of the spaces between each word. A good compositor is distinguished by uniformity of spacing: he will not allow the words to be very close together in some instances, and with a large gap between them in others. His duty is to equalize the spacing as much as he possibly can; and this is in some cases very troublesome. In composing poetry, or similar matter, where there is always a blank space at one of the ends of the line, spacing is very easily accomplished by filling up the blank with larger spaces, or *quadrats*. But whether prose or poetry, the matter of each line must be equally adjusted and *justified*, so as to correspond in point of compactness with the previously set lines. The process of composing is greatly facilitated by the compositor using a thin slip of brass, called a *setting-rule*, which he places in the composing-stick when he begins, and which, on a line being completed, he pulls out and places upon the front of the line so completed, in order that the types he sets may not come in contact with the types behind them, but glide smoothly into their places to the bottom of the composing-stick.

When the workman has set up as many lines as his composing-stick will conveniently hold, he lifts them out by grasping them with the fingers of each hand, and thus taking them up as if they were a solid piece of metal. He then places the mass in an elongated board, termed a *galley*, which has a ledge on one or perhaps both sides. The facility with which some compositors can lift what is called a *handful* of movable type without deranging a single letter, is very remarkable. This sort of skill can only be attained by practice; and one of the severest mortifications which the printer's apprentice has to endure, is to toil for an hour in picking up about a thousand letters, and then see the fabric destroyed by his own unskilfulness, leaving him to mourn over his heap of broken type, technically called *pie*.

Letter by letter, and word by word, is the composing-stick filled; and by the same progression the galley is filled by the contents of successive sticks. When the compositor has set up as many lines as will fill a page, he binds them tightly round with cord, and removes them from the galley. The annexed cut is a representation of a small page of types tied up, and placed on a board.



Sometimes, as in the case of newspaper and similar work, the *handfuls* of type are accumulated till they fill the galley, and are then removed in long columns. After the matter is thus so far prepared, it is the duty of the pressman to take an impression or *first proof* from the types, in order that the compositor may correct the errors which are sure to have been made. Proofs are usually taken by means of an old large press kept for the purpose. After the galley matter is corrected, and re-corrected by the compositor, it is divided into pages of the size wanted; and head-lines, or figures indicating the number of the page, being added, the pages are arranged upon a large firm table, and there securely fixed up in an iron frame or *chase*, by means of slips of wood and wedges, or *quoins*.

This process, which is called *imposing*, being completed, and the face of the types being levelled by a *plainer* and mallet, the *form*, as it is called, is proved and prepared for press. Proof-sheets being taken, they are subjected to the scrutiny both of a *reader* employed in this peculiar function in the office, and of the author. These having made their marks pointing out words and letters to be altered or corrected, the compositor once more goes over the form, correcting the errors by lifting out the letters with a bodkin, and when revised, the sheet is pronounced ready for working. It may be explained that the imposing table at which all these corrections are made, is usually composed of smooth stone or marble on the top, and requires to be a substantial fabric.

It need scarcely be told that the size of books greatly varies; but the sizes are all reducible to a standard determined by the number of leaves into which a sheet of paper is folded. The most common size is octavo, each sheet of which contains eight leaves, or sixteen pages; the next is *duodecimo*, containing twelve leaves, or twenty-four pages in the sheet; and the next *octodecimo*, or eighteens, containing thirty-six pages in a sheet. There are many other sizes, such as the larger *quarto*, the smaller *twenty-fours*, &c. To know how to place pages of types in a form so as to produce, when printed, a regular series upon paper, is one of the branches of the art to be acquired by the young compositor.

PROGRESSIVE IMPROVEMENTS IN TYPOGRAPHY.

The following particulars relative to the early productions of the press, will show how the style of book-printing was gradually improved:—"With respect to their forms, they were generally either large or small folios, or at least quartos; the lesser sizes were not in use. The leaves were without running title, direction word, number of pages, or divisions into paragraphs. The character itself was a rude old Gothic mixed with Secretary, designed on purpose to imitate the handwriting of those times; the words were printed so close to one another, that it was difficult and tedious to be read, even by those who were used to manuscripts, and to this method, and often led the inattentive reader into mistakes. Their orthography was various, and often arbitrary, disregarding method. They had very frequent abbreviations, which in time grew so numerous and difficult to be understood, that there was a necessity of writing a book to teach the manner of reading them. Their periods were distinguished by no other points than the double or single one—that is the colon and full point; but they a little after introduced an oblique stroke, thus /, which answered the purpose of our comma. They used no capital letter to begin a sentence, or for proper names of men or places. They left blanks for the places of titles, initial letters, and other ornaments, in order to have them supplied by the illuminators, whose ingenious art, though in vogue before, and at that time, did not long survive the masterly improvements made by the printers in this branch of their art. Those ornaments were exquisitely fine, and curiously variegated with the most beautiful colours, and even with gold and silver; the margins, likewise, were frequently charged with a variety of figures of saints, birds, beasts, monsters, flowers, &c., which had sometimes relation to the contents of the page, though often none at all. These embellishments were very costly; but for those that could not afford a great price, there were more inferior ornaments, which could be done at a much easier rate. The name of the printer, place of his residence, &c. &c., were either wholly neglected, or put at the end of the book, not without some pious ejaculation or doxology. The date was likewise omitted, or involved in some crampt circumstantial period, or else printed either at full length, or by numerical letters, and sometimes partly one and partly the other—thus, one thousand CCCC and lxxiiii, &c.; but all of them at the end of the book. There was no variety of characters, no intermixture of Roman and Italic; they are of later invention: but their pages were continued in a Gothic letter of the same size throughout. They printed but few copies at once, for 200 or 300 were then esteemed a large impression; though, upon the encouragement received from the learned, they increased their numbers in proportion."

About 1469-70, alphabetical tables of the first words of each chapter were introduced, as a guide to the binder. Catch-words (now generally abolished) were first used at Venice, by Vindeline de Spire. Early printed books had no signatures. Signatures are those letters of the alphabet which are put at the bottom of the right hand pages of sheets to distinguish their order. When the alphabet is finished, a second begins A a, or 2 A, instead of a single A; and when that is terminated, A a a, or * A, begin the third, and so on. In order to indicate more correctly the order of each sheet, printers add figures to the initial letter on the third, fifth, and seventh pages: the numbers of these figures, which do not pass the middle of the sheet, point out the size of the edition. Thus A 2 on the third page, A 3 on the fifth, and A 4 on the seventh, show a work to be in 8vo; in the 12mo size, A 5 on the ninth page, and A 6 on the eleventh page, &c.; but it is now customary to give signatures only on the first and third pages of 8vo, and on the first, third, and fifth pages of 12mo.

In some modern French works, figures are substituted for letters, and the other leaves are marked by asterisks. The invention of signatures is ascribed by M. Marolles to John of Cologne, who printed at Venice in 1474; the Abbe Rive attributes it to John Koelhof, a printer at Cologne, and a contemporary with the former, from whom we have a work dated in 1472. It is, however, of little consequence who was the originator, for, on the whole, signatures are rather a clumsy expedient merely to direct the binder in folding the sheet, and are generally much too conspicuous upon the pages.

One of the chief improvements in the style of typography has been the dismissal of abbreviations and connected letters from the founts. Formerly, abbreviations were very common: the word *the* was indicated by the letter *y* and a small *e* above it; the conjunction *and* was indicated by &, which is a contraction of *et*. There were many of this species of abbreviations in printing both the English and Latin languages, and these were not more unseemly than the connected letters; such, for instance, as the junction of the letters *c* and *t* by a curve stroke from the top of one to the other. In recent times all these connected letters have been disused, with the exception of *ffl* and *fl*, because the head of the common *f* would press against the *l*, and be broken. Another very great improvement has been effected in the dismissal of the long *s*, in the case of two of this letter coming together.

STEREOTYPING.

We may now offer a brief explanation of the process of stereotyping, which has been of immense service to literature. Stereotyping is the manufacturing of fictitious pages of types, and the invention is generally attributed to a Mr. William Ged, of Edinburgh, about the year 1725. When the art was properly made known, it was hailed with acclamation by the printing and publishing world; but as experience developed its powers, it was found to be strictly applicable only to a particular kind of work.

When a page is intended to be stereotyped, the same process of putting up the types is gone through that we have already described; instead, however, of being carried to the press, the page is plastered over with liquid stucco to the thickness of about half an inch, so that a level cake is formed on the surface of the types. As soon as the stucco hardens, which it does almost immediately, the cake is separated from the types, and on being turned up, shows a complete hollow or mould-like representation of the faces of the types, and every thing else in the page. There being no longer any use for the types, they are carried of and distributed. As for the cake, it is put into an oven, and baked to a certain degree of heat and hardness, like a piece of pottery. It is next laid in a square iron pan, having a lid of the same metal, with holes at the corners. At the bottom of the pan there is a movable plate, called the floating plate; and upon this plate, which has a smooth accurate surface, the mould is placed with its face downwards. The lid being now placed and held tightly on by a screw, the pan, by the assistance of a crane and other mechanism, is immersed in a pot of molten lead, and being allowed to fill by means of the holes, it is at length taken out and put aside to cool. On opening the pan a curious appearance is presented. The lead has run into the mould side of the cake, and formed a thin plate all over, exhibiting the perfect appearance of the faces of the types on which the stucco was plastered. Thus is procured a plate or fictitious page of types, not thicker than the sixth of an inch. When the plate comes out of the pan, it is in a somewhat rude state, and has to be carefully pruned at the edges, its little specks picked clean, and, if necessary, one or more bad letters cut out, and replaced by soldering in the heads of movable types. The plate is also planed upon the back by means of an ingenious rotatory cutting machine upon which it is fixed.

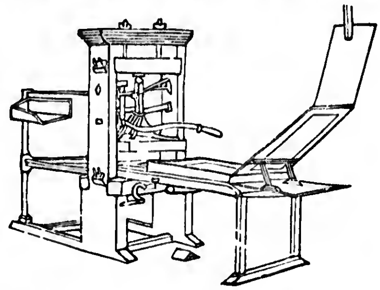
The stereotype plates, so prepared, are next taken to the printing-office, and made ready for press. This is done by placing them upon iron or wooden blocks, so that both plate and block make up the exact height of a page of real types. They are fixed to the blocks by the aid of small metal catches at the sides, head, and foot, which catches are held fast by slips of *furniture* properly wedged. Notwithstanding the great care taken in making the plates level and of a uniform thickness, it is seldom that they are perfect; and to make them as accurate as possible for a fair impression, scraps of thin pasteboard or paper are placed between them and the blocks at the thinnest parts. When the impression is completed, the plates are unfixed, packed up, and laid aside for future use. Now for the specific utility of stereotyping.

In all cases of common book-work, it is best to print from types to the amount of the copies required, and then distribute the types; but in most cases of books published in parts, sheets, or numbers, stereotyping becomes absolutely necessary. It is easy to perceive the reason for this. When books are published in numbers, it often happens that many more copies are sold of one number than of another, and unless the types be kept up to complete sets in the hands of the publishers, or to print copies according to the increased demand, a serious loss is sustained. The manufacture of stereotype plates, is, therefore, simply a means of keeping up fictitious types to answer future demands, at an expense greatly inferior to that of keeping the actual pages standing, or of putting the types up anew.

In the case of Chambers's Edinburgh Journal, a new feature of utility was for the first time developed in the stereotyping art. It was desired to have a separate impression of that work in London, and stereotyping furnished the means. The types being first set up and imposed, are sent to the foundery, where *two sets* of stereotype plates are cast from them, one to be retained for use in Edinburgh, and the other to be sent to London, and there subjected to a separate press. The expense of setting up the types anew in London, and the danger of errors being incurred from the want of editorial supervision, are thus avoided. Had not the stereotyping process been available, the arrangement for a separate impression of the Journal might not have been entered upon, and the progress of the work in circulation consequently obstructed to an indefinite extent. Advantage was afterwards taken of the art to the same purpose by the proprietors of other cheap periodicals, particularly the Penny Magazine, of the cuts of which we believe upwards of a dozen sets of stereotype copies are sent to be printed in different parts of the world.

PROCESS OF PRINTING.

The duties of the compositor do not involve the process of printing. When the forms are duly prepared in the composing-room, they are carried into the press-room, where they come under the charge of the pressmen. The earliest printing-presses were exceedingly rude, and seem to have resembled the common screw press, with a contrivance for running the form under the point of pressure. This must have been not only a laborious and slow operation, but one exceedingly defective, from the difficulty of regulating the impression, and the risk of injuring the faces of the types. The defects in these original presses were at length remedied by an ingenious Dutch mechanic, William Jansen Blaew,



who carried on the business of a mathematical instrument maker at Amsterdam. He contrived a press, in which the carriage holding the form was wound below the point of pressure, which was given by moving a handle attached to a screw hanging in a beam having a spring, which spring caused the screw to fly back as soon as the impression was given. This species of press, which was almost entirely formed of wood, continued in general use in every country in Europe till the beginning of the present century. With certain lever powers attached to the screw and handle, it is here represented.

In connection with the representation of the old common press, the process of printing may be described. The form, being laid on the sole of the press, is fixed at the sides so as to render it immovable from its position. There are two men employed; one puts ink on the form either by means of stuffed balls or by a composition roller—the other works the press. The latter lifts a blank sheet from a table at his side, and places it on what is called the *tympan*, which is composed of parchment and blanket stuff, fitted in a frame, and tightened like the top of a drum (and hence its name), and which, by means of hinges connecting it with the sole, folds down like a lid over the form. As the sheet, however, would fall off in the act of being brought down, a skeleton-like slender frame, called a *frisket*, is hinged to the upper extremity of the tympan, over which it is brought to hold on the paper. Thus, the frisket being first folded down over the tympan and the tympan next folded down over the form, the impression is ready to be taken. This is done by the left hand of the pressman winding the carriage below the *platten* or pressing surface, and the impression is performed by the right hand pulling the handle attached to the screw mechanism. The carriage is then wound back, the printed sheet lifted off and another put on the tympan, the form again inked, and so on successively. In the above engraving the press appears with the frisket and tympan sloping upwards, ready to receive the sheet, the frisket being sustained from falling backwards by a slip of wood depending from the ceiling. One of the greatest niceties connected with this art, is the printing of the sheet on the second side in such a manner that each page, nay, each line, shall fall exactly on the corresponding page and line on the side first printed. To produce this desirable effect, two iron points are fixed in the middle of the sides of the frame of the tympan, which make two small holes in the sheet during the first pressure. When the sheet is laid on to receive an impression from the second form, these holes are placed on the same points, so as to cause the two impressions to correspond. This is termed producing *register*, and unless good register is effected, the printing has a very indifferent appearance. Expert workmen perform these operations with surprising rapidity, though with considerable labour. Two men employed at press take the process of pulling and inking for alternate quantities. After the forms are wrought off, they are washed in a solution of potash to remove the remains of the ink, which is of a thick oleaginous character, and then carried back to the composing-room to be distributed. This last operation is very speedily performed by the compositors.

To suit paper for printing, it is necessary to wet it some hours previous to its being used. This is done by dipping alternate quires in water, and afterwards pressing the mass with a heavy weight, till the whole is in a half dry or damp state.

After the sheets are printed, they are hung up on poles in the printing-office to be dried. On being dried, they are individually placed between fine glazed boards, and in this condition subjected in a mass to the pressure of a powerful press. On removal, the indentations of the types are found to be levelled, and the whole sheet to be smooth and ready for the operations of the book-binder. Latterly a great improvement has been effected in the smoothing process, by employing the hydraulic or water press, which gives an enormous pressure with little aid from manual labour.

INK AND INKING-ROLLERS.

Much of the beauty of good printing depends on the quality of the ink, which it requires considerable skill to manufacture. The ink used by the earliest printers was of such excellent quality, that in many instances it remains intensely black to this day; but a long period afterwards elapsed, during which very bad ink was employed. Within the present century, great improvements have taken place in the composition of printing ink, which is now produced of a good quality in London by several manufacturers; it is, however, still inferior to the finer kinds of ink used in Paris, the French having evidently surpassed the English in producing a pure and intensely black ink which will preserve its colour. Printing ink is composed of genuine linseed oil, boiled to the consistency of a syrup, and then well-mixed and ground with lamp-black. The qualities desired in the composition are depth and durability of colour, and that it should be stiff without strong adhesion, and keep soft and mellow, but dry quickly after being put upon the paper. It is made of different qualities, from 1s. 6d. to 5s. and upwards per pound weight.

One of the greatest of recent improvements in the art of printing is in the mode of inking the forms. From the days of Guttenburg, this had been done by stuffed cushions, or balls covered with skins, by which no regularity could be preserved, and no speed acquired. Earl Stanhope, when he invented his improvement on the press, attempted the plan of inking by means of rollers, but he could not discover any species of skin suitable for the purpose; all that this nobleman so anxiously desired, was at length accomplished, in consequence of a chance observation of a process in the Staffordshire potteries, where rollers formed of a composition were used. A Mr. Forster, employed at a bookseller's printing-office at Weybridge, was the first who applied it to letter-press printing, by spreading it, in a melted state, upon coarse canvas; the inventors of printing machines soon caught the idea, and, by running the composition as a coat upon wooden cylinders, produced the perfect inking-rollers.

The composition is formed of treacle and glue, which, being heated and melted together, are poured into long iron moulds, in which the central rod has previously been inserted. The process resembles that by which moulded candles are made, the central rod being nearly in the same predicament in the one case as the wick in the other When taken out of the mould the roller is a cylinder of soft and elastic matter, resembling India rubber. If required for the hand-press, it is connected with a handle after the manner of a garden roller. The ink being placed, in moderate quantity, at the back of a smooth metal table, the workman, grasping the handle, draws the roller backwards and forwards along the table, distributing a little ink equably all over its surface; and having thus diffused some ink all over the roller, he applies the same to the types, drawing it backwards and forwards over them, to make sure that all have been inked. By this plan the types are inked more equably than by the balls, and in less than half the time.

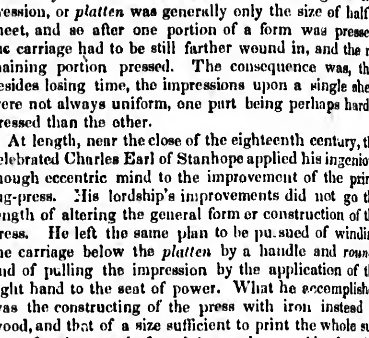
Within these few years, a plan has been devised for moving the rollers over the forms by an apparatus attached to the press. Self-inking presses are now coming into use.

IMPROVED PRINTING PRESSES.

As already mentioned, the original printing-press as slightly improved by Blaew, remained in general use throughout Europe till the beginning of the present century. Its defects were of such a nature, that it seems wonderful that no effort was made, during so long a time, to remedy them. The surface communicating the impression, or *platten* was generally only the size of half a sheet, and so after one portion of a form was pressed, the carriage had to be still farther wound in, and the remaining portion pressed. The consequence was, that besides losing time, the impressions upon a single sheet were not always uniform, one part being perhaps harder pressed than the other.

At length, near the close of the eighteenth century, the celebrated Charles Earl of Stanhope applied his ingenious though eccentric mind to the improvement of the printing-press. His lordship's improvements did not go the length of altering the general form or construction of the press. He left the same plan to be pursued of winding the carriage below the *platten* by a handle and *rounce*, and of pulling the impression by the application of the right hand to the seat of power. What he accomplished was the constructing of the press with iron instead of wood, and that of a size sufficient to print the whole surface of a sheet, and of applying such a combined action of levers to the screw as to make the pull a great deal less laborious to the pressman; the mechanism altogether being such as to permit much more rapid and efficient working.

The *Stanhope press*, which is here represented, consists of a massive frame of iron, cast in one piece. This is the body of the press, in the upper part of which a nut is fixed for the reception of the great screw, and its point

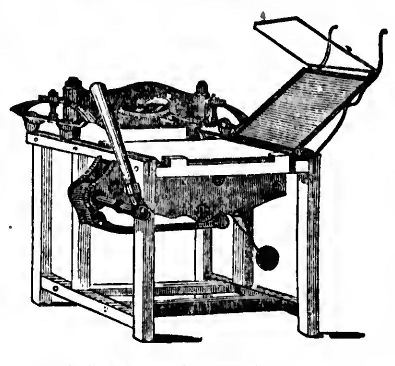


operates upon the upper end of a slider fitted into a dove-tail groove formed between the two vertical bars of the frame. The slider has the platten firmly attached to the lower end of it; and, being accurately fitted between the side guides, the platten must rise and fall parallel to itself when the screw is turned. The weight of the platten and slider is counterbalanced by a heavy weight behind the press, suspended by a lever which acts upon the slider to lift it up, and keep it always bearing against the point of the screw.

There are two projecting pieces cast with the main frame, to support the carriage when the pull is made: to these, rails are screwed, and placed exactly horizontal for the carriage to run upon, when it is carried under the press to receive the impression, or drawn out to remove the printed sheet. The carriage is moved by a rounce or handle, with leather girths, very similar to the wooden press. Upon the axle of this handle a wheel is fixed, round which leather belts are passed, one extending to the back of the carriage to draw it in, and two others which pass round the wheel in an opposite direction to draw it out. By this means, when the handle is turned one way, it draws out the carriage; and by reversing the motion, it is carried in. There is likewise a check strap which limits the motion of the wheel, and, consequently, the action of the carriage. The principal improvement of Earl Stanhope's press consists in the mode of giving motion to the main screw of it, which is not done simply by a lever attached to the screw, but by a second lever. The main screw has a short lever fixed on the upper end of it, and this communicates by an iron bar or link to another lever of rather shorter radius, which is fixed upon the upper end of a second spindle, and to this the handle or lever by which the press is worked is fixed. Now, when the workman pulls this handle, he turns round the spindle, and, by the connection of the rod, the main screw turns with it, and causes the platten to descend with it, and produce the pressure. But it is not simply this alone, for the power of the handle is transmitted to the screw in a ratio proportioned to the effect required at the different parts of the pull; thus, at first, when the pressman takes the handle, it lies in a direction parallel to the frame, or across the press: and the short lever (being nearly perpendicular thereto) is also nearly at right angles to the connecting rod; but the lever of the screw makes a considerable angle with the rod, which therefore acts upon a shorter radius to turn the screw; because the real power exerted by any action upon a lever is not to be considered as acting with the full length of the lever between its centres, but with the distance in a perpendicular, drawn from the line in which the action is applied to the centre of the lever.

The obvious excellence of the Stanhopian improvement in gaining power for the handle, led a number of printers to apply this species of lever power to the screw of the common press, but we believe not with marked success. The improvements of Lord Stanhope were speedily followed by the attempts of other individuals in Great Britain and America, to remedy the ancient defects in printing mechanism. So numerous, indeed, have these attempts been since the beginning of the present century, that it is quite out of our power to mention them in detail. With, we believe, one or two exceptions, all the modern improvers of the printing-press have confined their efforts chiefly to the process of communicating pressure to the platten, so as to modify labour, and procure greater rapidity of working. In these cases the screw has been generally dismissed, and power procured sometimes by the action of two or more inclined planes working against each other, in other instances by fulcrums and levers, and in others by the straightening of a joint. The latter is an exceedingly simple and beautiful form of power, and may easily be comprehended when we say, that it resembles the bending and straightening of the knee-joint: when the knee of the upright bar of the press is bent, the platten is drawn up; and when the knee is forced by a lever into a perpendicular position, the platten sinks, and the pressure is communicated. This may be considered the most efficient mode of compressing the platten yet discovered, and it would be difficult to rival it in the properties of simplicity and rapidity of execution. Nevertheless, such is the number and variety of improved presses in the present day, that it would not be easy to decide upon which has the best claims to the notice of printers. Among those which have gained a large share of approbation, may be mentioned the *Columbian press*, which is of American invention. This new press was brought to this country in 1818, by Mr. George Clymer of Philadelphia, and made the object of a patent. The pressing power in this instance is procured by a long bar or handle acting upon a combination of exceedingly powerful levers above the platten, and by many workmen this press is greatly preferred to any other.

The various improved presses which we have noticed, are, in most cases, made of at least three sizes, namely, *demy*, *royal*, and *super-royal*—that is, they are respectively able to print sheets of these sizes; and they accordingly vary in price from about £50 to £80 each. They are nearly all manufactured by the patentees in London. In the present day, the old wooden press of Blaew is entirely discarded from use in printing, and it is only to be seen occasionally in an obscure corner of the printing-office, reduced to the humble character of a proof-press.



The only instance worth mentioning, in which an improved press was made of quite a new construction, was in the case of the ingenious invention of Mr. John Ruthven of Edinburgh. This mechanician contrived a press in which the types stand upon a fixed frame or table, while the pressing part or platten is brought over the form by being hurled forward on wheels. On being brought over the form, a depending hook or notch at each end of the platten is caught and pulled down by the combined action of levers beneath the table, and operated upon by the left hand of the pressman. This was an exceedingly meritorious invention, and many presses on this plan were manufactured and sold, but experience has evinced that the contrivance is only valuable when applied to small presses, not larger than foolscap size, and chiefly useful for executing jobs. Mr. Ruthven makes his presses as small as quarto size; and as they stand on a table, and can be easily wrought by any gentleman, no better press could be recommended to the notice of the amateur printer. The above cut presents a correct representation of Mr. Ruthven's press, which it will be perceived is of an exceedingly compact and portable form.

THE CHAPEL.

It is worth while to remark, that till the present day the phraseology used in relation to the mechanical details of the printer, possesses certain traces of the early connection of the art with men of learning. A number of the technical terms, as may be seen from the description we have given, are a corruption of Latin words. We may instance *tympan*, from tympanum, a drum, and *stet*, (let it stand), which is used as a mark in correcting proof-sheets. The name *brevier*, applied to a certain size of type, originated, as has been already mentioned, in that letter being first used in printing the Breviaries of the Romish church. An exceedingly old practice prevails among printers of calling their office a *Chapel*, and under this title the compositors, pressmen, and all others engaged in the office, have been in the habit of meeting together, and forming a species of lodge, in order to settle affairs connected with the internal arrangements of the office, or any disputes which may occur among members. The general improvement in every thing connected with printing establishments, and the advance of manners, have greatly modified the spirit which used to prevail in those confederacies; nevertheless, the appellation of *the chapel* remains, and is of traditionary interest. It has been supposed by many writers that the title of Chapel originated in Caxton's exercising the profession of a printer in one of the chapels in Westminster Abbey; and it is exceedingly probable that it has an origin of this nature, for printing was at first carried on in many places in England in connection with religious houses. Hence, in M'Creery's poem, entitled "The Press," the author has the following lines:

> "Our art was hail'd from kingdoms far abroad,
> And cherish'd in the hallow'd house of God;
> From which we learn the homage it received,
> And how our sires its heavenly birth believed.
> Each printer hence, howe'er unblest his walls,
> E'en to this day his house a CHAPEL calls."

LAWS AFFECTING PRINTERS.

The proprietors and printers of newspapers are subject to various laws, enforcing the mode of publication, the use of stamps, and payment of advertisement duties; but printers of books, or any common species of work, are practically left at liberty to carry on their business in any manner or way that seems suitable to themselves. Each printer, however, by the act 2 V., c. 12, is required to print upon the front of any sheet, if printed on one side only, or upon the first or last leaf of every book consisting of more than one leaf, his name, place of abode, and business; penalty for omission £5, and the like penalty for dispersing any such publication without the imprint. But no actions for penalties can be instituted except in the name of the Attorney or Solicitor General for England, or the Queen's Advocate in Scotland. The queen enjoys the prerogative of printing the authorized versions of the Bible, Book of Common Prayer, Acts of Parliament and other state papers.

PRINTING BY MACHINES.

After all the ingenuity of Lord Stanhope and that of his successors had been lavished on the press, still the process of printing could not be executed but with considerable fatigue, and at a rate of speed seldom greater than that of throwing off 250 impressions, or 125 complete sheets, in an hour. It must appear evident that this was a state of things quite incompatible with the advancement of knowledge and the necessity for producing a large quantity of impressions in a short space of time, particularly as regarded newspapers. It became apparent that an entire revolution was required in the structure of the press; that the flat printing surface should be discarded, and cylinders brought into use. We have now to describe how this great new invention, applied to printing-machines, came to be adopted.

In 1790, Mr. Nicholson, the editor of the Philosophical Journal, procured a patent for certain improvements in printing, which patent imbodies almost every principle since so successfully applied to printing-machines; and although he did not carry his views into practical effect, little has been left for subsequent engineers to do, but to apply, in the most judicious manner, the principles he laid down in his patent. He may therefore be justly considered as the originator of the great modern improvements in printing machinery; for with him originated the idea of taking the impressions from types by means of cylinders, and of inking the forms with rollers instead of balls, which constitute the two essential parts of all effective modern printing-machines.

Whether Mr. Nicholson's ideas were known to Mr. König, a German, is now uncertain; but to him is due the distinguished merit of carrying steam printing first into effect. Mr. König, conceiving it possible to apply steam-power to produce accelerated speed with the common press, after various unavailing efforts to obtain assistance from the printers on the Continent, came to England. Arriving in London about 1804, he submitted his scheme to several printers there with no better success, until introduced to Mr. Bensley, senior, who, attracted by Mr. König's plans, entered into arrangements with him. After persevering for some time in various attempts to accelerate the speed of the common press, and at the same time render the attendance of the man who inks the types unnecessary, his exertions resulted, to use his own words, "in discovering that they were only employing a horse to do what had been before done by a man." He in consequence gave up all idea of his projected improvements of the common press, and turned his attention to CYLINDRICAL PRINTING.

After continued experiments for some years, a small machine was made, in which the two leading features of Nicholson's invention were embraced (the cylinders and the inking-rollers), which he exhibited to Mr. Walter, proprietor of the Times newspaper; and on shewing what further improvements were contemplated, an agreement was entered into for the erection of two machines for printing that journal. Accordingly, on the 28th November, 1814, the public were apprized that the number of the Times of that date was the first ever printed by machinery, steam-propelled. At this period but few persons knew of any attempts going on for the attainment of this object; whilst, among those connected with printing, it had often been talked of, but treated as chimerical.

After the utility of cylindrical printing had been thus proved, it was thought highly desirable that the principle should be applied to printing fine book-work, where accurate register is indispensable. This was, to a certain extent, attained, by using two large cylinders, the sheet of paper being conveyed from the bottom of the first cylinder (where it had received the first impression) by means of tapes, leading in a diagonal direction to the top of the second cylinder, round which the sheet was carried till the second side was printed. The first machine of this description was erected at Mr. Bensley's office, where it continued at work for some years, till more modern machines superseded it.

So sanguine were the patentees (Mr. König, Mr. Bensley, and Mr. R. Taylor) that no further improvement could be effected, that in March, 1817, they issued a prospectus, offering three kinds of machines at high prices, and requiring a considerable annual premium; but we believe these offers were not embraced.

