Snow, which in Britain falls generally most copiously during the months of December, January, and February, seldom occurs so early as October, and is generally, after remaining some time on the ground, dissipated by an increase of temperature, arising from the direct action of the sun's rays or the fall of rain. Occasionally, however, it disappears without any apparent thaw, or so much dissipates as to leave deep furrows on the snowy plain. This arises from the snow itself being evaporated, which will occur even below the freezing-point. "On the night of the 10th of February," says Luke Howard, "I exposed 100 grains of light snow, spread on a dish (which had previously the temperature of the air) of six inches in diameter. In the first hour after dark it lost five grains; in the third it acquired a grain, the wind having changed, and the temperature, which had been falling from 25°, inclining to rise again. In the course of the night the loss was about 60 grains." This very ingenious author adds, that this evaporation from snow probably supplies the water for the formation of those thin mists which appear during intense frost. The air then becomes partially loaded with particles of ice, or of water at so low a temperature as to be ready to become solid the moment they find support. Hence, too, may arise the rime-frost, which is found to accumulate on the windward side of the twigs and branches of shrubs and trees. Snow seldom remains long, in temperate latitudes, on plains or in valleys, but on the tops of high mountains it occasionally appears throughout the year. The cause of its continuance on these exalted spots, is the thinness of the atmospheric air, which is incapable of holding sufficient heat from the sun's rays to melt the general mass.

Sleet is only a modification of snow. When aqueous globules freeze in the higher regions of the atmosphere, they aggregate together, and form flakes of snow; and when these have partly thawed, and have again become frozen, they constitute sleet, which is thus caused by the variable temperature of the atmosphere. Sleet falls at all seasons, and sometimes changes into rain and sometimes into snow. It occasionally falls, indeed, very heavily, gathering and freezing additional moisture in its descent.

Hail is described by meteorologists as frozen drops of rain, the freezing having taken place while the smaller vesicles of water were assuming the heavier properties of the rain-drop. A cold current of air, blowing suddenly in the direction of a rain-cloud, is understood to is the immediate cause of most hail-showers. Hail-stones vary much in shape; they are generally oval or round, but sometimes thin, flat, irregularly globular, angular, pyramidal, occasionally irregular, having a central point whence proceed numerous icy spiculæ, like rays in all directions; and, also, although more rarely, they have appeared as six-sided prisms. Hail-stones vary in size from that of a small seed to that of a boy's marble, the smaller generally falling in the more northerly climates, the larger in the south of Europe. In different parts of France and Britain, very large hailstones have occasionally fallen, and done serious damage.

It is calculated that a single drop of water, the diameter of which is only the one-thousandth part of an inch, will, in descending through the air, acquire a velocity of nine or ten feet every second; wherefore it is less surprising that hailstones of such magnitude and weight should occasionally prove destructive, not only to delicate plants but even to animals. The large size of hailstones is attributed to an accumulation during the progress of their descent. It is probable that the largest commences its formation with a small nucleus, which receives continual accessions from vapoury particles which it freezes and attaches to itself as it proceeds. Accordingly, hailstones are found to be smaller on the tops of mountains than in the neighbouring plains or valleys; because, not falling so far, they do not augment their size by the addition of successive layers of congealed watery vapour.

Hoar-frost, which appears like a beautiful powdery crystallization on trees and herbage, is only frozen dew. The conversion of dew into hoar-frost is another wise arrangement in nature, by which plants are protected from the severity of a freezing cold atmosphere.

THUNDER AND LIGHTNING—STORMS.

Independently of the storms of regular occurrence in warm climates, such as monsoons and simooms, there occur sudden and violent atmospheric agitations, both at sea and land, the causes of which are various, though generally depending on rapid transitions of temperature and electrical influence. Two kinds of storms, in particular, are dependent on electrical action in the atmosphere and clouds—the common thunder-storms of temperate climates, and those of a very violent nature occurring in the form of hurricanes in tropical regions.

Thunder-storms.—Storms of thunder and lightning are simply a case of electrical discharges from one cloud to another, and are a means adopted by nature to restore electrical equilibrium in the atmosphere, and at the same time clear the air from unwholesome vapours or properties. The explanation of thunder-storms given by Professor Thomson, in his Outlines of the Science of Heat and Electricity, being the best we have seen, we shall lay it before the reader:—"Air and all gases are non-conductors; but vapour and clouds, which are composed of it, are conductors. Clouds consist of a kind of bladders of vapour, charged each with the same kind of electricity. It is this electric charge which prevents the vesicles from uniting together, and falling down in the form of rain. Even the vesicular form which the vapour assumes is probably owing to the particles being charged with electricity. The mutual repulsion of the electric particles may be considered as sufficient (since they are prevented from leaving the vesicle by the action of the surrounding air and of the surrounding vesicles) to give the vapour the vesicular form. In what way these clouds come to be charged with electricity, it is not easy to say. But, as electricity is evolved during the act of evaporation, the probability is, that clouds are always charged with electricity, and that they owe their existence, or at least their form, to that fluid. It is very probable that when two currents of dry air are moving different ways, the friction of the two surfaces may evolve electricity. Should these currents be of different temperatures, a portion of the vapour which they always contain will be deposited; the electricity evolved will be taken up by that vapour, and will cause it to assume the vesicular state, constituting a cloud. Thus we can see, in general, how clouds come to be formed, and how they contain electricity. This electricity may be either vitreous or resinous, according to circumstances. And it is conceivable that, by long-continued opposite currents of air, the charge accumulated in a cloud may be considerable. Now, when two clouds, charged, the one with vitreous and the other with resinous electricity, happen to approach within a certain distance, the thickness of the coating of electricity increases on the two sides of the clouds which are nearest each other. This accumulation of thickness soon becomes so great as to overcome the pressure of the atmosphere, and a discharge takes place, which occasions the flash of lightning.

"The noise accompanying the discharge constitutes the thunder-clap, the long continuance of which partly depends on the reverberations from neighbouring objects. It is, therefore, loudest and largest, and most tremendous in hilly countries. These electrical discharges obviously dissipate the electricity; the cloud condenses into water, and occasions the sudden and heavy rain which always terminates a thunder-storm. The previous motions of the clouds, which act like electrometers, indicate the electrical state of different parts of the atmosphere. Thunder, then, only takes place when the different strata of air are in different electrical states. The clouds interposed between these strata are also electrical, and owe their vesicular nature to that electricity. They are also conductors. Hence they interpose themselves between strata in different states, and arrange themselves in such a manner as to occasion the mutual discharge of the strata in opposite states. The equilibrium is restored; the clouds, deprived of their electricity, collapse into rain; and the thunder terminates. In thunder-storms, the discharges usually take place between two strata of air, very seldom between the air and the earth. But that they are sometimes also between clouds and the earth cannot be doubted. These discharges sometimes take place without any noise. In that case, the flashes are very bright but they are single flashes, passing visibly from one cloud to another, and confined usually to a single quarter of the heavens. When they are accompanied by the noise which we call *thunder*, a number of simultaneous flashes of different colours, and constituting an interrupted zigzag line, may generally be observed stretching to an extent of several miles. These seem to be occasioned by a number of successive or almost simultaneous discharges from one cloud to another, these intermediate clouds serving as intermediate conductors, or stepping-stones, for the electrical fluid. It is these simultaneous discharges which occasion the rattling noise which we call *thunder*. Though they are all made at the same time, yet, as their distances are different, they only reach our ear in succession, and thus occasion the lengthened rumbling noise, so different from the snap which accompanies the discharge of a Leyden jar.

"If the electricity were confined to the clouds, a single discharge, or a single flash of lightning, would restore the equilibrium. The cloud would collapse, and discharge itself in rain, and the serenity of the heavens would be restored; but this is seldom the case. I have witnessed the most vivid discharges of lightning from one cloud to another, which enlightened the whole horizon, continue for several hours, and amounting to a very considerable number, not fewer certainly than fifty, and terminating at last in a violent thunder-storm. We see that these discharges, though the quantity of electricity must have been immense, did not restore the equilibrium. It is obvious from this, that not only the clouds, but the strata of air themselves, must have been strongly charged with electricity. The clouds, being conductors, served the purpose of discharging the electricity with which they were loaded, when they came within the striking distance. But the electric stratum of air with which the cloud was in contact, being a non-conductor, would not lose its electricity by the discharge of the cloud. It would immediately supply the cloud with which it was in contact with a new charge. And this repeated charging and discharging process would continue to go on till the different strata of excited air were brought to their natural state."

After these explanations, it is only necessary to say, that however awful the noise which thunder usually makes, it is in no shape dangerous. The real danger is from the lightning, which has a tendency to strike high pinnacles of buildings or spires of churches; but if these high places be furnished with metal rods to conduct the lightning to the ground, no injury is likely to occur. Lightning, either silent or accompanied by thunder, is of much rarer occurrence in the British islands than on the continent of Europe.

Law of Storms.—Considerable attention has been bestowed by various men of science on what are supposed to be the regulating principles of storms; for it cannot be doubted that, however irregular their occurrence and apparent action, they are subject to certain fixed laws, and these it is important to discover. As yet, the law of storms has assumed no very distinct or generally recognised form, almost every student of atmospheric phenomena having his own theory on the subject. The question upon which the chief difference exists, is, whether storms blow in direct lines or in circles. The probability is that storms of wind are greatly influenced by the configuration of the localities over which they blow, as well as by the opposition they may meet with in their course: for example, a violent gale of wind, coming in direct force against a lofty mountain, will probably be transformed into a whirlwind; and a similar result will follow the opposing contact of two fierce winds.

At a meeting of the British Association at Newcastle in 1838, Lieut. Colonel Reid, of the Royal Engineers, laid before that body his views respecting the laws of storms, which have met with general acceptation. From extensive observations on foreign stations and at sea, he was of opinion, with Mr. Redfield and Colonel Capper, two persons who had previously investigated the subject, that hurricanes are great whirlwinds, and that these whirlwinds were progressive. "The general phenomena of these storms," he observed, "will be understood, if the storm, as a great whirlwind, be represented by a circle whose centre is made to progress along a curve, or part of a curve, which is in most cases of a form approaching the parabolic, the circles expanding as they advance from the point at which the storm begins to be felt—the rotatory motion, in the northern hemisphere, being in the contrary direction to that on which the hands of a watch goes round; while, in the southern hemisphere, the rotation is in the same direction as that in which the hands of a watch revolve. He pointed out how his views were illustrated by the disastrous storm of 1809, experienced by the East India fleet, under the convoy of the Culloden line-of-battle ship, and the Terpsichore frigate, and four British men of war, which left the Cape of Good Hope about the same time, intending to cruise about the Mauritius. Some of these vessels scudded and ran in the storm for days; some, by lying to, got almost immediately out of it; while others, by taking a wrong direction, went into the heart of it, foundered, and were never heard of more; others, by sailing right across the calm space, met the same storm in different parts of its progress, and the wind blowing in opposite directions, and considered and spoke of it as two storms which they encountered; while others, by cruising about within the bend of the curve out beyond the circle of the great whirl, escaped the storm altogether, which had been for days raging on all sides of them. This led him to draw the very important practical conclusion as to how a ship should act when she encountered a gale, so as to escape from it. By watching the mode of veering of the wind the portion of a storm into which a ship is falling may be ascertained; if the ship be then so manœuvred as that the wind shall veer aft instead of ahead, and the vessel is made to come up instead of being allowed to break off, she will run out of the storm altogether; but if the contrary course be taken, either through chance or ignorance, she goes right into the whirl, and runs a great risk of being suddenly taken aback, but most assuredly will meet the opposite wind in passing out through the whirl. To accomplish her object, he showed, by a diagram, that it was necessary the ship should be laid on opposite tacks, on opposite sides of a storm, as may be understood by drawing a number of concentric circles to represent the whirl of the hurricane, and then different lines across these, to represent the course of ships entering into or going through the storm.

Mr. Espy, an American gentleman, who laid a number of facts on the subject before the British Association in 1840, arrives at the same conclusion as Redfield, Capper, and Reid; but adds, that the whirlwinds blow progressively towards a common centre. This blowing inwards to a centre, Mr. Espy conceives to be the consequence of the sudden and powerful ascent of a column of air at that centre, from the atmosphere being there more heated than elsewhere.

If any careful observer of atmospheric phenomena, on the ocean, possess facts which tend to throw any light on this exceedingly important branch of science, it is his duty to make them known for the general benefit of mankind.

UNUSUAL METEORIC PHENOMENA.

Among the meteoric phenomena which are of less frequent occurrence than those already noticed, may be included rainbows, figures in the air, luminous meteors, ignis fatui, the aurora borealis, halos, parhelia, and aërolites. Having in the article OPTICS explained the cause of rainbows to be simply the refraction of light through the drops of a shower of rain (or through the spray of a cataract), nothing more need be said on the subject here. With respect to the appearance of figures in the air, such as representations of landscapes, men, and animals, ships at sea, and so on, it has likewise been shown, in the article OPTICS, that they are a natural consequence of peculiar refractive powers of the atmosphere at the time of the occurrence. The Mirage of the desert, the Fata Morgana of the Venetians, the Brocken of the Hartz Mountains in Germany, and the armies seen in the air, according to Scottish superstition, all belong to this class of meteoric phenomena.

Luminous Meteors.—These are of various kinds. One of the most familiar is the Will o' the wisp or *ignis fatuus* (the fire of fools), which appears at night on marshy grounds or places of sepulture. The appearance is that of a small flickering light, straggling in an irregular manner at the height of one or two feet from the ground, and sometimes standing for a few moments over a particular spot. When approached or pursued, the lights are agitated by the motion of the air, and seem to elude investigation. The cause of this species of meteor is well known to men of science; the light being nothing more than phosphuretted hydrogen gas, arising from decomposing substances in the ground, spontaneously lighted. The meteors commonly called *falling stars*, which shoot from the upper region of the atmosphere, are ascribed to a similar origin: they are masses of matter inflated with phosphuretted hydrogen gas, which, being spontaneously ignited, shout in a downward direction to the earth. The greatest height whence they come is not above two or three miles, and seldom so much. Electricity, it may be supposed, is also concerned in this class of meteors.

Aurora Borealis.—In extreme northern and southern latitudes, and generally in the coldest season of the year, the sky appears luminous with streams of soft light, called the aurora borealis or the northern lights. This beautiful phenomenon is comparatively seldom seen as far south as the centre of England, but is frequently observed in Scotland, where it is popularly known by the name of *streamers*. In the latter country it appears a little after sunset, and uniformly arises in the north, inclining generally a little to the west; and it occurs more frequently about the time of the equinoxes than at any other season of the year. Its manner of arising, and the general characters it assumes, vary extremely; indeed, so much so as almost to preclude any accurate description. Sometimes, an hour or two after dark, it seems to illumine the northern region of the sky with no more than a gentle and subdued twilight, which gives a soft relief to the surrounding darkness. Sometimes detached masses of light suddenly appear in different parts of the sky, from which silvery and tremulous beams shoot with dazzling and evanescent splendour. Not unfrequently, indeed, from one single spot of light the beams vividly and rapidly extend. Sometimes the phenomenon is first discernible in delicate streaks or threads of light, which enlarge and shift with inconceivable rapidity, until a tremulous arch is formed, which completely spans the azure vault. Very often one general or principal arch is observed, with smaller ones at unequal distances, which frequently move laterally towards each other, and suddenly unite into one broad brilliant mass. Often, from the horizon, in the north, one limb or segment in the arch springs up into the heavens, and sometimes several of these arise at distances from each other. The varying splendour of the coruscations, and the rapid and playful movements which they display, as they sweep across the heavens, excite alike the wonder and admiration of the spectator.

The height of the aurora has been variously computed to be from 100 to 700 miles above the surface of the earth, and consequently far beyond the sphere of our atmosphere. All the conjectures hazarded with respect to the nature and cause of the aurora have been unsatisfactory: the most feasible conclusion is, that the phenomenon is a demonstration of electric fluid in its passage from the polar to the equatorial regions. Well-digested facts are still required to form an exact and satisfactory theory on the subject.

Halos—Parhelia.—In the colder regions of the globe, and sometimes in temperate climes during cold weather, what are called halos and parhelia, or mock-suns and mock-moons, are sometimes seen. A halo usually consists of two concentric circles of coloured or refracted light, such as that of a rainbow, the one forming an angle of about 23½ degrees, the other an angle of about 47 degrees, with the sun or moon. In different parts of these circles, and chiefly in opposite points at a similar altitude with the sun, bright spots of unrefracted light are seen, which have received the names of mock-suns and mock-moons, according as the light is received from the sun or from the moon during the appearance of the halo. From these bright spots diverging horns of light are occasionally observable. It is generally agreed that a halo is produced by the sun or moon's light being refracted by frozen vapour in the atmosphere. The cause of the parhelia, or bright sun-like spot, is more difficult of definition. Some suppose it to be caused by the frozen vapour being arranged in such a manner at particular points, as allows the light of the sun or moon to be transmitted in a concentrated instead of a refracted form.

Aërolites.—These are fiery meteors, which, in various forms and sizes, are seen to shoot from the heavens, and, falling to the earth, are found to consist of certain kinds of stones. The chronicles of almost every age and country record the fall of these bodies, which sometimes arrive on the surface of our planet individually, and at other times in what must be called a stream or shower. The celebrated Gassendi informs us, that, on the 29th November, 1637, about ten o'clock, A. M., while the sky was perfectly serene and transparent, he saw a flaming stone, apparently about four feet diameter, fall on Mount Vaison, in Provence. This stone was encircled with a zone of various colours, like a rainbow, and accompanied in its fall with a noise resembling the discharge of artillery. It was of a dark metallic colour, extremely hard, and 59 lbs. in weight. In June, 1668, two stones, one of which weighed 300, and the other 200 lbs., fell near Verona. The event took place during the night, and when the weather was perfectly serene and mild. They appeared to be all on fire, descending in a sloping direction, and with a tremendous noise. The phenomenon was witnessed by a great number of people, who, when the sounds had ceased, and their courage was sufficiently re-established, ventured to approach these celestial deposits, and found that they had formed a ditch, such had been the force with which they had descended. One of the largest meteoric stones which have ever fallen, is now exhibited in a room in the British Museum; it is several feet in diameter, of great weight, shaped like a spheroid, and brown in exterior appearance.

All meteoric stones that have been examined, present a similar structure and appearance. The chemical analysis of one which fell in France in 1810, may be taken as a sample of the whole:—Silica, 38·4; alumina, 3·6; lime, 4·2; magnesia, 13·6; iron, 25·8; nickel, 6; manganese, 0·6; sulphur, 5; chrome, 1·5; total, 98.7. The velocity with which the stones are shot through the atmosphere renders them red hot, and some time elapses after their fall before they cool and can be handled.

With respect to the origin of aërolites, there are four theories, each having its supporters. According to Laplace, Poisson, Dr. Hutton, and others, they are stones projected from volcanoes in the moon; it being demonstrated that an initial velocity of 6000 feet per second would be sufficient to drive them beyond the moon's attraction, and to bring them within the greater attraction of the earth. Another set of philosopher's allege they are projected from volcanoes on the earth, which is exceedingly improbable. Playfair and others say it is not unlikely that the stones are formed in the atmosphere, by an aggregation of particles of matter, the result of gaseous vapours; this chemical theory is also very unsatisfactory. The fourth and most probable theory is, that the stones are *asteroids*, or diminutive planets, drawn to the earth's surface when our globe, in its annual revolution, arrives at points near which these bodies are performing circuits round the sun. A series of remarkable phenomena, of recent occurrence, serve to support this theory. On the morning of the 12th, 13th, or 14th of November, every year since 1833, there have occurred, at different parts of both Europe and America, showers of meteoric bodies, of a most brilliant appearance; and it has thence been conjectured that the earth, in its revolution round the sun, had fallen in with these bodies in the same or nearly the same part of its orbit. If such be the true hypothesis, it follows that these meteors are travellers in space, performing circuits like the planets, and have most likely been projected from the sun in the same manner as the earth and other planetary bodies are believed to have been hurled from that luminary. Showers of fiery meteors, sometimes only gaseous, and at other times solid, are, however, found to occur annually in August, December, and other periods of the year. In September, 1841, a shower of many millions of meteoric stones, the greater number of which were not larger than small hailstones, occurred in Hungary, their chief ingredients being oxydate of iron, oxyde of iron, and oxyhydrate of iron, with flint, lime, and clay earth.

THE WEATHER.

From the preceding account of the various phenomena of the atmosphere, it must be evident that prognostications respecting the weather must be extremely uncertain, if not, for the most part, quite illusory. According to an ancient prejudice, it has been supposed that the moon, on entering its different quarters, exercises an influence over the weather; but this is ascertained by men of science to be without foundation in truth. The moon affects the tides of the ocean, but in no other known manner has it any influence over the ordinary phenomena of our planet.

It has been seen that the winds are the grand disturbers of the weather, and that to them we may proximately ascribe the occurrence of clear skies, fogs, clouds, rain, &c. As the winds originate from circumstances frequently far beyond our horizon, and cannot consequently be foreseen, every prognostic of either fine or bad weather is liable to complete derangement. The chance floating of an iceberg from the northern polar regions to a temperate latitude in the Atlantic, has been known to shed such a cold over Britain as to destroy the best hopes of summer. To utter prophecies of the coming weather, in a country exposed to such contingencies, appears ridiculous. It has long been a favourite belief with certain classes of persons, that the weather goes in cycles—that, after a limited number of years, the same succession of weather in the different seasons of the year recurs, and is repeated periodically. A period or cycle of nine, eighteen, thirty-six, and fifty-four years, has been variously fixed upon. In Scotland, nineteen years has been more generally believed to form a cycle, and on that account, leases of farms are commonly made out for that period, in order to give the agriculturist the benefit of an entire round of weather. To suit and support these theories, which rest on no solid foundation, almanacs have been put forth, pretending to foretell the weather of the coming year; but, unless when favoured by accidental resemblences between the weather and the prediction, all such oracular prophecies have been disproved by facts. As far as the records of meteorological phenomena for a long series of years warrant a conclusion, the following principles respecting the weather may be considered settled:—1. The weather of each year stands by itself; 2. The weather differs annually, and is different in different places according to circumstances; 3. The weather in the interior of continents is so regular in its seasonal variations, that it may be foretold with considerable certainty; 4. The weather of the British islands is so irregular, from unforeseen causes, that predictions as to its condition are only warrantable in very general terms, at any season of the year, 5. That agricultural improvement, such as draining of moist grounds, improves climate, and tends to equalize temperature; and, 6. That the asperities of cold in our winters, and extreme heats of our summers, have been modified from this cause; while, though in some respects uncomfortable, our climate is improved in its salubrious properties, and by allowing out-of-door exercises and employment for a greater number of days throughout the year than that of most other countries, is highly conducive to health, longevity, and social advancement.

[RECENT DISCOVERIES IN METEOROLOGY.

The science of Meteorology has attracted more attention of late than in former times. Among the most successful inquirers is Mr. Espy, of Philadelphia, whose ingenious theories on the subject are founded on a course of observations and experiments continued regularly for some thirty years. His predictions respecting changes in the weather, and the precision with which he has pointed out the locality of storms raging at the moment at great distances from his own residence, have excited astonishment. These, however, are founded on scientific principles which he has developed in his theory of storms.

The facts and laws which he has discovered are generally recognised as having considerable practical value.

Other inquirers both in America and Europe are still earnestly endeavouring to advance the science and to reduce their discoveries to such practical results as may be useful to the agriculturist and the mariner.—*Am. Ed.*]

PHRENOLOGY.

It has of late been customary for the conductors of popular cyclopædias to admit articles on Phrenology; but in most if not all the instances in which this has been done, the articles were the composition of persons who denied that phrenology was a true system of mental philosophy, and whose aim rather was to show its want of sound foundation than simply to present a view of its doctrines. In every one of these instances, it was afterwards successfully shown by phrenological writers, that their science had been misrepresented, and its doctrines challenged on unfair grounds; so that the articles in question might as well not have been written, in so far as the instruction of candid inquirers was concerned. We have resolved to eschew this practical absurdity, by presenting a view of phrenology by one who believes it to be the true system of mind. This we conceive to be a course the more necessary, that phrenology, overlooking altogether its organological basis, presents a far more intelligible view of the faculties of the human mind, and the phenomena of their working, than any of the metaphysical systems. It is eminently, we think, the system of mental philosophy for the unlearned man, because it is much less abstract than any other. In perusing the account which it gives of the mind and its parts, ordinary people feel, for the first time in their attempts at psychological investigation, that they have ground whereon to rest the soles of their feet. Thus, supposing the observations made with regard to the connection of certain manifestations of thought and feeling with certain parts of the brain to be untrue, there is still a distinct value in phrenology, as an extensively available means of studying mind. We deem it right, at the same time, to mention that phrenology appears to us as beforehand likely to be true, in as far as it assigns a natural basis to mind; while we are equally sensible that its leading doctrines have acquired a title to a very respectful attention, from the support given to them by a vast amount of careful observation, and the strikingly enlightened and philanthropic aims for which many of its supporters have become remarkable. With these introductory remarks, we leave our readers to form their own opinions respecting the science, as far as they are enabled to do so by a treatise necessarily brief, and which, therefore, admits of but a slender exhibition of evidence.—*Ed.*

Phrenology is a Greek compound, signifying a discourse on the mind. The system which exclusively passes by this name, was founded by Dr. Francis Joseph Gall, a German physician, born in 1757. Dr. Gall was led, when a school-boy, to surmise a connection of particular mental faculties with particular parts of the brain, in consequence of observing a marked prominence in the eyes of a companion who always overmatched him in committing words to memory. Finding the same conformation in others noted for the same talent, he reflected that it was possible that other talents might be accompanied by external marks, and that dispositions might also be so indicated. He devoted himself to observing marked features of character; and on examining the heads, was struck with differences in their forms, there being prominences and hollows in some not found in others, with corresponding variations of character in the individuals. After most extensive and accurate observation, he first lectured on the subject in Vienna in 1796. There his lectures were suppressed by a jealous and ignorant despotism; upon which he abandoned Germany and settled in Paris, where he practised as a physician, and studied and extended his "doctrine," as he always called it, till his death in 1828. His great work, with its illustrative engravings, is one of the most extensive and beautiful examples of inductive evidence of which any science can boast. Many phrenologists, who had previously read the works of the British writers only, have expressed their astonishment, when they came to read Gall's work, at the immense fabric he had reared, and how little, in the way of proofs of the organs discovered by him, he left to be done. Dr. Gall never took any particular step for making phrenology known in our island. With the exception of a light and trivial article in the *Edinburgh Review* in 1803, and another in the *Edinburgh Medical and Surgical Journal* in 1806, the science was not heard of in Britain till introduced by Dr. Spurzheim in 1815. He was a native of Treves on the Moselle, born in 1776, the pupil and, from 1804, the associate of Dr. Gall. Besides making many valuable discoveries in the anatomy and physiology of the brain, and ascertaining several organs in addition to those discovered by Dr. Gall, Dr. Spurzheim had the distinction of systematizing the discoveries of both into a harmonious and beautiful mental and moral philosophy. Dr. Spurzheim died at Boston in the United States in 1832. Since then, the recognised head of the phrenological school has been Mr. George Combe, of Edinburgh, author of many able and popular works on the science, and its most distinguished and successful teacher, by his public prelections both in Britain and America. The applications of phrenology to insanity, health, and infant treatment, have been at the same time admirably made by Dr. Andrew Combe, Mr. George Combe's distinguished brother; and to the treatment and reformation of criminals, and the new or character-forming education, by Mr. George Combe himself and Mr. James Simpson of Edinburgh. Many writers of more recent date have followed in the track of these authors, for, indeed, no other is now followed with practical effect on the subjects enumerated; but to phrenology the sound views now current on these subjects can in a great measure be traced.

THE PRINCIPLES OF PHRENOLOGY.

1. The *brain* is the organ by and through which *mind* in this life is manifested. This truth is now disputed scarcely anywhere. It was a great though wide-spread error, before the discovery of phrenology, that we can recognise mind and body as two distinct entities or existences: under the influence of that error, they were treated of separately by two several orders of philosophers—the metaphysicians and the anatomists. In vain to the metaphysician was it obvious, that we have no knowledge of mind but through the medium of a bodily apparatus, with which it grows and decays; he continued to treat of mind as a spirit unconnected with body. The anatomical investigator reasoned quite as unphilosophically, when he assumed that mind was nothing but matter, the higher qualities of which were to think and feel. The phrenologist avoids both these unproved assumptions. He does not pretend to know, much less to assume, the *essence* or nature of either mind or matter. Whether they are one or distinct is known only to the God who made them; and whatever they are, they must, therefore, be the best possibly adapted to their end and design. This is his answer to the unproved and unwarranted assumptions of spiritualism on the one hand, and materialism on the other; while he confines himself to the observation of the laws

which regulate mental phenomena, in their invariable connection with bodily organization; and to the *brain*, as most obviously so connected, he has seen reason to address his chief attention. To all sane manifestations of mind, brain in healthy action is necessary. In sleep, fainting, and compression of the brain, mind is suspended. In perfect sleep, the brain reposes, and mind ceases to be manifested. Were it an immaterial spirit, acting independently of the brain, the repose of the material brain could not suspend the spirit's working. In fainting, the blood ceases for the time to supply the brain, and consciousness and motion are suspended. Pressure on the brain instantly suspends consciousness. Mr. Combe, in his "System of Phrenology" (4th edition, p. 14,) describes several most interesting and instructive experiments on compression, as made by Richerand, Cooper, Chapman, Cline, and others. In several individuals, when the brain was partially exposed by accidents, these gentlemen applied pressure to the exposed part, when speech and consciousness suddenly stopped, to return when the pressure was removed. Pinel* clearly traces to a *bodily* cause the diseased manifestation of mind called insanity, by the following cases:—"A man engaged in a mechanical employment, and afterwards confined in the Bicêtre, experiences, at irregular intervals, fits of madness, characterized by the following symptoms:—At first there is a sensation of heat in the abdominal viscera, with intense thirst, and a strong constipation; the heat gradually extends to the breast, neck, and face, producing a flush of the complexion; on reaching the temples, it is still greater, and is accompanied by very strong and frequent pulsations in the temporal arteries, which seem as if about to burst; finally, the nervous affection arrives *at the brain*." What then follows? All the effects hitherto described are purely corporeal. Pinel proceeds—"The patient is *then* seized with an irresistible propensity to shed blood; and if there be a sharp instrument within reach, he is apt to sacrifice to his fury the first person who presents himself." How powerfully this case connects mind and brain, and what a strong light it sheds upon that really bodily, that is, cerebral, disease called insanity! Pinel cites another case of total change of character, from mild to furious, in an insane person, when redness of face, heat in the head, and thirst, occurred. The brain, when exposed, has been seen *in action*, during emotion, conversation, dreams, &c. Sir Ashley Cooper refers to the case of a young man who had lost a portion of skull above the eyebrow. "I distinctly saw the pulsation of the brain," says Sir Ashley; "it was regular and slow; but at this time he was agitated by some opposition to his wishes, and directly the blood was sent with increased force to the brain, and the pulsations became frequent and violent. If, therefore, you omit to keep the mind free from agitation, your other means (in the treatment of injuries of the brain) will be unavailing."† Blumenbach saw a portion of exposed brain to sink in sleep, and swell when the patient awoke.‡ Dr. Pierquin, and a writer in the *Medico-Chirurgical Review*, adduce other instances of the brain swelling out in waking hours, and still more in mental agitations. In these, such as pain, fear, anger, the dressings were disturbed, and the brain throbbed tumultuously. The cause is obvious: increased activity of brain, as of muscle, is accompanied by increased flow of blood to the part. Dr. Pierquin cites a case which is extremely instructive. His subject was a female, twenty-six years of age, who had lost a large portion of the skull and dura mater, so that a corresponding portion of the brain was laid bare. When she was in a *dreamless* sleep, her brain was motionless, and lay inside the cranium; when her sleep was *imperfect*, her brain moved and protruded; in *vivid dreams*, the protrusion was considerable; and when awake, and particularly when engaged in conversation or mental action, it was still greater, and remained so while conversation lasted.*

‡ Elliotson's Blumenbach, 4th edition, p. 283.

Common feeling refers the mind to, or localizes it in, the head; and common phrases are in accordance with this conviction. We have *long-headed*, *shallow-pated*, *crack-brained*, *well furnished with brain*, &c.; as expressions in every one's mouth.

From the above facts, phrenologists assume:—1st, As there is no vision or hearing without their respective organs, the eye and ear, so there is no thinking or feeling without their respective organs in the brain; 2d, Every mental affection must correspond with a certain state of the organ, and *vice versa*; 3d, The perfection of the mind will have relation to the perfection of its organs. The study of the cerebral organs, therefore, is the study of the mind, in the only condition in which we can cognise it. Hence all previous study of the mind, without reference to cerebral organization, has, philosophically speaking, gone for nothing, if we except the shrewd but unsystematic guesses of superior sagacity;† and phrenology presents the first practical mental philosophy known to man.

The brain being the general organ of the mind, we come next to inquire whether it is *all* necessary to every act of feeling or thinking; or whether it is divided into parts, each part being the instrument or organ of a particular mental act. 1st. It is a law of organization that different functions are never performed by the same organ. The stomach, liver, heart, eyes, ears, have each a separate duty. Different nerves are necessary to motion, feeling, and resistance, and there is no example of confusion among them. Analogy, therefore, is in favour of the conclusion that there are distinct organs for observing, reflecting, and feeling kindness, resentment, self-love, &c. 2d. The mental powers do not all come at once, as they would, were the brain one indivisible organ. They appear successively, and the brain undergoes a corresponding change. 3d. Genius varies in different individuals; one has a *turn*, as it is called, for one thing, and another for something different. 4th. Dreaming is explained by the doctrine of distinct organs which can act or rest alone. Its disjointed images and feelings could never occur if the brain acted as a whole. Undivided, it must either all sleep or all wake; so that there could be no such thing as dreaming. 5th. Partial insanity, or madness on one point, with sanity on every other, proves the distinction

* More lately than all these examples, Mr. Combe has recorded one of his own observing in America, which goes not only to prove action of the brain corresponding to activity of mind generally, but action of ascertained organs when their corresponding mental manifestations were called forth. The subject was a girl of eight years of age, who four years before, from a fall out of a window, lost the portion of skull which covers the organs of Self-Esteem and Love of Approbation. The integuments and hair are the only protection her brain has in that region, and its movements can be felt by the hand, like a leech through a silk handkerchief. Mr. Coombe placing his hand on the part, led the conversation so as to pique the child's self-esteem, when the motion was distinctly felt. When she was requested to do some arithmetical lesson, to set in action her intellect, the brain at Self-Esteem ceased to move. She was praised for her success, when the organ of the Love of Approbativeness, hitherto quiescent, sensibly moved; again the child's attention was directed to something distinct from herself, and once more the organ of Self-Esteem and Love of Approbation reposed. Mr. Combe repeated his trials several times with the same results.—*Notes on the United States.*

† An opinion, not much different, was expressed by the last of the Scottish metaphysical school, towards the end of his life. We allude to Mr. Dugald Stewart, who denies as true, but indirectly confirms, the following confession of M. de Bonald:—"Diversity of doctrine has increased from age to age with the number of masters, and with the progress of knowledge: and Europe, which at present possesses libraries filled with philosophical works, and which reckons up almost as many philosophers as writers, poor in the midst of so much riches, and uncertain, with the aid of all its guides, which road it should follow—Europe, the centre and focus of all the lights of the world, HAS YET ITS PHILOSOPHY ONLY IN EXPECTATION."

of organs, and their separate action. 6th. Partial injuries of the brain, affecting the mental manifestations of the injured parts, but leaving the other faculties sound, prove distinctiveness of organs. 7th. There could be no such state of mind as the familiar one where our feelings contend, and antagonize and balance each other, if the brain were one organ.

These are grounds for presuming that the brain is not unique, but a cluster of organs, or at least that it is capable of acting in parts, as well as in whole. For this conclusion, the phrenologists have found satisfactory proofs in repeated observations, showing that particular manifestations of mind are proportioned, in intensity and frequency of recurrence, to the size or expansion of particular parts of the brain, and are thus to be presumed to depend on those parts. Every step they have taken in this investigation has been guided by the strictest rules of the inductive philosophy, each of their inferences being grounded on an overwhelming number of cases leading to one uniform conclusion. It is therefore considered by them as a settled point, that the brain consists of a congeries of organs. It is a necessary result of the same investigations, and one of the most important doctrines of phrenology, that the power of each organ, in other words, its degree of mental manifestation, is in direct proportion to its *size*. This is a law everywhere seen affecting organic nature;* a large muscle, the conditions of health, quality, and outward circumstances, being the same, has more power than a small one. The same is true of a nerve. Dogs have very large nerves for smelling, eagles for seeing, &c. A child's brain is smaller, and its mental power weaker, than those of an adult. A very small brain in an adult is the invariable cause of idiocy. Dr. Gall observed that a head not measuring more in horizontal circumference than fourteen inches, is always idiotic. A large head *may* be idiotic from cerebral disease, but a very small head, from defect of size alone, is always idiotic. We present a contrast. Fig. 1

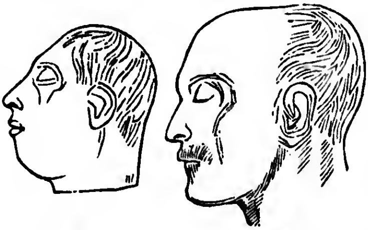

Fig. 1. Fig. 2.

is the head of an idiot of 20 years of age; fig. 2 is the head of the celebrated Hindoo reformer, Rammohun Roy, which was of great size, and, as is well known, manifested great power. It will in the sequel be shown that the Hindoo type of head is small, and the mental power correspondent; hence the exception, in both particulars, of Rammohun Roy's head, tells the more strongly for the doctrine. Men of great force of character, such as Napoleon, Franklin, Burns, had brains of unusually large size.

Powerful energetic nations exceed weaker ones in size of head, and invariably, when brought into collision with them, overcome them. The Gothic or Teutonic head is larger than the Celtic, which last race first occupied Europe, but was driven by the Gothic into the mountainous regions, where it was not worth the pains to follow it. The average European head is to the average Hindoo as the head of a man to that of a boy; and hence the conquest and subjection of a hundred millions of the latter by thirty thousand of the former. Figs. 9 and 10, to be found in a subsequent column, contrast a European with a Cingalese head. Indeed, the doctrine of size of brain accompanying power of character, is now generally admitted by the opponents of phrenology.

The general law, then, being that size of organ is accompanied by power of manifestation, we proceed to inquire, secondly, if there are any circumstances, and what these are, which modify this law. It will be found that *quality* of brain is a modifying circumstance, also *health* of brain, and *exercise* of brain.

1. Phrenologists conjectured that different brains differ in quality, but were long without any indications of these differences. The doctrine of the *Temperaments* has thrown considerable, though not perfect light on this point, and for this we are indebted to Dr. Thomas, of Paris. There are four temperaments, accompanied with different degrees of power and activity, in other words, quality of brain. These are the *bilious*, the *nervous*, the *sanguine*, and the *lymphatic*. These temperaments were observed and distinguished long before the discovery of phrenology, though to little purpose. They figure in the fanciful philosophy of Burton, and similar writers of former times, and much nonsense is written connected with them. Phrenology has adopted them, and made them intelligible and useful. They are supposed to depend upon the constitution of particular bodily systems. The muscular and fibrous systems being predominantly active, seem to give rise to the bilious temperament. The name is equivocal, and therefore not well applied; the other three are more appropriate. The brain and nerves predominating in activity, give the nervous; the lungs, heart, and blood-vessels, the sanguine; while the glands and assimilating organs present the lymphatic temperament. The predominance of these several bodily systems is indicated by certain sufficiently obvious external signs, whence our power of recognising them. The nervous temperament is marked by silky thin hair, thin skin, small thin muscles, quick muscular motion, paleness, and often delicate health. The whole nervous system, brain included, is active, and the mental manifestations vivacious. It is the temperament of genius and refinement. The bilious has black, hard, and wiry hair, dark or black eyes, dark skin, moderate fulness, but much firmness of flesh, with a harsh outline of countenance and person. The bilious temperament gives much energy of brain and mental manifestation, and the countenance is marked and decided; this is the temperament for enduring much mental as well as bodily labour. The sanguine temperament has well-defined forms, moderate plumpness and firmness of flesh, light or red hair, blue eyes, and fair and often ruddy countenance. It is accompanied with great activity of the blood-vessels, an animated countenance, and a love of out-door exercises. With a mixture of the bilious—for in most individuals the temperaments are mixed, often all four occurring in one person—it would give the soldier's temperament. The brain is active. The lymphatic temperament is indicated by a round form, as in the fat and corpulent, soft flesh, full cellular tissue, fair hair, and pale skin. The vital action is languid, the circulation weak and slow. The brain also is slow and feeble in its action, and the mental manifestations correspond.*

It must be kept in mind that the temperaments are only useful in comparing different brains; and this well illustrates what is meant by the condition of *cæteris paribus*, or other things being equal, a phrase much used in phrenology. If two brains, in every way similarly organized in size, differ in manifestation of power and activity, we must look to the temperaments of the individuals; and if we find one nervous and the other lymphatic, we

* See Essay by Dr. Andrew Combe, Phrenological Journal, vol. iv., p. 161.

* For a fuller description of the temperaments, see the article Account of the Human Body.

have a key at once to the difficulty. In the same brain all the organs, being influenced by the same temperament, must be subject to precisely the same modification. Various *causes* of the temperaments have been propounded, but none satisfactory; the *effects* more concern us, and these are now tolerably well recognised. In Mr. Combe's *System* (4th edition, page 43) there are coloured portraits of the temperaments, which convey a very satisfactory idea of them. We would recommend to our readers to see these, as we are precluded by our method of printing from introducing coloured engravings. The temperaments and their mixtures, for they are rarely if ever found unmixed, should be observed in living subjects.

2. The brain must be in a *sound healthy condition*, to manifest itself properly in the mental faculties. In judging of character, the phrenologist must inquire into this circumstance, as the external development does not reveal it.

3. Exercise—or whether or not, and how, the brain has been exercised—is another condition to be inquired into before judging of two individuals similarly organized. The brain which has been the more, and more judiciously, exercised, will manifest the greater degree of activity and power. The law of exercise is of universal application to animals, if not to organization in general. A muscle or nerve is strengthened by exercise; and a tree or plant by the motion given it by the wind. Over-exercise injures the brain. It is only another mode of inquiring into the circumstance of exercise of brain, when a phrenologist asks what opportunities of education an individual has enjoyed, and to what kind of society he has been accustomed. To this information he is entitled in judging of character, for the head alone will not reveal it.

If size of organ implies vigour of function, it is of great moment in what region of the brain the organs are largest —whether in the animal, moral, or intellectual. On this preponderance depends the character. Two brains may be exactly alike in size, generally, yet the characters may be perfect contrasts to each other. If the organs predominate in the moral region, the leading manifestations will probably be of a virtuous character; if in the intellectual, talent will be the probable consequence; if in the animal, there will be tendencies accordingly. There is nearly as much brain in fig. 4 as in fig. 3; yet fig. 3 is the head of Melancthon, the most virtuous and

Fig. 3.

Fig. 4.

talented of the reformers; while fig. 4 is the atrocious criminal Hare, who murdered by wholesale for gain. The superiority of fig. 3 in intellect is obvious by one glance at the high and full forehead, compared with "the forehead villanous low," as Shakspeare would have called it, of fig. 4. The horizontal line in fig. 4 shows the shallowness of moral brain. A line drawn from the same points in fig. 3 would show a much greater depth; while the mass of brain behind the ear in fig. 4, compared with fig. 3, shows the preponderance of animal brain in the former. Hare's head is an average specimen of the criminal type, of which there are hundreds in the phrenological museums, all of one unfortunate family likeness; while Melancthon's head may be taken as a type of high virtue and intelligence.*

THE PRIMITIVE FACULTIES OF MIND, AS CONNECTED WITH THEIR ORGANS IN THE BRAIN.

Mind, which was considered by the metaphysicians as a single thing or essence, was said by them to be capable of being in different *states*, in each of which states it made one of its various manifestations, as memory, judgment, anger, &c. In no particular does the phrenological hypothesis differ more from the metaphysical than in this. The phrenological doctrine is, that the brain, the organ of the mind, is divided into various faculties, each of which has its own mode of acting. It is held—

First. That by accurate observation of human actions, it is possible to discriminate the dispositions and intellectual power of man, such as love, anger, benevolence, observation, reflection, &c.

Secondly. That the true form of the brain† can be ascertained from the external form of the head; the brain, though the softer substance, being what rules the shape of the skull, just as a shell takes its form from the animal within.‡

Thirdly. The organs or parts into which the brain is divided, all of which organs are possessed by every individual except in the case of idiocy, appear on the brain's surface in folds or convolutions, somewhat like the bowels or viscera of an animal, but have a well-ascertained fibrous connection through the whole substance of the brain with one point at its base, called the *medulla oblongata*, which unites the brain to the spinal cord. The organs have thus each a conical form from the medulla oblongata to the surface; the whole being not inaptly compared to the stalks and flower of a cauliflower.

Fourthly. The brain is divided into two equal parts called *hemispheres*; on each side of the fosse or division between these hemispheres the same organ occurs; all the organs are therefore double, in analogy with the eyes, ears, &c. But when the term *organ* is used, both organs are meant. The organs which are situated close to the middle line drawn vertically on the head, though close to each other, are nevertheless double; for example, Individuality, Benevolence, Firmness, &c.

Fifthly. Besides the brain-proper, there is a smaller brain, attached to the hinder part of the base of the brain, called the *cerebellum*.

Sixthly. The brain, including the cerebellum, is divided into the *anterior*, *middle*, and *posterior lobes*. The cerebellum forms part of the posterior lobe. The anterior lobe contains all the intellectual faculties; the posterior and lower range of the middle lobe are the regions of the animal propensities; while the moral sentiments are found, with a sort of local pre-eminence, to have their organs developed on the top or coronal surface of the head.

* In these contrasted heads, the distinction may appear to be favoured by the way in which they are placed. We can assure our readers that the heads, however placed, fully make out the contrast here insisted on.

† A profile view of the naked brain, with the connected nerves and vessels, is given in the article entitled "Account of the Human Body."

‡ The skull being formed of two plates, a partial separation, generally in the forehead over the nose, often takes place, called the *frontal sinus*. This has given rise to much controversy, and more importance has been given it by opponents than it deserves. Its consequences, which do not affect the general truths of the science, are treated of in most of the phrenological works. We may add, that every student of phrenology should understand the anatomy of the brain, although such knowledge is not indispensable. We cannot enter on the subject of the brain here, but recommend Dr. Spurzheim's work on the brain, and a brief and clear exposition of its anatomy in Mr. Combe's *System*, 4th edition, p. 80.

The gradation in size of the organs is thus denoted:—

Very Small.	Moderate.	Rather Large.
Small.	Rather Full.	Large.
Rather Small.	Full.	Very Large.

It has been found convenient to express these degrees in numbers, thus:—

1.	8. (Rather Small.)	15
2. (Idiocy.)	9.	16. (Rather Large.)
3.	10. (Moderate.)	17.
4. (Very Small.)	11.	18. (Large.)
5.	12. (Rather Full.)	19.
6. (Small.)	13.	20. (Very Large.)
7.	14. (Full.)	21.

The intermediate numbers, 3, 5, 7, &c., denote something between the two denominations, and have been found useful.

In practice, the general size of the head is measured, in several directions, with calliper compasses. Twenty males, from 25 to 50 years of age, measured, from the occipital spine (the bony knot over the hollow of the neck) to the point over the nose between the eyebrows, on an average, $7\frac{1}{2}$ inches; some of them being as high as $8\frac{3}{8}$, and others as low as $6\frac{1}{2}$. From the occipital spine to the hollow of the ear, the average was $4\frac{3}{8}$, some being as high as 5, others as low as $3\frac{1}{2}$. From the hollow of the ear to the point between the eyebrows, as above, average nearly 5; some being $5\frac{1}{2}$, others $4\frac{1}{2}$. From the same hollow of the ear to the top of the head, about an inch behind the centre (the organ of Firmness), the average was $5\frac{9}{10}$; some being $6\frac{1}{2}$, others $5\frac{1}{2}$. Across the head, from a little below the tops of the ears (from Destructiveness to Destructiveness), the average was $5\frac{8}{10}$; some being $6\frac{1}{2}$, others $5\frac{1}{2}$. The averages are in these twenty individuals higher than those of the natives of Britain generally, some of them being large, and none small.

It ought never to be lost sight of, that, in estimating character from development, it is not legitimate to go out of the same head, and compare any organ with the same organ in another head. This will never ascertain the effect of a particular organ in the head where it exists; and for the plainest reason, that character is another word for the most powerful organs, as modified by their neighbours in the same head. A virtuous person may have the organ of Destructiveness absolutely larger than a person remarkable for a violent disposition; but it will be found that there are moral faculties to control, or that there has been education to modify, in the one person, and not in the other. The relative size of the organs in the same head has been compared to the relative size of the fingers in the same hand. We do not think of comparing any one finger with the same finger in other hands. But, in studying phrenology, different heads may be compared, in order to observe where particular organs are absolutely large, and where they are absolutely small. The learner should first attend to *extreme* cases of size, as the most easily observed.

We have said, the larger the brain, and of course the head, the more the power. The old adage, "Big head, little *wit*," is often true, but not always. It is true when, with a large brain, there is a lymphatic temperament, or when some damaging or deranging circumstance has taken place, to deprive the brain of its natural power, or when the largeness is not in the intellectual region. It is to be remarked, however, that even large animal brains have great *animal* power, in spite of their *intellectual* deficiency. A moderate-sized head, of which the brain is chiefly in the anterior or intellectual region, will have much more wit or cleverness than the other. Its power will be intellectual. The adage, which originated ages before these discoveries were made, must now, like many other adages, suffer modification.

Phrenologists further distinguish between *power* and *activity* in the organs of the brain. Power, in whatever degree possessed, is *capability* of feeling, perceiving, or thinking; while activity is the *exercise of power*, or the putting into action the organ with more or less intensity. An individual, for example, may possess great power of rage and destruction, and yet it may remain quiet, and the individual be perfectly calm. His large Destructiveness, however, will be more prone to start into activity than a smaller would. Activity is measured by the rapidity with which the faculties act. Clever brilliant men have active but moderate-sized brains, and do not make the impression, or command the homage, of larger, and of course more powerful, heads.

The powers of mind, as manifested by the organs, are called *faculties*. A faculty may be defined to be a particular power of thinking or feeling. A faculty has seven characteristics, in order to our concluding it primitive and distinct in the mind, namely, 1. When it exists in one kind of animal and not in another; 2. When it varies in the two sexes of the same species; 3. When it is not in proportion to the other faculties of the same individual; 4. When it appears earlier or later in life than the other faculties; 5. When it may act or repose singly; 6. When it is propagated from parent to child; and, 7. When it may singly preserve health, or singly manifest disease.

DIVISION OR CLASSIFICATION OF THE FACULTIES.

The faculties have been divided by Gall and Spurzheim into two great orders—FEELING and INTELLECT, or AFFECTIVE and INTELLECTUAL FACULTIES. The Feelings are divided into two genera—the *Propensities* and the *Sentiments*. By a propensity is meant an internal impulse, which incites to a certain action, and no more; by a sentiment, a feeling which, although it has inclination, has also an emotion superadded.

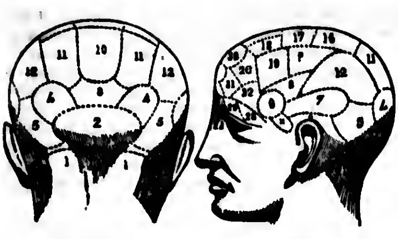
The second order of faculties, the Intellectual, also suffers division into the *Perceptive* or *Knowing*, and the *Reflective Faculties*. The Perceptive Faculties are again divided into three genera—1st, the *External Senses* and *Voluntary Motion*; 2d, the *Internal powers which perceive existence*, or make man and animals acquainted with external objects and their physical qualities; and, 3d, the powers which perceive *the relations* of external objects. The fourth genus comprises the *Reflective Faculties*, which act on all the other powers; in other words, compare, discriminate, and judge.

We owe to Dr. Spurzheim the names of most of the faculties as yet in use; and they have only been ridiculed, on account of their novelty, by those who did not perceive their logical accuracy.* In all the propensities, we find the termination *ive* to denote the quality of producing—as Destruct*ive*. To this is added the syllable *ness*, to denote the abstract state. Instead of *ive*, the termination *ous* is found in the name of a sentiment, with *ness* added—as Caut*ious*-ness, Conscienti*ous*-ness—to express the abstract quality. The names of the intellectual faculties require no explanation. The arrangement of the faculties generally adopted in the present state of the science, is that of Dr. Spurzheim in the third edition of his *Phrenology*, 1825—an arrangement to which he was led by the anatomy of the brain.

In the case of many of the organs, the proof from observation is so strong, that these are said to be *established*, while others are only *probable*; a very few are no more than *conjectural*.

The following is a representation of a bust of the human head in four points of view—front, side, back, and top—with the organs marked by numbers; and there follows a table of the names of the organs synoptically given, before we proceed to describe each faculty as related to its organ. The reader is requested to remember the number of each organ:—

* Dr. Gall created a prejudice against the science by naming certain faculties from their abuse, as the organs of *theft* and *murder*, &c. This was corrected by Dr. Spurzheim.



AFFECTIVE.

I.—Propensities.	II.—Sentiments.
1. Amativeness.	10. Self-Esteem.
2. Philoprogenitiveness.	11. Love of Approbation.
3. Inhabitiveness and Concentrativeness.	12. Cautiousness.
4. Adhesiveness.	13. Benevolence.
5. Combativeness.	14. Veneration.
6. Destructiveness.	15. Firmness.
[Alimentiveness.]	16. Conscientiousness.
[Love of Life.]	17. Hope.
7. Secretiveness.	18. Wonder.
8. Acquisitiveness.	19. Ideality.
9. Constructiveness.	20. Wit, or Ludicrousness.
	21. Imitation.

INTELLECTUAL.

I.—Perceptive.	
22. Individuality.	29. Order.
23. Form.	30. Eventuality.
24. Size.	31. Time.
25. Weight.	32. Tune.
26. Colouring	33. Language.
27. Locality.	II.—Reflective.
28 Number	34. Comparison.
	35. Causality.

ORDER FIRST.—FEELINGS.

GENUS I.—PROPENSITIES.

The propensities are common to man and the lower animals; they neither perceive nor reason, but only feel.

No. 1.—Amativeness.

This organ (No. 1 on the marked bust) is situated immediately over the nape of the neck, and fills up the space between the ears behind, or rather between the mastoid processes, or projecting bones behind the ears. It generally forms a projection in that part, and gives a thickness to the neck when it is large, and a spareness when small. The cerebellum, or little brain, is or at least contains the organ of this propensity. The nerves of sight and hearing can be traced into contact with the cerebellum, which probably accounts for blindness and deafness being often among the frightful consequences of abusing the propensity. In a popular work like this, it would not be proper to go into the details of this function. These are to be met with in the more scientific phrenological books, especially Mr. Combe's translation of Dr. Gall's proofs of the function of the cerebellum. Among other evidences of the function of the cerebellum, it may be stated that the organ scarcely exists in infancy. It was Dr. Spurzheim's opinion, that the fact that the cerebellum is the organ of the amative propensity, was supported by a more overwhelming mass of evidence than any other truth known to him. Many of the enemies of phrenology make the phrenologists a present of this organ, as not to be longer doubted; though, in doing so, they are unawares abandoning their chief tenet, that the brain is not divided into organs. Although Amativeness is the only ascertained function of the cerebellum, it is not impossible, from its size and structure, that it may have others; but no others have yet been discovered.

It is not necessary here to enter fully into the character of this faculty. As the basis of the domestic affections, it is one of great importance, and its regulation has ever been one of the prime objects of moral systems, laws, and institutions. For the evils and calamities, often amounting to national, which it has occasionally led to, in its abuse, we need only refer to history. Dr. Spurzheim held, with regard to this faculty, that, in education, a more candid and explicit mode of treating it might be advantageous; and much could be said in defence of his opinion.

We here present the reader with a head (fig. 5) in which the organ is small, and another (fig. 6) in which it is large. We shall, in the sequel, give a few of the organs as specimens, as we cannot afford space for the whole. This organ is established.

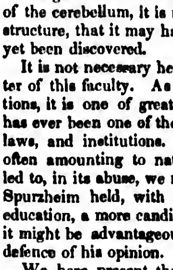


Fig. 5.

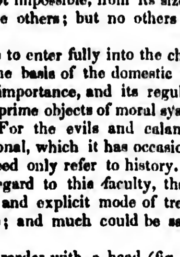

Fig. 6.

No. 2.—Philoprogenitiveness.

This, in man as well as animals, is the feeling of the love of his offspring. It depends on no other faculty, as reason or benevolence; it is primitive; and in the mother, who, for wise reasons, is gifted with it most strongly, its object, the infant, instantly rouses it to a high state of excitement. It is situated in the middle of the back of the head, and when large projects like a portion of an ostrich egg. See fig. 7. It is small in fig. 8.

Fig. 7.

Fig. 8.

It was discovered by Dr. Gall, from its extreme protuberance in monkeys: and we have only to visit a zoological garden to see how that animal cherishes its young. All naturalists are agreed in this as a quality of the monkey species. The organ is one of the easiest to distinguish in the human head. Those who are flat and perpendicular there, instead of being delighted are annoyed by children. It is generally smaller in males than in females, though sometimes found larger; and men so organized delight to carry about and nurse children. The feeling gives a tender sympathy generally with weakness and helplessness; and we find it often returned by the young themselves to the old and feeble. It is essential to a soft kind attendant on the sick, to a nurse or nursery-maid, and to a teacher of youth. It induces women to make pets of small and gentle animals, when tyrant circumstances have kept them single, and denied them offspring of their own. Its feelings are, by a kind Providence, rendered so delightful, that they are extremely apt to be carried the length of excess; and spoiling and pampering children, into vicious selfishness, is the ruinous consequence. The organ is large, and the character corresponds, in the Negroes and Hindoos, who are both good nurses, men as well as women—a fact practically known to our countrymen in the East and West Indies. The most savage races must have the impulse to protect their young, or they would become extinct. The Caribs, the most ferocious race known, are remarkable for a large development of this organ; a fact which may be said to prove, that the care of children is not an impulse of benevolence, as is insisted on by some. The Esquimaux have the organ large; and Captain Parry bears testimony, confirmed by Captain Lyon, to the extraordinary affection of that people for their children. Captain Ross could not, by any bribe, induce any of the parents to part with their children. The organ, like the other cerebral organs, may become diseased; and madness on the subject of children may be found in many asylums. Dr. Andrew Combe attended a woman who had a three days' fit of insane anxiety about her children. On her recovery, she said she had had a *pain in the back of her head*, pointing to this organ; but had forgotten every thing else that had passed. She was altogether unacquainted with phrenology. Under this mental aberration, the most delicate and virtuous female will boast, without the slightest foundation, of being in the family way with twins, nay, with six children at a time. Males have had the same hallucination, and in them the organ was large. This organ is held established.

No. 3.—Inhabitiveness—Concentrativeness.

The organ is situated immediately above the preceding. Two of the most distinguished phrenologists, Spurzheim and Combe, disagreed about the function of this organ—at least about its *whole* function. Dr. Gall did not discover its function at all; and Dr. Spurzheim, observing it large in persons attached to their native place, or any place in which they had long dwelt, called it *Inhabitiveness*. Mr. Combe does not disallow to it this function; and certainly man has such a faculty as attachment to place, often so strong as to render it impossible to move him from a particular spot by the most tempting inducements. The purpose of a faculty which prompts men to *settle* instead of roaming, which latter habit is inconsistent with agriculture, commerce, and civilization, is obvious; *nostalgia*, or home-sickness, is the disease of the feeling. Mr. Combe claims for it, however, a more extended sphere of action than love of place—one, at the same time, with which we have always thought love of place may be reconciled. He has observed the organ large in those who can detain continuously their feelings and ideas in their minds, while the feelings and ideas of others pass away like the images in a mirror, so that they are incapable of taking systematic views of a subject, or *concentrating* their powers to bear on one point. The first class of persons, in conversation, continue the same subject till it is exhausted, and pass gracefully to another connected with it: it is painful to converse with the others whose unconnected thinking gives us the notion of what is vulgarly called *scatter-brains*. Dr. Welsh, and Dr. Hoppe of Copenhagen, unknown to each other, communicated to Mr. Combe their opinion, that the faculty gives the tendency to *dwell in a place, or to dwell on feelings and ideas*, for a length of time, till all, or a majority of the other faculties are satisfied with regard to them. Mr. Combe illustrates a *continued* feeling, by the lengthened pauses in the declamations of Mrs. Siddons and Mr. John Kemble, in which the audience saw the mental state prolonged over the whole interval. We must content ourselves with what we have said, and refer the reader for proofs and arguments, on either side, to the works of Mr. Combe and Dr. Spurzheim. We may, however, observe, that the knowing faculties may be steadily directed by such a power as well as the reflecting. The rope-dancer fixes his eye steadily on the point, else he would lose his balance; and the American-Indian rifleman will lie for many hours behind an object which conceals him, with cocked piece, waiting for the appearance of a hostile head at some selected point, at which he instantly fires with deadly effect. The organ is stated as only probable, till further facts are obtained.

No. 4.—Adhesiveness.