In the course of 1818, Mr. Napier, and Messrs. Applegath and Cowper, took out patents for improvements in cylindrical printing machinery. Mr. Napier's invention consisted chiefly in using grippers instead of tapes, as in König's, for seizing hold of and leading the sheet of paper round the cylinders. Ingeniously as this machine was constructed, the principles upon which it worked caused it to give way in general estimation to those of Applegath and Cowper. These mechanicians' patent which expired in 1832, referred principally to the application of two drums placed betwixt the cylinders to ensure accuracy in the register, over and under which the sheet was conveyed in its progress from one cylinder to the other, instead of being carried, as in König's machine, in a straight line from the one cylinder to the other; and the mode of distributing the ink upon tables instead of rollers—two principles which have secured to machines of this construction a decided preference for fine work. Machines of this construction were made by Applegath and Cowper for the principal printing establishments in London, Paris, Edinburgh, and many other cities; and it is nearly upon the model of their machines that other manufacturers now construct their steam-presses for the execution of book-work.

Printing-machines are now made of various kinds, adapted to the peculiar descriptions of work for which they are required. These descriptions of work may be classed under two distinct heads, namely, the printing of newspapers, one side at a time, and the printing of a better kind of sheets, or book-work, both sides at a time. There can be nothing more easy than to make a machine capable of first printing one side of a sheet of paper, and afterwards the second, by the removal of one form and the introduction of another; but this process will not produce *register:* the second side may or may not be on the back of the first, and the work is therefore of a very inferior appearance, though suitable enough for newspapers, in the working of which despatch is chiefly required. This kind of press is therefore the best adapted to gain that end; for the first side of the paper may be printed deliberately, and the second side be made up to the last moment of time, and then thrown off. To produce a machine to print both sides at a time, and with perfect register, no small degree of mathematical accuracy, and no small share of ingenuity in the mechanician, are required. The great and important object to be attained in this kind of machine, is to cause the sheet, after it has received its first impression, to travel along the sides of the cylinders and drums at such a rate as to meet the types of the second side at the exact point which will cause the second side to fall with perfect accuracy upon the back of the first. To accomplish this exceedingly desirable end, the cylinders and drums must revolve at precisely the same speed as the carriage underneath; and therefore any inaccuracy in the turning of the axles, the cutting of the teeth of the wheels, or any other deficiency, however slight, will produce ill-registered sheets, and create an enormous degree of vexation to the printer. With these explanatory remarks, we pass on to a notice of four different machines, calculated to produce register and non-register sheets, under various modifications and rates of speed.

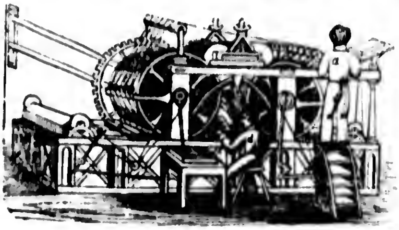
1. A machine with one cylinder, called a single machine, generally used for printing newspapers; it throws off from 900 to 1200 an hour on one side, requiring two boys, one to lay on the paper, and another to receive it when printed.

2. A machine with two cylinders, called a double machine, but only printing from one form of types at the rate of from 1600 to 2200 an hour, requiring two boys to lay on the sheets, and two to take them off, exclusively used for newspapers. It consists of two small cylinders, about ten inches in diameter, placed about five inches apart, and suspended from a beam at each end. A camb or eccentric causes the beams to vibrate, and with them the cylinders to rise and fall about one half of an inch. The cylinders turn in opposite directions, and as the machine only prints one form at a time, that cylinder only which is turning in the same direction as the types is permitted to rest upon the form, and take the impression, so that a sheet is printed by each cylinder alternately every time the type-carriage goes backwards or forwards. Two boys feed the paper into the machine, at two drums placed about three feet above the carriage, and the sheet is led down to the cylinders by tapes, which also convey it, after being printed, to the end of the machine, where two boys receive the sheets and lay them straight in a heap, ready to be again put through the machine when the second form is placed on the type-carriage to print the other side. There is a distinct and complete apparatus for inking the types at each end, similar in principle to that which is mentioned in the account of the book machine. Many of the largest sized and best newspapers are printed by machines of this construction. They are generally moved by manual labour, two men turning a winch, which operates upon the mechanism and fly-wheel.

3. A machine, similar to that used by the Times, with four printing cylinders, requiring the attendance of eight boys, and throwing off about 4000 impressions an hour. To attempt to describe this machine without diagrams, is difficult, but a general idea may be conveyed of its principle, by its being considered as two double machines placed in contact. There are four printing cylinders, about nine inches in diameter each, placed close together in pairs, but with a space of about seven inches between the centre ones, in which space there are two inking-rollers. Each pair of cylinders are secured to the ends of two strong beams, by means of adjustable connecting rods; to these beams a slight vibrating motion is given, by means of cambs, so as to cause the alternate cylinders to rise and fall about one-fourth of an inch. The type-carriage and inking-tables have a reciprocating motion, and the movements are so adjusted that those two alternate cylinders shall be depressed and press upon the types, whose motion coincides with the carriage, and, of course, the other two alternate cylinders are by the same means raised sufficiently to permit the types to pass free under them, till the carriage changes the direction of its motion, when the position of the cylinders is reversed, and the pair which formerly took the impression from the types are in their turn raised. Thus, every time the form of types moves backwards or forwards, two sheets of paper are printed. The paper is fed into the machine over four drums, placed in pairs over each other, at a considerable height above the machine, by four boys. The sheets are led down from the drums to their respective cylinders by means of broad tapes, and by other tapes they are conducted out to the ends of the machine, where they are received by four other boys, when printed, ready to be again passed through the machine, to receive the impression on the second side.

This ingenious machine has only two inking apparatuses, one situated at each end. There are three pairs of inking-rollers, one pair at each end, close to the two outer cylinders, the remaining pair being placed between the two centre cylinders. The inking-tables are about three feet wide, and the motion of the carriage is sufficiently long to bring each table not only under its respective pair of inking-rollers, but also to enable each table alternately to ink the centre pair. Thus, the form is first inked by one of the outer pairs of rollers; the first cylinder is raised; in passing under the second, an impression is given, and, of course, the ink is taken from the form, but it immediately becomes inked anew by the centre pair of rollers; the third cylinder is raised; the form passes to the fourth cylinder, where another impression is taken; and the motion of the form being continued a little farther, it gets again inked from the outer pair of rollers at the opposite end of the machine from whence it started. In its return, the two cylinders which had just taken the impression are raised; the other two now print in their turn, the inking process going on as before; and two sheets are again thrown off. Machines of this complex description are only used where extraordinary despatch, in the production of a large number of copies, is required. Few, besides that employed by the Times, and other London daily papers, are in use. The only one in Scotland, as far as we know, is that used in Edinburgh, for printing the North British Advertiser of Messrs. Gray, and which was made by Morton and Son, machine-makers, Leith Walk.

4. The fourth kind of machine is called a book or perfecting machine, printing both sides of the sheet in register before it leaves the machine. The machine from which the annexed engraving is taken, is one of this description, and bears a resemblance to that of Applegath and Cowper. It is about fifteen feet long by five



broad, and consists of a very strong cast-iron framework, secured together by two ends and several cross bars. To this frame all parts of the machine are fixed. In external figure, as seen in the cut, it is a large apparatus, of imposing appearance. On approaching it when at work, we perceive two cylinders, as large as hogsheads, revolving on upright supports; two smaller cylinders or drums revolving above them; and beneath, within the framework, a table on which lie the types at both ends, going constantly backward and forward. A belt from a steam-engine, acting upon a shaft in the frame, gives motion to the whole apparatus. It will further be observed that a boy marked *a* in the cut, is standing on the top of some steps feeding in sheets of paper, each of which, on being delivered, is swept round the first cylinder *b* (being held on by tapes), gets its impression below from the types, is carried over and betwixt the drums above, and then brought round on the second cylinder *c*; now it gets its second side printed, and issuing into the space between the cylinders, is seized by the boy *d*, who lays it on a table completely printed. The whole operation is accompanied with a loud noise, from the revolving of the cylinders, the working of the notched wheels, and the driving of the table to and fro by a rack beneath, but without any strain on the mechanism, or risk of injury to the attendants. On minutely examining the parts, we observe that at each end there is an apparatus of rollers taking ink from a ductor or reservoir of that material, and placing it upon a portion of the moving table beneath; here other rollers distribute it, while others take it off and roll it upon the pages of types, ready for each impression.

The two printing cylinders are nearly nine feet in circumference each, and are placed about two feet apart. They are accurately turned, so that the surfaces of the type-carriages and the cylinders may be perfectly parallel. The axis of each cylinder works in brass bearings in the upright framework, where, by means of screws, the degree of pressure with which the cylinders are allowed to rest upon the types may be regulated to any degree of nicety. Over about two feet of the circumference of each cylinder which forms the printing surface, two folds of cloth, called blankets, are stretched by means of rollers placed inside the cylinder. The lower blanket is seldom changed, but the upper one, on the second cylinder (which stands in the stead of what are called slip-sheets in hand-press printing) must be shifted as soon as the ink which it has absorbed from the printing on the first side of the sheet begins to set off, or soil the paper when receiving the second impression. This shifting is speedily effected, by unrolling a sufficient quantity of the cloth off one roller, and winding it up on the other, to present a clean portion to the printing surface.

The cylinders have a continuous rotatory motion towards each other, given by two large toothed wheels, whilst the type-carriages move backwards and forwards under them. The movements are so contrived that the type-carriages shall have gone and returned to the same point during the period that the cylinders have made one entire revolution; consequently, each successive impression is taken from the types by the same part of each cylinder; and thus, in order to bring the impression level, the same facility for patching or overlaying is afforded, as at the hand-press. The two drums placed between the cylinders are for the purpose of causing the sheet of paper to pass smoothly and accurately from one printing cylinder to the other.

To preserve the sheet in its proper place on the cylinders, and carry it forward through the different parts of its journey from the hand of the one boy to that of the other, there is an extensive apparatus of tapes, some of which are observable in the cut. These tapes are half an inch broad, and are formed into series of endless bands, arranged at certain distances apart, so as to fall into the interstices and margins of the forms, and therefore escape being crushed between the types and cylinders. The machine may be stopped at any instant, by turning the handle of a lever, which shifts the belt from the fast to a loose pulley, without stopping the engine.

To produce an impression with a flat surface from a large form, requires a force of about from forty to fifty tons; and even with a cylinder, where a line only is impressed at a time, the pressure is little short of a ton. But, in the machine, to prevent any undue pressure of the cylinders upon the forms, there are wooden bearers, of the same height as the types, screwed upon the sides of the carriages under the ends of the cylinders; thus effectually shielding the types from the enormous and injurious pressure which a cylinder might, through accident or otherwise, be caused to exert.

Four machines such as has been described are constantly employed printing the works of Messrs. Chambers at Edinburgh, the whole, together with a flat-pressure machine, being moved by a steam-engine of four-horse power. At the large printing establishment of Messrs. Clowes & Son, in London, we believe at least twenty machines of this kind are to be seen daily at work.

Besides those various descriptions of machines above alluded to, as being principally in use, there are others calculated to execute work of a more peculiar nature. Perhaps the most wonderful of these ingenious pieces of mechanism is a machine which has been made to print two colours by only one impression—a lower form charged with one colour being caused to rise through and come upon a level with another form, so that both may be printed at once. Hitherto the work which has been executed by this machine has consisted chiefly of the stamp-duty marks for the Excise, and for bank-notes, fancy labels for druggists, and other similar jobs.

A machine for printing newspapers (on one side at a time) has also come into use, constructed by Carr and Smith of Belper, on the plan of an advancing and retiring cylinder, while the table for the types is stationary. It is more easily turned than the other kinds of newspaper machines, and is said to be exceedingly suitable for printing newspapers of a limited number of impressions, such as are issued in many country towns.

The only other cylinder machine which we may here notice, is one invented by Mr. Cowper, intended to print from convex stereotype plates. The plates, instead of being fixed flat upon blocks, as will shortly be described, are fastened upon the cylinders, so as to give them a bent form, and the printing is effected with the face of the plate or type surface downwards; wherefore the paper is placed undermost instead of uppermost, as in all other printing. We have never heard what are the peculiar advantages of this fanciful contrivance.

We have now described the advantages of cylinder printing, and it is but proper that we should mention certain drawbacks to its universal use. The pressure by a round or cylindrical surface is less perfect than that given by an even surface. The cylinder has the effect of pressing partly on the edge of the type, both in coming up to the impression and in leaving it; therefore, the impression, in technical language, is not clean; it has a slight blurring, or wants that degree of sharpness and fairness that is required in fine book-work. Cylinder printing, from the same cause, wears down types much more quickly than flat presses. A fully more important defect is the time required to prepare a sheet of types, or forms, for the machine. A sheet, such as the present, seldom requires less than three hours to make ready, and a sheet of stereotype plates an hour longer. The pressure of the cylinders is so searching, that the smallest defect in the levelness of the forms or of the blanket and printing surface, is observable, and must be remedied by putting patches beneath the outer blanket. So much time is thus consumed in preparing a sheet for the cylinder machine, that it would be a positive loss to print any thing at it, unless a great number of copies were wanted. In other words, cylinder machines are only suitable for long impressions, and where a moderate fineness of work is sufficient.

These deficiencies of the cylinder machine have led to numerous and expensive attempts to apply steam power to machines with flat printing surfaces. The most successful of these attempts has been one by an American, and another by a gentleman in London, whose machines have been working for some years in Mr. Spottiswoode's printing-office. The latter is by far the best, and is now coming into general use. It consists of an upright frame and printing platten, resembling the common hand-press, with a type carriage at each side. The type carriages go below the platten alternately; so that, in point of fact, the apparatus is two presses with one printing surface to serve both. The movements to and fro of the type carriages, and the pull downwards of the platten, are effected by machinery beneath. The forms are also inked by an apparatus for the purpose. This machine requires a layer-on and taker-off of sheets at each end, besides a superintendent, and works about 700 sides per hour, or 350 complete sheets.*

By the introduction of the steam-presses, which we have now described, the profession of the printer has within these few years undergone a most extraordinary revolution; and although, perhaps, fewer hand-pressmen are now employed than formerly, the increase of employment to compositors, engineers, bookbinders, booksellers, &c., must be very great. The principal advance in the profession has been since the year 1832, when the printing of cheap literary sheets rose into importance, and by a fortunate coincidence the patents of various machines having about the same time expired, a new impulse was given to the trade. Hardly a newspaper is now anywhere printed with a hand-press, and few or no periodical publications. The making of printing-machines has in itself become a great business. One maker in London lately mentioned to us that he produced a machine regularly every three weeks upon an average all the year round, each at a price of about £400. Other manufacturers in London, and also now in Scotland, are similarly engaged; the machines being sent not only to all parts of Europe, but to America, Australia, and India. In a few years there will not be a civilized country of any consequence on the globe which does not possess these powerful distributors of human knowledge.

It will readily be supposed, that the introduction of a steam-press such as we have described, has caused a very extensive alteration, both in the dimensions of many printing-offices and in their organization. Printing is now a manufacture. The printing-office is a factory; and the interior of one of these concerns usually presents a remarkable spectacle of industry, animate and inanimate, which to a stranger leaves a lasting impression on the memory.

*Since the expiry of the patent, machines of this kind have been made by J. Brown and Co., engineers, Kirkaldy. The mechanism is very beautiful and effective.

ENGRAVING.

In the printing of letterpress or woodcuts, as has been already noticed, the impressions are effected by the raised faces of the letters, or marks, in the manner of a stamp. Printing from engraved plates is performed on a principle directly the reverse: in this case, the face of the metal, cleared of the ink daubed upon it, gives no representation—the printing is effected from the sunk lines. While wood-engravings may be printed along with type-matter, engravings on plates of metal require to be printed by themselves.

The discovery of the art of engraving on metal, for the purpose of making impressions on paper, is generally ascribed to Finiguerra, a goldsmith of Florence. He excelled in an art then much practised in Florence, called *niello*. It was the custom with jewellers, in those times, to engrave the outlines of Scripture subjects upon the vessels which they made for the use of the church. When this engraving was completed, they filled the lines with a black substance composed of a mixture of lead and silver, in solution with borax and sulphur; and impressions were taken from this in clay or sulphur. The black substance used was called *niello*, and hence the name of the art. The same process was also used when pieces of armour, household plate, and other articles, were engraved for the purpose of being inlaid with metals, wood, or ivory.

German writers claim the honour of the invention for a citizen of Antwerp, Martin Schoengauer, asserting that he practised the art before Finiguerra. It seems probable that it appeared nearly simultaneously in both countries. The earliest distinguished engravers, after the discovery of the art, however, were Italians.

It does not appear that Finiguerra pursued his invention any further than to take impressions on paper instead of clay. A contemporary, of the same profession and city, Baccio Baldini, improved upon the invention by engraving on plates for the express purpose of taking impressions on paper. He was greatly assisted by a distinguished painter, Antonio Pollajuolo, who furnished him with designs for his engravings, and also by another artist, Sandro Botticelli, who made a set of drawings, from which Baldini engraved plates for an edition of Dante, published in 1488, and supposed to be the first book ever embellished with copperplate engravings; though this notion has been proved false by a German writer. The works of Baldini attracted the attention of a Roman engraver, Andrea Mantegna, who had already become distinguished as one of the most successful of the *niellatori*. This artist not only assisted Baldini with original designs, but also turned his own efforts to the promotion of the newly discovered art, in which he soon became proficient.

In our notice of the early days of the art, we must not omit mentioning Albert Durer, one of the earliest Dutch engravers. Some knowledge of the art seems to have been previously possessed in Holland by Martin Schoengauer, who is thought by some German writers, as we have seen, to have invented it, and who was certainly a contemporary of Finiguerra. The works of Martin, and his disciple Wolgemuth, inspired the genius of Albert Durer, who did much for the improvement of the art, excelling equally on copper and on wood.* Marc-Antonio Raimondi, an Italian artist, having seen Durer's prints, improved upon them, and became at Rome a master in the art. Thus the profession was spread simultaneously over Holland and Italy. Although there have been various improvements in the profession of the engraver since this early period of its history, the mode of etching the plates remains substantially the same.

At present there are several kinds of engraving, each effected in a different manner, and of these we shall offer a short account.

Line-Engraving.—This is the principal as well as the most ancient species of engraving; it is employed for all elegant pictorial embellishments, and is more expensive than any other. This, as well as every other kind of copperplate engraving, is commenced by a process called *etching.* The plate is made perfectly clean on its polished surface, and heated sufficiently to melt a composition of asphaltum and Burgundy pitch, called etching-ground, which is rubbed upon it, and rendered equal all over by dabbing with a ball of wool covered with silk. The plate is then held up for the surface to receive the smoke of a wax taper, until it is rendered black and glossy, into which state it comes on not being suffered to cool during the process. These preparations being effected, and the plate becoming cold, the etching-ground, which is not thicker than a coat of varnish, is found to be of a hard consistence, and ready to receive the tracing of the subject intended to be etched. The previous preparation of the subject is a very important step in the process. The subject is drawn upon transparent paper with a black-lead pencil, and being laid with the face downwards on the etching-ground, the lines or marks of the drawing are pressed upon it with such force that they are left on the ground on removing the paper. This is called transferring; and, of course, the excellence of the representation to be produced, depends on the excellence of the drawing. Engravers, therefore, in copying paintings, require to possess a degree of skill in the art of delineation hardly inferior to that of the original artist. The drawing being transferred in the manner described, the engraver applies his tool, or etching needle, over the lines, carefully removing the ground, at the same time pressing sufficiently hard to scratch the surface of the copper. A wall of wax is now placed round the margin of the plate, and into the enclosure so formed, aquafortis is poured, to the depth of half an inch. This aquafortis decomposes or bites into the copper where the etching-ground has been removed. During this process, globules of air arise from the decomposition, and these are carefully removed with a feather, to allow free scope to the biting liquid. The length of time employed in biting the plate is regulated by the depth required, also by the state of the atmosphere; in ordinary cases, the operation may be performed in about an hour. When it is ascertained that the plate is properly acted upon, the aquafortis is poured off, the wall of wax removed, and the ground cleared with spirits of turpentine. The plate is now said to be etched, and when printed from in this state, exhibits the appearance of a pen and ink sketch. To this state of etching, but regulated by the nature of the subject, professional engravers bring the plates to be finished in the *line* manner. Different gradations of power are given by the aquafortis, and parts are rebitten to the depth required; after which, the light parts are put in with a sharp needle. Other parts are then cut with gravers of various sizes and forms, suited to the lines which will best express the respective objects. The engraver, in thus finishing his work, rests the plate on a small cushion, so that it may be conveniently turned with the left hand, while the incisions are cut with the graving tool by the right. These lines are re-entered, crossed in various directions, or cut in the spaces between the diagonal crossings, until the desired effect is produced. Landscapes and architecture are generally executed with the needle and aquafortis: portraits and historical subjects are chiefly cut with the graver.

Dotting is a style of engraving, in which dots of various sizes and depths in the copper, instead of lines, express the form and shades of the subject. They are first carefully made in the etching-ground, then bitten, and some parts stopped out, to prevent the further action of the aquafortis on them; while other parts receive additional bitings, till the subject has the power required. After this, the plate is cleaned, dotted up with the needle, stippled with the graver, or rebitten, until all the gradations of force are communicated. This style is generally used for portraits.

Mezzotinto engraving is in a great measure a reversal of those styles already described; being the reducing of a darkened surface of copper to one that is light. The operation is generally commenced by grounding or puncturing the plate with a circular-faced tool, on the edge of which are a number of points; this instrument by being rocked regularly over the surface of the copper in every direction, covers it so completely with marks or spots, that, if it were printed from, the impression would be perfectly black. On this dark ground the subject is traced, directing where the various gradations of light and half-tint are to be scraped out; which operation is performed with tools shaped like a surgeon's lancet, while the highest lights are burnished with a polished steel instrument, until the proper effect is produced. This style of engraving is used chiefly for portraits and historical subjects. It has a pleasing soft appearance, but it is understood that the copper soon fails in producing strong impressions, and it is therefore not well adapted for subjects of which great numbers are required.

Aquatinto engraving is an exceedingly complicated style of producing pictorial effect; but being executed at a lower price than that of the kinds previously mentioned, it is commonly resorted to for embellishing books of travels or other works requiring illustrations of a simple nature. In appearance, it resembles tinting with Indian ink, and the prints are susceptible of being finished with water-colours. In commencing the process of aquatint engraving, the plate must be cleaned with an oil rubber, which is a strip of woollen cloth rolled up hard, to about two inches in diameter; this, with a little impalpable crocus and sweet oil, will give to the copperplate, when perfectly cleansed from the oil, a proper surface to receive the ground, which is made with pulverized sifted rosin and spirits of wine, incorporated by gentle heat, till it appears like a varnish. This composition is poured over the plate while placed in a slanting position, so as to permit the superfluous liquid to run off. The operation must be so managed as to preserve an equal surface. As soon as the granulation, or drying of the grain, appears, the plate must be placed horizontally, when the spirit will evaporate, and the particles of rosin will adhere to the copper. When dry, the surface appears evenly covered, as with a diminutive honey-comb, and perfectly smooth. On this the subject is traced, and the highest lights painted out with a sable pencil in a mixture of turpentine-varnish and lamp-black, so as to prevent the aquafortis acting on those parts. The margin is also covered, and on it a wall of wax is fixed, with a spout at one corner. The aquafortis is regulated in its strength by the temperature of the weather and the hardness of the copper. Being poured on the plate, it remains until the first gradation of tint is bitten—the aquafortis having acted on the copper between the particles of rosin which adhered to the plate. The aquafortis is then taken off, the plate dried, and this first degree of tint stopped out or covered

* North American Review.

over with the blackened varnish. When hard, the aquafortis is again poured on, to bite the second degree of tint; and so on until all the tints have in succession been bitten in. The copper must then be cleansed, and a proof taken and compared with the original. A similar or re-biting grain must then be laid on the plate as before: when cold, a composition of treacle and lamp-black, well mixed, must be used to paint the projections of foliage on lights, or other touches which the masses of tint may require. When these are dry, the whole of the plate must be washed over with a thin coat of varnish reduced with turpentine, which will adhere to the untouched parts of the work. The wall of wax must then be replaced, and clean water poured on; in a short time the water will mix with the treacle touches, and loosen them. When all appear to be removed, the water is taken off, and aquafortis poured on, and allowed to remain until a sufficient degree of power is given to the touches, and the subject completed. Latterly, aquatint engraving has been in many cases superseded by lithography.

Plate-Printing.—Copperplates, engraved in any of the above styles, are ready for press as soon as they are finished by the engraver. The method of printing from these is very simple. Their engraved surface is daubed over with a thick oleaginous ink, so that the lines are effectually filled. As this dirties the whole face of the plate, it is necessary to clean it, which is done by the workman wiping it first with a piece of canvas and then with the palms of his hands rubbed on fine whiting. It may be calculated that a hundred times more ink is thus removed than actually remains in the indentations; however, such is necessary. The plate being thoroughly cleansed, it is laid on a press, with a piece of damped paper over it, and being wound beneath a roller covered with blanket stuff, it is forced to yield an impression on the paper. The plate requires to be kept at a moderate warmth during the operation. The frequent rubbing of the plate with the hand to clean it, as may be supposed, tends greatly to wear it down; and such is the wear chiefly from this cause, that few copperplates will yield more than a few thousands of impressions in good order. The earliest, called *proofs*, are always the best and most highly prized. In consequence of this defect in copper, the practice of engraving steel plates, for all subjects requiring long numbers, has now become very common.

Seal Engraving.—This is a branch of the profession altogether distinct from that of the engraver of plates. While the hardest metals are susceptible of being cut by a tool wielded by the hand of the artist, the different kinds of stone required to be operated upon by the seal-engraver are so extremely hard, that a much more powerful instrument than the hand has to be resorted to. The cutting tool is fixed into a turning machine or lathe, and is made to operate while in a rapid rotatory motion. The lathe is of a light and miniature construction, erected on an elevated bench or table in front of the artist, and is moved by a foot-board beneath. The engraver of metal plates sits while at his work, but the seal-engraver in general stands, in order to have greater command over his operations. He likewise requires to be exceedingly steady in the hand, for the slightest error would perhaps be irremediable; therefore, with both his elbows resting on cushions on the bench, and the palm of his left hand leaning on the top of an erect roundish-shaped bolt or pillar, his fingers of both hands are busy in pressing the stone to the edge of the whirling tool, or guiding it so that it may receive the appropriate indentations. One tool, however, cannot execute all parts of the device. The cutter possesses from one to two hundred tools, varying from a large to a small size. It is also necessary to explain, that the cutting part of each tool is shaped so as to present to the stone a sharp thin edge like the rim of a wheel. (By sticking a small wafer on the point of a pin, and conceiving the edge of the wafer, when turning round, to be the cutting part, a good idea may be obtained of this curious instrument.) As the tool projects horizontally, the artist, by holding the stone beneath it, with its surface to be cut uppermost, is thus enabled to watch the progress of his operation from beginning to end. Sharp as the cutting tools of the seal-engraver are, they would entirely fail in perforating the gems to which they are applied by the lathe, unless they were given an additional sharpness, by means of a foreign material occasionally applied to them while in rapid motion. This material is diamond dust. The diamond is so expensive an article, that the particles used by the seal-engraver are those which have been rejected as waste by the lapidary. These being placed in a hollow steel tube, having a tight-fitting rammer of the same material, a few smart blows on the upper extremity of the rammer reduce the particles to powder. A small portion of this dust is then mixed with a little highly refined oil, and being held to the tool in a state of motion, it is attached to or forced into the metal. If a powerful magnifying glass were taken to examine the tool after its absorption of the diamond dust, its edge would be observed to resemble a rasp or saw, the particles being partly imbedded and fixed in the steel; hence, properly speaking, it is not the tool, but the diamond dust upon it, which cuts the surface of the stone.

To cut an elaborate device, such as a bust or a coat of arms, upon the surface of a cornelian or other gem, a vast deal of care is necessary on the part of the artist. The precise depth of every turn and indentation is matter of serious study, and a momentary heedlessness might have the effect of ruining the work of several days. The operator, however, exercises caution in his ingenious labour. The stone being dimmed by friction, is drawn upon with a brass point to show the subject; the artist first traces the outlines of his figures, next opens them with the bolder tools, and gradually proceeds to the details with finer and finer instruments, frequently stopping to take impressions on wax, to see the effect which has been produced, before he gives the finishing stroke to his workmanship; lastly, the surface is repolished, and the seal completed.

Engraving, in all its branches, is a species of labour which requires payment higher than almost any other department of art; for not only must there be great ability brought to the task, but a degree of patience and perseverance beyond what is required in most other employments.

LITHOGRAPHY.

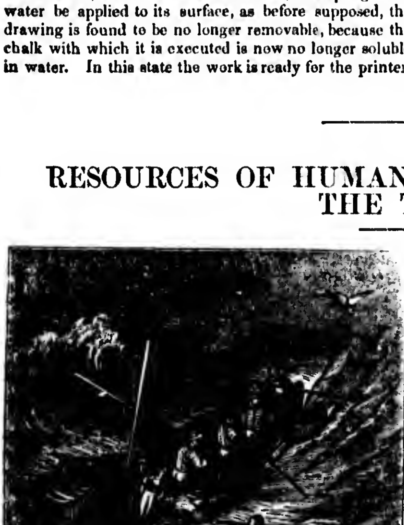
Lithography (from *lithos*, a stone, in Greek) is the art of printing from a peculiar kind of stone, and generally in a style which resembles the more ordinary kinds of engravings. It was invented at Munich, in Bavaria, between the years 1795 and 1798, by Alois Senefelder a person of literary ability, who, being too poor to pay for the printing of books in the usual manner, endeavoured to fall on a method of executing his productions from the surface of various metals and also of stone. Proceeding in his ingenious attempts, he was at length successful in discovering that drawing made on the surface of stone will form a sufficient type to yield inked impressions on paper. From Munich, the invention shortly spread over Germany; it was also introduced into France and England; and finally, after encountering the usual quantity of derision, lithography took its place alongside the more ancient arts of letterpress and copper-plate printing.

The stone employed for lithography is of a calco argillaceous nature (lime and clay), resembling in appearance a smooth yellow hone, and is found in quarries in Bavaria; it is likewise found in England but no stones are so good as those from Germany, and their importation is a considerable object of commerce. The stone, when prepared, usually varies in thickness from an inch and a half to two inches and a half; those which are large requiring the greatest thickness, in order to endure the severe pressure to which they are exposed. Of whatever dimensions, the stone requires to be perfectly flat, and highly polished on the upper surface. The ink to be employed in making the drawings for the stone varies in composition according to the precise nature of the work, and whether the drawing is made direct on the stone or transferred to it from paper. One kind, of a good quality, consists of dried tallow soap, mastic, subcarbonate of potash, Chinese or table varnish, and lamp-black, the varnish being the principal ingredient. The materials are incorporated in a close vessel over a fire, and when prepared are cast into moulds. The substance taken from the moulds forms a chalk, which may be pointed like a pencil, or it may be dissolved in water to form an ink.

The drawing is made on the stone either by the pencil or chalk, or by the ink and a fine pen or camel-hair pencil. "To render the lithographic process intelligible, let it be supposed that the artist now completes a drawing with the chemical chalk just described, upon a grained stone. If, while in this state, a sponge filled with water were passed over the face of the stone, the drawing would wash out, the chalk with which it is made being, as we have seen, soluble in water, by reason of the soap which it contains. Before, therefore, it is capable of yielding impressions, a weak solution of nitrous acid is poured over it, which unites with and neutralizes the alkali or soap contained in the chalk, and renders it insoluble in water. After this, the usual course is to float a solution of gum over the whole face of the stone, and when this is removed, if a sponge and water be applied to its surface, as before supposed, the drawing is found to be no longer removable, because the chalk with which it is executed is now no longer soluble in water. In this state the work is ready for the printer, who obtains impressions by the following process:— Having thrown with the ends of his fingers a few drops of water on the stone, and spread them with a sponge, so as to wet, or rather damp, the whole surface equally the printer finds that the water has been imbibed by the stone only on those parts not occupied by the drawing, which, being greasy, repels the water and remains dry. A roller properly covered with printing-ink is now passed over the whole stone, which will not even be soiled where it is wet, from the antipathy of oil and water. But the parts occupied by the drawing being, as we have seen, dry and greasy, have an affinity for the printing-ink, which therefore passes from the roller and attaches itself to the drawing. In this state it is said to be charged, or rolled in. Damped paper is then put over it, and the whole being passed through a press, the printing-ink is transferred from the stone to the paper, and this constitutes the impression. By repeating in this manner the operations of damping the stone and rolling in the drawing, an almost unlimited number of impressions may be obtained. Now, as we have said, the modes of lithography are various, but the illustration just given will explain the principle of them all. It consists in the mutual antipathy of oil and water, and the affinity which the stone has for both, that is, in its power of imbibing either with equal avidity."—*Penny Cyclopædia.*

The art, in whichever way pursued, requires great delicacy and dexterity. In drawing on the stone, the slightest mark of the hand will fasten on the surface and appear in the impression. The execution of the impression in an equally clear and dark manner is evidently a matter of difficult accomplishment, there being nothing more common than to see lithographic impressions light at one part and dark at the other. The process of printing differs from that of letterpress or copper-plates. The stone, properly [illegible] and with paper over it, lies in a box on the table of the press, covered by a piece of leather, and is drawn beneath a hard edge or scraper, the mechanism being assisted by a lever power.

RESOURCES OF HUMANITY—USEFUL RECEIPTS—THE TOILET.



RESOURCES OF HUMANITY.

Under this head may be appropriately included those inventions which have reference to the preservation of life from accidents by water, fire, and other agents of personal injury.

ESCAPES FROM DROWNING.

Life-boats.—The attention of the public has been called at an early period to the perils and fatalities of shipwrecks. Several boats for preserving lives in such cases were invented, and among others, one by Mr. Lukin in 1785. But an accident which occurred on the Herd Sands of South Shields, in September, 1789, led to material improvements in the art of constructing these vessels. The Adventure, a merchant-ship of considerable bulk, was wrecked within three hundred yards of the shore, in presence of an immense number of spectators; and almost every man of the unhappy band of mariners perished, without the possibility of receiving assistance from the shore. The consequence was, that the people of South Shields met soon afterwards, and offered a reward to any one who should invent a boat capable of being launched from the shore to the aid of ships in distress. Mr. Greathead gained the premium; and in 1790 a life-boat, constructed upon the plan proposed by him, was effectually used in saving the crew of a vessel stranded under circumstances similar to those of the Adventure. Several other trials of the life-boat proved its utility so fully, that in 1802 the Society of Arts presented the inventor with their gold medal and fifty guineas; and Parliament also decreed to Mr. Greathead a reward of £1200. The Trinity House followed the example; and the Committee of Lloyd's devoted £2000 to the purpose of building boats on the same principle. By these and other means, the dangerous parts of our coasts have been very generally furnished with these life-preservers.

The form of Mr. Greathead's life-boat is one well adapted to give it buoyancy, and keep it afloat in any sea. It is usually "made about thirty feet in length, ten in breadth, and three feet three inches deep at midships; both extremities are made precisely of the same form, so that it goes through the water with either end foremost; and its shape lengthwise is a curve, so formed that in a line drawn from the top of one stem to that of the other would be two feet and a half above the gunwale at midships. In this boat there are five thwarts, or seats for rowers, double-banked, so that it must be manned with ten oars. It is cased and lined with cork, which gives it such buoyancy that it will float and be serviceable, though so damaged by hard knocks as to be almost in pieces; and this the softness and elasticity of the cork is well calculated to prevent. The cork on the outside is four inches thick, and it reaches the whole length of the shear, or side of the boat; on the inside it is thicker, and the whole quantity is about seven hundred weight. It is firmly secured with slips or plates of copper, and fastened with copper nails. The advantages of this boat are stated to be, that its curvature gives it great facility in turning, a single stroke of the steering oars, of which there is one at each end, moving it as though on a centre; that the covering of cork, being immediately under the gunwale, gives great liveliness or disposition to recover its balance after being suddenly canted aside by a heavy wave; and that its capability of going with either end forwards increases its manageability." A view of the life-boat in action is presented at the head of our article.

The life-boat is kept in a boat-house, and placed on wheels, in order that it may be moved at an instant's notice. Where the road to the sea is smooth, this simple mode of moving the boat does well enough; but it has been found better in many cases to suspend the boat under the axis of the wheels, so that the shaking may be less injurious. At most of the life-boat stations, the boat is under the charge of a committee, and twenty or twenty-four men, composing two crews, are alternately employed in its navigation. A reward is given to these men in cases of shipwreck, and the vessel receiving aid is expected to contribute to this end. Of course the life-boat men are picked persons, of steady habits and active frames; and the individual in command requires to possess peculiar skill and knowledge of the coasts and currents.

It has been observed, that the occupation of the life-boat men gives a sort of dignity to their character, and elevates their tone of thought. Many noble actions have been performed by them, which no money could compensate. Of their general usefulness some idea may be gathered from the fact, that, between the date of Mr. Greathead's invention and 1804, *three hundred lives* had been saved at the entrance of Tynemouth haven alone.

Mr. Greathead recommends the life-boat to be painted white on the outside, as a colour that most readily catches the eye. He also advises the steersman to keep the head of the boat to the sea, and to give her an accelerated velocity to meet the wave. The strong reflux of the waves renders it necessary to approach a wreck with great caution, and the leeside is usually the safest of access. Of course the first object is to convey the wrecked crews on the shore, which, if they are numerous, must be done by degrees. Many lives have been lost by the impatience of crews, in attempting to go on shore in their own boats. This is always an act of folly where a life-boat is on the scene.

Captain Manby's inventions.—Since the date of its discovery, some improvements have been made on the common life-boat of Mr. Greathead; but the most important subsequent inventions for the humane end of saving lives at sea have been those of Captain Manby. This philanthropic gentleman was in the corps of engineers, and held the situation of barrack-master at Yarmouth, on the Norfolk coast, in the year 1807. That coast, it is well known, is full of shoals, and many vessels have gone to pieces within a hundred yards of the shore, in sight of multitudes of people, without any chance of giving relief. Life-boats could not be stationed at all points of an extensive coast, and perhaps could not be always used if they were present. The lamentable case of the Snipe, where sixty persons lost their lives near Yarmouth, made so deep an impression on Captain Manby, that he resolved to devote his mind and his life to the discovery of some means of relieving similar cases of distress. It appeared evident to him that the desired end was the discovery of *some means of throwing a rope from the shore to the ship, or from the ship to the shore.* Boats with the crews would obviously be thus drawn ashore in almost any circumstances.

"The active and philanthropic mind of Captain Manby was not tardy in pointing out a probable method. It struck him that a cannon shot affixed to a rope, and projected from a piece of ordnance over a stranded vessel, was a practicable mode of establishing the communication. But to reduce it to practice was found to be attended with much greater difficulty than the simplicity of the object seemed at first sight to promise. In the first place, the folding or manner of laying the rope, so as to unfold itself with the rapidity equal to the flight of a shell from a mortar, without breaking by sudden jerks at each returning fold, and without entanglement from the effect of uneven ground and boisterous winds, was no easy task. But it was at length attained by adopting what is called a French faking, in folds of the length of two yards; and by laying the rope in a flat basket always kept ready, with the rope in order, in a secure place, so that it could be transported at a moment's notice to the situation required, and laid upon rocks and uneven ground even in the most boisterous weather, without fear of disarrangement.

"The next difficulty consisted in the means of connecting the rope with a shot, so as to resist the inflammation of gunpowder in that part of it which must necessarily occupy the interior of the mortar. Chains in every variety of form and strength universally broke from the sudden jerks or play to which they were liable, which proved that not only an elastic, but a more connected body was necessary. 'At length,' says Captain Manby, 'some stout plaited hide, woven extremely close to the eye of the shot, to prevent the slightest play, extending about two feet beyond the muzzle of the piece, and with a loop at the end to receive the rope, happily effected it.'

"This apparatus, projected from a small howitzer over a vessel stranded on a lee-shore, so light as to be easily conveyed from one part of the coast to another, affords a certain means of saving the lives of the crew in the day-time, and when from cold and fatigue they are not disabled from seizing and fastening the rope, and in other respects joining their own exertions to those of their friends on shore. The following extract, from an account of experiments made before some colonels and field-officers of artillery, shows the celerity with which the service may be performed:—

"'A person is completely equipped with every necessary apparatus to effect communication with a vessel driven on a lee-shore. A man mounted on horseback was exhibited, accoutred with a deal frame, containing 200 yards of log line ready coiled for service, which was slung as a knapsack, with a brass howitzer of a three-pounder bore on its carriage, and two rounds of ammunition, the whole weighing sixty-two pounds, strapped on the fore part of the saddle. The person thus equipped is supposed to be enabled to travel with expedition to the aid of ships in danger of being wrecked on parts of the coast intermediate to the mortar stations; and with this small apparatus the log-line is to be projected over the vessel in distress, from which a rope should be attached to it to haul the crew on shore. Captain Manby caused the howitzer to be dismounted from the horse, and in a few minutes fired it, when the shot was thrown, with the line attached, to the distance of 143 yards. At a subsequent trial, the horseman, fully equipped, travelled a mile and a third; the howitzer was dismounted, and the line projected 153 yards in six minutes.'

"Such is the simple but efficacious nature of Captain Manby's first invention; and a few practical experiments soon ascertained the allowance to be made in pointing the mortar to the windward of the object over which the rope is to fall, in order to obviate the effect of a strong wind, which would of course carry it considerably to leeward. Experience also proved that the mortar should be laid at a low elevation, in order to insure the certainty of the rope's falling on the weathermost part of the rigging.

"This original invention, however, was obviously capable of many improvements. The first of these was to afford assistance to vessels whose crews, either from their being lashed to the rigging, or from extreme cold and fatigue, are incapable of assisting to secure the rope to the wreck when projected over it from the mortar. This was attained by adding a quadruple barb to the shot—that is, making four hooks project from the ball—by means of which, when the rope is hauled tight by the people on shore, one end is firmly secured on some part of the rigging or wreck, and a boat can of course be hauled to the relief of the crew, without any assistance on their part."

But in order to make this invention effective in the darkest night as well as by the light of day, the ingenious philanthropist had yet much to do and discover. He attained his end, difficult as the task was. "The requisite objects were—First, to devise the means of discovering precisely where the distressed vessel lies, when the crew are not able to make their exact situation known by luminous signals. Secondly, to discover a method of laying the mortar for the object with as much accuracy as in the light. Thirdly, to render the flight of the rope perfectly distinguishable to those who project it, and to the crew on board the vessel, so that they cannot fail of seeing on what part of the rigging it lodges, and consequently may have no difficulty in securing it.

To attain the first object, a fire-ball is used, such as is often thrown up in the attack and defence of fortified places to discover the situation of an enemy by night. It consists of a hollow ball of pasteboard, having a hole at top containing a fusee, and filled with about fifty luminous balls of star composition, and a sufficient quantity of gunpowder to burst the ball and inflame the stars. The fusee is [illegible]lated so as to set fire to the bursting powder at the height of 300 yards. On the stars being released, they continue their splendour while falling for nearly one minute, and strongly illumine every surrounding object: ample time is therefore allowed to discover the situation of the distressed vessel.

"During the period of the light, a board, with two upright sticks at each end (painted white to render them more discernible in the dark), is pointed towards the vessel, so that the two white sticks shall meet in a direct line with it, the wreck being a fixed object. This will obviously afford an undeviating rule by which to lay the mortar, making an allowance, as by daylight, for wind, &c. Thus the second object is attained.

"For the third, a shell (instead of a shot) is affixed to the rope, having four holes in it to receive fusees, and the body of the shell is filled with the fiercest and most glaring composition, which, when inflamed, displays so splendid an illumination of the rope that its flight cannot be mistaken."

Such are the most prominent features in the scheme of Captain Manby for the relief of ships in distress. The number of persons saved by these inventions has been very great. Almost immediately after turning his mind to the subject, Captain Manby had the gratification of rescuing ninety persons from a grave in the deep. The whole expense of his apparatus did not exceed £10. Captain Manby was deemed worthy of a parliamentary reward.

Floats and buoys.—In addition to such a flat boat as that recommended by Captain Manby, with rods and ropes furnished with hooks for grappling, humane societies usually possess floaters, consisting of short bars of wood, with buoys or masses of cork at each end. One of these being thrown out with a rope, a party in danger may grasp the bar, and be readily borne up till pulled ashore. Another provision of late invention consists of hollow girdles of cloth, air and water-proof, which being sustained by straps from the shoulders, can be filled with air from the mouth, and when the pipe is closed, will sustain the wearer perfectly in water.

Safety cape.—This is of later invention than the above-mentioned float-belts, which it is likely to supersede, inasmuch as it combines an article of dress with its principle of life preservation. It is the invention of a member of the Skating Club of Edinburgh, and is furnished by the Albion Cloth Company of that city. The cape, which is suited to lie easily round the neck and shoulders, is formed of Macintosh cloth, which may be partially inflated with air at pleasure, by means of a small mouth-piece hid from external observation. The cape we saw is outwardly a grayish serge (it may, however, be made of any material), and hangs down all round as low as the elbows. A tape from the inner part of the back, to be tied round the body, keeps the cape down, in the event of immersion in water. When blown up, the cape swells to about an inch in thickness, which presents nothing unsightly; however, it need not be inflated till the wearer goes into a condition of danger—into a boat on a sailing excursion, for instance, or upon unsafe ice. As a piece of dress, it may be worn by ladies as well as gentlemen.

With respect to the buoyant powers of the apparatus, they have been the subject of a critical experiment by the Edinburgh and Leith Humane Society, which is mentioned in nearly the following terms in the newspapers of the day:—"The use of a large cast-iron tank or tun having been obligingly placed at the service of the directors by a brewer in Edinburgh, it was filled with warm water to the depth of six feet two inches. A stout man, a sailor, five feet six inches in height, and about ten to eleven stone weight, went into the water with his clothes on, wearing the safety-cape, and, to the satisfaction of all present, floated vertically at his ease, with his head, neck, and part of his shoulders above water. Wishing to ascertain what degree of buoyancy he had to spare, weights were given to him, which he held in his hands. Seven pounds sank him to the throat, and four more to the lip, proving that he could have sustained another person in the water. The man came out repeatedly, and again plunged into the water, always declaring it difficult to immerse his head even for an instant. On this fact, the directors of the society found that, in the event of the ice giving way under a skater, the reaction will effectually protect him till relieved from his perilous situation."

After this satisfactory testimony, nothing more need be said on the subject. It is quite clear to us, that if people would but be persuaded to wear one of these safety-capes, they need be under no apprehension whatever of immediate drowning in the case of sudden mersion in water; and it is well known that, except in shipwrecks at a great distance from land, a power of buoyency for only a few minutes would save almost every life. The deplorable deaths from boat accidents on rivers, for lack of some such simple means of preservation, who can either number or sufficiently lament?

Dangers upon ice.—The preservation of lives endangered by the breaking of ice also arrested the attention of Captain Manby. In ordinary cases, ropes and a ladder are used for the purpose of relieving persons so situated, but Captain Manby's suggestions have reference to all possible circumstances of difficulty and danger. He recommends as one instrument a rope with a floating noose, distended by whalebone, with an egg-shaped piece of wood or cork at a convenient distance, to be easily grasped by the hand. The evident purpose of this rope is to be thrown to and grasped by the person in the water, who for a time usually sustains himself by holding the edges of the ice. Another machine for saving persons in similar cases, recommended by Captain Manby, is a boat of wicker or wood, made very flat and light, and placed upon wheels. The wicker boat may be rendered buoyant by tin boxes enclosing air. Such a boat is pushed over the ice by means of sprits or pikes, with sharp iron points, and may be rapidly taken to the scene of danger in almost every case. Where the person in peril has sunk, a grappling rod with hooks, two, three, or four in number, is used for the purpose of raising him, or dragging him from below the ice; and the points are guarded, so that no injury may be done to the body. The body will always be easily moved in the water. A ladder, with a considerable balancing weight at one end, forms another instrument of value, either for approaching a broken portion of *weak* ice, so that ropes may be thrown to a party in the water, or for communicating between the boat and safe ice, or between the boat and the shore.

Boat accidents.—If upset in a boat, or in any other way precipitated into the water without being able to swim, draw in the breath, keep your mouth as well shut as possible, and do not throw about with your arms. Endeavouring to hold your head up, yield yourself to the buoyant powers of the water, and stretch out your hands—but only below, not above, the surface. Remember that the less you expose above the surface the better are you buoyed up. Many persons are drowned merely from struggling and throwing up their hands.

Treatment of persons apparently drowned.—The treatment of persons taken from the water in an apparently lifeless condition is a question of the highest consequence to humanity. It was formerly supposed that the deluging of the lungs with water, was the direct and immediate cause of death in cases of submersion in that element; but, in reality, it has been ascertained that only a very small quantity of water enters the lungs in such circumstances. The deprivation of air is now understood to be the true cause of death. On being submerged for the space of three-quarters of a minute, a violent effort is made to inspire and expand the lungs, but no air, of course, can enter. Air, however, is expelled, and as the same effort at inspiration is repeated again and again, the expiration also is renewed, making obvious bubbles at the surface, until the lungs are completely exhausted. In the meanwhile, the blood, from want of oxygenating air, becomes rapidly changed from its arterial or red condition to a venous or dark state, and being then incapable of maintaining the vital action of the brain and other organs, as well as of supporting the animal heat, sensation, voluntary motion, and bodily warmth, are gradually extinguished, and death ensues. A convulsive cough keeps out water from the lungs in a great measure, and the small quantity that does enter is wrought up into a sort of froth. Little water is found to enter even the stomach. It is the collapse of the lungs from want of air which weighs down the body, and causes it to rest below the surface, till the formation of gases of putrefaction again lighten and raise it.

The phenomena attending the extinction or cessation of life by submersion in water, are of importance as regulating the attempts that may be made to restore the vital spark. It is impossible to say at what distance of time after submersion these attempts will be fruitless. A person has been found irrecoverable after being four minutes in water, and many have been restored after submersion for twenty minutes, and even for half an hour. Much depends on the treatment applied. Misled by the notion that the body was in all cases gorged with water, people were wont to hold up the drowned by the heels, roll them about, and use other means calculated only to destroy all chances of recovery. This fatal error is even yet too often practised. The true remedies in such cases are few and simple. The first object is the restoration of the animal heat. For this purpose, the wet clothes are to be removed without delay, and the body, after being well dried, is to be surrounded with warm air, for which purpose every humane society should have a portable warm-air bath. The heat should at first be moderate, and gently increased. In absence of the warm-air bath, the body should be laid in a well heated bed or blankets, and bottles of hot water laid to the feet and arm-pits. A warming-pan or heated bricks should be passed over the body, or gentle friction exercised with other warm substances. Meanwhile, by means of a pipe or bellows, continual though gentle attempts should be made to excite respiration artificially; and, if the apparatus be at hand, slight shocks of electricity should be kept up at the same time. If there be any signs of returning life, such as sighing or convulsive twitching, a vein may be opened. The throat may be tickled to excite a propensity to vomit, and a tea-spoonful of warm water administered to test the power of swallowing. If it exist, a table-spoonful of warm diluted wine or brandy may be given.

Even if no vestige of returning animation be discovered, these means of recovery should be persisted in for three or four hours. In a late remarkable case, mentioned in a note below, a person who had been under water for ten minutes was restored to life at the end of *four hours.**

---

* One of the most extraordinary cases of restoring animation to a human being after it had been suspended for nearly four hours, was mentioned to Mr. Baker, the coroner, at an inquest held before that gentleman, and the following particulars relative to it will not only be read with interest, but will instruct and shew the necessity, in all cases of immersion in the water, for diligence and perseverance to be used by the medical men called on to assist:—A few evenings since, a young gentleman, named Henry Stanhope, was amusing himself by angling in one of the basins of the West India Dock, when, by some means, he fell into the water, and immediately sank. A cry was raised of "a man overboard," and the drags were soon in requisition; but ten minutes elapsed before the body was recovered, life appearing quite extinct. Mr. Bloomfield, of High Street, Poplar, surgeon, was fetched on the first alarm, and was in attendance when the body was recovered. He immediately had it conveyed to the receiving-house on the docks, and placed in a warm bath. It was then taken out, wrapped in blankets, and bottles of hot water applied to the chest and soles of the feet. Several of the dock labourers were then called in, and were ordered to rub the body. This they did for about a quarter of an hour, when it appeared to get colder and more livid about the face. By their pressure and rubbing a great quantity of mud began to ooze from the mouth, upon seeing which Mr. Bloomfield ordered them to continue their exertions. In half an hour the muscles began to lose their rigidity, and a slight vibration of them was observed. This stimulated them to continue their exertions, and after four hours' indefatigable exertion, animation was so far restored that the person was able to articulate. Mr. Bloomfield applied a dozen leeches to his temples, and four hours after bled him. Stimulants were afterwards applied, and he was restored, but remains in a very weak state. The coroner, after paying a compliment to Mr. Bloomfield for his praiseworthy exertion, said the case was one of the most extraordinary he had ever known but thought the best things to be used in cases of drowning were vapour baths. —*Times, June*, 1842.

ESCAPES FROM BURNING.

Precautions as to Fire.—Houses are said to take fire by accidents, but these accidents are in general only acts of carelessness, and could with a reasonable degree of prudence be avoided. As prevention is better than cure, we offer the following precautionary advices:—

Never leave a candle burning at your bedside, or on a table when you go to bed, except it be a rush, wax, or floating light, burning in a basin at a considerable distance from the bed or window-curtains. The best place for setting the light is on the hearth.

Never put hot cinders or ashes into a bucket to set aside in a closet.

If you light candles with pieces of paper, take care that the burning paper is completely trampled out after being used. It is always safest to light candles and lamps with a small wax taper, which can be at once blown out. In large manufactories, where there are many lamps or gas-burners to light, let the lighting apparatus be a small hand-lamp, which shall be in charge of a particular person in the premises.

Never blow gas lights out; always turn them off; and turn off the gas at the main stop-cock at the door. Should the gas, from any cause, have escaped, and the smell be suddenly and offensively felt, at once turn off the supply at the meter or stop-cock, and open the windows to allow the entrance of fresh air. Be careful not to take a lighted candle into the apartment where the escape has taken place.

Cause the chimneys to be swept once in three months, or oftener if necessary, so as to prevent the accumulated soot from catching fire. Sometimes houses are set on fire from beams which encroach upon the chimneys. House builders ought to be particularly cautious in preventing any part of the woodwork from touching the flues.

The following are advices how to act when the catastrophe of fire actually takes place:—

Chimney on fire.—To extinguish speedily the fire in a chimney, it is only necessary to hang over the fireplace a piece of wet carpet or blanket: some handfuls of salt thrown into the fire at the same time will greatly aid the extinction. Unless to prevent the chance of timbers in the walls catching fire, it would be generally preferable to allow the burning in the chimney to exhaust itself.

Clothes catching fire.—The moment you see that your clothes are on fire, remain still and collected; do not, on any account, run away in a fright. If there be a loose rug, carpet, or table-cover at hand, snatch it up and roll it tightly about you. If you can get this done smartly, the flames will immediately be extinguished. Should no cloth of any kind be at hand, and no one be present to give assistance, lay yourself down on the floor, and try to extinguish the flames by rolling yourself about, always taking care to keep the garments as close together as possible. If a man be present, let him take off his coat and wrap it round you; and if a woman, her shawl will answer the same purpose. By one or other means, such as are here pointed out, the fire will be stifled, and perhaps the only personal injury will be some slight scorching of the hands, which must not be regarded in averting an infinitely greater evil.

House on fire.—In making way through a burning house, we ought not, if it be full of smoke, to walk upright, for then we shall run the risk of suffocation. It is best to creep along on hands and knees, the freest air being to be had close to the floor. On being awakened by an alarm of fire during the night, it is particularly important to preserve presence of mind, and not to act till a moment has been given for reflection. Preservation may depend on the choice we make of going *up* or *down* stairs, or on some selection of movements equally unimportant in ordinary circumstances.

Fire escapes.—The escape from a house v... on fire is sometimes prevented by the stairs being of wood, and either burning or already destroyed. In such an emergency, there are only two means of escape—issuing by the sky-light, and so reaching the next house, or going over the window. On this account, every house with wooden stairs should have a sky-light, accessible from the upper floors, and also some kind of apparatus for getting safely from the windows to the ground. The apparatus which meets with most general approbation is a rope-ladder, and this may be made in different forms. Captain Manby recommends "a rope with nooses distended by flat rests for the feet at convenient distances for stepping from one to another. In cases of danger, this might be instantly fastened by one end to a table or bed-post, while the other is thrown out of the window, thus furnishing a ready escape when perhaps there is no other possible means near those who are in momentary dread of being burned to death." Such a ladder may be serviceably kept by private parties; and we should advise that at all events every house with wooden stairs ought to be provided with one or more pieces of knotted rope, and these be deposited in the bed-rooms, for use when suddenly required. Where, from carelessness, no fire escape of this kind has been provided, two or more sheets or blankets taken from the bed may be tied to each other by the corners, and thus a rope of sheet be formed. There is no instance on record of a person being burnt to death in Edinburgh by fires in dwelling-houses, although the buildings are more than usually high; the reason of which is, that there the stairs are all of stone.

Every fire-establishment in towns, besides fire-engines, and buckets, should possess several long ladders, ready at all times to be applied to windows; also cords, which may be brought to bear wherever they are required.

Burns and Scalds.—When you receive a burn or scald, instantly plunge the part affected into cold water, or cover it with some cold moist substance. This will prevent the skin from rising in a blister, and the part will be easily healed. If you delay applying the cold water or cold substance, even for a few seconds, the skin will rise, and the application will have no good effect. If stockings or other coverings are upon a part at the time of its being burnt, they should be taken off immediately, as delay will only render their removal more difficult. One of the best applications to a burnt part that can be used is cotton or cotton-wad, an article generally abundant in every family. In many cases it is applied perfectly dry to the part, and in others it is wetted, on the side next the sore, with a mixture of lime-water and linseed oil. A rag wetted with some mixture may be used, where cotton cannot be had.

Cuts.—Almost any common cut may be cured by simply closing the edges of the wound, and holding them together so as to keep the air out. This may be done by sticking a piece of plaster on the closed wound, and keeping that plaster on till the part is completely well. The plaster has no healing property in itself—its entire use is to hold the edges of the cut together. A piece of linen rag may serve the same purpose, but the tying of it is apt to stop the circulation of the blood. If any dirt or foul substance has got into the cut, it must be carefully removed, otherwise the wound will fester, and not heal till it has been drawn and cleaned by a poultice.

Preservation against lightning.—When persons happen to be overtaken by a thunder-storm in the open air, it is customary for them to fly for shelter to any tree which may be at hand. They expose themselves to increased danger by so doing, particularly if the tree be a prominent one and standing alone, because it thus becomes a peculiar mark for the electrical fluid. But it is better to be placed at a short distance from such a tree or large object, than to be far from any thing of the kind. On an open bare moor, a single human body does not run any great risk, yet it is the most prominent mark if lightning be near the spot; whereas a large tree at a short distance would be the most attractive body. The human person is more secure when wet than when dry—another reason for refraining to seek the shelter of trees. All metallic bodies should be avoided when the atmosphere is charged with lightning. People in a house are rendered most secure by sitting quietly in the centre of their apartments; and it is even important to keep the mind as calm as possible.

Large buildings or establishments may be almost completely secured against the effects of lightning by means of metallic rods, rising from the earth to a height greater than that of the edifice to be protected. The lightning, if it does alight on the building, is conducted by the rod to the earth, and is there diffused or dispersed without noise or shock.

MISCELLANEOUS.

Ventilation and fumigation.—It is essential to health that the habitations occupied by us should be free of impure air and all noxious vapours. The first step towards this end is to effect and maintain a liberal circulation of fresh air, either by ventilators or by regularly opening the windows for stated daily periods. The kindling of fires also promotes the circulation of atmospheric currents. Noxious effluvia may be most effectually removed by occasional sprinklings of a solution of chloride of lime upon the floors and walls, the windows being kept open the while. It is always proper, also, that an infected house should be white-washed. We have seen recommendations to purify the air of rooms by closing them, and burning salt and oil of vitriol in a dish placed on the floor. In unskilful hands such plans are highly dangerous; and we strongly advise every one to confine the fumigating process to sprinkling with chloride of lime, and to ventilate by opening all outlets to the air. Lives are sometimes lost by sleeping in a close room in which charcoal is burning, the person in this case being stifled with noxious gas. We advise that every sleeping apartment should be airy, and that no one should go to bed with charcoal burning in the grate or stove. Bedrooms are always best without fires of any kind.

Hanging, or suspension by the neck.—In cases where a body is found in a suspended state, and life is seemingly extinct, the chief remedy consists in cupping the temples or opening the jugular vein, and so relieving the head of the blood which accumulates in its superficial veins in consequence of the ligature. Where the body is cold, from having been long suspended, friction, and the other means used for restoring animal heat in drowned persons, should be likewise resorted to. Electricity or galvanism may also be of service.