This organ will be observed on the engraving of the marked bust to be situated on each side of No. 3; a little lower down than No. 3, but a little higher up than No. 2, at the middle of the posterior edge of the parietal bone. It was discovered by Dr. Gall, from being found very large, and of the shape as on the bust, in a lady remarkable for the warmth and steadiness of her friendships; and was observed in so great a number of instances to accompany this propensity, and to be flat or hollow in those who never formed attachments, that he came to consider it as demonstrated. It attaches men, and even animals to each other, and is the foundation of that pleasure which we feel, not only in bestowing but receiving friendship. It is the faculty which prompts the embrace and the shake of the hand, and gives the joy of being reunited to friends. Acting in conjunction with Amativeness, it gives constancy and duration to the attachments of the married. Amativeness alone will not be found sufficient for this. Hence the frequent misery of sudden love marriages, as they are called, founded on that single impulse. The feeling attaches many persons to pets, such as birds, dogs, rabbits, horses, and other animals, especially when combined with Philoprogenitiveness. With this combination, the girl lavishes caresses on her doll and on her little companions. Added to Nos. 1, 2, and 3, with which it is in immediate contact and ascertained fibrous connection in the brain, it completes what has been called the domestic group of organs, or the love of spouse, children, home, and the friends of home, as brothers, sisters, cousins, &c. These domestic feelings bind the dwellers under the same roof to each other faster than chains of brass. The finger of God is here, benevolently, effectually, beautifully; for he has made the bonds not irksome but exquisitely delightful. Some of our ballads express Adhesiveness with much beauty. "John Anderson, my jo," and "There's nae luck about the house when our gudeman's awa'," are most touching examples. The feeling is strongest in woman. Her friendships, speaking generally, are more ardent than man's. The faculty is not kindness or benevolence; it is instinctive attachment, often felt by those who are selfish in every thing else—selfish even in their attachments. It is the faculty which prompts man to live in society; and its existence overturns the absurd theory of Rousseau and some others, that man is solitary, and that mutual interest alone bring men to congregate with their fellow-men. There are other faculties, the existence of which implies society as much as the lungs imply atmospheric air, or the eye light: Benevolence, Love of Praise, and Justice, are of the number. It is in this way that a true analysis of the primitive faculties settles, with a word, questions which philosophers agitated for ages without advancing a step. Various animals congregate under the impulse of adhesiveness—sheep, pigeons, deer, &c.; but it should be observed, that pairing for life, or *marriage*, is not found in all, though it is in some of, the congregating animals. M. Vimont thinks there is a distinct organ for the marriage adhesiveness, forming a part of what has been assigned to Philoprogenitiveness, on each side of it. This is yet open for further proof. Mr. Stewart and Dr. Brown both admit this faculty of attachment as primitive in our nature, and describe it nearly as the phrenologists do. Dogs manifest it very strongly. The organ is held to be established.

No. 5.—Combativeness.

The organ of this propensity is situated behind, and a little upwards from, the ear; anatomically, at the posterior-inferior angle of the parietal bone. Compare fig. 9, which is an outline of the skull of General Wurmser, at the organ 5, with fig. 10, that of a Cingalese, at the same

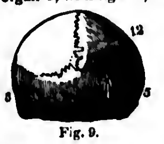

Fig. 9.

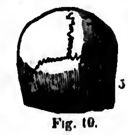

Fig. 10.

organ. No. 12 is the organ of Cautiousness, to be afterwards treated of. In this, the difference is reversed between these two heads. Dr. Gall discovered the organ by a vast number of observations on the heads of individuals whom he observed to be addicted to fighting. Dr. Spurzheim extended its function to *contention* in general, whether physical or moral. In this view Sir George Mackenzie concurs; and Mr. Robert Cox, in an interesting paper in the *Phrenological Journal* (vol. ix. page 147), endeavours to show it to be of the nature of opposition in general, and terms it *oppositiveness*. The condition of the physical world, full of difficulties and dangers, seems in itself to make it necessary that man should possess a faculty giving the impulse to meet boldly, and press vigorously through, such impediments. In the mingled scene, also, which forms the moral world, such an impulse is not less needed. It is easy, therefore, to reconcile with our ideas of divine wisdom and goodness the existence of this vehement quality of our nature, the true intent of which is expressed in the well-known adage of the Mantuan bard—"Ne cede malis, sed contra audentior ito," [*Do not give way to evils, but go the more daringly against them.*] A small endowment of this faculty manifests itself in that over-gentle and indolent character, which is easily aggressed upon, easily repelled by the appearance of difficulty and trouble, and which naturally seeks the shades and eddy-corners of life. Nations so organized—the Hindoos, for example—are easily conquered by others, under whom they naturally sink into a condition more or less of servitude. A large endowment, on the other hand, shows itself in a love of danger for its own sake, a delight in adventurous military life, and a tendency to bluster, controversy, and turmoils of all kinds. Society calls, no doubt, for all the over-average endowments of this faculty which exist, to perform its dangerous and difficult work; and we see such endowments rightly directed in the Leonidases, Wallaces, Tells, and Washingtons of history; in Luther, Knox, and the whole tribe of rational reformers; in the Columbuses, De Gamas, Cooks, and Parrys of nautical adventure, and in such professions as that of the fireman, the common mariner, and the land-clearer of the "far-west." But, being left free to act, and not being certain always to follow the guidance of the moral feelings and intellect, great combativeness often exhibits itself in painful forms—in aggressive war, blustering, bravadoing, outrageous polemics, and a habit of encountering dangers without any useful end in view. The French are much marked as a nation by irrationally directed combativeness. Persons with large combativeness may be readily recognised in private society by their disposition to contradict and wrangle. They challenge the clearest propositions, and take a pleasure in doubting where everybody else is convinced. The generality of boys manifest an active combativeness in their adventurous spirit, and their disposition to fighting, and to the working of all kinds of petty mischief. To control and guide the propensity is one of the most delicate, but also most important, duties of the educator. When combativeness is deranged, we have a violent and noisy, and often a dangerous patient. Intoxication generally affords a great stimulus to it; hence, drunken quarrels and fightings. The organ is established.

No. 6.—Destructiveness.

This organ is situated on both sides of the head, immediately over the external opening of the ear, extending a little forward and backward from it, and rising a trifle above the top or upper flap of the ear. It corresponds to the lower portion of the squamous plate of the temporal bone. When the organ is large, the opening of the ear is depressed. In fig. 11 the organ is large; in fig. 12 it is small. Dr. Gall discovered the organ by comparing

Fig. 11.

Fig. 12.

the skulls of carnivorous with those of graminivorous animals, and afterwards by observing the same prominence in those of several murderers sent him for examination. Dr. Gall, from observing the organ large in murderers, called it the organ of murder, thus describing it from an abuse, a mistake which gave occasion to a great outcry against his doctrines, and not without cause. It is still generally considered as giving the impulse to kill and destroy; but, in man, this propensity is shown to have, under the control of the higher sentiments and intellect, a legitimate sphere of exercise. Those roughnesses and difficulties in the physical world which have been shown to call for the exercise of combativeness, that man may not sink under them, also appear to call for a faculty which may prompt to the destroying or repressing of them, so that the way may be cleared for the future. The annoyances and troubles of the moral world call in like manner for a faculty which may be always endeavouring to put an end to them. There are many animate and inanimate things, and many institutions and social arrangements, which, though useful for a time, become in the end noxious, and require to be destroyed: the organ under notice appears to be that which is commissioned to do this duty. It prompts beasts and birds of prey to keep down the redundant breeds of the lower animals, and enables man to "kill" that he may "eat." It dictates the demolition and clearing away of obstructive objects of all kinds, and prompts Luthers and Mirabeaus to the extermination of bad systems. Anger, resentment, and indignation, in all their shapes, likewise spring from this faculty. St. Paul indicates its legitimate exercise in this class of its manifestations, in the words "Be ye angry and sin not." The penalties imposed in all civilized communities for offences arise from destructiveness, more or less under the guidance of reason and humane feeling. Blame may be described as a comparatively gentle emotion of destructiveness.

A small endowment of this faculty is one of the elements of a "soft" character. Persons so organized seem to want that which gives momentum to human operations, like an axe wanting in back weight. The Hindoos are deficient in Destructiveness as well as Combativeness, hence their remarkable averseness to the shedding of blood, and, in a great measure also, their being constantly the slaves of other and more energetic nations. Those, on the other hand, who have a large endowment of Destructiveness, are generally marked by an energetic, and probably fierce and passionate character. If uncontrolled by moral feelings naturally strong, or cultivated into activity by education, they are apt to be violent and vindictive. Low and untutored natures generally allow free exercise to this feeling, as we may daily see in their brutal swearing at each other, their horrible combats, their cruelty to every helpless creature under their care, and their delight in whatever is merciless and inhumane. The highly-trained gentleman generally masters the tendency to all such manifestations, but often shows the same native quality active in his nature, in polished sarcasm and invectives, in duelling, and in cold and stately alienation from those who have given him offence. The most notable abuses of the faculty is in homicide, a crime which the mind in a temperate state regards with horror. This act is often perpetrated under the influence of infuriate resentment, but is also sometimes committed without the appearance of any such prompting cause. Men have confessed to the committing of murder under impulses which they could not account for, but which they were equally unable to restrain. In these cases, we may surmise that the impulse took its rise in some morbid action of this organ. Frantic inclination to break and smash is also, probably, an effect of this organ in an unduly excited or diseased state. There are instances of rational and excellent men, who, at a particular and by no means advanced stage of intoxication, find themselves unable to refrain from breaking bottles, mirrors, and other articles of value near them.

In a very ingenious and elaborate paper in the Phrenological Journal, Mr. Robert Cox has expounded a law affecting Destructiveness and Benevolence. It is no more than the common observation of mankind, that every pleasure we enjoy tends to soothe and to create a feeling of good will to others; while every annoyance equally tends to ruffle and to produce a feeling of anger. Mr. Cox traces this to a sympathetic action, of which each of our faculties is capable with regard to Benevolence and Destructiveness. Are we undervalued?—our Self-esteem instantly awakens the latter faculty. Are we disappointed of a meal, or even of a favourite dish?—our Alimentiveness is equally alert in rousing this sleeping lion, and a certain exhibition of pettishness is the almost unavoidable consequence. Is a scene of wanton cruelty presented to our gaze?—our Benevolence sounds the alarm to the faculty which may be termed its declared enemy and antagonist, and we are all eagerness to punish the authors of the outrage; and so on. Even Destructiveness itself may be so much pleased by being allowed a free action, that a benevolent feeling may for a brief interval supersede it, and induce a wish to act kindly by its victims. Were this law affecting Destructiveness more generally held in consideration, many angry and violent scenes might be spared, and social life in general would be much sweetened.

The organ of Destructiveness is held to be established.

Alimentiveness, or Appetite for Food.

Some of the recent phrenological works treat, in this part of the order of the faculties, of a faculty of Alimentiveness, and also of another which follows, namely, Love of Life. The first being yet no more than *probable*, and the second only *conjectural*, they have no number allotted to them on the bust.

Alimentiveness is the desire of, or appetite for, food. In this feeling, as such, the stomach is not concerned: its functions are strictly confined to the reception and digestion of our food. But, that the mind is concerned in our desire of food, is proved by many circumstances. This desire often continues after the stomach is overloaded; it often prompts to a fulness and frequency of feeding, which must be in the highest degree inconvenient to the digesting organ. The *nausea* created in the sick by the idea of food—the rush of saliva to the mouth of the gourmand, on hearing a description of rich dishes—must alike be the effect of mental emotions. Appetite may be taken away by other organs of the brain being suddenly and strongly affected; as, for instance, in sudden accesses of joy, fear, or grief. In these cases, we may presume that the nervous influence is abstracted from the organ of Alimentiveness to supply the extra demand of the others. Were desire anywhere but in the brain, there could be no permanent character in individuals, as the glutton, the epicure, the abstemious. The stomach alone could make no such discriminations. Satisfied that appetite is a mental faculty, phrenologists have long been looking for its organ. Dr. Hoppe of Copenhagen was the first to observe, in those who manifested remarkably the gourmand or glutton, a fulness in front of Destructiveness, in the *fossa zygomatica*, between the top of the ear and the temple. Its place is marked by a cross † on the side view of the bust. Many phrenologists have confirmed this by observation. The convolution is developed in the base of the brain farther in than that of Destructiveness; but it is believed that it also shows itself by contact with the cranium at the point now described. A phrenologist once saw it obviously large in the head of a stranger who sat opposite to him in the saloon of a steamship going to London. He resolved to observe the individual's manifestations; whenever he heard the gentleman speaking, it was about excellent dinners and cookery, while his practice was eating and drinking, with short intervals, all his waking hours. The propensity is subject to insane action, one of the strongest proofs of its being a primitive faculty of mind. Voracity and insatiableness, far beyond the stomach's natural capacity, or the natural want, are then often the consequences. A patient in the Infirmary of Edinburgh was permitted, by way of experiment on the capacity of the stomach, to eat for six hours without stopping. He declared in a state of delirium, that nevertheless he was dying with hunger. His delirious cry was "Hunger! hunger! hunger!" He complained of pain in the spot where Dr. Hoppe observed the development of the organs, and nowhere else. Mr. Sydney Smith states, that a patient in the same circumstances was blooded with leeches at the same spot, and thereby relieved. M. Descuret mentions a woman in the Salpetrière, who ate the allowances of fifteen persons, and was always stealing bread and meat; when prevented she had recourse to raw vegetables, plants, and roots, and poisoned herself by devouring ranunculuses. Alimentiveness, from its near neighbourhood to Destructiveness, seems to have a peculiar influence on that faculty, rousing it to great energy when its own enjoyments are endangered or interrupted. It is not horses, dogs, and wild beasts alone, which are dangerous when feeding. The organ of Acquisitiveness is also close to this supposed organ. Mr. Simpson observed the organ of Alimentiveness large in a young man, with very large Acquisitiveness, who had periodical fits of indiscriminate theft; and expecting that Alimentiveness might probably be active at the same time, asked the question, and was answered, that the young man's friends knew when to look after his stealing propensity by being forewarned by his inordinate voracity. The function of this faculty is obvious from its object, namely, food suitable to the palate and digestion, and its end the preservation of the individual. In diseased action it is discriminating, as in the case of the devourer of ranunculuses; but when acting in health, it discriminates the food which is desirable, and rejects other substances. It has been said that animals are easily poisoned; this is true, but it is always by disguising the poison in the food which their alimentive faculty especially selects. The chick just out of the egg-shell picks up crumbs and seeds, but rejects pebbles and sand; and the new-born child, without the power of relieving any other pain, if all the medicines known were placed within its reach, instantly relieves the pain of hunger by applying its lips to the nipple and draining its mother's breast. Stimulating liquors are supposed to please this organ, so as to constitute it the organ of drinking as well as of eating. Hence the prevailing conclusion that drunkenness is a functional, if not an organic, disease; and in America, as well as this country, it has been treated as such. Tobacco and opium are believed to be cravings of this organ; but much observation is called for before phrenologists can speak positively on the subject. No attention has been paid to the proper training of this faculty in education. Its natural activity in the young, their bodies demanding much food, has been too much pampered and indulged, to the great injury of both health and character in after life. Gluttony and drunkenness stimulate the other animal organs, and hence the licentiousness of gluttons and drunkards—hence, too, their crimes. Insanity is one of the ordinary effects of starvation. The organ may now be said to be advanced from *conjectural* to *probable*.

Love of Life.

The self-preservation involved in the love of life is certainly not accounted for by any known organ or combination of organs. Cautiousness is fear of injury; fear of death; but it is not love of life. This feeling is powerfully manifested by some when their life is in no danger, but who look upon the close of life as a very great evil. Others are so indifferent on the subject, as scarcely to care whether they live or die, but for the disagreeable effect the contemplation of death has upon their other faculties—such as leaving children unprovided, &c. Mr. Combe thinks that the organ is situated in the base of the brain, and that its development cannot be ascertained on the skull during life. Dr. Andrew Combe had a patient whose constant theme was her love of life, and her unwillingness to part with it. After her death he saw the brain, and observed an enormous development of one convolution at the base of the middle lobe of the brain, lying towards the middle line, farther in than both Destructiveness and Alimentiveness. The base of the skull presented an uncommonly deep groove, in which the convolution lay. The Scottish phrenologists wait for further observation before coming to any conclusion on this supposed organ. The French phrenologists think they have discovered the organ immediately above the sphenoid bone; but their facts are too few and uncertain to be philosophically founded upon.

No. 7.—Secretiveness.

The order of this faculty will be observed, by its number on the bust, to be situated immediately above that of Destructiveness, at the inferior edge of the parietal bones, or in the middle of the side of the brain. Dr. Gall observed this fulness in one of his companions remarkable for finesse and cunning, and for its sly expression. He observed it in another companion, whose gait and manner were those of a cat watching a mouse. The first companion was honest, and only deceived for sport; the other, however, being deficient in moral restraint, turned out perfidious, and deceived his companions, his tutors, and his parents. One of Gall's patients, who possessed a large endowment of the organ, continued through life to deceive the world as to his real character; but his affairs on his death proved that he had been extensively fraudulent. Dr. Gall cites many other instances of deceitful and cunning characters, all showing the same development. An immense number of observations have confirmed the soundness of Dr. Gall's conclusions with regard to the function of this organ. The legitimate use of the faculty is to exercise that control over the outward manifestation of the other faculties, which is necessary to a prudent reserve. Without it, and of course, in those in whom the organ is small and the manifestation weak, the feelings express themselves too openly. Such individuals "wear their hearts upon their sleeves, for daws to peck at." They are too open and unsuspecting, and often all good taste and propriety are lost sight of by them, in the exposure of their feelings. Society would be insupportable were there no secretiveness. There is an amusing fairy tale called *The Palace of Truth*, designed to show how truly this is the case. We may consider secretiveness as an instinct to conceal the feelings or thoughts, till reason shows it to be prudent to declare them. This control evidently was not left to reason alone, whose judgment would have proved too slow for the end intended. Concealment is given to animals to enable them both to avoid and to prey upon each other. Many animals owe their safety from their destroyers to their cunning; while to others is given that quality to steal upon their prey unperceived; such as the fox, the cat, the tiger, &c. Mr. William Scott, in an essay in the *Phrenological Transactions*, has thrown much light on the functions of this organ. The secretive, he remarks, are always occupied with prying into the thoughts and motives of others, while they are closely veiling their own. The character of Louis XI., as drawn in *Quentin Durward*, is of the "calm and crafty" description; he used to say, that if his cap knew his secrets, he would throw it into the fire. Such are the intriguing politicians of the old, and yet too much of the modern school, who mistake cunning for wisdom.

In abuse, the faculty leads to lying, hypocrisy, and fraud. When acting with Acquisitiveness, it forms the thief, cheat, and swindler. The organ is almost always found large in these persons; and they have been known to say that they have great pleasure in the secretive part of their profession. All *ruses* and stratagems are exercises of secretiveness. The faculty, in combination with the Love of Approbation, occasions much of the hypocritical insincerity of civilized society. It is, according to Mr. Scott's view, the basis of that form of the ludicrous called humour, namely, concealing the mirth which is in one's own breast, and with a grave countenance and manner setting the table in a roar. The actor must possess the organ largely, if for no other purpose than to preserve his gravity while his audience is laughing; but still more to conjure down his natural faculties, that he may assume those of the character he plays. Mr. Scott allots both efforts to Secretiveness; while Mr. Combe, with more truth, limits Secretiveness to the concealment of the actor's own natural feelings, while the positive act of imitating those of his part must be the result of Imitation. Accordingly, in all great actors both Secretiveness and Imitation are large. To such an extent is Secretiveness carried in the practice of *malingering*, as pretending sickness is called in the army and navy, that incredible tortures have been submitted to without a wince. In such cases, Firmness, of course, aids Secretiveness.

We are indebted to Mr. Richard Carmichael of Dublin, for a report of the singular case of Anne Ross.* This girl, to gain the favour and charity of some pious ladies, thrust needles into her arm to produce disease, and went the length of submitting to amputation without revealing the truth. On dissecting of the arm, the needles were found, a circumstance which appeared to distress her much more than the loss of her arm. Mr Combe saw this extraordinary girl in Dublin, and found both Secretiveness and Firmness large in her head. He supposes that the power of enduring torture, without the expression of pain, which is the boast of the North American Indians, is the result of these two faculties, which are found large in all the skulls of that race in the museum of the Phrenological Society of Edinburgh.

* Phrenological Journal, vol. ii. p. 34.

The Hindoos are cunning, and Secretiveness is large in their skulls, in the same collection, and proved to be so by a much more extensive observation in India. The organ is subject to disease, and the cunning insane are difficult to deal with. Disease here leads to the belief in plots and conspiracies formed against the patient, so common with the insane. The manifestation of Secretiveness ought to be watched in education, and regulated, and the maxim impressed, that cunning is not wisdom. The organ is held by phrenologists to be established.

No. 8.—Acquisitiveness.

The organ of this faculty is situated farther forward than, and a little above, Secretiveness, at the anterior-inferior angle of the parietal bone. The existence of a cerebral organ for the desire of property, bearing a proportion in size to the degree of that desire, decides the question of the feeling being a primitive *animal* power, and not, as Hutcheson, Stewart, and Brown have held it, the natural result of calculation, wealth being the means of gratifying all our other inclinations. Man feels as an animal before he reasons. Lord Kames, whom the *regular* metaphysicians of his time considered as admitting too many faculties, takes, by sagacious anticipation —as he did when he recognised a hunting and killing propensity in man, phrenologically Destructiveness— the phrenological view of Acquisitiveness as primitive, and calls it "the hoarding appetite." This theory of it alone explains the miser's desire to accumulate, without ever putting his wealth to the use required by the metaphysicians above named, the purchase of enjoyment, the gratification of the other faculties. Mr. Combe illustrates this blind passion for wealth by alluding to the character of Trapbois in *The Fortunes of Nigel*. The very essence, he says, of this character, which is true to nature, is a desire for wealth, independent of every purpose of application.

Dr. Gall discovered the organ by resorting to what was a common practice with him, collecting a number of persons of the lower orders in his house, and encouraging them to the freest manifestation of their natural and unregulated instincts. He found that some in each group were characterized by the rest as thieves, and these were generally proud to avow their skill in this line. Among his very promiscuous visiters were some that abhorred theft, and others who were indifferent in the matter. He found the thieves with the organ large, those who abhorred theft with it small, and the medium individuals with a medium development. Among the deaf and dumb of an institution which he served as physician, he found some who showed the thieving propensity, with the corresponding organ. Visiting, as he did, houses of correction and prisons, he found the organ always large in thieves; and was unfortunately led to call it the organ of Theft, thus describing not the primitive function or legitimate use of the faculty, but one of its greatest abuses, and raising strange misconceptions with respect to his system of mind.

The faculty of Acquisitiveness could not, and no faculty could, be given to man by his Creator for a mean, grovelling, and immoral use; accordingly, when we consider it aright, we recognise in it the dignity of the greatest utility. In a word, it is the faculty through whose impulse man accumulates *capital*, and nations are rendered rich, great, and powerful. Without the faculty, man would be content to satisfy his daily wants, although even in this he would fail; but the surplus which, under the impulse, of this faculty, he contributes to the store of wealth which accumulates from generation to generation, would not exist. Under proper regulation, then, the faculty is of the greatest value to man; by means of it he "gathers up the fragments, that nothing may be lost." Excessive pursuit of wealth is, however, an abuse of the faculty, and too much the vice of civilization, when it advances, as it has hitherto done, without adequate moral improvement. This abuse withers up every generous purpose, perverts the intellect itself, and is a grand national evil. This country, at its present stage of progress, suffers from this abuse of Acquisitiveness. So, according to Mr. Combe, does America.* When accumulation becomes a passion in the trader, there is no end to it: it is necessary to his happiness, and hence one element of the *ennui* and regret of the retired tradesman or merchant.

The faculty is often diseased, so that those who are insane in this organ, without any temptation arising from their circumstances, which are often above want, and even prosperous, pilfer every thing of value, and often of no value, which comes in their way. Many incorrigible thieves in lower life, on whom the punishments of the law fail to have any effect, are diseased in this organ. Phrenology is daily demonstrating that many supposed criminals are in truth *patients;* and a more enlightened and benevolent system of criminal treatment, from which the element of vengeance shall be excluded, will in time come to deal with them as such. When treating of alimentiveness, we mentioned the case of a young man, the son of a man of fortune, who was subject to fits of *voracity* and *stealing* simultaneously; the following is an account of his case:—"An English gentleman, aged nineteen, and his tutor, a clergyman, requested that the development of the former should be taken, which was done by Mr. Simpson, and afterwards confirmed by four other phrenologists. General size of head, considerable; anterior lobe, large; temperament, two parts sanguine, two nervous, and one lymphatic. Development irregular and unusual. (Here follows an estimate of the organs, of which it is enough to say, that Amativeness, Philoprogenitiveness, and Acquisitiveness, are large, and Self-esteem, Benevolence, and Veneration, very large—the two last unusually so.) He had been rickety, scrofulous, and unable to walk alone until six years. His feelings were always, as his tutor expressed it, 'at high pressure.' Knowing that the impulses were thus strong, Mr. Simpson considered the case as one of a certain degree of derangement. He inferred that all that class of faculties, called the Feelings, would act with a force beyond the control of the individual. The tutor was much struck with the question, 'Does your pupil appropriate articles that do not belong to him?' And the answer was given that he had been forced to quit a great public educational institution for detected *theft*, committed both in shops and houses. Mr. S. then inquired respecting vicious manifestation of another of the propensities, and received, as in the former case, a strikingly affirmative answer. 'Did fits of *voracity* in food ever show themselves?' *Answer*. The three vices acted simultaneously, so that the others had to be watched when the voracity appeared. Mr. S. then observed to the tutor that his pupil was a patient, not a criminal. Yet, wherever he had turned, he had seen hostile society, and even legal vengeance; the walls of the late place of his study were chalked with his disgrace, and prosecution threatened by tradesmen. The present was the first time that his tutor had heard him humanely sheltered as an irresponsible being, visited with *disease* by his Maker's hand. The organization of the young man indicated great kindness of heart, which, his tutor said, was manifested at any expense of personal labour; great tenderness to children; and, what was most to his tutor's content, ardent devotional sentiments and active religious habits. Of course, all who knew the fatal propensity of theft to which the young man was subject, set his religion down to gross and disgusting hypocrisy. Phrenology teaches

* See Notes on the United States.

that such religious feelings, when mere feelings, as they are if undirected by intellect, are impulses quite as real as the acquisitive propensity itself. Flying from prosecution and persecution, without one friendly hand held out to him, save that of his kind-hearted tutor and a few pious persons who prayed over him in vain, the outcast comes at last, at the distance of hundreds of miles from his forbidden home, into contact with the disciples of a new and ignorantly-despised philosophy of man, by whom his case is at once understood and explained, and a means pointed out for his cure." We may add, from our own knowledge, that, at the suggestion of those who had judged of his case, the young man was boarded in the country, with a much larger pecuniary allowance than his relations at first intended for one whom they ignorantly held a disgrace to them; that he gradually recovered his health, was released from his bad habits, and is again of sound mind and correct conduct.

The periodical recurrence of disease in Acquisitiveness is a curious fact. The young man just alluded to was subject to such fits, and many other instances are detailed in the works of the phrenologists. Dr. Gall cites four cases of women, who, in their ordinary state, had no stealing tendency, but manifested it in the most marked, and, to those around them, unaccountable manner, when in a state of pregnancy: the brain at that organ, or its neighbourhood, must have been subjected to some morbid over-excitement during the peculiar condition of the system which pregnancy induces.

A variety of the inferior animals manifest the sense of property, and some of them of accumulation. It is a mistake to say that human laws establish property; a natural propensity does this, and laws become necessary to protect it. The organ is established.

No. 9.—Constructiveness.

The situation of this organ is immediately behind the temples, in the frontal bone, above the spheno-temporal suture. It is sometimes found higher up than its usual position; but a little practice familiarizes the observer with its appearance. The temporal muscle, which varies in thickness, throws some difficulty in the way of ascertaining this organ and also that of Acquisitiveness. This thickness can be felt in the living subject, while the lower jaw is moved, and its thickness may be allowed for; which cannot be done in a plaster cast. The difficulty is removed when the cast is taken, not from the head with the integuments, but from the skull. The faculty of which this organ is the instrument, is the power of mechanically making, constructing, and fashioning, by changing the forms of matter. Many of the inferior animals possess it, as the bee, the beaver, birds, and insects. Some savages have it in such small endowments as never to have built huts or made clothes, or even the simplest instruments for catching fish. Such are the New Hollanders, in whom the organ appears very slightly developed. Drs. Gall and Spurzheim verified this organ by a vast number of instances—in mechanicians, architects, designers, sculptors, and even painters. Indeed, the concomitance is so constant as to be a test of the fitness of individuals to be devoted to those branches of art. It is easily observed, and the student may verify it for himself. In the casts of the heads of the celebrated Brunell, the inventor of the block-machinery and engine work of the Thames tunnel, Sir W. Herschell, the painters Haydon, Wilkie, and Williams, it is remarkably large. In all operatives who excel in their art—engravers, joiners, tailors, &c.—and in children who early manifest a turn for drawing figures, and cutting them out in paper, the organ is large. Naturally the French, and still more the Italians, are more constructive than the English; yet, with the aid of capital, the division of labour, and other favourable circumstances, the English actually are the greatest manufacturing, in other words, constructive, people in the world. Were these advantages transferred to France and Italy, a greater prevalence of the faculty would make it more easy to procure skilful hands. The metaphysicians do not recognise a primitive faculty for Constructiveness, but consider mechanical skill to be the result of reason. This is an error, which the slightest observation contradicts. Were it true, the most sagacious animals would be the most constructive; yet the horse, the dog, the elephant, never construct; while the bee, the beaver, and many birds and insects, perform works, by this instinct, which excite our wonder. Very young children, long before reason could assist them, have manifested proficiency in making models, drawing, cutting with scissors, &c.; and a talent for mechanics, often amounting to a passion, turning, clock-making, lock-making, has been found in judges, statesmen, nobles, and even princes. This talent is often possessed in a high degree by men of very moderate and even inferior reflective powers; while some men of a great intellectual standard have been unable to make a pen. The primitive character of the faculty is proved by the power being often so much increased by insanity, as to appear to be created by it. Idiots are often skilful constructors, witness many of the Cretins of the Alps. Intellect is, however, important to the range, variety, and application of human Constructiveness; while the Constructiveness of the inferior animals is limited to one invariable result.

The use of this faculty is obvious. Physical nature consists of raw material, in scarcely any instance fitted for the convenience and accommodation of man. Constructiveness prompts him to form and fashion; and he continues to do so, advancing—which the inferior animals never do—from building the rude wigwam and making the stone hatchet, up to achieving the palace, the steam-engine, and the cotton-spinning machine. Man was held by Franklin to be the only tool-making animal; unlike the other animals, he constructs tools to apply to further objects of construction. Mr. Richard Edmonson, of Manchester, in an ingenious paper in the *Phrenological Journal* (vol. ix. p. 624), while he admits this organ to be that of the impulse and power to construct, form, and fashion, suggests that, inasmuch as we cannot construct, form, and fashion, without a nice perception of the application of the requisite force, it is therefore the organ of the faculty, which must exist, for the application of force in counteraction of mechanical resistance. He cites many cases in confirmation of this view. If he be correct, the function of the faculty must be much extended, for all animals apply force to antagonize resistance in many ways, without either constructing or fashioning. We shall, in the sequel, be brought back to this subject. The organ of Constructiveness is established.

GENUS II.—SENTIMENTS.

Mr. Combe introduces this branch of the subject thus:—"This genus of faculties embraces certain feelings which correspond to the 'emotions' of the metaphysicians. They differ from intellectual perception in being accompanied with a peculiar vividness, which every one understands, but which it is impossible to express by any verbal definition. They may be excited by the presentment of the external objects naturally related to them, as danger is to fear, or august appearances to reverence, or by the spontaneous activity of the organs. Dr. Spurzheim has named these faculties *Sentiments*, because they produce an emotion or feeling of a certain kind, joined with a propensity to act; but, as shown in the Appendix No. II., the detail of his classification is here by no means accurate. Several of them are common to man and the lower animals; others are peculiar to man. The former, styled the Inferior or Lower Sentiments, shall be first treated of." The argument referred to by Mr. Combe in his appendix, is an abridgment of an ingenious paper by Mr. Robert Cox, in the *Phrenological Journal* (vol. x. p. 154), in which he endeavours to show that, on the one hand, several of the propensities are accompanied by emotions as well as inclinations t act, and, on the other, several of the sentiments have likewise both qualities. We are inclined to go farther even than Mr. Cox, and to submit for the consideration of phrenologists, whether all the faculties, not excepting the intellectual, have not both a propensity to act and an emotion. At present, however, we will not disturb the old arrangement. The reader will judge for himself. Much is yet to be done in the metaphysical department of the subject.

I. SENTIMENTS COMMON TO MAN AND THE LOWER ANIMALS.

No. 10.—Self-Esteem.

The situation of this organ is at the top of the back of the head, at the centre; forming, as it were, the curve or turn between the back and top of the head. Technically, it is a little above the posterior or sagittal angle of the parietal bones. When it is large, the head rises far upward and backward from the ear, in the direction of the organ. It is large in fig. 13 and small in fig. 14. Dr. Gall first observed the organ in the head of a beggar. This man had spent a fortune, and was too proud to labour for his bread. Dr. Gall long hesitated to believe that pride could stoop to begging; but the individual positively averred that his sense of degradation in condescending to labour was much greater than in begging and living in idleness. The organ was noted by Dr. Gall, and found by him large in a great number of proud men. He cites many instances of this concomitance of organ and manifestation. A physician of Vienna, when

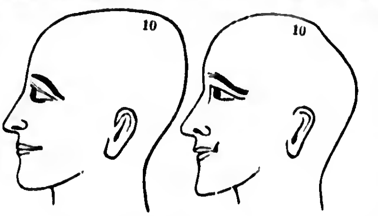

Fig. 13. Fig. 14.

called to consultations, always put himself before even his seniors, and insisted on placing his signature first on all occasions. At Heidelberg, Dr. Gall saw a girl of eighteen, who could not bear a word of familiarity. When she spoke, assurance and presumption were expressed in her features. She carried her head high and a little backwards, and all her movements expressed pride. Although of humble rank, she contrived to associate only with persons of rank superior to her own. Dr. Gall found the organ large in chiefs of brigands, whose pride was a main cause of their bad eminence. The legitimate use of the faculty of Self-Esteem, or Self-Love, is that degree of self-complacency which enhances the pleasures of life, and which gives the individual confidence in his own powers, and leads him to apply them to the best advantage. It is sometimes called proper pride, or self-respect, in which form it aids the moral sentiments in resisting temptations to vice and self-degradation: this is called being *above* doing a criminal, a vicious, or a mean action. Its deficiency renders an individual too humble, and the world take him at his word, and push him aside. In large and uncontrolled endowment, it produces great abuses, and causes much annoyance and often misery to others. It is the quarrelling, insulting, domineering tyrannizing, duelling faculty. In children it is pettishness, forwardness, and self-will, and produces disobedience. In adults, it gives arrogance, superciliousness, and selfishness. In nations, the feeling shows itself in national pride and boasting. It characterizes nearly all, if not all nations, every one concluding itself the most meritorious, if not the greatest people on earth. This produces contempt of other nations, and leads to international jealousies and hatreds, the origin of almost all the wars that have disgraced and desolated the world. It is not long since, in England, the young were trained up to call the French people their "natural enemies!" The Greeks and Romans styled all other nations barbarians, and the Chinese do the same at this day. The vainglorious records and anniversaries of our battles, the exultations because of our martial prowess, our illuminations, and our very *Te Deums*, are all the offspring of Self-Esteem. It occupies the individual so intensely with self, that he is insensible to all interests but his own; every thing is seen by him through the medium of self. The first thought, when a proposal is made, is, "How will this affect *me?*" Love of Approbation is often useful by subjecting the individual to some degree of dependence on the opinion of others, to moderate the intensity, the exclusiveness, of Self-Esteem. Without this counterpoise, the self-esteeming person becomes a self-erected standard of opinions, manners, and morals. It has been observed, that proud men often marry beneath their rank; less, we think, because they do not like to risk the mortification of refusal in their own rank, for they do not think it possible, but that they do not conceive that any thing which they may please to do can be degrading. These are your solemn men, your "Sir Oracles," who, mistaking, as they often do, the mere blind feeling of self-exaltation for talent and genius, speak forth the merest twaddle with a solemn emphasis extremely ludicrous to those who see its nothingness. But every thing that comes from a person of such self-importance *must* be admirable. Accompanying this high appreciation of self, we generally find depreciation of others. This is the basis of sensoriousness and invidiousness. Discussions of character, with vilifying remarks, come from a large Self-Esteem and that want of candour and fairness which is the result of an inferior endowment of Conscientiousness. Envy, which includes hatred, is Self-Esteem rousing Destructiveness; with deficient Benevolence and Conscientiousness, the envious could injure a fortunate individual merely because of his better fortune. It is a modification of invidiousness, although directed against things and not persons, to affect to undervalue every thing one sees—in other words, never seem pleased—in order to reap from this petty exhibition a fancied consequence, extremely gratifying to a large and active Self-Esteem. This character is satirized by Voltaire, who makes Candide naïvely exclaim, "What a great man that Pococuranté must be—nothing can please him." Never let the truth be forgotten, that the abuses of Self-Esteem, and also of Love of Approbation, invariably defeat their own end; they lower, but never exalt, the individual. The feeling magnifies not only self, but all that belongs to self. A vulgar Self-Esteem prompts the individual to dilate upon the excellence of "*my* horse, *my* gun, *my* yacht, *my* house," merely because they are *his*. Mr. Combe states, that an eminent phrenologist sailed passenger with a captain in whose head he saw the organ very large, and Reflection and Conscientiousness deficient. His manifestations were in accordance. His ship, which he thought a very ordinary vessel before it was his, "became the first of Sea-boats" when it became *his*. He himself was the most powerful of captains dictatorially telling his passengers that he would send them before the mast, and speaking always of himself. The phrenologist observing that the organ of Cautiousness was large in a petty tyrant, dexterously used it as a counter-working engine, and in his turn ruled the ruler. A large Self-Esteem renders its possessors what is called *touchy*—impatient of reproof, and irritated by it, however just, as if it were a positive injury. The *cause* of reproof in misconduct of their own, however marked to every one else, goes for nothing with, or rather is never admitted by, themselves. *They* are of course never in the wrong, *that* is impossible; and however they may have by some act injured others, to be even told that they have, is an injury which they deeply resent. They are always themselves in such cases the injured party. A loud and clamorous announcement of this is sometimes resorted to by the secretive and unconscientious, in order to avert the legitimate resentment of the really injured party. Yet as Self-Esteem is almost in every one a strong and also a tender feeling, it ought to be one of our earliest, longest-continued, and most earnestly-pressed exercises, to moderate its manifestations in ourselves, and treat it tenderly in others. The greater part of real politeness, and of its external manner, consists of an effort to reduce, outwardly at least, our own self-estimation and our general selfishness, and pay homage to, or treat delicately, these feelings in others. In low society, the rudeness and coarseness which work the most annoyance, are nothing else but an unregulated contest of the self-esteem of the individuals for temporary ascendency; and to this may be traced the quarrels and blows with which, in that society, even convivial meetings are often disfigured. Yet the refined visiters of the drawing-room, and the brawlers in the pot-house, are the same beings; only the one class restrain, while the other gives free vent to, Self-Esteem, and yet lower propensities. Intoxication, in some individuals, increases the activity of Self-Esteem. This was ludicrously experienced by a person who, when negotiating for the purchase of a horse, thought, by giving liquor to its owner, to find him more easily dealt with in his inebriety. He succeeded only in rendering him utterly impracticable. *His* horse rose above all price, and he resented as an insult the very proposal of the other to buy it. The self-esteeming individual uses the capital *I*, with *me*, *mine*, *myself*, and other correlatives, with great emphasis and abundance, both in discourse and writing. There is a joke against an author of this stamp, that, during the printing of a work of his, the press was stopped till the printer could get a fresh stock of capital I's. Cobbett was an example; his Self-Esteem and Combativeness led him to dogmatize quite as confidently *every time*—and the times were many—that he changed his opinions, as he had done before the change. All patronizers are self-esteeming and benevolent men. You will know them by such modes of address as "My good sir"—"My good fellow"—"Mark *my* words"—"That's *my* maxim," &c. Mr. Scott contributed an amusing paper to the *Phrenological Journal* (vol. i. p. 378), of great value, in which he shows the effects of Self-Esteem in combination with various other faculties. A *small* endowment of this faculty is exceedingly rare. A large endowment leads to a wish for selfish and exclusive pleasure. This feeling will be observed in children who value some indulgence the more that their brothers and sisters are not to share in it. Proper training would prevent this paltry and most unamiable manifestation; and likewise lead perhaps to less of that modification of selfishness seen in adults in the ambition of possessing *uniques*. Such persons have been known to purchase a duplicate, if they heard of the existence of one, in order to destroy it, and then boast of being the sole possessor of the article in the world. Parks and palaces are kept shut against the public by the same pitiful spirit. Self-Esteem gives love of power and dislike of power in others. Hence the notorious fact, that many violent republicans have become, when vested with power, the greatest tyrants. A due proportion of the feeling, however, is essential to independence in a people. The English have it large.*

Self-Esteem has a marked natural language. When powerful, the head is carried high, and reclining backwards, an attitude well known to stage kings and lords. The manner is cold, haughty, and repulsive; and two self-esteeming persons meeting, repel each other like the similar poles of magnets. Dr. Reid and Mr. Stewart acknowledge this sentiment, under the name of the Desire of Power. Dr. Thomas Brown calls it Pride. It is evident that these are narrow and partial views of the feeling—one or two only of its manifestations; phrenology alone has brought out all its phases. The organ and feeling are apparently possessed by some of the inferior animals, such as the turkey-cock, pea-cock, horse, &c. Lord Kames observed that the "master-ox" must have the lead, else he will not work. A cow of a herd refused to enter the cowhouse, if the others went in first; when this happened, they were turned out, and she then walked in and occupied her stall.

Self-Esteem is found insane perhaps more than any other faculty, and then shows itself in extravagant notions of self-importance. Such maniacs are kings, emperors, and even the Supreme Being. Pinel mentions many such patients: one man under his care believed himself to be the Prophet Mahomet, and moved about with the most dignified majesty. When cannons fired, he believed it was on his own account. In the great Hospital of St. George's Fields, there were at one and the same time several *George the Fourths*. The organ is generally larger in men than in women; and more men are insane from pride than women.

We cannot conclude our observations on this faculty, without adding that it is usually an element in religious intolerance. Cowper in one of his letters says, "There is no grace which the spirit of *self* can counterfeit with more success than a religious zeal. A man thinks he is fighting for Christ, while he is only fighting for his own notions. He thinks that he is skilfully searching the hearts of others, when he is only gratifying the malignity of his own; and charitably supposes his hearers destitute of all grace, that he may shine the more in his own eyes by comparison. When he has performed this notable task, he wonders that they are not converted: *he* has given it them soundly; and if they do not tremble, and confess that God is in *him* of a truth, he gives them up as reprobates, incorrigible, and lost for ever." This is a mirror for too many. The organ is established.

No. 11.—Love of Approbation.

This organ is situated on each side close to Self-Esteem, and commences about half an inch from the lambdoidal suture. It gives, when large, a marked fullness to the upper part of the back of the head. It cannot be shown in outline like the previous organ of Self-Esteem, which, when large, with Love of Approbation moderate, gives a conical shape to the top of the back of the head. Dr. Gall discovered the organ in an insane woman, who imagined herself Queen of France. He looked for the organ of Self-Esteem, of course, and was much perplexed to find a hollow where its prominence should have been, but, at the same time, a marked rising on both sides of the hollow. *The queen's* manifestations soon explained to him the difficulty. There was no calm, grave, arrogant, imperiousness in her, as in the kings and queens of Self-Esteem. She was restlessly *vain* of her rank; talked of it in the most frivolous and affected way;

* It thus happens that Self-Esteem is the natural defence against the *aggressive* operation of the same faculty in others. A proper endowment of it never acts on the offensive; but it can be roused to repel and spurn all such acts in others. These degrees, therefore, seem to call for a distinction between an *offensive* and *defensive* Self-Esteem. Phrenology alone affords a key to character thus discriminating.

and promised favours and honours to all with whom she conversed. She was a vain, not a proud, queen. From that time, Dr. Gall perceived the difference between Self-Esteem and Love of Approbation. "The *proud* man," says he, "is imbued with a sentiment of his own superior merit, and, from the summit of his grandeur, treats with contempt or indifference all other mortals. The *vain* man attaches the utmost importance to the opinions entertained of him by others, and seeks with eagerness to gain *their* approbation. The *proud* man expects that mankind will come to him and acknowledge his merits; the *vain* man knocks at every door to draw attention towards him, and supplicates for the smallest portion of honour. The *proud* man despises these marks of distinction, which, on the vain, confer the most perfect delight. The *proud* man is disgusted with indiscreet eulogiums; the *vain* man inhales with ecstasy the license of flattery, although profusely offered, and by no very skilful hand."

Dr. Gall named this faculty Vanity, from one of its abuses, as he named Self-Esteem Pride. Dr. Spurzheim elucidated the ultimate functions more satisfactorily. It is the desire of approbation, admiration, praise, and fame. Its legitimate function is regard to reputation and character, and it gives the sentiment of shame. It is an excellent guard upon morals as well as manners. The loss of character, to those largely endowed with this feeling, is worse than death. If the moral sentiment be strong, this sentiment will desire honest fame, and in the line, too, of the prevailing faculties—as poet, painter, orator, warrior, statesman. The love of glory is a passion with many, and has deluged the world with blood in all ages. The decorations, orders, stars, garters, of civilization, and the tattooing, nose-boring, and pluming, of savage life, all spring from Love of Approbation. When the propensities predominate, the vain man will be pleased to be thought the best fighter or greatest drinker among his acquaintance. A due endowment of this faculty is essential to an amiable character. "It gives," says Mr. Combe, "the desire to be agreeable to others; it is the drill-sergeant of society, and admonishes us when we deviate too widely from the line of march of our fellows; it induces us to suppress numberless little manifestations of selfishness, and to restrain many peculiarities of temper and disposition, from the dread of incurring disapprobation by giving offence; it is the butt upon which wit strikes, when, by means of ridicule, it drives us from our follies." What the world will think and say, is uppermost in the mind when Love of Approbation is too strong. A youth in whom it is powerful, cannot do this thing or the other, because everybody will look at him, or wonder at him. The young are extremely sensitive on this point, especially in relation to those of their own age. The admonitions of the parent or teacher are nothing with them, in comparison with the jeering of their companions. Ridicule is intolerable to a large Love of Approbation at any age. Hence the poet's thought, "the world's dread laugh which scarce the stern philosopher can scorn." Combined with Self-Esteem, it creates the impression that the world are all busy thinking of us, instead of themselves; which last is the truth. This excess of the feeling subverts all independence. The opinion of others is the unhappy individual's rule of morals, taste, religion, even philosophy.

As this faculty, and that of Self-Esteem in abuse, are the cause of much evil, both to the individual and others, education ought to moderate their activity. Under the new system this is attended to; but under the old the competition of pride and vanity, in places and school honours, is still the grand stimulus, to the injury of the character of the young for life.*

The faculty, unless kept in subordination by a very large and vigilant Conscientiousness, prompts to all the conventional insincerities and flatteries of society, from the dread that the truth will offend Self-Esteem, and draw down on the teller of it disapprobation. When Secretiveness is large and Conscientiousness small, Love of Approbation is profuse in the unmeaning compliments of society. These compliments many people scorn only when applied to others, but take them more complacently when addressed to themselves; their Self-Esteem supporting them, and persuading them that these compliments *have* a meaning, and value too, when *they* are the objects of them. It is held to be Love of Approbation, which prompts to the equivocation of "not at home," when the person does not wish to admit visiters. "The faculty of Conscientiousness would desire that the plain fact should be stated; but Love of Approbation produces an instinctive feeling that the Self-Esteem of the person calling will be offended, if any engagement can render it inconvenient to see *him*. To save this pang, Love of Approbation and Secretiveness resort to the invention of this little equivoque. The deceit is seen through by all; and, nevertheless, the use of it is more pleasing to persons in whom Love of Approbation and Self-Esteem are very large, than the announcement of the simple truth." Much of the acutest suffering of life consists in nothing else but wounded Love of Approbation, when the feeling is powerful. The rivalries of rank, wealth, and fashion, commence with school boys and girls. The youngest creatures will, unchecked by delicacy, boast of the importance, in these particulars, of *their* parents, and vilify their companions, to the intense suffering of the latter, who have not arrived at sufficient reflection and force of character to disregard such taunts. Successful rivalry wounds the feeling both in the young and in the old; equipage, dress, attendance, when superior in others, these being acquaintances, or who have been equals, are all tormenting distinctions of Love of Approbation. Refusing to acknowledge, or shunning, well-known acquaintances, when the vain happen to be in what they consider higher or more fashionable company, is a very usual abuse to the feeling. This is not only a pitiful weakness, and confession of want of personal merit, but not seldom an act of coldhearted, selfish, ingratitude. With a good endowment of regulating moral feelings and intellect, turned into their right channel by proper character-improving education, this paltry conduct would be of much more rare occurrence. The vain talk of themselves, their affairs, and connections, and much afflict their auditors by so doing. Education would moderate this variety of bad taste. The same weakness leads the vain to be impatient of the appearance of neglect or forgetfulness of themselves in company, and to resort to many artifices to attract attention. Dr. Johnson noticed this small ambition in Goldsmith, who, he said, often began to talk lest his presence should be forgotten. Vain children force themselves into notice in the same way; a teacup has been purposely broken to this end. Extravagances, and even crimes, have been committed for mere notoriety. In these extreme cases the organ is diseased. The incendiaries of the Temple of Ephesus and York-Minster, and the lunatic Oxford, who fired on the queen furnish examples. Shamelessness is the effect of the want of this faculty, often observed in criminals. It is a great defect in character; the individual is beyond the salutary government of the feeling; he cares not for the opinion of others, and laughs equally at their censure or approbation. The educator finds this negation very difficult to deal with, inasmuch as one engine, with which he might otherwise legitimately work, is useless to him. His pupil will not *draw* by Love of Approbation. This defect aids the impudent, who have a purpose to serve. Their importunity is often boundless and untiring. No repulses affect them, no indignities touch them, so long as absolute personal violence is not

* Simpson's Philosophy of Education, second edition, p. 108; and Phrenological Journal, vol. v. p. 613, and x. p. 9.

applied to their intrusions. The *blush* is the natural language of shame—one of the feelings of powerful and sensitive Love of Approbation. The organ is oftener found insane in women than in men, as in women it is more active than in the other sex generally. The patients whose Love of Approbation is diseased, are not solemn, haughty, and irascible, like the monarchs of Self-Esteem. They are generally in a bustle of display, overpowering the listener with details of their merits, their talents, their works, and even their beauty. They are decked out, without regard to taste or sense, in colours, flowers, feathers, ribbons, crosses, and orders; their rooms are decorated with trophies and all sorts of imaginary proofs of their own transcendent merit, worth, fame, and glory. Prompted by Acquisitiveness large, the subject of their boast is the fancied possession of wealth that has no bounds; and if to this combination be added Benevolence, checks on their bankers for immense sums are freely given to strangers who visit them. As Dr. Gall well observed, pride and vanity are never better distinguished than when manifested uncontrolled by the insane.

The organ and faculty are observed in some of the lower animals—dogs, horses, monkeys, and others. It is established.

No. 12.—Cautiousness.

The organ of this faculty is situated about the middle of the parietal bone on both sides. Dr. Gall discovered it by first observing the prominence large in two individuals, who positively harassed him with their doubts, fears, hesitations, and precautions. When he observed this cerebral mark for the peculiarity, he confirmed it by numberless subsequent observations. Dr. Gall's two first subjects of observation were a prelate and a councillor of the regency, in Vienna. The first, through fear of compromising himself, overlaid his discourse with never-ending qualifications and cautions, spoken with great slowness. A conversation with him was interminable; he stopped in his sentences, and cautiously recurred to the point where he began, to be assured that all was right before proceeding farther. He was always mending what he had said. His preparations were careful and cautious in the most insignificant matters, and his examinations and calculations most rigorous. The councillor, again, from his marked irresolution, was nicknamed Cacadubio. Sitting behind both of these individuals, on a public occasion, Dr. Gall had an opportunity of comparing their heads, and observed their agreement in the protuberances since called the organs of Cautiousness. The intellectual powers and dispositions of these two men were different in all other respects; but in Cautiousness and its external development they closely resembled each other. No organ is more easily observed than Cautiousness. It is evident to the eye as well as the hand, and there is none of which the concomitant mental feeling may be predicted with more confidence.

It has been said that *fear* is the fundamental feeling of this faculty. We doubt this. Fear is a disagreeable affection of the faculty, for it *is* one of its feelings; and we are disposed to think that the disagreeable or painful is not the root of any of our faculties. We are not necessarily conscious of the feeling of fear while we are taking the most circumspect precautions for our safety, and it is just when we have taken these precautions that fear is excluded. In our opinion, Cautiousness expresses the feeling better than Fear. The words *foresight* or *circumspection* are too intellectual for it; for it does not foresee or look around; it merely feels blindly, and stimulates the intellect to take the means of insuring safety: its motto is, "Take care." It is an important element in prudence, which places the individual on his guard, and warns him not to be rash in his moral as well as his physical movements. In general, the organ is large in children—a wise and beneficent provision for their protection. Children who are deficient in the organ are in constant mishaps and accidents; twenty keepers will not supply to them the place of the instinctive protection of Cautiousness. Mr. Combe mentions a boy of six years of age, in whom the organ was very small, who took off his clothes to plunge into the deep water of an old quarry, into which the wind had blown his cap. A child with a large Cautiousness is comparatively safe; much more so than any degree of care by others would render him. We have seen the organ so large on both sides as to deform the head, and give, by contrast, to the fore part a great narrowness, especially in children. Mothers are often alarmed with this appearance, seeing that water in the head often shows itself in this region. But there is also a natural and healthy development of the organ when extraordinarily large. The symptoms of a very large endowment will be great timidity, fears, and even imaginary terrors, especially in dreams; but the existence of these would argue that the substance itself of the brain is large, and not merely extended by hydrocephalous affection, in which last case there could be no increase of the power of manifestation in the organ, but the contrary. No feeling is more rapidly and extensively communicated by sympathy than fear; it is well known to run through and infect a whole army; in such cases, it has the name of panic. It is therefore of vital importance, and a chief object of an officer's attention in battle, to prevent even the commencement of a feeling of fear, by checking all outward manifestations of it, and setting an example of coolness and courage to the soldiers under his command. In the history of war, there are instances of panic affecting both the contending armies at the same time, when they have turned their backs upon each other and fled in opposite directions from the field. The organ is often diseased, and then produces causeless dread of evil, despondency, and often suicide. In the heads of suicides the organ is invariably large, and Hope deficient, Destructiveness also being of course large. Persons with the organ diseased will often shrink as if the house were about to fall over them, or a bridge under them. Those who do not distinguish feeling from thinking, imagine that such persons may be reasoned into a dismissal of their fears, on being shown that they are groundless; but if, as is demonstrable, the feeling results from a portion of brain being positively diseased, it would be as rational to attempt to reason a person out of the pain he suffers from a bodily wound or sore. A brief extract from Dr. Andrew Combe's admirable work on Insanity, which has greatly helped to revolutionize the whole science and practice of that interesting field of medicine, will serve the twofold purpose of showing in what manner Cautiousness becomes diseased, and likewise how clearly and intelligibly the phrenologist treats the subject of that disease of brain called insanity. "Among the functional causes of cerebral disease and mental derangement, the over-activity of *Cautiousness*—an organ second in size to none—stands pre-eminent. Under the present selfish system of society, there is perhaps no faculty which is called so often, so powerfully, and so permanently into action; and the natural result is, that none is so frequently the source of nervous disease. In times of public distress, the victims whose health it destroys, whom it deprives of reason, and throws into the cells of an asylum, are incalculably numerous. Timidity, apprehension, fear, despondency, and despair, are the different degrees of intensity of the same feeling of Cautiousness gradually roused to a higher and higher degree, till the health of the cerebral organ at last gives way, and the most sombre melancholy ensues. The wide prevalence of hypochondriacal affections, which embitter existence, by the gloomy depression to which they give rise, and which I have elsewhere shown to have for a common feature a morbidly active Cautiousness, is another and a very convincing proof of the influence of excitement of function in inducing cerebral disease. In the greater number of such cases, it is easy to trace their origin to real or fictitious causes of anxiety about the health of friends, the success or failure of schemes of advancement, the fluctuations of trade, and many other grounds, all directly addressed to the faculty of Cautiousness."

Dr. Combe here mentions two instances, one of which ended in suicide, and proceeds—"The effect of fear, or sudden and violent excitement of Cautiousness, in producing mental derangement, and all sorts of nervous disease, is well known. I have already quoted an instance from Boerhaave, in which a fright from thunder rendered a lady insane, and also of a girl in the Hotel-Dieu in Paris, who was frightened by a soldier with a drawn sword. Pinel received three young women into the hospital; one deranged from seeing a *ghost* clothed in white, by which some young men wished to frighten her; the second, from a tremendous clap of thunder which terrified her; and the third, from horror at finding herself in a house of bad character, into which she had been unconsciously decoyed. In the two first, and partly in the third also, the disease was evidently induced by the organ of Cautiousness roused to an inordinate degree, producing general disordered action in the brain. The story of the parrot which was driven mad by the noise of the great guns during a naval action, and ever afterwards could emit no sound but one imitative of the report of a cannon, is an instance of similar functional excitement."

Practical jokes, intended to frighten, have often fearfully overshot their aim, and produced insanity. A knowledge of this ought to put an end to them. Lord Kames is the only metaphysician who recognised *fear* as a primitive faculty of the mind. Nations are characterized by different degrees of this organ. The German head, including the English and Scotch, has it larger than the Celtic, including the native Irish, and also than the French. It is smaller, too, in the Turkish head than in the European. It is very large in many savages, and in the Hindoos and Cingalese. See fig. 10. It is small in fig. 9. The organ is held established.

Having brought to a close our account of the affective faculties common to man and the inferior animals, we will proceed to an analysis of the SUPERIOR SENTIMENTS PROPER TO MAN.

II.—SUPERIOR SENTIMENTS, PROPER TO MAN.

WE have hitherto considered the faculties which phrenologists describe as common to man and the lower animals; we are now to treat of those superior sentiments which they consider as peculiar to man. The organs of these sentiments lie in the superior region of the brain. That they are all of them entirely wanting in animals, is an opinion which the phrenologists will yet, probably, have to reconsider; but we deem it best, in the mean time, to follow the generally received view. It may only be remarked, that, while the convolutions of the brain which form Veneration, Conscientiousness, and Hope, are not found in animals, traces of the convolutions forming Benevolence and Imitation do appear; and these two last are the powers of this class with which it seems most likely that animals are endowed.

No. 13.—Benevolence.

The organ of this sentiment is situated at the upper part of the frontal bone, immediately before the fontanel, in the middle of the top of the forehead, where it turns to form part of the top of the head, or coronal surface. It is easily distinguished; and when large (see fig. 15) gives a round elevated swell to that region. When the organ is small (fig. 16) the forehead or top-front is low,

13

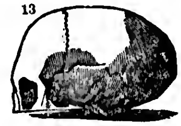

Fig. 15.

13

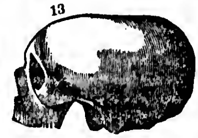

Fig. 16.

flat, and retreating. We cannot blame the unfortunate individual so organized, seeing that he did not make himself; but we are so constituted as instinctively to shrink from him, as deficient in one of the chief ornaments of human nature—the faculty of kindness and brotherly love. Dr. Gall discovered the organ, and at the same time distinguished the faculty as primitive, by observing in what region the heads of several remarkably benevolent, disinterested, and generous persons—whom, after suspecting the existence of the faculty, he placed together—agreed, however much they differed in other particulars. His subsequent observations left no doubt on the matter.

The faculty of Benevolence gives more than compassion for, and a desire to relieve, suffering; it gives a wish that others should be positively happy; prompts to active, laborious, and continued exertions; and, unless Acquisitiveness be very large and powerful, to liberal giving to promote its favourite object. It differs essentially in its charity, "which suffereth long and is kind," "and vaunteth not itself," from that which springs from Love of Approbation. Yet to this last selfish faculty, how often is it necessary to appeal when funds are wanted for benevolent purposes! Hence the *published* lists of subscribers' names; hence, too, the appeals to other selfish faculties by balls, plays, &c., for contributions to relieve suffering, as if it were to be charmed away by dancing and music. The Samaritan's conduct was pure benevolence. Addison portrayed the feeling well in Sir Roger de Coverley. All the phrenological books cite the case of Eustache, a St. Domingo negro, who was so striking an example of this faculty in great power and activity, that he received the *prize of virtue* from the French Institute. The organ in him was so large as to give an uncommon height to the front of his head. The faculty, like sunshine, lights as well as warms the whole of social intercourse. Mr. Combe well expresses this *leavening* influence. "It is a vulgar idea that this faculty cannot be manifested except in bestowing alms or money. It may be exerted in the domestic circle, in a thousand ways productive of advantage, without being accompanied by donation. It is benevolence to those with whom we live, to order our arrangements with a due regard to their comfort and happiness, and not to deny them proper gratifications; it is benevolence to suppress our own humours and tendencies when these would give unnecessary pain to others; to restrain Self-Esteem and Destructiveness in our commands; to be mild and merciful in our censures; to exert our influence and authority to promote the welfare of others: and one of the most benevolent of all exercises is, to visit the poor and vicious when suffering and wretched, even with the view of administering only the pecuniary bounty of others. Benevolence is an essential element in true politeness." Those who have the organ small are not on that account cruel; for cruelty is the result of a positive faculty, Destructiveness; they are merely indifferent to others' suffering, so that their Destructiveness meets with no check. Hare, the murderer, was an example. He required no effort, no drowning influence of liquor, as even the wretched Burke did, to steel him against the cries and struggles of his victims. See his head, fig. 4, contrasted with a benevolent development, fig. 3. Benevolence is the chief ground of an individual's popularity; when added to integrity and talent, it renders a public man justly an idol; it is always the most prominent inscription on his monument. The martial fame of Henry IV., of France, has descended in the mild company of the history of his benevolence; and his memory is yet, after nearly three centuries, dear to the French people. The air that bears his name is the first they call for in their theatres. Unregulated by Conscientiousness and Intellect, Benevolence degenerates into abuse, and becomes profusion and facility. Such an endowment gives indiscriminate alms, without reflecting that it is thereby probably encouraging fraud and crime. When Conscientiousness is weaker than Benevolence, we see the individual generous before he is just—making expensive presents, and leaving his tradesmen unpaid. Benevolence often co-exists with Destructiveness, although this has been ignorantly denied as an inconsistency in nature. How many individuals known to us are at once kind-hearted and hasty and irascible? Shakspeare has often portrayed characters showing both the feelings in extreme endowment. Dr. Currie, in his Life of Burns, says, "By nature kind, brave, sincere, and in a singular degree compassionate, he was, on the other hand, proud, irascible, and vindictive." To explain this seeming incongruity, phrenology steps in and shows that the two classes of manifestations depend on two distinct faculties. The sword of justice is Destructiveness, coming in aid of Conscientiousness and Benevolence. The knife of the surgeon has a benevolent purpose. While Destructiveness arms the soldier, Benevolence provides the surgical staff that follows him to the field. Horses and dogs are known to be mild or vicious by the breadth and roundness, or the narrowness and flatness of the region of their foreheads in the middle, a little way above the eyes. In the inferior animals, Benevolence is little more than passive mildness, and is quite enough distinguishable from the faculty as above described in man, to warrant the general position that Benevolence is peculiar to man. Mr. Combe, however, mentions several examples of benevolence more positive in certain of the lower animals. The Scotch metaphysicians in general admit this faculty as primitive. Hobbes, who traced all our benevolent and just actions to selfish calculation, denies it. Phrenologists account for such a theory by concluding that the organs of Benevolence and Justice must have been small in Hobbes's own brain, so as never to have inspired him with their legitimate feelings. As already mentioned in the section on Destructiveness, Mr. Robert Cox has shown, by a variety of facts and arguments, that when the other faculties are *agreeably* excited, Benevolence, as a feeling, is increased; while Destructiveness is excited by the disagreeable activity of the other faculties. Happiness, therefore, gives generosity and sweetness of temper, while misery gives sourness and irritability. From these principles important practical results are to be deduced. The organ is established.