Poison.—When you have reason to know that you have accidentally swallowed a poisonous substance, and proper medical advice is not at hand, take an emetic. This may be done almost instantaneously by swallowing a cupful of warm-water mixed with a teaspoonful of mustard. If you have not dry mustard in the house, you are almost sure to have a mustard-pot, and a quantity from that put into the water will very quickly empty the stomach. As mustard may thus prove of so much use, it should never be wanting in any house; but even should there be no mustard at hand, warm water by itself forms a tolerably efficacious emetic.

Coach accidents.—Should the horses run off, in defiance of any restraint, while you are in a coach, sit perfectly still, and in anticipation of the possible overturn, keep your legs and arms from straggling. Sit easily and compactly, so that, when upset, you will gently roll over in the direction you are thrown. We have seen ladies in these circumstances scream wildly, and throw their arms out of the windows, thus exposing themselves to the chance of broken limbs. If run away with in a gig, either sit still collectedly, or drop out at the back, so as to fall on your hands. Never jump from a rapidly moving vehicle, unless (supposing it impossible to slip down behind) you see a precipice in front, in which case any risk of personal damage is preferable to remaining still. The Duke of Orleans lost his life by neglecting these simple precautions.

Alarms in churches and theatres.—Alarms, whether with reference to fire or the falling of galleries, often take place in these and similar places of resort. In general, they are raised without due cause, often from a circumstance of the most trifling nature, and perhaps occasionally from a deliberate spirit of mischief. However originating, they almost invariably generate a panic, and occasion much damage, which a little reflection would have enabled those present to avoid. The newspapers teem with accounts of incidents of this nature. In most instances, the whole mischief is caused by *yielding too much to alarm.* We anxiously recommend every one to cultivate the power of suppressing such idle emotions. When a cry of fire, or of the falling of galleries, is raised in church, *sit still*, and remain tranquil till the assemblage is allowed to disperse in the usual way. On no account yield to alarm. Granting that there is a real cause of danger, you are infinitely more safe sitting still than trying to rush wildly to the door.

Attacks of madmen.—A person in a house may become suddenly insane, and make a violent and deadly attack on those within reach. The best way to avert any serious calamity in cases of such attack is to remain calm and collected, and, if necessary, humour the madman till assistance be procured. A lady of our acquaintance kept a boarding-house; and one day a boarder entered the room in which she was sitting, armed with a carving knife, and with great coolness said he had taken a fancy to cut off her head. The lady was alone. She saw her extreme danger, but did not scream or appear alarmed, for that would have precipitated the catastrophe. She humoured the madman, and proposed that she should go and fetch a cloth to lay on the floor, so as to prevent the blood from damaging the carpet. This bait took, and she got safely out of the room, and into her bed-chamber, in which there was a key in the door in the inside. She instantly locked the door, and flying to the window, cried for help to the passengers in the street. The madman was speedily secured. This lady clearly owed her life to presence of mind.

We would add, *let every door in a house have its key*, and let the key remain in it both night and day. Every night, on going to bed, isolate each room, by locking it, and lock your own door in the inside. Always look beneath the bed and into any cupboards in the room before going to rest.

USEFUL ADVICES AND RECEIPTS.

Under this head we propose to offer a few advices connected with housekeeping, and certain operations in reference to the cleaning of dwellings, furniture, apparel, extirpation of vermin, removal of stains, &c.

HOUSE FURNISHING AND MANAGING.

Choice of a house.—There are certain important points on which you should obtain satisfactory information in making choice of a house. First, take care that it is not damp. Dampness may arise from several causes, but imperfect drainage, and a too close contact of the floors with the ground, are the principal. When a house is damp in any part, no matter from what cause, we advise you by all means to avoid it, for it may produce the most pernicious effects on the health of your family. Second, see that the house has a free open exposure for fresh air, and, if all other circumstances suit, prefer that which has an exposure to the south, and possesses the beneficial influence of the sun's rays. A house with a pleasant southern exposure enjoys a climate several degrees warmer than a house which is not so favourably situated. In general, too little attention is paid to this circumstance. Third, ascertain if there be a plentiful supply of good water in the premises, and if there be proper means at hand for drying and bleaching clothes. Fourth, learn whether the vents go well, and do not smoke. The inquiries you may make in reference to freedom from vermin and other particulars are left to your own judgment.

Furnishing.—When you design to furnish a house, take care to set out on a right principle in the selection of articles. It is essential, for the sake of neatness, and for pleasing effect to the eye, that there should be a harmony of colours, and also a similarity of style in the main articles of furniture. Therefore, if you do not exercise a little taste and judgment in your *first* selections, you may find that you have committed a blunder which will cost you much subsequent annoyance. For example, let the tints of the carpet, of the paper or paint of the walls, and of the window curtains, be all in harmony in each room—that is, either possess a general resemblance of colour, or various colours in pleasing contrast and harmony with each other. If the colour of your curtains be scarlet, and the colour of your walls or carpet blue, a most inharmonious and unpleasing effect will be produced; but brown and green, or green and gold, will be in harmony, and may therefore be placed together. Carpets being the most expensive articles, it is safest to buy them first, and then to let their colour lead the tone and style of curtains, paper-hangings, chair-covers, hearth-rugs, and all other articles. It is also a good economical plan to buy carpets for the same pattern for several rooms, because, in the event of removal to a house with different sized apartments, a piece of one carpet may be taken to eke out another.

Tables, chairs, &c.—When you are bargaining for tables, chairs, and other wooden articles of a fine quality, take care to specify that they must be of a solid fabric, and not veneered. Veneering is only tolerable in a few articles which are not to be subjected to much tear and wear; nevertheless, a practice has begun of veneering articles in daily use, such as chairs and tables, and consequently they are soon destroyed. This practice, we are sorry to say, is done in cases where the highest price is paid for solid articles, and we mention the circumstance to put you on your guard. Examine closely the back and seat-frames of every mahogany chair, and reject it if it be veneered. In ordering sofas, you should also take care to bargain for genuine hair stuffing, for in many instances the stuffing is composed of what is technically called *pob*, or a composition of tow, wool, and other kinds of rubbish. Likewise, the hair should be well baked or prepared. We have seen a hair sofa, for which the highest price was paid, swarming with a species of louse, shortly after being sent home from the upholsterer's, in consequence of the animal substance about the hair not having been properly dried by baking.

Earthenware and China.—In purchasing sets of earthenware articles for the table, also take care to set out on a right plan. Select that set which, in case of breakage, can at all times and in all places be easily matched. If you buy a set of table ware which is peculiar or rare in its pattern, and afterwards break several pieces, you may be put to a very great degree of trouble, or even find it impossible, to restore them. Thus, a peculiar set of earthenware or china, however beautiful and cheap, may ultimately prove a source of vexation and considerable expense.

Plate.—Whatever silver articles you require, buy them of a genuine kind, or of sterling silver plate, which always keeps its value, however old and worn it may become. Avoid all plated goods, for the plaiting is not long in wearing off, and then the article is valueless. A tarnished plate fork, spoon, or salver, has an excessively mean appearance. If you find it inconvenient to purchase sterling silver plate, your most economical plan, consistent with elegance of appearance, will be to purchase a few articles of German silver. This is properly the metal called *nickel*, and closely resembles sterling silver in texture and colour: it is not just so white as sterling silver, but the difference is not noticed unless a close comparison be made. In hardness and durability, it is much superior to sterling silver, and its price is in some cases only about a tenth of what genuine plate would cost. German silver is now manufactured to a large extent in England, and is made into spoons, forks, ladles, tea-pots, salvers, dish-covers, and all other articles for the table. It is not probable that German silver will ever be purchased to a large extent in order to supersede the sterling article, because it possesses no intrinsic value like bullion, but it forms a great stretch in advance of plated or Britannia metal goods, and is likely to come into extensive use. The articles in Britannia metal were once of a durable fabric, but they are so no longer; their good character is gone, and they should on no account be purchased by an economical house-wife. A tea-pot, for instance, of that metal, for common use, and costing seven or eight shillings, will probably not last twelve months, while a tea-pot of German silver, costing about three pounds, will last for fifty years. Thus the German silver article is by far the cheaper of the two, independent of all considerations as to elegance of appearance.

Fire-grates.—In choosing fire-grates or stoves for your rooms, do not buy those which have burnished steel fronts, as they require a considerable degree of care in cleaning, and are very liable to rust during summer when not in use. The best and neatest, as well as the cheapest, grates, are those which are made of cast-iron, and of an ornamental pattern. Let the grates which you select be small or of moderate size in the fireplace. Wide, open grates, by admitting cold air into the chimney, are exceedingly liable to smoke.

Gilding.—Order all the gilding of your picture frames and other articles to be done in oil. Oil gilding is not susceptible of flatting and burnishing like water-gilding, but it is infinitely more durable. You may wash an oil-gilt frame without injuring it, whereas one that is water-gilt cannot be cleaned, and is soon tarnished. We never knew a gilder who would gild in oil unless it was expressly insisted upon.

Baths and foot warmers.—Few houses possess the convenience of baths, but every one may command the use of small movable bathing vessels for the feet, or for infants. The best kind of foot and leg bath is a deep wooden pail; those of earthenware are exceedingly liable to break, and, besides, are very expensive. There are various kinds of close vessels for holding warm water, which are used for producing warmth in bed. The best article of this nature which we have seen is a vessel made of sheet tin. It measures twelve inches in length and six inches in diameter, being round like a bottle, with bulged out rounded ends. At one end there is a small brass screw cap, placed over an orifice at which the water is admitted. This cap being well screwed down, and a small leather washer being used to assist in the tightening, not a drop of water will ooze out when the vessel is laid in bed. With this simple apparatus, tied in a flannel bag, the feet or any part of the body will be effectually warmed, either during illness or in the cold of winter.

Housekeeping.—Every good housewife is expected to keep a regular and continuous account of her income and expenditure. This is, indeed, perhaps the most essential in the routine of domestic duties, and she must possess an ill-regulated mind, or have had an insufficient education, who neglects it. When properly set about and methodically managed, there is little or no trouble in keeping the household accounts. Some housewives have one method, and some have another. Always presuming that we are addressing young housewives in the middle ranks of society, with whom frugality is an object, we beg to suggest the following simple plan of keeping house accounts:—Procure a small slate-book—that is, a little book composed of three slates, bound in a plain cover. This, which you write upon with a slate pencil, is your *day-book*; it is always at hand for you to scroll down any note of outlay, and will keep several days' or a week's accounts at a time. At any leisure moment, you carry the entries of outlay from the slates to a small ruled paper book, which is your *ledger*. One page of this is devoted to money received, and the opposite page to money paid out. By doing this regularly, and comparing the entries of sums received with the entries of sums expended, so as to see that they square with each other, you will find that you possess a complete record of family expenses, satisfactorily alike to yourself and to your husband, should he make any inquiry into the subject. The keeping of an account of receipts and disbursements, in this or any other convenient manner, is calculated to have the most salutary and agreeable effects. The tendency to over-expenditure, or living beyond the means, is constantly checked, or at least you are not deceived upon the subject, and in all likelihood much future distress in circumstances is avoided.

In referring to housekeeping accounts, we must put you on your guard against the very mischievous practice of buying on credit, and running up bills with tradesmen. If you can at all avoid taking credit, do so. By paying for every article with ready money, you will possess two decided advantages—you get every thing cheaper as you want it, and you can go anywhere to seek out the best markets. Housewives who run up bills become the slaves of tradesmen, and can possess no proper independence of principle or self-respect.

Servants.—The old practice of hiring domestic servants for six months at once is rapidly declining. Both mistresses and servants find, by experience, that a bargain for such a length of time very often produces disagreements. It is best for all parties that the term hired for should be only one month at a time, with one month's notice for separation. By this plan, a servant can leave a place which does not please her without any lengthened delay; and in the same way a mistress can give a servant warning to quit at a short notice, should it be found that she is unsuitable. In this manner there is no vexatious obligation to keep together, and a separation can always take place amicably. All servants and mistresses who try this plan, find it so agreeable that they never like to change it. Many servants remain years in a place, though hired on the understanding that it is only from month to month, or, what is the same thing, hired for no fixed period, but just so long as both parties agree; and that, in the event of any dissatisfaction, there shall be a week or a month's warning given to leave. This practice has been long common in London, and the sooner it is universal the better.

It is a very old remark, that good mistresses make good servants; and though not strictly correct in all instances, there is, on the whole, much truth in it. A good mistress endeavours to seek out and attach a good servant to herself. She effects this attachment and good-will by simply laying before the servant what is to be her line of duties, or what is expected of her, and then leaving her undisturbed to execute these duties in a regular methodic manner. No servant likes to be interfered with in her work, or to be called away from one thing to do another; nevertheless, some mistresses are not happy unless they are going in and out of the kitchen, or bustling up and down the house, ordering and counter-ordering, or in some other way worrying the servant out of all patient endurance. Mistresses of this fidgetty turn can hardly expect to keep good servants, should they be so fortunate as to procure them. We advise the young housewife to commence on the wise plan of prescribing to her servants, in simple plain terms, the duties which she expects they will daily and regularly execute; and if the servants are unfit to take advantage of this friendly and liberal arrangement, and require to be continually urged and "spoken to," it is better for both that there should be a separation. Where two or more servants are engaged, it is absolutely necessary that the precise duties of each should be expressly defined, in order to prevent disputes between them, and that the work of the house may be duly performed.

CLEANING

The best way to clean a house is to *keep it clean* by a daily attention to small things, and not allow it to get into such a state of dirtiness and disorder as to require great and periodical cleanings. Some mistresses, and also some servants, seem to have an idea that a house should undergo "regular cleanings," or great washing and scrubbing matches, once every three or six months, on which occasions the house is turned almost inside out, and made most uncomfortable. All this is bad economy, and indicates general slovenliness of habits.

Wooden floors, if kept in order by daily sweeping and other small attentions, may be effectually cleaned by washing them with warm water and soap; but if spots of grease are to be removed, the spots must previously be taken out with fuller's earth. Ink spots may be discharged with spirits of salt. Some mistresses make a practice of ordering the floors of bed-rooms to be frequently washed. We wish to guard both mistresses and servants against this practice. It is most dangerous to the health of the person who occupies the bed-room to wash or scour it, unless the weather be very fine or warm, in order to allow the window to be opened for thoroughly drying the room before night. The utmost that should be done, except in favourable circumstances, is to pass a damp mop lightly over the floor.

Carpets.—Ordinary Kidderminster carpets can only be cleaned by shaking and beating; if cleaned by means of washing, they become so soft as to be speedily dirtied again, and their appearance is spoiled. Brussels carpets may be cleaned as follows:—Take them up and shake and beat them, so as to render them perfectly free from dust. Have the floor thoroughly scoured and dry, and nail the carpet firmly down upon it. Take a pailful of clean cold spring water, and put into it about three gills of oxgall. Take another pail with clean cold water only. Now, rub with a soft scrubbing brush some of the oxgall water on the carpet, which will raise a lather When a convenient sized portion is done, wash the lather off with a clean linen cloth dipped in the clean water. Let this water be changed frequently. When all the lather has disappeared, rub the part with a clean dry cloth. After all is done, open the window to allow the carpet to dry. A carpet treated in this manner will be greatly refreshed in colour, particularly the greens. It is very advisable, in laying down carpets at first, to cover the floor beneath them with large sheets of paper, so as to prevent dust from rising between the boards. A carpet lasts longer by adopting this precaution.

Oil-Cloths.—Oil or painted cloth should be laid only on dry floors; if the floor be in the least degree damp, the cloth will soon mildew and rot. Such cloths, laid even in the driest situation, should be wetted as little as possible. When to be cleaned, they should be wiped with a wet cloth, and rubbed gently till dry.

Marble hearths and chimney-pieces may be cleaned as follows:—Mix a gill of soap-lees, half a gill of turpentine, and a bullock's gall, and make them into a paste with pipe-clay, which lay upon the marble, and let it remain a day or two, then rub it off, and the stains will have disappeared, unless they are of long standing, when the paste must be again applied. Polished marble requires careful treatment, as any acid will destroy the polish. In general, warm water and soap will be found the safest thing for cleaning chimney-pieces.

Walls of houses.—The outer surfaces of walls, formed of brick or sandstone, sometimes imbibe moisture from the atmosphere, and this gives a dampness to the interior. If it be found unsuitable to plaster and whitewash the outside, the damp may be greatly prevented by painting the walls with a single coat of oil-paint, which, by being light in colour, will give a neat and clean effect.

Walls of rooms.—When walls of rooms or staircases are to be painted in oil, let the paint be of the best description. It is not unusual for inferior tradesmen to use whiting, instead of white lead, as a pigment: by this deception the paint will afterwards scarcely endure washing. Supposing, however, that the paint has been of the best kind, considerable care will be required in cleaning it. The safest and most simple plan is to take a pail of hot water and put into it as much common yellow or soft soap as will raise a lather or froth. Now wash the walls with a flannel cloth dipped in this water; then wash this soapy water off with clean flannel and clean warm water. Dry with a clean linen cloth. Do all this equally, so as not to leave smears or parts better washed or wiped than others.

Paper-hanging should be first dusted, and then cleaned by a stale loaf of bread, with the crumb surface cut smoothly, and gently rubbed, the dirty face of the bread being cut away from time to time. The imitative marble-paper, highly varnished, may be washed with cold water and soap. *Papier-mâché*, now much used for mouldings and ornaments in rooms, may be cleaned with soap and water.

Picture-frames of varnished or French-polished wood may be washed with soap and warm water, and sponge or flannel. As already mentioned, frames which are gilt in the ordinary manner, or "water-gilt," cannot endure washing or rubbing; but if "oil-gilt," they may be washed with cold water and a soft brush.

Ivory may be restored to its original whiteness by cleaning it with a paste of burnt pumice-stone and water, and then placing it under glasses in the sun's rays.

Brass inlaid work is best cleaned as follows:—Mix tripoli and linseed oil, and dip into a rubber of hat, with which polish the work. If the wood be ebony or rosewood, polish it with a little finely-powdered elder-ashes; or make a paste of rotten-stone, a little starch, sweet-oil, and oxalic acid, mixed with water. The ornaments of a French clock are, however, best cleaned with bread-crumb, carefully rubbed, so as not to spoil the wood-work. Ormolu candlesticks, lamps, and branches, may be cleaned with soap and water. They will bear more cleaning than lacquered articles, which are spoiled by frequent rubbing, or by acids, or strong alkalies.

Windows and looking-glasses.—Dip a moistened rag or flannel into indigo, fuller's earth, ashes, or rotten-stone, in impalpable powder, with which smear the glass, and wipe off with a dry soft cloth. Powder-blue or whitening, tied up in muslin, and dusted upon the glass, and cleaned off with chamois leather, also gives glass a fine polish. The spots in the silvering of old looking-glasses are caused by damp at the back. The Vauxhall plates are no longer prized, for the glass made in the present day is *whiter* and better. Window-panes may be made to resemble ground glass by daubing them with putty, or a brush with a little thin paste.

Brass and copper are best cleaned with sweet oil and tripoli, powdered bath-brick, rotten-stone, or red brick-dust, rubbed on with flannel and polished with leather. A strong solution of oxalic acid in water gives brass a fine colour. Vitriol and spirits of salts soon make brass and copper very bright, but they very soon tarnish, and consequently require more frequent cleaning. A strong ley of roche-alum and water will also improve brass.

Stove-grates are cleaned with black-lead mixed with turpentine, or with stale beer and yellow soap, and polished off. The finer lead is used dry, in lump or powder. The bronzed work of stoves should be only lightly brushed. Rottenstone, or fine emery and sweet oil, is used for the bright work of stoves and polished fire-irons; the higher the latter are polished, the less likely are they to rust. To prevent rust in articles not often used, rub them with sweet oil, and dust over them fine lime; or with the following mixture:—To a quart of cold water add half a pound of quicklime; let it stand until the top is clear, when pour off the liquid and stir up with it some olive oil, until it becomes of a pasty consistence, when it should be rubbed on the metal articles to be preserved. To fill cracks in stove-backs, make a paste of wood-ashes, salt and water. To remove rust, mix tripoli, sulphur, and sweet oil, and clean the articles with it; or mix boiled soft soap with emery No. 3, which will also discharge the fire marks from bright bars. Steel-work may also be kept from rust by varnishing it with turpentine in which is dissolved a small proportion of India rubber (caoutchouc). Polished fire-irons may be best preserved from rust by being closely wrapped up in strong brown paper.

Kitchen vessels.—The crust on boilers and kettles, arising from the hard water boiled in them, may be prevented by keeping in the vessel a marble, or a potato tied in a piece of linen. Tin plate vessels are cleanly and convenient, but unless dried after washing, will soon rust in holes. Iron coal-scopes are liable to rust from the damp of the coals. The tinning of copper saucepans must be kept perfectly clean and dry, in which case they may be used with safety. Copper pans, if put away damp, or a boiling-copper, if left wet, will become coated with poisonous crust, or verdigris. Untinned copper or brass vessels, even if scoured bright and clean, are always dangerous. If made dishes be allowed to cool and stand for some time in copper vessels, the articles will become poisonous. In the year 1837, a lady and her family, residing in Paris, were poisoned by partaking of a stew which had been allowed to stand and get cold in a copper pan. A German saucepan is best for boiling milk in. This is an iron saucepan, glazed with white earthenware instead of being tinned, the glaze preventing its tendency to burn. A stewpan made like it is also preferable to a copper pan, since simple washing keeps it sweet and clean. A method of glazing saucepans with earthenware has lately been the object of a patent in England. Zinc sieves are more easily kept clean than those made of hair, will last longer, and not rust.

Dish-covers are cleaned with fine whitening and sweet oil, and polished with dry whitening powder. Britannia metal teapots, &c., should be rubbed with sweet oil on flannel, then polished by the hand with rottenstone, and next washed with soap and hot water, and finished with wash-leather and whitening powder. Pewter is scoured with fine white sand and a ley made with wood-ashes, or soda and water.

Knives are best cleaned by rubbing on a flat board, on which is put finely powdered brick-dust. Some recommend leather to be put on the board; this may prevent the knives from wearing, but it deprives them of an edge fit for cutting. Never put knives in hot water, for that loosens the handles and spoils the temper of the steel. For simple cleaning after use, wipe them only with a damp and then with a dry cloth.

Lamps.—When lamps are foul inside, they should be cleaned with hot water and pearl-ashes, and well rinsed and set by the fire to dry before the oil is again put in. Spirit-lamps should be filled with great care, lest the spirits take fire; and unless the spirits of wine be pure, it will not burn. Naphtha, which is burnt in some lamps, is so inflammable as to be dangerous to use.

Lamp-glasses.—If the lamp-glasses be ground, burnt spots upon them cannot be removed, but they may be cleaned from the effects of smoke by washing with soap and water, and then rubbing with a dry cloth. The glasses should always be ground on the outside.

Furniture.—Mahogany furniture is always best cleaned by continual rubbing; and no ordinary stuff that may be applied will compensate the want of this requisite. Some furniture is what is called "French polished;" but this French polish is an unguent possessed and applied only by cabinet-makers, and cannot readily be had by housekeepers. In ordinary circumstances, therefore, the furniture must be well rubbed, and with some easily-procurable material. The following are the materials we suggest:—Take a gill and a half of unboiled linseed oil, one gill of turpentine, and a teaspoonful of pounded loaf-sugar. Shake all well together, and rub a portion on the furniture with a piece of flannel, and polish with a linen cloth.

An oil for darkening furniture may be made as follows: —Mix in one pint of linseed oil an ounce of powdered rose-pink, to which add one ounce of alkanet root, beaten in a metal mortar; let the mixture stand in a warm place for a few days, when the substances will have settled, and the oil, of a deep rich colour, may be poured off for use: or mix one ounce of alkanet root, four ounces of shell-lac varnish, two ounces of turpentine, and the same quantity of scraped bees'-wax, with a pint of linseed oil; and when they have stood a week, the mixture will be ready for use.

Furniture paste is made by scraping a quarter of a pound of bees'-wax into half a pint of turpentine, and letting it stand to dissolve. This will keep the wood light. If, however, a quarter of a pint of linseed oil be added to the above, the composition will darken the wood. Another paste, useful for very light wood, is made as follows:—In a quart of hot water dissolve six ounces of pearl-ash, add a quarter of a pound of white wax, and simmer the whole for half an hour in a pipkin; take it off the fire, and when it has cooled, the wax will float upon the surface, and should be worked in a mortar, with a little hot water, into a soft paste. With this, furniture may be highly polished, as may also marble chimney-pieces. It is necessary to mention, that furniture cleaned with paste has the disadvantage of receiving heat-marks more readily than if polished with linseed oil, which, however, requires more time and labour. In any case, the furniture should be cleansed from grease and stains before polishing is attempted; and this may be done by washing the wood with hot beer, or with soap and water. The safest way to heat furniture paste or oil is to place the vessel containing it in another holding boiling water upon the fire.

A fine varnish for mahogany or other furniture may be thus made:—Put into a bottle two ounces of gum-sandrac, one ounce of shell-lac, half an ounce of mastic, half an ounce of gum-benjamin, one ounce of Venice turpentine, and a pint of spirits of wine. Colour red with dragon's blood, or yellow with saffron. Let it stand in a warm place until the gums are dissolved, when strain it for use.

Varnishing.—Before new furniture is varnished, it should have a coat of boiled oil (if wished to be darkened) or linseed oil, and be left a day or two to harden; or a thin size, made from isinglass or gum-tragacanth, dissolved in water, or very thin glue, is used; so that the pores of the wood be filled up, and both varnish and time be thus saved. A good varnish may be made by dissolving eight ounces of white wax and half an ounce of yellow rosin in a pint of spirits of turpentine.

Bottles.—Cut a raw potato into small pieces, and put them in the bottle along with a table-spoonful of salt, and two table-spoonfuls of water. Shake all well together in the bottle till every mark is removed, and rinse with clean water. This will remove stains of wine, green marks of vegetation, and other discolourations. Hard crust in bottles may be cleaned off by rincing with water and small shot. Take care to wash out all the shot before putting the bottles aside.

Plate.—Articles of plate, after being used, should be washed in hot water, or, if stained, they should be boiled, and rinsed and dried before you attempt to clean them. They should be carefully handled, else they may receive deep scratches, which are very difficult to remove. Besides, the object is not merely to clean the plate, but to polish it, so that it may appear almost as brilliant as when it was received new from the silversmith. For this purpose quicksilver was formerly much used in plate-powder, and it gives the silver great lustre, which soon, however, disappeared, and the article became tarnished and blackened.

The best plate-powder consists of dried and finely sifted whiting or chalk. The greater part of the whiting sold in the shops is coarse trash, unfit for rubbing upon plate, and great care must be taken to procure the finest London whiting, which will not scratch.

Brushes, hard and soft, sponge, and wash-leather, are requisite for cleaning plate; if the powder be mixed with spirits of wine laid on with a sponge, and rubbed off with wash-leather, all tarnish will be removed. Salt stains (blackish spots) and sulphur marks from eggs are more difficult to remove. It is a good plan to boil a soft fine old cloth in water with some prepared chalk dissolved in it, and to dry the cloth, and use it for polishing The soft brush is for the same purpose, the hard brush being for chased work, edges, and crests, so that no a portion of dry powder may remain in them. Plate should in all cases be finished with a fine dry wash leather.

Plated articles should be carefully wiped dry after washing them, else they will rust or canker at the edges, where the silver first wears off; and on this account, also, they should be cleaned as rarely as possible. German silver may be cleaned in the same manner as plate.

Embroidery and gold lace should be cleaned only with spirits of wine, or brushed with finely-powdered roche-alum and chalk. For gold chains, dissolve three ounces of sal-ammoniac in six ounces of water, in which boil the chain; then boil it in soft soap and water, wash it in cold water, rub it dry with flannel, and shake it in a bag with very dry bran.

Flannel or woollen articles.—Wash them quickly in warm water, with soap. Wring and shake them well, and hang them up to dry. Do not let them lie wet. The more quickly they are dried, the less likely are they to shrink.

Silks.—No silks look well after washing, however carefully it be done, and should therefore never be resorted to but from absolute necessity. We have seen it recommended to sponge faded silks with warm water and soap, then to rub them with a dry cloth on a flat board, after which to iron them on the inside with a smoothing iron. Sponging with spirits will also improve old black silks The ironing may be done on the right side, with thin paper spread over them to prevent glazing.

Bed feathers.—Put a manageable quantity into a pillow case or bag, which wash with warm water and soap Wring out the lather, and rinse them in clean water Wring them as dry as possible, and hang them up to dry Shake them frequently while drying. When quite dry beat them to free them from any dust. They may be now taken from the bag, and are ready for use.

Lace.—When lace has lost its colour, soap it well and put it in cold water, just enough to cover it. If much discoloured, change the water at the end of twenty-four hours. When steeped sufficiently, rinse it out; starch it a little; pick it out as evenly as possible; roll it in a towel, and when nearly dry, iron it. All kinds of lace veils may be treated in a similar manner.

Scarlet cloth.—Pour boiling water upon bran, strain it, and, while hot, wash the cloth in it, and rinse with hot water. Soap should not be used. Purple cloth may be washed in hot water and pure ley. Saxony or dark print dresses should be washed in two lathers, and in the second should be poured a little ox-gall, which will freshen reds, blacks, and greens; and a handful of salt added to the last rinsing-water will prevent the colours running.

Clear starching is practised as follows:—Rinse the articles in three waters, dry them, and dip them in a thick starch, previously strained through muslin; squeeze them, shake them gently, and again hang them up to dry; and when dry, dip them twice or thrice in clear water, squeeze them, spread them on a linen cloth, roll them up in it, and let them lie an hour before ironing them. Some persons put sugar into the starch to prevent it sticking while ironing, and others stir the starch with a candle to effect the same end; we object to these practices as injurious to the article starched, or as very nauseous. The best plan to prevent sticking is to make the starch well, and to have the irons quite clean and highly polished.

Stains.—Stains of fruit or wine may be generally removed from linen or cotton cloth by placing the articles over the top of a pail, and pouring boiling water through them till the marks disappear.

Ink marks or *iron moulds* may be removed by placing a plate (a pewter one is the best) on the top of a basinful of boiling water; then spread the articles on the plate; wet the spot, and rub it with a small quantity of the salts of lemon; as the article dries, the stain will disappear. If this fail, repeat the operation. A small box of salts of lemon will be found very useful in a household.

Paint or grease spots may be removed from woollen cloth by turpentine. Smith's scouring drops is a liquid sold in small bottles, which will also be found efficacious in removing oil or grease marks; it is more expensive than turpentine, but has a less offensive odour.