No. 11.—Veneration.

The organ of this faculty occupies the centre of the coronal region just at the fontanel—the centre of the top of the head. It was discovered by Dr. Gall in the pious and devout; and is very obvious in the bald head of the monk of real sentiment and not of mere interest. The function of the faculty is the sentiment of veneration, or deference in general for superiority, for greatness, and goodness. Its highest object is the Deity. It is remarkable in how many instances the painters of sacred subjects have given large development of this organ in the heads of their apostles and saints—no doubt, because the pious individuals whom they would naturally select as studies for such characters, possessed the organ large. Veneration has no special object: it finds appropriate exercise with regard to *whatever is deemed superior*. One man may venerate what another treats with indifference, because his understanding leads him to consider that particular object as superior, while his neighbour deems it upon his own level, or beneath it. But any man with a large endowment of the organ will have a tendency to consider things as superior: he will be naturally disposed to look up, and not to look down. Self-Esteem is a positive faculty opposite to Veneration. The one prompts to a regard for, and appreciation of, self; the other to a regard for, and appreciation of, others, or something above self. He in whom there is much Veneration, with a moderate or defective Self-Esteem, will always be disposed to think well of what other persons do, and to put himself under their guidance and advice, which he will scrupulously follow, although his own understanding might have suggested better courses. Veneration is the basis of the feeling of loyalty: it is a main element in such political parties as the Jacobites of England and the Carlists of France. We see it irrationally exercised in the savage, with regard to his idols of stone and wood, and, in civilized society, with regard to the mere idea of rank unattended by worth. It is, on the other hand, rationally exercised with regard to persons of real excellence, and those who have been invested with important functions for the benefit of society. It is, indeed, at the root of all subordination, and even of that courtesy which forms so important an element in private life. Without this sentiment to make man look up to man, a people would be like a rope of sand, and society could not exist. The democratic spirit, when not entertained as a dogma in philosophical politics, depends expressly on a preponderance of Self-Esteem over Veneration. There are many so constituted in this respect, that submission to authority of any kind would be to them positively painful. "I am as good as he," is a formula of words in which such a nature finds appropriate expression. The fact may be, that the individual referred to is possessed of infinitely superior endowments, and has a high place in society, which the other wants; but the defective Veneration does not allow of the difference being appreciated.

Veneration, having the Deity for its highest objects, forms an element in the purest and most exalted religious feeling. But while there can be no perfectly pious man without it, we are bound to admit that individuals are often found, passing for very fair religious characters, in whom Veneration is by no means conspicuous. Such show little reverence or care in the handling of divine things, and often address the Deity in their prayers in a style calculated to shock others by its familiarity. Some languages are said to be better adapted for addressing the Deity than others: the Gaelic of the Scotch Highlanders bears this reputation. Such a circumstance would seem to show that the people whose language that is, are nationally characterized by large Veneration.

Phrenologists trace to this faculty a love of antiquities, and a tendency to approve of every thing that is old. They ascribe to it the awe with which many visit ancient temples, cathedrals, and the sepulchres of the illustrious dead. It is said by them to delight in collecting relics, and archaiological objects generally. They describe it as looking back to past times with regret that they *are* past, and as being the basis of the often-exposed fallacy as to the wisdom of our ancestors. There is some reason, however, to conclude that these manifestations, in some degree at least, belong to another organ, for which a site has been assigned in a space heretofore unmarked in the busts, and whose primitive function may be defined as a love of, or regard for the past, as hope is a love of or regard for the future.

So liable is the organ of Veneration to disease, that devotional exaltation is well known to be one of the most common forms of insanity. The religiously insane abound in the asylums. Drs. Gall and Spurzheim adduce many examples, and in all of them the organ of Veneration was found large. Esquirol justly remarks, that, although a particular sermon is often blamed for deranging religiously the mind, yet it has that effect in consequence of a predisposition to the disease, and probably a pre-existence of it in the individual.

No. 15.—Firmness.

The organ of this faculty occupies the top of the head, behind Veneration, in the middle line. It is a faculty of peculiar character. Dr. Gall held that it was neither an inclination nor a power, but a *manière d'être*—a mode of existing or being firm, resolute, and determined. He who is deficient in the faculty, is the sport of circumstances and impressions. Dr. Spurzheim says that Firmness is apt to be mistaken for Will, because those that have the organ large are prone to say, "I will," and "I wont," that being the natural language of determination; but the feeling is quite different from what is properly called the Will. It gives fortitude, constancy, perseverance, and determination; and when too powerful, it produces obstinacy, stubbornness, and infatuation. The organ will be found large in obstinate and intractable children. Firmness has no relation to external objects; its influence is within the mind, and adds a quality of endurance to each or all of the other faculties. For example, it renders Combativeness determined bravery; Conscientiousness, inflexible integrity, and so with others. With Self-Esteem, it renders the individual absolutely impracticable. The want of it is a great defect in character; it is unsteadiness of purpose. Fig. 18 is that of the head of a lady who had several houses taken because she could not *determine* in which she should live: her Conscientiousness (marked 16) will be observed large, and this feeling she manifested by faithfully and punctually paying the rents of them all. The English soldier has more of Firmness than the French, although in courage and spirit they are equal. The battle of Waterloo illustrated the two characters in a remarkable manner. The organ is large in the torture-enduring American Indian. Dr. Gall mentions that he found it large in the head of a highwayman, who firmly resisted the most horrible tortures, and contrived to escape from agony and confession, at once, by suicide. After his death, the parietal bones were found separated just over this organ. Dr. Gall did not conclude from that single case that this separation was the effect of the excessive energy of this portion of the brain, but he recommends the fact as worthy of notice in similar cases. The insanity of the faculty has not been observed; it must naturally be a morbid aggravation of its symptoms. The insane often manifest indomitable obstinacy, in refusing food, &c. The faculty is a difficult feeling to deal with in education. To contend with it, as many parents and teachers do, is to aggravate it. Such procedure resembles an attempt to extract a nail by striking it on the head with a hammer. Firmness is an established organ. In figs. 18 and 20, it is small; in 17 and 19, large.

No. 16.—Conscientiousness.

The organ of this sentiment is situated on each side of the organ of Firmness, between the latter organ and that of Cautiousness. Dr. Spurzheim discovered the organ, and thereby incalculably benefited mental and moral science. Previously, metaphysicians differed in opinion as to the existence of a moral sense—a primitive instinctive feeling of truth and justice. Hobbes and Mandeville held justice to be a mere selfish calculation. Even Paley considered it as influenced by the hope of eternal reward, and therefore no better than a selfish calculation. Adam Smith placed the standard of moral approbation in sympathy, Hume in utility,

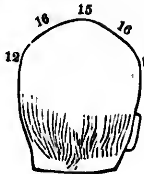

Fig. 17.

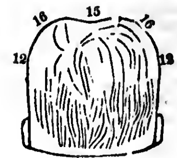

Fig. 18.

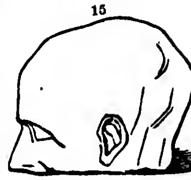

Fig. 19.

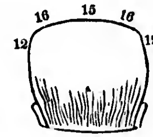

Fig. 20.

Clarke in the fitness of things; while Hutcheson, Cudworth, Kames, Reid, Stewart, and Brown, all contend for a *faculty* which produces the sentiment of right and wrong, independently of all other considerations. Mr. Combe says that these conflicting theories will serve "to convey some idea of the boon which phrenology would confer upon moral science, if it could fix on a firm basis this single point in the philosophy of mind —that a power or faculty exists, the object of which is to produce the sentiment of justice, or the feeling of duty and obligation, independently of selfishness in any form, hope of reward, fear of punishment, or any extrinsic motive; a faculty, in short, the natural language of which is '*Fiat justitia ruat cœlum.*' Phrenology does this by a demonstration, founded on numerous observations, that those persons who have the organ now under consideration large, experience powerfully the sentiment of justice; while those who have that part of the brain small, are little alive to the emotion. This evidence is the same in kind as that adduced in support of the conclusions of physical science." Without this faculty, the sentiments which guard, or rather constitute, morality, would be incomplete. Benevolence prompts to kindness, and is offended with cruelty; Veneration induces piety, and is shocked with blasphemy; but neither of these faculties gives the perception or feeling of obligation, duty, incumbency, truth— in a word, justice. When, however, Conscientiousness is added, the defect is supplied, and morality completed —that morality which Scripture recognises in the precept "to do *justly*, to love *mercy*, and to walk humbly with *God*." This is a beautiful accordance of Scripture morality with natural, and demonstrates the identity of their divine origin. In the last quotation we have distinguished by *italics* the three words which correspond to Conscientiousness, Benevolence, and Veneration. The word "*humbly*" is important; it expresses the self-abasement of Veneration, when directed to its highest object, the Omnipotent, and the utter incompatibility of pride, which was not made for man—in other words, the abuse of Self-Esteem—with that lofty sentiment. In these three words there is a complete system of ethics or morals; for an action is right which satisfies all, and wrong which offends any one of these three faculties. So simple is truth—a few words thus make clear what volumes written in the dark have failed to do.

Conscientiousness gives the emotion of justice, but intellect is necessary to show on which side justice lies. The judge must hear both sides before deciding, and his very wish to be just will prompt him to do so. This faculty regulates all the other faculties by its rigid rules. It says to them, "thus far and no farther, or you will do injustice." Benevolence and Veneration themselves require its guardianship, to prevent the one from running into generosity without justice, the other into bigotry, fanaticism, and persecution. Conscientiousness not only curbs our faculties when too powerful, but stimulates those that are too weak, and prompts us to duty even against strong inclinations. To cultivate it in children is most important. No organization, however favourable, compensates a want here; yet phrenologists are forced to confess that it is not the largest organ in the great majority of brains, and hence the injustice that is, silently as well as openly, at work in society. The training of it by practical exercise in infant education is explained in the volume on Infant Education in *Chambers's Educational Course.* Conscientiousness not only prompts to honesty and truth, in opposition to common fraud and falsehood, but, more delicately still, renders the individual who is blessed with it in large measure candid and fair in his judgments of the conduct, opinions, and talents of others. It is from its defect to this extent, that in controversy we hear so much complaint of misrepresentation and misquotation. It pays debts, keeps appointments, performs promises, and gives a beautiful consistency and trustworthiness to the whole conduct, which secures the respect, and, when blended with Benevolence, the love, of all within the range of its influence. Without Benevolence, it is apt to be too severe and stringent. When Conscientiousness is weak, or when, as happens in perfectly "*honest*" and "*honourable*" people, in the broad sense of these terms, it is not something more than average in its power, the defect will run through the whole conduct and judgments of an individual. It is important to observe the manner of this. Mr. Combe says, "The predominant propensities and sentiments thus act without this powerful regulator. If Adhesiveness and Benevolence attach the individual to a friend, he is blind to all his imperfections, and extols him as the most matchless of human beings. If this model of excellence happen to offend, he becomes a monster of ingratitude and baseness; he passes, in an instant, from an angel to a demon. Had Conscientiousness been large in the offended, the other would have been viewed all along as a man; esteem towards him would have been regulated by principle, and the offence candidly dealt with. If Love of Approbation be large, and Conscientiousness deficient, the former will prompt to the adoption of every means that will please, without due regard to justice and propriety. If an individual have a weak point in his character, Love of Approbation will lead to flattering it; if he have extravagant expectations, it will join in all his hopes; if he be displeased with particular persons, it will affect to hate with his hatred, altogether independently of justice. In short, the individual in whom this faculty is deficient, is apt to act and also to judge of the conduct of others exactly according to his predominant sentiments for the time; he is friendly when under the influence of Benevolence, and severe when Destructiveness predominates; he admires when his pride, vanity, or affection give him a favourable feeling towards others; and condemns when his sentiments take an opposite direction, but is always unregulated by principle. He is not scrupulous, and rarely condemns his own conduct, or acknowledges himself in the wrong. Minds so constituted may be amiable, and may display many excellent qualities, but they are never to be *relied on* where justice is looked for. As judges, their decisions are unsound, and often partial; as friends, they are liable to exact too much, and perform too little; as sellers, they are prone to misrepresent, adulterate, and overcharge; as buyers, to depreciate quality and quantity, or to evade payment." This is a painful but true picture of what is too often found in society. We often hear people complaining that a particular friend is "*uncertain.*" This word expresses concisely the defect of Conscientiousness above described. The faculty powerful, is essential, in both parties, to a sincere and lasting friendship.

Honour, as it is misnamed in society, is often Pride or Self-Esteem, and Love of Approbation, without Conscientiousness. The individual will fight, and thereby increase the wrong he has done, but he will not acknowledge the wrong by an apology. There is no philosophic mind without powerful Conscientiousness. Without it, scientific men only acknowledge *fashionable* truth. Mr. Combe again says on this point—"I have observed that individuals in whom Love of Approbation was large, and Conscientiousness not in equal proportion, were incapable of conceiving the motive which could lead any one to avow a belief in phrenology, while the tide of ridicule ran unstemmed against it. If public opinion should change, these would move foremost in the train of its admirers. They instinctively follow the doctrines that are most esteemed from day to day, and require our pity and forbearance, as their conduct proceeds from a moral deficiency, which is their misfortune rather than their fault." The existence of Conscientiousness as an independent element in the human constitution, renders intelligible many supposed inconsistencies in human conduct—that a man, for instance, will be kind, forgiving, even devout, and yet not just. It is a great mistake with regard to those who, after many years of sanctimonious professions, are detected in dishonest acts, to say that they must have been all along mere hypocrites. It is quite possible that many of their religious feelings and convictions may have been sincere, but only insufficient in force to compensate for the lack of direct Conscientiousness. Conscientiousness gives remorse when the individual has been tempted to sin. Criminals seldom experience remorse; it is erroneously supposed that they do; their terrors are dread of punishment only. In fig. 18, Conscientiousness is large; in fig. 17, it is small, and appears in a slope from Firmness; and in fig. 20, it is small, from the general flatness of the coronal region above fig. 12, or Cautiousness. In this last, Firmness itself is small. It represents the head of a boy remarkable for falsehood and deceit. The organ is larger in some nations than others. It is larger generally in Europeans than in Asiatics and Africans; very generally it is deficient in the savage brain. It evidently grows in civilization; indeed, it constitutes an essential of civilization. English and Scotch skulls, found in numbers in old cemeteries and battle-fields three and four centuries old, present much greater deficiency in that organ than modern skulls of the same nations.

The organ is often found diseased, and the insanity consists in morbid self-reproach, imaginary debts, and unfounded belief in merited punishment. Cowper, the poet, once believed that the arrangements were made in the market-place for his own execution for a fancied crime.

Mr. Combe's theory to account for the denial by some philosophers of a sense or sentiment of justice, is, that it was weak in themselves, from defect of organization. Those in whom the organ is large express astonishment that the existence of a moral faculty, primitive in man, could ever be the subject of doubt. The organ is established.

No 17.—Hope.

The organ of this faculty has its place on each side of Veneration, partly under the frontal, and partly under the parietal bone. It was discovered by Spurzheim, but never admitted by Gall, who considered Hope as a function of every faculty that *desires.* To this Dr. Spurzheim answered, that we desire much of which we have no hope; a criminal on the scaffold intensely desires life, but has no hope of it. Dr. Spurzheim considered Hope a faculty *sui generis*, producing hope, in general, of good, or gratification to the other faculties; and, by careful observation in nature, found the organ in the situation just described. It seems to have been given to man to make him happy. It produces gayety and cheerfulness, looks on the sunny side of every thing, and paints the future with bright colours. When not regulated by the intellect, Hope leads to rash speculation, and, in combination with Acquisitiveness, to gambling, both at the gaming-table and in the counting-house. It tends to render the individual credulous, and often indolent. In religion, hope leads to faith, and strongly disposes to a belief in a happy life to come. Mr. Combe observes (*System*, vol. i. p. 372): "I have already stated an argument in favour of the being of a God founded on the existence of a faculty of Veneration, conferring the tendency to worship, of which act God is the proper and ultimate object. May not the probability of a future state be supported by a similar deduction from the possession of a faculty of Hope? It appears to me that this is the faculty from which originates the notion of futurity, and which carries the mind forward in endless progression in periods of everlasting time. May it not be inferred that this instinctive tendency to leave the present scene and all its enjoyments, to spring forward into the regions of a far distant futurity, and to expatiate, even in imagination, in the fields of an eternity to come, denotes that man is formed for a more glorious destiny than to perish for ever in the grave?" Addison beautifully enforces this argument in the *Spectator*, and in the Soliloquy of Cato; and phrenology gives weight to his reasoning by showing that this "ardent hope, this longing after immortality," are not factitious sentiments, or a mere product of an idle and wandering imagination, but that they are the results of two primitive faculties of the mind—Love of Life, and Hope, which owe at once their existence and their functions to the Creator. The well-known lines of Pope introduce hope as the foundation of the Indian's anticipation of a happy hereafter:—

"Lo! the poor Indian, whose untutor'd mind
Sees God in clouds, and hears him in the wind,
His soul proud science never taught to stray
Far as the solar walk or milky way:
Yet simple Nature to his *hope* has given
Beyond the cloud-topt hill an humbler heaven—
Some safer world in depth of woods embraced,
Some happier island in the watery waste,
Where slaves once more their native land behold,
No fiends torment, no Christians thirst for gold."

The metaphysicians admit Hope as a primitive faculty; phrenology, therefore, only points out its organ, and the effects of different degrees of its endowment.

No. 18.—Wonder.

The organ of this faculty is situated on each side of that of Benevolence, with one other organ, that of Imitation, interposed. Technically, it has its place in the lateral parts of the anterior region of the vertex. Dr. Gall discovered it by observing it large in the seers of visions and dreamers of dreams, and in those who loved the marvellous. Socrates, Tasso, Joan of Arc, and Swedenborg, were examples. The two first believed they were attended by a familiar spirit.* Swedenborg believed and declared that he was admitted to the presence of God in heaven, to receive a revelation of the true religion. Joan of Arc related that she *saw* St. Michael, and received from him her commission to raise the siege of Orleans, and enthrone Charles VII. as king. There are many other examples in the phrenological books. In modern times, Joan of Arc would have been held to be a mere maniac.

Persons with the faculty powerful are fond of news, especially if striking and wonderful, and are always expressing astonishment; their reading is much in the regions of the marvellous, tales of wonder, of enchanters, ghosts, and witches. When the sentiment is excessive or diseased, it produces that peculiar fanaticism which attempts miracles, and with Language active, speaks with unknown tongues. It draws the ignorant and fanatically-inclined, who have the organ large, with ease by its pretensions; hence the numerous followers of Johanna Southcote, Courtenay or Thom, and Edward Irving. Mr. Combe says of the latter—"I examined his head before he was established as a preacher, and when his peculiarities were unknown, and observed that the organs of Wonder and Self-Esteem were very large. They gave a tinge to his whole public life. The organs of Benevolence, Conscientiousness, Veneration, and Intellect, were also amply developed, so that he possessed the natural elements of the Christian character in great strength, but their direction was rendered unprofitable by the predominance of Wonder and Self-Esteem." Mr. Combe quotes the extraordinary case of Dr. Anderson, of Cupar-Fife, who was tormented by the belief that there were invisible enemies planning his destruction by supernatural means. On examination of his brain after death, an inflammatory deposit, of apparently old standing, was found over the organ of Wonder. During life the part was painfully heated, and Dr. Anderson was in the habit of sponging it with cold water. Pain in the seat of the organ of Wonder has been localized by several ghost-seeing patients, who knew nothing of phrenology. Many instances are mentioned in the phrenological books. Second sight, as the Highlanders call it, is explained by over-excitement of the organ of Wonder. Mr. Combe adds—"At the same time, it is difficult to comprehend how an exalted state of this organ should produce these effects, unless we suppose it to excite the organs of Form, Size, Colouring, and Individuality, so as to prompt *them* to conjure up illusions of objects fitted for the gratification of Wonder, just as the involuntary activity of Cautiousness during sleep excites the intellectual organs to conceive objects of terror, producing thereby frightful dreams. This theory is rendered probable by the fact, that morbid excitement of the knowing organs produces spectral illusions, independently of an affection of the organ of Wonder. Mr. Simpson has communicated an admirable paper on this subject to the *Phrenological Journal* (vol. ii. p. 290), to which I shall have occasion afterwards to refer." We shall also refer to that paper in the sequel. The general function of the organ is held to be ascertained, but the metaphysical analysis is still far from being perfect. Dr. Spurzheim named the faculty Marvellousness instead of

* Mr. Combe has thus translated from the French, as given in *Black's Life of Tasso*, the following anecdote, extracted from the *Memoirs of the Marquis of Villa*, the friend of Tasso. "Tasso, in his delirium, believed that he conversed with familiar spirits. One day, when the marquis endeavoured to drive that idea from his mind, Tasso said to him, 'Since I cannot convince you by reason, I shall do so by experience; I shall cause the spirit in which you refuse to believe to appear before your eyes!' 'I accepted the offer,' says the marquis, 'and next day when we sat by the fire conversing, he turned his eyes towards the window, and looking with steadfast attention, appeared so completely absorbed, that when I called to him he did not answer.' 'See,' said he at length; 'see! my familiar spirit comes to converse with me.' 'I looked with the greatest earnestness, but could see nothing enter the apartment. In the mean time, Tasso began to converse with the mysterious being. I saw and heard himself alone. The subject of his discourse was so elevated, and the expressions so sublime, that I felt myself in a kind of ecstasy. I did not venture to interrupt him, or to trouble him with questions, and a considerable time elapsed before the spirit disappeared. I was informed of its departure by Tasso, who, turning towards me, said, 'In future you will cease to doubt.' 'Rather,' said I, 'I shall be more skeptical, for though I have heard astonishing words, I have seen nothing.' Smiling, he replied, 'You have perhaps heard and seen more than'—He stopt short, and fearing to importune him by any questions, I dropt the conversation.'" We hope to account for Tasso's spectral illusion, for it could be nothing else in the sequel.

Wonder, because, as he argues, it causes astonishment by the contemplation of both natural and supernatural circumstances. Mr. Combe holds Wonder to be the better name for the fundamental feeling, just because it is excited by natural circumstances, to which Marvellousness does not apply.

No. 19.—Ideality.

The organ of this faculty is situated farther down, but close to that of Wonder, along the temporal ridge of the frontal bone. Dr. Gall discovered it in the busts and portraits of deceased, and in the heads of a great number of living, poets. This confirmed to him the old classical adage, that the poet is born, not made; in other words, that his talent is the result of a primitive faculty. Dr. Gall called the organ the organ of Poetry. Dr. Spurzheim corrected this, and gave it the elegant name it now bears; which has, as well as others of the expressive names of the phrenological organs, been adopted into ordinary language. He says—"It is impossible that poetry in general should be confined to one single organ, and I therefore think that the name 'Organ of Poetry,' does not indicate the essential faculty. In every kind of poetry the sentiments are exalted, the expressions warm; and there must be rapture, inspiration, and what is commonly called imagination or fancy."

The faculty delights in the perfect, the exquisite, the *beau-ideal*—something beyond the scenes of reality—something in the regions of romance and fancy—of the beautiful and the sublime. Those writers and speakers who possess it large, adorn all they say or write with its vivid inspirations. It is the organ of imagery. The sermons of Chalmers owe much of their charms to it, and the organ is very large in his head. Shakspeare created such beings as Ariel, Oberon, and all the imaginings of the "Tempest," and "Midsummer Night's Dream," under its influence. Prospero's speech, when he abjures the art of magic and breaks his staff, is unequalled as a specimen of Ideality. The passage is well known—

"I have bedimmed
The noontide sun, called forth the furious winds,
And 'twixt the green sea and the azure vault
Set roaring war," &c.

The faculty renders conversation elevated, animated, and eloquent, the opposite of dry and dull.

Nature abounds in beauty and splendour to gratify Ideality—a proof of pure beneficence in the Creator; for it is a pleasure of unmixed gratuity, if we may so speak; man might have been created without it, but Divine goodness superadded that, the most exquisite, to his other enjoyments. The organ is small in criminals and other coarse and brutal characters, for it is essential to refinement. It prompts to elegance and ornament in dress and furniture, and gives a taste for poetry, painting, statuary, and architecture. Some religious sects, as the Friends, condemn elegance and ornament. They should revise their standards, now that it is discovered that a faculty is given to man whose function it is to enjoy these without abusing them. A point of interrogation is placed on the bust on the back part of the region of this organ, conjectured to be a different organ, but one allied to Ideality. Some phrenologists have considered it the organ of the Sublime, from its touching on Cautiousness, which the grand, at least the terrific grand, in some degree affects. A writer in the *Phrenological Journal* suggests the love of the past as its function. The existence of the faculty of Ideality demonstrates that the sentiment of beauty is an original emotion of the mind, and settles the controversy in which Professor Stewart, Lord Jeffrey, Dr. Brown, and others, took a part, as to the origin of our perception of beauty.

The following passage from Combe's *System* (vol. i. p. 407) is well worth quoting. It gives practical aid to our conceptions of the nature of Ideality, and affords an example of the application of phrenology to literary criticism. "In composition, this faculty imparts splendour and elevation to the style, and manifests itself in prose as well as in verse. The style of Lord Bacon is remarkably imbued with the splendour of Ideality, sometimes to excess, while that of Locke is as decidedly plain; and the portraits of both show that their heads corresponded with these different manifestations. Hazlitt's head indicated a large development of Ideality, and the faculty glows in his compositions. It was the sustaining power which gave effect to his productions, for he was eminent for neither sound principles, correct observations, nor extensive knowledge. He seems to have relied chiefly on his imagination and language for his success, and his works are already sinking into the shades of oblivion. In Lord Jeffrey's head, as it appears in the bust, Ideality does not predominate. The report was current at the time, that the review of Lord Byron's tragedies, which appeared in No. LXXII. of the *Edinburgh Review*, (Feb. 1822,) was the joint production of these two celebrated authors; and keeping in view the fact, that Mr. Hazlitt's Ideality is larger than Lord Jeffrey's, it would not be difficult, by a careful analysis of the article, to assign to each the sentences which he wrote. Lord Jeffrey's predominating intellectual organs are Eventuality, which treasures up simple incidents or events; Comparison, which glances at their analogies and relations; and Causality, which gives depth and logical consistency to the whole. Hazlitt, on the other hand, possessed a large Comparison, respectable Causality, with a decidedly large Ideality, elevating and adorning his intellectual conceptions. Proceeding on these views, I would attribute the following sentence to Lord Jeffrey's pen, as characteristic of his manner. Speaking of the qualities of Shakspeare's writing, the reviewer says, 'Though time may have hallowed many things that were at first out common, and accidental associations imparted a charm to much that was in itself indifferent, we cannot but believe that there was an original sanctity, which time only matured and extended, and an inherent charm from which the association derived all its power. And when we look candidly and calmly to the works of our early dramatists, it is impossible, we think, to dispute, that after criticism has done its worst on them—after all the deductions for impossible plots and fantastical characters, unaccountable forms of speech, and occasional extravagance, indelicacy, and horrors—there is a facility and richness about them, both of thought and diction, a force of invention and a depth of sagacity, an originality of conception and a play of fancy, a nakedness and energy of passion, and, above all, a copiousness of imagery, and a sweetness and flexibility of verse, which is altogether unrivalled in earlier or in later times, and places them in our estimation, in the very highest and foremost place among ancient and modern poets.' In this passage we have the minuteness of enumeration of Eventuality, the discrimination of Comparison and Causality, and the good taste of a fair, but none of the elevation, ornament, and intensity of a large, Ideality. In another part of the review we find the following sentences. In Byron 'there are some sweet lines, and many of great weight and energy, but the general march of the verse is cumbrous and unmusical. His lines do not vibrate like polished lances, at once strong and light, in the hands of his persons, but are wielded like clumsy batons in a bloodless affray. * * * He has too little sympathy with the ordinary feelings and frailties of humanity, to succeed well in their representation. "His soul is like a star, and dwells apart." * * * It does not "hold the mirror up to nature," nor catch the hues of surrounding objects, but, like a kindled furnace, throws out its intense glare and gloomy grandeur on the narrow scene which it irradiates.' Here we perceive the glow of Ideality, the simplicity of the former style is gone, and the diction has become elevated, figurative, and ornamental. I am not informed regarding the particular sentences which each of the above-named gentlemen wrote in this review, but these extracts will serve as brief examples of the differences produced on style when Ideality sheds few or many beams on the pen of the author; and I regard the probabilities as very strong that the passages are assigned to their actual sources." The organ is established.

No. 20.—Wit, or the Ludicrous.

The organ of this faculty is situated before, and a little lower than that of Ideality. When large, it gives a breadth to the upper region of the forehead. In the portraits of Sterne, his forefinger is represented resting on this angle of the forehead, which in him was very large, and the mental manifestation powerful.

The phrenological writers have discussed at great length, and with not a little controversy, the metaphysical nature or analysis of this faculty. We do not require to follow them into this inquiry, as most of them are agreed that, by means of this faculty, we see and enjoy the *ludicrous*, and experience the emotion of laughter. Man is the only laughing animal, and the impulse and its result are too well marked characteristics not to be the manifestations of a special faculty. Dr. Beattie's theory is the most satisfactory of any—that the objects of the ludicrous are incongruities, with a certain mixture of congruity. When the butcher put his wig on his dog's head in the pit of the theatre, that he might wipe his heated brow, Garrick was so tickled with the incongruity, mixed, be it observed, with the congruity of a wig belonging to *a head*, that he ran off the stage to conceal his laughter. When this organ is large, the individual both enjoys and creates the ludicrous, and is apt to give a ludicrous turn to every thing that passes through his mind. For the discussions in which Mr. Scott, Mr. Watson, and Mr. Schwartz of Stockholm, have taken a part, as well as for the opinions of Gall, Spurzheim, and Combe, we must refer to Mr. Combe's *System* (4th edition, p. 416.) We may observe that Mr. Scott and Mr. Hewet Watson consider the organ, No. 20, as that of an intellectual and not an affective faculty. Mr. Scott views it as the faculty by which we discriminate or observe differences; and this, by much ingenious reasoning, he is inclined to hold to be the function of a different faculty from that by which we perceive resemblances. Mr. Watson thinks the function of No. 20 is to investigate what may be called intrinsicalities—the intrinsic nature of things. Mr. Combe thinks the facts adduced by Mr. Watson make it probable that there is a faculty for this power, but that it is not No. 20. Dr. Spurzheim unsettles both Mr. Scott's and Mr. Watson's theories anatomically, by showing that the portion of brain is in the same region with Ideality, and is therefore the organ of an affective and not an intellectual faculty. He farther holds, that the same faculty which perceives resemblances perceives differences; and both he and Mr. Combe, observing that all those who deal largely in the ludicrous have the Organ 20 large, conclude, that whatever may be the object or objects of the ludicrous in nature—whether something specific, like colour, or odour, in a rose, or some *condition* of things, which in themselves are not necessarily ludicrous—there is a mental sentiment or emotion which moves, or *is* laughter. No. 20 is the organ essentially of this emotion, and so far they hold it established. Our own observation in numerous instances confirms this conclusion. Primitive function is best observed in extreme development, and when No. 20 is very large, the individual exists in a world of the ludicrous. This conclusion is agreed upon, generally, by all the controversialists on the function of this faculty, as their discussions relate to the metaphysical analysis of the faculty only. Curran and Sheridan were both considered witty men, yet in neither is the organ 20 large. Mr. Combe thinks that their cases only confirm the view of the faculty, which he with Dr. Spurzheim is disposed to take. He thinks that in Curran's works there are none of the witty contrasts of Sterne, Voltaire, and a living wit, the Rev. Sydney Smith. Curran's is burlesque humour, of a coarse satirical kind. Secretiveness and Imitation, with Eventuality and Comparison, gave him fertility of invention, copiousness of illustration, *savoir faire*, and tact, and Destructiveness gave his ideas a pungent sting, which he wielded with much address. Sheridan, again, notoriously *stole* from others his witty sayings, and applied them in his own compositions. "The Rev. Sydney Smith," says Mr. Combe, "is a living example of a really witty mind. His wit is always pertinent to the object about which he reasons. It is the seasoning to solid argument, and in fact is often in itself argument. Sheridan, when he drew on his own resources, manifested Individuality Eventuality, and Comparison, in enumerations and descriptions of physical objects and events, and by means of a moderate organ of wit, he tinged them with the ludicrous. Sydney Smith, on the other hand, impregnates the abstract deductions of reason with wit, presenting the strongest arguments in the most ludicrous attire, yet keeping the wit always subordinate to the logic. Causality, combined with a large organ of Wit, appears to me to be indispensable to the manifestation of these qualities." Mr. Combe adds the following true observation, which every one is enabled to verify in the circle of his own acquaintance. "Some individuals, who possess a large development of Individuality, Eventuality, and Comparison, particularly when Secretiveness and Imitation (which are great elements in the talent for acting) are also large, often enjoy a great reputation for wit and drollery among their companions, although in them the organ of the Ludicrous is by no means large. Two explanations may be given of this fact. First, the conceptions formed by the faculties here named are palpable and striking, and if even a moderate portion of the ludicrous be infused into them, they produce a great effect on ordinary minds. Secondly, many persons take every thing for wit that makes them laugh, and, in consequence, dignify with that name mere imitations, and sometimes even absurdities, when uttered with a confident air, as if they had legitimate pretences to be considered ludicrous."

No. 21.—Imitation.

This organ is situated on each side of that of Benevolence. Dr. Gall found the protuberance accompanied by instinctive and often irrepressible mimicry. A deaf and dumb boy had this power quite unconsciously. The purpose of the faculty is to enable the young to learn from the more advanced, and keep a convenient uniformity in the manners and externals of society. Celebrated players always possess it largely, and by it imitate the supposed manner, and even feel the sentiments, of their characters. In the *Transactions of the Phrenological Society* (page 169), Mr. Scott has shown that Secretiveness must concur with Imitation to complete the actor. He must conceal his own, as well as imitate the character he plays. The Imitative arts depend on this faculty; and its organ is found large, accordingly, in painters and sculptors of eminence. Ventriloquism, as shown by Mr. Simpson in two papers in the *Phrenological Journal*, is nothing more than exquisite power of imitating sounds according to position and distance. What a fund of amusement and delight comes from the group of faculties whose organs are all in this one region of the head, well named "The Poet's Corner," namely, Ideality, Wonder, Imitation, Wit or the Ludicrous, Time and

Tune! The faculty of Imitation has been recognised in a state of disease, when the impulse to mimic is beyond the individual's control. Pinel makes mention of an idiot girl who was affected in this way. Parrots, monkeys, and the mocking-bird, imitate and mimic. The last-mentioned often attracts other birds by the cries of their own kind; and then, waggishly, as it were, scares them away with the cry of some bird they dread. The organ is established.

ORDER SECOND.—INTELLECTUAL FACULTIES.

By these faculties man and animals perceive or gain knowledge of the external world, and likewise of their own mental operations. The object of the faculties is to know what exists, and to perceive qualities and relations. Dr. Spurzheim divided them into three genera:—1. The External Senses; 2. The Internal Senses, or Perceptive Faculties, which procure knowledge of external objects, their physical qualities and relations; 3. The Reflecting Faculties.

From the great length to which our observations on the Feelings have extended, and from the more metaphysical nature of the analysis of the Intellectual Powers, we must be more brief in our exposition of them—referring to the phrenological books for a fuller treatment of this branch of the subject.

GENUS I.—EXTERNAL SENSES.

By these, man and the inferior animals are brought into communication with the external material world. Much metaphysical acumen has been wasted, and much nonsense written, about the senses. Before phrenology discovered *internal* faculties, of which the senses are the ministers—they themselves giving only passive impressions called sensations, but forming no ideas—the senses were considered the *sole* sources of our knowledge. They are necessary to that knowledge, but would never of themselves have completed it. The subject is admirably treated by Mr. Combe in his *System* (4th edition, page 436). By each sense we discover some quality of material nature. The Senses, as generally received, are five in number—*Touch, Taste, Smell, Hearing*, and *Sight*. There are certainly two more, namely, the *sense of Hunger* and *Thirst*, and the *Muscular sense*, or that by which we feel the state of our muscles as acted upon by gravitation and the resistance of matter. Without this last sense we could not keep our balance, or suit our movements to the laws of the mechanical world. Dr. Thomas Brown conjectured this sense many years ago, and Sir Charles Bell has thrown much light on it by proving that separate roots, afterwards joining in one apparent nerve, but evidently being two, give muscular motion and muscular sensation. Mr. Simpson has long given his attention to this interesting subject, and thrown so much light upon it, as to render it next to certain that all animals have a *passive sense* of material resistance, and also an *active faculty* for applying counter resistance—both being necessary to every muscular exertion.* The senses, there is every reason to hold, are not five, but seven in number.

GENUS II.—INTELLECTUAL FACULTIES, WHICH PROCURE KNOWLEDGE OF EXTERNAL OBJECTS, OF THEIR PHYSICAL QUALITIES, AND VARIOUS RELATIONS.

These faculties correspond in some degree with the perceptive powers of the metaphysicians, and form ideas.

No. 22.—Individuality.

The organ of this faculty is situated in the middle of the lower part of the forehead, immediately above the top of the nose. It takes cognisance of individual existences—of a horse, for example. Other knowing faculties respectively observe the form, colour, size, and weight of the horse, but a faculty was necessary to unite all these, and give the individual idea of a horse. It furnishes the substratum which has form, colour, &c., an old desideratum of the metaphysicians. Individuality is the storehouse of knowledge of things that simply *exist*. It is often large without being accompanied by reflecting power; when this is the case, the individual has been compared to an encyclopædia, full of facts, but unable to reason from them. All the objects of Individuality are *noun substantives*. Verbs and adjectives are the perceptions of other faculties to be afterwards noticed. As Individuality merely observes existences without regard to their modes of action, it is the faculty of the naturalist. Those who possess it large and active, observe the minutest objects; nothing escapes them, and they remember even the minutest objects so well, that they will miss them when taken away. On the contrary, those who have it small, observe nothing, and give the most imperfect account of the objects which have been in their way. In the artist, the faculty gives great minuteness of detail, and with Imitation and Form, great power of hitting likenesses in portrait-painting. The faculty prompts to personification of abstract ideas, as Fame, Envy, Wisdom, Folly. Mr. Combe says—"In adults, the *frontal sinus* is generally present at the situation of this organ, and this throws a difficulty in the way of judging of its size. The function, however, is ascertained by observing young persons in whom the sinus is not formed, and also by the negative evidence; that is, when the external part of the skull at the top of the nose is narrow, contracted, and depressed, the portion of brain below is necessarily small and then the mental power is found invariably weak This concomitance of large size and great power in young persons, and of deficiency of size and feebleness of power in all ages, proves the function." The organ is established: the metaphysical analysis of the faculty requires further inquiry. For able discussions on this field of inquiry by Mr. Scott, Mr. Hewet Watson, and Mr. Schwartz of Stockholm, see *Phrenological Journal* vol. v. 226, vi. 328, and vii. 213.

No. 23.—Form.

This organ is situated on each side of, and close to the *crista galli*, and occupies the space between the eyes In those who have it large, the eyes are wide asunder and *vice versa*. Dr. Gall discovered the organ in persons remarkable for recognising faces after long intervals, and although, perhaps, only once and briefly seen. The bust of George III. furnishes the best example in the Phrenological Society's collection; and it is well known that he never forgot a face. Townsend, the famous Bow-street officer, had the same talent, one most essential to his office. As every material object must have a form, regular or irregular, this faculty was given to man and animals to perceive forms, and they could not exist without it. When large, it constitutes an essential element in a talent for drawing, but requires Size and Constructiveness to perfect the talent. Forms are capable of great beauty, and of affording much pleasure, and in nothing more than in the human figure.

Many persons who have the organ of Form large, connect their words and ideas with forms, and these often fanciful and of their own creating. A singular instance of this is recorded in the *Phrenological Journal*, vol. viii. p. 216. Mineralogists and crystallographers generally possess this power in large endowment. The celebrated Cuvier owed much of his success in comparative anatomy to his large organ of Form. De Candolle mentions, that "his (Cuvier's) memory was particularly remarkable in what related to forms, considered in the widest sense of

---

* See *Phrenological Journal*, vol. ix. 193, x. 535, xi. 275, and previously in vol. iv. 266. Sir George Mackenzie has contributed an ingenious paper on this subject, vol. ix. 349; and Mr. Noble of Manchester, x. 730, xii. 206. See additional views by Mr. Simpson, in *The Lancet* of 17th July, 1841.

that word; the figure of an animal seen in reality or in drawing, never left his mind, and served him as a point of comparison for all similar objects." Mr. Bewick, the first celebrated English wood-engraver, showed an uncommonly great distance between the eyes. The organ is established.

No. 24.—Size.

Every object has a size or dimension Hence a faculty is necessary to cognise this quality. The organ is situated at the inner extremities of the eyebrows, where they turn upon the nose. A perception of Size is important to our movements and actions, and essential to our safety. There is no accuracy in drawing or perspective without this organ. A singular instance of a defect in the power of perceiving perspective, accompanied with a small organ of Size, is mentioned by Mr. Combe (*System*, vol. i. p. 472). "Mr. Ferguson, tutor in the family of Sir George Mackenzie, stated that he had a difficulty in 'understanding a landscape' in a picture, and explained that 'it appeared to him to present a group of objects on a plain surface, without any perceptible fore or back ground.' He attributed this defect in his perceptions to his not having been taught the rules of perspective at school. In the course of further interrogation, he stated that he sees the forms of objects distinctly, as also their colours; that he likes brilliant tints best, and that in nature he perceives distances also. He has visited Roslin (in the neighbourhood of Edinburgh), and not only perceived the beauty which characterizes that delicious spot, but enjoyed it with a keen relish. He has also seen many pieces of Highland scenery, and been delighted with them. Rivers, meadows, trees, and cultivated ground are, however, the objects which interest him most. On turning his back upon any natural landscape, or shutting his eyes, his recollections instantly become very confused. He is not able to call to his mind the 'relative positions' of the objects, while he distinctly recollects the *pleasing impressions* which they made upon him; this remembrance does not soon fade." Mr. Ferguson's organs of Ideality, Wonder, and Intellect, are good; but his Size, Form and Locality, are all deficient. His description of his experience looks very like a defect in all three. Sir George Mackenzie thinks that the faculty of Size, as it cognises dimension of every kind, whether in length, breadth, thickness, height, depth, or distance, is that faculty whereby we perceive *space* in general, analogous to to the faculty of Time, by which we perceive time. Different individuals manifest different degrees of the power of perceiving size. Some seem not to possess the power of estimating distance or dimension, while others can draw a circle without compasses, and find the centre of one already drawn with the greatest accuracy. A young lady is mentioned by Mr. Combe, whose drawings were accurate in the form, but always erroneous in the size of the objects or parts. The organ is established.

No. 25.—Weight.

Weight is a quality of matter quite distinct from all its other qualities. The weight of any material object is only another name for its degree of gravitating tendency—its attractability to the earth. A power to perceive the different degrees of this attraction is essential to man's movements, safety, and even existence. There must be a faculty for that perception, and that faculty must have a cerebral instrument or organ. Phrenologists have generally localized that organ in the superorbitar ridge or eyebrow, immediately next to Size, and farther from the top of the nose. But as yet the function of the Organ 25 has given rise to so much discussion, as to leave it far from certain what that precisely is. Mr. Combe says, "Persons who excel in archery and quoits, and also those who find great facility in judging of momentum and resistance in mechanics, are observed to possess the parts of the brain lying nearest to the organ of Size largely developed; and the organ is now regarded as probable. Persons in whom Individuality, Size, Weight, and Locality are large, have generally a talent for engineering, and those branches of mechanics which consist in the application of forces; they delight in steam-engines, water-wheels, and turning-lathes. The same combination occurs in persons distinguished for successful feats in skating, in which the regulation of equilibrium is an important element. Constructiveness, when Weight is small, leads to rearing still-fabrics, rather than to fabricating working machinery. Mr. Simpson has given much attention to this faculty (*Phrenological Journal*, vol. ii. p. 412), and opened up some original views for discussion in the phrenological world;—a new chapter, as Mr. Combe calls it, in the science of mind. He cites a number of noted mechanicians and engineers in whom the Organ 25 is large. In the bust of James Watt it is particularly prominent. Children who walk early and steadily have uniformly the organ large, and the inference was drawn that the faculty gives the power of preserving equilibrium, or that balance of forces which is essential to the application of animal power, and even to animal existence. The instances of Mr. John Hunter, the anatomist, a young lady, Miss S. L., and the English Opium-eater, are adduced in confirmation of the action of this power, these persons exhibiting the effects of a suspension of it. Mr. John Hunter, in an illness, felt as if he had drunk too much, although he had been extremely temperate—as if he were suspended in the air, as if the room went round with him, and as if he were insensible of his own centre of gravity—so he expressed himself. The young lady had the same sensations, and *saw perpendiculars at other angles*. The Opium-eater felt as if he were falling millions of miles, as he expresses it, without ever finding a bottom. Intoxication sports with *perpendiculars*, it is well known. Sir George Mackenzie suggested Resistance as the function of this power. Mr. Simpson considers Resistance to be the passive sensation of a *sense* (see External Senses), and the Organ 25 that of applying Force, or, the adaptation to resistance of counter-resistance. For his matured views, see *Phrenological Journal* (vol. ix. p. 193). Mr. Richard Edmonson of Manchester, in the *Phrenological Journal* (vol. vii. p. 106, and ix. p. 624), argues that the Organ 25 gives the perception of the *direction* of gravitating force—in other words, the *perpendicular* or *vertical*; and cites instances among his own numerous workmen, and others, of individuals who could guess the perpendicular without applying the plumb-line; and Mr. Edmonson, as he himself states, makes use of Mr. Simpson's facts, especially the cases of diseased perception above cited, in support of his own theory. There is much worthy of reflection and farther observation in this view. A standard of the direction of gravitation is essential to our safety in person, buildings, &c., and the standard is *the vertical*. A fine perception of this is certainly necessary to the engineer and mechanician. But it appears to us that the perception of the mere *direction* of gravitation were useless to us without the perception of gravitation itself, which is just another term for Weight. Mr. Hytche, in a paper in the *Phrenological Journal* (vol. xiv. p. 109), adduces many proofs in favour of the conclusion, that No. 25 is the organ of the application of mechanical power. In a paper lately read to the Phrenological Association met in London,* Mr. Simpson suggests, that what appear to be different manifestations, according to the views of Mr. Edmonson, Mr. Hytche, and himself, seem all to be necessary to the action of one single power, the mechanical perception and application of force; in a word, that the labours of all three may be found tending to the same object. Mr. Edmonson, however, adduces some facts to show that the active application of force in its due proportion is the function of the organ of Con

* An abstract is published in *The Lancet* of 17th July, 1841.

struct veness. Yet *construction* is change of form, and all animals apply force, while few construct. The functions imputed by Mr. Edmonson to both 25 and 9 are yet "an open question," waiting for further proofs by facts. The student of phrenology should read all the papers to which we have referred.

No. 26.—Colouring.

As every object must have a colour, in order to be visible, it seems necessary that there should be a faculty to cognise this quality. The organ is the next outwards from Weight in the eyebrows, occupying the precise centre of each eyebrow. A hollow there, into which the end of the finger could be put, or such a flatness in the ridge of the eyebrow that a perpendicular line dropped from it would pass through the eyeball, has, times without number, been found to be accompanied with a want of power to discriminate colours, often to a ludicrous extent. A mercer's apprentice, who used to offer red to match green, was dismissed as unfit for his trade. The organ is large in great painters, especially great colourists, and gives an arched appearance to the eyebrow; for example, in Rubens, Titian, Rembrandt, Salvator Rosa, Claude Lorraine, and others. A large endowment of the organ gives great delight in flowers and brilliant colouring of all kinds. Nature has widely and profusely provided for the gratification of this faculty, by the exquisite colouring in which her works are dressed. Some metaphysicians consider the pleasure we derive from colours to be the result of the association of ideas. Phrenology has discovered that it is the direct gratification of an organ forming part of our constitution. Like that of Ideality, the pleasures we derive from Colour are gratuitous goodness from the Creator's hands. Light and shade, mere black and white, might have rendered objects visible, but what a sombre hue would nature in that case have worn! In some individuals the love of flowers amounts almost to a passion. This organ is held established.

No. 27.—Locality.

Dr. Gall was led to the discovery of this faculty as primitive, by comparing his own difficulties with a companion's facilities, in finding their way through the woods, where they had placed snares for birds, and marked nests, when studying natural history. Every material object must exist in some part of space, and that part of space becomes *place* in virtue of being so occupied. Objects themselves are cognised by Individuality; but their place, the direction where they lie, the way to them depend on another faculty, a faculty given for that purpose. Without such a power, men and animals must, in situations where objects were numerous, and complicated in their positions, as woods, have lost their way. No man could find his own home, no bird its own nest, no mouse its own hole. The use of the faculty will be rendered plain by considering what it is we do when we wish to remember our way through the streets of a large city; we note particular objects, buildings, for example, and observe how they stand in relation to each other, and these relations we can remember, although with a faint recollection of the forms of the objects themselves. This induced Sir George Mackenzie, in his "Illustrations," to attribute to this faculty the perception of *relative position* of objects. It is evident that the objects must be fixed—at least, if movable, fixed for the moment—in order to be in a particular place, to enable us to find or go to that place. There is another relation, namely, that between ourselves and the place. Hence the use of the points of the compass, which are the [illegible] of determining the direction of places in relation to ourselves and these places. The organ is large in those who find their way easily, and vividly remember places in which they have been. It materially aids the traveller, and is supposed to give a love for travelling. The organ was large in Columbus, Cook, Park, Clark, and other travellers. Geometricians, whose study is the relation of spaces, have the organ large—as was the case with Kepler, Galileo, Tycho Brahe, and Newton. The faculty, when active, prompts the individuals to localize every thing, and think of it as in its place. One glance at a paragraph or advertisement in a newspaper fixes its place in their minds, so that they will turn over the largest and most voluminous newspaper, and know in what column, and part of a column, they will find it; or direct others to do so. Many public speakers make use of the faculty by connecting their topics with places; and those who have written their speeches, remember the pages, or parts of pages, where particular parts of their discourse are noted down. Indeed, the word *topic* is derived from the Greek *topos*, a place; hence, too, the word *common-place* subjects. A person with the faculty powerful, will go in the dark to find what he wants, and will find it in its place. Skilful chess-players invariably have the organ of Locality large, and it is believed that it is the organ of which they make the principal use; for it gives the power of conceiving, before making a move, the effect of new relative positions of the pieces. Migratory birds are believed to be directed by this organ; and animals, like dogs, and, it is said, cats—which, after being carried far from home, contrive, to the astonishment of every one, to reappear there, however distant. We refer to the *Phrenological Journal* (vol. vii. p. 747) for an amusing instance of a temporary suspension of the power of using the faculty of Locality, which will perhaps better explain the nature and use of that power than much abstract description.*

No. 28.—Number.

The organ of this faculty is placed at the outer extremity of the eyebrows and angle of the eye. It occasions, when large, a fulness or breadth of the temple, and often draws downwards the external corner of the eye. When it is small, the part is flat and narrow between the eye and the temple. Their number is a very important relation or condition of things, and requires a distinct perspective power. Our safety, and even existence, may depend on a clear perception of Number. Dr. Gall called the faculty "*Le Sens de Nombres*," "The Sense of Numbers," and assigned to it not only arithmetic, but mathematics in general. Dr. Spurzheim more correctly limits its functions to arithmetic, algebra, and logarithms; geometry being the exercise, as already shown, of other faculties. Dr. Gall first observed the organ in a boy of nine years of age, near Vienna, who could multiply and divide, mentally, in less time than expert arithmeticians could do with their pencils, ten or twelve by three figures. Dr. Gall adds, "he had created his own method." An advocate of Vienna regretted to Dr. Gall that his son was so much engrossed with calculating, that he attended to nothing else. Dr. Gall compared the heads of these two boys, and found no particular resemblance but in one place—that described above—where they exactly agreed. Dr. Gall then went to noted arithmeticians—among them an author of tables of logari[illegible] the same [illegible]tion. Many othe[illegible] found in the phrenological books; and the organ is easily observed in nature. The most wonderful arithmetical prodigy yet known to phrenologists is George Bidder, now a civil engineer. When quite a child, and without any instruction, he showed an extraordinary talent for mental calculation. When he came to Edinburgh—where some scientific gentlemen undertook to educate him, with the view, if possible, of ascertaining his method, which they never

* Reprinted in *Chambers's Edinburgh Journal*, No 506.

did, as he is yet unable to put it in words—he was eleven years of age, and could, in a minute or two, answer the most complicated questions in algebra, without writing down a figure. He was presented to Mr. Combe, along with two other boys, all three strangers to him, one deficient in arithmetical power, and another clever at school in that line. Dr. Combe at once pointed out the deficient and the good arithmetician; and, by the largest organ of the three, without difficulty decided that the third was George Bidder. The case of Zerah Colburn, detailed by Dr. Gall, was a striking one, but less so than Bidder's; casts of both are in the Museum of the Phrenological Society in Edinburgh. Neither of these young men turned out more than ordinary geometricians. In Humboldt, brother of the traveller, the organ and power are both great. The negative evidence is also strong; there are individuals in whom the organ is small, and who find great difficulty in mental calculation. Some have been utterly unable to learn the multiplication table.

Some savage tribes are unable to count above thirty or fifty. Humboldt particularizes the Chaymas of South America, who, with an expression of great mental labour, can reach these numbers; and it is curious that Humboldt remarked that the external angles of their eyes are turned *up*, instead of down, as they are when the organ is large. The Greenland tribes can reach twenty by the aid of their ten fingers and ten toes. The inferior animals, there cannot be a doubt, possess the faculty. A dog was accustomed to be fed by successive small pieces thrown to him. He went away satisfied when he had received the full tale, but not one morsel sooner. Magpies, it is said, count three. Dupont de Nemours asserts that they count nine.

The organ is often found in a state of diseased activity; and when the other faculties were dormant, it has been known to perform most difficult arithmetical and algebraical feats. Mr. Combe saw a patient in the Lunatic Asylum in Newcastle, in whom he observed a very large organ of Number, and was informed by the resident surgeon that he was perpetually employed in figures. The organ is established.

No. 29.—Order.

The organ of this faculty is placed in the eyebrow, between Colouring and Number, and is large and prominent, and often pointed like a limpet-shell, in those who are remarkable for love of method, arrangement, and symmetry, and are annoyed by confusion and irregularity. The marked love of order in some persons, and their suffering from disorder, are feelings which no other faculty, or combination of faculties, seems to embrace. Several cases are mentioned in the phrenological books, where it characterized idiots, deficient in almost every other faculty. An idiot girl in Edinburgh would not enter her brother's room, which was always in confusion; and Dr. Spurzheim mentions the Sauvage de l'Aveyron, who replaced every thing instinctively which others, often purposely to try him, disarranged. Mr. L., a late medical gentleman in Edinburgh, was remarkable for the organ and its manifestation. He was pointed in his engagements—for the faculty gives this important habit—neat and careful in his writings, regular in his accounts, precise in his dress, and cleanly in his person: the last-mentioned habit being likewise one manifestation of order. The faculty was hereditary in that gentleman; for his father was so precise in his arrangements, that on one occasion, having put his penknife into a *wrong* pocket, he would not for some time be persuaded to try any other than what he held to be the *right* one. He yielded, however, at last, and was much disconcerted when he found the unwontedly misplaced article. In savages, whose habits are slovenly, filthy, and disgusting, like the Esquimaux, the organ is small. When we consider the abridgment and facilitation of our labour which result from arrangement, we can see a purpose in the endowment of this faculty. We doubt not that a more extended and careful analysis may discover for it yet more important functions. The organ is established.

No. 30.—Eventuality.

The organ of this faculty is situated in the very centre of the forehead, and when large, gives to this part of the head a rounded prominence. Individuality has been called the faculty of *nouns*; Eventuality is the faculty of *verbs*. The first perceives mere existence; the other motion, change, event, history. All knowledge must be of one or the other of these two descriptions—either things that *are* or things that *happen*. In the following examples—the MAN *speaks*, the WIND *blows*, the DAY *dawns*, the nouns cognised by Individuality are printed in capitals, while the verbs, addressed to Eventuality, are in italics. The first is simple existence; the other is action, event, history. Dr. Gall distinguished, as the metaphysicians do, *verbal* memory, *local* memory, *real* memory. It is now phrenological doctrine that all the intellectual faculties have their own memory. Form remembers forms; Colour, colours; Size, dimensions; Individuality, objects; Eventuality, actions; Tune, music; Comparison, resemblances and analogies; Causality, logical reasons.

The most powerful *knowing* minds have a large endowment of both Individuality and Eventuality; and such individuals, even with a medium reflecting organization, are the clever men in society—the acute men of business—the ready practical lawyers. When the one organ is more developed than the other, the difference will be marked in the writings of the individuals. Mr Combe (*System*, p. 518) adduces some striking proofs of this in extracts from celebrated writers, and refers to some acute and interesting observations by Mr. Hewet Watson (*Phrenological Journal*, vol. vi. pp. 383–451) on this aid to literary criticism. The organ of Eventuality is generally well developed in children, and their appetite for *stories* is well known. Those, however, in whom eventuality is moderate, and Individuality large, are prompted less to listen to tales than to "see things," as they call the exercise of their more powerful faculty. In after life, the latter will observe minute existences—will tell how many nails are in a door, and miss one if taken out before their next inspection. Miss Pratt, in the novel called the "Inheritance," is an example. The former will make use of incidents when they wish to recall any matter of memory. Dame Quickly convicts Sir John Falstaff of a promise of marriage, by recalling to his recollection a whole catalogue of simultaneous occurrences (*Second part of Henry IV.*, act 2d, scene 2d). Both faculties are important, we may say essential, to a teacher of youth. The organ is established.

No. 31.—Time.

Whatever be the essence of time as an entity, it is a reality to man, cognisable by a faculty by which he observes its lapse. Some persons are called walking timepieces; they can tell the hour without looking at a watch; and some even can do so, nearly, when waking in the night. The faculty also marks the minute divisions of duration, and their relations and harmonies, which are called *time* in music, and *rhythm* in versification. The impulse to mark time with the head, hands, feet, and whole body, is too common, too natural, and too strong, not to be the result of a faculty; it is the impulse to dance, and almost universal in both savage and civilized man; and its existence settles the question with the "Friends," of the innocence or *sinfulness* of dancing. In some, the impulse, when well-marked time is offered—the better if combined with music, though a well-beat drum may be danced to—is often irresistible.

It exists in a diseased state, for we have seen dancing madmen. Mr. Combe refers to a paper by Mr. Simpson in the *Phrenological Journal* (vol. ii. page 134), in which much light is thrown upon this faculty. Mr. Simpson accounts for the dancing of the deaf and dumb; time being communicable through the eye, and by touch, quite as much as through the ear. Masters of time in music are called good *timists*. The organ was deranged in a lady of Copenhagen attended by Dr. Hoppe: she complained that she had no conception of time; things that happened appearing sometimes very long ago, and sometimes only a few moments. She complained of pain in the forehead, and placed her finger on the very organ. Dogs, and even horses, give plain indications of possessing the faculty, by their conduct on the return of particular days, occasions, &c.: Mr. Combe mentions several instances. The organ, situated on each side of Eventuality, is held to be established.

No. 32.—Tune.

The organ of this faculty is situated still farther out than that of Time, giving roundness to the point where the forehead turns to form the temples. It is large in great musicians; and when small and hollow, there is an utter incapacity to distinguish either melody or harmony. The organ is sometimes diseased. A young lady, a patient of Dr. Combe's, was seized with an irresistible craving for music, which haunted even her dreams, and she complained of pain in the very situation of the organ. Music may be defined as a species of natural language, depending immediately on either a melodious succession, or a harmonious unison, of tones—tones, again, being distinguished from simple noises by a peculiarity in the mode of their production. A noise is the result of some isolated concussion of the air; when concussions or impulses on the air follow in a sufficiently rapid succession, they melt into each other, and the effect is a tone. These are facts in natural philosophy, and have been curiously illustrated by a piece of mechanism, which, in its slow movements, produces only noises, but, when impelled with great rapidity, gives forth tones. The musical notes are repetitions of a series of seven tones, each of which is produced by a certain number of impulses on the air within a given space of time, and the numbers of these impulses all bear certain nice mathematical relations to each other. The organ of Tune in the human brain appears to have been constituted in relation to these physical facts, and, in cases of good endowment, to have a most exact perception of all their niceties, and a power of using them to the production of the species of natural language which we term music. Cases of a low endowment of the musical faculty, or of persons said to want *musical air*, are of frequent occurrence, though, perhaps, in many such instances, early culture would have brought out some trace of the faculty. The great bulk of mankind possess the organ in a moderate endowment, so as to be capable of enjoying music in some degree. The individual possessing it in high endowment becomes, in all stages of society, a distinguished artist, exercising a peculiar power over his fellow-creatures, so as to rouse, melt, soothe, and gratify them at his pleasure. But the gift, in this active form, is liable to be much modified according as it is accompanied by Ideality, Benevolence, Wit, and other faculties. The organ, as connected with music, is held established; but its fundamental function—suggested by Mr. Simpson to be *sound*,* or the perception of the sonorous in nature—yet remains far from being fully elucidated.

No. 33.—Language.

When the faculties are in activity, either singly or in combination, the impulse in almost all individuals is strong, in many irresistible, to communicate to others the feelings or thoughts produced by them. This may be done by signs, which is natural language, or by words, which constitute conventional. A faculty is given to man and animals which connects feelings with signs and cries; but to man alone is given articulate speech. The comparative facility with which different men clothe their thoughts in words, depends on the size of this organ, which is situated in the super-orbitar plate, immediately over the eyeball, and when large, pushes the eye outwards, and sometimes downwards, producing, in the latter case, a wrinkling or pursing of the lower eyelid. There is no fluent speaker deficient in this organ. There is some doubt of the faculty giving the power of learning languages, and the spirit of languages in philology; the prevailing opinion is, that the faculty of Language has less to do with this power than Individuality, imitation, and some other faculties. Learning the words and structure of other languages is quite a different thing from applying our own to express our thoughts.

None of the organs have been better proved to be primitive, by diseased manifestation, than this. The instances are numerous of persons losing the power of finding words for their thoughts, and recovering it again; and in many of these cases, the brain in the organ, when examined after death, has been found diseased. Pain in the region often accompanies the loss of appropriate speech, in plague, yellow and typhus fever. But we must refer, for further information on this interesting subject, to the works on phrenology, especially Mr. Combe's *System* (4th edition, p. 542). Mr. W. A. F. Browne, Medical Superintendent of the Dumfries Lunatic Asylum (lately of the Montrose), has enriched the subject (*Phren. Journal*, vol. ix.) by classing the cases of disease, either in involuntary activity or deprivation of this faculty, which have come under his own observation—such as rapidity of voluntary and involuntary utterance, partial loss and total loss of memory of words, loss of perception of the relation of words to things. Mr. Browne has had patients who have, for many years, spoken with unknown tongues; thereby explaining a recent exhibition in this country of insane fanaticism. Mr. Browne's work on Insanity is an invaluable contribution to this subject. Dr. William Gregory observed, that taking morphia produced in himself loss of control over the faculty of Language, so that he could not stop speaking. He concluded that that medicine acted on the anterior lobe of the brain, especially the convolutions of Language. (*Phren. Journal*, vol. viii. p. 161.) Some intoxicated persons are more talkative than when sober, pouring out mere words without meaning. Dr. Gregory entreats phrenological medical men to note the effect of different medicines on the faculties, as a possible source of valuable light. Dr. Otto, of Copenhagen, physician to the King of Denmark, read a paper to the Phrenological Association, which met in London in June, 1841, on this subject. (See *Phrenological Journal*, vol. xiv. p. 288). The inferior animals communicate with their kind by, to them, intelligible language; and the dog, the elephant, the cat, even the horse, can be made to comprehend words, otherwise there would be no use in talking to them. How well a dog that wishes to walk understands and disrelishes, "Go home, sir!" This organ large, with its corresponding manifestation, in a companion of Gall first suggested phrenology. It is established.

Internal Excitement of the Knowing Organs—Spectral Illusions.

The Knowing Organs are for the most part called into activity by *external* objects, such as forms, colours, sounds, individual things, &c.; but internal causes often excite them, and when they are in action objects will

* See papers in *Phrenological Journal*, ii. 120, 530; x. 436, 731; xi. 33, 207, and xiii. 193.

be perceived which have no external existence, and which, nevertheless, the individual will believe to be real. This is the explanation of visions, spectres, and ghosts, and at once explains the firm belief of many that they have appeared to them, and the fact that it never happens that two persons see the same spectres at the same time. The Marquis de Villa did not see Tasso's familiar spirit, although sitting beside him when he declared it appeared to himself. We formerly remarked, when treating of Wonder, that excess or disease in that organ predisposes the patient to believe in the marvellous and supernatural, and probably stimulates the knowing organs into action, when spectral illusions are the consequence. We promised to return to the subject, and submit this as the proper place, after having concluded our analysis of the Knowing Organs. Mr. Simpson has given much attention to this subject. In a paper furnished by him to the *Phren. Journal* (vol. ii. p. 294, and several other confirmatory communications), he has succeeded in clearing up the mystery of apparitions, which have so long terrified mankind; and in doing so, has at the same time furnished the most pointed evidence of the distinctive functions of the organs situated along the eyebrows—organs so much doubted, because of their small size, although chemists and naturalists have to distinguish much smaller, often microscopic, objects. A young lady, known to Mr. Simpson, and mentioned in the phrenological books by the initials of S. L., lived in indescribable horrors for above a year, in consequence of the visits of the spectral forms of persons and other objects, and the perception of bright lights, brilliant colours, music, and other illusions. At the time of these false perceptions, as we stated when treating of the organ of Weight and the sense of Resistance, she lost the power of preserving her balance, and saw perpendiculars and horizontals at other angles. She complained of sharp pain when her visitants appeared to her; and although ignorant of phrenology, and even the situation of the organs, she put her finger and thumb, when asked where she felt the pain, to the organs of Form and Individuality. For several weeks, these were the site of her pain exclusively; and then the figures which appeared to her were *forms* without *colour*, resembling, as she stated, cobweb. Here plainly was Form active, but Colouring dormant. Some weeks after this, her objects became naturally coloured, and the pain extended along the eyebrows, including the organ of Colouring. Embracing, as the progress did, Size, her illusions referable to that organ in morbid activity were singular; she saw objects sometimes gigantic, sometimes dwarfish, and even minute. The pain proceeding onwards along the whole eyebrows, Order and Number became affected, and her visiters came in great numbers and most annoying confusion, so that sometimes they seemed to tumble into her apartment like a cascade, a confused mass of persons, limbs, heads, &c. Her apparitions began at last to *speak* to her, and her terrors were much aggravated. It was probable that the organs of Language and Tune became affected; for she often heard bands and choruses of music. We may add, that she was greatly relieved when the true nature of her spectres was explained to her. In time the affection left her entirely.

It is likely that the proximate cause of these morbid manifestations was an undue determination of blood to the region of the head where the knowing organs are situated. Nicolai, the bookseller of Berlin, when subject to the same disease, applied leeches along the eyebrows; and as the leeches filled, the illusions vanished, becoming fainter and fainter. Such are often the slight causes, revealed by science, of important and otherwise bewildering effects. The mysteries of the English Opium-Eater have been made plain by the case of Miss S. L. He saw faces in millions, insufferable lights, brilliant colours, &c., and, as we have stated when treating of the organ of Weight, he lost the sensation of support or resistance, and seemed to fail millions of miles. Mr. John Hunter, the anatomist, whom we mentioned as having something like that horrible sensation, likewise suffered from illusions of *Size* and *Weight*, his leg often extending, as he thought, many miles in length, and having the weight of a mountain. Many persons suffering from the same cause, and experiencing the same effects, have communicated their cases to the *Phrenological Journal*, since the publication of those above mentioned.

GENUS III.—REFLECTIVE FACULTIES.

The Intellectual Faculties already considered, give us knowledge of objects, and the qualities and relations of objects, also of the changes they undergo, or events. The two remaining faculties, according to Dr. Spurzheim, "act on all the other sensations and notions;" that is, they judge of the relations of different ideas or classes of ideas produced by the Knowing Faculties. They minister to the direction and gratification of all the other faculties, and constitute what by excellence is called reason, in other words, reflection.

No. 34.—Comparison.

Dr. Gall discovered the organ of this faculty in a man of science, who reasoned chiefly by means of analogies and comparisons, and rarely by logical deductions. He *illustrated* every thing, and carried his opponent along with him with a flood of resemblances, concluding that the thing disputed must be true, being *like* so many things that are known to be true. In his head was a fulness in the form of a reversed pyramid, just in the middle of the upper part of the forehead. The faculty perceives analogies and resemblances. Every faculty can compare its own objects. Colouring can compare colours; Weight, weights; Form, forms; Tune, sounds; but Comparison can compare a colour with a note, or a form with a weight, &c. Analogy is a comparison not of things but of their relations. The Saviour, for example, in his parental apostrophe, does not compare Jerusalem with himself as two objects; but compares the relation of a hen to her chickens covered with her wings, with the relation of his own benevolent feelings towards that devoted city. In doing this, he addressed the faculty of Comparison in his hearers. It is constantly addressed in Scripture by similes, parables, allegories, and all kinds of analogies. As the faculty deals in these, and in illustrations in general, it forms the great power of the popular orator. Dr. Spurzheim thought that the faculty perceives difference. Mr. Scott dissents from this, and attributes that function to the faculty of Wit. The precise fundamental function of the faculty is yet controverted. Mr. Hewet Watson (*Phrenological Journal*, vol. x. p. 168) argues ingeniously that it is the perception of *conditions*, of the condition in which objects exist. "The *young* man dies." Man is cognised by Individuality—his act of dying by Eventuality; but neither the one nor the other of these can take notice of his condition, as being young; and as it requires the adjective to qualify a condition, Comparison is the *adjective* faculty, as Individuality is the *noun*, and Eventuality the *verb* faculty. Mr. Combe thinks there is soundness in Mr. Watson's speculation, and that it is really *conditions* we do compare—the condition, for example, of the hen covering her chickens with that of the Saviour gathering Jerusalem under his metaphorical wings. As the organ of analogies, similitudes, and comparison of ideas, it is established.

No. 35.—Causality.

This is the highest and noblest of the intellectual powers, and is the last in the phrenological analysis of the faculties. Dr. Spurzheim so named it, from obsering that it traces the connection between *cause* and *effect*, and sees the relation of ideas to each other in respect of *necessary consequence*. Its organs are situated on each side of Comparison. Some metaphysicians have held that we have no idea of cause, but see only sequence, or one thing following another. It is true that we do see sequence. When, for example, fire is put to gunpowder, Individuality perceives the existence of the powder and of the match; Eventuality sees the motion which unites them, and the change or event which takes place in the explosion; but we have a *third* idea, namely, that of power, agency, or efficiency, existing in some way in the cause, to produce the effect. Whence do we get this third idea?—from a third or distinct faculty, and that is Causality. We are just as little entitled, by means of Causality, to deny the perceptions of Individuality and Eventuality, which the celebrated Bishop Berkeley did, who denied the existence of a material world, as by these last to deny the conclusions of Causality. With a powerful perception of *causation*, the individual reasons from cause to effect by logical or necessary consequence. It is the faculty which sees principles and acts upon them, while the other two faculties only try experiments. Resource in difficulties, and sound judgment in life, are the result of powerful Causality. Dr. Thomas Brown came very near the phrenological division of the intellectual faculties into Knowing and Reflecting, when he distinguished them into powers of simple suggestion and relative suggestion. Causality existing as a faculty gives powerful aid to the natural argument for the existence of God. Causality desiderates a cause, and goes upwards to a First Cause, as that which *must* exist; else the faculty in man has no legitimate object, and was bestowed in vain. This proof, added to that drawn from the existence of the faculty of Veneration for the adoration of the First Cause, as traced by Causality, constitutes an immense addition to the argument for the existence of God from the light of nature; and when yet further fortified by the existence of faculties in man of Benevolence and Justice, which necessarily imply a benevolent and just Creator, phrenology may be said to have been a contributor to the evidence of the highest and holiest of truths, the existence and attributes of the Most High. The organ is established.

Adaptation of the External World to the Intellectual Faculties of Man.

We quote the following passage from Mr. Combe's *System*, (4th edition, p. 593:)—"The human mind and the external world having emanated from the same Creator, ought, when understood, to be found wisely adapted to each other; and this accordingly appears in an eminent degree to be the case. If the reader will direct his attention to any natural or artificial object, and consider, 1st, its existence; 2d, its form; 3d, its size; 4th, its weight; 5th, its locality or relation in space to other objects; 6th, the number of its parts; 7th, the order of physical arrangement of its parts; 8th, the changes which it undergoes; 9th, the periods of time which these require (we would add here, its sound-producing quality or sonorousness, as quite different from all those enumerated); 10th, the analogies and differences between the individual object under consideration and other objects; 11th, the effect which it produces; and, lastly, if he will designate this assemblage of ideas by a name, he will find that he has obtained a tolerably complete notion of the object." We may add, that the relations between the affective faculties or feelings of man and the moral world are not less harmonious; and demonstrate design in a manner altogether irresistible.

Relation between the Functions and the Structure of the Brain.

In the introduction to his translation of that part of Dr. Gall's work on the *Physiology of the Brain* which treats of the functions of the cerebellum, Mr. Combe has stated the result of certain observations of his own, which tend to confirm as true the allotment of function to the different regions of the brain, which has been ascertained by phrenologists. An accumulation of facts, which amounts to proof more cogent than is to be found in regard to any other physical truth, has connected with the *anterior* lobes of the brain the Intellectual Faculties, and with the *middle* and *posterior* lobes, the Feelings. The Intellectual Faculties constitute the WILL of man, and in obedience to the will are the *voluntary* motions. But the feelings, when in activity, as is well known, have certain *involuntary* motions connected with them. Now, the spinal cord has two columns, the one, the anterior, observed to produce the motion, and therefore called the *motory* tract; and the other to produce sensation, and therefore called the *sensory* tract. These two tracts join the brain by what is called the *medulla oblongata*: and here a most striking distinction takes place. The motory tract *alone* communicates with the anterior lobes, in which, in the intellectual organs, resides the will. Hence, in *voluntary* motion, as an effect of will, the motory tract obeys the anterior lobe alone; in other words, the anterior lobe of the brain *manifests* will, and the motory tract *executes* will. The sensory tract has no connection with the anterior lobes or intellectual organs.

Again, the *sensory* tract has a fibrous connection with the middle and posterior lobes of the brain, and with the cerebellum, and most appropriately, for these are the organs of the *feelings*. But as the feelings have *involuntary* motions when acting, these are provided for by a fibrous connection between the organs of the feelings and *both* the sensory and motory tracts. Yet, as the motions consequent upon the energy of passion are not voluntary but instinctive, we should expect a separate motory tract for instinctive motion, with which, and not with the tract of voluntary motion, the organs of the feelings should be connected. This distinction, however, has only been conjectured, it is not yet ascertained. Mr. Combe farther adds—"It is certain that mental *emotions* exercise a powerful influence over the organic functions; when the emotions are agreeable, they stimulate these functions to healthy action; and when painful, they depress their energies and produce liability to disease. Reciprocally, when the organic functions, such as digestion, respiration, and secretion, are disordered, an irritable and distressing state of the mental feelings is induced. The intimate relations between the convolutions of the brain devoted to the mental emotions and the sensory tract of the spinal cord, is in harmony with these facts. The habit of contending with *intellectual* difficulties, if unconnected with feeling, does not injure the organic functions so severely as do strong and powerful emotions; but it weakens the locomotive powers. Sedulous students of abstruse problems acquire a great aversion to locomotion. These facts correspond with the arrangements of structure, by which the convolutions of the anterior lobes, devoted to intellect, spring from the motory tract, and are not connected with the sensory tract of the spinal marrow." We are not aware that anatomical and physiological investigations have unfolded facts more interesting than those now detailed. The light they throw on phrenology, and the support they afford it, are truly invaluable.

Natural Language of the Faculties, or Pathognomical and Physiognomical Expression.

What has been stated in the preceding section will prepare the reader for the fact, that, by means of involuntary motions, each organ of feeling produces movements, attitudes, and expressions peculiar to itself. The chief aim of the dramatic actor and pantomimist is to study and represent these movements, attitudes, and expressions; and hence such of them as have studied phrenology have declared that it affords them the most valuable guidance. Dr. Gall's *Physiology of the Brain*, and Dr. Spurzheim's *Physiognomical System*, enter fully into this curious subject, and have ascertained the laws which determine the natural language of the faculties. It has been laid down as the leading principle, that the instinctive motions are always *in the direction of the organs.* Self-Esteem, for example, throws the head high and slightly backwards, vulgarly called "turning up the nose" at any thing. Firmness gives an erect stiffness to the person. Cautiousness throws the head backwards and to the side. Veneration slowly forward; hence the reverence and the bow. The involuntary motions extend to the features of the face; hence the dark and harsh expression of Destructiveness, and the smile of Benevolence and Love of Approbation. The countenance tends to take a permanent expression from the prevalence of particular feelings. It is this which renders the physiognomy of phrenology scientifically trustworthy. It was in Lavater's hands a mere empirical art. Skilful phrenologists have often predicted the organs from their expressions in the countenance; and when aided by the pathognomy, or attitudes and motions, and, not least, the sounds of the voice—Destructiveness giving harsh, and Benevolence soft, &c.—there is a power possessed by phrenologists of judging of character which almost renders manipulation of the head unnecessary. When this last, however, is added, the key to character is complete.

The Organs arranged in Groups.

It is instructive to find the organs of such of the human faculties as have an affinity to each other, placed contiguously in the brain, and to observe that, by an apparent sympathy, they stimulate each other to activity. 1st, The supposed organs of the Love of Life and Alimentiveness—the essentials of Self-Preservation—lie contiguous in the brain. But man has a carnivorous stomach and teeth, and must destroy animal life to preserve his own. Destructiveness, accordingly, lies close to the two organs mentioned. He must not only devour the gentler animals, but must not be devoured by the ferocious; hence his Cautiousness, Combativeness, and Secretiveness, are all close neighbours of the three organs mentioned, and of each other. The accumulation of surplus, above his immediate wants, so important to man's preservation, is prompted by Acquisitiveness; while, without Constructiveness, he would perish for want of shelter and clothing. Thus a cluster of no fewer than *seven* organs forms to man the *self-preservative* group of faculties. 2d, Man is commanded to do more than "subdue;" he is enjoined, by multiplying his species, to "replenish the earth." Behold, then, another group of faculties for this purpose, which may be called the *species-preservative*, or *domestic* group—Amativeness, Philoprogenitiveness, Inhabitiveness, and Adhesiveness. 3d, Designed for the society of his fellow-men, man asserts his own rights and legitimate power by Self-Esteem or Self-Love; while he is influenced, by the opinion of others, to the proper regulation of his conduct, by Love of Approbation, or regard to character. Firmness aids Self-Esteem in asserting right. The three organs located close to each other form our *rights and character-preservative* group. 4th, The *moral* group, by excellence, is formed by Conscientiousness, Benevolence, and Veneration *earth-directed*. 5th, The *religious* group is formed by Veneration *heaven-directed*, Wonder, Hope, and Ideality; the last being claimed as a religious faculty by Sir George Mackenzie, as the love of the perfect. 6th, A bountiful Providence has provided a rich fund of recreative pleasure for man, in what may be called the *poetical* or *recreative* group of his faculties, namely. Imitation, Wonder, Ideality, Wit, Tune, and Time, all lying contiguous in the brain, and not inappropriately called the "Poet's Corner," as they form a corner of the head. These are the faculties addressed by artists of every kind—the poet, the actor, the painter, the architect, and the musician. The theatre engages them all. Lastly, Turning to the intellectual powers, we have them in one splendid and "godlike" assemblage in the forehead of man, subdivided into three groups, according to their uses. The lowest range, the *simply-perceptive* group, gives the perception of objects and their qualities. Above it is placed the *relatively-perceptive* group, for perceiving the relations of objects and events; and, above all, the organs of the highest of man's faculties, his reflecting powers, which perceive the relations of ideas, and reasons upon them; or the *reflective* group. The organs of the human brain, as found to be grouped in correlative clusters, were not so discovered. The great majority of them were observed singly, and the full display of their harmonies came forth on the completion only of the successive emergence of the organs, and presented a combined force of truth which well merits the character of irresistible: "There is magic in the web of it."

CONTINUATION OF PHRENOLOGY AS A COMPLETE PHILOSOPHY OF MIND.

The phrenologists have chiefly confined their attention to the organs of the brain, and the various faculties of which these are the instruments. The former writers on mind (Reid, Brown, Dugald Stewart, and others), gave, on the contrary, their chief care to the mental acts called Attention, Perception, Conception, &c., which they considered as faculties. The phrenologist does not overlook the importance of this department of mental philosophy, but differs from the metaphysicians in considering perception, conception, &c., as only *modes* in which the real faculties above described *act*. This distinction is one of great importance.

According to the phrenologists, the faculties are not mere passive feelings; they all tend to action. When duly active, the actions they produce are proper or necessary; in excess or abuse, they are improper, vicious, or criminal. Small moral organs do not produce abuses; but they are unable to prevent the abuse of the animal organs, as the larger tend to do; thus, small Benevolence is not cruel, but it does not offer sufficient control to Destructiveness, which then impels to cruelty. Large organs have the greatest, small the least, tendency to act—each faculty producing the feeling or idea peculiar to itself. Seeing that all the organs tend to action, the Creator must have intended a legitimate sphere of action for them all. *He* could never have created either bad or unnecessary faculties.

The PROPENSITIES and SENTIMENTS cannot be called into action by the will. We cannot fear, or pity, or love, or be angry, by willing it. But *internal* causes may stimulate the organs, and then, whether we will or not, their emotions will be felt. Again, these feelings are called into action in spite of the will, by the presentation of their *external* objects—Cautiousness by objects of terror, Love by beauty, and so on. The force of the feelings, whether excited from within or without, will be in proportion to the activity of the temperament. Excessive action of the affective faculties, or the removal of their object, causes pain. Excessive rage is painful to Destructiveness; and the death of an infant pains the Philoprogenitiveness of the mother. Insanity is a frequent result of over-activity of the affective feelings. An affective faculty may be diseased, and yet the intellect sound. The converse is also true. When the organ is small, its feeling cannot be adequately experienced. Hence the frauds of those with small Conscientiousness and large Secretiveness and Acquisitiveness. The will can *indirectly* excite the affective feelings, by setting the intellect to work to find externally, or conceive internally, the proper objects. This accounts for different turns and pursuits. The value of the truth, that large organs give strong, and small weak impulses, is incalculable in society; all the practical arrangements by which persons may be selected to perform certain functions, and excluded from others where they would be profitless or unsafe, depend upon it. Moral training by educators is founded on it. The weak faculties should be strengthened, and the strong regulated. Lastly, the affective faculties do not form ideas, but simply feel; and therefore have no memory, conception, or imagination. They have *Sensation* only; in other words, they feel. Hence Sensation belongs to all the faculties which feel, and to the external senses and nervous system in general. Sensation, therefore, is a state or condition, not a faculty, as it is held to be by the metaphysicians.

The Knowing and Reflecting Faculties, or Intellect, form ideas, perceive relations, and are subject to, or rather constitute, the Will; and minister to the affective faculties. They may be excited by external objects, and by internal causes. When excited by the presentation of external objects, these objects are *perceived*, and this *act* is called Perception. It is the lowest degree of activity of the intellectual faculties; and those who are deficient in a faculty cannot perceive its object. We often see, for example, inability to perceive melody, colour, analogy, or necessary consequence, from defective Tune, Colouring, Comparison, and Causality. Every faculty, as a percipient, has its own perception.

Conception is also a mode of action of the faculties, not a faculty itself. It is the activity of the faculties from internal causes, either willed, or involuntary from natural activity. Imagination is Conception carried to a high pitch of vivacity. Thus, Perception is the lowest degree of activity of any of the intellectual faculties, Conception the second, and Imagination the highest. Imagination is often confounded with Ideality, but is quite distinct from it. Each faculty conceives in its own way. Form conceives forms, and may *imagine* them exquisitely beautiful; Tune conceives music; and so on. Curious effects result when these faculties are morbidly active. The whole mystery of spectral illusions is thus made plain.

Dreaming, to account for which so many volumes have been written in vain, is at once explained by the excitability of the organs from *internal* causes; and as some organs may be awake while others are asleep, the disjointed images of our dreaming moments are, to the phrenologist, a thing which was to have been expected. The kind of dreams most frequent with us could be predicted by the phrenologist from the size of the predominating organs.

Memory, too, is not a faculty, but a mode of action. It necessarily follows that there can be no such thing as the *general* memory of the metaphysicians, but every faculty must have its own memory. Memory belongs, however, only to the intellectual faculties. It differs from Conception and Imagination in this, that it recollects *real* objects or events which it has actually perceived, and adds the consciousness of time elapsed since they were perceived. The other named modes of action do not require realities or time.

Judgment, in its proper sense, is the perception of adaptation, fitness, and necessary consequence; and is a mode of action of the reflecting powers. In a certain sense, the knowing faculties may each be said to possess judgment; as Colouring judges of colours, Form of form, Tune of music. When, however, we use the word judgment, we mean right reasoning, sound deciding. To this a proper balance of the affective faculties is essential. There is no sound judgment, even with great reflecting powers, if any of the feelings are excessive. Hence the difficulty of convincing each other experienced by heated controversialists. What is called a person of good sense, is one who has not only clear and strong reflecting powers, but well-balanced feelings, thus allowing the reflecting powers to have undisturbed action.

Consciousness is the knowledge which the mind has of its own existence and operations, whether these last are affective or intellectual; but as it does not reveal the existence or nature of the powers themselves which think and feel, it was an error in the metaphysicians to attempt to discover these powers by reflecting on their own consciousness. As they could have, by this means, no access to know the consciousness of others, they fell into the error of supposing all men constituted alike.

Attention is not a faculty, but the stretch, application, or *tension*, of any or all of the intellectual faculties.

Association is that succession of ideas in the mind, each seeming to call up that which succeeds; so that, in our waking hours, the mind is never without an idea passing through it. This is a state or condition of the faculties, not a faculty. The metaphysicians have endeavoured to discover laws by which, in every mind, this succession is regulated. This attempt is utterly vain—as vain as to subject the succession of the fleeting clouds or fitful breezes to regular laws. The uniform associating powers, according to the old notions, are resemblance, contiguity in time and place, and contrast; yet any one who thinks on the subject, cannot fail to be sensible that there are many connecting links of thought which cannot be reduced to any of these three. The phrenological view is, that the predominant faculties in each mind create the associations. It is in the philosophy of Mr. Stewart that Association is made to play a part most disproportioned to its actual nature. He even holds that Association produces *new* principles of action, and names *Avarice* (which phrenology proves to be the abuse of a primitive faculty called Acquisitiveness) as one of them. Association is a very important principle in mental science. There is a mutual influence of the organs, which produces associations; a natural association between certain external objects and certain faculties; and artificial associations may be formed between objects and faculties. For example, long exercise of a particular organ or organs in performing certain acts, renders those acts easy, by the rapid association of the ideas necessary to their performance. Professional skill, in all its varieties, is thus accounted for. Mutual action of the faculties arises from the beautiful arrangement or grouping which we have already described. The organ of Language associates signs with ideas, with well-known rapidity. Artificial Memory, or *Mnemonics* as it is called, avails itself of our most easy and natural associations, which will always be regulated by our organization. One person will connect his ideas with *forms*, another with *colours*, and many do so with *places*. Prejudices are associations of false ideas with the feelings. In short, to arrive at any thing like laws of association, we must not look to the ideas themselves, but the faculties that form them.

Passion is any faculty in excess. Thus, there are as many passions as faculties. Love is the passion of Amativeness in union with Veneration; avarice of Acquisitiveness; rage of Destructiveness.

Pleasure and Pain also belong to each faculty, according as it is agreeably or disagreeably affected.

Patience and Impatience are respectively the results of certain combinations of faculties. Thus, Benevolence, Veneration, Hope, Conscientiousness, and Firmness, with moderate Self-Esteem, produce a quiet, meek, resigned, and patient spirit. Apathy is quite different, although often confounded with Patience; it arises from lymphatic temperament, or deficient brain. On the other hand, Self-Esteem, Combativeness, and Destructiveness when larger than Benevolence, Conscientiousness, and Veneration, will be impatient of contradiction. Large Time and Tune give impatience of bad music.

Joy and Grief arise from agreeable and disagreeable affections of the faculties by causes of considerable power. Wealth, power, and praise, give joy to Acquisitiveness, Self-Esteem, and Love of Approbation; while, on the other hand, the death of a beloved relative affects Adhesiveness with grief.

SYMPATHY, as its name (from the Greek) signifies, is feeling with another, or partaking of his emotions. The laws which regulate the activity of the faculties show the nature of this affection and the circumstances in which it occurs. Two individuals of similar constitution of mind naturally feel alike. This is the sympathy felt in the theatre, listening to eloquence, or witnessing distress and suffering. But there is another kind of sympathy, namely, that which is called up by the activity of a particular feeling in another's mind, manifested by the natural language of the active faculty; thus, the haughty air of Self-Esteem instantly calls up a defensive Self-Esteem in those who witness it, if the faculty be powerful in them. On the other hand, Benevolence, with its kind natural language, excites the same feeling in another. Wonder, too, spreads rapidly; and so on. We sympathize with the animal feeling of Combativeness and Destructiveness only when they are awakened and guided by Conscientiousness and Benevolence. But we sympathise with Benevolence directly, provided we do not detect a mixture of a selfish feeling in the actions it produces, such as vanity or love of gain. The doctrine of sympathy leads to valuable practical consequences in life. In education, for example, it explains the greater power of Benevolence than of Self-Esteem and Destructiveness in the treatment of the young—of kindness than of harsh and imperious commands and punishments.

HABIT may be defined as the power of doing any thing well by frequently doing it. But before it can be done at all, there must be the faculty to do it, however awkwardly. Habit, then, is the acquired strength of the faculty by its repeated exercise. The act of performing skilfully on a musical instrument is the best illustration. Mr. Stewart erred when he held that "a genius for poetry, painting, music, or mathematics, is gradually formed by particular *habits* of study or of business. These phrenology shows to be the results of original primitive powers which habit does not form, but only improves.

TASTE was held by Mr. Stewart to be a faculty, and acquired by habit. Phrenology holds that good taste is the result of a harmonious action of all the faculties. Bad taste is evinced when particular faculties, especially propensities, break out beyond due limits. Lord Byron's Destructiveness and other animal faculties often prompted him to sin against good taste. Too much Causality is bad taste in Poetry; while Homer and Moore have too much Comparison. Social converse is injured by bad taste in various ways—by displays of vanity, disputatiousness, &c. Bad morality is bad taste; but it is more, it is turpitude. A standard of taste, about which so much has been written, is not a decision of certain objects or qualities of objects as beautiful or perfect to *all* men. This were a vain attempt; but it may be approximated, by appealing to the taste of individuals of very favourable and harmonious organization, which has received the highest possible culture. It cannot fail to strike that good taste, sound judgment, and good morals, all require well-balanced faculties.

For other conditions of mind, which may appear to require explanation, we must refer to the works of the phrenologists.*

[BOOKS ON PHRENOLOGY.

The writings of Gall and Spurzheim will always be entitled to respect on account of the discoveries of those eminent phrenologists. Other writers have been successful in enlarging the science, giving it greater exactness, and making it popular. Among these Mr. George Combe has been one of the most industrious and best known. He has published "*Elements of Phrenology*," "*Lectures on Phrenology*," and a phrenological "*Tour in the United States*." These works are written with great ability, and are particularly valuable on account of the great mass of facts and illustrations bearing upon the subject which they present. His work on the Constitution of Man also contains many important facts connected with phrenology. A small book entitled "Uncle Sam's Recommendations of Phrenology," is a familiar exposition of the leading principles of the science, intended for young people and beginners.

"*Fowler's Phrenology*" is an excellent popular view of the subject. There are several phrenological journals published in Europe and the United States, to which the student who wishes to devote himself to a thorough investigation of the subject will have recourse.—*Am. Ed.*]

* Those who may have little opportunity of knowing the extent of phrenological literature, are referred to the following list of works, and their authors:—

ELEMENTARY WORKS ON PHRENOLOGY.

Gall on the Anatomy and Physiology of the Nervous System and Brain, in French, with an Atlas of 100 Engravings. This work has been translated at Boston, United States. Spurzheim's Phrenology, Philosophical Principles of Phrenology, Physiognomical System. Phrenology in Connection with Physiognomy, Outlines of Phrenology, and Anatomy of the Brain and Nervous System. George Combe's Outlines. Elements. System of Phrenology. Letter to Mr. Jeffrey, and Translation of Gall on the Cerebellum. Abernethy on "Gall and Spurzheim." Sir George Mackenzie's Illustrations of Phrenology; Vimont's Human and Comparative Phrenology (the Phrenology of the Inferior Animals); Scott's Phrenology, as affording a systematic view of human nature: Deville's Manual; Caldwell's Elements; Elliotson's Translation of Blumenbach's Physiology, with Notes; Macnish on Phrenology; Sidney Smith's Principles: Toulmin Smith's Synopsis; Hewet Watson's Statistics of Phrenology; Noble on Estimating Character; the Phrenological Journal. 14 volumes; Selections from the First Five Volumes of the same.

WORKS ON THE APPLICATIONS OF PHRENOLOGY.

Generally to Human Life.—Spurzheim's Sketch of the Natural Laws of Man; Combe's Constitution of Man, Moral Philosophy, and Notes on the United States.

To Education.—Spurzheim's Principles; Combe's Lectures; Poole on Education: Simpson's Philosophy of Education; Caldwell on Physical Education: Brigham's Mental Culture; Dr. A. Combe's Physiology Applied to Health and Education, Physiology of Digestion, and Treatment of Infancy; Sir George Mackenzie's Observations on Education; the same author on Taste: Bray's Education of the Feelings.

To Insanity.—Spurzheim on Insanity; Dr. A. Combe on Mental Derangement; W. A. F. Browne on Insanity and Asylums.

To Treatment of Criminals.—Simpson's Treatise on Criminal Treatment, and on Homicidal Monomania—both appended to the first edition of his work on National Education; his Treatise on Capital Punishment for Murder, in *London Monthly Chronicle* for June, 1841; Sampson's Criminal Jurisprudence in Relation to Mental Organization.

Also, the Phrenological Journal, on all these applications. Watson's Statistics of Phrenology, page 171, gives a list of sixty-four phrenological and eleven anti-phrenological published works.

PRINCIPLES OF CIVIL GOVERNMENT.

INTRODUCTORY.

It is impossible to imagine man, such as we know him, existing out of society. Man is a being who, from his birth to his death, is continually undergoing changes from weakness to strength, and from strength to weakness. Without the aid of others, the child could not live to become a man. Again, any one man's powers of observation would be quite inadequate to procure for him any thing like the amount of knowledge which a number of men, imparting their information to each other, and disputing about it, store up by means of this co-operation. Lastly, the wishes, fears, likings, and dislikings, in which a man habitually indulges, and the actions which they prompt him to undertake, and the opposition which he meets with from others, contribute to form what we call his peculiar character. These feelings could not be excited to the extent they are, without the sympathy and antipathy of beings like himself, nor could he anywhere meet with opposition to his wishes so strong as what he experiences from the rivalry of his fellow-men. In short, man is, during a great part of his life, dependent upon the assistance of others for the preservation of his existence; the passions which spur him on to act are excited, or at least strengthened, by the sympathy or opposition of men feeling like himself; his knowledge is increased, and his wits are sharpened by conversation with other men. It is barely possible to imagine a creature of flesh and blood, with a thinking principle like our own, living in utter solitude; and such a being, could it exist, would differ widely from man, made what he is by living among creatures like himself.

Again, government of some kind or another seems necessary to the very existence of society. Two men cannot be long together, but there will be a chance of their both desiring to take possession of the same object, or one of them wishing the other to give up some pursuit in which the latter is engaged, in order to assist him in his. The stronger, or the cleverer of the two, contrives to force or persuade his companion to comply with his wish; in other words, he governs him. Among all rude people, we find women and children old enough to be able to work, in short, the weaker members of society, governed by the strong—made to do what the strong want them. In societies a little more advanced, we find individuals not possessed of much bodily strength, making up for the want by cunning, by winning manners, or by reasoning, or by a mixture of all these. The kind of government which, as a society advances in civilization, immediately succeeds that which savage tribes call the "fighting-men," is that of the priests. Priestly government, in its rudest form, is found in the *fetishes* of the Negro nations, and the "great medicines" of the red Indians of America. It is a proof of a narrow mind, when a man can see nothing but what is bad, even in these (to us) ludicrous instances of priestly government. The priest-ruler is generally more of a thinking being than the mere "fighting-man." He must have experienced the influence of devotional feeling—rude as his own uncultivated mind, but substantially the same elevating emotion which adds such a dignity to the most enlightened minds—or he would not be capable of laying plans to work upon that feeling in the minds of others. He is not necessarily altogether or maliciously selfish; for history has many examples even of the juggler-priest playing off tricks upon his dupes in order to frighten them into good behaviour. Most governments that the world has seen, have been a compound of the government of the "fighting-men" and the priests—an alliance between these two classes, each acknowledging the power of the other, and giving up something to secure its assistance. The few whose strength and courage, or whose ambition and talents, enable them to become warrior chiefs or priests, were stimulated, some by desire of luxury, some by desire of wealth, some by desire of power, some by desire of doing good. Even the merely selfish among them were obliged to do good to some, in order to procure faithful servants. The government of the wise (the word *wise* is used here comparatively—they were wiser than those they governed) and the strong was yielded to by some, because they were all used by their rulers, by the rest, because experience taught them that the settled condition of a society in which there is a recognised government, is better than the irregular condition of a society in which the ruler of to-day may be the slave of to-morrow. When a government has existed for a considerable time, a number of the persons living under it must have been born under it: it was a government at the earliest time of which they have any recollection, and is a government still. As in every thing else, men jump at the conclusion in this matter, that because they can remember no other state of affairs, there can have been no other. They come to look upon the government under which they live as something that necessarily exists, that cannot be otherwise. It is in this way of thinking that we must seek the origin of those notions regarding the rights of royal and noble families, which, combined with men's sense of the power of the warrior castes, have, from the time that history begins down to a very recent period, made up most men's conceptions of a government.

Some of our readers may think that it was not necessary to take up so much time and room as we have bestowed upon the two preceding paragraphs, in order to prove that men have always lived in society, and that society has always had a government of some kind or another. It can, however, easily be shown, that the detail into which we have entered is not useless. Men need, more often than they confess or are aware of, to be told over again what is not new to them. It is not enough to hear a thing, unless some effort is made to understand it, and keep it in mind. Our object in laying so much stress upon so undeniable a fact, as that we know nothing of man but as he has been made by society, is to impress upon the reader's mind, so that the truth shall be constantly present to him, the fact that to live in society is as necessary and unalterable a condition of our existence as to breathe. A man, by bringing some of his neighbours to think with him, and by subjecting them to his power, may produce a small, very small change, in the condition of that part of society which is within his reach; but, in return, society makes him almost all that he is. Society is not a thing that man can make, but the result of natural tendencies. It has assumed, in every civilized country, the character it bears, from the natural operation of the mental and physical constitution of man—we find in all a variety of professions and pursuits, some of high and others of inferior intellectual endowment, and, from a concurrence of causes, one class leisurely and wealthy, and another more constantly employed and depending more for subsistence on personal exertion. That even in the best organized societies there are faults, no one denies; but in as far as any such are inconsistent with man's mental faculties, they are susceptible of remedy, and will accordingly be remedied as the society advances in mental culture. Viewing these faults in too gloomy a spirit, men have, on various occasions, endeavoured to reorganize society on new, and, as they believed, more rational principles; but all such attempts have signally failed. Efforts, for example, to establish universal equality of condition, with community of goods, as well as to banish religious belief, have in every instance come to naught, because they were absolutely incompatible with the fundamental principles of human nature, which are the same, only slightly varied by circumstances, in every age and country. All reformers who have set out with the opinion that society must and can be reconstructed upon other principles than those that have hitherto held it together, from the days of Plato down to those of Robert Owen, have been attempting an impossibility and throwing away their labour.

Further, the detailed exposition of the nature of government was entered into for the purpose of impressing upon the reader's mind, in a lively and lasting manner, the fact, that as society is necessary to the existence of man, such as we know him, government is inseparable from the existence of society. Wherever two or three are met together, there must be government; it may be good or bad, wise or foolish government, but government of some kind there will be. There will always be in every society some who have a desire to rule over others—to make others work out their purposes—and some who are satisfied to submit to the domination of those who are more ambitious. There will always be among those who are ambitious of government some who unite to the desire, the talents necessary to enable them to attain their ends, and others who do not; some who seek to found their power upon their own force, or upon the superstition of others, or upon their power of persuading or convincing men that they know better what is good for them than they do themselves. The propensities and faculties which induce and enable some men to aspire to be leaders, others to contest the leadership with them, and others, again, contentedly to follow the lead, are implanted in them by nature; they cannot help having or exercising them. But it is with these elements of our nature as it is with our instinctive propensities to eat and drink, to love or hate; by the proper use of their knowing and reflecting powers, men may so control and direct them as to render them instruments for producing great good and happiness to the whole human race. A long experience was necessary to teach men this truth; it is, therefore, not to be wondered at that nothing approaching to a clear conception of it dawned upon the minds of men till within the last two centuries, or that even yet it should be acknowledged by comparatively few, and rightly understood by a still smaller number. The idea, however, after visiting, with less and less of obscurity, the minds of great thinkers in different ages, has, in the progress of time, revealed itself with considerable clearness, and has been spoken aloud, and has fallen on the ears and touched the hearts of men. The history of the European race for the last hundred years, is little more than an account of men's efforts to apprehend aright, and apply in practice this important truth—of errors, and controversies, and unreasonable getting angry, and attempting to convince each other, not by arguments but by hard blows. Society has become convinced that government may be converted into an instrument of greater good than it has ever yet proved, and will not rest till it has solved the problem.

These remarks have appeared to us a necessary introduction to the PRINCIPLES OF CIVIL GOVERNMENT—necessary, in order to place in a clear light the nature of the thing proposed to be inquired into, and the object of the inquiry. The study of government embraces two distinct questions—What is government? In what manner can government be made productive of the greatest amount of good; or in what manner can any mischievous tendencies it may have be most effectively neutralized? Government is simply the exercise of power by one person or by many associated persons. The inquiry into the nature of government is therefore an inquiry into the source of its power. Its power must be derived from some peculiarities in the characters of those who obtain and exercise it, on the one hand, and from some peculiarities in the characters of those over whom it is exercised, on the other. The inquiry into the faculties and propensities which make some men governors and others subjects, exhausts the inquiry into the nature of government. This investigation, it is clear, must precede the inquiry, how government can be most effectively rendered productive of good, or prevented from doing harm. Having arrived at a distinct notion of what constitutes a government, of wherein consists its power, the second, the practical question thus subdivides itself—In what cases is the interference of a government likely to be productive of good to the great body of society? In what cases is its interference likely to be productive of evil? By what means can government be rendered capable of producing the greatest possible amount of good, in cases where its interference is of use? By what means can government be kept from meddling where its interference is likely to do harm?

The answers to these two classes of questions constitute the principles of civil government, or the theory of civil government. The reader cannot fail to have observed that they imply, on the part of the person able to solve them, some acquaintance with the constitution of man. There are few persons of this class likely to take an interest in these pages, who can be entirely ignorant of the nature of man: they may not have an accurate or systematic knowledge of it, but by reading and conversing, they must have picked up a sufficiency of floating notions regarding it to enable them, with ordinary attention, to follow us whenever we may have to touch upon that branch of knowledge. At the same time, it is right to tell them that their understanding of the principles of government will be rendered much easier and much more correct, by a careful perusal of some book or treatise giving a clear and concise account of the constitution of man. Mr. George Combe's work bearing that title, is what we would recommend as the best.

A theoretical knowledge of the principles of government is not, however, enough: or, we would rather say, that the mere study of a systematic explanation of those principles is not enough to enable a man to master them to any good or practical purpose. You cannot get a right knowledge of any thing by looking at it from one point of view only. If you want to have a correct knowledge of a country, it will not do to stick close to the high road, though that will carry you most easily through it. You must turn into by-lanes, to the right and to the left. You must ascend hills to obtain bird's-eye views, and you must scramble through valleys to get a notion of the shape, size, and position of hills. Again, if any man would have a correct judgment of what human life really is, and what its value, he must not hastily decide, when in youth or early manhood he sees the untravelled path stretched out before him: he must wait till he has at least attained the midway heights of life, and can look back on the ascent he has climbed, forward upon the descent before him. And so, whoever would thoroughly comprehend the principles of civil government—who would obtain such a practical mastery of them, that he shall be able to make them a rule of action—must seek to look at them from different points of view. He must accustom himself, on the one hand, from such a study of the nature of government, and the means of turning it to the best account, as we have just chalked an outline of, to provide himself with a standard whereby to judge the actions of government. And then, again, he must accustom himself to read the history of past ages and other countries, and to keep a dispassionate watch over what is going forward in his own, with a view to find in these observations practical lessons regarding the nature and operation of government, that may modify and render more accurate his abstract opinions, or serve as illustrations and explanations to enable him to understand them more thoroughly.

In accordance with these views, we propose to subdivide this tract into two sections. In the first, we will treat of the principles or theory of civil government, according to the plan that has been already laid down; in the second, we will analyze the constitution of our own country, in order to point out the actual working of these principles, and to furnish the reader with illustrations of the principles stated in the first section, and an experimental test of their truth. The first of these sections is entitled THEORY OF CIVIL GOVERNMENT; the second, GOVERNMENT AS IT ACTUALLY EXISTS.

Any thing that a mere man can teach another, must be necessarily incomplete—the partial knowledge of a limited, a finite mind. When a man has done his best to make a subject clear, he must, if his object be to disseminate truth, rest his hope of success, in no small degree, on his power of stimulating those he addresses to think and inquire for themselves. It is on this account that we earnestly wish that every one of these our tracts may inspire our readers with a resolution to inquire farther into the matters they treat of. We hope, for example, that we shall be able to give such a foretaste of the important and interesting study to which this number is devoted, as will induce them, when they have leisure, to consult different authors who have treated of it—to compare or contrast their opinions with ours, and with one another. In the hope that some at least may do this, we have added a third section, containing a very short list of the principal authors. It has been the practice of some writers to prefix a history of their science to their systematic explanations of it. To us, on the other hand, a distinct conception of the nature and sphere of the inquiry, such as can only be obtained from entering upon it, is requisite, to enable us to derive advantage from a record of the successive efforts which have brought it to the stage of advancement in which we find it. Every science, however, and most of all a practical science like the theory of government, has light reflected upon it by tracing it from the undeveloped form in which it first presented itself to men's minds, through the various efforts and casualties which have brought it to the condition in which we find it. But the only way to master the history of a science, is to read the works of the great men who have treated of it one after another, and to note how each, taking the subject up where his predecessor left it, has been enabled to advance it. And it is impossible to escape misunderstanding authors, unless, by studying the history of their science, we know the preconceptions which they entertained, and the practical objects they had immediately in view in writing, inasmuch as these necessarily warped their judgment, and led them to adopt their peculiar forms of expression.

SECTION I.—THEORY OF CIVIL GOVERNMENT.

1. What is Government?

Many writers upon government, some of them of no mean note, have thought it necessary to start with a definition of what they mean by the word *government*. This affectation of severe exact thinking is copied from the forms of demonstration adopted by mathematicians, but is out of place in reasonings about things which exist independent of the reasoner. The mathematician may define his circle, because part of his process is to construct his circle; but the reasoner on government does not make government; he finds it existing before him.

We use the word government in its common, it may be unscientific, but perfectly intelligible, application. When we talk of *a* government, we mean the same thing as when we talk of the British government or the Chinese government. We mean simply that man or body of men who govern, or, in other words, exercise power over a nation. So long as such a man or body of men possess power over a nation, are obeyed by it, so long are they a government; when they cease to be obeyed, they cease to be a government. They may be an unjust government, and continue to reign, or they may be unjustly deposed; that does not alter the state of the fact. The holders and exercisers of power are a government, by whatever means they exercise that power, or whether they exercise it for good or evil.

The government of a nation is the man or body of men possessing and exercising power over the rest of the community. By power, we mean what was possessed by the centurion, who said to our Saviour, "I say to one man, go, and he goeth; and to another, come, and he cometh; and to my servant, do this, and he doeth it." Power, as was intimated in the introductory part of this essay, may be acquired by different means. A strong man punishes a weak man for not obeying his commands; and the weak man, convinced that similar disobedience will always draw down upon him a similar punishment, obeys him ever after. A cunning man persuades a foolish man, that he possesses supernatural powers—that his prayers and invocations can call down blessings or curses upon others; and the dupe obeys him, in order to obtain the one and escape the other. A wise man convinces a man of good understanding that he understands what is for their common advantage, and thus persuades him to follow his advice, which is a more polite way of expressing—to obey him. When a certain number of individuals have, by the use of one or more of these means, secured the obedience of a certain number of followers or dependents, another, in the same manner, secures their obedience (and with that of all their retainers) to himself. In this manner small states were first formed, which, in process of time, by the operation of wars, alliances, and other means, were melted together into great ones. But the greatest and most civilized states, when closely examined, will be found to be still held together by the same means which were originally instrumental in forming small ones. A man who has much wealth, has influence with a certain number of his fellow-citizens. A man who does much good, has influence with another portion of them. A man who is believed in any way to have it in his power to do good or harm to others, possesses similar influence. Two or more of the persons possessing such influence, form a party, and choose or are gained by a leader; and the man or association of men who, by this complicated process, command the services of a decided majority of the citizens, are the government.

This is the case in every nation that has a government, whatever the external name and form of that government may be. In an enlightened country like our own, in which men have acquired a habit of obeying the laws, the process is carried on in conformity with the forms of law. In countries less advanced in civilization (as was the case among our own ancestors), the acquisition of power, and its transference from one party to another, is effected by means of violence. But in both instances the fact remains unaltered, that the man, or combination of men, who possess the largest amount of stored-up capital, the greatest quantity of practical talent for managing men, and by those means the services of the greatest number of the strong and resolute men of a country, always exercise, directly or indirectly, in their own names or in the name of some other persons, the sovereign power in that country.

It is clear from this analysis that the source of all political power is intellectual ability; that the means by which all numerous bodies of men are kept in obedience, is their being led to believe in the ability of their rulers —led to believe that it is more for their advantage to obey them than to resist them. In other words, the only means by which a government can establish its power upon a stable and permanent foundation, is, by making the great body of the people feel or believe that it contributes to their happiness. We certainly read of nations which have submitted to the exactions, oppressions, and contumelies of despots and powerful aristocracies, but on closer examination we will see that even their benefits, real or imaginary, were the influences which kept the people in subjection. The uncivilized man is incapable of looking beyond the necessities of the day—of making arrangements with a view to provide for the security and comfort of years—of sacrificing the gratification of the moment to ensure a greater and more lasting pleasure at a future time. A class of men a little more enlightened than the rude crew we have been describing, can easily, by conferring upon them cheap immediate pleasures, incline them to submit to lasting sacrifices; and when a portion of them experience a passing discontent, put them down with the aid of those of their own number who happen to be satisfied at the moment. A few capable of making combinations can thus hold in check a multitude less enlightened. But still their chief engine of authority is their ability to persuade at least a portion of their subjects that they are kind to them. They may cheat them in the bargain; but still the bargain is, "Do us good, and rule over us." But comparatively highly civilized nations, it will be said, have been seen tamely submitting to tyranny, as was the case in France before the revolution. In such cases, it will be found, either that the rulers have flattered the vanity of the people, paid them in false coin which they took for sterling, or that the people have thrown themselves into the arms of a despotism as a refuge from evils of which, having experimental knowledge, they were more afraid—invasions, it may be, by foreigners, or internal anarchy. Still, the prospect of advantage to themselves was the source of the subjects' allegiance; they acted upon the principle—of two evils, choose the least.

Having thus attempted to show what government is, in answer to the first question proposed in the introduction, we now proceed to try to solve the questions involved in the second branch of our inquiry:—By what means the beneficial tendencies of government may be increased to the greatest extent, and any mischievous tendencies it may have most effectively neutralized? These questions constitute the next two heads of this division of our subject.

2. In what Cases is the Interference of a Government, with a view to control its Subjects' Liberty of Action, calculated to be productive of Good to the great Body of Society, or the Contrary?

In attributing "liberty of action" to individual members of society, we do not pretend to decide upon the knotty question of the liberty or necessity of human actions. We use the word *liberty* merely to express a man's freedom from physical control exercised by others —his power of action in conformity to the dictates of his own will, whether that will be a free or a necessary agent. We find, on looking to the practice of different governments, that some have been accustomed to command or prohibit actions, which others have left their subjects free to perform or leave undone as their own choice determined. The laws of China are said to prescribe the very forms of domestic mourning for the loss of relations—matters which with us are left to the discretion of individuals or to the vague unauthoritative laws of fashion. On the other hand, the imperfect regulations of the old feudal governments of Europe allowed a latitude of action to the powerful barons, which seems to us incompatible with the existence of an efficient government or the security of private citizens. Again, some governments leave the speculations of commerce to be regulated by the judgment of the merchant; others take upon them to teach him which channels of trade are most advantageous, and to order him to abstain from some and embark in others. All nations, however, have practically declared that there ought to be limits placed to a government's right or power of controlling its subjects' actions. We are now about to inquire whether this opinion be well founded, and what actions ought to be left free, what subjected to regulation.

Among the actions over which almost all governments have attempted to exercise a control, are those actions or operations of the mind by means of which men's opinions are formed. Penalties have been attached to the avowal of certain opinions; nay, tribunals have been established (as, for example, the Spanish Inquisition) with a view, by cunningly devised questions, and even by the application of torture, to extort from men confessions that they entertained opinions which they had jealously concealed from all the world. It is not probable that any person who peruses these pages will require any argument to show the impossibility of preventing men from forming opinions. Opinions are not matter of choice; a man cannot think or believe what he pleases; punishment cannot deter him from forming opinions, which come upon him whether he will or not. Again, opinions kept to a man's self do harm to no one. If they are of a nature to incline him to commit dishonest actions, these actions are punishable, and that punishment is a sufficient safeguard against his depraved inclinations. Penalties attached to the secret entertaining of obnoxious opinions are, therefore, at once unnecessary and incapable of producing any effect. To punish men for holding opinions, the utterance of which can only be wrung from them by deceit and cruelty, is to inflict suffering on human beings for no purpose—it is a wanton waste of cruelty. The case of individuals who not only entertain but openly avow their opinions, and seek to gain converts to them, is somewhat different. It is possible to deter men from uttering certain opinions; and it is possible that men may seek to disseminate opinions, which, if acted upon, must do harm. Even in this case, however, serious difficulties present themselves. Who are to decide what opinions are dangerous? Is punishment an efficient method of checking opinions admitted to have a bad tendency? History furnishes us with numerous examples to show that it is unsafe to leave to government the determination as to what opinions are dangerous. Bad and unjust governments necessarily think or pretend all opinions mischievous which have a tendency to make their actions appear in their true colours. Again, most men are afraid of novelty of any kind in matters of thought, and ready to condemn an opinion as dangerous, merely because it is contrary to some that they entertain. Socrates, and a greater still, are not the only persons who have suffered for teaching truths with benevolent intentions, in consequence of rulers taking upon themselves to punish men for uttering opinions which they thought, or pretended to think, dangerous. To place in any human hands a power of punishing the promulgators of opinion, is a step quite as likely to repress true and useful opinions as those which are false and dangerous. Again, no opinion was ever put down otherwise than by fair argument. Punishments may have impeded the progress of an opinion, but they have more frequently, by raising up martyrs, given it a more rapid currency. The reign of error is necessarily of short duration, and it has never been abridged by penalties; the reign of truth, once established, is eternal; it has been postponed, but never hastened, by the operation of penal laws. Laws commanding the punishment of avowed opinions, are quite as unavailing as those which command the punishment of concealed ones. The only possible effect of either is to make martyrs or hypocrites. Here, then, we have a broad and marked limitation of the power of government. Whenever government interferes to repress free thought, or the free utterance of opinions, it does harm. What the lawyers call "overt acts"—actions in the common acceptation of the term, physical actions, or words which may injure the reputation and feelings of others—are the only legitimate objects of government control.

Turning our attention next to actions, properly so called, we find that, with regard to some even of them, there has always existed in men's minds a jealousy of the interference of government. Is that jealousy well or ill founded? and in what cases? The power of government, we have seen, is derived from the conviction entertained by the subjects, that they derive benefit from being subjected to its control. There are some actions, regarding which it is at once apparent to dispassionate minds that all have an interest in government interfering to prevent them. Thus, when two men quarrel, and proceed to blows, it is clear that if one of them be dangerously or fatally wounded, it would have been for his advantage had government interfered to prevent their fighting. But as a general rule, every person has an interest in government preventing fighting among its subjects; for it is more for a man's advantage to be secured from the danger of being hurt and killed, than it is to retain the power of hurting and killing others. It is clearly for the good of all, that government should interfere to prevent any one of its subjects from hurting, or killing, or committing any injury upon the person of any other. In the same way, it might be shown that every body will derive benefit from government interfering to prevent any one of its subjects depriving any other of his property by force or fraud. In a virtuous and highly civilized community, the chastity of its women, and the purity of both sexes, are so clearly recognised to be advantages of which the owners ought not to be forcefully or fraudulently dispossessed, that the enforcement of laws forbidding such offences is acknowledged by all to be generally beneficial. A man's (or woman's) reputation for integrity, is not only an object of commendable pride, and therefore a possession the loss of which must occasion pain, but a valuable property for all who are engaged in business. There is, therefore, a universal assent given to the laws which inflict punishment upon those who defame their neighbours. This brief retrospect is sufficient to show that the whole community will be benefited by government interfering to prevent any one citizen injuring another—in person, property, or reputation; and to oblige him who has inflicted an injury upon his neighbour, in these respects, to make amends as far as he can. It is evidently for the advantage of the criminal, that his punishment, and the reparation he is to make, shall be decided by an impartial third party, not by the person injured; and but little reflection is required to show that even the party injured will derive benefit from such an arrangement, inasmuch as, where no man is allowed to take the law into his own hands, there can be no colourable excuse invented for the aggression made upon him, while he is, at the same time, secure from the after dangers incurred by all in his position in those countries where retaliation is tolerated by the government.

An opinion has been very commonly entertained, that government can benefit society, not only by prohibiting men from doing injury to one another, but by obliging them to do good to one another. The fallaciousness of this opinion can be easily demonstrated. The aggregate happiness of the community cannot be increased by any man doing good to another at the expense of injuring himself. It cannot even be increased by any action, the tendency of which is to increase the happiness of the person receiving the benefit, in a less degree than it diminishes the happiness of the person conferring it. These are intricate and delicate questions, regarding which even the parties mentioned can scarcely ascertain the truth, much less any third party, and least of all a government encumbered with a multiplicity of distracting calls upon its attention. The safest way for the government is to leave the performance of benevolent actions to the consciences of its subjects: by trying to enforce the performance of them, it is quite as likely to create unhappiness as the reverse.

There remains a numerous class of actions which contemplate neither good nor harm to a man's neighbours. To this belong all pursuits of enjoyment by means which injure no man—all attempts to increase a man's fortune by perfectly just and honest means, though without any reference to the advantage of others. It might appear an unnecessary affectation of omitting nothing, to state that government ought in no way to interfere with actions of this class, to hinder, promote, or direct them; and yet the sheer love of meddling, so strong in some men, has constantly led governments to transgress this law of common sense. If the hunter after pleasure, by means which harm no one, seek it where it is not to be found, it is only his own loss: no one can say positively that another cannot find pleasure in certain pursuits, for no one can know how another's mind is constituted; and therefore to prescribe to him that he shall abstain from such and such pursuits, is to run the risk of diminishing his happiness. It is also, on the part of the government, wasting time that might be better employed. In the pursuit of wealth by honest industry and enterprise, a man's whole attention is generally severely tasked; the government, encumbered with other affairs, is not likely to discover what he, whose eyes are sharpened by self-interest, has overlooked. The meddling of governments with the mercantile speculations of their subjects, has its origin in the absurd notion that what is one man's gain must be another's loss—in forgetfulness of the truth, that the wealth of the whole community is merely the sum of the fortunes of all the individuals composing it, and that to impede the gains of any one is to diminish the total increase.

It appears sufficiently, from these considerations, that the interference of government with the conduct of its subjects one to another, ought to be cautiously guarded, in order to secure their prosperity and happiness. It ought to be restricted almost exclusively to what is, in the technical language of the laws of England, called "preserving the peace." This opinion does not necessarily imply what imaginative enthusiasts would call low and narrow views of the capacity and destiny of man. To say that security in person, property, and reputation, is the highest benefit that can be bestowed upon man through the instrumentality of a government, is not to say that these are the utmost benefits man is capable of receiving. Government cannot make a man wise: that must be accomplished by the exertion of his own intellectual faculties. Government cannot make a man good; that must be the consequence of the habitual regulation and control of his feelings and actions, by the efforts of his own will, directed by his own reason. Government cannot make a man rich (except by making others poorer); that must be the result of his own sagacious and persevering industry. But though government cannot make any man wealthy, wise, and good, it may render it more easy for the great body of its citizens to become all three, by establishing security of person, property, and reputation, for all who act honestly and peaceably, and thus removing temptations to do wrong, diminishing the dangers against which men must guard, and leaving them a greater amount of leisure to devote to industrious pursuits, or to the cultivation of wisdom and virtue.