To extract grease from silk.—As soon after the discovery of the injury as possible, hold the part firmly, and with a clean soft white cloth, or an old cambric handkerchief, rub the spot briskly, changing the portions of the handkerchief frequently, and in a minute or two the spot will disappear. On silks which fray easily, this plan will be unsuitable.

MISCELLANEOUS.

To remove a tight stopper.—It frequently happens that the stopper of a glass bottle or decanter becomes fixed in its place so firmly, that the exertion of force sufficient to withdraw it would endanger the vessel. In this case, if a cloth be wetted with hot water, and applied to the neck of the bottle, the glass will expand, and the neck will be enlarged, so as to allow the stopper to be easily withdrawn.

Economical fuel.—In places where coal is scarce and dear, a tolerably good fuel may be made by mixing the culm or refuse dross of coal with clay, and moistening the whole with water—masses in the form of bricks or balls may be made, which, when dry, will burn with an intense heat. Where peat prevails, that article may be easily charred by burning in a covered pit or stove; and this charred peat will be found to give a great heat when used in an open fire. The Dutch make much use of their turf in this manner. Another economical fuel easily procurable where there are woods of Scotch firs consists of fir cones or tops, which contain a great quantity of solid woody matter in addition to the resinous, and are excellently adapted for domestic fires.

To light a fire, clear the ashes from the grate, leaving a few cinders for a foundation, upon which put a piece of dry crumpled brown paper, and lay on a few small sticks crosswise, then some of larger size, and on them a few pieces of coal, and next the large cinders; and when the flames have caught the coal, add a backing of small coal and cinders. When the fire has become low, stir it together, but do not turn the large cinders; clear the front of the lower bar to admit air, and pass the poker into the bottom of the fire to clear it of ashes; and then with tongs put on a few large pieces of coal towards the front of the fire, but not on the upper bar, else the fire will smoke. Coals should not be thrown on, but put on gently with a scoop or shovel; and even the smallest ashes may be burnt at the back of the fire, if they be covered with small coal. The best and quickest mode of restoring a neglected fire is to stir out the ashes, and with the tongs to fill up the spaces between the bars with cinders. If carefully done, it is surprising how soon this process will produce a glowing fire.

Ashes and small cinders mixed with water into a mass, and put on the back of a fire with a few coals, burn well, so that ashes may thus be entirely burnt up. In stoves under boilers, this mixture is very useful, as it lasts long with little addition.

Smoky chimneys.—The causes of smokiness in chimneys are various; but all are connected with the properties of air and heat, for the smoke is only particles of culm ascending through the agency of heated air. To make a chimney vent well, the column of heated air from the fire must not be entangled with cold air from beneath, nor retarded by cold air coming down the chimney. To effect these objects, the fireplace must not be much larger than the grate, and the chimney must be of a certain length and bend. The great leading cause of smokiness is cold air somehow or other mixing with the warm air about the mouth or throat of the chimney, and so causing a sluggishness in the ascent, or no ascent at all. Therefore, the nearer the air is made to pass the fire on all sides, the more rarefied it will be; and the less vacancy there is in the chimney-place, it will ascend with the greater rapidity. A proper contraction of the mouth of the chimney, at the same time allowing the fire to be fed freely with air, will be found in most instances to cure smoke. Of late, certain contrivances called dampers, by which the chimney throat can be narrowed, have been the means of effecting draughts, and so curing smoke. It should be noted, that in contracting chimney throats, the contraction should not be all at once, but at first gradual, and then straight upward, so as not to allow a volume of cold air to lurk in a hollow above. A chimney being wide at bottom, and gradually narrowing towards the next story, allows the coldish air to hang about the lower parts, by which, when a gust of wind comes, the smoke is driven back into the room. This kind of smokiness is the most teasing of all the forms of chimney diseases. Every little puff of wind sends a smaller or larger quantity of smoke into the apartment, and often when it is least expected. Perhaps this kind of smokiness is not in all cases caused by wrong construction, but arises from the situation of the house; and of this we shall immediately say a few words.

If a funnel of a chimney be made too narrow to afford an easy passage to the top, the smoke will then naturally be forced into the room to find some other passage; this defect is very common, and the remedy troublesome and difficult. The most effectual cure, if the situation will admit, is to build a small additional flue, and open a hole into it from the back of the chimney, near the level of the mantel-piece, slanting upwards in an easy direction; this supplemental flue must be carried to the top of the building to receive the surplus of the smoke, and will prove a certain cure. If the situation will not allow of this expedient, the fireplace may be contracted both in breadth and height, a smaller grate used, and the chimney heightened at the top; which will oblige the air to pass close over the fire, and carry up the smoke with greater rapidity, for the quicker the current, the less room it requires. Should the chimney still smoke, a blower, or front plate, to put on and take off at pleasure, will be of use. But if none of these prescriptions answer, then something must be done to improve the current of air towards the fire. This brings us to a consideration of the want of ventilation in the room.

If the chimney and fireplace be faultless, and yet smoke, it is almost certain that there is a want of ventilation. In ordinary circumstances, as much air is admitted by chinks in windows and doors as will feed a fire; but if the room be rendered very close by closing as many chinks as possible, how is the fire to receive air? According to the plan on which houses are generally built, ventilation is left to be a matter of chance. To ventilate an old house is therefore no easy task. The following plans are worth considering, for they have been found to answer:—Contrive to bring a small tube from the external air, or from a staircase or lobby, to a point beneath the grate, so as to cause a free current of air to reach the fire. If the mouth of the tube below the grate be topped with a cowl, the ashes will be prevented from falling into it. Some years ago, the rooms of a public office in Edinburgh were completely cured of smoke by this simple contrivance, after all other means had failed. Another plan consists in perforating small holes in the cornice or roof, for the air to gain admission, but, unfortunately, unless care be taken to prevent draughts, the cure is apt to be worse than the disease.

Cases are by no means uncommon of fire-places giving out a puff of smoke every time the door of the room is shut. The cause of this kind of smokiness is the want of ventilation in the room. In shutting the door, it pulls out a certain quantity of air, which cannot be afforded to be lost, or it causes such distraction of the current towards the fire, that the equilibrium that carries up the smoke is destroyed, and a puff downwards—in other words, a rush of air loaded with smoke from the chimney—is the consequence. It will be remarked, that this smokiness occurs most frequently when the door is on the same side of the room as the fireplace. We would therefore advise house-planners to avoid this bad arrangement. If possible, let the door be on a different side from that in which the fire is placed. Most houses in which the chimneys go up the middle walls instead of the gables, have the fault we mention. A remedy for this smokiness is to contract the mouth of the chimney, and, if possible, heighten the stalk; for if the chimney be pretty long, the heated air ascending it goes with such a force that the outer heavy air cannot get down, at least not to so great an extent as to cause a puff when the door is shutting. In some cases, the cause of the disease will be found to be air rushing up behind the grate, if a register, and then coming down to supply the fire, the action of the door disturbing the current. This is therefore an argument for always taking care to build register stoves quite close behind, not leaving the smallest crevice for air to steal up the chimney without first going through the fire.

In erecting chimneys, it should be a rule to carry them up a good way in a perpendicular direction, before making a turn, by which means the heated air gains a force in its primary vertical ascent, which carries it over future difficulties. In walls in which the fireplace of one story is immediately below the fireplace above, it is impossible to get a perfect straight for any great length; therefore this must be left to the judgment of the builder. It is also advantageous for all chimneys to have a bend in them before reaching the top, and a garret chimney should have two bends. For want of attention to this top bending, many cottage and small villa chimneys smoke. The use of bends is obvious. Strong, sudden, and accidental gusts of wind sometimes enter, and beat into the top of the chimney; a turning or bend, therefore, will break the force of the wind, and prevent it repelling the heated air downwards. But if the chimney is straight, and the gust meet with no interruption, it will stop the passage of the smoke for a while, and of course force what rises from the fire immediately into the chamber. It is to be observed, that the farther the wind gets down the funnel the greater strength will be required to repel it; therefore the nearer to the top the bend or winding is, the better. Also, if there is a storm of wind, with heavy showers of hail, snow, or rain, falling perpendicularly in great drops, the first bend of turning will, in part, stop their progress; but if the funnel is perpendicular all the way down, the great drops of hail, snow, and rain, will fall freely to the bottom, repelling the smoke into the room; and if the funnel is foul, great quantities of soot will be driven down. These reasons recommend a bend in some part of the funnel as absolutely necessary.

Garret chimneys are more liable to smoke than any other in the house, owing to the shortness of the funnel: for when the composition of rarefied air and smoke has made its way up a high funnel, it forms a strong column, and to repel it requires a proportionably great force; but in a garret chimney this strong column cannot be obtained; therefore, what cannot be had from nature must be aimed at by art. The fault in most garret chimneys is being carried up in a straight direction from bottom to top in a slovenly manner, and with funnels as large as any in the house; whereby the little internal rarefied air has the whole immediate pressure of the atmosphere to resist, which, in general, is too powerful for it. But a garret or cottage chimney carried up and executed in a proper manner, with due proportion in every part, according to the size of the room, and the funnel in an easy crooked direction, will draw and be as clear from smoke as any other.

When smokiness is produced by too short a chimney, it will be necessary to add to its length either by building the stalk higher, or inserting an earthenware pot or iron tube at the summit. The building of higher stalks is an infallible remedy, provided all be right below, but it is attended with danger to adjoining roofs. Pots or cans are useful both in adding to height and in causing a free disengagement and shooting of the smoke as soon as it enters the outer atmosphere.

Another very common cause of smokiness is fires overpowering one another. For instance, if there be two chimneys in one large room, and you make fires in both of them, the doors and windows close shut, you will find that the greater and stronger fire shall overpower the weaker, and draw air down its funnel to supply its own demand; which air descending in the weaker funnel, will drive down its smoke, and force it into the room. If, instead of being in one room, the two chimneys are in two different rooms, communicating by a door, the case is the same whenever that door is open. In a very tight house, it has been known that a kitchen chimney on the lowest floor, when it had a great fire in it, has overpowered any other chimney in the house, and drawn air and smoke into its room, as often as the door was opened communicating with the staircase. The remedy for this is, to take care that every room in a house has the means of supplying itself with what air it requires, so that it does not need to borrow air from other rooms. Back smoke is only cold air loaded with smoke coming down into a room from an adjoining chimney-top, in order to supply, in the readiest manner, air to that room.

Thus, fires in the lower part of a house will draw air even from a garret room, and this garret room will draw air to supply its deficiency, by taking it in a smoky condition from next house.

Smokiness is also produced when the tops of chimneys are commanded by higher buildings, or by a hill, so that the wind blowing over such eminences falls, like water over a dam, on the tops of chimneys that lie in its way, and beats down the smoke contained in them. Sometimes we have seen the droll phenomenon—though it is no laughing matter—of every particle of smoke all of a sudden pouring into the room, in consequence of a gust of wind blowing pertinaciously for several minutes down the chimney. Such a form of smokiness arises chiefly from the situation of the house, and the want of a bend in the chimney. The remedy to be applied is fixing on the top of the chimney a turning cap or cowl, which acts like a weather-cock, and keeps its closed side to the wind. These cowls, however, are creaking, noisy things; and being hence insufferable near sleeping rooms, are only to be resorted to when more simple means have failed.

Preserving meat.—To preserve meat for a few days fresh in warm weather, wash it lightly over with a brush or sponge, with a mixture composed of two thirds pyroligneous acid, and one third water. The acid, which is a kind of vinegar, gives it no flavour, and the meat requires no washing before being cooked.

Meat may be preserved fresh for any length of time by being put in tin cases secluded from the air. To do this effectually, put the meat in the case; then solder on the top or lid, but leaving in it a small hole the size of a pea; now plunge the case in a vessel full of steam, where let it remain a few minutes, by which the air will be expelled. The case is now to b taken out, and the small hole instantaneously closed by soldering a piece of tin the size of a wafer over it. By means such as this, meat, fish, and soup, may be preserved for years, and when used, they will be found quite fresh.

Salting and smoking meat.—The following method, which requires only forty-eight hours, may be adopted for salting and smoking meat:—A quantity of saltpetre, equal to the common salt that would be required for the meat in the usual way, must be dissolved in water. Into this the meat to be smoked must be put, and kept over a slow fire till all the water is evaporated. It must then be hung up in a thick smoke for twenty-four hours, when it will be found equal in flavour to the best Hamburgh smoked meat that has been kept several weeks in salt, as red throughout, and equally firm.

To purify water, put into a hogshead of it a large table-spoonful of powdered alum, stir it, and in a few hours the impurities will be sent to the bottom. A pailful of four gallons may be purified by a single teaspoonful of alum. Freshly-burnt charcoal is also an excellent sweetener of water.

To filter water.—Put into an earthen vessel (such as sugar-bakers use to form the loaves in, with a small hole at the bottom or pointed end) some pieces of sponge, and on them a sufficient number of small clean pebbles to quarter-fill the vessel. Hang this filter end downward, in a barrel with the head out, leaving a space of about two or three inches between the end of the filter and the bottom of the barrel. The upper part of the filter should be kept a little above the top of the barrel, which must always be kept full of water. The sediment of the water will remain at the bottom of the barrel, and the pure water will rise through the sponge and pebbles to the vacant part of the filter. It may be hung in a cistern, or water-butt if more convenient. The pebbles and sponge should be cleansed occasionally.

Another economical filter may be made by taking out the head of a cask, setting it upright, and at a distance of about one-third from the bottom putting in a shelf or partition pierced with small holes; this shelf being covered with pebbles, upon which is a layer of fresh charcoal made from bones; and over this lay fine sand, to the depth of an inch, covered with another layer of pebbles; and upon this should be placed another shelf, pierced with holes, to prevent the pebbles, sand, and charcoal being disturbed by the water which is poured or runs in at the top of the cask; and after passing through the filter, is drawn off by a crane placed at the bottom of the cask.

Drying flowers as specimens.—A writer in the "New Monthly Belle Assemblée" recommends the following plan:—"As pressure is necessary for drying flowers, the first thing requisite is to construct a press, which in this instance is composed of two of the thickest milled boards, each twenty inches in length and fourteen in width; also two leather straps with buckles, and holes at intervals, to allow for the varying bulk of the press; then procure two quires of coarse sugar paper, which can be purchased at a grocer's. After having selected the most perfect specimens of flowers, with their stems, lower leaves, and roots, when practicable—and carefully observe that the plants be free from dew or moisture—lay every portion out nicely on one of the coarse sheets, being careful, at the same time, that one part of the specimen does not interfere with another: the leaf should be filled. Allow several sheets to intervene before another sheet is occupied by specimens. If the flowers be delicate, their colour will be better preserved by placing blotting-paper between the folds, to absorb the moisture. The plants are now ready to be put into the press, the straps forming the pressure, which, however, must not be great at first. It is necessary to remove the flowers every day, and dry the papers at the fire. When the specimens are quite dry, they should be taken from the press, and each plant separately sewed or fastened with gum on to half sheets of foolscap (a very sufficient substitute for gum will be found in the margins of the penny stamps, when cut into narrow strips); they may then be arranged in their natural orders, with the Linnæan class and order, and their place of growth, appended in the lower corners of the paper. The sheets thus classed make up the Herbarium or *Hortus Siccus*, and are kept in trays, boxes, or in a cabinet constructed for the purpose, in a dry room, when they will be ready for future reference, which is the principal use to be derived from making a collection of plants."

Preserving flowers fresh.—In the "Gardeners' Chronicle," the following appears on this subject:—"It is now eighteen years ago since we first saw, in the drawing-room of a gentleman, in the hot dry weather of the dog-days, flowers preserved day after day in all their freshness by the following simple contrivance:—A flat dish of porcelain had water poured into it. In the water a vase of flowers was set; over the whole a bell-glass was placed with its rim in the water. This was a 'Ward's case' in principle, although different in its construction. The air that surrounded the flowers, being confined beneath the bell-glass, was constantly moist with the water that rose into it in the form of vapour. As fast as the water was condensed, it ran down the sides of the bell-glass back into the dish; and if means had been taken to enclose the water on the outside of the bell-glass, so as to prevent its evaporating into the air of the sitting-room, the atmosphere around the flowers would have remained continually damp. What is the explanation of this? Do the flowers feed on the viewless vapour that surrounds them? Perhaps they do; but the great cause of their preserving their freshness is to be sought in another fact. When flowers are brought into a sitting-room, they fade because of the dryness of the air. The air of a sitting-room is usually something drier than that of the garden, and always much more so than that of a good greenhouse or stove. Flowers, when gathered, are cut off from the supply of moisture collected for them by their roots, and their mutilated stems are far from having so great a power of sucking up fluids as the roots have. If, then, with diminished powers of feeding, they are exposed to augmented perspiration, as is the case in a dry sitting-room, it is evident that the balance of gain on the one hand by the roots, and of loss on the other hand by their whole surface, cannot be maintained. The result can only be their destruction. Now, to place them in a damp atmosphere is to restore this balance; because, if their power of sucking by their wounded ends is diminished, so is their power of perspiring; for a damp atmosphere will rob them of no water—hence they maintain their freshness. The only difference between plants in a 'Ward's case' and flowers in the little apparatus just described is this—that the former is intended for plants to grow in for a considerable space of time, while the latter is merely for their preservation for a few days; and that the air which surrounds the flowers is always charged with the same quantity of vapour, will vary with the circumstances, and at the will of him who has the management of it. We recommend those who love to see plenty of fresh flowers in their sitting-rooms in dry weather to procure it. The experiment can be tried by inserting a tumbler over a rose-bud in a saucer of water."

DESTROYING VERMIN.

The best plan for preventing the attacks of vermin in houses is to keep the house scrupulously clean; for where there is cleanliness and ordinary precautions, no vermin will generate or exist.

Rats and mice.—These might in most instances be completely prevented from encroaching in dwellings by giving a solid foundation to a house, cutting off the approach by grating the drains, but especially by filling up all open spaces beneath pavements and in walls and partitions. Mice might be effectually kept out by only filling up the spaces behind skirting boards in rooms. These vacant spaces are invariably the habitations of mice, and the first thing any person should do in entering into possession of a domicile, is to cause all the spaces behind the skirting-boards and wainscot to be filled with plaster. When mice and rats have gained a footing in a house, they should be taken off by a cat or trap, and when one kind of trap fails, another may be tried. All schemes for poisoning them with arsenic or other ingredients are dangerous, and cannot be recommended.

Bugs.—These pests exist only in dirty houses. A careful housewife or servant will soon completely destroy them. The surest method of destruction is to catch them individually when they attack the person in bed. When their bite is felt, instantly rise and light a candle and capture them. This may be troublesome, but if there be not a great number, a few nights will finish them. When there is a large number, and they have gained a lodgment in the timbers, take the bed in pieces, and fill in all the apertures and joints with a mixture of soft soap and Scotch snuff. A piece of wicker-work, called a bug-trap, placed at the head of the bed, forms a receptacle for them, and then they may be daily caught till no more are left. Fumigations are very dangerous, and rarely effectual, therefore attempt no such project. Oil-painting a wall is a sure means of excluding and destroying them.

Fleas.—There is no way of ridding a bed or house of these vermin but excessive cleanliness. Keep the floors well swept and washed, and if you have a dog, comb and wash it frequently. Fleas are bred in the ground, or among dust.

Lice are now almost unknown in England. Wherever they are found, there certainly also is found dirtiness. Ignorant people imagine that these nauseous vermin breed spontaneously; this is a gross error. By cleanliness they are completely prevented; and the more warm the climate, so is the necessity for cleanliness greater.

Beetles, Cockroaches, and Crickets.—These may be caught in traps. A simple trap for them is a glazed basin or pie-dish half-filled with sweetened beer or milk, and to the edge of which a piece of wood is laid from the floor as a gangway. Do not attempt poisoning or fumigation.

Flies.—It is difficult to rid a house of flies by any other plan than poisoning, and that is too dangerous to be recommended. A composition of milk, sugar, and pepper, will attract and kill them, and so will a decoction of quasia; but both cause them to make offensive marks on the walls and furniture before they die. Gilt frames and chandeliers should be shrouded in thin yellow gauze or paper, in situations where the flies are likely to spoil them. Trees about a house form a harbour for flies, as well as dirt of all kinds. Cleanliness and airiness are the best preventives.

Moths.—The best way to preserve furs or worsteds from moths is to sew them closely up in a bag of new unwashed linen; if this be not done, the next best is to take the articles frequently out and brush and air them. The odour of camphor, shavings of Russia leather, lavender, &c., are much less efficacious than they are supposed to be. Kill every flying moth which you see.

Slugs.—Take a quantity of cabbage leaves, and either put them into a warm oven, or hold them before a fire till they are quite soft; then rub them with unsalted butter, or any kind of fresh dripping, and lay them in the places infested with slugs. In a few hours the leaves will be found covered with snails and slugs, which may then be destroyed in any way you think fit.

SMALL DOMESTIC MANUFACTURES.

The attempt to make all sorts of articles for domestic use is now far from economical, as the time and expense bestowed upon them are often of greater amount than what would buy the things ready made from the shops. We therefore confine our directions to articles which may require to be manufactured in families at a great distance from towns, or for the families of emigrants in remote settlements.

Blacking for shoes.—There are many ways of making this article, the chief ingredients employed being ivory-black, vinegar or sour beer, sugar, a little sweet oil, and oil of vitriol. A good blacking may be made as follows:—Mix three ounces of ivory-black, two ounces of treacle, a table-spoonful of sweet oil, one ounce of vitriol, one ounce of gum-arabic dissolved in water, and a pint of vinegar.

For *blacking-balls*, mix one pound of ivory-black, one pound of lamp-black, a quarter of a pound of gum-arabic dissolved in water, six ounces of brown sugar, half an ounce of melted glue, and a quart of water; and make into balls. A fine blacking for dress-shoes may be made by well beating two eggs, and adding a table-spoonful of spirits of wine, a lump of sugar, and ivory-black to thicken. This blacking may also be used for restoring the black leather seats and backs of chairs, &c. It should be laid on and polished as other blacking, and then left a day to harden.

Boot-top liquid.—Dissolve in a quart of water, one ounce of oxalic acid, and the same of white vitriol; with which sponge the leather previously washed with water; then wash off the composition with water, and dry. This mixture is for *white* tops. For *brown*, mix one ounce of oxalic acid, one ounce of spirits of salts, a scruple of cochineal bruised, and a pint of boiling water, and use as above. These mixtures should be labelled "poison." For brown tops, also, mix with a pint of skimmed milk, half an ounce of spirits of salts, half an ounce of spirits of red lavender, one ounce of gum-arabic dissolved in water, and the juice of two lemons; keep the mixture closely corked, sponge the tops when dry, and polish them with a brush or piece of flannel.

Blacking for harness.—Melt two ounces of mutton suet with six ounces of bees'-wax; add six ounces of sugar-candy, and two ounces of soft soap dissolved in water, and one ounce of indigo finely powdered; and when melted and well mixed, add a gill of turpentine. Lay it on the harness with a sponge, and polish off with a brush.

Cement.—Various preparations are used for mending broken china, earthenware, and glass. The most successful are as follow:—Beat the white of an egg with quicklime, in impalpable powder, into a paste; to which is sometimes added a little whey, made by mixing vinegar and milk. A little isinglass, dissolved in mastic varnish, is another cement. Nature supplies some cements ready to our hands—as the juice of garlic, and the white slime of large snails; and it has been stated in a respectable scientific journal, that a broken flint has been joined so effectually with this snail cement, that when dashed upon a stone pavement, the flint broke elsewhere than at the cemented parts. In their anxiety to unite broken articles, persons generally defeat themselves by spreading the cement too thickly upon the edges of the article, whereas the least possible quantity should be used, so as to bring the edges almost close together; and this may be aided by heating the fragments to be joined.

Paste is useful in a house for papering walls, cupboards, boxes, labelling, &c. Dr. M'Culloch, of Edinburgh, employs paste made of flour in the usual way, but rather thick, with a proportion of brown sugar, and a small quantity of corrosive sublimate. The use of the sugar is to keep it flexible, so as to prevent its scaling off from smooth surfaces; and that of the corrosive sublimate—independently of preserving it from insects—as an effectual check against its fermentation. This salt does not, however, prevent the formation of mouldiness; but a drop or two of oil of lavender, peppermint, or aniseed, is a complete security against this.

Waterproof stuff for shoes.—In winter, or during wet weather, shoes may be rendered durable by applying to the soles and seams a composition made of the following materials:—Half a pint of unboiled linseed oil, two table-spoonfuls of turpentine, one ounce of bees' wax, and a quarter of an ounce of Burgundy pitch. Melt the whole together, and apply with a brush before the fire. Repeat the application till the soles will absorb no more. Neats'-foot oil, alone, will be found an excellent preservative of shoes in wet weather.

Ink.—An excellent ink suitable for writing with steel pens, which it does not corrode, may be made of the following articles:—Sixty grains of caustic soda, a pint of water, and as much Indian ink as you think fit for making a proper blackness.

Bottle wax.—A good kind of bottle wax or cement may be cheaply made as follows:—Put into an iron ladle half a pound of rosin, two ounces of bees' wax, and when melted over the fire, stir in Venetian red, lamp-black, or other colouring; and apply while hot. If kept for after use, melt with a candle as usual when applied.

Potato-starch.—Wash and peel a gallon of good potatoes, grate them into a pail of water, stir frequently, and then let them settle. On the following day the starch will be found at the bottom of the pail; when pour off the water, add fresh, stir as before, and let it subside a second time; when pour off the water, and dry the sediment in the sun or a slow oven. An excellent starch may also be made by setting in a cool place the water in which rice has been boiled (though not in a cloth), which will in twenty-four hours become a strong starch.

Potashes.—Settlers in the backwoods of America, or other woody regions, have an opportunity of manufacturing potashes, an article of great use and considerable value. A vast quantity of this substance is annually made in Canada, and exported to Great Britain. Potashes are made from the ashes of burnt trees. In burning timber to clear the land, the ashes are carefully preserved and put in barrels, or other vessels, with holes in the bottom; and water being poured over them, a liquid or alkali is run off; this ley being boiled in large boilers, the watery particles evaporate, and leave what is called black salts, a sort of residuum, which, when heated to a high degree, becomes fused, and finally, when cool, assumes the character of potash.

By these potashes the Canadians make their own soap; the ley of a barrel of ashes, boiled along with ten pounds of tallow, till it is of a proper consistence, produces about forty pounds of very good soft soap. It is related, that when the land has been covered with heavy timber of a hard nature, there is such a quantity of ashes produced that their value will pay for clearing the land.

Maple sugar.—In the woody districts of Canada, the inhabitants have it in their power to make sugar for domestic consumption as well as for exportation. This sugar is produced from the sap of the maple tree, one of the most valuable vegetable products of the American forests. An active farmer and his wife may make, it is said, about 700 lbs. of sugar annually, not inferior in quality to that of the West Indies, and worth about 4d. per pound. The manufacture of this native sugar greatly tends to lower the price of West India sugars, which would be otherwise as high as 1s. 6d. a pound. Talbot, in his "Five Years' Residence in the Canadas," writes with enthusiasm of the value and use of this manufacture, which it seems is far from being properly attended to by the settlers. "Maple sugar might be manufactured," says he, "by the rudest mountaineer in your country, as well in the first season after his arrival here, as by the most eminent sugar-refiner in Jamaica. The manufacture is generally commenced early in the month of April, when the sap of the tree is first put into motion at the return of spring, and when no other agricultural operation can be carried on to good purpose by the farmer, on account of the unpleasant weather which occurs at that period. A part of the estate is selected which contains the largest quantity of flourishing maple-trees nearly contiguous to each other, and a temporary hut is erected for the accommodation of the operators, but not more than two or three being required for the management of a hundred trees, from every one of which the sap is oozing out at the same time. In rainy weather, the trees yield their valuable juice rather tardily; and, during the whole month which is sometimes devoted to this employment, it often happens that only eight or nine days are propitious to this part of the settler's labours. The best weather for the purpose is that in which the night is frosty, and the day cheered by the rays of a warm sun. If the process of boiling were not continued both day and night, the sap would accumulate too rapidly in the reservoir, and soon evince symptoms of vinous fermentation, which would change its quality, and render it useless for the manufacture of sugar.

"The first thing necessary for commencing the manufacture of this article is a metal boiler, which costs in Upper Canada about £2 10s. sterling. This holds nearly thirty gallons, and, with a small cooking-pot, is sufficient, in a prosperous season, to boil down 500 lbs. One hundred and fifty troughs, eight reservoirs, and four hand-buckets, will be necessary for the regular supply of this boiler. The troughs cost about 16s. 3d. per hundred; the reservoirs, which are barrels without heads, about 4s. each; and the buckets 2s. 6d. each. These are the only utensils which an emigrant will need the troughs may be made by himself, if he has acquired any skill in the use of his axe during the preceding winter. An expert hand can make thirty or thirty-five troughs in a day, which, though formed only with the axe, will last for many years, if carefully placed under cover during summer. The t..es are tapped either by means of an incision made by an axe, or the perforation of an auger. But the latter mode is considered the less injurious to the growth of the tree, and is therefore the more approved plan. A small shoot about nine inches long is made the conductor of the sap from each incision to its respective trough, from which, when nearly full, it is conveyed in buckets to the reservoirs, and there allowed to subside. When the grosser particles of the sediment have been left to sink to the bottom, the sap is drawn off into the boilers, and reduced to molasses by the simple process of evaporation. The liquid in this purer state is then drawn from the boilers, and placed in the reservoirs or coolers, until it becomes nearly cold, when it is strained through a woollen cloth into a smaller boiler, and, after being clarified with eggs, milk, or bullock's blood, is boiled down to the consistency of sugar, and poured into moulds of the particular shape which it is intended to assume as a sort of candy; but if to be used as soft sugar, the syrup in its last stage of purification is left in a sugar-cask, which is perforated, to allow the moist particles, in the form of molasses, to ooze through the bottom. Many people neither clear nor strain the molasses, and consequently make very coarse and dirty sugar; but by a strict adherence to the simple directions which I have given, the most ignorant novice in the art might manufacture sugar equal to any that is imported into England. Some of it, indeed, has what is called 'a smack,' or peculiar taste, derived often from the kind of wood of which the troughs are made, and sometimes from being neglected while in the act of boiling, and suffered to burn. Every tree, on an average, will from a single wound yield about twenty gallons of sap, and a proportionate quantity from any number of incisions not exceeding four. Five gallons of sap contain at least one pound of sugar."