What has already been said, has included both what government must do and abstain from, in so far as its own subjects are concerned, in order to promote their happiness. It has also in its power to contribute to their prosperity, by guarding them against injuries at the hands of those who are not its subjects. It can watch the approach of danger from without, and take precautions to avert it. It can organize, arm, and discipline its subjects, to defend their homes, or to extend their protection to their fellow-citizens engaged in the pursuit of their honest industry on the ocean or in foreign countries. With a view to the defence of the country from foreign aggression, the government may, to a limited extent, and generally for a limited period of time, interfere with the actions of its citizens, in a greater degree than could with propriety be conceded, when the internal relations of rulers and subjects alone were taken into consideration. The nature and limits of this more extended interference will appear from the discussion of the topics which occur under the next division of our subject.

3. By what Means can Government be Rendered Capable of Accomplishing the Greatest Possible Amount of Good, and most Effectually Prevented from doing Harm?

A government is an association of men with all the feelings of other men. They are possessed of power, and liable, in consequence of the propensities of human nature, to abuse it in two ways:—By indolence, or neglecting to use their power—that is, by not performing the duties of their station; by excessive or wrong exercise of their power—that is, by meddling where they can only do mischief, or by acting, with a short-sighted selfishness, in a manner injurious to the great body of the nation. The only way of guarding against these abuses, is by instructing the people, in the first place, accurately as to what are the duties of government; and by furnishing them, in the second place, with some plan, which may be easily understood, and worked by men of average capacity, for checking government when it exceeds its powers, or urging it on when it is lazy, by orderly and legitimate means.

The general abstract view of the principles of government, laid down in the preceding head, will not be found sufficient for the purpose of informing the people what are the duties of government, so as to enable them to say, at any given time, government is doing what is right, or government is exceeding its powers, or government is neglecting its duty. No one man can, in his own person, execute all the functions of government. Its members must take different departments, and be assisted in them by a number of clerks and other subordinate officers. But as the great end of government is one—to protect its subjects in the full enjoyment of security in person, property, and reputation—and as all these departments are only of use in so far as they contribute to that end, there must be one master-mind controlling and directing them all, taking care that they do not clash with or counteract each other. It is only when people know what are the different departments of government, and what is the proper task of each, that they can mark the exact points in which government is negligent or oppressive, lay the blame upon the real defaulters, and thus make such applications for redress, so clearly stated, that it is impossible to evade them.

In watching over the security of its subjects, government has to guard it against attacks from two quarters—from violence offered by one citizen to another; from violence offered to one or more citizens by persons who are not its subjects—by foreigners. The discharge of the former duty belongs to what is called the *home department* or *domestic affairs*; the latter to the *foreign department*. The great engine by which a government preserves security of person, property, and reputation, to its subjects, in so far as these are threatened by disputes among themselves, is the law. To the production of a good and efficient body of law there are requisite—first, the legislator, or law-maker; second, the judge, or the person who declares in what manner the general precepts of the law apply to particular cases; third, the executive power, which enforces the decision of the judge when the party against whom it is given proves contumacious. The means by which government defends its subjects against aggression from foreigners, or procures them redress for injuries done by foreigners, are twofold. They are either peaceable, that is, by the way of representation, persuasion, and argument; or they are forcible, that is, by the way of war. The management of the former mode of averting or redressing injury, belongs to the diplomatic; the latter, to the war department. The business of government, like all other kinds of business, requires money to defray its expenses, and this renders necessary another department—that of finance. It appears from this review that the great natural departments among which the business of government falls to be distributed, are as follows:—

The Home Department, which resolves itself into the *Legislative*, *Judicial*, and *Executive* Departments.

The Foreign Department, which resolves itself into the *Diplomatic* and *War* Departments.

The Financial Department.

These embrace all the necessary, essential functions of a government. Even in rude tribes, among whom one ruler takes upon him the whole task of government, and finds it too little to occupy the whole of his time, he must, in a scrambling way, discharge all the offices of these departments, though he never thinks of distinguishing and classifying them. He must lead or send out the warriors of his tribe to drive away intruders upon their hunting-grounds; he must treat with the sachems of neighbouring tribes, when the hatchet is to be buried or dug up; he must devise laws, decide between litigants, and enforce his own decision; he must levy his "ways and means"—the duty least seldom neglected. Even among highly civilized states, limited in point of territory and population—although, for the sake of order and the facility it gives in the transaction of business, the offices of these departments and their records will be kept separate—it will sometimes be found, for the sake of economy, or because there is not enough of business in any one of them to occupy a man's whole time, that the duties of more than one are discharged by the same person. On the other hand, in large and powerful states like our own, it is found necessary still further to subdivide them. Thus, instead of a simple war department, we have an admiralty, a secretary-at-war with the Horse Guards, and an ordnance department. The number of offices, of departments (of *bureaux*, to adopt the French phraseology), is comparatively unimportant; the great matter is to have the business of government so distributed that every man, knowing exactly what he has to do, may set about it with the least possible degree of confusion and embarrassment, and that all men knowing what he has to do, the force of public opinion may more easily be brought to bear upon him if he exceed his powers or neglect his duty. Some of these departments, however, from the peculiar nature of their duties, ought never to be intrusted to the same individual. For example, the office of making the laws ought never to be intrusted to the person who has the charge of explaining and applying them; and neither task ought to be intrusted to him who is called upon to enforce them. When the judge is not the law-maker, he will interpret the law according to its apparent tenor; but if the law-maker be judge, he may say, I meant so and so, and explain it in a way nobody ever suspected. If the judge is law-maker, he may take upon him to supply deficiencies in the law on the spur of the moment, and thus expose citizens to the injustice of being tried by a law not in existence at the time they are said to have offended. The qualities required in a good executive or police minister are quite different from those required in the judge or lawgiver, and rarely combined with them in the same person. Above all, however, the functions of finance minister ought never, in whole or in part, to be intrusted to the minister of any other department. The practice which prevails in many governments, of allowing office-bearers to pay themselves, and intrusting the collection of different branches of the revenue to various departments of government, is sure to lead to extortion and peculation, to profligate waste of money, and oppression of the subject.

These are the essential departments of a government—their duties are those which, however rudely or confusedly, must be discharged whenever there is any government at all. There are other departments, not certainly of less importance, but without which many governments have been carried on; and the duties of which have been discharged by private exertions, but which may with advantage be discharged by the general government. The departments to which we allude are those which have the charge of national education and the provision for the poor.

The circumstance of the state or government taking upon it to direct the education of the whole people, has been brought about, in point of fact, by a variety of contradictory causes. Among heathen people it was owing to the strong influence acquired, at a very early stage of civilization, by the priesthood; the continuance of the power of a priestly *caste* depended upon the people continuing to believe in their pretensions to supernatural power and more than ordinary virtue. The most natural way to keep up this belief was by graving it deeply on the minds of the young. In the small states of Greece, as they advanced in civilization, the secular statesmen emancipated themselves from the alliance of the priests; and, in consequence, we find the influence of the latter as teachers superseded to a great extent, especially at Athens, and in the small Greek kingdoms erected out of the fragments of Alexander's empire, by philosophers in the pay of the government. In the great Roman empire, which incorporated into itself all those Greek and many other minor heathen states, both the philosophers and the priests ceased to be the authorized immediate agents of a government education, though in the provinces they continued to teach. The founders of the Christian religion disclaimed such connection with the state as had been maintained by the priests who preceded them; accidental circumstances, however, connected with the decline of the Roman empire, united again, in the persons of the dignitaries of the Christian church, the offices of teachers and rulers. In the countries throughout which the Mohammedan religion gained the ascendency, that modification of the Christianity of the time has become, as among heathen nations, an engine of government. Among the nations of Europe, and those which have been planted in different parts of the world within the few last centuries by Europeans, the progress of science has produced an effect analogous to that mentioned as having been produced by it among the small Greek states of antiquity. It has shaken, not the belief in the Christian religion, but the opinion of the benefit derived from making it, like the old heathen religions, an engine of government. At the same time, the opinion of the importance of civilizing the whole body of the people by the influence of education, has led men to inquire whether government could not with advantage undertake the task of educating them. The bigoted advocates of a dominant church fear secular education, as calculated to encourage a spirit of free inquiry inconsistent with implicit belief in a state creed. Many advocates of secular education, irritated by this opposition, see in the established clergy nothing but a body of men who would put down all instruction except what is calculated to impress ineffaceably the belief of their peculiar dogmas on the infant mind. The discussion regarding the utility of a national system of education, and the best kind of national education, has hitherto been conducted with too exclusive a reference to the partisan views of these opposing parties.

This historical retrospect has been introduced for the purpose of placing the present state of the controversy in a clear light. It must be argued differently if we are to arrive at a true and practical conclusion. The success of state religions, in diffusing such a general knowledge of their dogmas among the community as is requisite to enable men to conform to them in outward appearance, is a proof that an organized government possesses great powers for the diffusion of information. By intrusting the superintendence of national instruction to a separate board, there will be no interference with, or obstruction of, the discharge of the other duties of government. Arrangements for providing a supply of competent teachers, books, instruments, &c., will be, as on a grander scale, more efficient, as they will at the same time be more economical than the desultory efforts of private individuals. So far the advantages of a national system of education are apparent. The difficulty is here: harm is done whenever government interferes with the free formation and expression of opinion, and it is difficult to teach without giving a bias to opinions. Out of this difficulty we are rescued by a suggestion, derived from viewing the question in another point of view. It is part of the essential duties of a government to take care that its laws are made known to all who are called upon to obey them, and that competent officers are intrusted with the management of the details of government. The invention of printing enables government to multiply to any extent the copies of its laws; but this is not enough, unless that the persons among whom these copies are distributed are able to read and understand them. The simplest mode by which a government can ensure the complete publication of its laws, is by teaching all the people the elementary branches of knowledge—reading, writing, and the grammar of their native language. Again, with a view to secure efficient officers of government, they must be educated for their employments: no one ought to be employed in any office under government who cannot show that he possesses the requisite knowledge. High schools or universities, supported out of the national funds, will be found the cheapest method of putting the means of acquiring this knowledge within the reach of the able and aspiring of all classes. There the lawyer, the soldier, the diplomatist, the lawgiver, the financier, the elementary schoolmaster, may procure the deeper scientific learning necessary to the right discharge of their respective duties, in the highest perfection and at the least expense. At these institutions, the young clergy of all churches might acquire their literary and scientific instruction: their peculiar theology might be taught them at institutions supported by their respective sects. A competent number of such elementary schools and universities, teaching only those branches of knowledge in which there is no sectarianism, would be for the advantage of all sects, and would interfere with the peculiar views of none. They are of the class of institutions which government has a right to establish, and neglects its duty if it does not.

The propriety of government taking upon it to raise and distribute funds for the support of the poor, admits of being more briefly illustrated. In all countries there has ever been, and as long as human nature continues what it is, there ever will be, a certain number of destitute poor—of paupers; and this number will be greater in proportion as population becomes more dense. The indolent, the weak-minded, the slaves of sensual passion, will remain in native poverty, or drift down into pauperism from a more affluent condition. It is in vain to say that it is their own fault. The revolutions of a commercial system like ours, so mighty and complicated that it sways those involved in it blindfold hither and thither amid its waves, often throw thousands at once out of employment and bread, without any fault of theirs. Even the dissolute and imbecile have their degrees of criminality—the guilt of omission, varying from highly culpable to venial. Human nature revolts from the thought of denying them relief; but if it be left to casual charity to relieve them, the donations will be insufficient to supply the wants of all; and the burden of supporting these encumbrances upon the public which supports itself, will be unequally distributed. The humane will be oppressed, while the callous pass free. But the main argument for imposing upon government the charge of supplying the wants of the paupers, is the fact, that, apart from all considerations of humanity, the relief of their necessities is a precaution tending to give additional security to persons and property. It is want that is the chief prompter to turbulence, violence, and dishonesty. It is among the classes who are dependent upon a precarious supply of food to relieve their daily necessities, that the half-savages are found, who prowl, in quiet times, under the shade of night, in search of plunder, and, in times of public excitement, rush from their hiding-places as infuriated mobs. It is among their squalid haunts that are engendered the pestilence and diseases which from time to time strike whole nations. It is the duty of government, in its office of preserver of the lives and properties of its subjects, to take measures for rendering this class less dangerous, by diminishing their temptations to dishonesty, and relieving them from that state of squalid destitution which endangers the health of the whole community.

When in any country the different labours of government have been parcelled out in the manner here suggested, and allotted to different functionaries, each having attached to him a sufficient staff of assistants, each being subjected to one recognised head of the government, whose business it is to watch over all their proceedings, to urge on the indolent, to check the erring, to appoint to vacancies, and remove offenders, a great step has been taken towards securing a just and efficient government. The peculiar and limited duties of government have been indicated to all, and the persons pointed out upon whom devolve the responsibility of discharging them. There remains, however, this danger to guard against. All men love ease, and all men love to have their own way. Again, men united for any purpose—the pursuit of either a business or a pleasure common to them all—immediately contract what the French call *esprit de corps*—a clannish or corporation spirit. They act and feel as having a common interest opposed to the interests of all who do not belong to their body. This *clique* or *coterie* spirit, animated by the love of ease, and the self-will more or less natural to all men, has a tendency to convert every organized government into a knot of oppressors. This reflection carries us, by a natural transition, to the remaining inquiry under the present head—By what means a government is to be kept in the line of its proper duties.

It cannot have escaped the notice of the reader, that every government acts upon its subjects by means of themselves; it employs its subjects to keep its subjects in obedience. The consequence of this is, that in every country, and in all ages, the most seeming despotic government is kept in check by the opinions of its subjects. No government has ever with impunity set at defiance the opinions, be they well grounded or be they prejudices, moral and religious, of its subjects. The Ottoman sultan, at the time when his power was greatest, never dared to act contrary to the law of the Koran. Henry II. of England was obliged to humble himself before the religious sentiments of his age, outraged in the person of Thomas-à-Becket. Thomas Moore, in his *Fables for the Holy Alliance*, has ludicrously but aptly illustrated this truth, by figuring the soldiers kept on foot by the monarchs of the Holy Alliance, as extinguishers made of combustible materials, and the military insurrection which brought about the Spanish revolution of 1821, as these extinguishers set on fire by the light they were meant to put out. This is no statement of what *ought* or *ought not* to be; it is a statement of what *is*—a fact that exists whether men affirm or deny it. Civil government—political action—is human ingenuity working by human means. It is this necessity under which every government lies, of governing its subjects by its subjects, which puts the whole community in possession of an engine, by the proper application of which, government may be obliged to work for the general good.

We have already pointed out what is necessary to enable the government to make justice and the good of the community its aim: it is to organize the government so as to render its action easy and powerful, and to enlighten it as to its duties. The same process is to be followed with the community, in order to enable it to act as a check upon the government when it is inclined to go wrong, and to organize the community in such a manner that its opinions and wishes may be brought to operate easily, powerfully, and, by consequence, tranquilly upon the government. There is another object to be gained by thus enlightening and organizing the people, besides that of making them an efficient check upon government when it goes wrong; it is only by enlightening and organizing the people that they can be rendered capable of lending due force to the operations of government, when these are what they ought to be. An unenlightened people is quite as likely to entertain mistaken notions of what is for its good as correct ones; it is quite as likely to oppose government when it tries to do what is right, and to support it when it tries to do what is wrong, as the reverse. Government was in the right when, about the year 1780, it repealed some of the worst enactments against the Catholics; but the people were so far from heartily approving of this act of justice, that Lord George Gordon's riots in London, and the rabbling of Catholic chapels in Edinburgh, had nearly frightened government out of its good intentions.

The first step, then, in making such arrangements as are necessary for keeping government in its just and useful line of action, is to enlighten the people. There goes more towards enlightening the people than merely schoolmastering them. It is not enough that the teacher tell what he knows, repeat line upon line and precept upon precept, or even make his pupil repeat what he has told him, to show that he remembers it. The pupil must himself be active, and make exertions to catch the true meaning of what he is taught; and in this he will not always, in spite of his best efforts, succeed at first. Every person who has exerted himself to master any branch of knowledge, must remember instances of this kind, where he has pored for hours, day after day, upon some dark passage in a book—some step in the reasoning which he must understand, or all that followed would be dark—and yet could not get at its meaning, till some time, when he was thinking of n thing less, taking a walk, and looking at trees or the running stream, or engaged in striking a bargain, some chance word or stray thought has recalled the puzzling passage to his mind, and all at once a light has broke in upon him. His previous reflections had not been so useless as they seemed; they had been gradually opening his mind, and had so far succeeded, that nothing but an accidental impulse from without was wanting to make him see his way. It is knowledge gained after this fashion that really instructs and forms the mind: information thus earned, we may say, in the sweat of a man's brow, is too deeply graven on his memory ever to be forgotten, and the rude exercise his struggles to understand have given his mind, strengthens and invigorates it for future exertions. All that teachers can do in the way of instruction, is to show their pupil what is to be learned, to tell him how to set about learning, and to watch over him, and, by motives either of pain or pleasure, to stimulate him to perseverance in the work. All the rest must be his own doing. Hence it is that some pass through the hands of a teacher and learn less than those who, from poverty and strong desire of learning, have been driven to teach themselves, with no other assistance than occasional hints. Hence it is, as most men who have received a regular education and made good use of it must be aware, that the most important part of their education is that which they have given themselves after leaving school, availing themselves of what they remembered of their teacher's precepts to enable them to acquire a complete understanding of what they had only repeated like parrots, and immediately in a great measure forgotten.

Our object in this seeming digression is to make as clear as we can that mere communication of instruction, which is all one human being can do for another, is not enough to enlighten and discipline a man's mind; that many receive it without being much the better, and that many make considerable progress in acquiring knowledge without having the benefit of it. There is an enlightenment—a practical training, and a storing of the minds of men with knowledge—that must in all cases complete what the teacher has begun, and that often carries men a good way without the aid of a teacher. It is the education which man's natural curiosity, cooperating with the observations forced upon him, and the exertions necessary to keep him alive, as it were, force upon him. The great source of men's amusement, that which is more or less within the reach of all, is conversation, which, even in its rudest and most stupid, or weakest and silliest form, is a giving and receiving of information more or less valuable. The rudest process by which the mere savage procures his daily food, involves an exertion of design or forethought. He resolves, it may be, to go to the sea-shore, and pick up shell-fish; he plans out beforehand what he is going to do, and he executes his intention. The changing of the seasons forcing him to procure food by different means at different times, or by making him experience want, suggesting the advantage of laying in a store beforehand, gives fresh exercise to what Dr. Reid has called "the active powers" of his mind. Acting in concert with others, debating what is the best plan of attaining their common object, getting angry and being soothed, or soothing another who gets unreasonable, defending his own share from a plunderer, or trying to outwit his associate—every action of a man's life, even in the rudest stages of society, is a part of education. As the society advances in wealth, it advances in the acquired knowledge and skill of its members. This is a process quite independent of design on the part of men, which is carried a great length before teaching, as we understand it, is ever thought of. Men become reasoners about what is right or wrong, practical politicians, skilful mechanics, projecting merchants, lawgivers, and lawyers, after a fashion, long before they give these pursuits their different names, or dream of theories, and science, and teachers. This is what we call *civilization*, which means the intelligence, and skill, and polish of manners which men acquire by living and acting in a numerous and wealthy society. Men never think of teaching or being taught until the society in which they live has made considerable advances in civilization. This is the kind of enlightenment which must prepare any people for acquiring a good government.

We cannot carry back our inquiries to the first origin of society, and show that it has advanced from rudeness to civilization in the way here described. But we know from history that a part at least of the process has been gone through by all civilized nations; and we know from the observation of travellers, that even in our own day there are tribes in different parts of the earth which are still in the mere rudiments of civilization. But there is a still more curious fact, which, for the purposes of the inquiry now in hand, it is most necessary to know, and in all our reasonings to make allowance for. In the same society or nation, especially if it be large, there may be, there almost always is, a great variety in the degrees of civilization which different classes of its citizens have attained; some may have reached a very high grade, whilst others remain as low as human beings have ever been found. This has been the case in every country where there has been a priestly *caste*—in old Babylon, Egypt, and Hindostan. This was still more strikingly the case in Rome, and is so at present in the slave-holding states of the European race. One frequent cause of this inequality of civilization in members of the same society, has been the establishment of great empires by conquest, by which means many different races have been brought under the same government. It is in this inequality of civilization that the institution of slavery has had its origin. The relation between master and slave could only be established where there existed a great disparity of intellectual culture between the governing and the governed class. Slavery must be admitted to be a necessary institution in such stages of society, although it has the disadvantage of perpetuating, and even of increasing, the inequality which gives rise to it, to say nothing at present of its other disadvantages. But it is not merely where it presents itself in this startling form that inequality of civilization exists among different classes of society. Wherever we find great inequality of power and privilege prevailing, we find this inequality of civilization giving rise to it. An aristocracy, a class of privileged nobles, has its origin in the circumstance that greater skill, enterprise, intelligence, and perseverance, at first threw a comparatively great amount of wealth and power into the hands of a few families; that the management of that wealth, and the exercise of the power and influence, were occupations calculated to give a greater practical development to the propensities and faculties of their descendants, than the routine drudgery of those who earned their daily food by their daily labour. We have no desire to palliate the evils of aristocratic government. That degree of enlightenment which enables men to lord it over others, is not necessarily accompanied by that higher enlightenment which teaches the beauty and utility of self-control and the exercise of justice to all. But we must not, therefore, shut our eyes to the fact, that aristocratic government is one of the stages through which all societies must pass in their way to something better; that society advances as man walks, by putting one part of the body foremost and dragging the rest up to it; that the love of power, and skill in acquiring and exercising it, must be realized in the few, in order to excite the desire of a share of it in all. That inequality of civilization, which gives rise to aristocratic power and influence, exists in many different forms and modifications. Even in our own country an uncivilized class is found—that unfortunate class which supplies the precarious demand for the lowest kinds of unskilled labour, and fills our police-offices and other courts of justice with the greater part of the victims to the security of society.

In a rude society, there is wanting that enlightenment which is necessary to confer upon the subjects or citizens the power of keeping their government in the path of its duties. In a partially civilized society—a society in which some classes are considerably advanced in civilization, while others are still rude, helpless, and ignorant —only a portion of the citizens will be able to exercise this control. They will exercise it to their own advantage, neglecting the interests of the powerless classes, most frequently from thoughtlessness, but sometimes at the impulse of motives still less excusable. The only guarantee men can have for good government, is their *power* to exact it, and the foundation of that power is knowledge or intelligence—intelligence imparted by civilization and heightened by teaching—knowledge diffused through all ranks of society. Wherever there is an ignorant class, it will be weak; and wherever men are weak, they will be oppressed.

But this power which the subjects or citizens of a government or state derive from knowledge and intelligence, must be rendered available by organization. It is true, on the one hand, that none but civilized, that is instructed and intelligent (we do not mean book-learned) men, can be organized, or can organize themselves, for the purpose of making their government do them justice. But it is also true, on the other hand, that unless men do associate, and each take upon him a certain part of the labour (which is what is meant by organization), they never can attain their end. Public opinion is strong; but unless public opinion is imbodied in public assemblies met to discharge certain business, or to choose the persons who are to discharge it for them, it is impotent when opposed to an organized government. The power which the citizens, meeting in public assemblies, possess of checking the government, is derived from a circumstance in the very constitution of government that has been noticed above—the fact that government can only enforce the obedience of its subjects by employing the organized force of a portion of themselves. If a decided majority of the citizens resolve not to obey the commands of government, not to become its agents in compelling others to obey it, and not to allow any of their fellow-citizens to enforce obedience from the rest, except under certain conditions, government must come to terms with them. Whenever, in any country, the great body of the inhabitants have discovered this truth, they have succeeded at intervals in averting the oppression of those who exercised the government for the time being. It was in this manner that the Roman plebeians, when they retired to the "Sacred Mount," obliged the patricians to abstain from tyrannizing over them. It was in this manner that the Dutch relieved themselves from the yoke of Philip II. of Spain. It was in this manner that the Swiss emancipated themselves from the house of Austria. It was in this manner that the Reformation of Religion was effected in all the Protestant countries of Europe. It was in this manner that our own Revolution in 1688 was effected.

We are not stating what ought to be done on such occasions—that might be mere matter of opinion: we are stating what has on all such occasions been attempted, with more or less success, and what, so long as man continues to be man, will be attempted. If a government persist in oppressing the people, it will drive them to revolt against it. If the people are sufficiently advanced in civilization to estimate the amount of their wrongs, and to devise some rational means of obtaining redress, their revolt must be successful. All parties have an interest in preventing matters from coming to this extreme. The members of government risk the possession of the power and profit which their subjects, for the sake of a tranquil and secure life, would gladly allow them. The great body of the people have their industrious pursuits interrupted, their property diminished, perhaps their personal security endangered. Whenever resistance is thus offered to a government, it is as the least of two evils—it is always in itself an evil, though it may be a necessary one. A conviction of this truth has, on more than one occasion, induced both governors and governed, while the evils of a struggle between them were yet fresh in their memory, to attempt to prevent its recurrence by some permanent arrangement. The Roman plebeians, for this purpose, obtained from their rulers, at different times, tribunes invested with power to guard their rights, the right of electing one of their own number to be consul, and various other concessions, which at the time appeared to them to be sufficient to assure them of just government in time to come. In our own country, Magna Charta and the Bill of Rights were bargains struck between the governors and the governed, for the same purpose. All these arrangements, whether well adapted to promote the end in view or not, are what are called constitutions, or constitutional governments. They are bargains struck between the government and the people at large, awarding to each party certain powers or privileges, which the other becomes bound to respect. The object in view is to render it possible to check those evils at the very outset, which, if allowed to go on, lead to revolts and revolutions; to enable the people, by keeping a steady watch over the motions of their rulers, to mark their first aberrations from the right, to remonstrate in time—to prevent injustice instead of revenging it.

Constitutions of government have been devised and adopted, as various as the habits, opinions, amount of wealth and knowledge, and distribution of them among the people who have devised them. Our own will be examined in the second section, and will serve as an illustration. Our object at present is to point out what the knowledge or opinions which prevail in Europe lead us to believe is the most efficient kind of constitution. A constitution is adopted in the belief, that it will secure the enjoyment of their just rights, alike to the governors and the governed. If it effect this, men will rest contented with it; if it do not, they will look about for a better. The only thing that has ever convinced a people that their constitution worked ill, has been experience. No people have ever changed their constitution in consequence of a mere abstract demonstration that the new one proposed to them was calculated to work well: no people have remained quiet under a constitution that worked ill. Any constitution, however imperfect, is legitimate, and ought to be obeyed, so long as the people are satisfied with it. The only use in trying to discover the most perfect and efficient constitution that can be adopted, is with a view to insure its permanency, to prevent the necessity of having recourse to the evil of a change. The plan of organizing society for the purpose of keeping government in the line of its duty—the constitution about to be traced—is not held out as recommendable or possible to our own or any nation at any given time: it is an attempt to imbody principles which ought never to be left out of view: it ought to be approached as nearly as circumstances admit.

It has been shown above, that opinion is, after all, the engine by which stable, permanent governments are maintained. The existence of a government is a proof that the great majority of the people are satisfied with it, or that it is the common belief that they are satisfied with it; and therefore any attempt to resist it is hopeless. Civil wars, except in a few cases where a minority have been rendered desperate by oppression, and have rushed on death rather than continue to suffer, have been promoted by the uncertainty whether the supporters or the adversaries of the existing government were the more numerous and powerful. The object of a constitution is to provide the means of ascertaining which party is the more numerous, in order that the less numerous may see the necessity of submitting, without being forced to do so by actual suffering. The only way in which this can be done is by coming to a vote. All *constitutions*, taking the word in the sense in which it is generally used in modern Europe, when investigated, are means of ascertaining by whom the people wish to be governed. They are adopted in the belief—that the people wish to be well governed, that is, that when the majority of the people are comfortable, they will not seek for change; and that when the majority are uncomfortable, they will seek for change; and that the minority who believe the choice of the majority to be wrong, will the more willingly submit, if they see that, should it be in their power to bring over a majority to their opinion, they can alter the decision. When a nation has got the habit of acting in this way, the conduct of government necessarily comes to be more narrowly scrutinized. The incessant cavilling of the discontented minority, provokes arguments in defence from the majority, and not an action of their rulers escapes discussion. Experience, if nothing else, teaches the government that this incessant disputation may, unless it is particularly guarded, loosen the hold it has on the opinions of the majority, and makes it more guarded in its proceedings; or if it misconduct itself, disregarding this hazard, its own blameable conduct diminishes the number of its supporters, until they become a minority. The object of a constitution being to afford a means of working out this process peaceably, it is clear that the first and most important requisite in a government—in a constitution—is a method of ascertaining beyond doubt to whom the majority of the people wish to intrust the charge of governing them.

The problem, then, is, How are we to ascertain the wishes of the whole people—their real, their sincere wishes? There is only one way, by allowing every one of them to declare who it is they wish should govern them, and allowing them to do this free from fear of the consequences. In states which consist, like those of the old Grecians, of a single city, the ballot-box and a convocation of all the citizens was sufficient for this purpose. In states which, like Great Britain, France, or the United States of North America, extend over a large tract of country, the votes must be taken by districts; otherwise many would be prevented from voting by loss of time and the expense of travelling, and thus the opinion of an unquestionable majority could not be obtained, and the election would occupy a dangerous length of time. The rule to be observed, in dividing the country into voting districts, is, that they shall be sufficiently small to admit of every citizen giving his vote at the expense of a very trifling loss of time and personal inconvenience; and that they shall at the same time be sufficiently large to contain such a number as shall prevent secret voting being merely nominal.

The next requisite in a constitution is, that care be taken to prevent confusion in the discharge of the different functions of government, and to ensure the greatest possible amount of fitness for their respective duties in the persons elected. It has been shown above, that it is of great consequence that the law-makers, and the law-expounders (judges), and the law-enforcers (executive government), should all be different persons, independent of each other. It is therefore advisable that the people should directly elect all these separate functionaries, with the express understanding that each is to confine himself to his own particular field. There is this difference between the first of these classes of functionaries and the other two, that its office is deliberative, while the offices of the others are to act. "In a multitude of counsellors there is safety;" it is desirable that the deliberative, the law-making body, should be numerous. On the other hand, experience teaches that, where action is required, the controlling power ought to be vested in as few as possible. Hence it is advisable that, in elections of executive governors and judges, the votes of all the districts ought to be added, as only a small number are required; but that, in elections of legislators, as the number required would be so numerous as to render it inconvenient for each district to vote upon all, each district should be allowed to send a certain number of legislators to the general assembly. By this means greater variety of character and opinion will be introduced into that body, which, though destructive of action, promotes discussion.

For the same purpose—the keeping the different functionaries of government independent of each other, and preventing as far as possible collusion among them, with a view to promote their own ends instead of the public good—it is desirable that each district should elect those local functionaries who are required to be resident within it. In a large country, it is necessary to have judges within reach of every man; and it is necessary to have one supreme judge, whose decisions shall preserve uniformity among all those different courts, and to whom those who are dissatisfied with the decision of their own court may apply to have it reconsidered. So, while the central executive government takes care of the whole nation, there are many little details to be attended to in every locality, which are best discharged by persons residing on the spot, which could not be so well managed by the central government, and would occupy an undue share of its time. These officials ought to be elected by the inhabitants of the district over which they preside, in the same manner as the great functionaries are by the whole nation. By this means alone can security be given that they will be chosen solely for their fitness, not with a view to secure interested supporters of the central government, which, were they nominated by it, they would infallibly become.

The last essential point is, that the elections of the functionaries of government should recur at brief stated intervals. The use of a constitution is to keep government in the line of its duty, by making it feel that it holds its power only so long as it retains the confidence of the people, and by enabling the people to change a government which it finds incorrigible. Unless the members of government are elected at first for a definite limited period, with a common understanding that the process of election is to be gone through at the expiry of a certain time, the object of framing a constitution will not be obtained. There will be no means of ascertaining when the whole country thinks it advisable to proceed to a change: the minority will pretend that the proper time for election has not come, and absent themselves, in order to have a pretext for denying that the result shows the opinion of the majority. The elections must therefore be ordained to take place at stated intervals, and these intervals must be calculated with a view to two considerations—they must not be so far apart as to allow a government time to do much mischief unchecked; they must not be so near as to prevent the government from developing in practice the system on which it intends to act—they must be long enough to enable it to be judged, not by isolated actions but by its general policy. At the same time, care must be taken to institute such arrangements respecting the period for which the elected should serve, as will conciliate and secure men of respectable standing in society—men, in fact, who may be supposed to be placed beyond the suspicion of serving for basely selfish purposes, and who are in the habit of taking enlarged views of social organization.

FORMS OF GOVERNMENT ACTUALLY EXISTING.

In the first section an attempt has been made to convey a distinct general notion of the ends proposed to be accomplished by government, and of the means by which the nature of man and society render it necessary for government to accomplish these ends.

The use of such general notions is to serve men as a test or standard whereby to ascertain how and to what extent any actual government approaches to or falls short of what it ought to be, and as a chart by which to work when circumstances offer an opportunity of introducing any improvements into the machinery of any existing government. In affairs of practical politics, as in all other human transactions, it is of great advantage to those who are called upon to act, to have it in their power to take up a position beforehand, from which they can see at once the whole field of operations, and the relative positions and bearings of all its parts.

But such general notions, if not combined with knowledge of practical details, are at times apt to mislead, and are not at any time sufficient of themselves to enable men to decide on any occasion what is best to be done. The preceding analysis of the elements of government is an outline of what exists in reality, but so general in its features that it is applicable to every government that has ever existed. Whoever would avail himself of the practical lessons that may fairly be deduced from those general truths, must first of all apply himself to ascertain the peculiar form under which those general principles exist and operate in his own country. He must not allow himself to be misled by vague sentiments—by predilections or antipathies for particular names or even forms of government, but endeavour to discover the amount and kind of the effects they produce, and judge of them by their effects. Liberty and loyalty—monarchies and republics, aristocratical or democratical—are words about which much argument and much blood has been wasted. And yet, after all, it is not the name of a government, nor even the external forms of its framework, that are of importance. If a government protects the persons and properties of its subjects, without interfering with their freedom of thought and action so long as they do not injure their neighbours; if, by example and precept, it encourages industry and intellectual development, and high moral and religious sentiment; and if its constitution is such as to afford a guarantee for its action being permanently (not by fits and starts) thus beneficial—be the name or form of that government what it will, it is a good one; and on further investigation it will be found that its goodness is owing, in the first place, to the aptitude of its organization for effecting the ends of government—that is, to the skilful organization of legislative, judicial, and executive functionaries; and in the second place, to circumstances which render these functionaries subject to the control of public opinion.

It must always be kept in mind, that government, in the great majority of cases, must be exercised by, as well as upon, individuals of the nation in which it exists, *by* individuals not materially wiser or better, in the average, than those whose imperfections render the control of a government necessary to preserve peace and justice in society. And it follows from this, as a necessary consequence, that at different stages of civilization, different forms of government may be not only the most easy to establish and support, but the most beneficial for the community. With all the defects necessarily attendant upon a non-resident government, there can be little doubt that the government of the British East India Company is not only a better than India ever had before, but a better than the inhabitants of Hindostan could at this moment give themselves, if left to their free choice. The feudal forms of government in Europe during the middle ages, the hierarchy of Thibet or ancient Egypt, the monarchy of Charlemagne, have all been in turn the best for the particular tribes subject to them at the particular period.

The mutual adaptation of governments and nations is a point that cannot with safety be left out of account, in cases where the shades of difference are much more delicate and difficult to detect than in those which we have selected for the sake of illustration. A difference in the kind as well as in the degree of civilization of two different nations, can render the government which works well in the one impracticable in the other. A nation is what we have attempted to show a government to be, more a necessary product of human instincts than a creation of conscious design. Governments and nations are the creatures of human intellect and will—but of whole races and generations, not of individuals, or even of the collective men of one age. There goes time, long time, to the making of both. They grew up together; they are inseparable but by the destruction of both; the capacity and peculiar character of the nation determine the kind of government fitted for it. Every nation must work out its own happiness—in consonance, it is true, with the universal general laws of human nature—but, at the same time, in harmony with all those minor differences which characterize, and throughout its history have characterized it as differing from all other nations.

DESPOTISMS.

At the present time, the greater proportion of the governments throughout the world are of the character of *despotisms*, and comparatively few possess what are called *constitutions*. Of the multifarious class of despotisms which exist among barbarous nations, it is here needless to say any thing; for the question of form of government only becomes interesting when applied to a wholly or partially civilized people.

Russian Government.—The most powerful despotism in Europe is that of Russia, which, in virtue of hereditary right, is governed by a monarch with the title of Emperor. No restraint can be imposed on the Emperor's government, except voluntarily; and, either from benevolence or fear, the Emperors have partially qualified their unlimited power, which is further moderated by rights and privileges enjoyed in certain parts of the empire, on which no monarch could infringe with impunity. (See article GEOGRAPHY.) Russia is chiefly distinguished as a great military power. Within the last seventy or eighty years, it has, by military rapine, acquired territories containing upwards of twenty-three millions of subjects; this extent of acquisition, however, is much less than that of Great Britain in India during the same period of time. A severe censorship of the press; the existence of seignorial rights of serfs (a kind of slavery); a widely ramified police spy-system; restriction of personal locomotion by passports; and, in short, a complete absence of all tokens of civil liberty, mark the Russian government as a pure despotism. The despotism of Austria is scarcely more liberal; the only qualifying features are the establishment of a national system of elementary education, and science is not persecuted.

Prussian Government.—Prussia at present offers the remarkable spectacle of great improvement in intellectual and social condition, with ample protection of life and property, and yet with a form of government very little removed from that of a pure despotism. As little is popularly known respecting the Prussian government, and as it is the best example we can give of its class, we shall go a little into detail on the subject.

Prussia has increased from the condition of a dutchy—that of Brandenburg—to a large kingdom, within less than two centuries. A liberal reception of persecuted religionists, and military conquest, have been the chief basis of its greatness. Protestants flying from persecution in the Netherlands in the sixteenth century, found a refuge in Brandenburg; and great numbers of the French

Huguenots, who fled from their country on the revocation of the edict of Nantz, were encouraged to settle there; both classes of immigrants, by the example of their skill and industry, richly repaid the retreat afforded them. The Brandenburg territories were the focus of the desolating activity of the Thirty Years' War; but the destruction thus occasioned, operating upon an industrious and energetic race, a large proportion of whose ancestors were martyrs for conscience' sake, only stimulated them to redoubled exertions when peace was restored. The last prince of the country, who bore the title of elector, Frederick-William the Great, who reigned from 1640 to 1688, was of a character similar to that of his subjects: he found his country a waste when he assumed the reins of government; he introduced a degree of civil and military organization, that rendered it, long before his death, not only the most powerful division of the German empire, but a state, the alliance of which was courted by the most powerful princes in Europe. From the time the sovereign of this state assumed the kingly title, down to the dissolution of the empire, its history has been little more than the development of the organization begun by Frederick-William, under the auspices of a line of princes, all of them possessing more than average talent, and one of them unquestionably a man of genius. Prussia continued, as before, a place of refuge for all who fled from oppression of any kind. The victims of the devastation of the Palatinate by Louis XIV. found a home here; the objects of religious persecution in Switzerland, Salzburg, and Bohemia, came in successive flocks to Prussia—in one instance 20,000 at a time; and all were welcomed. The peculiar relation of Prussia to the empire seems to have exercised a favourable influence on the policy of its monarchs: possessed of all the power of independent sovereigns, they were not embarrassed in their internal government by foreign interference; and at the same time, *nominally* subjects, they were encouraged in a taste for the homely household management of their territories. The narrow limits within which the Brandenburg territory, the nucleus of the state, was contained, rendered it more manageable; the complete organization was easily extended to later acquisitions. The circumstances attendant on the dissolution of the empire in 1806, were such as to impress a severe lesson of economy on the sovereign of the in every respect independent state; and the necessity of entering into a death-struggle against the conqueror of Europe for the preservation of that independence, gave the finishing touch to its organization. Prussia is every way an anomaly—an uncontrolled monarchy, with a highly educated population, every adult male of which has been trained to the use of arms—a monarchy, in every public department of which as severe an economy prevails as in the democratic republic of North America.

The government of Prussia is a hereditary unlimited monarchy; the state is one and indivisible. The King exercises generally, by his ministers, the supreme legislative and executive authority, and appoints the judges. All laws bear to be framed by the King alone; but in fact they are prepared by the Council of State (*Der Staatsrath*). This body (established by royal ordinance of 20th March, 1817) consists of—1. The princes of the royal family, who have completed their eighteenth year; 2. Officers of state, who are *ex-officio* members of the Council, namely, the President of the Council, the field-marshals, the Cabinet ministers, the President of the Supreme Court, the President of the Chamber of Accounts, privy-councillors, and (for military affairs) reporting adjutants-general, the President of the National Debt Office, the Secretary of State, the generals commanding provinces, and the presidents of provinces when in Berlin; 3. Officers of state specially appointed by the King. The Council meets regularly on appointed days for nine months of the year; fifteen members, exclusive of the royal princes, being required to form a *quorum*. During June, July, and August, it meets only in the event of pressing emergencies. The business of the Council is to deliberate upon questions of policy regarding which the ministers are not authorized by the constitution to decide; the establishment of principles for the guidance of. the executive authorities; the preparation of laws; the organization of the different departments of state; the settlement of contested jurisdictions between ministers; and, in addition to these, the scrutiny of any question submitted to them by the King. Six committees are appointed to put any business to be submitted to the Council into shape, before it is discussed in full assembly; namely, the Committees of Foreign, Military, Judicial, Financial, Domestic, and Educational Affairs. Each of these committees is composed of five councillors not holding executive offices in the department of state, the business of which is submitted to their review: the president from time to time appoints individuals who do not belong to the council—government officials, scientific or mercantile men, or landed proprietors—to attend the sittings of the committees, for the purpose of giving information. The minister of department subjected to the inspection of each committee, must be present at its sittings either personally or by deputy, for the purpose of giving all necessary information, but is not allowed a deliberative voice. Matters of business, thus brought into proper form, are discussed in the general meetings of the council. After the report of the committee has been read, any member of it who dissents from the report is heard in support of his peculiar views. The minister to whose department the business belongs, is next heard to speak. Any other members of Council who wish to be heard, intimate their desire to the president, who calls upon them in the order in which they stand in the list of members. When all who desire to be heard have been heard, the referendary prepares an abstract of the opinions expressed by each, and the president takes the vote. A simple majority decides; and, in the event of an equality, the president has a casting vote. After a decision has been come to, with or without discussion and a vote, the resolution or draught of a law, together with a report of the proceedings, is laid before the King, who approves, rejects, or modifies it. Resolutions, laws, and ordinances of the Council, have no authority until they receive the royal sanction. All representations from the provincial assemblies are submitted to the Council through the ministers of departments. The business of the committees proceeds uninterrupted during the annual vacations. The Secretary of State has the charge of preparing all protocols and draughts of laws, and superintending the signature of such as are approved. Each committee has an establishment of clerks. The Council has a library, which contains the laws of the monarchy and all its provinces, and all the laws of the states of the Germanic Union that have been printed.

The supreme judicial organization is very perfect, and so, likewise, is that of the provinces and inferior divisions. With respect to the central executive, it is conducted by ministers appointed to the different departments, including a minister for spiritual, educational, and medical affairs. The executive is charged with the duty of supervising the products of the press, each minister exercising a censorship over publications relating to the concerns of his own department.

The naturally stringent quality of despotic rule is somewhat modified by the peculiar organization of the provincial executive; in point of fact, certain popularly appointed local councils or municipalities restrain the action of the central despotism. The eight provinces of the monarchy are divided into governments, these into circles, and these again into communalties. 1. At the head of each province is a High President, (who, when in Berlin, has a seat in the Council of State,) to whom are attached a council, a secretary, and several subordinate officials. The High President presides in meetings of provincial consistories, and the commissioners of school and medical affairs; he transacts business with the representatives of the province; he makes arrangements with the generals commanding the troops of the province; he exercises the censorship of all publications in the province, with the exception of some reserved for the Cabinet ministers; he exercises superintendence and control over the executive authorities in each government of his province; he controls the tax-collectors of the province; and, in emergencies, he is authorized to act in name of the central government until directions can be received from the capital. In each province there is a representative body called the *Land-Stände* (*etats provinciaux*). The general edict of the year 1823, which "called these bodies into active existence," declares that property in land is the basis of the representation, and that the Stände is "the constitutional organ of all classes of subjects in each province." The Stände consists of noblemen having a right to appear in person, noblemen, or great landowners appearing as representatives of knots of five, six or seven, who have a "collective voice," and representatives of towns and of cultivators of the soil. In Saxony, Westphalia, and the Rhine Province, the representatives of the commons are elected by districts; in the other four provinces, by towns, districts of towns, and rural districts. A more distinct idea of the functions of the Stände, than can be derived from the vague expression "organ of all classes of subjects," is conveyed by the fact that courts of arbitration have been established in Prussia, Brandenburg, Pomerania, Silesia, and Saxony, in consequence of representations from those bodies. The Stände meets and deliberates, and represents to the crown, through ministers, what legislative or financial reforms they wish, the crown reserving to itself the power of refusing the request, or complying with it in its own way. Every province is divided into governments, at the head of each of which is a president and council, composed of heads of departments; namely, the councillor at the head of the executive department, the superintendence of schools and churches, and the management of *direct* taxes, demesnes, and forests; several councillors who have no specific department; and some assessors. Business of weight is transacted by meetings of the whole council; affairs of less importance in meetings of the councillors belonging to specific departments. The executive officers of a government are appointed by the president; the councillors and assessors are appointed by ministers, on the recommendation of the president; the government treasurer and some other officials, on the recommendation of the whole council. The public business of the circles into which every government is divided, is managed under the direct superintendence of the provincial government, by a councillor in each, with the assistance of a council composed of the Stände of the circle. The members of the last body are all proprietors of equestrian lands, (or, under certain restrictions, their delegates,) the representatives of the towns, and the representatives of the peasantry. The commonalties in each circle are either town or rural. The towns are managed by town-councils, elected by the burgesses, and magistrates chosen (with the exception of the principal burgomaster) by the council. To the magistrates is intrusted the care of the executive police: the council manages the town property, and all matters of local finance. At the head of every rural district is a village justice (*Schulze*), with two assistants (*Schöppen*), who exercise a limited authority in matters of police. The village judge and the magistracy of towns are under the control of the executive department of the government in which they are situated.

Although the nation generally may be described as still in a rude condition, and perhaps not able for self-government, great advances are making to give the whole population intelligence, which is the basis of all true liberty. The state, in many respects, exercises a paternal and kindly sway. It has established national education on the broadest possible foundation; for each child is legally compelled to receive elementary instruction at school, and it is considered a disgrace to remain ignorant of letters. The state also takes charge of all the public highways, and keeps them in the best condition. It protects travellers from imposition, by regulations affecting posting, innkeepers, &c. It restrains idleness and drunkenness, by compelling all men to support their families; and places barriers in the way of that source of many evils—too early marriages. It gives perfect toleration to all religions and forms of worship; and the security it affords to persons and property is quite equal to that afforded in England. The worst of its features is the censorship of the press, which strikes at the root of constitutional freedom. The people, also, cannot meet publicly to discuss political affairs; personal locomotion is restricted by passports; the towns are walled and garrisoned; every able-bodied male must serve for a time in the army—all which circumstances tend to show that the nation, with all its social improvements, is still in the infancy of civil liberty.

CONSTITUTIONAL MONARCHIES.

A *constitution* is a legal and fixed compact between governors and governed, that the just rights of all shall be respected; and therefore implies a liberal concession of the governing party to the opinions, wants, and wishes of the community. Europe abounds in constitutional governments, but many of them are scarcely entitled to the name. Sardinia, Saxony, Sweden, Hamburg, and all the smaller German states, have constitutions of one kind or other; that is to say, the king, grand-duke, chief-ruler, or by whatever title he is called, is restricted in his designs by estates composed of delegates from different orders of the people. We should consider it quite useless to present detailed explanations of these constitutions, because all, or nearly so, are little better than a mockery. The reigning monarch can either directly neutralize the will of the estates, or he and they, together or separately, are under the influence of armed intervention. The King of Hanover, for example, has lately trampled on the constitution of that country, and yet he is protected by the other states of Germany. In point of fact, the whole of central Europe is at the mercy of Prussia and Austria, whose armies can be marched to any point where constitutional freedom has the appearance of starting into life. The Dutch have a constitution, but they have no right of public meeting for political objects; their press is under a censorship; all must carry passports; and every citizen, in any kind of trade or profession, is required to pay for a license. The infant and still disorganized constitutions of Spain and Portugal it is unnecessary to notice.

The constitution of France, since the Revolution of July, 1830, has been greatly liberalized; but, from the occurrence of recent events, it appears that the press is liable to oppression, without legal remedy; that citizens can be treated as the vilest criminals before trial, and merely on suspicion; and that the people have not the liberty of meeting for political discussion. Passports are required, a number of the large towns are walled and controlled by garrisons, and the very capital (January, 1842) is in the course of being placed under the guns of formidable batteries. Constitutional freedom is therefore either not yet understood or appreciated in France, and future disasters, doubtless, await that naturally fine country.

British Constitution.—From the raw and ill-regulated constitutions of most continental nations, we ascend to the old-established and well-guarantied constitution of the United Kingdom of Great Britain and Ireland. The government of this large empire (which we need not here particularize, as it has been fully treated of in our article CONSTITUTION AND RESOURCES OF THE BRITISH EMPIRE) is a perfect anomaly, and, though frequently imitated, has never, in a monarchical form, been excelled. The legislature, as is well known, consists of a hereditary sovereign (king or queen, as the case may be), a hereditary House of Peers, and an elected House of Commons. A *Parliament* is the term used to express the collective bodies of King, Lords, and Commons. Electors of members of the House of Commons must be native or naturalized subjects, males of twenty-one years or upwards, of sane mind, not concerned in the management or collection of the revenue, not holding any office in the metropolitan police, and not legally convicted of perjury, subornation of perjury, or bribery. In counties, an elector must be possessed of property in perpetuity or liferent to the value of £10 yearly, or lands held at a yearly rent of £50. In cities or boroughs he must be proprietor of a house or shop valued, along with the land attached to it, at £10 yearly, and upwards; or must occupy premises for which he pays a rent of at least £10 per annum.

Such, with certain modifications, is the principle on which members are elected. In practice it is found that the great bulk of the elective privilege is exercised by, or under the influence of, the landed gentry, in which we include the titled aristocracy of the country. At no time have what are called the lower or working classes possessed the vestige of the elective privilege: and it has only been since the passing of the Reform Act that the middle classes (shopkeepers, master tradesmen, manufacturers, farmers, &c.) have had the semblance of direct representation. With this alteration, however, it cannot be said that the legislature has undergone any sensible improvement. In the main, the members are still nominees of the landed gentry, or of corporations; and so much time is usually spent in electoral intrigues, parliamentary debates which lead to nothing, as well as the conciliation of parties, that the business of the nation is continually falling behind, or improperly executed.

In whichever way it is viewed, the legislature of the United Kingdom is essentially the reflex of the landed gentry and aristocracy, and consequently the interests of these classes are uniformly the chief matter for consideration. The next great interest cared for is the West India interest; next the shipping interest; next the military and naval interests; and, lastly, the commercial interest, and the interest of the people. The executive, reposed in the hands of a responsible ministry, takes its character from these competing interests. The execution of any project of law or government is, to all appearance, rarely a result of principle, but in almost every case an immediate consequence of temporary expediency. Power is attained by skill in gaining a number of supporters, and retained by skill in keeping them together. So much of the British statesman's efforts, during his apprenticeship to power, and his exercise of power, are devoted to the getting and keeping of power, that he is necessarily deficient in natural and acquired administrative talent. The manner in which the administrative functions of government are executed, depends upon the industry and honesty of officials not responsible to public opinion, not liable to be dismissed unless convicted of gross dereliction of duty, and of whom their chiefs ask little more than sufficient attention and skill to save them from successful criminations by opposition. This kind of organization weakens the direct pressure of public opinion upon administration; and, at the same time, by encouraging personal canvassing for political support, and the cultivation of impressive oratory, diverts public attention from the dry business of government, to sympathize with personal squabbles, and attention to great abstract questions, more imposing but less immediately important than practical details. The consequence is, that the British government, more than any other in Europe, has been characterized by the aimless expenditure of immense energy with very disproportionate results.

Whether any further introduction of the democratic principle (lowering the elective franchise) into the constitution would improve its qualities, is extremely doubtful. The people, taken in the mass, are still far from being instructed. A vast number can neither read nor write: and such is the distressing state of poverty and wretchedness of large communities in towns, that, with their small knowledge of public affairs, and liability to be corrupted, it is to be feared they would appoint men of inferior qualifications, or whoever paid them most liberally. The freemen voters (working men) of Norwich and some other towns, make a regular sale of their votes on the occasion of elections. In this strangely complicated condition of affairs, with great class interests to be protected, the only real restraint on government is the action of public opinion, expressed through the medium of the newspaper press and public meetings. Without these two qualifying elements, the government and legislature would be, not only in name but in character, a powerful oligarchy. As the case is, the restraint, though clumsy, is on the whole efficacious; and, therefore, with all its errors and anomalies, the constitution is one of the most favourable to civil liberty. The very weakness of the executive, as respects the means of keeping its place, and its obligation to conciliate parties, is highly favourable to popular freedom. In no monarchy on the face of the earth is the executive so liberal —that is, interferes so little with private conduct. Under its administration, the following important conditions are secured:—Liberty of speech within constitutional limits; a similar liberty of the press in all its departments (newspapers, however, requiring to be stamped); liberty of personal locomotion, no passports being required; liberty of carrying on almost every branch of trade without inquiry or license; liberty of meeting in masses to be instructed by lectures on political or other subjects; liberty of meeting to discuss any political topic, general or local; liberty of presenting petitions to parliament and memorials to the crown; religious toleration, and liberty for the performance of all forms of worship; liberty of setting up schools to instruct pupils in any branch of learning; protection from the law to life and property, without respect of person; privilege of trial by jury, and of forcing on a trial for any alleged offence; privilege of being held as innocent till proved to be guilty; incorruptibility of judges, these being no way exposed to intimidation either from power or popular prejudice. To these great bulwarks of civil liberty may be added the absence of military conscription; the non-existence of fortified or walled towns; the promptitude with which riotous proceedings are quashed and the peace preserved; and the absence of any restriction to prevent the most humble individual from rising to the highest rank and consideration. The drawbacks on all these advantages may be comprised in the following circumstances:—The existence of a set of laws so complex as to be unintelligible, and so expensive in administration, that legal redress, as far as private interests are concerned, is almost beyond the reach of the lower classes; the most odious restrictions on free commercial intercourse with foreign nations; the too prevailing treatment of all great questions in Parliament with reference to classes instead of to the whole people, and consequently the imposition of burdens, in an irregular manner, difficult to be borne by the poorer orders of the community; and, lastly, the absence of a national system of education, which might in time elevate the minds and morals of the people, and altogether produce a more wholesome social condition. Fortunately, these circumstances are all of a nature which admits of amendment, and they will, as a matter of course, be amended, as *public opinion, enlightened by knowledge*, is brought to bear upon them.

REPUBLICAN GOVERNMENTS.

A republic or commonwealth is a form of government in which the people, or at least a large portion of them, are acknowledgedly the source of power, and have the direct appointment of the officers of the legislature and executive. There are few of this class of governments in existence. The only republics worthy of the name in Europe, are those of the Swiss cantons; each of which is a territory of generally a few square miles in size, and inhabited by a few thousands of people, chiefly engaged in husbandry. In these cantons there are no great properties, and no families equivalent to our landed gentry. There are some wealthy and intelligent merchants in the large towns; but the bulk of the population are a hard-toiling race of small farmers, and little is seen above a condition of mean mediocrity. The legislative and executive functions are conducted in accordance with this state of things. Some of the laws are contemptible, from the narrow-minded views they exhibit—such as laws in some cantons to prevent dancing, and to prevent the purchase of houses or land by strangers; but other enactments, particularly as to freedom of trade, are much to be commended. These republics, centering in a general diet or congress, are greatly under the influence of Austria and other monarchies, by which, indeed, they are in a great measure tolerated only from mutual jealousy, and because the country is in some places almost inaccessible to hostile invasion. A constant drainage of the overplus population into France and to North America, helps to avert the catastrophe of a universal degradation to semi-pauperism.

On the continent of America, various republics have been founded on the wreck of the colonial institutions of Europe. The principal is the United States of North America, now upwards of half a century old. We have alluded to this great modern republic in the article DESCRIPTION OF THE UNITED STATES, and have no intention of going deeply into the subject here. The form of the legislature and executive is very nearly that of England; the main difference being an elective President as chief magistrate, instead of a hereditary sovereign, and the appointment of judicial and other functionaries by the people, instead of by the crown. The country is not one but an aggregation of republics; each state being independent of the others as respects internal management. The power of legislation for the States, in their united character, is vested in a House of Representatives and a Senate, jointly forming a Congress. The House of Representatives is composed of members chosen every second year by the people of the United States. The electors in each state are required to have the qualifications requisite in the electors of the most numerous branch of the state legislature. Representatives are apportioned among the several states of the Union according to their respective numbers, which are determined by adding to the whole number of free persons (including those bound to serve for a term of years, and excluding Indians not taxed) three-fifths of all other persons. The House of Representatives consists of one member for every 77,700 persons in each state, estimated according to this rule: the enumeration is made by a general census taken every ten years. No person is eligible as representative who has not completed his twenty-fifth year, and been seven years a citizen of the United States, and who is not, when elected, resident in the state for which he is chosen. The Senate of the United States is composed of two senators from each state, elected by the legislature thereof for six years. One-third of the Senate goes out and is replaced by a new election every two years. A senator must be thirty years of age, nine years a citizen, and resident in the state for which he is elected. All members, both of the general and state legislatures, are paid for their services.

The President is elected by the whole people, for a term of four years: at the close of that period he may be re-elected; and, with the exception of three, all the presidents of the United States have been re-elected for a second term. Each state appoints a certain number of electors, who meet in their respective states, to vote for President and Vice-President, one of whom, at least, shall not be an inhabitant of the state. In Delaware, South Carolina, and Tennessee, the legislature chooses the electors; in Maine and Maryland, electors are chosen by the people voting for one or more in each district; in all the rest of the states, they are chosen by a "general ticket," upon which the whole of the electors vote. The electors transmit sealed lists of all the persons voted for as President, and all those voted for as Vice-President, to the president of the Senate, who opens the lists and counts the votes, in the presence of the Senate and House of Representatives. If for the person having the greatest number of votes for President, a majority of the whole electors have voted, he is declared President; if fewer, the House of Representatives elects by ballot one of the three who stand highest on the list. If for the person having the most votes for Vice-President, a majority of all the electors have voted, he is declared Vice-President; if not, the Senate names one of the two who stands highest on the list. The President and Vice-President must be natural-born citizens, thirty-five years of age, and fourteen years resident within the United States. The principle of electing representatives to the state legislatures, is almost that of universal suffrage; in most instances, every male citizen above twenty-one years of age, who has resided a year in the state, is an elector.

With an immensely large unoccupied territory, and general thinness of population, it is impossible to draw any just inference as to the stability of this still comparatively raw and untried republican government. It is suitable to the present condition of the country, but whether it will maintain this character after its population has become as dense as that of England, and great diversities of wealth and intelligence have arisen, is a question which time only can settle. In the meanwhile, the general character of the executive is feeble. The people, in a sense, are masters of the law, and have it in their power (in virtue of elective privileges) to intimidate its officers, or absolutely to set them at defiance. In the middle and eastern states, the efficiency of government for the repression of crimes is about the same as in Great Britain; but in the western states neither life nor property is safe from popular outbreak. The prevalence of slavery in the southern states aggravates this evil: personal security in New Orleans is at a lower ebb than in Italy or Madrid. Still, with these drawbacks, the United States is a great nation, in which civil freedom is on a grand scale, and is worthy of the enlightened community which has established and supports it.

GENERAL REMARKS.

The three great classes of governments which have been enumerated, among which Prussia is the most favourable type of a despotism, Great Britain of a constitutional monarchy, and the United States of a republic, require a word of concluding comment. Each of these nations has reached pretty nearly the same grade of civilization. The educated class of citizens in all of them will be found pretty nearly equal in respect to ge neral information, industrial skill, enterprise, and military courage. If the free citizens of the United States possess a greater amount of political power than those of Great Britain or Prussia, in neither of the two latter do we find a class of personal slaves. If the possession of the political franchise in Great Britain lends a greater degree of energy and self-respect to the middle classes of Britain than are possessed by those of Prussia, we will look in vain in the latter country for a class suffering such privations as the peasantry of Ireland, or the unskilled labourers of our den..ly peopled manufacturing districts. In America, the number of inhabitants who have received a common school education is greater than in either of the other; but the proportion which have received a university education is much lower. In Prussia, the direction given to the higher studies by the government, has placed the average scientific community far in advance of Great Britain: there has nothing been done in this country for the last twenty years to compare with what has been effected in history, geography, and science, *en masse*, in Berlin. On the other hand, British genius, developed uncontrolled by the school discipline, and encouraged by the demand of a wealthy community, has in individual cases soared to a higher pitch of invention. The morality of the three nations is much upon a level; as also the efficiency of their governments for repressing crime. The higher price paid by Great Britain for the services of government, is largely swelled by the amount of poor-rates: it is a compensating principle, redressing the less equal distribution of property which prevails in this country than in either the United States or Prussia. The price paid by Prussians for the services of government is greater than what is paid by Americans; but, in return, the organization of government over a large portion of America is more imperfect, and the protection it affords to person and property less complete. The secret of the high pitch of excellence to which government has been carried in all these countries, is, on the one hand, the power exercised by public opinion over the government; on the other, the power possessed by the state of availing itself of talent wherever it is to be found. Public opinion works directly upon government in the United States through the periodical elections; more indirectly in England, through the power of the press, and the House of Commons; more indirectly still in Prussia, through the training of the whole population to arms, and the constitution of the army. The universality of the elective principle in the United States, throws open the offices of state to all who are ambitious and capable. The forms of the British constitution oblige those possessed of political power to enlist the services of talent wherever they can find it. And in Prussia, the universities, and the appointment only of persons who have studied and undergone a severe examination, together with the order of promotion both in the civil and military service, open a career to the talent of all ranks. Government is well conducted in all these countries, in proportion as its duties are discharged as a matter of business, not of mere show or parade. The superstitious regard for the hereditary power of a monarch in Prussia, of an aristocracy in Great Britain, somewhat diminish the utility of government. On the other hand, the almost exclusive attention paid in America and Great Britain to guarding the individual rights of citizens, has left the organization of their executive government more slovenly. The executive of Prussia is more completely and skilfully organized: the individuals composing the executive governments of the United States and Great Britain evince, on the whole, greater robustness and energy of intellect; and we find in both these countries, what is found nowhere in continental Europe—an ability of self-government in localities far aloof from the central executive. On the whole, the review we have taken of the organization of these states, powerfully corroborates the conclusion arrived at in our theoretical section:—That good government, although it certainly promotes the civilization of a country, is much more its consequence than its cause; and that attention to the conduct and constitution of government, although a duty of the citizen, is only one of many public duties not less important and necessary, both to the general well-being of society and the happiness of the individual

LANGUAGE.

Language, in the largest sense of the term, may be defined as the means by which thought is expressed. Thought, as is well known, may be expressed by means of mute signs, as frowns, sighs, kind looks, gestures of the body; or by inarticulate sounds, as groans, cries, sobs, laughter. The first are usually called *natural language*, and the second *inarticulate language*; and these means of expression partly belong to the lower animals. Finally, there is *articulate language*, peculiar to man alone, and consisting of a multitude of sounds, each of which represents a distinct idea. To this last mode of expression, generally known by the simple term *language*, our attention is for the present to be directed.

ORIGINAL FORMATION OF LANGUAGE.

Overlooking the controversies which have taken place on this point, and from the revival of which no good could be expected, we are anxious on the present occasion to limit ourselves to the consideration of the hypothesis advocated by Dugald Stewart and others, that the formation of language is an effort within the scope of the faculties which man has received from his Maker. It may, we think, be considered under two points of view.

First, it is sufficiently clear that the vocal organs of men are constituted with a view to his expressing himself by speech. The larynx, epiglottis, pharynx, tongue, palate, and lips, are all of them framed in such a manner as to show incontestably that they were designed for producing such sounds as we employ in articulate language. It is scarcely less obvious that there is a distinct faculty of the mind for language. Some have powers of expression above all other intellectual endowments, so as to be considered as merely men of words. Others have good general powers of mind, but want adequate powers of expression, so that their gifts become of comparatively little use to their fellow-creatures. These diversities seem to shew that language is an intellectual faculty independent of all others. If, then, we consider that it is the nature of all faculties to be active, we can be at no loss to conceive how a variety of human beings, in a primitive condition, would begin to form language. They could not, indeed, be together, without beginning to use both their voices and mental gifts in a gabble, from which it would be but a work of time to resolve certain conventional sounds, as expressive of particular ideas. The imitative faculty would also help to form language. Objects would be named by words formed from sounds connected with them, as the wind from its whistling noise, the cow from its lowing, and so on. The Celtic language, which is probably one of the first that existed upon earth, is full of such descriptive words. In our own language, we still speak of the *mewing* of the cat and the *cawing* of rooks. The word *cuckoo*, so exactly descriptive of the note of the bird thus designated, ramifies through several languages. It is spelt *coucou* in French, and *cuculo* in Italian.

The other point of view in which we may contemplate the hypothesis, is that furnished by observation of the proceedings of children and of uneducated persons in expressing their ideas. The first language of a child is that of inarticulate sounds; it cries when it is hungry, screams when it is angry, moans when it is in pain. A tender mother can tell the state of feeling of her infant by the tone of its voice. Similar to these would be the first indications of feeling in the members of a primitive society; and by such means, unquestionably, they would communicate their sensations to each other. As children take the next step in language by imitation of the speech of the persons around them, they furnish us with no evidence as to the first formation of words in a primitive society; yet it is remarkable that, while the first consonants which children learn to articulate are those which are called *labials*, because formed by a meeting of the lips, the words denoting father and mother are, in most languages, composed of that very class of consonants. The strong resemblance which subsists between the words in different languages expressive of the first social ties, is also worthy of observation. Thus, the word mother is

Em and *am*	in Hebrew and Arabic.	*Modor*	in Anglo-Saxon.
Madr	··Persian.	*Moder*	··Swedish
Matr	··Sanscrit.	*Moder*	··Danish.
Mētēr	··Greek.	*Moeder*	··Dutch.
Mater	··Latin.	*Mutter*	··German.
Madre	··Italian.	*Mater*	··Russian.
Mère	··French.	*Mathair*	··Celtic.

Children and uninstructed persons show us how the next step would be taken—namely, how a word, originally applied to an individual or single object, would come to be applied to a whole species of similar objects. If a child, for instance, has been accustomed to call its father *pa*, it invariably, till it learns better, uses the same word with regard to any male stranger who may come into its presence. It considers that person as *a pa*. Adam Smith mentions that he had known a clown who did not know the proper name of the river which ran by his own door. It was *the river*, he said, and he knew no other name for it. His experience had not led him to observe any other river. The general word river, therefore, was, in his acceptation of it, a proper name signifying an individual object. If this person had been carried to another river, would he not, says Dr. Smith, have readily called it a river? We can thus see how, in a primitive society, if any of the chance sounds of their first jargon came to be applied to a natural object, such as a certain mountain near by, or a cave in which they took shelter, that sound would come to have a general application wherever they became acquainted with another mountain or another cave. And, in point of fact, we have still in existence examples of such primitive applications. *Uisk*, the Celtic for water, is the original of the names of a vast number of rivers throughout the wide territories originally peopled by the Celts: for instance, the Esk in Scotland, the Ouse and Isis in England, the Ouse in Holland, the Aisch in Bavaria, the Esker in Turkey, and the Uska in Southern Russia.

Grammarians have been struck by the remarkable fact, that the imperative mood is in most languages the simple form of the verb. For instance, in Latin, the imperative moods of the verbs, *dicere*, to say, *sonare*, to sound, *vivere*, to live, are *dic*, *sona*, *vive*. When, in Latin, the syllable *bam* is added to the imperative, it forms, in an immense number of instances, the imperfect of the indicative: thus, *sona-bam*, I did sound; *vive-bam*, I did live. This has suggested to philosophical inquirers into the origin of language, that entreaties and commands, expressions of the necessities and unregulated passions of primitive men, were the first form of the verb which they used, and that all other forms proceeded from these. Some even go so far as to say that this form of the verb must have preceded the formation of names of things. It is, however, generally admitted, that names of objects or nouns, and verbs, or words expressive of the motion and state of being of objects, were most probably the parts of speech first formed; and next to these, propositions, or that class of words which define the motion of verbs and show the relation of objects. "The noun and verb," says an eminent writer, "had each its archetype in matter and motion; and the proposition that marked local relation, and the termination or auxiliary that denoted the tenses of a verb, had each its original in space and time long anterior to the appearance of man upon earth."

Words expressive of the physical qualities of objects would probably be next introduced. Then words expressive of the nature, manner, quality, or intensity of the motions of those objects. The latter class of words grammarians have named adverbs.

The social feelings must have speedily given rise to the possessive pronoun; for it is natural to suppose that men would early learn to say *my* father, *my* brother, *my* daughter. When division of property began to be instituted, the selfishness and acquisitiveness which form such active principles in human nature, would lead to the frequent use of the possessive pronoun, and to the odious distinction between "mine and thine" (*meum et tuum*), which will create so much disturbance amongst us.

When man began to compare the qualities of surrounding objects, and to form consecutive sentences, another set of words, called by grammarians conjunctions, would necessarily be introduced. The word conjunction is derived from *con*, with, and *jungo*, I join, because it joins sentences together.

Interjections, or words intended to rouse the attention of the hearer, or to express the excitement of the speaker, would be used in the very earliest stages of society. The article, or word which is used to point out the noun, was apparently the last part of speech which was added to language.

The words used by the primitive members of society seem to have been all simple and uncompounded. What we now call compound words were, in many instances, originally composed of two distinct words, which, in process of time, have become inseparably joined. The two words which were united to form a third, were definitions of the object designated. Analogy and order can be traced in the construction of most primitive words; and it is probable that no word was originally formed from mere caprice. Even proper names, which now seem so destitute of signification, were originally indicative of some circumstance respecting the individuals or nations whom they designated. Thus, the King of the Goths, who was engaged in the destruction of the Roman empire, derived his name (Alaric) from two words signifying *universal king*. The name Ariovistus is compounded of two words which mean *much honoured*. The names of nations, countries, rivers, lakes, and mountains, were originally compounded on the same principles; so that the proper names of localities in different countries still serve as a sign to indicate by what primitive race the regions so named were inhabited in past centuries.

Language, after being first concrete, and then meta phor'cal, became, in process of time, abstract. There are two kinds of metaphor which pervade all language. The first kind of metaphor is used when the name of any object, in which a particular quality predominates, is diverted from its original signification to denote a similar quality in some other noun. For instance, the name *fox* was applied to men noted for their craftiness. A king of England was called Cœur de Lion, that is, *heart of a lion*, on account of his courageous deeds. The same kind of metaphor is used when we speak of the "silver moon." All languages abound with similar expressions. When the natives of Otaheite first saw horses, they called them "mighty hogs." The French call potatoes *pommes de terre*, literally, "apples of the earth."

The other kind of metaphor is used when we adopt a term originally applied to some physical object to denote some metaphysical abstraction. It has been observed that a sort of natural analogy exists between what comes within the scope of the senses and the abstract conceptions of the mind. Hence the metaphors of all nations, in every stage of civilization, are similar. No nation has yet been known to call truth darkness, or error light. Among all tribes, the word heart has been used metaphorically to express affection, the word rock to denote security, and sleep to signify death.

When the primitive men, advancing from early necessities and simple tangible ideas, found it necessary to have words to represent the abstractions of the mind, they still proceeded according to the dictates and analogies of nature. We have some trace of the course which they followed, in the history of the words which have been used to express the immaterial part of man. They felt that there was something within their corporeal frames which gave these impulse and direction, and they naturally formed the idea that this something was of an incorporeal nature. They also felt in the wind a something possessing strength and force, but which was impalpable to the sight. The wind, therefore, became at once a fitting emblem to describe the immaterial principle or soul of man. Hence, the Latin *anima*, the soul, is derived from the Sanscrit *an*, the wind. The Greek *psyche*, the soul, is connected with, and probably derived from, *psychos*, cold air. The Greek *pneuma*, a spirit (whence pneumatology, mental science), is from *pneō*, to blow. Our word spirit is from *spiro*, to breathe or blow. The Hebrew word for spirit signifies air or breath. Our word ghost or ghaist, a spirit, is of Saxon origin, and the same with *gust*, a blast of wind. These things evidently are so by virtue of a law of the mind, causing it everywhere to form the same ideas respecting the same things, and everywhere to pursue the same line of operations under certain circumstances.

The first framers of language pursued a similar course whenever they wanted a word to express any conception of the mind. In all languages, every term expressive of mental operations is borrowed from the material world. Some of the terms thus applied are signally appropriate. For instance, the word reflection signifies, primarily, the throwing or bending back of light; but, when applied metaphorically, it signifies, says Locke, "the bending back of the mind to take a view of its own operations." The same may be said of the verb to ruminate, which, in its original acceptation, means the action of an animal in chewing the cud; but, metaphorically, it signifies the action of the mind in recalling and meditating upon the knowledge (or mental food) previously acquired. Adjectives are constantly and familiarly used in a metaphorical sense. Thus we say "a warm heart," "a superior mind;" the adjective superior is simply a derivative from the Latin adjective *superus*, high. Prepositions are frequently used to convey metaphysical ideas. The words *above*, *below*, *under*, *beneath*, were originally applied to express the relations of natural objects. The primitive members of society, perceiving that the rain and the sunshine, the thunder and the lightning, proceeded from *above*, probably applied words synonymous with *above* to express what they admired and venerated in mental character. As *below* is the opposite to *above*, their ideas of what is degraded and vicious were expressed by terms synonymous with *below*; hence those common phrases—"he is *above* deception," she is *under* a mistake."

In the present stage of language we have become so habituated to the use of terms applied metaphorically, that we seldom reflect on their original import. There are many instances in which the metaphorical word remains, when its primary signification has been forgotten. For instance, the word *capricious* does not suggest the idea of a goat, although it is derived from the Latin *caper*, a goat, to denote the character of a person who bounds from subject to subject, without paying due attention to any; like a goat, which bounds from rock to rock, without settling long in any one spot.

During one period of the world's history, the only language may be said to have been that of metaphor. History, religion, systems of philosophy and of morality, were all wrapt up in allegory and metaphor. This is still peculiarly the language of the Eastern nations; perhaps it is mainly attributable to their imaginative and poetic temperament. The language of poetry, in every clime, is almost exclusively that of metaphor.

DIVERGENCE OF LANGUAGE.

The remarkable divergence in the languages of different nations is in part attributable to the following causes:—First, it is an ascertained fact, that few languages have any claim to be considered as the primitive dialect of any one race. Most languages afford indisputable traces of having been derived from some other language. Like many well-known operations in chemistry, by which the union of two or more substances produces a compound different in its properties and in its appearance from any one of its constituent parts, so, in many instances, several languages have contributed to form a new language, differing in its structure according to the proportion in which its constituent elements have been combined, and yet possessing distinctive characteristics of its own. These characteristics frequently vary according to slight peculiarities in the anatomical structure of the vocal organs of the individuals by whom it is spoken. It is well known that many people find it difficult, and in some cases impossible to pronounce certain consonants. A foreigner has great difficulty in articulating the English *th* in such words as thine, thee, and that. The English, on the other hand, seldom succeed in giving the right pronunciation to the guttural sound *ch*, which is of such frequent occurrence in the German language, and which is daily pronounced by the natives of Scotland, in such words as loch, light, and many others. Many persons are said to *lisp*, because they cannot pronounce the sound *sh*. The Ephraimites forfeited their lives from their incapacity of pronouncing this sound. If the Greeks had been at the fords of Jordan, they would likewise have found themselves in a similar predicament, for the syllable *sh* does not occur in the Greek language. The word *shibboleth* means an ear of corn, and in the Septuagint it is rendered by the word σταχυς (*stachus*), which in Greek has the same signification as the Hebrew shibboleth; but no Greek word could be found to express the sound *sh*; therefore in the Septuagint the narrative is imperfect. The natives of Otaheite could not be taught to say Captain Cook. They always called him *Toptum Toot*. The letter *c* does not occur in their alphabet.

It is impossible, at this distance of time, to calculate the amount of influence which this incapacity of articulating certain sounds must have had during the first periods of the world's history, in occasioning the present divergences of languages. It is a matter of daily observation, that children have great difficulty in articulating certain sounds every child has some particular way at first of pronouncing certain consonants, and uniformly exhibits the same peculiarity in the pronunciation of all words in which those particular consonants occur. Might not the dispersing children of a primitive society in this manner have carried away varieties of pronunciation, to be in time modified so far that resemblance was nearly or entirely lost? It seems natural to some men to sink certain consonants and to substitute others; this is particularly the case with those letters which have an organic affinity; thus, the Hebrew name *David* is in Greek *Dabid*. The Celtic word *pen* signifies an elevation; hence, the mountains which traverse Italy from north to south are called the *Apennines*. But the consonants which compose the word *pen* vary in different languages. Thus, in Scotland, we find the letter *p* converted into *b* in the names of mountains, as *Ben* Lomond, *Ben* Lawers, and *Ben* Nevis. In Spain, the consonants *p* and *n* are retained, but *g* is inserted; thus, in Biscay, there is a mountain called *Pegna* Cerrada, and another in Leon is called *Pegna* de San Romano. The Celtic word still retained in the Welsh language for a flow of water is *auon*: there are eight familiar instances in which the *u* in this word has been changed into *v*; for the name given to four different rivers in Wales, and to four in England, is *Avon*. Londoners make a constant practice of substituting *v* for *w* and *w* for *v*.

It seems natural, also, to sink one part of a word and to retain another. Instances of these abbreviations are very frequent. Thus the monosyllable *priest* is derived from the Greek πρεσβύτερος (*presbuterŏs*). The words *church* and *kirk* both come from the two words κυρίου οἶκος (*kuriŏu oĭkŏs*), literally, "the house of the Lord." The word *deacon* is derived from a word of four syllables, διάκονος (*di-ak-o-nos*). From the Greek word γάλακτος (*galaktos*), milk, the following words have sprung:—

Lacte in Latin.	*Leche* in Spanish.
Latte ·· Italian.	*Llaeth* ·· Welsh.
Leite ·· Portuguese.	*Lait* ·· French.

In all these words the first syllable of the original is omitted, and only part of the remaining syllables retained.

The principal sounds in a word are frequently transposed. The natives of Somersetshire, for instance, always say *claps* instead of clasp, *ups* instead of asp, *birsh* instead of brush. The word *garnet* is derived from the Latin *granatus*, and *purpose* from *propositus*. False orthography may also have been the cause of some variations in languages. A few centuries ago, it was considered marvellous when a gentleman or lady could either read or write. Du Guesclin, Constable of France, who died towards the close of the fourteenth century, could not sign his own name. During these periods of ignorance, many changes must have been made in the methods of spelling, and consequently of pronouncing words. Inattention and the love of novelty may also be assigned as causes of many divergences in languages.

A dialect is now in the process of formation in the West Indies, which has greatly attracted the attention of philologists, because it develops the principle upon which all languages at present existing are presumed to have been formed. It is called the *Talkee-talkee*, or Negro dialect. Its basis is the modern English, with which it combines many Dutch, Portuguese, and Spanish phrases. When a Negro attempts to speak English, he finds a difficulty in pronouncing the sound *th*, and substitutes *d*; he introduces vowels, even where they do not properly occur; and softens the language by omitting the harsh consonants, frequently substituting liquid ones. All these peculiarities are of course found in this new language; for instance, *drie* is three in Talkee-talkee; *dem* is them; *bakka* is back; *holi* is hold; *bruiloft* is bridal; *wilni* is wine; *morro* is more. The language still retains so much English, that our countrymen in the colonies can generally understand it. A version of the Scriptures in this language has been issued by the Bible Society. Many objections were made to this version. Those who contemplated the future emancipation of the Negro, contended that, by giving stability to a mere barbarous and fluctuating jargon, it was shutting up the avenue to future improvement; and that, though it might be advantageous to place the Scriptures within the comprehension of the Negro, yet that this version would render all the literature of England and of the world inaccessible to him, unless it could be possible to convey it in the barbarous Talkee-talkee. Time only can show whether the Talkee-talkee is destined to hold a higher place than it does at present in the scale of languages. A period might be mentioned when the English language was in a similar state of dissonance and incongruity. It is, as we shall hereafter require to mention, composed, like the Talkee-talkee, of a heterogeneous medley of languages; but its jarring elements are now amalgamated, and it is universally admitted to be one of the most polished languages of the world.

The political history and government of a country have considerable influence upon its language. In an enlightened community, in which a judicious attention is paid to the elementary education of the whole people on a uniform plan, varieties of dialect must in time almost cease, and a common style of speech be used. But where little attention is paid to this subject, or where no uniform principle is pursued, all kinds of jargons and dialects will abound. Great Britain is at present in the latter condition; the dialects of Yorkshire, Lancashire, Somersetshire, Cornwall, and some other counties, bear little resemblance to a pure English speech. A uniform system of education, communicated by teachers sent forth from a central institution, along with a greater intercourse by means of travelling, might be expected in time to eradicate this unseemly diversity.

CLASSIFICATION AND ANALOGIES OF LANGUAGES.

We are mainly indebted to the German critics for whatever advance may have been made in the comparative study of languages. Adelung, a German, was among the first who awakened the attention of Europe to this important study, and he has been followed by his countrymen Grimm, Bopp, and others whom it is needless to mention. It appears that the result of an extensive study of languages, is the conviction that two sorts of analogy prevail among them: first, a resemblance in words; and, secondly, in grammatical structure. Three different grammatical systems seem to prevail among languages; that is to say, the formation of parts of speech, and of the inflections from the primitives of the language, may be effected in three different ways—namely, first, by changes in the letters which compose the roots; second, by the addition of formative syllables to the root; and, third, by the use of separate words, instead of inflecting the roots. Which of these systems is the most ancient, is a question which has created much dispute. Humboldt, Bopp, and also Adam Smith, contend that the second method was the first adopted. It appears, from the history of languages, that, with the remarkable exception of the Chinese, in which the relations of syntax supply the place of inflected words, a gradual progress of simplification has been going on in all languages. Thus the Greek and most of the Oriental languages have a passive form of the verb, inflected cases of the noun, and a dual form. The Latin, which probably was partly derived from the Greek, retained the passive verb and inflected declensions, but rejected the dual form. The Italian and French, which were derived from the Latin, rejected both the passive form of the verb and the inflected cases of the noun. The remaining step of simplification was, to substitute the natural distinctions of gender for those previously in use, which were formed on arbitrary principles, depending chiefly on the termination, and to do away with the necessity of making the adjective agree with the noun in gender and number. This was effected by the English. The whole history of this process reminds us of that of many mechanical inventions, which at first were complex in the extreme, but which by degrees were made to part first with one unnecessary wheel, and then with another, thus becoming more and more simple in their structure, and perhaps more available for the purposes for which they were designed. As grammatical systems are thus found to vary in process of time, and in languages, too, which are evidently derived from the same root, languages are classified more with regard to their vocabulary than according to the structure of their grammar. In the best systems of classification, particular attention has been paid to the agreement in sound of those words which are used in the first stages of society. When terms expressive of hunger, thirst, the sun, moon, stars, are found nearly alike in several languages, it is apparent that the nations by which they are used belonged, in bygone centuries, to the same tribe, and migrated from the same district. The study of languages often enables us to trace the origin of nations, when all other avenues of information are lost in obscurity and fable, and it is hence, in other words, the study of man's history.

The number of languages and dialects, ancient and modern, has been computed by Adelung to be 3064: namely—

Belonging to Asia	987
.. .. Europe	587
.. .. Africa	276
.. .. America	1214
Total	3064

It would take more space than our limits permit, to give a tabular view of all languages: the following summary contains the principal families, and the classes in which they are generally placed:—

I. *Monosyllabic Class.*—Chinese, Siamese, Avanese, Japanese.

II. *Shemetic* or *Semetic Class.*—Aræmean (Chaldee Syriac), Hebrew, Phœnician, Arabic.

III. *Indo-European* or *Indo-Germanic Class.*—Sanscrit, Celtic, Teutonic or Gothic, Pelasgic or Greco-Latin, Sclavonic, Hungarian, Tartarian or Turkish.

IV. The *Polynesian Class*, consisting of the dialects spoken in the Indian archipelago and islands of the South Seas.

V. The *African Class.*—Remains of the ancient Lybian in the north; Soosoo and Foulah (between the rivers Senegal and Gambia); Ashantee: Amaaric, spoken in parts of Abyssinia; Hottentot, in the south; Caffre, extending from the south along the east coast as far as Delagoa Bay.

VI. *Polysynthetic Class*, extending from north to south of both continents of America, and comprising Chilian, Peruvian, Brazilian, Mexican, Western dialects of North America, Boreal dialects of North America, &c.

The contrast between the first and the last of these classes, presents an apparent anomaly. The Chinese languages have existed among a polished people from very remote antiquity, and yet are as rude and simple as if they had been just devised for the use of a nation but recently emerged from barbarism; whereas the languages in common use among the wild tribes of America, are complex and difficult in their structure, and seem as if they had been invented by a people who had made great advances in civilization. It has consequently been surmised that America was at one time the residence of a civilized people, of whom the Indian tribes are the degenerated remains.

WRITTEN LANGUAGE.

The first origin of written language may be traced to a desire, apparently natural to man, to perpetuate a record of his actions, thoughts, and feelings, beyond the narrow span of his own existence: he knows that the past is no longer his, that the present is fast fleeting away, and therefore he seeks to be in some way connected with the future. Even savages devise means of transmitting to their children's children a record of themselves. The American Indians at this day carve upon the handles of their tomahawks figures of warriors without heads, to denote how many of their enemies they have scalped. The Mexican picture-writing appears to have been equally simple. When the Spaniards first invaded Mexico, the natives painted an exact representation of the Spanish ships upon cloth, which they sent as expresses to their emperor, Montezuma. The records of their empire were delineated in the same manner. A conquered town was represented by a house, generally with some emblem annexed, to show what particular town was meant. Some of these paintings, which may well be considered as the most curious specimens of art which have yet been discovered in America, are carefully preserved in the Bodleian Library at Oxford. The representation of natural objects seems to have been the first step which was taken in the art of writing. The next step was probably the delineation of invisible ideas by symbolic representations: such, for instance, as *strength*, which was represented by the figure of a lion, on account of the great strength of that animal. As civilization advanced, more time was devoted to writing, and it was then discovered that part of an object would represent an idea as well as the whole. Thus, a sceptre was made to represent a king. Smoke ascending, symbolized fire. A battle was represented by two hands, one holding a bow and the other a shield. By degrees, these signs became conventional; that is to say, it became a matter of agreement that certain ideas should be represented by certain signs. This kind of symbolic writing was much in use among the Egyptians. It has been proved by Champollion, who devoted twenty years to the investigation of the subject, that the symbolic characters which they used were limited to 864, which he has arranged under the following eighteen classes:

Celestial bodies	10
Human figures in various positions	120
Human limbs taken separately	60
Wild quadrupeds	24
Domestic quadrupeds	19
Limbs of animals	[illegible]
Birds either whole or in parts	50
Fishes	10
Reptiles either whole or in parts	30
Insects	14
Vegetables, flowers, and fruits	60
Buildings	24
Furniture	100
Coverings for feet and legs, head-dresses, weapons, ornaments, and sceptres	80
Tools and instruments	150
Vases and cups	30
Geometrical figures	20
Fantastic forms	50
Total	864

The reason of this limitation is very obvious. As all natural objects might be used as symbols, the number of characters might have been multiplied *ad infinitum*, unless regulations had been made to restrict the number. By degrees, as these characters became universally known as fixed and permanent signs of the ideas they represented, less trouble was taken in their accurate delineation, so that they were made less like the visible object of which they were originally the image. At length, all traces of resemblance were lost, but the character, in its abridged and mutilated form, still continued to be conventionally recognised as the sign of the same idea of which it was originally the symbol. This is the exact state in which the written language of China now stands. The elementary Chinese characters are 214 in number, and are called *keys*. These keys are merely formed by the various combinations of six straight and variously curved lines. From these keys, the other characters, which are generally reckoned to be 80,000 in number, are formed. Each character represents, not a letter but a word; and though the characters have now no resemblance to any particular object, yet there is little doubt that, at some remote period, they were, like the ancient Egyptian hieroglyphics, accurate transcripts of some objects in nature.

Much labour has lately been bestowed upon the study of the Egyptian writing, particularly by Young and Champollion. It appears that three kinds of writing were common among the Egyptians.

I. The HIEROGLYPHIC, so called from ἱερος (*hièrŏs*), "sacred," and γλυφω (*gluphō*), "I carve," because it was at first believed that this kind of writing was intelligible only to the priests. It consisted of the images of visible objects, and was chiefly used in monumental inscriptions.

II. HIERATIC, also from ἱερος (*hièrŏs*), "holy," because used by the priests. Some of the manuscripts which have been found attached to mummies, consist of this kind of writing, which was merely the rude outline of images.

III. DEMOTIC, so called from δημοτικος (*dēmotikos*), "of the people," because it was in common use. It was also called *epistolographic*. Another name for it is *enchorial*, from εγχωριος (*egchoriŏs*), "of the country," because the characters were different from those of Greece. This kind of writing was a still further reduction or simplification of the others, approaching very nearly to the Chinese method.

Nothing was known in Europe respecting the meaning of the Egyptian writing, until the French, in digging a fort at Rosetta, found an irregular block of basalt. This stone, which is smooth on one side, has three inscriptions; one in hieroglyphics, the second in enchorial or demotic characters, and the third in Greek. The Greek inscription concludes with the information, that the decree it contains was to be engraved in three different characters; namely, in the sacred letters, in the letters of the country, and in the Greek. Profiting by this information, M. Champollion succeeded, by means of the Greek, in deciphering part of the other inscriptions. Other documents have recently thrown more light upon the meaning of Egyptian writings; but the Rosetta stone is still justly considered to have been the key to the whole mystery.

By degrees, as knowledge increased, and as writing became more and more resorted to, it was discovered that the labour would be greatly diminished by making each symbol represent, not a word or idea, but a simple elemental sound. This increased the number of characters in one word, and at the same time greatly diminished the number in the language; for previously only one character had represented a word, and for each word there was a distinct character; but by this arrangement the elemental sounds of the language were analyzed, and a particular character appropriated to each. This is the origin of alphabetic writing. The Hebrew is evidently the connecting link between the symbolic and the alphabetic modes of writing. It appears that each character, like the Chinese, originally represented a word. Tradition ascribes a meaning to each letter, as is shown in the following table; these words are now obsolete, and are not to be found in any lexicon:

HEBREW LETTERS	NAME.	MEANING.
א	Aleph.	Ox.
ב	Beth.	House.
ג	Gimel.	Camel.
ד	Daleth.	Hollow.
ה	He.	Hook.
ו	Vau.	Armour.
ז	Zayin.	Travelling scrip.
ח	Cheth.	Serpent.

This table might be extended throughout the whole Hebrew alphabet, but the foregoing examples will suffice to show the transition from the symbolic or hieroglyphic to our present system of alphabetic writing.

The similarity in the names and original signification of some of the Greek characters, proves that they were derived either from the Hebrew or from some of the cognate dialects. The most ancient method of reading and writing among the Greeks was that called βουστροφηδον (*bŏustrŏphēdŏn*), "ploughed by oxen," because the custom was to read backwards and forwards, in the same way that an ox draws the plough: thus, one line was read from right to left, and the next from left to right. Cadmus introduced from the East only sixteen letters, and it has long been a matter of conjecture as to when the other characters were added. The invention of four additional letters is ascribed to Palamedes, about 1164 years B. C.

The art of writing seems to have been known at a very early period, but after all the researches that have been made, it is not yet possible to say with certainty to what nation we owe the invention of this useful art; so that the poet's question still remains unsolved—

> "Whence did the wondrous mystic art arise
> Of painting speech and speaking to the eyes?
> That we by tracing magic lines are taught
> How to embody and to colour thought."

Inscriptions, of which it is impossible to fix the date, have been found at Babylon and at Persepolis, which have created much conjecture among the learned. The characters found at both places seem to be essentially the same, making due allowance for the difference of the material; the Persepolitan characters being finely sculptured on marble, while the Babylonian are rudely carved upon bricks. They are commonly known by the name of the *arrow-shaped* characters, on account of their general resemblance to arrow-heads.

The art of writing must have been discovered before the Israelites left Egypt, which was B. C. 1491, because, in the history of their journey through the wilderness, many allusions are made to writing, as if it were an art well known to them. See Exodus xvii. 14—"Write this for a memorial in a book," &c. Also, Deuteronomy chap. vi. 9; xi. 20; xvii. 18; xxiv. 1; xxvii. 3, 8. It is an established fact that Moses wrote a great part of the Pentateuch himself. Many have supposed that the book of Job was written at a still earlier period. The characters used by the Jews before the Babylonish captivity were those which we now call the Samaritan. This appears to have been the case, from some coins which were struck before the revolt of the ten tribes, of which the inscriptions are in Samaritan characters. While the Jews were in Babylon, they became accustomed to use the characters of that empire, so that their own, from disuse, became partially forgotten. It was on this account that Ezra copied out the books of the law into the square letters of the Chaldees. These are the characters which constitute what we call the *Hebrew* alphabet.

It is very difficult to ascertain at what period alphabetical writing was first practised in Europe. We are told that Cadmus introduced it into Greece about 1519 years B. C.; but it has been conjectured that it was previously known to some of the other European nations. Odin, or Woden, who lived at so remote a period that his history is almost lost in fable, is said to have introduced the Runic alphabet into Scandanavia. Tradition relates that he brought it from the East. It contained only sixteen letters, which seems to have been the number of all the primitive alphabets. The Runic characters were used by all the Gothic nations, and were applied by the priests or bards to magical incantations. They pretended to have, by means of these characters, the powe of "calling down the moon and stars from heaven, or arresting the course of the most rapid rivers, of quenching fire, of bursting asunder the gates of death, and of calling departed spirits from the deep." After the introduction of Christianity, many attempts were made to prevent the use of these characters, which had gradually become perverted to the worst of purposes. They were ordered to be suppressed by the council of Toledo in the year 1116.

There is a striking resemblance between the Welsh and the Runic alphabets. They were both evidently contrived for a people who had no materials or implements for writing but wood and a pointed flint or stone. The early events of history in England were recorded in songs by the bards or Druids, and thus handed down from father to son. Various inscriptions have been found in Ireland, which prove that the Irish were in possession of the art of writing at an earlier period than is generally supposed. Like the Romans, who, at an early period of their history, wrote upon wood, the Irish made use of the wood of the beech; hence the letters themselves received the name of *Feadha* or woods. Besides the alphabet in common use, the Irish had an occult form of writing, called *Ogam* or *Ogma*, apparently of very high antiquity. The derivation of the term *ogam* was long unknown; it has but very lately been discovered that it is a primitive Celtic word signifying the *secret of letters*. There are some letters still carefully preserved in the Harleian Library, written in these occult characters by Charles I. to the Earl of Glamorgan. The alphabet is formed of a perpendicular line, from whence lateral scratches diverge to the right and left. These scratches are never more than five on each side, answering to the number of fingers. They are very similar to those found in Egypt by Mr. Hammer, and to those which were used by the Manchew Tartars. It has been conjectured that this alphabet was originally used by the Chinese, who still write from top to bottom. The method of communication called the *Quipoz*, used by the Peruvians, was by knotted cords, each knot representing an idea or sound. The invention of printing, which took place about the middle of the fifteenth century, forms quite a new era in the history of language and of man. It is utterly impossible to estimate the effects of this invention in the diffusion of knowledge and in the development of the human mind. A written language has been devised also for the blind. The alphabet consists of embossed letters. Sometimes the Roman characters are used, but more frequently, perhaps, different modifications of triangles are found available. The sense of touch is made to compensate for the loss of sight; the idea is conveyed almost instantaneously from the written sign to the mind by the medium of the hand, and thus a vast accession of pleasure and of consolation is obtained by this afflicted portion of our race. There is another kind of writing well known in England called *stenography*, from στενος (*stenos*), "short," and γραφω (*graphô*), "I write;" it is designed to lessen the labour of writing by substituting more quickly formed characters for those in general use. Another art has lately been added to the various forms of abbreviated writing, which seems far more available than any which have hitherto been invented. It is called *phonography*, or, literally, *writing by sound*—that is, writing each word exactly as it is pronounced. It does away altogether with the tedious method of spelling, for it has distinct signs for all the sounds of the human voice. It is applicable to all languages. We have before us a book containing part of the Scriptures in English, French, German, Chinese, and Hebrew, all written in the phonographic character. Nothing has yet been invented which comes so near to the "universal character" so much desired by Bishop Wilkins. If generally introduced, it would be a very valuable acquisition to the deaf and dumb, enabling them to express their thoughts with almost as much rapidity as we can do by speech.

MONOSYLLABIC CLASS OF LANGUAGES.

The name given to this class arises from the circumstance, that every word in the languages strictly belonging to it consists only of one syllable. To express a complex idea, two of these syllables are put together, in the same way that we say, in English, *book-case*, *snuff-box*. The Chinese language, although consisting of very few radical words, appears extremely difficult to a European, on account of the different meaning given to each word by the various inflections of the voice. One word is often susceptible of five distinct meanings, according to the tone of voice in which it is uttered; so that, though there are only 328 primitives, these different intonations of voice greatly augment the number of words. It would require the labour of a whole life to become acquainted with all the words in the language, but those which are in common use are comparatively of easy acquirement. All that is required of their mandarins, or learned men, is merely to be able to read and write 2000 of their characters. The language of China has continued in a stationary state for many centuries. This may be ascribed not only to their confined and isolated position, secluded by a jealous policy from intercourse with other nations, but also to the early introduction of a singular sect among them, who inculcate that total quietism or inactivity is the only way to perfection. Another sect taught that "the nearer they approached to the perfect inaction of inanimate bodies, the more they resembled the Deity." Taking into account the influence of these pernicious maxims, and the tyrannical despotism of the government, it ceases to be a matter of surprise that the language of China should, century after century, remain unchanged and unimproved. There is no doubt but that the Chinese, at some very remote period, had intercourse with the Egyptians; this seems evident from the affinity between the written languages of the two nations. There are several reasons which might lead us to suppose that the Chinese and Egyptians originally constituted but one people; but this a subject which is much involved in conjecture. Ethnography, or the study of nations and languages, may almost be said to be yet in its infancy. As the science advances, more light will no doubt be thrown upon this most interesting subject. An analogy has already been traced between the pronominal affixes and suffixes of the Coptic or modern Egyptian and those of the Hebrew. An affinity has also been found to exist between some of the Chinese and Hebrew characters. Perhaps it may be proved that the Hebrew is a connecting link between the Chinese and Egyptian languages.

THE SHEMETIC CLASS OF LANGUAGES.

This class is usually divided into three principal branches—namely, the Aramean, the Hebrew, and the Arabic. The Median or Persian is by many classed among the Indo-European languages; but its close connection with the Arabic seems to justify its being placed in the Shemetic class. Chardin relates that the Persians study the Arabic grammar and syntax in order to make themselves acquainted with their own language; the only difference between the construction of the two languages being, that the Persians have no dual form.

Of all the Shemetic languages, the Arabic is the most widely extended. It is still the vulgar language in Egypt, Lybia, the shores of Africa, as well as in Arabia and Palestine. In Turkey, Armenia, Mesopotamia, Persia, India, and Tartary, it is extensively cultivated, and used as the vehicle of communication between different nations. Most of the other Shemetic dialects are either extinct or spoken in districts of small extent. The structure of all the Shemetic languages is very simple. They are written from right to left. Their grammatical connections are formed by prefixes and suffixes. They have no form of comparison. The nouns have two genders; no terminations or inflexions of case; but a peculiar form called the *construct*, for expressing the relation of the possessive or genitive case. Most of the radical words consist of three letters forming two syllables, though some consist of only two letters. The words are generally short, and the compounds inartificial.

The Hebrew is distinguished for its simplicity, purity, and energy. The verb is in this language the most important part of speech, and the root of most of the others. In all the western languages, such verbs as *jacère*, to throw, and *jacēre*, to lie, form separate and distinct conjugations. But in Hebrew, verbs thus connected in signification are also connected in the method of conjugation, and are regularly and analogically conjugated by varying one of the vowels or by doubling or adding letters. The inflexion of the personal pronoun, for expressing the relation of case, is also different from the inflexions of pronouns in any of the Indo-European languages. The personal pronoun never occurs as a separate word, except in the nominative case; thus, אֲנִי (*ani*) signifies I, and הוּא (*hu*) he; but to express the genitive, or other oblique cases, fragments of these pronouns are subjoined to the noun or verb, so as to form but one word; for instance, דָּבָר (*davar*) signifies a word, and דְּבָרִי (*dèvari*) my word; קָטַלְתִּי (*katalti*) signifies I have killed, and קְטַלְתִּיהוּ (*kètaltihu*) I have killed him.

When Hebrew ceased to be a spoken language, the correct mode of pronunciation was gradually forgotten. To remedy this inconvenience, the vowel points were invented, which are merely strokes or dots placed beneath the consonants, to denote what vowel sound is to be combined with the consonants under which they stand. The antiquity of the vowel points has created much dispute; but it is generally supposed that they were invented by the Jewish rabbins about five or six hundred years after Christ.

No writings in pure Hebrew are extant except the Bible. The modern or rabbinical Hebrew is so much compounded with other languages, that it has become quite a new dialect. The Chaldee language was closely allied to the Hebrew, and was early introduced into Babylon. There are 268 verses of pure Chaldee in the Bible. The ancient Syriac was another cognate dialect, and is still cultivated by the Nestorian and Maronite Christians in the East. The ancient language of Ethiopia, or, as it is now called, Abyssinia, was Chaldee. The Arabic may in some respects be called a copious language. It has 500 names for a lion, 200 for a serpent, 1000 for a sword. The multitude of synonymous words renders it so difficult, that Mahomet pretended that he had been taught by the angel Gabriel the language of Ishmael. There are many Arabic idioms in the book of Job. The country in which Job lived, if not included in Arabia, was situated on its very borders; and his three friends were Arabian. It is scarcely possible to comprehend the depth of meaning in the book of Job without a knowledge of Arabic. The language of Arabia has been much corrupted since the Koran was written, by admixture with other tongues. The unconquered tribes among the high lands of Yemen preserve it in the greatest purity, because they have had less intercourse with strangers. The language of the Koran is taught in colleges at Mecca with the same care that Latin is taught at Rome. It is now, in fact, the learned tongue of the country. The ancient Persian language was divided into two branches—Deri, which was spoken at court, and Pahlavi, the language of the learned. There was, besides, a third dialect, but so obscure and abstruse, that it was accessible only to priests and philosophers: only one book was written in this dialect: it consists of religious precepts; the letters in it are called *zend*, and the language *avesta*. Of all the Persian dialects the Deri was the most soft and harmonious; so that it became a common saying, "that God delivered his stern commands in the rapid accents of Arabic, and his milder mandates in the delicate accents of the Deri." The modern Persian is very different from the ancient, and the Arabic characters are now generally adopted.

Such were the principal languages of the Shemetic class. They all agree in grammatical structure, and in a remarkable stiffness of construction, arising from the want of particles and of forms for expressing the various relations of things. They had not sufficient scope to admit of much philosophical or metaphysical reasoning. The character of a people, as well as their literature, may be always inferred from the genius of their language; for language is but a mirror in which the ideas of the soul are reflected and made visible. Therefore, as might be expected from their language, the Shemetic nations made few advances in mathematical or philosophical science. Their attainments in the liberal arts were but limited, and they made few valuable discoveries. The invention of letters has been attributed to the Phœnicians; but this rests on very doubtful authority, and all that now remains of their language is the inscriptions on a few coins. The science of astronomy has, in the same way, been supposed to have originated with the Chaldeans; but it is evident, from all their writings, that their notions on this subject were very obscure and confused. For instance, they thought that the shape of the earth was that of a boat, and that, when all the planets meet in Cancer, it will be destroyed by fire; and when they meet in Capricorn, it will be swept away by an inundation. Several books were written about the time of the Christian era, which, the authors pretended, were the production of the ancient Chaldeans and Persians; and as it is not always very easy to detect the forgery, much caution is requisite in investigating the subject. The writings of the ancient Shemetic family, which are known to be genuine, contain but little real philosophy. The object of the so-called wise men among them was to excite wonder rather than to disseminate the truth. The little they knew was imparted only to the few, and concealed from the vulgar by studied mysticism of language.

THE INDO-EUROPEAN CLASS OF LANGUAGES.

The languages belonging to this class are spoken in the greater part of Europe and in part of Asia—from the island of Ceylon to the shores of Iceland. They still form a connecting link between nations who now resemble each other but little in form or colour, and whose religion, government, and institutions are widely different. The Sanscrit is one of the most ancient of languages. Its name imports the *language of perfection*. It contains the roots of the Latin, Greek, Celtic, German, and Slavonic languages. It is more easy in this language than in any other to analyze compound words, and reduce them to their primitive radicals. It contains many compound words; some consists of no less than twenty syllables. The grammar is complex and difficult. There are, as in Hebrew, Chaldee, Arabic, and Greek, three numbers—singular, dual, and plural. A distinguished scholar, Sir William Jones, has said, that "Sanscrit is more copious than the Latin, more perfect than the Greek, and more exquisitely refined than either; yet that it bears to each of them a stronger affinity, both in the roots of verbs and in the form of grammar, than could possibly have been produced by accicient." It appears that Sanscrit was once the current language of India; now, it is shut up in the libraries of the brahmins or priests of the country, invested with mysterious sanctity, and used alone for religious purposes. It is cultivated only by the learned, so that it now takes its place among the dead languages. The names of objects in all primitive languages are descriptive and often highly poetical. This is eminently the case in Sanscrit. The name given to

A frog, - -	signifies, literally,	The leaper.
An elephant, -	.. .	The handy one.
A bee, - -	.. ..	The flower-drinker.
A bird, - -	.. ..	The frequenter of the sky.
A serpent, -	.. ..	The mover on his breast.
Rice, - -	.. ..	Tuft-growing.
A cloud, -	.. ..	Water-giver.*

Another respect in which the Sanscrit closely resembles the Greek, is in the use of the *a* privitive. Thus, *cartum* signifies *to do*, but *acarm* signifies *a crime*, or, literally, that which should *not* be done. Almost all the languages which are spoken in India, are merely dialects of the Sanscrit, and immediately derived from it. The Sanscrit family is therefore a very large one. The dialect called Bali, or *Magudha*, that is *mixed*, is spoken beyond the Ganges; Bengalee is spoken in and about Calcutta; the Hindee or Hinduvee, about Agra; Hindustanee prevails in Lower Hindostan. The Afghan dialect contains more Hebrew words than any of the above. A Persian tradition relates, that the Afghans came from the north about two thousand years ago, and that they are the descendants of King Saul. The Multan dialect, which is spoken to the north of Sindh, contains a great many Persian words and idioms. The language spoken among the Gipsies approximates more to this dialect of the Sanscrit than to any other; so that it is probable they originally emigrated from this part of Asia. They are known in various countries by the name of Bohemians, Gitanos, Zigani, &c.; but in every part of the world, they invariably style themselves and their dialect *Romany*, from a word signifying husband. The Celtic family is also of Asiatic origin. Europe has been successively occupied by different tides of population, which poured in from the East. The Celts appear to have been the first settlers in Europe. They were compelled to move more and more westward, to make room for the other Asiatic tribes who successively invaded Europe. The Celts, or Celtæ, as they were then called, thus irresistibly impelled westward, at length reached Gaul, whence they are supposed to have crossed the sea to Britain, whose first inhabitants they are believed to have been. If this was the case, the first language spoken there was, of course, the Celtic. The Celtæ were not allowed, however, to remain in quiet possession of Britain; the successive invasions of the Romans, Saxons, and Danes, drove them to the north and western parts of the island, where their descendants are still found, and where dialects of their language are still spoken. The Celtic language now comprises the following dialects:—1. Gaelic, spoken in the Highlands of Scotland; 2. Erse or Irish, spoken in Ireland; 3. Welsh, spoken in Wales; 4. Manks, spoken in Isle of Man; 5. Cornish, spoken in Cornwall; 6. Armorican, spoken in Bretagne or Brittany. History affirms that, at a very early period, the Phœnicians traded with the first inhabitants of Britain for tin. If this be true, it may account, in some degree, for the words of Eastern origin which exist in the Celtic dialects. The affinity, however, which they still retain to the Sanscrit, although their structure has been considerably altered by the lapse of centuries, clearly proves them to be of cognate origin.

It is not known exactly at what period the Celtæ became first settled in Ireland. The Highlanders of Scotland are descended from a colony of these Irish Celts, who, about the beginning of the sixth century, migrated to the west of Scotland, bringing with them the dialect of the Celtic which was then spoken in Ireland, and the name of Scuite or Scots.

The Welsh, Cornish, and Armorican dialects, are formed from that branch of the Celtic family which was called the Cymbric. The frequent changes of the initial letters of the radical words, in the formation of cases and numbers, are the characteristics of all the Celtic dialects. In Welsh, there are nine mutable initial letters, called *literæ umbratiles*, from the Latin *umbra*, a shadow, because they change and vanish like a shadow: for instance, *tâd* is father, *ei thâd* is her father; *ei dâd* his father; and *fy nhâd*, my father. *M* also is frequently converted into *f*; this *mam* is mother, and *ei fam*, his mother.

The Basque language is a dialect of the old Spanish or Iberian. It is spoken in Biscay and Navarre in Spain, and in Lower Navarre and Soule in France. In some words it resembles the Celtic family; thus, father is *aita* in the Basque, and in Irish *aidir*. The celebrated traveller Humboldt affirmed that he discovered a strong resemblance between the Basque language and that of the American Indians.

The Teutonic or Gothic Family.

The second tide of population which poured into Europe from the East, consisted of the Germanic tribes: they are generally called the Teutons, or Goths, in history. In this family we are more especially interested, as it is from the Teutonic branch that the principal portion of the present inhabitants of Great Britain are descended

The languages of the Gothic tribes parted into two main branches. The *first*, called the GERMAN or TEUTONIC BRANCH, gave rise to two sub-branches—from one of which originated the Anglo-Saxon, Friesic, and Old Saxon; from the Anglo-Saxon came the modern English, and from the Friesic and old Saxon came the Low German or Dutch, and the Flemish, spoken in Belgium. From the other sub-branch sprang the Mœso-Gothic, the Alemannic and Frankic; and from a union of these three originated the High Dutch or German proper. The *second* great branch is comprehensively called the SCANDINAVIAN. It was the language of the ancient Scandinavians, spoken in Denmark, Norway, Sweden, Iceland, Greenland, Feroes, and the Shetland and Orkney Islands. From it have sprung two distinct branches, one of which is the modern Icelandic, and the other is that comprehending the modern Danish, Swedish, Norwegian, and the dialect called Lowland Scotch.

German Language.—The *Hoch Deutsch*, or, as it is called by us, the German language, is spoken in the various countries on the Upper Rhine (Baden, Nassau, and many other states), in Prussia, Austria, part of Switzerland, and various countries on the Baltic, including part of Russia. To an Englishman it appears harsh, and at first very disagreeable; but it improves on acquaintance, and is found to be expressive and copious. It is said to consist of at least 80,000 words, or more than double the number in the French or English languages. Originally consisting of various dialects, including those of the Mœso-Goths and Franks, it has latterly, by the progress of literature and education, been established in the distinct form in which it appears in German literature. Luther's Bible, of which the first edition was issued in 1545, was principally instrumental in the establishment and dissemination of this peculiar combination of dialects. The German language since that period has had few if any changes; the German of 1841, compared with that of 1545, will be found to differ chiefly in orthography. In German, as in Eng-

* See *Etymological Researches*, by J. Townsend, M.A. Bagster, London.

tal, there are two articles, the definite and the indefinite, but the definite article has a plural, and in all the various cases of the singular number it has distinct terminations for the three genders; so that it denotes whether the substantive before which it stands is masculine, feminine, or neuter, and also whether it is singular or plural. Both articles have four cases. One peculiarity of the German is the frequent addition of the termination *inn* to denote the feminine gender. For instance, *der löwe* signifies the lion, and *die löwinn* the lioness. This termination is also used to express a female title, it being the custom in Germany for a wife to share the title of her husband. Thus, *der rector* signifies the rector, and *die rectorinn* the *rectoress* or rector's wife. *Die professorinn* signifies the professor's wife, and *die doctorinn* the doctor's wife. The following are specimens of the mode of conjugating the two important auxiliary verbs *to have* and *to be*:—

HABEN, *TO HAVE.*

INDICATIVE.		CONJUNCTIVE.	
		PRESENT	OPTATIVE.
Ich habe,	*I have.*	Ich habe,	*I may have.*
Du hast,	*thou hast.*	Du habest,	*thou mayest have.*
Er (sie, es) hat,	*he (she, it) has.*	Er, (sie, es) habe,	*he (she, it) &c.*
Wir haben,	*we have.*	Wir haben,	*we may have.*
Ihr habet,	*you have.*	Ihr habet,	*you may have.*
Sie haben,	*they have.*	Sie haben,	*they may have.*
	IMPERFECT.	CONDITIONAL.	OPTATIVE.
Ich hatte,	*I had.*	Ich hätte,	*I might have.*
Du hattest,	*thou hadst.*	Du hättest,	*thou mightest have.*
Er hatte,	*he had.*	Er hätte.	*he might have.*
Wir hatten,	*we had.*	Wir hätten,	*we might have.*
Ihr hattet,	*you had.*	Ihr hättet,	*you might have.*
Sie hatten,	*they had.*	Sie hätten,	*they might have.*

SEIN, *TO BE.*

INDICATIVE.		CONJUNCTIVE.	
		PRESENT.	OPTATIVE.
Ich bin.	*I am.*	Ich sei,	*I may be.*
Du bist,	*thou art.*	Du seist,	*thou mayest be.*
Er (sie, es) ist,	*he (she, it) is.*	Er (sie, es) sei,	*he (she, it) may be.*
Wir sind	*we are.*	Wir seien,	*we may be.*
Ihr seid.	*you are.*	Ihr sei(e)d,	*you may be.*
Sie sind	*they are.*	Sie seien,	*they may be.*
	IMPERFECT.	CONDITIONAL.	OPTATIVE.
Ich war,	*I was.*	Ich wäre,	*I might be. I were.*
Du warest,	*thou wast*	Du wärest,	*thou mightest be.*
Er war,	*he was.*	Er wäre,	*he might be.*
Wir waren,	*we were.*	Wir wären,	*we might be.*
Ihr waret,	*you were.*	Ihr wäret,	*you might be.*
Sie waren,	*they were.*	Sie wären,	*they might be.*

It may likewise be interesting to know the names of the cardinal numbers in German, with a view to comparing them with our own Anglo-Saxon terms.

CARDINAL NUMBERS—(*Grundzahlen*).

Eine	1	Ein und zwanzig	21
Zwei	2	Zwei und zwanzig	22
Drei	3	Drei und zwanzig	23
Vier	4	Vier und zwanzig	24
Fünf	5	Fünf und zwanzig	25
Sechs	6	Sechs und zwanzig	26
Sieben	7	Sieben und zwantzig	27
Acht	8	Acht und zwantzig	28
Neun	9	Neun und Zwantzig	29
Zehn	10	Dreissig	30
Eilf (elf)	11	Ein und dreissig	31
Zwölf	12	Vierzig	40
Dreizehn	13	Ein und vierzig,	41
Vierzehn	14	Fünfzig	50
Fünfzehn	15	Hundert	100
Sechszehn	16	Hundert und eins	101
Siebzehn	17	Hundert und zwei	102
Achtzehn	18	Zwei hundert	200
Neunzehn	19	Drei hundert	300
Zwanzig	20	Tausend (ein tausend)	1,000

Unfortunately, the Germans hold with great pertinacity to an old and barbarous character in their alphabet, by which a more general study of their literature is in some measure retarded. This peculiar character is similar to the Old English,—𝔞, 𝔟, 𝔠, 𝔡, 𝔢, 𝔣, &c.; 𝔄, 𝔅, ℭ, 𝔇, 𝔈, 𝔉, &c.

Dutch Language.—This language, or Lower German, spoken only in Holland, and though used in the literature of the people of that country, has never made any progress elsewhere. In speaking of this language, in his work on Batavian Anthology, Dr. Bowring remarks, that "the Dutch is not soft or musical, but it is sonorous and emphatic. it has not the beauties of the vowelled idioms of the south, but it has beauties they can never possess; and especially in the variety and grace of its diminutives (a quality in which our own language is singularly deficient), it may be compared with the richest among them. It may be studied in its perfection, in that beautiful and emphatic version of the Bible which owes its existence to the Synod of 1618–19; to the expression of devout and dignified emotion it is particularly adapted, and a high tone of religious feeling pervades all its literature." Believing that the language is already perfect, the Dutch are most scrupulous about admitting terms from any other language; when any new word is required, as in science, they form a compound for the purpose. Thus, astronomy is called *sterrekunde*, from *ster*, a star, and *kunde*, knowledge. Another term for the same science is *hemelloopkunde*, from *hemel*, heaven, *loop*, a course, and *kunde*, knowledge. Grammar is *taalkunde*, from *taal*, language, and *kunde*, knowledge; literally signifying the knowledge or science of language. Occasionally this plan may be advantageous, but it produces inelegance, and is adverse to improvement. The Flemish language has borrowed many words from the French, but it is very similar to the Dutch. It is chiefly distinguished by a more nasal pronunciation, while the Dutch is rather a guttural language. The orthography of the two languages differs; for the Flemish writers have devised a different method of spelling those words which agree in sound but not in signification. Thus, *wagen*, is to hazard, and *waegen* to weigh; *leven* is life, and *leeven* is to live. Another language is spoken in the Netherlands, which is neither Dutch nor Flemish. It is the popular language in Hainault, Namur, Liege, and part of Limbourg, and is called the Walloon; it is a kind of corrupt French. In Brussels, the people in the lower city speak Flemish, and in the upper city Walloon. Of these languages, the Dutch most closely resembles our own. Its similarity to English is shown by the following Dutch proverb, coupled with a literal translation:—

> "Als de wyn is in de man,
> Is de wysheid in de kan."
> "When the wine is in the man,
> Is the wisdom in the can."—BOWRING.

As all classes of persons above those in the humblest ranks, both in Holland and Belgium, speak French, and as the bulk of the literature is in that language, it is not unlikely that the native vernacular will in course of time sink to the character of provincial dialects—which, indeed, they have already reached in the Flemish districts.

The English Language.—This language, as already mentioned, is based on the Anglo-Saxon, "the language of the Angles, one of the tribes of that Saxon confederacy which, about the beginning of the sixth century, supplanted the Celtic inhabitants of Britain, and drove them into the mountains of Wales and Scotland. The incursions of the Danes into England, and their settlement in several parts, made little alteration on the Anglo-Saxon, as the Danish tribes were kindred with the Saxon, being descendants of the same great Gothic or Teutonic family. In the eleventh century, the Normans, or North-men, another kindred tribe, who had, two centuries before, seized and possessed that part of France since called Normandy, subdued England. They brought with them the French language, which, in the course of time, they had adopted from the people amongst whom they had been settled. This they continued, in England, to use in common discourse, and in schools and courts of law, for more than two centuries after the Conquest. Yet as they were not so numerous as the Saxon population, the old language finally prevailed; and though many French words found their way into the English, the bulk of the language continued to be Saxon.

"The French tongue being founded on the Latin, its introduction caused the infusion of a great number of Latin words into our language; afterwards, as Roman literature was studied, a great number of other Latin terms were introduced into English. It is in some measure possible to distinguish the Latin introduced through the French, by the words being more changed in their form than the other Latin terms which were adopted directly by the learned. From the addition of so many Latin words, a species of double language has been formed—the Saxon English, which we commonly employ in conversation, and the Latinized English, which is principally employed in learned composition. Mixed, however, as the two are, each language preserves an idiomatic character; for, with few exceptions, the prefixes and affixes of the one cannot be conjoined with the words of the other.

"A further addition has been made to the English by the introduction of Greek words. This has been going on since the commencement of the study of Greek literature in the sixteenth century. As we had Latin through the French, we had unconsciously many Greek words through the Latin, which may be regarded as a variety of the Greek. The words which we have received immediately from the Greek are comparatively few, with the exception of terms of art and science, which are now extensively taken from that language.

"When we look back to the early history of our language, it may be said that we see it approaching our country in two great but unequal streams; one of which comes from the shores of the Baltic, while the other, leaving Greece, passes along the shores of the Mediterranean, and finally reaches us through France. Though the Celtic inhabitants, or Britons, are said to have been expelled by the Saxons, some of their words have been left in our language. The names of rivers, mountains, and other natural objects, in England as well as in Scotland, are generally Celtic, and the names of many places are founded on terms in the same language. As in the case of the Latin passing into the English through the French, we have words of Celtic origin through the French, France having been at one time widely inhabited by Celtic tribes. In many of the names of places in France, Spain, and Italy, the Celtic is also still discernible."*

The language of England-proper is now spoken over the whole British islands, and has been fixed at a standard by the diffusion of literature and the labours of Johnson and other lexicographers. In the common speech of the people, however, there are, as we previously noticed, numerous dialects differing less or more from pure English. The most remarkable of these dialects is that spoken by the humbler classes in the Lowlands of Scotland, of which we have specimens in the poetry of Ramsay and Burns, and the prose fictions of Scott. A controversy has existed respecting the origin of this dialect. By some it has been considered only an unimproved English, such as was spoken and written generally in England three or four centuries ago; by others, it has been defined as a distinct branch of the original Teutonic, through the Scandinavian branch; and this, in our opinion, is the true view of the matter. We now, then, have upon our island two branches of an original Gothic tongue, one of which has taken the lead in literature, while the other has continued as a local vernacular, and must in the course of time disappear.

The English language, as finally established, consists of about 38,000 words, of which about 23,000, or nearly five-eighths, are Anglo-Saxon. Many words, however, may be said to be in a state of disuse, particularly those from the Latin introduced by a fantastic mode of writing in the sixteenth and seventeenth centuries. Possessing all the force and bluntness of the Anglo-Saxon, with a due share of the polish and dignity of the Roman tongue, the English is powerful, copious, and adapted to express the most refined emotions of feeling, as well as the complex doctrines of an enlightened philosophy. For honesty and sincerity it has no equal—a peculiarity distinctly referable to the upright character of the English. One of the chief peculiarities of the language is its slight dependence on inflection, and the abundant use of articles, prepositions, &c., such as *a*, *on*, *the*, *of*, *to*, *with*, *by*; also, *shall*, *will*, *may*, *might*, *could*, *would*, *should*, &c. (all Anglo-Saxon), the meaning of which is usually provided for in languages of Latin origin by the various terminations of the verbs or main words in the sentence. The rules of English orthography are exceedingly indecisive, partly from the want of any authoritative academy to lay down a law on the subject, and partly from the diffidence of grammarians in attempting any change. This irregularity in the adaptation of spelling to pronunciation, and the constant shifting of sounds in the letters *a*, *c*, and *g*, without any apparent rule, render the language difficult of acquisition by foreigners. The sound expressed by *th*, as in *the*, *month*, *pathos*, equivalent to the sound of the letter *theta* in Greek, is also rarely mastered by natives of France or Germany who come to reside amongst us.