Dyes.—The most simple rule for dyeing is to put the dye into very hot water, and when well mixed, to pass the stuff through it until it sufficiently imbibes the colour, but on no account to squeeze it; it should then be hung up, and when cold, plunged twice into soft water, and then into hard water with a little alum dissolved in it; the stuff may then be again hung up, and when nearly dry, ironed or pressed. Most colours are made brighter by the addition of a little cream of tartar, and darker by pearl-ash. Dyes may be purchased ready prepared. We would recommend that all ordinary dyeing, and particularly when fancy or delicate colours are required, should be consigned to the hands of the professed dyer; and dyeing of a coarse kind only be done at home. In such cases, *brown* may be produced from a decoction of birch bark; and *black* from logwood with green copperas. (See article CHEMISTRY APPLIED TO THE ARTS.)

Temperance drinks.—The simplest beverage of a cooling and pleasing quality, which contains no intoxicating fluid, is *lemonade;* this may be very easily made by pouring boiling water on sliced lemons, and sweetening with sugar to taste. Lemons, however, are not always to be procured, and in such a case, citric acid, or cream of tartar, may be employed instead. Superior lemonade is made with lump sugar. *Ginger beer* may be made as follows:—Take of lump sugar 3 pounds, bruised ginger 2 ounces, cream of tartar 1 ounce, one or two lemons sliced, boiling water 4 gallons, and yeast 8 ounces. Let the whole stand to work in a cask for four days, and then bottle off for use.

Treacle beer is a cheap drink, which may be made as follows:—Boil as much water as will fill twelve common quart bottles; and to it add one pound of treacle, or more, according to taste. When the treacle is dissolved, take the pot from the fire, and let the solution cool. When lukewarm, put into it half a gill of yeast. As soon as it is cold, bottle it, but do not put in the corks till next morning, when the yeast will have wrought over the top of the bottles. Let it stand in a cool place for two or three days, when it will be fit for use. Unless care is taken as to the proportion of yeast and keeping cool, also to corking tightly, the bottles may burst, which is a serious loss to a poor family.

THE TOILET.

Personal cleaning and decoration are the proper duty at the toilet, which requires regular performance daily. We shall speak first of matters connected with the gentleman's toilet.

Shaving.—Some beards are more hard and difficult to shave than others. The usual plan is to soften them with soap lather, but this is not sufficient with beards which are somewhat stubborn. We recommend all to try the following plan: Rub the face or beard with a little soap and water with the hand over the basin, and when pretty well rubbed or softened, apply the lather. Raise the lather from warm water, and apply with a brush. The best kind of soap for shaving is Bandana, but Windsor is also generally liked. Although warm water is most agreeable and suitable for shaving with, it is advantageous for every one to accustom himself to shaving with cold water, as it will render him independent of assistance when travelling or in cases of emergency.

It is of no use going to great expense in purchasing razors. A razor of the best kind may be had for from five to eight shillings, and as their tempering is very much a matter of chance, sometimes a first-rate razor may be had for two or three shillings. Supposing a sharp and good razor to be procured, it may last a whole lifetime with ordinary care. We have used one for twenty years, and it is still as good as new. Some persons prefer keeping six or seven razors, and changing them daily, but in this there is no absolute utility. Razors become blunt more from bad management than fair work in shaving. When to be used, dip the razor in hot water, for this adds keenness to the edge; and before putting it away, wash the razor gently to remove all impurities. Do not wipe it with or upon paper, for that spoils the edge; w[illegible] it only with a fine rag. Before putting it away in its case, give it a turn or two on a strop. Several kinds of strops are [illegible] offered for sale; and all, very properly, are mounted [illegible]ard board. The best we have seen has several sides, [illegible]rent degrees of fineness; one being for use in taking out small bluntnesses or flattenings on the edge, called *setting*, and another for simple stropping. In any case, take care always to draw the razor smoothly and flatly *from heel to point* along the strop. Do not draw first one way and then push another. In general one or two turns will be enough. Never leave your razors in drawers or cases which are accessible to servants or children. By locking them up, you will keep them in better order than by all the other means you employ.

A cut in shaving.—The bleeding may be at once effectually stopped by placing on the wound a small portion of wool from a beaver hat. We have known cases in which bleeding from very serious wounds have been stopped by the application of hat stuff when all other means failed.

The teeth.—The cleaning and proper management of the teeth is the most difficult operation of the toilet. Whether arising from heat of the stomach or other caustitutional causes, the teeth of some persons are much more liable to become discoloured and decay than others. In general, even in the worst cases, much might be done in youth to prevent future deterioration of teeth; but children are ignorant, and parents are lamentably careless on this important matter of personal economy, and remedies often require to be applied when too late. Parents desirous of seeing their children grow up with good teeth, should cause them to be cleaned with scrupulous regularity daily, though only with a brush and tepid water. If the teeth appear crowded, so that there is a fear of one tooth shooting over another, a dentist ought by all means to be employed to thin the row, and allow all to grow straight.

The daily cleaning of the teeth should take place every morning after washing the face. Employ in preference tepid water and a moderately hard brush. Various dentifrices or powders are offered for sale, and which the opulent have opportunities of testing; but we know of none better than finely-powdered charcoal, that is, charred wood well ground in a mortar, and kept in a box secluded from the air. It may be purchased, ready for use, at a small price from perfumers. By putting a little of this on the wet brush, and rubbing the teeth with it, impurities and discolourations will be removed without injuring the enamel. Rinse well afterwards with clean water. A much more strong dentifrice consists of the powder of burnt tobacco; but it contains silica, or gritty particles of sand, and cannot be recommended for common use.

The nails.—Keeping the nails of the fingers in order is a proper duty of the toilet. They should be brushed with soap and water when washing the hands. While still wet, or when wiping the hands with the towel, push back the skin which is apt to grew over the nail, and thus keep the top of the nails neatly rounded. The points of the nails should be regularly pared once a week.

Stray hairs.—These sometimes grow in the nose and ears to an uncomfortable extent. Remove them smartly with a pair of tweezers.

Pomatum.—This is a soft unguent which is valuable for softening the hands, and preventing them chopping in cold dry weather, or for moistening the hair. It was originally named from its containing apple (*pomum*, Latin), and consisted of lard, rose-water, and the pulp of apples. It now consists of perfumed hog's-lard, the apple being omitted. The famed *sultana pomatum* is made as follows:—Melt together half a pound of beef suet, the same of bear's grease, an ounce of white-wax, and two ounces of olive oil; and add to it, tied up loosely in muslin, one ounce of bruised cloves, half an ounce of cinnamon, two bruised tonquin beans, and four grains of musk; strain and put into pots. The article called bear's grease, usually sold in the shops, is little else than perfumed beef-marrow; and the many oils offered for restoring and softening the hair are chiefly olive or almond oil, perfumed with different scents. In general, if the hair be well brushed, no such applications are necessary, and in most cases they create a scurf on the head which it requires considerable trouble to get rid of.

Pomade divine.—This is a soft and valuable unguent, possessing a fine aromatic odour. Dr. Biddoes recommends it to be made as follows:—Steep twelve ounces of beef-marrow in water ten days (changing the water occasionally), and then steep it in rose-water. Put it into a jar with half an ounce of flowers of benjamin, the same of storax and orris-root in powder, and two drachms each of cinnamon, nutmeg, and cloves, in powder. Cover the jar closely, set it in a vessel of water, and put it on the fire; and when the pomade is thus melted, strain it for use. As a very small quantity is ever used at a time, in general it will be found much more economical to buy a small bottle of it than to prepare the article.

Cold cream.—This is a simple and cooling ointment, exceedingly serviceable for rough or chopped hands in winter, or for keeping the skin soft. It is very easily made. Take half an ounce of white wax, and put it into a small basin, with two ounces of almond oil. Place the basin by the side of the fire till the wax is dissolved in the oil. When quite melted, add two ounces of rose-water. This must be done very slowly, little by little; and as you pour it in, beat the mixture smartly with a fork to make the water incorporate. When all is incorporated, the cold cream is complete, and you may pour it into jars for future use. This cold cream is much better than that which is usually sold in shops, and which is too frequently made of inferior ingredients.

Spermaceti ointment.—This is a cooling and healing ointment for wounds. Take a quarter of an ounce of white wax and half an ounce of spermaceti (which is a hard white material), and put them in a small basin with two ounces of almond oil. Place the basin by the side of the fire till the wax and spermaceti are dissolved. When cold, the ointment is ready for use. This is an article which it is also much better to make than to purchase. When you make it yourself, you will know that it has no irritating or inferior materials in it

The feet—corns.—To keep the feet in a proper condition, they should be frequently soaked and well washed. At these times, the nails of the toes should be pared and prevented from growing into the flesh. Corns are the most troublesome evils connected with the feet. They are of two kinds—soft and hard. The soft corns are those which grow between the toes. They may be easily removed by applying ivy leaf steeped in vinegar; if the corn be very painful, change the piece of ivy leaf every morning. The leaf may be steeped for one or two days before using. Hard corns, which grow on the outside of the toes, are caused by friction from the shoes, and we know of nothing so likely to prevent them as easy soft shoes and very frequent soaking of the feet in warm water. Every method of extracting corns seems but to afford temporary relief, and never will be attended with complete success unless attention is paid to the shoes. It is very dangerous to cut corns too deep, on account of the multiplicity of nerves running in every direction of the toes. The *bunion*, or swelling on the ball of the great toe, is produced by the same cause as the corn—pressure and irritation by friction. The treatment recommended for corns will succeed in cases of bunions; but in consequence of the greater extension of the disease, the cure of course is more tedious. When a bunion is commencing, it may be effectually stopped by poulticing, and then opening with a lancet; but this must be committed to the hands of a surgical attendant.

Cosmetics.—These consist of washes and pastes for improving the skin, and are in general highly objectionable; for the greater number contain poisonous ingredients, and while removing from the surface any discolouration, drive the disease inward, and therefore do much more harm than good. Lotions for pimples, freckle washes, milk of roses, rouge, and all such trash, we studiously discommend. The best purifier is water with a cloth; the best beautifiers are *health*, *exercise*, and GOOD TEMPER.

PROVERBS AND OLD SAYINGS.

SCRIPTURAL PROVERBS.

A FALSE balance is an abomination to the Lord; but a just weight is his delight.

A fool uttereth all his mind; but a wise man keepeth it till afterwards.

A fool's wrath is presently known; but a prudent man covereth shame.

A good name is rather to be chosen than great riches, and loving favour rather than silver and gold.

A man that has friends must show himself friendly; and there is a friend that sticketh closer than a brother.

A man of understanding holdeth his peace.

A man's pride shall bring him low; but honour shall uphold the humble in spirit.

A merry heart doeth good like a medicine; but a broken spirit drieth the bones.

A righteous man regardeth the life of his beast; but the tender mercies of the wicked are cruel.

A soft answer turneth away wrath; but grievous words stir up anger.

A virtuous woman is a crown to her husband; but she that maketh ashamed is as rottenness in his bones.

A wise son maketh a glad father; but a foolish son is the heaviness of his mother.

A word fitly spoken is like apples of gold in pictures of silver.

As a bird that wandereth from her nest, so is a man that wandereth from his place.

As a dog returneth to his vomit, so a fool returneth to his folly.

As a jewel of gold on a swine's snout, so is a fair woman who is without discretion.

As a madman who casteth firebrands, arrows, and death, so is the man that deceiveth his neighbour, and saith, Am not I in sport?

As the crackling of thorns under a pot, so is the laughter of a fool.

As the whirlwind passeth, so is the wicked no more; but the righteous is an everlasting foundation.

As vinegar to the teeth, and as smoke to the eyes, so is the sluggard to them that send him.

Be thou diligent to know the state of thy flocks, and look well to thy herds; for riches are not for ever.

Before honour is humility.

Better is a dry morsel and quietness therewith, than a house full of sacrifices with strife.

Better is a dinner of herbs where love is, than a stalled ox and hatred therewith.

Better is a little with righteousness, than great revenues without right.

Blessings are upon the head of the just; but violence covereth the mouth of the wicked.

Boast not thyself of to-morrow; for thou knowest not what a day may bring forth.

By much slothfulness the building decayeth; and through idleness of the hands, the house droppeth through.

By pride cometh contention.

Cast thy bread upon the waters, for thou shalt find it after many days.

Even a fool, when he holdeth his peace, is counted wise; and he that shutteth his lips is esteemed a man of understanding.

Faithful are the wounds of a friend; but the kisses of an enemy are deceitful.

Favour is deceitful, and beauty is vain; but a woman that feareth the Lord she shall be praised.

Fear God, and keep his commandments; for this is the whole duty of man

For men to search their own glory* is not glory

Go from the presence of a foolish man, when thou perceivest not in him the lips of knowledge.

Go to the ant, thou sluggard; consider her ways and be wise.

God hath made man upright, but they have sought out many inventions.

He becometh poor that dealeth with a slack hand; but the hand of the diligent maketh rich.

He that observeth the wind shall not sow, and he that regardeth the clouds shall not reap.

He that passeth by, and meddleth with strife belonging not to him, is like one that taketh a dog by the ears.

He that is slow to anger is better than the mighty, and he that ruleth his spirit than he that taketh a city.

He that loveth pleasure shall be a poor man: he that loveth wine and oil shall not be rich.

He that is greedy of gain troubleth his own house; but he that hateth gifts shall live.

He that is of a merry heart hath a continual feast.

He that is first in his own cause seemeth just; but his neighbour cometh and searcheth him.

He that hath pity upon the poor lendeth unto the Lord; and that which he hath given will he pay him again.

He that hideth hatred with lying lips, and he that uttereth a slander, is a fool.

He that spareth the rod hateth his son; but he that loveth him chasteneth betimes.

He that gathereth in summer is a wise son; but he that sleepeth in harvest is a son that causes shame.

He that walketh uprightly walketh surely; but he that perverteth his ways shall be known.

He that is surety for a stranger, shall smart for it; and he that hateth suretiship is sure.

He that keepeth [silent] his mouth, keepeth his life; but he that openeth wide his lips shall have destruction.

He that troubleth his own house shall inherit the wind; and the fool shall be servant of the wise of heart.

Heaviness in the heart of a man maketh it stoop; but a good word maketh it glad.

Hell and destruction are never full; so the eyes of man are never satisfied.

His own iniquities shall take the wicked himself, and he shall be holden with the cords of his own sins.

Hope deferred maketh the heart sick.

If sinners entice thee, consent thou not.

If the iron be blunt, and he do not whet the edge, then must he put to more strength; but wisdom is profitable to direct.†

If thine enemy be hungry, give him bread to eat; and if he be thirsty, give him water to drink: for thou shalt heap coals of fire upon his head, and the Lord shall reward thee.

If thou faint in the day of adversity, thy strength is small.

If ye cast pearls before swine, they will turn again and rend ye.

In all labour there is profit; but the talk of the lips tendeth only to penury.

Iron sharpeneth iron; so a man sharpeneth the countenance of his friend.

It is nought, it is nought, saith the buyer; but when he is gone his way, then he boasteth.

It is better to dwell in a corner of the house-top, than with a brawling woman in a wide house.

Let another man praise thee, and not thine own mouth; a stranger, and not thine own lips.

---

* To talk of their own doings.
† Knowledge is power.—*Bacon.*

Love not sleep, lest thou come to poverty: open thine eyes, and thou shalt be satisfied with bread.

Much food is in the tillage of the poor; but there is that is destroyed for want of judgment.

Of making many books there is no end; and much study is a weariness of the flesh.

Pride goeth before destruction, and a haughty spirit before a fall.

Remove not the old land-mark; and enter not into the fields of the fatherless.

Reprove not a scorner lest he hate thee; rebuke a wise man and he will love thee.

Righteousness exalteth a nation; but sin is a reproach to any people.

Say not unto thy neighbour, Go, and come again, and to-morrow I will give, when thou hast it by thee.

Seest thou a man diligent in his business, he shall stand before kings; he shall not stand before mean men.*

Seest thou a man that is hasty in his words: there is more hope of a fool than of him.

Strive not with a man without cause, if he have done thee no harm.

The blessing of the Lord, it maketh rich, and he addeth no sorrow with it.

The curse causeless shall not come.

The drunkard and the glutton shall come to poverty: and drowsiness shall clothe a man with rags.

The hand of the diligent shall bear rule; but the slothful shall be under tribute.

The labour of the righteous tendeth to life, the fruit of the wicked to sin.

The memory of the just is blessed; but the name of the wicked shall rot.

The race is not to the swift, nor the battle to the strong.

The rich man is wise in his own conceit; but the poor that hath understanding searcheth him out.

The rich man's wealth is his strong city; the destruction of the poor is their poverty.

The rich ruleth over the poor; and the borrower is servant to the lender.

The simple believeth every word; but the prudent man looketh well to his going.

The sleep of the labouring man is sweet, whether he eat little or much; but the abundance of the rich will not suffer him to sleep.

The sluggard will not plough by reason of the cold; therefore shall he beg in harvest, and have nothing.

The slothful man saith, There is a lion without; I shall be slain in the streets.

The poor is hated even of his neighbour; but the rich hath many friends.

The profit of the earth is for all: the king himself is served by the field.

The upright shall dwell in the land, and the perfect shall remain in it. But the wicked shall be cut off from the earth, and the transgressors shall be rooted out of it.

The wicked flee when no man pursueth;† but the righteous are bold as a lion.

The wise shall inherit glory; but shame shall be the promotion of fools.

There is that maketh himself rich, yet hath nothing; there is that maketh himself poor, yet hath great riches.

There is that scattereth, and yet increaseth; and there is that withholdeth more than is meet, but it tendeth to poverty.

To all the living there [illegible]: a living dog is better than a dead lion.

Train up a child [illegible] he should go, and when he is old he will [illegible] from it.

* Anciently, in the [illegible] was an honour to be permitted to *stand* in the presence of king[illegible] it is to *sit* before them in our own country.

† Conscience makes cowards [illegible] all.—*Shakspeare.*

Treasures of wickedness profit nothing; but righteousness delivereth from death.

Wealth maketh many friends; but the poor is separated from his neighbour.

Whatsoever thy hand findeth to do, do it with thy might, for there is no work, nor device, nor knowledge, nor wisdom in the grave, whither thou goest.

When goods increase, they are increased that eat them, and what good is there to the owners thereof, saving the beholding of them with their eyes.

Where no counsel is, the people fall; but in the multitude of counsellors there is safety.

Where no wood is, then the fire goeth out; so where there is no tale-bearer, the strife ceaseth.

When pride cometh, then cometh shame; but with the lowly is wisdom.

Who can find a virtuous woman? for her price is far above rubies.

Whoso findeth a wife findeth a good thing, and obtaineth favour of the Lord.

Wine is a mocker, strong drink is raging; and whosoever is deceived thereby is not wise.

Withdraw thy foot from thy neighbour's house, lest he be weary of thee, and so hate thee.

Withhold not good from them to whom it is due, when it is in the power of thine hand to do it.

Yet a little sleep, a little slumber, a little folding of the hands to sleep: so shall thy poverty come as one that travelleth, and thy want as an armed man.

ENGLISH PROVERBS.

A bad workman quarrels with his tools.
A bird in the hand is worth two in a bush.
A happy heart makes a blooming visage.
Absence cools moderate passions, and inflames violent ones.
A burden which one chooses is not felt.
A cat may look at a king.
Aching teeth are ill tenants.
A chip of the old block.
A clear conscience fears no accusation.
A contented mind is a continual feast.
A creaking door hangs long on the hinges.
A day after the feast.
A drowning man will catch at a straw.
Adversity flattereth no man.
A fat kitchen makes a lean will.
A fault confessed is half redressed.
A fool and his money are soon parted.
A fool can make money; it requires a wise man to spend it.
A fool may give a wise man counsel.
A fool's bolt is soon shot.
After death the doctor.
After dinner sit a while, after supper walk a mile.
After meat, mustard.
A friend in need is a friend indeed.
A full purse never lacks friends.
A gentleman without a living is like a pudding without suet.
A good layer-up is a good layer-out.
A good maxim is never out of season.
A good name keeps its lustre in the dark.
A good servant [illegible] a good master.
A good word is [illegible] soon said as an ill one.
A goose cannot graze after him.
A great dowry is a bed full of troubles.
Agues come on horseback, but go away on foot.
A guilty conscience needs no accuser.
A hair of the dog that bit him.
A handful of good life is better than a bushel of learning.
A hungry man's an angry man.
A king's favour is no inheritance.
A libertine's life is not a life of liberty.

A lie has no legs, but scandal has wings.
A light-heeled mother makes a heavy-heeled daughter.
A light purse is a heavy curse.
A little body doth often harbour a great soul.
A little leak will sink a great ship.
A little pot is soon hot.
All are not friends that speak us fair.
All are not hunters that blow the horn.
All are not thieves that dogs bark at.
All feet tread not in one shoe.
All gone to sixes and sevens [confusion and ruin].
All is fish that comes to the net.
All is not gain that is got into the purse.
All is not gold that glitters.
All lay load on the willing horse.
All the honesty is in the parting.
All the fat's in the fire.
All things are soon prepared in a well-ordered house.
All work and no play makes Jack a dull boy.
Almost and very nigh, save many a lie.
Always put the saddle on the right horse.
A man forewarned is forearmed.
A man may buy gold too dear.
A man may cause his own dog to bite him.
A man may hold his tongue in an ill time.
A man may lose his goods for want of demanding them.
A man must ask his wife leave to thrive.
A man never surfeits of too much honesty.
A man without reason is a beast in season.
A miss is as good as a mile.
An apple, an egg, and a nut, you may eat after a slut.
An empty purse fills the face with wrinkles.
An evil lesson is soon learned.
Anger dieth quickly with a good man.
An honest man's word is as good as his bond.
An hour in the morning is worth two in the afternoon.
A nice wife and a backdoor often make a rich man poor.
An idle brain is the devil's workshop.
An oak is not felled with one blow.
An obedient wife commands her husband.
A nod from a lord is a breakfast for a fool.
An old knave is no babe.
An old sack asketh much patching.
An ounce of mother-wit is worth a pound of clergy.
Antiquity is not always a mark of verity.
An unlawful oath is better broke than kept.
Any thing for a quiet life.
A penny saved is a penny earned.
A pin a day is a groat a year.
A pitcher goes often to the well, but is broken at last.
A quiet conscience sleeps in thunder.
A quiet tongue shows a wise head.
A rolling stone gathers no moss.
A rotten apple injures its companions.
A rotten sheep infects the whole flock.
A single fact is worth a ship-load of argument.
A small pack becomes a small pedlar.
A small spark makes a great fire.
A smart reproof is better than smooth deceit.
A spur in the head is worth two in the heel.
As the bell is, so is the clapper.
As the crow is, the egg will be.
As the fool thinks, the bell clinks.
As the old cock crows, the young cock learns.
A stitch in time saves nine.
As welcome as flowers in May.
As you make your bed, so must you lie on it.
As you sow, so you shall reap.
A tree is known by its fruit.
A wager is a fool's argument.
A wilful man will have his way.
A willing mind makes a light foot.
A word before is worth two behind
Aye be as merry as you can.

Bachelors' wives and maids' children are always well taught.
Beauty is a blossom.
Beauty is no inheritance.
Before thou marry, be sure of a house wherein to tarry.
Beggars have no right to be choosers.
Be it for better, or be it for worse, be ruled by him that beareth the purse.
Be not too hasty to outbid another.
Be slow to promise, and quick to perform.
Better do it than wish it done.
Better go about than fall into the ditch.
Better known than trusted.
Better late than never.
Better ride on an ass that carries me, than a horse that throws me.
Better to be alone than in bad company.
Better to be beaten than to be in bad company.
Better to bend than to break.
Better to go to bed supperless than to rise in debt.
Between two stools we come to the ground.
Birds of a feather flock together.
Birth is much, but breeding is more.
Borrowed garments never fit well.
Brag is a good dog but Holdfast is better.
Bread at pleasure, drink by measure.
Brevity is the soul of wit.
Building and marrying of children are great wasters.
Burning the candle at both ends.
Business is the salt of life.
Buy at a market, but sell at home.
By others' faults wise men correct their own.

Care killed a cat.
Carrying coals to Newcastle.
Catch not at the shadow, and lose the substance.
Catch the bear before you sell his skin.
Change of fortune is the lot of life.
Charity begins at home, but does not end there.
Cheating play never thrives.
Children and chickens must be always picking.
Children are uncertain comforts.
Children suck the mother when they are young, and the father when they are old.
Climb not too high, lest the fall be the greater.
Confession of a fault makes half amends for it.
Confine your tongue, lest it confine you.
Conscience is never dilatory in her warnings.
Conscience is the chamber of justice.
Constant occupation prevents temptation.
Content is the true philosophers' stone.
Contentment to the mind is as light to the eye.
Conviviality should ever be free from intemperance.
Courtesy on one side never lasts long.
Covet not that which belongs to others.
Craft bringeth nothing home.
Custom is a second nature.
Cut and come again.
Cut your coat according to your cloth.
Daub yourself with honey, and you will have plenty of flies.
Death is deaf and hears no denial.
Death keeps no calendar.
Debt is the worst kind of poverty.
Deeds are fruits, words are but leaves.
Deep rivers move with silent majesty, shallow brooks are noisy.
Defer not till the evening what the morning may accomplish.
Delays are dangerous.
Deliberate slowly, execute promptly.
Depend not on fortune, but on conduct.
Dependence is a poor trade to follow.
Deride not any man's infirmities.

Desires are nourished by delays.
Deserve success, and you shall command it.
Despise none, despair of none.
Diligence is the mistress of success.
Diseases are the interests paid for pleasures.
Do as the most do, and fewest will speak evil of you.*
Do as you would be done by.
Dogs wag their tails not so much in love to you as to your bread.
Doing nothing is doing ill.
Do not burn daylight upon it.
Do not halloo till you are out of the wood.
Do not make fish of one and flesh of another.
Do not rip up old sores.
Do not spur a free horse.
Do not throw your opinions in everybody's teeth.
Don't be all your days trotting on a cabbage leaf.
Don't buy a pig in a poke.
Don't measure other people's corn by your bushel.
Don't neglect to feather your nest.
Don't run away with more than you can carry.
Don't value a gem by what it is set in.
Do what thou oughtest, and come what can.
Down with the dust [pay the money].
Drunkenness is a pair of spectacles to see the devil and all his works.
Drunkenness reduces a man below the standard of a brute.
Eagles fly alone, but sheep flock together.

Early to bed, and early to rise,
Makes a man healthy, wealthy and wise.

Eat what you like, but pocket nothing.
Empty vessels make the greatest sound.
Enough is as good as a feast.
Entertain honour with humility, and poverty with patience.
Evening oats are good morning's fodder.
Ever drunk ever dry.
Ever spare and ever have.
Every bean hath its black.
Every dog has his day.
Everybody's business is nobody's business.
Every couple is not a pair.
Every herring must hang by its own head.
Every Jack has his Jill.
Every man is the architect of his own fortune.
Every one for himself, and God for us all.
Every one puts his fault on the times.
Every one to their liking, as the old woman said when she kissed her cow.
Every path hath a puddle.
Every shoe fits not every foot.
Every thing hath an end, and a pudding hath two.
Every thing is good in its season.
Every thing is the worse for wearing.
Example teaches more than precept.
Experience is the mother of science.
Experience teaches fools.
Evil communications corrupt good manners.
Evil gotten evil spent.
Faint heart never won fair lady.
Fair and softly go far in a day.
Fair words make fools fain.
Fall not out with a friend for a trifle.
False friends are worse than open enemies.
Fancy may bolt bran and think it flour.
Far-fetched and dear-bought is good for ladies.
Fat paunches make lean pates.
Fat sorrow is better than lean sorrow.
Few take care to live well, but many to live long.
Fiddler's fare—meat, drink, and money.
Fine feathers make fine birds.
Fine words butter no parsnips.

* In most cases this would be a bad advice.