In writing English, some authors adhere more closely to Anglo-Saxon roots than others; but the best English is that in which no particular rule on this subject is followed. To show what difference may exist in styles, according as the Anglo-Saxon or Latin are followed, we present the following specimens; those words not Anglo-Saxon being in *Italics*. The first is from the authorized version of the Bible, which has few Latin words.

"In the beginning God *created* the heaven and the earth. And the earth was without *form*, and *void*; and darkness was upon the *face* of the deep: and the *Spirit* of God moved upon the *face* of the waters. And God said, Let there be light; and there was light. And God saw the light, that it was good: and God *divided* the light from the darkness. And God called the light Day, and the darkness he called Night. And the evening and the morning were the first day."—*Genesis*, i. 1—6.

"And it came to pass, that when Isaac was old, and his eyes were dim, so that he could not see, he called Esau his eldest son, and said unto him, My son. And he said unto him, Behold, here am I. And he said, Behold now, I am old, I know not the day of my death. Now therefore take, I pray thee, thy weapons, thy quiver and thy bow, and go out to the field, and take me some *venison*; and make me *savoury* meat, such as I love, and bring it to me, that I may eat; that my soul may bless thee before I die. And Rebekah heard when Isaac spake to Esau his son. And Esau went to the field to hunt for *venison*, and to bring it. And Rebekah spake unto Jacob her son, saying, Behold, I heard thy father speak unto Esau thy brother, saying, Bring me *venison*, and make me *savoury* meat, that I may eat, and bless thee before the Lord before my death."—*Genesis*, xxvii. 1—7.

The second specimen is from Robertson, showing an abundance of Latin roots:—

"This great *emperor*, in the *plenitude* of his *power*, and in *possession* of all the *honours* which can *flatter* the heart of man, took the *extraordinary resolution* to *resign* his kingdom, and to withdraw *entirely* from any *concern* in business or the *affairs* of this world, in *order* that he might spend the *remainder* of his days in *retirement* and *solitude*. *Diocletian* is *perhaps* the only *prince* *capable* of holding the *reins* of *government*, who ever *resigned* them from *deliberate* choice, and who *continued during* many years to *enjoy* the *tranquillity* of *retirement*, without fetching one *penitent* sigh, or *casting* back one look of *desire* towards the *power* or *dignity* which he had *abandoned*."

For further details respecting the English language, we refer to the article on ENGLISH GRAMMAR.

* Graham's English Etymology.

The Pelasgian or Graeco-Latin Family.

The first inhabitants of Greece were called the Pelasgi, and seem to have been the ancestors of the Greeks; but the early history of these nations is lost in fable.

The Greek is a most powerful and expressive language. It is divided into four dialects, which arose from the peculiar pronunciation of the inhabitants in different parts of the country, thus occasioning a change in orthography. The Attic dialect is generally considered the most polished and the most classical; it is subdivided into the old, middle, and new. Solon wrote in the old Attic, which is almost the same as the Ionic. The historian Thucydides, the tragic writers Æschylus, Sophocles, and Euripides, used the middle style, as did also Plato and Xenophon, and Aristophanes, the writer of comedy. Demosthenes, and later orators and writers of comedy, adopted the new Attic style. The name of the Attic dialect is derived from Attica, the country in which it originated; the political and literary pre-eminence of the Athenians, or people of Attica, eventually rendered it almost the universal dialect of Greece. It is distinguished by its contraction of vowels. The Ionic dialect uses the contracted inflections of nouns and verbs. It is smooth and harmonious, and was adopted by the historian Herodotus, Hippocrates the physician, and by Anacreon the poet. The Doric and Eolic dialects were more harsh and unpolished than the others. The Doric has a very broad pronunciation, and frequently substitutes *ā* for the other vowels. The Eolic has no dual form, and, in other points, resembles the Latin more strongly than the other dialects. The New Testament was originally written in Greek. We find in it instances of all the four dialects, and several Hebraisms or Hebrew idioms.

We have seen that one of the leading grammatical systems followed in the structure of all languages, consists in the addition of syllables to the root, or, as we may briefly describe it, in a variety of terminations. These are called *inflections*, because the word in this case is, as it were, *bent* or *turned*. In the Greek, we see the inflective system in its greatest extent. The noun is inflected for the expression of the various cases, genders, and numbers. The verb is inflected for active, middle, and passive voice, and all the usual variety of tenses in the first, second, and third persons. There is also a form of the verb for use with reference to two persons, called therefore the dual form. Thus, the imperfect of the indicative of the verb τύπτω (*tupto*), I strike, appears in the following variety of forms:—

	SINGULAR.	
1. ἔτυπτον	2. ἔτυπτες	3. ἔτυπτε
(*etupton*),	(*etuptes*),	(*etupte*),
I was striking.	Thou wert striking.	He was striking.
	DUAL (*two persons*).	
	2. ἐτύπτετον	3. ἐτυπτέτην
	(*etupteton*),	(*etupteten*),
	Ye two were, &c.	They two were, &c.
	PLURAL (*any number*).	
1. ἐτύπτομεν	2. ἐτύπτετε	3. ἔτυπτον
(*etuptomen*),	(*etuptete*),	(*etupton*),
We were striking.	Ye were striking.	They were striking.

The modern Greek derives most of its words from the ancient language, but a great many Italian and Turkish terms have been introduced. Perhaps the difference between the ancient and modern Greek cannot be better illustrated, than by comparing parallel passages from the same writer. The passage selected is the 1st chapter of John's Gospel, 1st verse:—

ANCIENT GREEK.	ROMAIC OR MODERN GREEK.
Εν ἀρχῇ ἦν ὁ λόγος καὶ ὁ λόγος ἦν πρὸς τὸν Θεὸν καὶ Θεὸς ἦν ὁ λόγος.	Εις τὴν ἀρχὴν ἦτον ὁ λόγος καὶ ὁ λόγος ἦτον μὲ τὸν Θεὸν καὶ Θεὸς ἦτον ὁ λόγος.
En arche en ho logos, kai ho logos en pros ton Theon, kai Theos en ho logos.	*Eis ten archen eton ho logos. kai ho logos eton me ton Theon kai Theos eton ho logos.*

The Latin, or language of ancient Rome, may be regarded as a composition of the early languages spoken in central Italy, particularly the Etrurian, and of the Greek, brought to the same country by colonists, and by the study of Greek literature among the Romans, after they had attained a certain degree of civilization. It has been remarked that the Eolian, more than any other variety of the Greek, has contributed to the formation of Latin. The Latin, in its grammatical structure, follows the Greek, but dispenses with the dual form of the verb. We shall here more particularly illustrate the inflective system, for the sake of those whose studies have not embraced any language besides their own. For example, while the Latin word for a speech, in the nominative case, is *sermo*, our ideas of *a speech, to a speech, with a speech*, are expressed respectively by the words *sermonis, sermoni, sermone*. The verb presents a great variety of terminations for the two *voices*, the various *moods, tenses*, and *persons*, &c. Thus, for example, while *I love* (active voice) is expressed by *amo*, *I am loved* (passive voice) is *amor*. While *I had loved* (pluperfect of indicative mood) is *amaveram*, *I might have loved* (pluperfect of subjunctive mood) is *amavissem*. The whole of the last tense is—

	SINGULAR.	
1. Amavissem,	*I might or could have loved.*	
2. Amavisses,	*thou mightst or couldst have loved.*	
3. Amavisset,	*he might or could have loved.*	
	PLURAL.	
1. Amavissēmus,	*we might or could have loved.*	
2. Amavissētis,	*ye might or could have loved.*	
3. Amavissent,	*they might or could have loved.*	

It may be remarked, for the sake of an unlearned class of readers, that there are various forms for the termination of nouns, called declensions. A large class, in which the nominative ends in *a* as in *penna*, a pen, *ala*, a wing, are of the first declension, and these are generally of the feminine gender. Two other large classes, in which the nominative ends either in *us* or in *um*, as *dominus*, a lord, *regnum*, a kingdom, belong to the second declension. There are in all five declensions, all including nouns of peculiar terminations. The singular of *dominus* appears as follows, under its various cases:—

Nominative.	Dominus,	*a lord.*
Genitive.	Domini,	*of a lord.*
Dative.	Domino,	*to a lord.*
Accusative.	Dominum,	*a lord.*
Vocative.	Domine,	*O lord.*
Ablative.	Domino,	*with or by a lord.*

The conjugations of verbs are analogous to the declensions of nouns. *Amo* is an example of a class in which the imperfect of the indicative always ends in *abam*, the future in *abo*, and in which all the other tenses take certain terminations in like manner. This class of verbs are said to be of the first conjugation. There is another class in which the present of the indicative always ends in *eo*: thus, *moneo*, I advise, *moveo*, I move; and in which the imperfect of the indicative always ends in *ebam*, the future in *ebo*, &c. These constitute the second conjugation. The other two conjugations, for there are four, all observe certain rules as to the formation of the various parts of the verb; in other words, all the various parts of the various verbs of the Latin language are formed after four schemes or modes, these being called conjugations.

In the syntax of the Latin language, there is one principle carried to an unusual extreme, namely, the transposition of words. Generally, the verb was among the last words placed in a sentence. The specimens of early Roman writers which are preserved, show the language in a rude state, as the English was about the thirteenth century. The language was afterwards polished, and became remarkable for its smoothness and harmony. Of the beautiful literature of which, like the Greek before it, it became the honoured vehicle, this is not the place to speak.

Italian, Spanish, and Portuguese Languages.—When the empire of Rome sank, as it were, beneath the weight of its own greatness, the different tribes by whom it was dismembered introduced a complete change into the language. Not only were new words introduced, but the very structure of the grammar was altered. The barbarians, probably finding a difficulty in remembering the various forms of the passive voice, substituted the use of an auxiliary with a participle throughout the verbs, and introduced prepositions to express the various relations of nouns, instead of the old system of declension. The language was thus rendered more simple and flexible. It is probable that many of these changes first sprang up among the Latins themselves, and that they were originally conventionally used by the vulgar in provincial districts. It would be very interesting if we could trace, step by step, the process of the conversion of the Latin language into the Italian. But this, like the history of the transmutation of the ancient into the modern Greek, is a subject upon which little satisfactory information can be gained. One characteristic in Italian, is the little use that is made of the letter *h*. "Not worth an *h*," is a familiar saying in Italy. The only office of *h* in the language, is to indicate when *c* is to be pronounced like *k*; as for instance, in such words as *cheto*, &c., which is pronounced *keto*.

Italian, says Metastasio, is "*musica stessa*" (music itself). It is a language of great compass and variety, well adapted to express passion and emotion. There are many dialects in Italy; with respect to these, a common proverb says, "Lingua Toscana in bocca Romana," meaning that the Tuscan dialect is the most classical and the Roman pronunciation the purest.

There are other languages besides the Italian which are derived from the Latin. Of these the Spanish preserves the strongest resemblance to the genius and structure of the Latin. It is almost equally pompous and solemn. The Spanish character is likewise akin to that of the ancient Romans, both nations being conspicuous for their prowess and dignity of mind. A great many Latin words may be traced in the Spanish, particularly if it be remembered that the *c* of the Latin language always becomes *g* in the Spanish; for instance, *Dico* becomes *Digo*: and that *t* is changed into *d*, so that the Latin word *totus* is discernible in the Spanish form *todo*. The Romans occupied Spain between six and eight hundred years. About 416, the Goths entered it, and effected some little change in the language, which was then called *Langue romance*, because derived from the Roman or Latin. About A. D. 741, Spain was again invaded by the Arabs, who gave an oriental tincture to the language. One peculiarity in the Spanish language, is the constant occurrence of *ll* at the commencement of a word; for instance, *llamar*, to call; *llaneza*, equality; *llave*, a key; *llegar*, to arrive; *llevar*, to carry; *lluvia*, to rain. The sound given to these double consonants is similar to the *gl* of the Italian, in *figlio*, son; to the *lh* of the Portuguese, in *filho*, son; and also to the *ll* of the French, in *fille*, daughter. There is another distinguishing sound in the Spanish, which is connected in pronunciation with the French. The Spanish *n* is pronounced like the French *gne* in Bretagne; so that such words as *senor*, sir, *mana*, dexterity, and *manana*, to-morrow, are to be read as if written *segnor*, *magna*, &c.

The Portuguese language has not so close an affinity with the Spanish as might have been expected from the geographical position of the two countries. The Portuguese attracted but little attention in the rest of Europe before the appearance of the *Lusiad*. Derivatives are in this language very numerous; thus, from the root *pedra*, a stone, we get the following derivatives:—*pedregal*, a stony place; *pedregulho*, gravel; *pedregóso*, stony; *pedreyra* or *pedréyro*, a stone-cutter; *pedrada*, a blow with a stone. By the simple addition of the termination *ada*, many words are formed, which in other languages could not be expressed without circumlocution; thus, *pancada*, a blow with a stick or club; *cutilada*, a cut with a sword; *estocada*, a stab with a sword or dagger. The Portuguese, like the French and Italians, have no adjectives of a triple form, as in Latin. Some of their adjectives mark the distinction in gender of the nouns which they qualify, as *formoso*, *formosa*, beautiful; *alto*, *alta*, high; and others are unchangeable; thus, *tempo breve*, a short time; *manhãa breve*, a short morning; *cavallo forte*, a strong horse; *egoa forte*, a strong mare.

French Language.—This language is also, in a great measure, a broken and re-organized Latin. It originated in the following manner:—"The Celtic, remnants of which were long preserved in Brittany, was the language of the Gauls. After the conquest of the country by the Romans under Julius Cæsar, Latin became the predominant language. On the overthrow of the Western Roman empire, this language was corrupted partly in its pronunciation by Teutonic organs, and partly by the mixture of words and expressions originally Frankish, Burgundian, Ostrogothic or Visigothic. This corrupt language was called the *Romance*, and was divided into two branches. They are denominated from their respective terms for expressing *yes*—the southern, or *Langue d'Oc* (dialect of Oc, Occitanic dialect), and the northern, spoken north of the Loire, or *Langue d'Oui* or *d'Oïl*, from the latter of which the modern French language is derived. In the beginning of the twelfth century, Raymond de St. Gilles, Count of Provence, united the south of France under one government, and gave the whole the name of *Provence*. From that period the two dialects were called the *Provençal* and the *French*. The former, though much changed, is still the dialect of the common people in Provence, Languedoc, Catalonia, Valencia, Majorca, Minorca, and Sardinia. In the thirteenth century, the northern, or Norman French dialect, which was much more prosaic than the former, gained the ascendency. This was partly owing to the influence of the *Conteurs*, who roamed into all parts of the country; but chiefly to the circumstance that Paris became the centre of refinement, philosophy, and literature, for all France. The *Langue d'Oui* was deficient, from its origin, in that rhythm which exists in the Italian and Spanish languages. It was formed rather by an abbreviation than by a harmonious transformation of the Latin. The Franks and Normans deprived the Latin words of their characteristic terminations, substituting in their stead the obscure German vowel, which was afterwards entirely dropped in conversation, and retained only in singing and orthography. With the exception of these differences, the French Romance dialect was formed on the same grammatical model as the Italian, Spanish, and Portuguese. A regular accentuation of syllables, according to their quantity, was at first preserved; but the metrical character of the language was gradually lost. The French thus became more accustomed to a rhetorical measure than to poetical forms. The nature of the language itself led them to eloquence rather than poetry, and their natural liveliness contributed essentially to encourage nice dialectics. Francis I. established a professorship of the French language at Paris in 1539, and banished Latin from the courts of justice and public documents. Cardinal Richelieu, by establishing the Academy in 1635, carried the language to a higher degree of perfection. The French academy became the supreme tribunal both for the language and literature. It put an end to the arbitrary power of usage, and fixed the standard of pure French; but it deprived genius of its prerogative of extending the dominion of the mind over the language. Nothing was approved by the academy unless it was received at court, and nothing was tolerated by the public which had not been sanctioned by the acatury. The language now acquired the most admirable precision, and thus recommended itself, not only as the language of science and diplomacy, but of society, capable of conveying the most discriminating observations on character and manners, and the most delicate expressions of civility, which involve no obligation. Hence its adoption, as the court language, in so many European countries."—*Conversations Lexicon*

The words in the French language are much less rounded by vowels than the other tongues founded on the Latin; they also abound in silent letters, contractions, and peculiar accents. While in the English, as other Teutonic tongues, the adjective is placed before the substantive, in French it is the reverse. This produces a degree of circumlocution which the English as a people could never tolerate; thus, while we at once go to the point in the term *steamboat*, the French express the idea in the roundabout form of *bateau à vapeur*. The French is also defective in its genders, of which it has only two; every thing is either masculine or feminine—*he* or *she*—a peculiarity which throws considerable difficulty in the way of its acquisition. Another peculiarity is the use of two words, *ne* and *pas*, to express a negative, as, *il n'est pas*—it is not, or, as we should literally translate the phrase, *it not is not*. It has been remarked by foreigners, that in speaking English the hissing sound of *s* has an unpleasant frequency of recurrence; in French, the nasal sounds *ung* and *ong* similarly predominate.

The Slavonic Family.

The Slavonians formed the third great tide of population which rolled from Central Asia into Europe, and planted their language in Russia, Servia, Croatia, Poland, Bohemia, Dalmatia, and some other countries, where it is now spoken in different dialects by the common people. The Slavonic tongue is understood to be remotely connected with the Sanscrit, and as Latin has a similar alliance with that language, it happens that a number of the Slavonic terms resemble words of Greek and Latin. The chief dialect or variety of the Slavonic is the Russian, which attained a standard in the reign of Peter the Great. In 1704, Peter invented a set of written letters, similar to the Roman alphabet, and introduced them among his countrymen in place of the cumbrous characters previously in use, in order to facilitate their intercourse with the other European nations. Of late, much attention has been paid to the old songs and traditions of Russia, for it is thought that they bear a strong resemblance to the old ballads of England, Spain, and Scandinavia, forming a connected series of popular traditions. The oldest documents in the Russian language are Oleg's treaty of peace in A. D. 912, and Igor's treaty with the Greek Emperor in 945. "The literature," says Dr. Bowring, "had its birth but yesterday, and certainly its present strength and beauty give fair hope for to-morrow: in it are elements of improvement, and buds and blossoms of future expectation." The Russian prose is at present inferior to the poetry. It is a flexible and harmonious language. The nouns have seven cases, of which five are similar to those of other languages. The sixth is called the *instrumental*, and agrees with the Latin ablative. The seventh is called *prepositive*, and is peculiar to this language.

The Polish language is characterized by the multiplicity of its consonants: it is generally considered more harmonious and flexible than the other Slavonic dialects. Upon the introduction of Christianity in 965, Latin was brought into use as the only written language. Thus the progress and improvement of the Polish language were considerably retarded; but, during the reign of Stanislaus Poniatowski, it made such rapid advances, and attained to such strength and vigour, that it has continued to flourish, uninjured, among all the storms and convulsions which have erased Poland from the map of Europe. The literature of Poland is eminently national and patriotic: it contains few philosophical or scientific treatises, but abounds in historical and poetical productions.

The Hungarian language can scarcely be called a Slavonic dialect, and yet it seems difficult to know where else to place it. Some curious affinities have lately been discovered between it and the Finnish, Laplandish, and Esthonian languages; such, for instance, as that the verb *to have* is wanting in all, so that possession is indicated by an expression equivalent to the words *to be to*. There are many different opinions respecting the origin of the Hungarians. Some have asserted that they are descended from the Egyptians. The word by which they designate themselves and their language, is *Magyar*. This is a term of Mogul extraction, and signifies *foreigner* or *stranger*. The most remarkable feature of the Hungarian language, is the division of the vowels into two genders; *a o u* are called masculine, and *e i ö* are considered feminine. A masculine or feminine affix is used according to whether the word terminates with a masculine or feminine vowel; this of course produces a singular uniformity of sound. About the thirteenth century, the Komans, a Turkish race, were compelled, by the disasters of war, to take refuge in Hungary. Here, being separated from the rest of their race, they soon forgot their language, and adopted that of the Hungarians. Hence it is that so many Turkish words are found in the language of the Magyars.

The Tartarian or Turkish Family.

The inhabitants of Central Asia are known in Europe by the general name of Tartars. They occupy the great elevated regions of Asia, from the Northern Ocean to the confines of Persia, India, and China. One language prevails throughout this vast extent of country, which is also frequently used in Egypt, Barbary, the Levant, part of Persia, and on all the shores of Africa. It comprises ten dialects, of which the principal is the Osmanlis, or that which is spoken in European Turkey. The Osmans derive their name from one of their leaders. They left Turkestan in A. D. 545, and conquered Persia. In A. D. 1543, they established themselves in Constantinople, where they still remain, and are known to the Europeans by the name of Turks. Their dialect prevails more or less in Bosnia, Illyria, Servia, Bulgaria, and in the Morea; but the purity, sweetness, and elegance of the language can only be learned at Constantinople. It has been observed of the Osmanli, that they have made the nearest approach towards uniting the genius of the two hemispheres. Situated both in Europe and in Asia, it is probable that they will one day combine in their literature the metaphysical imaginative style of the eastern hemisphere with the manly simplicity of the western. It is a very mistaken notion, that Mohammedan nations are precluded by their religion from making advances in literature or science. "Seek knowledge," said Mahomet, "were it even to China." The Turks of Europe have now many works on astronomy and mathematics, but they have little knowledge of experimental science. The best and most numerous works in the Turkish language are those on moral philosophy; this science they call "Adeb;" with them it is a system of ethics couched in a series of amusing tales and fables,* which contain many beauties of thought and of language. The nouns in the Turkish language have five declensions, which are formed by retaining the nominative throughout and adding terminations. No language contains more inversion of phraseology—not even the Latin. Prepositions are subjoined instead of being prefixed to nouns; and in all parts of speech the governed precedes the governing. The Jagatarian dialect of the Turkish is spoken in the greater part of Bokharia and of Independent Tartary. Many words, now obsolete in Constantinople, still exist in this

* Davids' Turkish Grammar.

dialect. In the same way, observes Davids, that the name Tartar has been applied indiscriminately to the nation, so the term Mongol has been given to the literature. The famous *Tezukat Timur*, or Commentaries of Timour, generally called a Mongol production, is really written in the Jagatarian dialect.

Balbi, the geographer, has given the name of Austro-Siberian to the various Turkish dialects spoken in part of Siberia. These dialects are much compounded with other languages.

THE POLYNESIAN CLASS.

It has been proved that all the languages spoken in the South Sea Islands and Indian archipelago, are but dialects of one primitive language.* This is evident from the similarity which subsists between them. It seems impossible to discover with certainty the language from which these have sprung. The difference in pronunciation is so great in various islands, that the inhabitants cannot understand one another. The change of dialect seems to correspond with the names of the islands. Thus, in Tahiti the aspirate abounds. At Ai-tu-tak-i the language has the addition of the letter *k*. At Roro-tonga the language is characterized by the nasal sound *ng*, which is also the case at New Zealand. The Tahitian vocabulary abounds with obsolete words, which was caused by the following curious circumstance: when any word had a sound similar to that which was contained in the king's name, the word was instantly changed. A similar custom prevails in China. Many of the obsolete Tahitian words are found in the language of the Sandwich Islands. In New South Wales, tribes who live within a hundred miles of each other are not able to converse together. This arises not only from the difference of pronunciation, but from several names being given to one object. Thus, they have distinct names for the kangaroo, according to its age, sex, size, and the district in which it is found.

The characteristic of all the Polynesian dialects is the frequency of the vowel sounds. The Polynesian languages have likewise a tendency to a monosyllabic form. Their modes of conjugating verbs are similar to the Hebrew. They have the dual of the Greek, and also a form of the dual peculiar to these islands, which is so constantly in use that no conversation can be carried on without it, and they have peculiar forms to express it; thus, *buli*, we two, *bula*, ye two, *bulo*, they two, &c.

The Papuas or Eastern Negroes inhabit the wild and mountainous parts of New Guinea. They are also found in the Philippines, where the Spaniards call them *Negritos del monte*. There are also mountainous regions in the continent of India inhabited by savages evidently of the same stock. Little is known concerning their language; the Malays compare it to the chattering of birds. The Malays who inhabit Malacca and the coasts of the adjacent islands, speak a language possessing some analogy to the Sanscrit; it is soft and harmonious in sound, and has on that account been called the Italian of the East. Nearly all its literature consists of poetry, which is, however, characterized by monotony and repetition.

THE AFRICAN CLASS.

Little, comparatively, is yet known respecting the languages spoken in Africa. There is a very poor Arabic dialect spoken in Abyssinia called Geez, which has been improperly confounded with the Ethiopian. The well-known version of Scripture, erroneously called the Ethiopic, is really in the Geez dialect. To the west of the river Tacazze, the language chiefly spoken is the Amaric, or Modern Abyssinian, now called *Lesan Neghus*, that is, royal idiom, because it is the language of the court at Gondar.

There are scattered tribes in the north, who are strongly suspected to be the descendants of the ancient Lybians. The old Guanchee language, once spoken in the Canary Islands, but now almost extinct, seems to belong to the same stock as the Lybian; but so little is known respecting either language, that this is mere conjecture. Turkish and Arabic idioms prevail in the sea-shores of Africa but distinct and peculiar dialects prevail in the interior, and of these the Soosoo is perhaps the most extensively used. On the Ivory or Tooth Coast, between Cape Palmas and Cape Three Points, a singular dialect is found, which is called *Quaqua*, these being the words with which the natives salute each other when they meet.

The South of Africa is occupied by two races—the Hottentots and the Caffres. The Hottentot language is immediately known from all others, by its extraordinary clipping sounds, produced by a quick action of the tongue upon the palate.

THE POLYSYNTHETIC CLASS.

The languages spoken by the Indian tribes of America, have received from Mr. Du Ponceau, an able investigator into the subject, the name of *Polysynthetic*, from the manner in which words are abbreviated and combined to express ideas. This forms a most remarkable class of languages; and we shall best convey a notion of its peculiarities by the following extract from the *Conversations Lexicon*, founded on Du Ponceau's investigations. The great distinction of these languages from those of other races of mankind is the agglutination of words. "One example, from the Delaware language, will convey a clear idea of the process of compounding; 'and I have chosen,' says Mr. Du Ponceau, 'this word for the sake of its euphony, to which even the most delicate Italian ear will not object. When a Delaware woman is playing with a little dog or cat, or some other young animal, she will often say to it, *Kuligatschis*, which I would translate into English—*Give me your pretty little paw*, or, *What a pretty little paw you have!* This word is compounded thus; *k* is the inseparable pronoun of the second person, and may be rendered *thou* or *thy*, according to the context; *uli* (pronounced *oolee*,) is part of the word *wulit*, which signifies *handsome* or *pretty*: it has also other meanings, which need not be here specified; *gat* is part of the word *wichgat*, which signifies a *leg* or *paw*; *schis* (pronounced *shees*) is a diminutive termination, and conveys the idea of *littleness*: thus, in one word, the Indian woman says *thy pretty little paw*; and, according to the gesture which she makes, either calls upon it to present its foot, or simply expresses her fondling admiration. In the same manner, *pilape*, a youth, is formed from *pilsit*, chaste, innocent, and *lenape*, a man. It is difficult to find a more elegant combination of ideas, in a single word, of any existing idiom. I do not know of any language, out of this part of the world, in which words are compounded in this manner. The process consists in putting together portions of different words, so as to awaken, at the same time, in the mind of the hearer, the various ideas which they separately express. But this is not the only manner in which the American Indians combine their ideas into words. They have also many of the forms of the languages which we so much admire—the Latin, Greek, Sanscrit, Slavonic, &c.—mixed with others peculiarly their own. Indeed, the multitude of ideas which in their languages are combined with their verbs, has justly attracted the attention of the learned in all parts of the world.

It is not their transitive conjugation, expressing, at the same time, the idea of the person acting, and that acted upon, that have excited so much astonishment. These are found also, though not with the same rich variety of forms, in the Hebrew and other Oriental languages. But when two verbs, with intermediate ideas, are combined together into one, as in the Delaware *n'schingiwipoma*, I

* Prichard's History of Man.

do not like to eat with him, which the Abbé Molina also declares to exist in the idiom of Chili—*iduanclorlavin*, I do not wish to eat with him—there is sufficient cause to wonder, particularly when we compare the complication of these languages with the simplicity of the Chinese and its kindred dialects in the ancient world. Whence can have arisen such a marked diversity in the forms of human speech? Nor is it only with the verbs that accessory ideas are so curiously combined in the Indian languages; it is so likewise with the other parts of speech. Take the adverb, for instance. The abstract idea of time is frequently annexed to it. Thus, if the Delawares mean to say, *if you do not return*, they will express it by *mattatsch gluppiwequi*, which may be thus construed: *matta* is the negative adverb *no*; *tsch* (or *tsh*) is the sign of the future, with which the adverb is inflected; *gluppiwequi* is the second person plural, present tense, subjunctive mood, of the verb *gluppiechton*, to turn about, or return. In this manner, every idea meant to be conveyed by this sentence, is clearly understood. The subjunctive mood shows the uncertainty of the action; and the sign of the future tense, coupled with the adverb, points to a time not yet come, when it may or may not take place. The Latin phrase *nisi veneris* expresses all these meanings; but the English *if you do not come*, and the French *si vous ne venez pas*, have by no means the same elegant precision. The idea which, in Delaware and Latin, the subjunctive form directly conveys, is left to be gathered, in the English and French, from the words *if* and *si*, and there is nothing else to point out the futurity of the action. And where the two former languages express every thing with two words, each of the latter requires five, which yet represent a smaller number of ideas." Mr. Du Ponceau then justly asks, to which of all these grammatical forms is the epithet *barbarous* to be applied? This very cursory view of the general structure of the Indian languages, exemplified by the Delaware, will at least convince us that a considerable degree of art and method has presided over their formation.

Mr. Du Ponceau has summed up the general results of his laborious and extensive investigations of the American languages, including the whole continent, from Greenland to Cape Horn, in three propositions—"1. That the American languages in general are rich in words and in grammatical forms, and that, in their complicated construction, the greatest order, method, and regularity prevail; 2. That these complicated forms, which I call *polysynthetic*, appear to exist in all those languages, from Greenland to Cape Horn; 3. That these forms appear to differ essentially from those of the ancient and modern languages of the old hemisphere."

These explanations of Du Ponceau surprised the philologists of Europe; and his statements were for some time controverted and ridiculed. It now, however, appears beyond a doubt that the languages of these barbarous Indian tribes are among the most expressive of any tongue dead or living, and that the principle of their construction is most ingenious and perfect. We refer readers who may be curious on the subject to the *Conversations Lexicon*, article *Indian Languages*.

BROKEN LANGUAGES.

Lingua Franca.—Along the coasts of the Levant and European Turkey, the natives of a superior class, and particularly merchants, hold intercourse with the French, English, Italians, and other foreigners, in a dialect called the *Lingua Franca*. It is a jargon composed chiefly of corrupt Italian with Turkish and other words, and cannot be said to aspire to a grammar or any regular form. As the Turks call all Europeans Franks, this language has been named from them.

Romansch Language.—In that part of Switzerland called the Grisons, and the neighbouring alpine region of Tyrol, the inhabitants of which, according to local tradition, are the descendants of some fugitives driven from Lower Italy by the Gauls, a corrupted Latin is spoken, supposed to resemble the vernacular of the Roman peasantry, and called the *Lingua Romanscha*. Of this Romansch there are several dialects, and in one of them a newspaper is published at Coire.

Chinese-English.—We have already noticed the broken English spoken by the Negroes of the British West Indies, known by the name of the Talkee-talkee. A similarly broken English is in use at Canton, in China, by which an intercourse is carried on between English and native tradesmen. This Chinese-English, composed of English words, with a few terms from the Portuguese, but altered to suit the powers of pronunciation of the Chinese, is a barbarous jargon, governed by no rules of grammar. The word "change" is pronounced *cheen-che*; "dirty" is *tah-tee*; "wife" is *wi-foo*; "three," *te-le*; "four," *faw*; "five," *fi*; "six," *sik-she*, and so on. Of the words from the Portuguese, "great" is *kah-lan-tee*, a corruption of *grande*; "orange" is *loo-lan-che*, for *laranga*; "to know" is *sha-pe*, for *sabe* (French, *savoir*), to know—a term also common in the Talkee-talkee of the West India Negroes. This Chinese gibberish also includes a few expressions from the native language of China; as, *chin-chin*, for "if you please;" *chow-chow*, for "dinner," &c. At Macao there is a similar lingo, formed principally from Portuguese and some Chinese words.

CONCLUDING OBSERVATIONS.

From what has been stated, it appears that some hundreds, if not thousands, of languages, are spoken over the globe, the whole, however, divided into certain leading classes, and by far the greater proportion being dialects or altered varieties of original roots. The predominance of any individual language by no means corresponds with either its valuable qualities or its antiquity. The Celtic, for example, the oldest language of most European countries, is now confined to a few unimportant localities; the Hebrew, following the fate of the people to whom it belonged, is not spoken as a vernacular by any nation; the ancient Greek has been modernized or altered as a spoken tongue; and the dignified and sonorous Latin, once spoken by the learned orators of ancient Rome, is also numbered with the dead languages.

Out of the wreck of ancient tongues, certain new languages, as has been observed in the preceding pages, have arisen and taken a lead in the civilized world. Of these the French was the first which attained general estimation. It was spoken at courts, became the language of diplomacy, and still is the medium of converse among all refined classes of persons throughout continental Europe. Except, however, in two or three of the Swiss cantons, and part of Belgium (also in the remains of French colonies abroad), it is nowhere the vernacular beyond the confines of France. In short, with all its superficial dissemination, it is limited in its sphere, and is not making new conquests among either barbarous or civilized races. The Italian, though rich and harmonious, is only a local tongue. The Spanish, by means of conquests in Central and South America, has been widely extended; but its progress has been arrested. The Spanish colonies, founded on the most odious oppression, and perpetuated with a disregard to any principles of rational advancement, have in every instance revolted, and the people, to all appearance incapable of civilized rule or independent support, will in all likelihood sink before the external pressure of the Anglo-Saxon republicans; if so, the Spanish tongue will disappear from the American continent.

The next great language of modern Europe is the German, which, as already mentioned, is spoken over a vast extent of country, and is distinguished for the great riches of its literature. Yet, this eloquent and copious tongue is also not making aggressions on new domains, not becoming universal—a circumstance arising from that fixity of habits in its people, which prevents them from pushing into new scenes of enterprise. The Dutch, Swedish, Norwegian, and other branches of the Teutonic, are all substantially confined each to its own little spot, from which it does not appear likely that they will ever be extended.

The English language, which, as we have seen, is little else than Saxon tinged with Latin, seems to have been reserved for a singular destiny, in no respect foreseen at the period of its formation. First spreading over the British islands, and pushing out several varieties of Celtic, it has been conducted by national enterprise to the American continent and islands, where it is now the leading form of speech of civilized men, everywhere overwhelming the native and transplanted tongues. By similar processes of colonization, it has been planted in the great Asiatic peninsula (India) and its islands, in Australia, Van Diemen's Land, New Zealand, the southern extremity and various parts of the western coast of Africa, besides other possessions of Britain in different parts of the world. Perhaps the most extraordinary incident in its eventful progress has been its plantation in Liberia, on the coast of Africa, by a society of Anglo-American colonists, and where it now forms the vernacular of a Negro race, the intelligent descendants of liberated slaves. Thus, while most tongues have been confined, by the force of circumstances, to the place of their birth, the English has gone forward in the van of civilization to almost all accessible parts of the habitable earth; and, preserved from deflection by a common standard literature, will in all probability become a universal language.

The study of languages, with a view to philosophic comparisons and conclusions, and also with the design of throwing light on man's social progress, has in recent times assumed the character of a distinct branch of learning, under the name of *Philology*, and among the patient scholars of Germany the study has been pursued to a great and honourable extent. France has likewise attained celebrity for its linguists. Except by the publication of Polyglott bibles, England has done little comprehensively in this department of letters, and few men have distinguished themselves as linguists, a facility in acquiring languages not falling apparently within the scope of the national mind and habits. The late Sir William Jones, who conquered all difficulties by his perseverance, was a remarkable exception. He was acquainted with twenty-eight languages. The method of study which he pursued, and which he recommends to others, was that which has been called *double translation*. It was his custom, after he had translated a passage into English from some foreign author, to restore his own translation to the language of the author, and then to compare this re-translation with the original. By this means, he was enabled to detect his own errors, and to acquire the peculiar style and idioms of each language. It has frequently been found highly advantageous to read the same work in different languages. By comparing the words, grammatical structure, and idioms of each language, the powers of comparison and reflection are called into active exercise, and the facts more strongly imprinted on the memory.

SPECIMENS OF LANGUAGES.

With the view of affording the unlearned reader an idea of the appearance of some of the principal languages, dead and living, we append the passages from the New Testament composing the Lord's Prayer, in Greek, Latin, Italian, Spanish, French, German, Dutch and English—for the sake of clearness, the Greek is printed in the Roman alphabet, the aspirate at the beginning of certain words being represented by the letter *h*. The reader is called on to observe the difference between the Greek and Latin words, and how evidently the Latin is the parent of the Italian, Spanish, and French, the latter, however, possessing the least resemblance in orthography and arrangement to its original. He will also have an opportunity of comparing the German with its kindred tongue the Dutch, and both with their relation to the Anglo-Saxon or English.

GREEK.

Pater hemōn ho en tois ouranois, hagiastheto to onoma sou. Eltheto he Basileia sou. Genetheto to thelema sou, hōs en ouranō, kai epi tes ges. Ton arton hemōn ton epiousion dos hemin semeron. Kai aphes hemin ta opheilemata hemōn, hōs kai hemeis aphiemen tois opheiletais hemōn. Kai me eisenegkes hemas eis peirasmon, alla rusai hemas apo tou ponerou; hoti sou estin he Basileia, kai he dunamis kai he doxa, eis tous aiōnas. Amen.

LATIN

Pater noster, qui es in cœlis, sanctificetur nomen tuum. Adveniat regnum tuum. Fiat voluntas tua, sicut in cœlo, et in terra. Panem nostrum quotidianum da nobis hodie. Et remitte nobis debita nostra, sicut et nos remittimus debitoribus nostris. Et ne nos inducas in tentationem, sed libera nos a malo. Tibi enim est regnum, et potentia, et gloria, in sempiternum. Amen.

ITALIAN.

Padre nostro, che sei ne' cieli, sia santificato il tuo nome. Il tuo regno venga. La tua volontà sia fatta in terra come in cielo. Dacci oggi il nostro pane cotidiano. E rimettici i nostri debiti, come noi ancora gli rimettiamo a' nostri debitori. E non indurci in tentazione, ma liberaci dal maligno. Perciochè tuo è il regno, e la potenza, e la gloria, in sempiterno. Amen.

SPANISH.

Padre nuestro, que estás en los cielos, sea sanctificado tu nombre. Vénga tu reyno; sea hecha tua voluntad, como en el cielo, ansi tambien en la tierra. Danos oy nuestro pan quotidiano. Y sueltanos nuestras deudas, come tambien nosotros soltamos a nuestros deudores. Y no nos metas en tentacion, mas libranos de mal. Porque tuyo es el reyno, y la potécia, y la gloria, por todos los siglos. Amen.

FRENCH.

Notre Pere qui es aux cieux, ton nom soit sanctifie. Ton règne vienne: ta volonté soit faite sur la terre, comme au ciel. Donne-nous aujourd'hui notre pain quotidien. Pardonne-nous nos péchés, comme aussi nous pardonnons à ceux qui nous ont offensés. Et ne nous abandonne point à la tentation, mais délivre nous du malin. Car à toi appartient le regne, la puissance, et la gloire, à jamais. Amen.

GERMAN.

Unser Vater in dem Himmel, dein Name werde geheiliget. Dein Reich komme. Dein Wille geschehe auf Erden wie im Himmel. Unser tägliches Brod gieb uns heute. Und vergieb uns unsere Schulden, wie wir unsern Schuldigern vergaben. Und führe uns nicht in Versuchung, sondern erlöse uns von dem Uebel. Denn dein ist das Reich, und die Kraft, und die Herrlichkeit, in Ewigkeit. Amen.

DUTCH.

Onze Vader, die in de Hemelen zijt, uw naam worde geheiligd. Uw Koningrijk kome. Uw wil geschiede, Gelijk in den hemel. Zoo ook op de aarde. Geef ons heden ons dagelijksch brood. En vergeef ons onze schulden. Gelijk ook wij vergeven onzen schuldenaren. En leid ons niet in verzoeking, Maar verlos ons van den booze. Want Uw is het koningrijk, En de kracht, en de heerlijkheid, In de eeuwigheid. Amen.

ENGLISH.

Our Father which art in heaven, hallowed be thy name. Thy kingdom come. Thy will be done in earth, as it is in heaven. Give us this day our daily bread. And forgive us our trespasses, as we forgive them that trespass against us. And lead us not into temptation, but deliver us from evil. For thine is the kingdom, the power, and the glory, for ever and ever. Amen.

ENGLISH GRAMMAR.

INTRODUCTION.

Grammar (from the Greek word *gramma*, a letter,) is, in its largest sense, that branch of knowledge which refers to the component parts of language.

The purpose of language is to express our ideas. Similar classes of ideas necessarily arise in the minds of every portion of the human family; for the mind is everywhere the same, in kind if not in degree, and the circumstances and desires of mankind are everywhere less or more alike. To express these classes of ideas, men, in all countries and in all stages of society, use corresponding classes of words, although the words may themselves be different. For example, men everywhere see tangible objects around them. To these they apply distinct *names* or *appellations*, which form, it may be said, one class of words—Nouns. They see things perform *acts*; as, for instance, they see cattle *browse* and kids *dance*. Thus arises another class of words—Verbs. They see *white* cattle and *black* cattle; hence Adjectives. These and other kinds of words, or, to use the common phrase, *parts of speech*, are found equally in the language of the North American Indian and in the refined discourse of the European philosopher. To exhibit the nature and power of words, taken singly and in combination, viewed as a vehicle of thought or a medium of communication, is the first and highest object of grammar.

In the speech of every nation there are also many peculiarities, both in the formation of words to express varieties of sense, and in the way in which words are arranged, these being partly the result of intellectual peculiarities of the people, and partly the effect of accident. Grammar also takes cognisance of such peculiarities. Hence, there is not only universal grammar, which relates to whatever is common to the structure of all language, but likewise a grammar for each particular tongue; as, for instance, the Greek grammar, the Latin grammar, the French and the English grammars. Our present business is with English grammar, or to set forth, as well as we can, within a small compass, the structure and the usages of the English language.

There are four parts in English, as in other grammars, *Orthography*, *Etymology*, *Syntax*, and *Prosody*.

Orthography, from the Greek words, *orthos*, right, and *graphe*, a writing, is that part of grammar which teaches the nature and powers of letters, and the just method of spelling words.

Prosody, from the Greek word *prosodia*, the accent of a word, treats of the pronunciation of words, and of the laws of versification.

On both these departments we mean to say nothing, principally because, as we apprehend, they can only be effectually taught by the living voice; besides, as far as relates to Orthography, so few general rules have been ascertained, that they afford little help to the young or inexperienced student. Practice alone can give facility and correctness in spelling. With regard to Prosody, we may further remark, that it relates to a mere luxury of language; because, to the effectual communication of thought, metrical arrangement of language is by no means necessary, and, in an elementary work on grammar, it may, without impropriety, be omitted.

This leaves us Etymology and Syntax, which undeniably constitute the chief parts of grammar; and of these we shall treat as fully as our limits permit.

In Etymology we shall be guided by this principle, which we hold to be established, that every word has of itself a distinct office to perform, and we shall be careful to exhibit the force and significance of words taken singly.

In Syntax we shall not attempt to lay down *rules*, as they are called, for every mode of expression, but rather to exhibit a few of the leading principles of our language, the complete understanding of which will supersede the necessity of minute observation on our part, as will enable the student to make them for himself.

We cannot approve of the exhaustive system of teaching Syntax—framing a rule for every peculiarity that the language contains; much better is it to conduct the student at once to the *principles*, which are, as it were, the fountain heads of *rules*. In the one way, we should but exhibit to him every thing *by our torch-light*; but, in the other, *we kindle his own*, and, having pointed out the road in which he is to travel, leave him to himself. When the student is familiar with the principles, it may be desirable to exercise himself on minute details, and a school-grammar should provide exercises on the minutest peculiarities of the language.

ETYMOLOGY.

Etymology, from the two Greek words, *etumon*, the root of a word, and *logos*, a discourse, is that part of grammar which treats of the various classes into which words are arranged, of the different modifications they undergo to express difference of meaning, and of their origin and history.

I. CLASSIFICATION.

Words are the symbols of ideas, and they are classified and named, not from their form, but from the nature of the idea that they represent or stand for. The class of any particular word is only to be ascertained by observing the office which it performs. What it *does*, alone indicates what it *is*.

It would be quite impossible to say, previous to actual inspection, how many sorts of words, or, as they are generally called, *parts of speech*, exist in any language; but, upon examination, it is ascertained that all words used in the English language may be arranged under eight heads.

The eight parts of speech are—Noun, Adjective, Pronoun, Verb, Adverb, Preposition, Conjunction, and Interjection.

A definition of each of these classes of words ought to point out the characteristic or specific idea by which it is distinguished from all the others; and every individual word, brought under any of the eight heads, must agree with the definition, *if it is adequate*—that is, neither too extensive nor too limited.

THE NOUN.

A Noun, from the Latin word *nomen*, a name, is the name of any person, place, thing, quantity, or principle; or, more generally, it is the name of whatever can be an object of contemplation or subject of discourse.

The characteristic of the noun is this: it gives of itself a distict idea or object of thought; thus, of the words, *to*, *pen*, *just*, *alas!* *he*, *terrify*, and *ship*, the only ones that present a picture to the "mind's eye" are *pen* and *ship*. These, therefore, we call *nouns*; but the others do not belong to this class.

It should be carefully observed, that every proposition, or sentence that asserts any thing, must contain at least a noun and a verb—the noun to express the thing spoken about, and the verb to indicate what is affirmed concerning it.

Nouns are divided into two great classes, *Proper* and *Common*.

Proper nouns are such as are applied to individual persons or things only; such as *Victoria*, *Britain*, *Edinburgh*.

Common Nouns are applicable to whole classes of persons or objects; as, *queen*, *island*, *city*. Common Nouns are by some divided into three sub-classes, called *Abstract*, *Collective*, and *Verbal*; by which arrangement the class of Common Nouns, in the limited acceptation of the term, includes only the names of things obvious to some of the five senses.

An abstract noun is the name of a quality thought of apart from all consideration of the substance in which the quality resides. The term bears reference to an act of the mind, called *abstraction*, by which we fix our attention on one property of an object, leaving the others out of view. Snow, chalk, and writing-paper, are white, and, from this quality, are oppressive to the eyes. Abstracting the quality from the substance, we say "Whiteness is oppressive to the eyes." *Whiteness* thus becomes an abstract noun.* An abstract noun may also be a name indicating the want of a quality, as *unworthiness*. Comprehensively, abstract nouns are the names of *immaterial existences, acts, or states*.

Collective Nouns are those which, though singular in form, may suggest the idea of plurality. They are such as, *army*, *clergy*, *crowd*.

The imperfect participle of a verb (which will be treated of afterwards), when used as the *name* of an action, is called a Verbal Noun. In the sentence, "The eye is not satisfied with seeing, nor the ear filled with hearing," the words *seeing* and *hearing* are called Verbal Nouns.

THE ADJECTIVE.

An Adjective is a word that qualifies a noun, that is, marks it out from other things that bear the same name.

The characteristic of the adjective is, that it limits the application of the noun: thus, the term *island* is applicable to every portion of land surrounded by water; but if the adjective *fertile* be affixed to it, all islands not distinguished by the property of fertility are excluded from our consideration.

This part of speech seems to have received its name from an accidental circumstance, and not from any thing essential to its nature. In the Latin language, it was usual to place the word modifying the noun after it, thus, *tabula longa*, while we prefix it, and say, *a long table*; the Latin grammarians, therefore, called this class of words *adjectives*, from *ad*, to, and *jectus*, thrown, and we retain the term, although our modifying word goes first. If the student has learned to recognise the *noun*, he will feel no difficulty in knowing the *adjective*, because its office is to point out some peculiarity which distinguishes the noun.

"Nouns adjective are the words which express quality considered as qualifying, or, as the schoolmen say, in concrete with some particular subject. Thus, the word *green* expresses a certain quality considered as qualifying, or as in concrete with the particular subject to which it is applied. Words of this kind, it is evident, may serve to distinguish particular objects from others comprehended under the same general appellation. The words *green tree*, for example, might serve to distinguish a particular tree from others that were withered or blasted."*

Adjectives are generally divided into two great classes, Attributive and Numeral, or those which denote quality and those which refer to number.

The words *a* or *an* (two different forms of the same word) and *the*, are reckoned by some grammarians a separate part of speech, and receive the common name of *Article*—*a* or *an* being called the *indefinite*, and *the*, the *definite* article; but, as they in all respects come under the definition of the adjective, it is unnecessary, as well as improper, to rank them as a class by themselves.

In signification, *a* or *an* is equivalent to the numeral adjective *one*, and *the* to the demonstrative adjective *that*: and the only difference between them is, that *a*, *an*, and *the*, convey the idea less emphatically than *one* and *that*. Whoever reads Dr. Crombie's remarks on the "Article," must be convinced of the absurdity of reckoning it a distinct part of speech.

Various other words, generally arranged under the head of Pronoun, seem more properly to belong to the adjective. For instance, the eight words, *my*, *thy*, *his*, *her*, *its*, *our*, *your*, *their*, corresponding exactly in office with the definition of the adjective; but as they are derived from, and answer to, the *personal pronouns*, they may be called *pronominal adjectives* with more propriety than *possessive pronouns*. If they ever stand alone, they do not exactly supply the place of a noun, but merely have it understood, and so, as will presently appear, do not come under the definition of *pronoun*. In like manner, the words *this* and *that*, with their plurals *these* and *those*, by many called *demonstrative pronouns*; and also the four words *each*, *every*, *either*, and *neither*, named *distributive pronouns*—must in strict propriety be considered as adjectives, in as much as they both precede and designate nouns, but never supply their place.

THE PRONOUN.

A Pronoun is a word that supplies the place of a noun.

Pronouns may be divided into *Personal*, *Relative*, and *Interrogative*.

The Personal Pronouns are three in number—*I*, *thou*, and *he*, *she*, or *it*.

I is used when the person speaking refers to himself; *thou*, when he refers to the person addressed; and *he*, *she*, or *it*, when he speaks of some other person or thing.

In a work equally interesting to the grammarian and the philosopher, we find the following account of the Personal Pronouns, and we confidently recommend it to the attention of our readers:—"In all speech there is a *speaker*; there is some *person spoken to*; and there is some *person* or *thing spoken of*. These objects constitute three classes, marks of which are perpetually required. Any artifice, therefore, to abridge the use of marks of such frequent occurrence, was highly to be desired. One expedient offered itself obviously, as likely to prove of the highest utility. *Speakers* constituted one class, with numerous names; *persons spoken to*, a second class; *persons* and *things spoken of*, a third. A *generical* name might be invented for each class—a name which would include all of a class, and which singly might be used as the substitute of many. For this end were the personal pronouns invented, and such is their character and office. 'I' is the generical mark which includes all marks of the class *speakers*; 'thou' is a generical mark which includes all marks of the class *persons spoken to*; 'he,' 'she,' 'it,' are marks which include all marks of the class *persons* or *things spoken of*."†

* Though we thus distinguish one class of nouns—those, namely, which come from adjectives or are closely connected with them—by the title *abstract*, we are far from wishing it to be inferred that *common nouns* are not apprehended by the same faculty. On the contrary, metaphysical propriety compels us to admit that such is the case; and if any of our readers feel an interest in the question, we request him before condemning our opinion, to peruse the third chapter of the third book of Locke's *Essay concerning Human Understanding*, and also Adam Smith's *Dissertation on the Formation of Languages*.

* Adam Smith.

† Mill's *Analysis of the Human Mind*, vol. i. p. 142

All pronouns refer to some noun, which, as it generally goes before, gets the name of *antecedent*, but as it may come after, *correlative* would appear a better term. In the case of one class of pronouns, the reference is so obvious and immediate, that they have been called Relative, by way of distinction. These are, *who*, *which*, *that*, and *as*. *Who* is used when the reference is to a person; *which*, when it is to a thing; *that* and *as* refer either to persons or to things.

The Interrogative Pronouns, so called because they are used to ask questions, are *who*, *which*, *what*, and *whether*. When *what* is not used to ask a question, it gets the name of Compound Relative Pronoun, as it includes in itself the ideas of both correlative and relative; thus, "Give me *what* is in your hand" is equivalent to "Give me *the thing which* is in your hand."

The inseparable word *self*, with its plural *selves*, is called the Reciprocal Pronoun, and denotes that the object and agent of the verb are the same.

Self is added to personal pronouns for the same purpose that *own* is affixed to pronominal adjectives; that is, to express emphasis or opposition. Thus, "I did it with my own hand;" that is, without the assistance of any other person: "He did it all *himself*;" that is, without help.

The Verb.

A Verb is a word that *affirms* something of a noun.

The characteristic of the verb is affirmation; it may, indeed, in common with the adjective, denote a *quality*; but this is accidental, and not essential to its nature. The *attribute* and the *assertion* are often conjoined in one word, as in the sentence "The man *rejoices*;" but they may be separated, and then an adjective will denote the attribute and a verb will indicate the assertion; thus, "The man is *joyful*." It is but fair to add, that this doctrine of the verb is not universally received, although, after weighing the adverse arguments of Horne Tooke and Mr. Mill, we are inclined to consider it well founded.

On attending carefully to the nature of the idea presented by verbs, we find that, while they all *assert*, they differ in this respect, that some of them express a sort of action which affects or operates upon some person or thing different from the agent, and that others either denote no action at all, or else a sort of action which is limited to the actor. The first class is called Transitive, and the second Intransitive Verbs. If the student consider with attention the state of his own mind when he repeats, with intelligence, the sentences, "James *strikes* the table," "James *walks*," he will have no difficulty in discerning the distinction that exists between a Transitive and an Intransitive Verb.

We have already stated, but the importance of the remark will justify its repetition, that as the noun denotes the thing spoken of, so the verb indicates what we affirm concerning it. Without affirmation there could be no communication of sentiment; and hence the class of words by which affirmation is made has been dignified by the appellation of verb, or *the word*. "Verbs must necessarily have been coeval with the very first attempts towards the formation of language. No affirmation can be expressed without the assistance of some verb. We never speak but in order to express our opinion that something either is or is not. But the word denoting this event, or this matter of fact, which is the subject of our affirmation, must always be a verb."*

The Adverb.

An Adverb is a word that qualifies a verb, adjective, or another adverb.

As a *description* of a fact in grammar, this is unobjectionable; but it cannot be received as a *definition*, since the word defined is made use of in the definition. Its application may be thus explained. If we wish to modify the noun or *subject* of a sentence, we must use an adjective; but if the *predicate* is to be modified, or any additional modification to be put on a word already qualifying it, the verb then used must be an adverb: thus, in the sentence, "The sun shines," we have a simple subject, "sun," and a simple predicate "shines." If we wish to express any quality of the subject, we must use an adjective; and if the predicate is to be modified, we must bring in an adverb: thus, "The *bounteous* sun shines," and "The sun shines *equally* on all."

Adverbs may be divided into four great classes:—

1. Adverbs of *Manner*; as well, ill, justly, wisely.
2. Adverbs of *Time*; as now, then, soon, when.
3. Adverbs of *Place*; as here, hence, there, where.
4. Adverbs of *Quantity*; as much, considerably.

The adverb, it may be observed, is an abbreviated mode of expression, and the idea could in all cases be conveyed by the use of two or more words. They have a close affinity to adjectives, not only in English, but in most other tongues. Ruddiman justly says, "That adverbs seem originally to have been contrived to express compendiously in one word what must otherwise have required two or more." The truth of this doctrine will appear by an inspection of the following table of Adverbs of Place:—

	In.	To.	From.
This place	Here	Hither	Hence
That place	There	Thither	Thence
What place	Where	Whither	Whence

The Preposition.

A Preposition is a word that connects two words together, in such a manner as to indicate the relation which the things or ideas signified by them bear to each other.

This part of speech, like the adjective, which it resembles in other respects, has received its name from an accidental circumstance. It generally goes immediately before the object related to the other thing named; but the essence of the preposition, it should be carefully observed, is to signify *relative position*.

We subjoin a list of the prepositions in most common use, and we recommend the student to exercise himself in putting them all, one after the other, into sentences. In this way he will learn to apprehend their real significancy; and, instead of calling a word a preposition because it is so named in a compendium of grammar, he will recognise it from its function. Doubtless, by committing the list to memory, a practice as common as it is mischievous, he might be soon able to parse; but his knowledge would be mere deception, and he himself would be but "as sounding brass and a tinkling cymbal."

LIST OF PREPOSITIONS.

Above	Between }	In	Till }
About	Betwixt }	Into	Until }
After	Beyond	Near	To }
Against	Before	Nigh	Unto }
Among }	Behind	Of	Toward }
Amongst }	Beneath	Off	Towards }
Amid }	Below	Over	Under }
Amidst }	Besides	On }	Underneath }
Around }	By	Upon }	Up
Round }	Down	Since	With
At	For	Through }	Within
	From	Throughout }	Without

The following remarks on this part of speech by Adam Smith, and his scarcely less illustrious disciple, Mr. Mill will amply repay an attentive examination:—

"Prepositions are the words which express relation considered in concrete with the correlative object. Thus, the prepositions *of*, *to*, *for*, *with*, *by*, *above*, *below*, &c., denote some relation subsisting between the objects expressed by the words between which the prepositions are placed; and they denote that this relation is considered in concrete with the correlative object. Words of this kind serve to distinguish particular objects from others of the same species, when those particular objects

* Adam Smith.

cannot be so properly marked out by any peculiar qualities of their own. When we say 'The green tree of the meadow,' for example, we distinguish a particular tree, not only by the quality which belongs to it, but by the relation which it stands in to another object." And again, "Every preposition denotes some relation considered in concrete with the correlative object. The preposition *above*, for example, denotes the relation of superiority—not in abstract, as it is expressed by the word *superiority*, but in concrete with some correlative object. In this phrase, for example, 'The tree above the cave,' the word *above* expresses a certain relation between the *tree* and the *cave*, and it expresses this relation in concrete with the correlative object, *the cave*. A preposition always requires, in order to complete the sense, some other word to come after it, as may be observed in this particular instance."*

To the same purpose Mill says—"It is easy to see in what manner prepositions are employed to abridge the process of discourse. They render us the same service which, we have seen, is rendered by adjectives, in affording the means of naming minor classes, taken out of larger, with a great economy of names. * * * Prepositions always stand before some word of the class called by grammarians nouns substantive. And these nouns substantive they connect with other nouns substantive, with adjectives, or with verbs."†

The Conjunction.

A CONJUNCTION is a word used to join words and propositions together.

Conjunctions are of two sorts, *Copulative* and *Disjunctive*. The Copulative not only join the words, but indicate that the things are to be united; while it is the office of the Disjunctive to unite the words but keep separate the things. The youngest child cannot fail to perceive the difference between these two sentences: "Will you have an apple *and* an orange?" and "Will you have an apple *or* an orange?" In the first case, he is to get both things—we therefore use a copulative conjunction; in the second, he is to have one only—we therefore use a disjunctive conjunction.

In one respect the preposition and conjunction agree—they both connect words; but each class does something not done by the other. The preposition indicates the nature of the connection, which the conjunction does not; and, on the other hand, the conjunction can connect not merely single words but clauses or sentences. If I say, "Give me a knife *and* the book," you may present the objects named separately or together—the knife being *under* the book, *in* the book, or *on* it, and in each case my request will have been complied with: but if I say, "Give me a knife *in* the book," the *relative position* of the objects is fixed, and there is only one way of complying with my demand.

We have asserted that the conjunction couples individual words as well as propositions; but, as in this we go against authorities so respectable as Ruddiman, Harris, and Mill, we must take some pains to make good our position. Ruddiman says, "A conjunction is an indeclinable word, that joins sentences together, and thereby shows their dependence upon one another;" and, in a note to his rule of syntax—"Conjunctions couple like cases and moods"—he tells us, that "the reason of this construction is, because the words so coupled depend all upon the same word, which is expressed to one of them and understood to the other." To much the same purpose Mr. Mill says—"The conjunctions are distinguished from the prepositions by connecting predications, while the prepositions connect only words. There are seeming exceptions, however, to this description, the nature of which ought to be understood. They are all of one kind; they all belong to those cases of predication in which either the subject or predicate consists of enumerated particulars, and in which the conjunction is employed to mark the enumeration. Thus, we say, 'Four and four, and two, are ten.' Here the subject of the predication consists of three enumerated particulars, and the conjunction *seems* to connect words and not predications." We do not think that Mr. Mill's argument is conclusive. There is no *seeming* about the matter. We wish it, however, to be distinctly understood that we do not charge his doctrine with being altogether erroneous; it is only not complete. It is right so far as it goes; what we maintain is, that it is too limited.

Ruddiman is correct in maintaining, that in the example, "Honour thy father and thy mother," the word "honour" is again understood before mother; but this will not do in every case. The sentence, "Charles and John rode to town," may certainly be resolved into two clauses, "Charles rode to town" and "John rode to town." But can the sentence "Charles and John carried fifty pounds," be resolved into the two, "Charles carried fifty pounds," and "John carried fifty pounds?" Obviously not. The conjunction *and*, in that case, connects the two words "Charles" and "John," and shows that conjointly they are the *subject* of the *predicate* "carried." In like manner, in the sentence, "The man of piety and virtue secures the favour of God," it is not implied that "the man of piety" secures the favour of God, and that "the man of virtue" secures the same; but that the man uniting the two qualities, the *marks* of which are united by the conjunction *and*, secures it. Mr. Mill himself, indeed, would appear not to have felt quite satisfied as to the conclusiveness of the mode of reasoning which we have been animadverting on, for he immediately shifts his ground, and argues that, because in such a sentence as "His bag was full of hares and pheasants and partridges," we may substitute the preposition *with*, and read, "His bag was full of hares, with pheasants, with partridges," the word *and* is properly to be considered a preposition. To this extraordinary specimen of reasoning it is sufficient to say, that by a similar process we might conclude, to use a homely illustration brought forward by Dugald Stewart on a like occasion, that because people can "supply the want of forks by their fingers, that therefore a finger and a fork are the same thing." On the whole, we consider that nothing can well be clearer than that these great grammarians have taken up a wrong position; but perhaps we have said as much already as the importance of the subject warrants.