Fire and water are good servants, but bad masters.
Fire is not to be quenched with tow
First deserve and then desire.
Fly pleasure, and it will follow thee.
Fools make feasts, and wise men eat them.
Fools should never see half-done work.
Fools tie knots, and wise men loose them.
Fools will be meddling.
Forbearance is no acquittance.
Forgive and forget.
Forgive any sooner than thyself.
Fortune favours the brave.
Fortune has no power over discretion.
Fortune knocks once at least at every man's gate.
For want of company, welcome trumpery.
From fame to infamy is a beaten road.
Gather thistles, except prickles.
Gentry sent to market will not buy one bushel of corn.
Get thy spindle and distaff ready, and God will send flax.
Give a dog an ill name and hang him.
Give a rogue rope enough, and he will hang himself.
Give it plenty of elbow grease [hard rubbing].
Give the devil his due.
God help the rich, the poor can beg.
God helps those who help themselves.
God send you more wit, and me more money.
God tempers the wind to the shorn lamb.
Go farther and fare worse.
Good counsel is above all price.
Good harvests make men prodigal, bad ones provident.
Good to be merry at meat.
Good ware makes quick markets.
Good wine needs no bush.
Good words cost nothing, but are worth much.
Goods are not theirs who enjoy them.
Gossipping and lying go hand in hand.
Grasp all, lose all.
Great barkers are no biters.
Great cry and little wool.
Great gain and little pain make a man soon weary.
Half a loaf is better than no bread.
Handsome is that handsome does.
Happy is he whose friends were born before him.
Happy is he who knows his follies in his youth.
Happy is the wooing that is not long in doing.
Harm watch, harm catch.
Hasty resolutions seldom speed well.
Have not thy cloak to make when it begins to rain.
Hear twice before you speak once.
He dances well to whom fortune pipes.
He doubles his gift who gives in time.
He fights with his own shadow.
He giveth twice that gives in a trice.
He has a bee in his bonnet.
He has brought his noble to ninepence.
He has had a bite upon his bridle.
He is a wise man who speaks little.
He is proper that hath proper conditions.
He knows not a B from a bull's foot.
He knows not a hawk from a hand-saw.
He lacks most that longs most.
Hell is paved with good intentions.
Help the lame dog over the stile.
He liveth long that liveth well.
He'll find some hole to creep out at.
He loses nothing for the asking.
He loseth his thanks who [illegible]eth and delayeth.
He loseth nothing that [illegible] for his friend.
He loves roast meat well that [illegible] the spit.
He may well be contented who needs neither borrow nor flatter.
He must needs run whom the devil drives.
He must stoop that hath a low door.
He plays well that wins

He's a Jack in office.
He's gone upon a sleeveless errand.
He that always complains is never pitied.
He that blows in the dust fills his eyes.
He that falls in an evil cause, falls in the devil's frying-pan.
He that goes a-borrowing goes a-sorrowing.
He that has no shame has no conscience.
He that has no silver in his purse should have silver on his tongue.
He that hath a good harvest may be content with some thistles.
He that is angry is seldom at ease.
He that is warm thinks all are so.
He that lendeth loseth double. [Loses both his money and his friend.]
He that licks honey from thorns pays too dear for it.
He that lies down with dogs, must expect to rise with fleas.
He that lives not well one year sorrows for it seven.
He that liveth wickedly can hardly die honestly.
He that reckons without his host must reckon again.
He that runs fast will not run long.
He that runs in the night stumbles.
He that sows not corn plants thistles
He that stays in the valley will never get over the hill.
He that will not be saved needs no preacher.
He that will not be counselled cannot be helped.
He that will steal an egg will steal an ox.
He that would thrive must rise at five, he that has thriven may lie till seven.
He was born with a silver spoon in his mouth.
He who is hasty fishes in an empty pond.
He who knows himself best esteems himself least.
He who lies long in bed his estate feels it.
He who marrieth for wealth doth sell his liberty.
He who rises late never does a good day's work.
He who runs after a shadow has a wearisome race.
He who sows brambles must not go barefoot.
He who spends all he gets is in the highroad to beggary.
He who swims in sin will sink in sorrow.
He who would catch fish must not mind getting wet.
He who would reap well must sow well.
Hiders are good finders.
His bread is buttered on both sides.
His eye is bigger than his belly.
His tongue's no slander.
Home is home though it be ever so homely.
Hope is a good breakfast but a bad supper.
Hot love is soon cold.
Hot sup, hot swallow.
Humility is the foundation of all virtue.
Hunger is the best sauce.
Hungry dogs eat dirty puddings.
I can see as far into a millstone as the picker.
Idle folks have the most labour.
Idle folks have the least leisure.
Idleness is the greatest prodigality.
Idleness is the parent of want and shame.
Idleness is the root of all evil.
Idleness is the sepulchre of a living man.
If every one would mend one all would be amended.
If the brain sows not corn, it plants thistles.
If the cap fit, wear it.
If the mountain will not come to Mahomet, Mahomet must go to the mountain.
If things were to be done twice all would be wise.
If we subdue not our passions they will subdue us.
If wishes were horses, beggars would ride.
If you give an inch, he will take an ell.
If you have too many irons in the fire, some of them will burn.
If you would enjoy the fruit, pluck not the flower.
Ignorance is the parent of many injuries.
I have a crow to pluck with him.
I have lived too near a wood to be frightened by owls.
I have other fish to fry.
I'll trust him no farther than I can fling him.
Ill examples are like contagious diseases.
Ill gotten goods seldom prosper.
Ill news travel apace.
Ill wedding and ill wintering tame both man and beast.
Ill weeds grow apace.
In a calm sea every man is a pilot.
In at one ear and out at the other.
In vain he craves advice that will not follow it.
Inconstancy is the attendant of a weak mind.
It costs more to revenge injuries than to bear them.
It cuts both ways, like a two-edged sword.
It is a bad horse that refuses to carry his provender.
It is a long road that has no turning.
It is an ill wind that blows nobody good.
It is better to do well, than to say well.
It is good to begin well, but better to end well.
It is less painful to learn in youth than to be ignorant in age.
It is never too late to learn.
It is no small conquest to overcome yourself.
It is not the cowl that maketh the friar.
It's a bad cause that none dare speak in.
It's a bad sack will abide no clouting.
It's a good horse that never stumbles.
It's a poor sport that's not worth the candle.
It's a sad heart that never rejoices.
It's a wise child that knows its own father.
It's an ill procession where the devil holds the candle
It's easy to bowl down hill.
It's ill healing an old sore.
It's ill shaving against the wool.
It's merry in the hall when beards wag all.
It's more painful to do nothing than something.
It's not the gay coat makes the gentleman.
It's possible for a ram to kill a butcher.
It's wit to pick a lock and steal a horse, but wisdom to let them alone.
Jack Nokes and Tom Stiles.
Jack of all trades and master of none.
Jesting lies bring serious sorrows.
Judge not of a ship as she lies on the stocks.
Judge not of men or things at first sight.
Keep a thing seven years, and you will find a use for it.
Keep counsel thyself first.
Keep good men company, and you sh[illegible] of the number.
Keep no more cats than will catch mice.
Keep the bowels open, the head cool, and the feet warm and a fig for physicians.
Keep thy shop, and thy shop will keep thee.
Keep your tongue within your teeth.
Kill two birds with one stone.
Kindness is lost upon an ungrateful man.
Kindnesses, like grain, increase by sowing.
Kissing goes by favour.
Knavery may serve a turn, but honesty is best in the end.
Land was never lost for want of an heir.
Lazy folks take the most pains.
Least said is soonest mended.
Lend thy horse and thou mayest have back his skin.
Let every pedlar carry his own burden.
Let every tub stand on its own bottom.
Let not your tongue cut your throat.
Let sleeping dogs lie.
Let the cobbler stick to his last.
Let them laugh that win.
Life is half spent before we know what it is.
Life without a friend is death without a witness.
Light come, light go.
Lips however rosy must be fed.
Little and often fills the purse.

Little boats must keep near shore
Little pitchers have great ears.
Little sticks kindle the fire, but great ones put it out.
Live and let live.
Live not to eat, but eat to live.
Lowly set, richly worn.
Lock the stable door when the steed is stolen.
Long looked-for comes at last.
Look before you leap.
Look to the main chance.
Look twice ere you determine once.
Lookers-on see more than players.
Losers are always in the wrong.
Love asks faith, and faith asks firmness.
Love me, love my dog.
Lovers live by love as larks by leeks. [Ironical.]
Lucky men need little counsel.
Make a virtue of necessity.
Make hay while the sun shines.
Make not your sail too large for your ship.
Make the best of a bad bargain.
Making [illegible] a pleasure.
Man doth what he can, and God what he will.
Man proposes, God disposes.
Manners often make fortunes.
Many a slip betwixt the cup and the lip.
Many a true word is spoken in jest.
Many can pack the cards that cannot play.
Many go out for wool and come home shorn.
Many hands make light work.
Many words will not fill the bushel.
Marry in haste, and repent at leisure.
Marry your sons when you will, your daughters when you can.
Mills and wives are ever wanting.
Mischiefs come by the pound and go away by the ounce.
Misfortunes seldom come alone.
Misreckoning is no payment.
Modesty is the handmaid of virtue.
Money makes the mare to go.
Money will do more than my Lord's letter.
More afraid than hurt.
Much is expected where much is given.
Much water goes by the mill the miller knows not of.
Much would have more and lost all.
Muffled cats are bad mousers.
Murder will out.

My son is my son till he gets him a wife,
But my daughter's my daughter all the days of her life.

Necessity is the mother of invention.
Neither praise nor dispraise thyself; thine actions serve the turn.
Never carry two faces under one hood.
Never fall out with your bread and butter.
Never find any thing before it is lost.
Never fish in troubled waters.
Never light your candle at both ends.
Never look a gift horse in the mouth.
Never make a mountain of a mole-hill.
Never quit certainty for hope.
Never ride a free horse to death.
Never sound the trumpet of your own praise.
Never split against the grain.
Never tread on a sore toe.
Never trust to a broken staff.
Never venture out of your depth till you can swim.
Never wade in unknown waters.
New brooms sweep clean.
New lights often come through cracks in the tiling
New lords, new laws.
Next to love, quietness.
No alchemy is equal to saving.
No man can serve two masters.
No man should live like a toad under a harrow
No mill, no meal.
None are so deaf as those that will not hear.
None knows the weight of another's burden.
None so blind as those who will not see.
No pot is so ugly as not to find a cover.
No receiver, no thief.
No rose without a thorn.
Nothing comes out of the sack but what was in it.
Nothing dries sooner than tears.
Nothing down, nothing up.
Nothing is impossible to a willing mind.
Nothing venture, nothing win.
Of all studies, study your present condition.
Of all the crafts, to be an honest man is the master craft.
Of all prodigality, that of time is the worst.
Of two evils choose the least.
Old bees yield no honey.
Old birds are not to be caught with chaff.
Old friends and old wines are best.
Old friends to meet, old wine to drink, and old wood to burn.
Old reckonings breed new disputes.
One bad example spoils many good precepts.
One barber shaves not so close but another finds work
One eye-witness is better than ten hearsays.
One flower makes no garland.
One good turn deserves another.
One half the world knows not how the other half lives.
One hour's sleep before midnight is worth two after.
One is not so soon healed as hurt.
One man may steal a horse, when another may not look over the hedge.
One man's meat is another's poison.
One nail drives out another.
One never loses by doing a good turn.
One ounce of discretion is worth a pound of wit.
One scabbed sheep will mar a flock.
One swallow makes not a spring, nor one woodcock a winter.
One tale is good till another is told.
Open rebuke is better than secret hatred.
Opportunity makes the thief.
Opportunities neglected are irrecoverable.
Our own opinion is never wrong.
Out of debt, out of danger.
Out of sight, out of mind.
Out of the frying-pan into the fire.
Passion is a fever that leaves us weaker than it finds us.
Passion is ever the enemy of truth.
Patience and time run through the longest day.
Patience is a flower that grows not in every one's garden.
Patience is a plaster for all sores.
Pay as you go.
Penny wise and pound foolish.
People who live in glass houses should never throw stones.
Perfection is the point at which all should aim.
Petulent contentions engender malice.
Plain dealing's a jewel.
Positive men are most often in error.
Possession is nine points of the law.
Poverty makes a man acquainted with strange bedfellows.
Poverty parts friends.
Praise a fair day at night.
Praise the sea but keep on land.
Prevention is better than cure.
Prettiness dies quickly.
Pride of heart foreruns destruction.
Pride will have a fall.
Procrastination is the thief of time.
Promise little and do much.
Promises are too much like pie-crust.
Provide for the worst, the best will save itself.
Pry not into the affairs of others.

Pull hair and hair, and you'll make the carle bald.
Put no faith in tale-bearers.
Quick at meat quick at work.
Quick resentments are often fatal.
Quick returns make rich merchants.
Quit not certainty for hope.
Raise no more spirits than you can conjure down
Ratify promises by performances.
Ready money will away.
Reckless youth makes rueful age.
Remove an old tree and it will wither.
Rome was not built in a day.
Rule the appetite and temper the tongue.
Safe bind, safe find.
Sauce for the goose is sauce for the gander.
Saving at the spigot and spending at the bung.
Say no ill of the year till it be past.
Saying and doing are two things.
Search others for their virtues, thyself for their faults
See a beggar and catch a louse.
Seeing is believing.
Seek till you find, and you'll not lose your labour.
Seldom seen, soon forgotten.
Self-preservation is the first law of nature.
Set a thief to take a thief.
Shameless craving must have shameless way.
Sharp stomachs make short graces.
She shows many more airs than graces.
Show me a liar, and I will show you a thief.
Short reckonings make long friends.
Silence does seldom any harm.
Silks and satins put out the fire in the kitchen.
Sit in your place and none will make you rise.
Sleep without supper and wake without owing.
Sloth is the mother of poverty.
Soldiers in peace are like chimneys in summer.
Soon ripe, soon rotten.
Soon well, long ill.
Sooner said than done.
Sorrow will pay no debt.
Sour grapes, as the fox said when he could not reach them.
Spare well and spend well.
Spare when you are young, and spend when you are old.
Speak the truth and shame the devil.
Speech is the gift of all, but thought of few.
Stars are not seen by sunshine.
Stick your opinions on no person's sleeve.
Stretch your legs according to your coverlet.
Strike while the iron is hot.
Study to be worthy of your parents.
Such a welcome, such a farewell.
Such as the tree is such is the fruit.
Take care of the pence, and the pounds will take care of themselves.
Take heed of an ox before, an ass behind, and a knave on all sides.
Take heed will surely speed.
Take the will for the deed.
Take time by the forelock.
Talk of the devil and he'll appear.
Talking pays no toll.
Tell me the company you keep, and I'll tell you what you are.
Temperance is the best physic.
That is well spoken that is well taken.
That penny is well spent that saves a groat.
That's placing the cart before the horse.
That was laid on with a trowel.
The absent party is still faulty.
The ass that brays most eats least.
The best physicians are Dr. Diet, Dr. Quiet, and Dr Merryman.
The better day the better deed.
The blind man's wife needs no painting.
The cobbler's wife is the worst shod.
The comforter's head never aches.
The covetous man is his own tormentor
The crow thinks her own bird the fairest.
The devil is not as black as he is painted.
The devil was sick, the devil a monk would be;
The devil grew well, the devil a monk was he.
The end of a feast is better than the beginning of a fray.
The eye of the master does more work than both his hands.
The farthest way about is often the nearest way home.
The faulty stands on his guard.
The formost dog catches the hare.
The galled jade will wince.
The goodness of a pudding is known in the eating.
The gray mare is the better horse.
The greatest burdens are not the gainfullest.
The greatest strokes make not the best music.
The greatest wealth is contentment with little.
The groat is ill saved that shames the master.
The guilty mind needs no accuser.
The handsomest flower is not the sweetest.
The hasty hand catches frogs for fish.
The hastiest man that is must wait while his drink is drawing.
The highway is never about.
The highest branch is not the safest roost.
The hotter war the sooner peace.
The last drop makes the cup run over.
The last suitor wins the maid.
The lion's skin is never cheap.
The longest day must have an end.
The market is the best garden.
The married man must turn his staff into a stake.
The mill cannot grind with the water that is past.
The mob has many heads but no brains.
The more noble the more humble.
The more the merrier, the fewer the better cheer.
The more you heap, the worse you cheap.
The nearer the church the farther from God.
The offender never pardons.
The path of virtue is the path of peace.
The rat which has but one hole is soon caught.
The receiver is as bad as the thief.
The still sow sucks the most wash
The sweetest wine makes the sharpest vinegar.
There is a tide in the affairs of men, which taken at the flood leads on to fortune.
There is luck in leisure.
There is reason in roasting eggs.
There's a salve for every sore.
There's no compassion like the penny.
There's no fool like an old fool.
There's no general rule without an exception.
There's no joy without alloy.
The table robs more than the thief.
The truest jests sound worst in guilty ears.
The truth may be blamed but not shamed.
The weakest must go to the wall.
The wearer best knows where the shoe pinches him.
There would be no ill language if it were not ill taken.
There would not be great ones if there were no little.
They love too much that die for love.
They must hunger in frost, that will not work in heat.
They need much whom nothing will content.
Think of ease, but work on.
Those who live longest will see most.
Those who play with edge tools must expect to be cut.
Threatened folks live long.
Time and tide stay for no man
Time is a file that wears and makes no noise.
Timely blossom, timely fruit.
'Tis the second blow that makes the fray.
To a child all weather is cold.

To a crazy ship all winds are contrary.
To be hail fellow well met with one. [In good fellowship.]
To be in a merry pin.
To dine with Duke Humphry. [To go without dinner.]
To err is human, to forgive divine.
To find a mare's nest. [To discover something already well known.]
To give and keep there is need of wit.
To go through thick and thin. [Stick at nothing.]
To go to pot.
To have nothing but one's labour for one's pains.
To have the law in one's own hand.
To have two strings to one's bow.
To kill two birds with one stone.
To laugh in one's sleeve.
To leave a morsel for the Duke of Rutland. [That is—to leave it for the sake of *manners*, Manners being the family surname of the Duke of Rutland.]
Too many cooks spoil the broth.
Too much familiarity breeds contempt.
To play the dog in the manger. [Not to eat yourself nor let anybody else.]
To put one's nose out of joint.
To rob Peter to pay Paul.
To seek a needle in a bottle of hay.
To send one away with a flea in his ear. [In a state of trepidation and astonishment.]
To set up one's staff of rest. [To propose to abide in a place.]
To stand in one's own light.
To starve in a cook-shop.
To strain at a gnat and swallow a camel.
To take a wrong sow by the ear.
To tell tales out of school.
To throw the helve after the hatchet. [Giving up a thing in despair.]
To twist a rope of sand.
Trade is the mother of money.
Tread on a worm and it will turn.
Trim-tram—like master, like man.
True praise takes root and spreads.
Truth has always a fast bottom.
Two heads are better than one.
Two of a trade seldom agree.
Two swallows do not make a summer.
Unknown, unmissed.
Unminded, unmoved.
Use the means, and God will give the blessing.
Valour is worth little without discretion.
Valour that parleys is near yielding.
Venture a small fish to catch a great one.
Venture not all in one bottom.
War is death's feast.
Waste not, want not.
Wealth makes worship.
Welcome is the best cheer.
We must eat a peck of salt with a man before we know him.
We never know the worth of water till the well is dry.
What cannot be cured must be endured.
What is bred in the bone will not come out of the flesh.
What is got over the devil's back is spent under his belly.
What the eye sees not the heart rues not.
What the good wife spares the cat eats.
When a dog is drowning every one offers him water.
When all is consumed, repentance comes too late.
When fortune smiles on thee, take the advantage.
When many strike on an anvil, they strike by measure.
When poverty comes in at the door, love flies out at the window
When rogues fall out, honest men get their own.
When sorrow is asleep, wake it not.
When the cat's away the mice play.
When the goodman's from home the goodwife's table is soon spread.
When wine's in wit's out.
When two Sundays meet. [Never.]
When you are at Rome, do as they do at Rome.
When we have gold we are in fear, when we have none we are in danger.
When drink enters, wisdom departs.
Where much smoke is there must be some fire.
Where the carcass is, there the ravens will collect together.
Where the king is, there is the court.
Where the will is ready the feet are light.
Where there is a will there is always a way.
Write injuries in dust, but kindnesses in marble.
While the grass grows the cow starves.
While there's life there's hope.
Who dainties love shall beggars prove.
Who loseth his due getteth no thanks.
Who perisheth in needless danger is the devil's martyr.
Who spends more than he should, shall not have to spend when he would.
Who spits against the wind spits in his own face.
Wide will wear, but narrow will tear.
Wilful waste makes woful want.
Wise men care not for what they cannot have.
Wisely and slow: they stumble who run fast.
Wool sellers know wool buyers.
Words may pass, but blows fall heavy.
Wranglers never want words.
York—every man pay his share.
You are busy as a hen with one chick.
You come like a godfather after the christening.
You can look at teeth and not be bitten.
You can't see green cheese but your teeth must water.
You cannot catch old birds with chaff.
You cannot eat your cake and have it also.
You cannot have blood out of a stone
You cannot hide an eel in a sack.
You cannot kill a dog with a bone.
You cannot make a silk purse out of a sow's ear.
You cannot wash the blackamore white.
You need not grease a fat sow.
You taste the broth soon as the meat is put in.

SCOTS PROVERBS.

A begun turn is half ended.
A bit is often better gi'en than eaten.
A blate cat makes a proud mouse.
A black hen lays a white egg.
A borrowed len' should gae laughing hame.
A fidging mare should be weel girded.
Affront your friend in daffin', and tine him in earnest.
A fou man and a hungry horse aye mak haste hame.
A friend's dinner's soon dished.
Aft ettle, whiles hit.
After a storm comes a calm.
A gi'en horse shouldna be looked i' the mouth.
A gi'en piece is soon eaten.
A greedy e'e ne'er gat a gude pennyworth.
A green Yule maks a fat kirk-yard.
A gude cause maks a strong arm.
A handfu' o' trade is worth a gowpen o' gowd.
A hantle cry murder, yet are aye uppermost.
A hasty man never wanted wae.
A hunger and a burst.
A kiss and a drink o' water mak but a poor breakfast
A man's weel or wae as he thinks himsel sae.
Ane cannot wive and thrive baith in ae year.
Ane may be lo'e a haggis, that wadna hae the bag thrown in his teeth.
Ane ne'er tines by doing gude.
An ilka-day braw makes a sabbath-day daw
An ill shearer never got a gude heuk.

An ill wife and a new-kindled candle should hae their heads hadden down.
An inch o' gude fortune is worth a fathom o' forecast.
An inch o' a miss is as gude as a span.
A nod o' honest men is enough.
A pound o' care winna [illegible] ay an ounce o' debt.
A rough bane makes a fou wame.
As dark as a Yule midnight.
As gude fish in the sea as e'er came out o't.
As gude may haud the stirrup as he that loups on.
A Scotch mist will wet an Englishman to the skin.
A sillerless man gangs fast through the market
A sorrowfu' heart is aye dry.
A' Stewarts are no sib to the king.
A tale never tines in the telling.
A tarrowing hen was never fat.
A tocherless dame sits lang at hame.
At open doors dogs gae ben.
A wee mouse can creep under a great corn stack.
A wee thing puts your beard in a bleeze.
A wight man ne'er wanted a weapon.
A wilfu' man should be unco wise.
Auld men are twice bairns.
Auld sparrows are ill to tame.
Auld springs gie nae price.
Bairns speak in the field what they hear in the ha'.
Bargain is bargain.
Be a friend to yoursel, and others will.
Bear and forbear is gude philosophy.
Bear wealth weel, poortith will bear itsel.
Be aye the same thing you would be ca'd.
Be lang sick that ye may be soon hale.
Best to be off with the old love before we be on with the new.
Be thou weel, be thou wae, thou wilt not be aye sae.
Better a bit in the morning than fast a' day.
Better a finger off than aye wagging.
Better a tocher in her than on her.
Better a toom house than an ill tenant.
Better a wee bush than nae bield.
Better a wee fire to warm you than a big fire to burn you.
Better be blithe wi' little than sad wi' naething.
Better buy than borrow.
Better lang something than soon naething.
Better skaith saved than mends made.
Better sma' fish than nane.
Better to haud than draw.
Better wear shoon than wear sheets.
Blind men shouldna judge o' colours.
Bode for a silk gown and ye'll get a sleeve o't.
Broken bread makes hale bairns.
Burning a halfpenny candle seeking a farthing.
Burnt bairns dread the fire.
By chance a cripple may catch a hare.
Cadgers have aye mind of lade saddles.
Canny stretch, soon reach.
Carrying saut to Dysart.
Cast a bane in a deil's teeth.
Cast not a clout till May be out.
Castna out the dowed water till ye get the fresh.
Cauld cools the love that kindles ower het.
Change your friend ere you hae need.
Cheatery kythes.
Cleanliness is nae pride, dirt's nae honesty.
Come unca'd sits unserved.
Come wi' the wind and gang wi' the water.
Confess and be hanged.
Confess debt and crave days.
Corn him weel, he'll work the better
Count again is not forbidden.
Count siller after a' your kin.
Courtesy is cumbersome to him that kens it na.
Covetousness brings naething hame.
Craft maun hae claes, but truth gaes naked
Credit is better than ill luck.
Credit is better than ill-won gear.
Credit keeps the crown o' the causey.
Credit lost is like a broken glass.
Daffin and want o' [illegible] auld wives donart.
Dame, deem warily, [illegible] wha wytes yoursel.
Dauting and laving [illegible] sure fishing.
Daughters and dead fish [illegible] nae keeping ware.
Dawted bairns dow bear little.
Daylight will peep through a sma' hole.
Deal sma' an' serve a'.
Death and marriage break term-day.
Death at ae door and hardship at the other.
Deil be in the house that ye're beguiled in.
Deil stick pride, for my dog died o't.
Ding down the nest, and the rooks will flee away
Dinna cast awa' the cog when the cow flings.
Dirt bodes luck.
Dinna gut your fish till ye get them.
Do as the lasses do, say Na, an' tak it.
Dogs bark as they are bred.
Dogs an' bairns are aye fond o' fools.
Do not meddle wi' the deil an' the laird's bairns.
Do not touch him on the sair heel.
Dool an' ill life soon mak an auld wife.
Double drinks are aye gude for drowth.
Do weel an' doubt nae man, do ill an' doubt a' men.
Do weel an' hae weel.
Dows an' dominies leave aye a foul house.
Do your turn weel, an' nane will speer what time ye took
Draff he sought, but drink was his errand.
Dree out the inch when ye have tholed the span.
Drink an' drowth come nae aye thegither.
Drink little that ye may drink lang.
Drive a cow to the ha', she'll run to the byre.
Early birds catch the worms.
Early master, soon knave.
East or west, hame is best.
Easy learned, soon forgotten.
Easy learning the cat the road to the kirn.
Easy to that thy ain heart wills.
Easily working when will's at hame.
Eat in measure, an' defy the doctor.
Eat pe[illegible] wi' a prince, an' cherries wi' a chapman.
Eat-w[illegible] Drink-weel's brither.
Eating [illegible]ing only require a beginning.
Eat[illegible]ng puts awa the stamach.
E[illegible]le merchandise.
E[illegible] the soul and torture of the body.
[illegible] turn but when it means an ill ane.
[illegible]t day may you wear't.
[illegible]a
E[illegible] the dyke where it's laighest.
Every [illegible] trade, quoth the browster to the bishop.
Every bird thinks its ain nest best.
Every cock craws crousest on his ain midden head.
Every day [illegible] no Yule-day—cast the cat a castock.
Every fault has its fore.
Every flow has its ebb.
Every inch of joy has an ell ot annoy.
Every man bows to the bush he gets bield frae.
Every man buckles his belt his ain gate.
Every man can guide an ill wife weel but him that has hea
Every man can tout best on his ain horn.
Every man has his ain draff pock.
Every man's tale's gude till anither's be tauld.
Every May-be hath a May not be.
Every miller wad weise the water to his ain mill.
Every play maun be played, an' some maun be the players
Fair words break nae banes, foul words mony.
Fancy flees before the wind.
Far-awa fowls hae fair feathers.
Farther east the shorter west.
Fause folk should hae mony [illegible]

Fauschood makes ne'er a fair hinder-end.
Favour unused is favour abused.
Fill fu an haud fu', that makes a man stark.
Flaes an' a girning wife are waukrife bed-fellows.
Flee ne'er so fast, your fortune will be at your tail.
Fleeing a bird is not the way to grip it.
Fling-at-the-goad was ne'er a gude ox.
Flitting o' farms mak mailens dear.
Fools are aye fond o' flittin'.
Fools are aye seeing ferlies.
Fool's haste is nae speed.
Fools laugh at their ain sport.
Fools set far trysts.
Fools shouldna hae chappin'-sticks.
For fashion's sake, as dogs gang to the market.
For want of a steek a shoe may be tint.
Forbid a fool a thing, an' that he will do.
Frae saving comes having.
Fresh fish and poor friends grow soon ill-faured.
Friends are like fiddle-strings, they maunna be screwed ower tight.
Friends gree best at a distance.
Friendship canna stand aye on ae side.
Fry stanes wi' butter, and the broe will be gude.
Gathering gear is a pleasant pain.
Gaily wad be better.
Gear is easier gotten than guided.
Gentle partans hae lang taes.
Gentle servants are poor men's tinsel.
Get weel, keep weel.
Gie a bairn its will an' a whelp its fill, and neither will do weel.
Gie your tongue mair holidays than your head.
Giff-gaff maks gude friends.
Glasses and lasses are brittle ware.
Glowering's no gainsaying.
God ne'er sent the mouth, but he sent the meat wi't.
God send water to that well that folk think will ne'er rin dry.
God shapes the back for the burden.
Good wine makes a bad head and a lang story.
Gratitude is a heavy burden.
Great comfort is like ready gold in need.
Greedy folks hae lang arms.
Griening wives are aye greedy.
Guessed work's best if weel done.
Gude advice is ne'er out o' season.
Gude ale needs nae wisp.
Gude bairns are eith to lear.
Gude breeding and siller mak our sons gentlemen.
Gude claes open a' doors.
Gude company on a journey is worth a coach.
Gude gear's not to be gapped.
Gude fishing in drumly water.
Gude folk are scarce, tak care o' ane.
Gude forecast fathers the wark.
Gude health is better than wealth.
Gude kail is half meat.
Gude watch prevents harm.
Gude will ne'er wants time to show itsel.
Gude will should be ta'en in part payment.
Gudely cow, gawsy calf.
Hae, gars a deaf man hear.
Hand-in-use is father o' lear.
Hang a thief when he's young, an' he'll no steal when he's auld.
Hang hunger an' drown drouth.
Hankering an' hinging-on is a poor trade.
Happy the wife that's married to a motherless son.
He can hide his meat and seek mair.
He can say Jo, and think it no.
He can see an inch before his nose.
He cares na wha's bairns greet if his laugh.
He comes oftener wi' the rake than the shool.
He complains early that complains of his kail.
He doesna ken what end o' him's uppermost.
He doesna aye ride when he saddles.
He doesna like his wark that says *now* when its done.
He eats the calf i' the cow's wame.
He gangs awa in an ill time that ne'er comes again.
He gangs lang barefoot that wears dead men's shoon.
He girns like a sheep-head in a pair o' tangs.
He has a coup for a' corn.
He has a gude judgment that doesna lippen to his ain.
He has a hearty hand for gieing a hungry mealtith.
He has a slid grip that has an eel by the tail.
He has been rowed in his mither's sark tail.
He has brought his pocket to a braw market.
He has come to gude by misguiding.
He has coosten his cloak on his ither shoulder.
He has coupit the meikle pot into the little.
He has faut o' a wife that marries mam's pet.
He has feathered his nest, he may flee when he likes.
He has gotten the whip hand of him.
He has lain on his wrang side.
He has licked the butter off my bread.
He has mair wit in his little finger than ye hae in a' your bouk.
He has muckle prayer but little devotion.
He has some wit, but a fool has the grinding o't.
He has the best end of the string.
He has wit at will that wi' an angry heart can sit still.
He has't o' kind, he coft it not.
He hears wi' his heel, as geese do in harvest.
He kens his ain groats among ither folk's kail.
He kens whilk side his cake is buttered on.
He'll gie you the whistle o' your groat.
He'll have eneugh some day, when his mouth's fu' o' mools.
He'll mak an ill runner that canna gang.
He'll mend when he grows better, like sour ale in summer.
He'll neither dance nor haud the candle.
He'll no gie an inch o' his will for a span o' his thrift.
He'll no let grass grow at his heels.
He'll no sell his hen on a rainy day.
He'll soon be a beggar that canna say No.
He'll tell it to nae mair than he meets.
He lo'ed mutton weel that licked where the ewe lay.
He lo'es me for little that hates me for nought.
He looks like the far end of a French fiddle.
He maun be soon up that cheats the tod.
He maun hae leave to speak that canna haud his tongue.
He may find fault that canna mend.
He needs a long spoon that sups wi' the deil.
He ne'er did a gude darg that gaed grumbling about it.
He reads his sin in his punishment.
He rides sicker that never fa's.
He's a fool that forgets himsel.
He's a fool that marries at Yule; for when the bairn's to bear, the corn's to shear.
He's a hawk of a right nest.
He's a man of a wise mind, that of a foe can mak a friend.
He's a proud cook that maunna lick his ain fingers.
He's a proud fox that winna scrape his ain hole.
He's a silly chiel that can neither do nor say.
He's a worthless guidman that's no miss'd.
He's as welcome as water in a riven ship.
He's horn deaf on that side o' the head.
He should sit close that has riven breeks.
He sleeps as dogs do when wives sift meal.
He's like a flae in a blanket.
He's like the singet cat, better than he's likely.
He's no the best wright that casts maist spails.
He's no sae daft as he lets on.
He's ower soon up that's hanged e'er noon.
He's poor eneugh that's ill lo'ed.
He's sairest dung that's paid wi' his ain wand.
He starts at straes, and lets windlins gae.
He's the gear that winna traik.

He's unco fu' in his ain house that canna pick a bane in his neighbour's.
He's weel worthy o' sorrow that buys it.
He's weel boden there ben, that will neither borrow nor len'.
He's wise that's timely wary.
He's worth nae weel that can bide nae wae.
He that blaws best let him beat the horn.
He that buys nuts buys shells, but he that buys gude ale buys naething else.
He that canna mak sport should mar nane.
He that cheats me ance, shame fa' him; if he cheat me twice, shame fa' me.
He that counts a' costs will ne'er put plough i' the ground.
He that deals in dirt has aye foul fingers.
He that does you an ill turn will ne'er forgie you.
He that forecasts a' perils will win nae worship.
He that fa's a gutter, the langer he lies the dirtier he is.
He that fishes before the net, fishes lang or he fish get.
He that gets forgets, but he that wants thinks on.
He that gets gear before he gets wit, will die e'er he thrive.
He that has a mickle nose thinks ilk ane speaks o't.
He that has but ae e'e maun tent that weel.
He that has mickle wad aye hae mair.
He that has nae gear to tine may hae shins to pine.
He that has twa hoards will get a third.
He that keeks through a hole may see what will vex him.
He that lends his pot may seethe his kail in his loof.
He that looks to freets, freets will follow him.
He that rides or he be ready, wants aye some o' his graith.
He that's aught the cow gangs nearest the tail.
He that's ill to himsel will be gude to naebody.
He that seeks motes gets motes.
He that shows his purse bribes the thief.
He that speers all opinions comes ill speed.
He that steals can hide too.
He that tholes overcomes.
He that will cheat in play winna be honest in earnest.
He that will not tole maun flit mony a hole.
He that will to Cupar maun to Cupar.
He that winna when he may, shanna when he wad.
He that would eat the kirnel maun crack the nut.
He wad gang a mile to flit a sow.
He wad gar you trow that the moon's made o' green cheese.
He wad tine his lugs if they were not tacked to him.
He was mair fleyed than hurt.
He was scant o' news that tauld his father was hanged.
He was the bee that made the honey.
He winna send you awa' wi' a sair heart.
Highlanders—shoulder to shoulder.
I canna sel' the cow an' sup the milk.
I hae mair to do than a dish to wash.
I ken by my cog my cow's milked.
If ae sheep loup the dyke, a' the rest will follow.
If the deil be laird, ye'll be tenant.
If the deil find you idle, he'll set you to wark.
If the lift fa', the laverocks will be smoored.
If you win at that, you'll lose at naething.
If ye sell your purse to your wife, gie her your breeks to the bargain.
Ill bairns are aye best heard at hame.
Ill bairns aye get broken brows.
Ill beef ne'er made gude broe.
Ill comes upon waur's back.
Ill counsel will gar a man stick his ain mare.
Ill doers are aye ill dreaders.
Ill getting het water frae 'neath cauld ice.
Ill hearing maks wrang rehearsing.
Ill herds mak fat foxes.
Ill laying up maks mony thieves.
Ill payers are aye gude cravers.
Ill will ne'er spak weel.
Ill-won gear winna enrich the third heir.
Ill workers are aye gude onlookers.
I'll ne'er brew drink to treat drunkards.
I'll ne'er keep a cow when I can get milk sae cheap.
I'll ne'er keep a dog and bark mysel.
I'll ne'er lout sae laigh and lift sae little.
I'll ne'er put the rogue aboon the gentleman.
I'll rather strive wi' the lang rigg than the ill neighbour
I'll serve ye when ye hae least to do.
I'll tak the best first, as the priest did o' the plums
I might bring a better speaker frae hame than you.
I'm no every man's dog that whistles on me.
I'm no obliged to summer an' winter it wi' you.
I'm no sae blind as I'm bleer-eyed.
I'm no sae scant o' clean pipes as to blaw wi' a brunt cutty
I'm o'er auld a cat to draw a strae before.
I'm speaking o' hay and you o' horse corn.
I ne'er sat on your coat-tail.
I think mair o' your kindness than its a' worth.
It maun be true what a' folk says.
It's a far cry to Lochaw.
It's a hard task to be poor and leal.
It's a mean mouse that has but ae hole.
It's a nasty bird that files its ain nest.
It's a silly hen that canna scrape for ae bird.
It's an ill pack that's no worth the custom.
It's better to sup wi' a cutty than want a spoon.
It's by the head that the cow gies milk.
It's far to seek an' ill to find.
It's gude baking beside the meal.
It's gude sleeping in a hale skin.
It's gude to be sib to siller.
It's gude gear that pleases the merchant.
It's gude to be in your time, ye kenna how lang it may last.
It's gude to dread the warst, the best will be the welcomer.
It's hard both to have and want.
It's hard for a greedy e'e to hae a leal heart.
It's hard to sit in Rome an' strive wi' the pope.
It's ill bringing butt what's no ben.
It's ill speaking between a fu' man and a fasting.
It's ill wared that wasters want.
It's kittle for the cheeks when the hurlbarrow gaes o'er the brig o' the nose.
It's kittle shooting at corbies and clergy.
It's kittle to waken sleeping dogs.
It's lang before the diel be found dead at the dyke-side.
It's lang ere the deil dee.
It's nae laughing to girn in a widdy.
It's nae play when ane laughs and anither greets.
It's needless to pour water on a drowned mouse.
It's no lost what a friend gets.
It's not what is she but what has she.
It's ower far between the kitchen an' the ha'.
It's ower late to spare when the back's bare.
It's past jouking when the head's aff.
It's stinking praise comes out o' ane's ain mouth.
It's the best spoke in your wheel.
It's well that our faults are not written in our face.
It was never for naething that the gleg whistled.
It will be feathered out o' your wing.
It will be lang ere ye wear to the knee lids.
I wad be scant o' claith to sole my hose wi' dockens.
I would rather see't than hear tell o't.
I wadna be deaved wi' ye're keckling for a' your eggs.
I wadna ca' the king my cousin.
I wish you readier meat than a rinnin hare.
Joke at leisure, you kenna wha may jibe yoursel
Jouk and let the jaw gang by.
Keep out o' his company that cracks o' his cheatery
Keep something for a sore foot.
Keep the feast till the feast day.
Keep the staff in your ain hand.
Keep your ain fish guts to your ain sea-maws.

Keep your breath to cool your own porridge.
Keep your mouth shut and your e'en open.
Ken when to spend and when to spare, and ye needna be busy, and ye'll ne'er be bare.
Ken yoursel, and your neighbour winna misken you.
Kend folk's nae company.
Kings and bears aft worry their keepers.
Kings' chaff's worth other folk's corn.
Kings' cheese gaes half away in parings.
Kings hae lang hands.
Kindle a candle at baith ends, it will soon be done.
Kindness comes o' will, it canna be coft.
Kindness will creep where it canna gang.
Kiss a carle and clap a carle, that's the way to tine a carle.
Kythe in your ain colours, that folk may ken you.
Laith to bed and laith to rise.
Lang fasting gathers wind.
Lang fasting hains nae meat.
Lang standing and little offering maks a poor priest.
Lang straes are nae motes.
Laugh at leisure, ye may greet ere night.
Law's costly, tak a pint and gree.
Law makers shouldna be law breakers.
Lay the head o' the sow to the tail of the grice.
Lay your wame to your winning.
Leal heart never lied.
Learn the cat the road to the kirn, and she'll aye be lickin.
Learn you to an ill habit, and ye'll ca't custom.
Learn young, learn fair.
Let a' trades live, quoth the wife, when she brunt her besom.
Let alane, maks mony a loon.
Let byganes be byganes.
Let him cool in the skin he het in.
Let him tak a spring on his ain fiddle.
Let his ain wand ding him.
Let ilka ane soop before their ain door.
Let ilka sheep hang by its ain shank.
Let na the plough stand to kill a mouse.
Let the horns gang wi' the hide.
Let the mickle horse get the mickle windlin.
Let the tow gang wi' the bucket.
Let them care that come behind.
Let your meat dit your mouth.
Light burdens break nae banes.
Like a cow on an unco loan.
Like a sow playing on a trump.
Like butter in the black dog's hause.
Like hens, ye rin aye to the heap.
Like the bairns o' Falkirk, ye mind naething but mischief.
Like the cat, fain fish wad ye eat, but ye are laith to weet your feet.
Like the wife that aye took what she had, and never wanted.
Like the wife that ne'er cries for the ladle till the pot rins o'er.
Like the wife wi' the mony daughters, the best comes hindmost.
Like's an ill mark.
Lippen to me, but look to yoursel.
List to meat's gude kitchen.*
Little dogs hae lang tails.
Little folk are soon angry.
Little Jock gets the little dish, and that hauds him lang little.
Little kennel, the less cared for.
Little meddling maks fair parting.
Little wats the ill-willy wife what a dinner may haud in.
Little wit in the head maks mickle travel to the feet.
Little meuse to the cheeks to bite aff the nose.
Living at heck and manger.

* Hunger is the best sauce.

Lock your door, that you may keep your neighbours honest.
Lo'e me little, an' lo'e me lang.
Love and lairdships like nae marrows [equals].
Love is as warm among cottars as courtiers.
Love overlooks mony faults.
Maidens should be mild and meek, quick to hear and slow to speak.
Mair by luck than good guiding.
Mair haste the waur speed, quoth the tailor to the lang thread.
Mair than eneugh is ower mickle.
Mak a kirk an' a mill o't.
Mak nae toom ruse.
Malice is aye mindfu'.
Marriage and hanging go by destiny.
Marry a beggar, and get a louse for your tocher.
Marry aboon your match, and get a master.
Marry for love, and work for siller.
Master's will is gude wark.
Mastery maws the meadows down.
Maun-do is a fell fallow.
May-be's are no aye honey-bees.
Measure twice, cut but ance.
Meat feeds, claith cleads, but manners mak the man.
Mickle musing mars the memory.
Mickle power maks mony faes.
Mickle about ane, quoth the deil to the collier.
Mickle gifts mak beggars bauld.
Mickle head, little wit.
Mickle maun a gude heart thole.
Mickle meat, mony maladies.
Mess and meat ne'er hinder'd wark.
Mettle's dangerous in a blind mare.
Money is like the muck midden, it does nae gude till it be spread.
Money is welcome any way.
Money maks a man free ilka where.
Mony an honest man needs help that hasna the face to seek it.
Mony ane kisses the bairn for love o' the nurse.
Mony ane lacks what they would fain hae in their pack.
Mony ane serves a thankless master.
Mony ane speers the gate they ken fu' weel.
Mony ane's gear is mony ane's death.
Mony gude-nights is laith away.
Mony kinsfolk, but few friends.
Mony littles mak a mickle.
Mony purses haud friends lang thegither.
Mony ways to kill a dog, though ye dinna hang him.
Mony wyte their wife for their ain thriftless life.
Nae fleeing without wings.
Nae man can live langer in peace than his neighbours like
Nae man can mak his ain hap
Nae man has a tak o' his life.
Nae wonder to see wasters want.
Naething but fill and fetch mair.
Naething is a man's truly but what he comes by duly
Naething is got without pains but dirt and lang nails.
Naething is sae difficult but we may overcome by perseverance.
Naething sa bauld as a blind mare
Naething to be done in haste but gripping flaes.
Naething to do but draw in your stool and sit down.
Nane are sae weel but they hope to be better.
Nane can play the fool sae weel as a wise man.
Need maks greed.
Need will gar an auld wife trot, and a naked man rin.
Ne'er draw your dirk when a dunt will do.
Ne'er fash your thoom.
Ne'er let on, but laugh in your ain sleeve.
Ne'er lippen owre mickle to a new friend or an auld enemy.
Ne'er marry a widow unless her first man was hanged

Ne'er owre auld to learn.
Ne'er put a sword in a madman's hand.
Ne'er put the plough before the owsen.
Ne'er put your hand farther out than your sleeve will reach.
Ne'er rax aboon your reach.
Ne'er sca'd your lips in ither folk's kale.
Ne'er seek a wife till ye ken what to do wi' her.
Ne'er shaw me the meat but the man.
Ne'er shaw your teeth unless ye can bite.
Ne'er speak ill o' them whase bread ye eat.
Ne'er strive against the stream.
Ne'er tak a forehammer to break an egg.
Ne'er tell your fae when your foot sleeps.
Neither to haud nor to bind.
Neither sae sinfu' as to sink nor sae haly as to swim.
Next to nae wife, a gude wife is the best.
Nobility without ability is like a pudding without suet.
O' a' sorrow, a fu' sorrow's the best.
Owre braw a purse to put a plack in.
Owre reckless may repent.
Owre sicker, owre loose.
Owre strong meat for your weak stamach.
Of a' flatterers, self-love is the greatest.
Of ae ill comes mony.
Of ill debtors men get aiths.
Ony thing for you about an honest man's house but a day's wark.
Open confession is gude for the soul.
Our sins and debts are often mair than we think.
Out o' the peat pot into the gutter.
Owre mony grieves only hinder the wark.
Pay him in his ain coin.
Placks and bawbees grow pounds.
Play's good while it's play.
Please your kimmer, and you'll easily guide your gossip.
Plenty maks dainty.
Poor folk's friends soon misken them.
Poverty is the mother o' a' arts.
Pride and grace ne'er dwell in ae place.
Pride finds nae cauld.
Pride ne'er leaves its master till he get a fa'.
Pride that dines wi' vanity sups wi' contempt.
Provision in season makes a bien house.
Put a coward to his metal and he'll fight the deil.
Put on your spurs and be at your speed.
Put twa pennies in a purse and they'll keep thegither.
Put your finger in the fire, and say it was your fortune.
Put your hand twice to your bonnet for ance to your pouch.
Quality without quantity is little thought of.
Quey calves are dear veal.
Quick, for you'll ne'er be cleanly.
Quietness is best.
Rather spoil your joke than tine your friend.
Raw dads mak fat lads.
Raw leather raxes weel.
Reckon up your winning at your bed-stock.
Red wood maks good spindles.
Reputation is often got without merit and lost without crime.
Rich folk hae routh o' friends.
Rich mixture maks gude mortar.
Riches are got wi' pain, kept wi' care, and tint wi' grief.
Ride fair and jap nane.
Right wrangs nae man.
Rob Gib's contract—stark love and kindness.
Roose the fair day at e'en.
Rue and thyme grow baith in ae garden.
Rule youth weel, for eild will rule itsel.
Saut, quoth the souter, when he had eaten a cow a' but the tail.
Saw thin, shear thin.
Say still No, and ye'll ne'er be married.
Scanty cheeks mak a lang nose.
Scart-the-cog wad sup mair.
Send your gentle bluid to the market, and see what it will buy.
Serve yoursel till your bairns come of age.
Set a stout heart to a stey brae.
Shame fa' them that think shame to do themselves a gude turn.
She brak her elbow at the kirk door.
She hauds up her head like a hen drinking water.
She looks as if butter wadna melt in her mouth
She looks like a lady in a landward kirk.
She that gangs to the well wi' an ill will, either the pig breaks or the water will spill.
She'll keep her ain side o' the house, and gang up and down yours.
She'll wear like a horse-shoe, aye the langer the clearer.
She's better than she's bonny.
Show me the man, and I'll show you the law.
Sic as ye gie, sic will ye get.
Silence grips the mouse.
Slander leaves a sair behind.
Smooth waters run deep.
Soon eneugh if weel eneugh.
Soon eneugh to cry Chuck, when it's out o' the shell.
Sorrow and ill weather come unsent for.
Sorrow is soon eneugh when it comes.
Speak good of pipers, your father was a fiddler.
Spilt ale is waur than water.
Stay nae langer in a friend's house than you're welcome
Stuffing hauds out storming.
Tak a man by his word and a cow by her horn.
Tak the bit and the buffet wi't.
Tak time ere time be tint.
Tak wit wi' your anger.
Tak your ain will, and ye'll no die o' the pet.
Tak your thanks to feed your cat.
Tak your venture, as mony a gude ship has done.
That's Halkerston's cow.*
The black ox ne'er trod on his foot.†
The book o' maybes is very braid.
The cost owergangs the profit.
The deil aye drives his hogs to an ill market.
The deil doesna aye show his cloven cloots.
The deil gaes awa when he finds the door steekit against him.
The deil's bairns have aye their daddy's luck.
The deil's aye gude to his kin.
The deil's gane ower Jock Wabster.‡
The deil will tak little ere he want a'.
The deil's aye busy wi' his ain.
The first fuf o' a fat haggis is the bauldest.
The foot at the cradle and the hand at the reel, is a sign that a woman means to do weel.
The grace o' a gray bannock's in the baking o't.
The head for the washing.
The higher the hill the laigher the grass.
The hurt man writes wi' steel on marble stane.
The king may come in the cadger's gate.
The kirk's mickle, but you may say mass in the end o't.
The laird may be laird, and yet need his hind's help.
The master's foot's the best measure.
The o'ercome only fashes folk to keep.
There is an act in the Laird o' Grant's court, that no aboon eleven speak at ance.
There was a wife that kept her supper for her breakfast, and she was dead ere day.
There was ne'er a gude town but there was a dub at the end o't.
There was never a silly Jocky but there was as silly a Jenny.

* A story told the reverse of the real occurrence.
† Death never gave him sorrow.
‡ All things are gone wrong.

There was ne'er a thrifty wife wi' a sheet about her head.
There's a dub before every door.
There's a tough sinew in an auld wife's heel.
There's a whaup i' the raip.*
There's aye some water where the stirkie drowns.
There's beild aneath an auld man's beard.
There's steel in the needle point, though little o't.
There's the end o' an auld sang.
The simple man's the beggar's brither.
The smith's mare and the souter's wife are aye the warst shod.
The tod ne'er sped better than when he gaed his ain errand.
The thing that lies na in your gate breaks na your shins.
The thrift o' you and the woo o' a dog wad mak a braw web.
The worth o' a thing is best kenned by the want o't.
The wife's aye welcome that comes wi' a crooked oxter.†
They'll gree better when they gang in by different kirk doors.
They that board wi' cats maun count upon scarts.
They that burn you for a witch lose a' their coals.
They that gie you hinder you to buy.
They that lie down for love should rise up for hunger.
They that love maist speak least.
They were scant o' bairns that brought you up.
They are sad rents that come in wi' tears.
They hae need o' a canny cook that hae but ae egg to their dinner.
They may ken by your beard what has been on your board.
They ne'er saw great dainties that think a haggis a feast.
They should kiss the guidwife that wad win the guidman.
They speak o' my drinking, but ne'er think o' my drouth.
They that get a word o' soon rising may lie a' day.
They that see you a' day winna break the house for you at night.
Three can keep a secret when twa are away.
Thrift is a gude revenue.
Time tint is ne'er to be found.
Time and thinking tame the strongest grief.
Time tries a'.
Tine heart and a's gane.
Tine thimble, tine thrift.
Tit for tat's fair play.
To him that wills, ways are seldom wanting.
Toom stalls mak biting horses.
Truth will aye stand without a prop.
Try your friend ere you need him.
Twa words maun gang to that bargain.
Virtue never grows auld.
Waes the wife that wants the tongue, but weel's the man that gets her.
Want o' wit is waur than want o' wealth.
War maks thieves, and peace hangs them.
We are aye to learn as lang as we live.
We are bound to be honest and no to be rich.
Wealth has made mair men covetous than covetousness has made men wealthy.
Wealth maks wit waver.
Weans maun creep ere they gang.
We canna baith sup and blaw.
Wedding and ill wintering tame baith man and beast.
Weel kens the mouse when the cat's out o' the house.
Weel is that weel does.
We'll never ken the worth o' water till the well gae dry.
We maun live by the living and no by the dead.
Wha can haud what will be away.
Wha can help misluck.
Wha can help sickness, quoth the wife, when she lay in the gutter.
Wha comes oftener and brings you less.
Wha daur bell the cat.

* Something amiss.
† Bringing something under her arm.

Wha invited you to the feast.
Wha wad misca' a Gordon on the raws of Strathbogie.
What better's the house when the daw rises soon.
What may be done at ony time will be done at nae time.
What put that i' your head, that didna put the sturdy wi't.
What's my case the day may be yours the morn.
What's waur than ill luck.
What we first learn we best ken.
What winna do by might do by flight.
What ye do when your drunk ye may pay for when your dry.
What ye want up and down ye hae hither and yont.
When a' men speak, nae man hears.
When ae door steeks, anither ane opens.
When friends meet, hearts warm.
When he dies of age ye may quake for fear.
When ilka ane gets his ain, the thief will get the widdy.
When my head's down my house is theiked.
When petticoats woo, breeks come speed.
When the barn's fu' ye may thresh before the door.
When the cap's fu', carry't even.
When the cow's in the clout she soon runs out.
When the guidman drinks to the guidwife, a' wad be weel.
When the guidwife drinks to the guidman a's weel.
When the heart's fu' o' lust, the mouth's fu' o' leasing.
When the tod preaches, tak tent o' the lambs.
When the tod wins to the wood, he caresna how mony keeks at his tail.
When the wame's fu', the banes wad be at rest.
When the well's fu' it will rin owre.
When wine sinks, words swim.
When ye're gaun an' comin' the gate's no toom.
When ye are weel, haud yoursel sae.
When ye win at that, ye may lick aff a het girdle.
When you're served, a' the geese are watered.
When drums beat, laws are dumb.
Where the buck's bound there he maun bleet.
Wrang has nae warrant.
Ye're like auld maidens, ye look sae high.
Ye're like gude maut, ye're lang o' coming.
Ye're like Macfarlane's geese, ye hae mair mind o' your play than your meat.
Ye're like the chapman, ye're aye to handsel.
Ye're like the miller's dog, ye lick your lips ere the pock be opened.
Ye're like the cow's tail, ye grow backward.
Ye're like the tod, ye grow gray before ye grow gude.
Ye fand it where the Highlandman fand the tangs.
Ye hae fasted lang and worried on a midge.
Ye hae gotten the chapman's drowth.*
Ye hae gotten a ravelled hesp o't.
Ye hae ower foul feet to come sae far ben.
Ye hae put a toom spoon in my mouth.
Ye hae stayed lang and brought little wi' ye.
Ye hae taen the measure o' his foot.
Ye hae tint the tongue o' the trump.
Ye'll get nae mair o' the cat but the skin.
Ye'll hae baith your meat and your mense.†
Ye'll sit till ye sweat, and work till ye freeze.
Ye'll worry i' the band, like M'Ewan's calf.
Ye look as sharp as a Lochabar axe new come frae the grindstane.
Ye look like Let-me-be.
Yelping curs will raise mastiffs.
Ye maun have it simmered and wintered.
Ye're a gude seeker, but an ill finder.
Ye're best when ye're sleeping.
Ye're bonny enough to them that lo'e ye, and ower bonny to them that lo'e ye and canna get ye
Ye're busy seeking the thing that's no tint.

* Hunger.
† Offer a person a thing, and as he will not take it, you will at least have the credit of having made the offer.

Ye're come o' bluid, and sae's a pudding
Yer een's yer merchant.
Ye're feared for the day ye never saw.
Ye're gear will ne'er owergang ye.
Ye're never pleased, fu' nor fasting.
Ye're of sae mony minds, ye'll never be married.
Ye're sair fashed handing naething thegither.
Ye're teeth's langer than yer beard.
Ye shape shoon by your ain shachled feet.
Ye wad be a gude piper's dog, for smelling out bridals.
Ye wad be gude to fetch the deil a drink.
Ye wanta where a blessing may light.
Ye are a sweet nut, it ye were weel cracked.
Young folk *may* die, and auld folk *maun* die.
Your head will never fill your father's bonnet.
Your purse was steekit when that was paid for.
Your tongue rins aye before your wit

LATIN PROVERBS AND PHRASES.

Ab initio. From the beginning.
Ab uno disce omnes. From a single instance you may infer the whole.
Ad captandum vulgus. To catch the rabble.

Causus belli. The cause or reason for war.
Caput mortuum. The worthless remains.
Cede Deo. Submit to God.
Cede magnis. Give way to the powerful.
Cedant arma togæ. Let arms yield to eloquence.
Certum pete finem. Aim at a sure end.
Communia proprie dicere. To express common things with propriety.
Compos mentis. In a state of sane mind.
Concordia res parvæ crescunt. Small things increase by union.
Confide recte agens. Fear not while acting justly.
Contra bonos mores. Against good morals.
Corpus delicti. The body of the crime.
Credat Judæus apella. Let the circumcised Jew believe that.
Cui bono? To what good?
Currente calamo. With a running pen.
Data. Things given or granted.
De facto—de jure. From the fact—from the law.
Delectando pariterque monendo. By imparting at once pleasure and instruction.
Delenda est Carthago. Carthage must be destroyed. (The words of Cato.)
De mortuis nil nisi bonum. Let nothing be said of the dead but what is favourable.
Deo favente—juvante—volente. With God's favour—help—will.
Desideratum. The thing desired.
Desipere in loco To play the fool at the right time.
Desunt cætera. The remainder is wanting.
Deum cole, regem serva. Worship God, serve the king
Deus protector noster. God is our protector.
Dilige amicos. Love your friends.
Divide et impera. Divide and govern.
Dulce et decorum est pro patria mori. It is sweet and glorious to die for one's country.
Dum vivimus vivamus. Let us live while we live.
Est modus in rebus. There is a medium in all things.
Esto perpetua. Be thou perpetual.
Esto quod videris. Be what you seem to be.
Ex cathedra. From the chair; authoritatively.
Exempli gratia (E. g. and Ex. gr.) By the way of example.
Ex nihilo nihil fit. Nothing produces nothing.
Ex officio. By virtue of his office.
Ex parte. On one part.
Ex pede Herculem. Judge of the size of the statue of Hercules by the foot.
Experto crede. Believe an experienced man.
Extempore. Without premeditation.
Fac simile. Do the like: an engraved resemblance of handwriting.
Fama semper viret. A good name will shine for ever
Familias firmat pietas. Devotion strengthens families.
Fas est et ab hoste doceri. It is allowable to derive instruction even from an enemy.
Felo de se. A suicide.
Fiat justitia, ruat cœlum. Let justice be done, though the heavens should fall.
Fortuna favet fortibus. Fortune favours the bold.
Fruges consumere nati. Men born only to consume food.
Haud passibus æquis. With unequal steps.
Hinc illæ lachrymæ. Hence proceed these tears.
Id est (i. e.) That is.
Id genus omne. All persons of that description.
Imprimatur. Let it be printed.
Impromptu. Without study.
In forma pauperis. In the form of a poor man.
In propria persona. In person.
In re. In the matter of.
In terrorem. In terror.
In transitu. In passing.
Ipse dixit. He himself said it: dogmatism.
Judex damnatur cum nocens absolvitur. Guilt attaches to a judge when the guilty are suffered to escape.
Jure divino—humano. By divine—by human law.
Labor omnia vincit. Labour conquers every thing.
Lapsus linguæ. A slip of the tongue.
Lex talionis. The law of retaliation.
Locum tenens. A deputy or substitute.
Magna est veritas, et prævalebit. The truth is powerful, and will ultimately prevail.
Materiem superabat opus. The workmanship surpassed the materials.
Medio tutissimus ibis. A medium course will be the safest.
Memento mori. Remember death.
Mens sibi conscia recti. A mind conscious of rectitude

Mirabile dictu. Wonderful to tell.
Multum in parvo. Much in little.
Mutatis mutandis. After making the necessary changes.
Necessitas non habet leges. Necessity has no law.
Nem. con. An abbreviation of *nemine contradicente.* Without dissent or opposition.
Ne plus ultra. Nothing beyond—the utmost point.
Ne quid nimis. Too much of one thing is good for nothing.
Ne sutor ultra crepidam. Let not the shoemaker go beyond his last.
Nisi Dominus frustra. Unless the Lord assist you, all your efforts are in vain.
Noscitur ex sociis. He is known by his companions.
Nota Bene (N. B.) Mark well.
Obiter dictum. A thing said by the way or in passing.
Onus probandi. The weight of proof; the burden of proving.
O si sic omnia! Oh that he had always done, or spoken thus!
O tempora, O mores! Oh the times, oh the manners!
Otium cum dignitate. Ease with dignity.
Palmam qui meruit ferat. Let him who has won bear the palm.
Pari passu. By a similar gradation.
Par nobile fratrum. A noble pair of brothers.
Particeps criminis. An accomplice.
Passim. Everywhere.
Per fas et nefas. Through right and wrong.
Per se. By itself.
Poeta nascitur non fit. Nature, not study, must form a poet.
Primâ facie. On the first view, or appearance.
Primæ viæ. The first passages: the upper part of the intestinal canal.
Primum mobile. The main spring; the first impulse.
Principiis obsta. Oppose the first appearance of evil.
Pro aris et focis. For our altars and firesides.
Pro bono publico. For the public good.
Pro et con. For and against.
Pro re nata. For a special business.
Pro tempore. For the time.
Quid nunc? What now?—applied to a news-hunter.
Quid pro quo. What for what; tit for tat.
Quoad hoc. To this extent.
Quod erat demonstrandum. Which was meant to be shown.
Rara avis in terris, nigroque simillima cygno. A rare bird in the earth—very like a black swan.
Reductio ad absurdum. A reducing to an absurdity.
Re infecta. Without attaining his end.
Requiescat in pace. May he rest in peace.
Res angusta domi. Narrow circumstances at home
Respice finem. Look to the end.
Seriatim. In order.
Sic itur ad astra. Such is the way to immortality.
Sic passim. So everywhere.
Sic transit gloria mundi. Thus the glory of the world passes away.
Sine die. To an indefinite time.
Sine qua non. An indispensable condition.
Status quo antè bellum. The state in which both parties were before the war.
Suaviter in modo, fortiter in re. Gentle in the manner, but vigorous in the deed.
Sub silentio. In silence.
Summum bonum. The chief good.
Suum cuique. Let every man have his own.
Tabula rasa. A smoothed tablet.
Tempora mutantur, et nos mutamur in illis. The times change, and we change with them.
Toties quoties. As often as.
Ubi suprà. Where above mentioned.
Vade mecum. Go with me: a constant companion. (Usually applied to a pocket-book.)
Veluti in speculum. As if in a mirror.
Veni, vidi, vici. I came, I saw, I conquered.
Vis inertiæ. Force or property of inanimate matter.
Versus (v.) Against.
Vice versa. The terms or cases being changed.
Vi et armis. By main force.
Viva voce. By or with the living or loud voice.
Viz. (videlicet.) Namely.
Vox et præterea nihil. A voice and nothing more.
Vox populi, vox Dei. The voice of the people is the voice of God.