The Interjection.

AN INTERJECTION is a word used to express emotion or excitement of mind.

Pure interjections are mere instinctive emissions of the voice, few in number and unimportant in character; and, as to other parts of speech used *interjectively*, the expression is, we apprehend, elliptical; but this circumstance cannot properly change the nature and character of a word. Horne Tooke considers that "interjections have no more claim to be called parts of speech than the neighing of a horse or the lowing of a cow;" but as there are words in the language which express mental emotion and nothing else, we must have a name for them, and it would be difficult to find a better than the one in universal use.

PARSING.

The student should now be able to analyze, or *parse*, as it is generally called by English grammarians, any sentence submitted to him. Various artificial rules have been devised to enable one to know what part of speech any word belongs to; but these we mean not to mention, being fully persuaded that such *helps* are altogether "from the purpose" of grammar, inasmuch as they ren-

* Adam Smith

† *Analysis*, &c., vol. i. p. 148.

der thought first unnecessary and then impossible. No person can parse a sentence which he does not understand, and, when he does so understand it, he can have no difficulty in referring each individual word to the class to which it belongs. All he has to do is to compare the idea suggested in his mind by the word to be parsed with the definitions of the various classes with which he must be familiar; and by this mental effort it will soon be ascertained to what class the word belongs. The idea suggested by any word, and the characteristic idea of a class, being brought before the mind at the same time, their identity or difference must be at once apparent. But not to deal in general reasoning more, we shall present the *analysis* of a short sentence by way of example:—

"A man that is young in years may be old in hours, if he has lost no time; but that happeneth rarely."—*Bacon's Essays.*

A is an adjective, because it limits the signification of the noun *man*.

Man is a noun, because it is the name of a class of beings.

That is a relative pronoun; its correlative is *man*.

Is is a verb, because it asserts something (existence.)

Young is an adjective, qualifying the noun *man* understood. Every adjective must have a noun understood or expressed.

In is a preposition, inasmuch as it points out the *relation* that "years" has to "young man."*

Years is a noun, being the name of a portion of time.

May is a verb, asserting something (power) of the noun *man*.

Be is a verb, asserting or denoting existence.

Old is an adjective, qualifying the noun *man* understood.

In is a preposition, as above.

Hours is a noun, being the name of a division of time.

If is a conjunction, connecting the clause, "A man that is young in years may be old in hours," to the following clause, "he has lost no time." As *if* in such cases points out the *condition* on which the assertion going before it is to be received, it is called by many grammarians a conditional conjunction.

He is a personal pronoun, standing instead of the noun *man*.

Has is a verb, asserting something (possession.)

Lost is a verb indicating an act. On the nature of this part of the verb we shall have more to say afterwards.

No is an adjective, qualifying the noun *time*.

But is a conjunction. It connects the two clauses, and at the same time indicates, or, to adopt the apt expression of which Mr. Mill frequently makes use, *connotes* that the clause coming after it is in opposition to the one going before, and therefore it is called a disjunctive conjunction.

That is a demonstrative adjective, qualifying the noun *thing* understood.

Happeneth is a verb, asserting something of its subject, "that thing."

Rarely is an adverb of time, modifying the verb *happeneth*.

As an additional exercise in *parsing*, we shall transcribe a stanza from Campbell's beautiful ode, "Farewell to Love," containing, according to our view, ten of each of the three classes, nouns, adjectives, and verbs; five of the two, pronouns and prepositions; two conjunctions, and three adverbs. The student is requested to make a careful analysis for himself, and see how far our enumeration be consistent with his own:—

"Hail! welcome tide of life, when no tumultuous billows roll;
How wondrous to myself appears this halcyon calm of soul!
The wearied bird blown o'er the deep would sooner quit its shore,
Than I would cross the gulf again that time has brought me o'er."

To the subject of parsing we shall return before we quit Etymology; but for the present we wish to direct the attention of the reader to the various modifications put on words to express a difference of meaning.

II. INFLECTION.

Any change made upon the termination of a word is called its *accident* or *inflection*; thus, the words, *boy's*, *harder*, *its*, *loved*, and *sooner*, are said to be inflected forms, or simply inflections of the words *boy*, *hard*, *it*, *love*, and *soon*. Of the eight parts of speech, five only—the noun, adjective, pronoun, verb, and adverb—are declinable, that is, capable of being inflected; while the remaining three—preposition, conjunction, and interjection—are indeclinable, that is, cannot be varied in such a way as to express any modification in meaning.

Inflection of Nouns.

The noun is varied in three ways—Number, Gender, and Case.

NUMBER shows whether one or more than one thing is meant by the noun.

There are two Numbers, the Singular and the Plural. The singular expresses one of a class; as river, horse. The plural denotes more than one; as rivers, horses. The plural is generally formed from the singular, by adding the letter *s*; thus, table, table*s*; book, book*s*; pen, pen*s*. But nouns ending in any of the five following terminations, *s*, *sh*, *ch* (when pronounced soft), *x*, and *o* (*impure*, that is, preceded by a consonant), form their plural by adding *es* to the singular; thus, brush, brush*es*, church, church*es*; box, box*es*; hero, hero*es*.

When *ch* is pronounced hard, and when *o* is preceded by a vowel, the plural is formed by adding *s*; thus, monarch, monarch*s*; folio, folio*s*.

When a noun ending in *y* is to be formed into the plural, *s* is added if the *y* is preceded by a vowel; but if a consonant goes before the *y*, then the *y* is changed into *ies*; thus, in boy, there is a vowel before the *y*, we therefore add *s*, boy*s*; but in duty there is a consonant before the *y*, the plural therefore is dut*ies*.

Nouns ending in *f* or *fe*, generally form the plural by changing the *f* or *fe* into *ves*; thus, loaf, loa*ves*; knife, kni*ves*.

Nouns derived from dead or foreign tongues, for the most part retain their original plurals; thus,

From the Latin we have—

SINGULAR.	PLURAL.
Effluvium	Effluvia
Radius	Radii
Larva	Larvæ
Vortex	Vortices
Axis	Axes
Genus	Genera
Magus	Magi
Medium	Media
Oasis	Oases
Nebula	Nebulæ
Stratum	Strata

From the Greek come—

SINGULAR.	PLURAL.
Phenomenon	Phenomena
Crisis	Crises
Hypothesis	Hypotheses
Criterion	Criteria
Automaton	Automata
Thesis	Theses
Elipsis	Elipses
Metamorphosis	Metamorphoses
Basis.	Bases.

The Hebrew words *cherub* and *seraph* form their plurals *cherubim* and *seraphim*; and the French *beau* and *monsieur* form their plurals *beaux* and *messieurs*, which last is contracted into *messrs.*

A few nouns, in very common use, form their plurals quite anomalously; thus,

SINGULAR.	PLURAL.
Man	Men
Foot	Feet
Tooth.	Teeth.

GENDER.—Gender is that accident of a noun which points out the sex or the absence of sex. Every existence is either male or female, or neither the one nor the other. The Masculine Gender includes all males, the Feminine, all females; and the Neuter, all things destitute of sex, or animals when the sex is not regarded.

Adam Smith remarks, that, "in many languages, the qualities both of sex and of the want of sex are expressed by different terminations in the substantive which denote objects so qualified." After showing that, in Latin, certain *terminations* were appropriated to expressing certain genders, he adds, "The quality [of sex] appears in nature as a modification of the substance and as it is thus expressed in language by a modification of the noun substantive which denotes that substance, the quality and the subject are, in this case, blended together, if I may say so, in the expression, in the same manner as they appear to be in the object and the idea

*It must be confessed that it is not in all cases easy for the mind to apprehend the nature of the relation pointed out by a preposition. The student will do well to familiarize his mind with *physical relations* in the first place, and moral will afterwards become more easily recognisable. In the following sentence it is at once perceived what relation the first *in* expresses, but much more difficult to get the distinct idea meant to be conveyed by the second:—"Diogenes sat *in* a tub, but he was generally *in* good humour."

Hence the origin of the masculine, feminine, and neuter genders, in all the ancient languages."

Admitting the truth as well as the ingenuity of this speculation, as far as regards ancient languages, it does not appear to be the *genius* of the English language to assign any particular termination (as we find in the Latin) to the different genders; there, are, however, some cases in which gender may be recognised, from the mere termination of the noun, as will appear from the following table:—

MASCULINE.	FEMININE.
Actor	Actress
Governor	Governess
Heir	Heiress
Lion	Lioness
Master	Mistress.

In some cases, difference of sex is expressed by a totally different word, and the gender cannot be known but by knowing the exact idea attached to the word. Of this sort are the following:—

MASCULINE.	FEMININE.
Boy	Girl
Father	Mother
Brother	Sister.

Sometimes the same word is applied to males and females indiscriminately; and when we wish to distinguish the sex, we prefix another word. Thus, the word *servant* signifies either a male or female; but if we desire to notify which, we can use the compound words *man-servant* or *maid-servant*. Of the same kind are *he-goat* and *she-goat*, *cock-sparrow* and *hen-sparrow*, and many others.

CASE.—Case is that accident of a noun which points out the relation which it bears to other parts of the sentence.

Nouns have three Cases—Nominative, Possessive, and Objective.

The noun is said to be in the Nominative, when it is the subject of discourse, and represents the person or thing of whom or which some assertion is made. Thus, in the sentence, "John reads," the proper noun *John* is said to be in the nominative, because it names the person of whom the assertion *reads* is made.

The possessive represents a vast variety of relations, but the principal one is that of ownership or possession. Thus, "John's book is lost," where *John's* is in the possessive, because it names the owner of the *book*.*

The inflection of the Possessive Case (the only case in English that has an inflection) corresponds exactly in import to the preposition *of*. In the line,

"An angel's virtues and a woman's love,"

we could easily dispense with the possessive, and introduce the preposition, where the whole meaning would be preserved; thus,

The virtues *of* an angel and the love *of* a woman.

Adam Smith asserts that inflections would probably be made before *prepositions* were invented; observing very justly, that it requires much less *abstraction* to express the nature of the relation that subsists between two objects *by a change on the name denoting one of them*, than to call into use a class of words expressing relation and nothing else. "To express relation by a variation in the name of the correlative object, requiring neither abstraction nor generalization, nor comparison of any kind, would at first be much more natural and easy than to express it by those general words called prepositions, of which the first invention must have demanded some degree of all these operations."

This speculation is exceedingly ingenious; but whether it be true in general is, to say the least, doubtful; and as far as the possessive of the English noun goes, it must be allowed, we think, to be wide of the truth.

The noun is in the Objective Case—1st, when it names the *object* on which the action expressed *by* a transitive verb operates; and, 2d, when it names the thing *shown* to be related to something else by a preposition. In the sentence, "John destroyed his book," *book* is expressing the *object* on which the verbal action operates; it is therefore said to be in the objective case. Again, in the sentence, "The cloud rises over the hill," *hill* is in the objective, because it is the word shown to be related to *cloud* by the preposition *over*.

The Nominative and Objective of nouns are alike in form; and it is only by observing how the noun stands related to other words that we can say when it is in the one and when in the other. To decide on the case of a noun, we must "look before and after." The Possessive, however, may be recognised by its form, as well as by its function, as it for the most part ends with 's in the singular, and ' after the *s* in the plural.

A noun is thus declined:—

	SINGULAR.	PLURAL.
Nominative.	Brother	Brothers.
Possessive.	Brother's	Brothers'.
Objective.	Brother	Brothers.

When the plural does not end in *s*, the Possessive is formed in the same way as the singular; thus,

	SINGULAR.	PLURAL.
Nominative.	Man	Men
Possessive.	Man's	Men's
Objective.	Man.	Men.

Inflection of Adjectives.

In many languages, the Adjective is changed in termination to correspond with the noun which it qualifies; but in the English tongue there is no such modification; and here, as in many other respects, our language seems superior in metaphysical propriety to most others, because the accident of gender cannot properly belong to a quality which is itself but an accident and no self-existing thing. "Gender, it is to be observed, cannot properly belong to a noun adjective, the signification of which is always precisely the same, to whatever species of substantives it is applied. When we say 'a great man,' 'a great woman,' the word *great* has precisely the same meaning in both cases, and the difference of the sex in the subjects to which it may be applied makes no sort of difference in its signification. *Magnus, magna, magnum*, in the same manner, are words which express precisely the same quality, and the change of the termination is accompanied with no sort of variation in the meaning. Sex and gender are qualities that belong to substances, but cannot belong to the qualities of substances."*

But while the nature of the thing which the adjective is employed to express cannot be varied, yet it may exist in different proportions; and hence the adjective is varied to express different degrees of the quality indicated by it, and these variations are called Degrees of Comparison.

When the simple quality is denoted, the adjective is said to be in the Positive Degree. When a higher

* Concerning the origin of the possessive case, English grammarians and critics are not agreed. Some maintain that it is what we may call indigenous to the language, corresponding, they affirm, to an inflection of the Saxon noun; but we rather incline to the opinion of Addison, who thinks that the possessive termination is only a contraction for the pronoun *his*. Had the *possessive* case been native to our tongue, it is hardly conceivable that the translators of the Bible would have used such an expression as "Asa his heart was perfect." It has been ingeniously objected to Addison's explanation, that while it is very easy to see how "the king his crown" might have been contracted or corrupted into "the king's crown," it is impossible to imagine that "the queen her crown" or "the children their bread" could have been subjected to the same contraction. But surely this objection is not unanswerable; for when the convenience of the contraction was seen in the case of singular nouns masculine, it might very easily be transferred to nouns feminine and plural. We would not be understood, however, to speak confidently on the point; and in whatever way the possessive was introduced, it is now impossible, supposing it were desirable, to displace it.

* Adam Smith.

degree is signified, the adjective is in the Comparative; and when the highest degree is expressed, it is said to be in the Superlative. Logically considered, indeed, the *positive* involves the idea of comparison as much as the comparative: thus, when we affirm of a mountain that it is *lofty*, we must have a tacit reference to other mountains; when we affirm of any particular river that it is *rapid*, we (unconsciously, perhaps, but yet actually) make a comparison between it and some other rivers. We consider it, therefore, impossible to state any essential difference between the *degrees of comparison*; but, in addition to what we have already said, we may mention that the *comparative degree* denotes that the quality expressed by it belongs to one of two objects in a greater degree than to the other; and the superlative, that it belongs to one of several in a greater degree than to any of the rest. For example, when we say that the line A—— is longer than the line B——, the meaning is, that both lines have a certain quality—length, but that A has more of it than B. When the comparison is drawn between more things than two, we use the *superlative*. Thus, we say of the lines A——, B———, C———, D——, that C is the longest. In the same way, speaking of stone and wood, we might say, "Stone is the *harder* body of the two;" but if we are discoursing of iron, stone, and wood, we must use the superlative, and say, "Iron is the *hardest* body of the three."

The whole class of Numeral Adjectives, from their very nature, cannot be in any other degree than the positive; and, with respect to Attributive Adjectives, it is to be observed that those only which express a quality which may exist in greater or less proportions, can be compared: for instance, if the exact *ideas* represented by the words, *circular*, *square*, *triangular*, and also such words as *chief*, *extreme*, *universal*, and *eternal*, be apprehended by the mind, by the very act of apprehension it will be seen that it would be contradictory to their nature to admit of any increase. Let the student reflect on this, and then he will be able to dispense with rules about the use of *chief*, *perpendicular*, &c., because he will see at once, from the nature of the idea suggested by the word, whether it admits of increase or diminution.

The Comparative is formed by adding *er* to the Positive, if it end with a consonant, and *r* simply, if it end in the vowel *e*; thus, hard, harder; large, larger.

Adjectives compared in this manner are called Regular; but some adjectives follow no rule in forming their degrees of comparison, and these are called Irregular. The following are those most commonly in use:—

POSITIVE.	COMPARATIVE.	SUPERLATIVE.
Good	Better	Best
Bad	Worse	Worst
Little	Less	Least
Much *or* many.	More.	Most.

Sometimes the same idea is conveyed by prefixing an adverb to the adjective in its simple state: thus, instead of saying *juster*, we might say *more just*: but it is not therefore to be inferred that *more just* is the comparison of *just*. Were this principle admitted, we should soon be in inextricable confusion. In such cases *more* is an adverb in the comparative, qualifying the adjective *just*, and the two words should be parsed separately. The prefixing of an adverb cannot, with any justice, be called a variation of the adjective.

A few adjectives have a plural form, particularly the demonstrative, *this* and *that*: in the plural, *these* and *those*: *one other*, and *another*, are also sometimes varied by number or case.

Inflection of Pronouns.

The Pronoun is varied by Gender, Number, Person, and Case.

The Personal Pronouns are thus declined:

SINGULAR NUMBER.

	NOMINATIVE.	POSSESSIVE.	OBJECTIVE.
1st *Person*,	I	Mine	Me
2d "	Thou	Thine	Thee
3d "	He, she, it.	His, hers, its.	Him, her, it.

PLURAL NUMBER.

	NOMINATIVE.	POSSESSIVE.	OBJECTIVE.
1st *Person*,	We	Ours	Us
2d "	Ye *or* you	Yours	You
3d "	They	Theirs	Them.

By inspecting the two following lines, the student will understand what we meant by saying, that the Possessive Pronouns, or, as we prefer calling them, Pronominal Adjectives, were derived from, and corresponded with, the Personal Pronouns.

I	thou	he	she	it	we	you	they.
mine	thine	his	hers	its	ours	yours	theirs.

The Relative and Interrogative Pronouns, *who* and *which*, are alike in both numbers, and are thus declined:—

	Who.	*Which.*
Nominative.	Who	Which
Possessive.	Whose	Whose
Objective.	Whom.	Which.

That and *as* are indeclinable.

Inflection of Verbs.

The Verb is varied in *four* ways—Number, Person, Mood, and Tense.

There are two Numbers, Singular and Plural, as in the case of the noun; and three persons, as in the pronouns.

The Moods are generally reckoned *five* in number—the Indicative, the Subjunctive, the Potential, the Imperative, and the Infinitive. But it may well be questioned if there is any real ground for such distinction, as far at least as the Subjunctive and Potential are concerned. The Subjunctive, as it is called, is merely an elliptical mode of expression, and the Potential is made up of two or more verbs, and therefore it can with no propriety be called an *inflection* of any one of them.

This leaves us the Indicative, by which simple assertions are made; the Imperative, by which commands are issued; and the Infinitive, which is neither more nor less than the name of the verb, and in use corresponds exactly to a noun.

The Tenses are two in number—the Present and the Past: the Future is not expressed by any *inflection* of the verb in English, as it is in Latin, French, and other languages, but by the help of another verb; and it is surely absurd to force a distinction upon the English verb, merely because it exists in Latin.*

The Participles of the verb are likewise two in number—the Perfect and the Imperfect. They are often called the Present and Past, but in themselves they have no reference to time, and merely indicate the *completion* or *non-completion* of an action.

According to this view of the verb—the only consistent one—it has no such thing as a passive voice. What is called the passive voice is not formed by any variety of termination, and so cannot be acknowledged as an *inflection*, without opening a door to all manner of confusion.

"The English verb," says Crombie, "has only one voice, namely, the active. Dr. Lowth, and most other grammarians, have assigned it two voices—active and

* "A little reflection may, I think, suffice to convince any person, that we have no more business with *a future tense* in our language than we have with the whole system of Latin moods and tenses: because we have no modification of our verbs to correspond to it: and if we had never heard of a future tense in some other language, we should no more have given a particular name to the combination of the verb with the auxiliary *shall* or *will*, than to those that are made with the auxiliaries *do*, *have*, *can*, *must*, or any other."—PRIESTLEY'S *Rudiments of English Grammar.*

passive. Lowth has, in this instance, not only violated the simplicity of our language, but has also advanced an opinion inconsistent with his own principles. For, if he has justly excluded from the number of cases in nouns, and moods in verbs, those which are not formed by inflection, but by the addition of prepositions and auxiliary verbs, there is equal reason for rejecting a passive voice, if it be not formed by variety of termination. Were I to ask him why he denies *from a king* to be an ablative case, or *I may love* to be the potential mood, he would answer, and very truly, that those only can be justly regarded as cases or moods which, by a different form of the noun or verb, express a different relation or a different mode of existence. If this answer be satisfactory, there can be no good reason for assigning to our language a passive voice, when that voice is formed not by inflection but by an auxiliary verb. *Doceor* [being an inflection of the word *doceo*] is truly a passive voice; but *I am taught* cannot, without impropriety, be considered as such."*

By *conjugating* a verb, is meant mentioning the present and past tenses and the perfect participle.

The past tense and perfect participle are formed from the present tense by adding *ed*, if it end in a consonant, as *rain, rained*, and simply *d* if it end in a vowel, as *change, changed*.

If these parts are formed in any other way, the verb is called Irregular; and if it wants any of these, it is said to be Defective.

We subjoin a few of the Irregular Verbs in most frequent use, or in which mistakes are apt to arise:—

PRESENT.	PAST.	PERFECT PARTICIPLE.
Am	was	been
Awake	awoke	awaked
Bear	bore	born
Beseech	besought	besought
Bereave	bereft	bereft
Bid	bade	bid
Choose	chose	chosen
Cleave	cleft, clave	cleft, cloven
Clothe	clothed	clothed, clad
Crow	crew	crowed
Deal	dealt	dealt
Drink	drank	drunk, drunken
Eat	ate	eaten
Fly	flew	flown
Hang	hung	hung
Lay (to deposit)	laid	laid
Lie (as on a bed)	lay	lain
Rive	rived	riven
Run	ran	run
Shrink	shrunk	shrunk
Shoe	shod	shod
Slink	slunk	slunk
Spit	spit	spit
Tread	trod	trodden
Win	won	won

The Regular Verb is thus inflected:—

To Love.

Present Tense.	*Past Tense.*	*Perfect Participle.*
Love.	Loved.	Loved.

PRESENT TENSE.

SINGULAR.		PLURAL.	
1st *Person,*	I love	1st *Person,*	We love
2d "	Thou lovest	2d "	Ye *or* you love
3d "	He loves.	3d "	They love.

PAST TENSE.

SINGULAR.	PLURAL.
1. I loved	1. We loved
2. Thou lovedst	2. Ye *or* you loved
3. He loved.	3. They loved.

Imperative, Love. *Infinitive,* To love.

PARTICIPLES.

Imperfect, Loving. *Perfect,* Loved.

The verb *To Write* is irregular, and is thus conjugated and declined:—

To Write.

Present Tense.	*Past Tense.*	*Perfect Participle.*
Write.	Wrote.	Written.

PRESENT TENSE.

SINGULAR.	PLURAL.
1. I write	1. We write
2. Thou writest	2. Ye *or* you write
3. He writes.	3. They write

PAST TENSE.

SINGULAR.	PLURAL.
1. I wrote	1. We wrote
2. Thou wrotest	2. Ye *or* you wrote
3. He wrote.	3. They wrote.

Imperative, Write. *Infinitive,* To write.

PARTICIPLES.

Imperfect, Writing. *Perfect.* Written.

The Irregular Verbs, *Be, Do, Have*, and the Defective Verbs, *Shall, Will, May, Can*, from their frequent occurrence, ought to be carefully examined. Tables of them are here presented:—

To Be.

Present Tense.	*Past Tense.*	*Perfect Participle.*
Am.	Was.	Been.

PRESENT TENSE.

SINGULAR.	PLURAL.
1. I am	1. We are
2. Thou art	2. Ye *or* you are
3. He is.	3. They are.

PAST TENSE.

SINGULAR.	PLURAL.
1. I was	1. We were
2. Thou wast	2. Ye *or* you were
3. He was.	3. They were.

Imperative, Be. *Infinitive,* To Be.

PARTICIPLES.

Imperfect, Being. *Perfect,* Been.

The verb To Be has a peculiar inflection, to express contingency or conditionality, which we here subjoin. It may be called the Conditional or Subjunctive Mood. In the case of other verbs, this form is elliptical.

CONDITIONAL TENSE OF THE VERB TO BE.

SINGULAR.	PLURAL.
1. I were	1. We were
2. Thou wert	2. Ye were
3. He were.	3. They were.

To Do.

Present Tense.	*Past Tense.*	*Perfect Participle.*
Do.	Did.	Done.

PRESENT TENSE.

SINGULAR.	PLURAL.
1. I do	1. We do
2. Thou doest *or* dost	2. Ye do
3. He does *or* doth.	3. They do.

PAST TENSE.

SINGULAR.	PLURAL.
1. I did	1. We did
2. Thou didst	2. Ye did
3. He did.	3. They did.

Imperative, Do. *Infinitive,* To Do.

PARTICIPLES.

Imperfect, Doing. *Perfect,* Done.

To Have.

Present Tense.	*Past Tense.*	*Perfect Participle.*
Have.	Had.	Had.

PRESENT TENSE.		PAST TENSE.	
SINGULAR.	PLURAL.	SINGULAR.	PLURAL.
1. I have	1. We have	1. I had	1. We had
2. Thou hast	2. Ye have	2. Thou hadst	2. Ye had
3. He has.	3. They have.	3. He had	3. They had

Imperative, Have. *Infinitive,* To have.

PARTICIPLES.

Imperfect, Having. *Perfect,* Had.

Shall.

PRESENT TENSE.		PAST TENSE.	
SINGULAR.	PLURAL.	SINGULAR.	PLURAL.
1. I shall	1. We shall	1. I should	1. We should
2. Thou shalt	2. Ye shall	2. Thou shouldst	2. Ye should
3. He shall.	3. They shall.	3. He should.	3. They should

* The Etymology and Syntax of the English Language, p. 94

WILL.

PRESENT TENSE.		PAST TENSE.	
SINGULAR.	PLURAL.	SINGULAR.	PLURAL.
1. I will	1. We will	1. I would	1. We would
2. Thou wilt	2. Ye will	2. Thou wouldst	2. Ye would
3. He will.	3. They will.	3. He would.	3. They would.

MAY.

PRESENT TENSE.		PAST TENSE.	
SINGULAR.	PLURAL.	SINGULAR.	PLURAL.
1. I may	1. We may	1. I might	1. We might
2. Thou mayst	2. Ye may	2. Thou mightst	2. Ye might
3. He may.	3. They may.	3. He might.	3. They might.

CAN.

PRESENT TENSE.		PAST TENSE.	
SINGULAR.	PLURAL.	SINGULAR.	PLURAL.
1. I can	1. We can	1. I could	1. We could
2. Thou canst	2. Ye can	2. Thou couldst	2. Ye could
3. He can.	3. They can.	3. He could.	3. They could.

INFLECTION OF ADVERBS.

Adverbs, for the most part, admit no modification or inflection: a few, however, are compared, like adjectives.

Some are Regular, as—

POSITIVE.	COMPARATIVE.	SUPERLATIVE.
Soon	Sooner	Soonest
Often	Oftener	Oftenest
Seldom	Seldomer	Seldomest.

Others are Irregular, as—

POSITIVE.	COMPARATIVE.	SUPERLATIVE.
Well	Better	Best
Badly *or* ill	Worse	Worst
Little	Less	Least
Much	More	Most.

The student will now be able to *parse* a sentence, mentioning not merely what part of speech any word is, but what *inflection* it has undergone, and how it stands related to other words. By way of example, we shall parse one sentence from Bacon.

"A single life doth well with churchmen; for charity will hardly water the ground where it must first fill a pool."

A, a numeral adjective, qualifying the noun *life*. It is commonly called the indefinite article.

Single, an attributive adjective, designating the noun life. It cannot be compared.

Life, a noun, singular in number, neuter gender, and the nominative case, because it is the thing of which something is asserted. The plural of *life* is *lives*.

Doth, a verb, because it asserts something of the noun *life*: it is in the present tense, indicative mood, and the third person singular, to agree with its noun *life*. *Doth* is now almost obsolete, *does* being the word in common use. The verb to do is conjugated thus: *Present Tense*, Do; *Past*, Did; *Perfect Participle*, Done.

Well, an adverb, expressing how "a single life doth." *Well* is in the positive degree, and is compared thus:—*Positive*, Well; *Comparative*, Better; *Superlative*, Best.

With, a preposition, used in a metaphorical sense, to connect *churchmen* with *single life*.

Churchmen, a noun plural, masculine, and the objective; being the object shown to be related to something else by the preposition *with*. The singular is *churchman*. All nouns, it should be remembered, are of the third person.

For, a conjunction, connecting the clause that follows with the one which went before.

Charity, a noun, being *primarily* the name of a disposition of mind, and *secondarily* of the course of action resulting from that disposition; singular, neuter, and the nominative to the verb *will*.

Will, a verb, present tense, singular number, and third person, to agree with *charity*.

Hardly is an adverb of degree, qualifying the verb *water*.

Water is a verb in the infinitive mood. *To*, the sign of the infinitive, is suppressed after a great number of verbs, and *will* is one of them. *Will* is a defective verb, and is conjugated thus:—*Present Tense*, Will; *Past Tense*, Would.

The, numeral adjective, or definite article, qualifying the noun *ground*.

Ground, a noun, singular, neuter, and the objective, being the *thing* which is affected by the verb *water*.

Where is of the nature of a conjunction, since it unites the two members of the last clause; but it also has in it the force of an adverb, being equivalent to *in the case in which*. We may therefore call it a conjunctive adverb.

It is a personal pronoun, singular, neuter, and the third person, supplying the place of the noun *charity*. *It* is the nominative to the verb *must*.

Must is a verb, asserting something of the pronoun *it*. It is in the present tense, and third person singular.

First is an adverb of time, qualifying the verb *fill*.

Fill is a verb in the *infinitive*, *to* being understood after *must*, in the same way as it was after *will*, in the former part of the sentence.

A, numeral adjective, or indefinite article, designating the noun *pool*.

Pool, a noun, singular, neuter, and objective case, being the thing affected by the transitive verb *fill*.

Additional Remarks.—Before quitting this division of our subject, we must inform the reader, that the same word is frequently used in different ways, and consequently belongs to different parts of speech. Nothing can be more certain that every word must have been originally significant of only one idea; but in the progress of language other ideas attach themselves to it, and the grammarian must not resist this extension of meaning, but carefully observe it. To discover, then, what class of words any word belongs to, we must "look before and after;" but a few examples will illustrate our meaning best.

"Come out of the *wet*." Here *wet* is a noun, because it is a name expressive of a certain state of the elements. "John threw off his *wet* clothes." Here *wet* is an adjective, because it qualifies the noun *clothes*. "A shower came on and *wet* the ground." Here *wet* is a verb, because it expresses an action. The shower did something—"wet the ground."

On the following examples let the student exercise himself, in satisfying himself as to the justness of our assertions with regard to the *class* of those words which may belong to one or more.

1. The sun is the great source of *light* (noun). Feathers are *light* (adjec.)

2. Beloved, let us *love* (verb) one another; for *love* (noun) is of God.

3. Then he arose and rebuked the winds and the sea, and there was a great *calm* (noun).

> Thy brow is *calm* (adjec.) and bright,
> Wearing no trace of sorrow or of sin.
>
> To still the pang that conscience can impart,
> And *calm* (verb) the restless pulses of the heart.

4. How often have I loitered o'er thy *green* (noun),
Where humble happiness endear'd each scene.

> Yet wandering, I found, on my ruinous walk
> By the dial-stone aged and *green* (adjec.)

5. Thy *nightly* (adjec.) visits to my chamber made.

> When the blue wave rolls *nightly* (adverb)
> On deep Galilee

6. Yes! there are charms *that* (rel. pron.) scorn the spoiler time.

> Blessed are those,
> Whose blood and judgment are so well commingled,
> *That* (conjunc.) they are not a pipe for fortune's finger
> To sound what stop she pleases. Give me *that* (demon. adjec.) man
> *That* (rel. pron.) is not passion's slave, and I will wear him
> In my heart's core.

7. The common *still* (noun) can only be employed, &c.

> Hope quickens the *still* (adjec.) parts of life.
>
> Is this the Talbot so much feared abroad,
> That with his name the mothers *still* (verb) their babes?

It hath been anciently reported, and is *still* (adverb) received, &c.

John has been very foolish, *still* (conjunc.) I will not dismiss him.

Let the student further exercise himself in what respects one part of speech resembles another, and wherein it differs. He will find that the noun and pronoun, adjective and adverb, preposition and conjunction, resemble each other in some respects, but that they yet are quite distinct.

We conclude this subject with two brief extracts from Locke:—"Besides words which are names of ideas in the mind, there are a great many others that are made use of to signify the connection that the mind gives to ideas or propositions one with another. The mind, in communicating its thought to others, does not only need signs of the ideas it has then before it, but others also, to show or intimate some particular action of its own, at that time, relating to those ideas. This it does several ways; as *is* and *is not* are the general marks of the mind affirming or denying. But, besides affirmation or negation, without which there is in words no truth or falsehood, the mind does, in declaring its sentiments to others, connect not only the parts of propositions, but whole sentences, one to another, with their several relations and dependencies, to make a coherent discourse."

"Though prepositions and conjunctions are names well known in grammar, and the particles contained under them carefully ranked into their distinct subdivisions, yet he who would show the right use of particles, and what significancy and force they have, must take a little more pains, enter into his own thoughts, and observe nicely the several postures of his mind in discoursing."—*Human Understanding*, book iii. chap. 7.

Whoever wishes really to understand the nature and use of words, should study carefully the third book of Locke's invaluable essay.

III.—DERIVATION.

Derivation is that part of Etymology which traces words to their original form and signification.

The ideas attached to words are purely arbitrary and conventional; there being no reason, for instance, why the sound represented by the combination of letters f i r e, should suggest the idea of heat, while that of i c e, should give the notion of cold. From this principle it follows that the real import of any word can be ascertained only by induction, that is, by observing the common idea which it suggests in every different position that it may occupy. Some, indeed, have affirmed, that in order to ascertain with precision the philosophical import of a word, it is necessary to trace its progress historically, through all the successive meanings it has been employed to convey, from the moment that it was first introduced into the language; and others, not content with this, prosecute their etymological research till they arrive at the literal and primitive sense of the root from which it springs. But it may well be doubted if such a course of procedure is followed by any substantial benefit at all proportionate to the labour which it imposes on the student; and one thing is certain, that an appeal to etymology from use is altogether nugatory, and displays an utter ignorance of the nature and function of words. The derivation or pedigree of a word will by no means universally lead to its real meaning. Horne Tooke and his followers have employed themselves in tracing words to their sources, and with wonderful success; but their speculations, however interesting in some respects, are almost useless, as far as the grammar of our language is concerned; and, certainly, though that school of philologists should succeed to their utmost desire in chasing every word now in use up to some Icelandic or Gothic origin, it would in no way interfere with the present structure of the English tongue. It may be very interesting to trace our language from the period when it was only the rude jargon of wandering hordes of savages, down to the present time, when it is capable of expressing with precision the minutest distinctions of the metaphysician or the most glowing conceptions of the poet; but it belongs rather to the philologist to enter on such investigations than the grammarian. Still, some ground is common to both, and it is necessary to say a few words on the subject.

Words are divided into two classes, *Primitive* and *Derivative*.

A Primitive word is one not derived from any other word in the language: as, *man*, *school*.

A Derivative word is either compounded of two significant words in the language, or of one significant word and some termination that modifies its meaning as, *schoolman*, *scholar*.

The bulk of the English language is Anglo-Saxon, and so are the forms of its grammar. A considerable number of its words, however, are from the Latin, and not a few from the Greek, both as entire words, and as parts of words or prefixes.* The following is a list of these Prefixes, together with examples of the manner in which they enter into combination with other words.

LATIN PREFIXES.

A, *ab*, or *abs*, from; as *avert*, to turn from; *absolve*, to loose from; *abstract*, to draw from.
Ad, to; as, *adhere*, to stick to.
Am, round about; as, *ambition*, literally, a going round about.
Ante, before; as, *antecedent*.
Circum, round; as *circumnavigate*.
Con, together; as, *conjoin*, *convoke*.
Contra, against; as, *contradict*.
De, down; as, *destroy*, *demolish*.
Di or *dis*, asunder; as *divert*, *dissolve*.
E or *ex*, out of; as, *evolve*, *extract*.
Extra, beyond; as, *extraordinary*.
In, in, or into; as, *inject*.
Inter, between; as, *intervene*.
Intro, within; as, *introduce*.
Juxta, nigh to; as, *juxtaposition*.
Ob, in the way of; as, *obstacle*.
Per, through; as, *perforate*.
Post, after; as, *postpone*.
Pre, before; as, *prefix*.
Pro, instead of; as, *pronoun*.
Preter, beyond; as, *preternatural*.
Re, back; as, *replace*.
Retro, backward (implying motion); as *retrograde*.
Se, aside; as, *secede*.
Sub, under; as, *sublunary*.
Super, above; as, *superinduce*, *superfluous*.
Trans, across; as, *transport*, *transatlantic*.

GREEK PREFIXES.

A, without; as, *anomalous*, *amorphous*.
Amphi, both; as, *amphibious*.
Ana, up, through; as, *anatomy*.
Anti, against; as, *Antichrist*.
Apo, from, away; as, *apostate*.
Cata, down; as, *catastrophe*.
Dia, through; as, *diagonal*.
Epi, upon; as, *epilogue*, *epidemic*.
Hyper, overmuch; as *hypercritical*.
Hypo, under; as, *hypocrite*.
Meta, change; as, *metamorphosis*.
Para, near to; as, *paraphrase*.
Peri, round about; as *perimeter*.
Syn, together; as, *synod*, *synagogue*.

Affixes.

It is not so easy to trace the Affixes to their original meaning, as they now seldom retain any signification when taken by themselves, but are used merely to modify other words. We shall present a few of them, with examples, but we are far from thinking that the list is complete.

AFFIXES FORMING NOUNS.

an *ant* *ar* *ard* *ary* *eer* *ent* *er* *ist* *or* *ster*	denoting the agent or doer of a thing; as,	Tragedian, historian. Claimant, combatant. Scholar, liar. Drunkard, dotard. Adversary, actuary. Engineer, auctioneer. Adherent, correspondent. Accuser, believer. Apologist, chartist. Actor, creator. Punster, spinster.

AFFIXES FORMING VERBS.

en *fy* *ise* or *ize* *ate*	denoting to make or cause; as,	Harden, strengthen. Purify, clarify. Civilise, equalize. Alienate, assassinate.

AFFIXES FORMING ADJECTIVES.

ful *ous* *ly* *some* *y* *ical* *ive*	denoting full of, or [illegible]	Artful, beautiful. Bounteous, plenteous. Fatherly, homely. Troublesome, toilsome. Wealthy, mighty. Democratical, methodical. Expensive, instructive.

* The reader [illegible] to the article LANGUAGE, in this work for more inf[illegible] this point.

AFFIXES FORMING ABSTRACT NOUNS.

ment		Amusement, abatement.
ness		Goodness, hardness.
sion		Convulsion, expansion.
tion	denoting	Production, vindication.
ty	state of,	Piety, probity.
hood	considered	Childhood, manhood.
ship	abstractedly.	Friendship, courtship.
dom		Christendom, kingdom.
ric		Bishopric.
tude		Lassitude, fortitude.

All words must originally have had only one meaning, but subsequently they come to have various secondary significations. These are attached to them according to fixed laws of the association of ideas; but in the case of each individual word, the signification must be inferred from the relation which it bears to the other words with which it stands connected.

A very large and important class of words, whose primary signification refers to the operation of sensible things, are applied secondarily to modes of thinking; as, imagine, apprehend, comprehend, adhere, conceive, instil, disgust, disturbance, tranquillity, abstraction, sincere, foresight, penetration, acuteness, inclination, aversion, deliberation, sagacity, attention, &c. But the prosecution of this subject falls more within the province of the logician than the grammarian, and here we may draw our observations on derivation to a close.

SYNTAX.

Syntax, from two Greek words, *syn*, together, and *taxis*, a putting or placing, is that part of grammar which shows how words are connected and arranged.

Etymology, we have seen, treats of the materials of language, *individual words;* but it is the business of Syntax to point out by what rules these words are put together, so as to form *sentences*. By a *sentence*, is meant a number of words so united as to make sense; that is, to declare or affirm something: thus, the words, "The city of Edinburgh," do not form a sentence, because they declare nothing; but if we say, "The city of Edinburgh is the capital of Scotland," a distinct assertion is made, and therefore the words form a sentence.

We must here remind the reader, that every sentence must contain at least a subject and a predicate, the subject being the thing spoken of, and the predicate the action or state of being affirmed of it.

When the verb forming the predicate is transitive, the word which it affects is called the *object:* thus, in the sentence, "John learns his lesson," *John*, being the subject of discourse, is in the nominative, and *lesson*, being the thing affected by the predicate *learns*, is in the objective case.

RULES OF SYNTAX.

Rule I.—Nominative and Verb:

A verb agrees with its nominative in number and person; as, *I read, he learns.*

This rule is of very extensive application, and if understood in its full import, it will render useless many others that are commonly set down by grammarians. It may be expressed in more general terms, thus: "The number and person of the subject of a sentence determine the number and person of the verb. For example, in the sentence, 'John runs,' *John*, the subject, is singular, and, like all nouns, of the third person; we therefore use the third person singular of the verb, *runs*. Again, in the sentence "John and James read," the subject, *John* and *James*, expresses an idea of more than one, and so the verb must be plural, *read*, not *reads*, as it would have been had only one name been mentioned. In this sentence, "John or James intends to accompany me," it is obvious, from the very nature of the conjunction *or*, that *intention* is predicated or asserted only of one of the persons, and therefore the verb is in the singular, *intends*.

As collective nouns, though singular in form, may yet suggest the idea of plurality, they are joined either to a singular or a plural verb, according as the idea suggested is that of unity or plurality. Thus, when we say, "The army *is* on its march," we seem to lose sight of the individuals composing the idea represented by the word *army*, and speak of it as one mass; but if we say, "The peasantry *go* barefooted," this mode of expression seems to give us an idea of a number of people existing separately, and we therefore put the verb in the plural. With respect to the collective noun, the only thing further to be observed is, that if in one part of a sentence it is made to stand as singular, it ought not in another to be used as plural.

A noun is sometimes put in the nominative, even when it is not the *subject* of the sentence, but merely stands connected with a participle; thus, in these lines of Cowper—

> "Thou, as a gallant bark from Albion's coast
> (The *storms* all weather'd and the *ocean* cross'd)
> Shoots into port," &c.

The words *storms* and *ocean*, joined to the participles *weathered* and *crossed*, are neither the nominatives to any verb, nor are they the *object* affected by a transitive verb or a preposition. Still they are in the nominative; and this construction is known among grammarians as the nominative absolute. Some grammarians, indeed, contend, and not without reason, that there is an absolute case, quite distinct from the nominative; and that to speak of the "nominative absolute" involves a contradiction of ideas. It must at once be conceded, that the noun conveys very different ideas in the two cases referred to, and we cannot well deny that they ought to have separate names, in the same manner as we give different names to the nominative and objective, although they are the same in form.

In every case, the *idea* represented by the *subject* must be carefully noticed, and then the *predicate* be conformed to it.

To each rule, we shall subjoin a few examples of erroneous construction, being persuaded, in common with Crombie, of the truth of Lowth's remark, that a good way "of teaching right, is to show what is wrong."

1. This *course* of lectures *were* delivered last spring.
2. In the human species, the *influence* of reason and instinct *are* generally assisted by the lessons of experience.
3. *Was you* present at the meeting?
4. There *are abundance* of treatises on that subject.
5. At this time *the House of Commons were* of little weight.
6. *Every one* of these theories *are* unfounded.
7. *Was* the *master and his scholars* there?

Rule II.—Possessive Case.

When the relation of ownership is to be pointed out the Possessive Case of the noun denoting the owner is used: thus, "This is John's hat." Here the relation of ownership is to be declared as existing between the person *John* and the thing *hat*, and consequently the name of the possessor is put in the possessive case.

If the name of the owner be a compound name, the last of the component parts only receives the sign of the possessive: thus, "The Queen of Great Britain's prerogative; also when there are two separate names, as, "Robertson and Reid's office."

1. This is John Thompson *his* book.
2. James is in *Walker's and Son's* office.
3. Charles is a member of the *Mechanic's* Institution.
4. Have you read *Chamber's* Journal.

Rule III.—Objective Case.

Active transitive verbs and prepositions take the Objective Case after them: thus, "Do justice love *mercy* and walk humbly with *God*." In this sentence, *justice* and *mercy* are in the objective, being affected by the verbs *do* and *love* respectively; and *God* is also in the objective, being the object of the relation pointed out by the preposition *with*.

Some active transitive verbs appear to take two objective cases after them; but it is much more consistent with the analogy of the language to understand a preposition: thus, "He sent me the book," where *me* and *book* are both in the objective. It is quite clear that *book* is the thing immediately affected by the verb *sent*, it therefore must be in the objective; but as to *me*, it seems most natural to understand the preposition *to*, when the sentence would be, "He sent the book to me." Ellipses of this sort are quite common, and it is altogether unnecessary to bring in any new rule or principle to account for idiomatic expressions thus produced.

Under this rule we may further observe, that all words denoting *measure*, whether of time or space, are capable of being put in the objective, a preposition being understood. Thus, in the sentences, "The wall is seven *feet* high," "I was three *days* in the country," the words *feet* and *days* are in the objective, the preposition *for* or *during* being understood. As, however, the nominative and objective of all nouns in English are alike, this remark must be allowed to be of limited utility.

1. I *told ye* that I would come.
2. *Who* should I *love*, if not my father?
3. Do you know *who* you speak *to?*
4. *He* that can doubt whether he be any thing or not, I speak *not to*.—LOCKE.

Rule IV.—Pronouns.

Pronouns agree in gender, number, person, and case with the nouns for which they stand, and are in all respects to be treated as the nouns would have been had they been used. In the sentence, "The master instructs *his* pupils," the pronoun supplies the place of the possessive case of the noun, *master*, which is of the singular number, third person, and masculine gender; we therefore use *his*, which corresponds to all this. Again, "John and James learn *their* lesson:" here *their* stands for two nouns, and so must be plural.

1.—Thou shalt also make a *laver* of brass, and *his* foot also of brass.
2. For my *name and memory*, I leave *it* to men's charitable speeches, and to foreign nations, and to the next age.—BACON.
3. Rebekah took goodly *raiment* that was in the house, and put *them* on Jacob.
4. I saw the whole *species* delivered from *their* sorrows.—ADDISON.
5. Those are the *birds whom* we call gregarious.

Rule V.—The Infinitive.

One verb governs another in the Infinitive: as, "He loves to study," where *to study* is the object of the verb *loves*.

Before the verb denoting the object of the predicating verb, the preposition *to* is generally put; and it is in this case called the *sign of the infinitive*. But as we already saw that the infinitive is nothing but a noun, the utility of this rule may well be questioned.

The sign *to* is omitted after the following verbs:—Bid, can, dare, feel, hear, let, make, may, must, need, shall, see, and will. We do not say, "He bade me to go," but, "He bade me go." The infinitive of a verb may also come after a noun or an adjective, as well as after another verb.

1. Sylla *obliged* them *submit* to such terms as the *senate were* pleased to impose. (See also Rule I.)
2. The king *caused* them *feel* the weight of his displeasure.
3. I *desired* him *call* in the evening.
4. You *need* not *to trouble* yourself on my account.
5. God *maketh* the sun *to rise* on the evil and on the good.

Rule VI.—Apposition.

Nouns and pronouns added to other nouns and pronouns to explain them, are put in the same case; thus, "Edinburgh, the capital of Scotland, is celebrated for its university." Here *Edinburgh*, being the subject of the sentence, is in the nominative; and the noun *capital*, with its adjunct *of Scotland*, being added to explain it, is in the nominative also. The two words in cases of this kind, are said by grammarians to be in apposition.

"Brutus killed Cæsar in the Capitol; him who had been his friend." Here *Cæsar* is in the objective, governed by the verb *killed;* and as the succeeding pronoun refers to it, it must be in the objective too. If it were *he*, there would be no violation of any rule in grammar, but a misrepresentation of a historical fact, as it would lead us to believe that Brutus befriended Cæsar, whereas it was Cæsar that had befriended Brutus.

There seems to be an exception to this rule in such expressions as "I called at Smith's the bookseller," where *Smith's* and *bookseller* are evidently marks of the same idea, but yet the one has the sign of the possessive ('s), which the other has not. As far as the possessive case (so called) is concerned, it is in most instances awkward to add any explanatory word to it; and the sentence runs much more smoothly if we use the preposition *of;* thus, "I called at the shop of Smith the bookseller," where both words are obviously in the objective.

1. Your *friend, him* whom you introduced to me yesterday, very soon departed.
2. Why do you treat *Mary Ann* so harshly, *she* who has always been so affectionate?
3. The *leader* was taken, *him* who defied the law.
4. I am going to see my *friends* in the country; *they* whom we met at the ferry.

Rule VII.—The Verb To Be.

The verb To Be has the same case after it as it has before it: thus, "*Alfred* was a good *king*." Here the work *king*, coming after the verb *was*, is in the nominative, because it is descriptive of *Alfred*, the subject of the sentence. "She, supposing *him* to be the *gardener*, saith unto him." Here *gardener* is to be considered in the objective, because *him*, going before the verb *to be*, is in the objective, governed by the verb *supposing*.

It requires very little penetration to perceive that this seventh rule is included in the sixth, for the verb *to be* does nothing more, in such cases, than mark that the two nouns between which it is put are different names for the same thing. On this subject, Mr. Mill reasons with his usual acuteness. In showing how the name of a class comes to be used for the name of an individual, he says, "I have the name of the individual, *John*, and the name of the class *man;* and I can set down my two names *John*, *man*, in juxtaposition. But this is not sufficient to effect the communication I desire, namely, that the word *man* is a mark of the same idea of which *John* is a mark, and a mark of other ideas along with it; those, to wit, of which James, Thomas, &c., are marks. To complete my contrivance, I invent a mark which, placed between my marks *John* and *man*, fixes the idea, I mean to convey, that *man* is another mark to that idea of which *John* is a mark, while it is a mark of other ideas of which James, Thomas, &c., are marks. For this purpose, we use in English the mark *is*. By help of this, my object is immediately attained."*

Those capable of understanding this dissertation, will immediately see the virtual identity of our sixth and seventh rules; but here, as in other cases, we have been anxious not to depart from the common doctrine, and a repetition of the rule, while it may be useful to some, can do harm to none.

1. You believe *it* to be *he*.
2. *It* was not *me* who said so.
3. *It* appeared to be — who carried on the business
4. Though I was blamed, *it* could not have been *me*.

* Analysis [illegible] I. p. 117.

These we take to be the great leading principles on which the Syntax of the English language is founded, and by the thorough understanding of which, the student will be enabled to see the construction of almost any sentence. Many grammarians, some of whom—particularly Crombie and McCulloch—we highly respect, have given many more; but we adhere to the decision of the dictator of English literature, who says, that "our language has so little inflection or variety of terminations that its construction neither requires nor admits any rules."*

A few miscellaneous remarks (we cannot dignify them with the name of rules) will conclude this part of our subject.

1. Every adjective must qualify a noun, either expressed or understood: thus, in the lines—

> "*Auspicious* Hope! in thy *sweet* garden grow
> Wreaths for *each* toil, a charm for *every* wo,"

every adjective is immediately followed by its noun. But in this,

> "*Few* shall part where *many* meet,"

the noun *men* is obviously understood.

We have already seen that *a* and *an* (commonly called the indefinite article) are identical in meaning; but there is this difference in their application, that *a* is prefixed to words beginning with the sound of a consonant, the long sound of *u*, and vowels sounding like *w*; and *an*, to words which begin with the sound of a vowel. Thus, we say, *a* man, but *an* ox; *a* house, but *an* hospital; *a* one-horse coach; *a* unicorn; *an* easterly wind, &c.

2. The exact import of the four words, *each*, *every*, *either*, and *neither*, which are known by the name of Distributive Adjectives, ought to be carefully attended to, and, from their very meaning, it will appear that they must always be joined to a noun in the singular.

Each means the one and the other of two: thus, Cowper, in his ode, "The Lily and the Rose," says properly—

> "Until a third [flower] surpass you both,
> Let *each* be deemed a queen."

Every refers to any number more than two, considered individually: thus, Byron, referring to the unfortunate separation of himself and Lady Byron, says—

> "Both shall live, but *every* morrow
> Wake us from a widow'd bed."

Either means the one *or* the other of two; *neither*, not either, not the one *nor* the other of two. The use of both words is seen in these lines—

> ——"Lepidus flatters both,
> Of both is flattered: but he *neither* loves,
> Nor *either* cares for him."—SHAKSPEARE.

Milton makes a wrong use of *either* in these lines—

> ——"She was cheer'd,
> But silently a gentle tear let fall
> From *either* eye."

3. In English, as already noticed, the adjective is not generally inflected for any purpose except to express degrees of comparison; but to this remark there are two exceptions. These are the Demonstrative Adjectives *this* and *that*, which have corresponding plurals, *these* and *those*: thus, we say, *this* man, but *these* men; *that* map, but *those* maps.

4. It is not the office of an adjective to qualify either a verb or another adjective; this must be done by an adverb. We do not say, "James reads *good*," but "James reads *well*." "I am myself *indifferent* honest," should be, "I am myself *indifferently* honest."

"In general, no quality, when considered in concrete, or as qualifying some particular subject, can itself be conceived as the subject of any other quality, though, when considered in abstract it may. No adjective, therefore, can qualify any other adjective. A *great good man*, means a man who is both *great* and *good*. Both the adjectives qualify the substantive; they do not qualify one another."—*Adam Smith.*

That this is the *genius* of our language, admits not of reasonable doubt; but there are several exceptions. We speak of a thing as being of a *florid red* colour, and of iron as being *red hot*. We say, "a *great many* were present;" "the doors were *wide open*;" Byron speaks of the "*pale blue* sky;"—in all which cases it is quite clear that the first adjective, in some degree, modifies the second. Whether this idiom is capable of being *metaphysically* defended against the reasoning of Smith, or whether such expressions are to be regarded as, to use the words of Johnson, "spots impressed so deep in the English language, that criticism can never wash them away," is a question into the discussion of which we shall not enter. About the *authority* of the expressions there can be no dispute.

It was already pointed out that certain adjectives, from their very nature, do not admit of comparison; and it should now be observed that, for the same reason, many of them, such as *universal*, *omnipotent*, and others, whose signification cannot be increased, ought not to be qualified by any adverb.

5. Tautological expressions ought to be avoided, and no word should be introduced into a sentence which has not some distinct function to perform.

"From whence came he?" should be, "Whence came he?" because, as we already saw, *whence*, in itself, means "*from* what place." Again, in the sentence, "I doubt not but that he will come," it is obvious, on a little reflection, that the idea intended would be completely conveyed by this form of expression—"I doubt not that he will come," and the insertion of *but* serves no useful purpose. By reversing the sentence, this may be more obvious—"He will come, I doubt not that (*thing*)."

In this sentence, taken from Goldsmith's *History of England*—"The New Englanders were determined to attack the royal forces as soon as *ever* they should march out of Boston"—the word *ever* is of no use, and consequently should be omitted.

Perhaps under the same remark might be included the following, which, however, from its extensive application, we shall keep separate.

6. Two negatives ought not to be used, unless affirmation is meant.

In this respect Bacon, Shakspeare, and Locke, and indeed all our early writers, frequently offend. Usage was in their times divided; but it has now become fixed, and that on the side of metaphysical propriety.

Bacon says—"The joys of parents are secret, and so are their griefs and fears; they cannot utter the one, *nor* will they *not* utter the other." Shakspeare says—

> "Be *not* too tame neither."

And again,

> "*Nor* do *not* saw the air too much."

Goldsmith, too, has violated the idiom of the English tongue in this respect, although he has offended in good company: "Never was a fleet more completely equipped, *nor never* had the nation more sanguine hopes of success." *Never* should be *ever*. "He is *not unjust*" is right, if we mean to express much the same idea as is conveyed by the words, "He is just." By some it is maintained that this mode of expression strengthens the affirmation, and certainly it may do so in spoken language; but in writing it serves only to introduce ambiguity, and so ought to be avoided.

7. Certain conjunctions go in pairs: thus, both, and; either, or; neither, nor; though *or* although, yet; whether, or; so, that; not only *or* not merely, but also; so, as; as, as; such, as. Most of these words are conjunctions, but not all.

"I will *neither* come or send" is wrong; because *or* is not the correlative of neither: it ought to be, "I will *either* come *or* send," or, "I will *neither* come *nor* send."

* Dr. Johnson. Preface to Dictionary.

8. Derivative words generally take the same prepositions after them as their primitives.

Goldsmith offends again in saying, "Catiline was insatiable *of* wealth;" because we do not say to satiate (the primitive of insatiable) a person *of* wealth, but *with* wealth.

9. Certain prepositions are appropriated to certain words and phrases

We do not say, "To have faith *to* a person," but "*in* a person;" "To find a difficulty *with* doing a thing," but "*in* doing it;" "To differ *with* a person," but "*from* a person."

Such idiomatic expressions are only to be made familiar by an extensive and well-directed course of study; or, as Milton has it, "by a well-continued and judicious conversing among pure authors."

10. After the comparative degree, whether of adjectives or adverbs, and the adjective *other*, the conjunction *than* is used: thus, "*Better* is a little with righteousness, *than* great revenues without right;" "This is none *other than* the house of God." Shakspeare has offended against this idiom—

> "The sun no *sooner* shalt the mountains touch,
> *But* we will ship him hence."

But ought to be *than*. "Scarcely had Austria been crushed, *than* it was announced," &c.—GOLDSMITH. *Than* ought to be *when*.

11. The Perfect Participle, and not the Past Tense, is used after the verbs *have* and *be*.

This remark requires to be attended to in using irregular verbs, but in verbs that are regular, no mistake can arise, as both parts are the same. In nothing, we venture to remark, does defective scholarship sooner betray itself than in a wrong conjugation of the irregular verbs.

"They *had* from the beginning *begun* to embrace opposite systems."—GOLDSMITH. *Began* ought to be *begun*.

> "You must not think,
> That we are made of stuff so flat and dull,
> That we can let our beard *be shook* with danger."
> —SHAKSPEARE.

Shook should be *shaken*.

12. Adverbs ought to be placed so as to leave no doubt what word is affected by them.

"The negroes are to appear at church *only* in boots." By this position of *only*, it appears that the negroes were not to come to church unless "in boots," or with nothing else but boots; but the meaning intended was that they should appear at church, and no where else, in boots. The sentence should therefore have stood thus:—"The negroes are to appear only at church in boots." "Pompey played a despicable part *enough* betwixt them." *Enough* ought to be immediately after *despicable*. "Cæsar so turned the fate of the day, that the barbarians were *almost* cut off to a man." It ought to be, "were cut off *almost* to a man."

EXERCISES.

To all these remarks, we shall adjoin a few miscellaneous examples, on which the student may exercise himself. We shall refer to the Rule or Remark violated as we go on.

1. Are either of us to blame? (Rule I. Remark 2.)
2. Those kind of things give most satisfaction. (Rule I. Remark 3.)
3. I acted in compliance to his request. (Remark 8 and 9.)
4. Let such teach others who themselves excel.—POPE. (Remark 7.)
5. These new divines offered salvation upon easier terms, substituting practice to belief and a man's own efforts to a vicarious satisfaction.—AIKEN'S *Letters*. (Remark 9.)
6. There is nothing more pleases us as to have our performances praised. (Remark 10.)
7. Antony led the way direct to Italy. (Remark 4.)
8. Neither of them appealed to impotent laws which could afford them no protection.—ROBERTSON. (Rule IV. Remark 2.)
9. It is wonderful how preposterous the affairs of this world are managed.—FRANKLIN. (Remark 4.)
10. During the rest of his consular year, Bibulus could only escape outrage by not only avoiding all assemblies of the people, but every solemn and important meeting of the senate.—*History of Rome, Cabinet Cyclopædia*. (Remark 12.)
11. I never did repent for doing good,
    Nor shall not now.—SHAKSPEARE. (Remarks 6 and 9.)
12. The wisest princes need not think it any diminution to their greatness, or derogation to their sufficiency, to rely upon counsel.—BACON'S *Essays*. (Remark 9.)
13. The hostilities which twice interrupted the progress of the community, neither seemed to originate in any imperative claim of national honour or advantage.—WADE'S *British History*. (Remarks 12 and 7.)
14. It was observed to me, that in this country no man who is able to work need to go supperless to bed. This far he stated the fact.—COMBE'S *Notes on America*. (Rule V. Remark 4.)
15. When a nation forms a government, it is not wisdom but power which they place in the hands of the magistrate.—ROBERT HALL. (Rule IV.)
16. The leaders of the fleet and the army began mutually to accuse each other.—GOLDSMITH. (Remark 5.)
17. Royal proclamations continued as omnipotent as in the preceding reign.—WADE.
18. There have been three riots in England of late, each of which have been levelled against dissenters.—ROBERT HALL. (Remark 12.)

The student should now be so familiar with the *Rules of Syntax*, which are nothing but generalized facts regarding the customary modes of uniting words and sentences together, that he will be able to commit his thoughts to appropriate language; that is such as shall convey to others the exact meaning he has in his own mind. To do this, however, not merely with accuracy but with ease, besides attending to the rules of syntax, he must take care, first, that all the words he uses belong to the English tongue; and, secondly, that they be employed in their usual and recognised acceptation.

A word *not English* is termed a *barbarism*, and when used in a sense different from its established one, an *impropriety*; both should be equally avoided, either in writing or speaking.

PUNCTUATION.

Punctuation, or the insertion of *points* in written language, is usually considered a part of grammar, and a knowledge of its principles is desirable for correct literary composition. The introduction of points is said to be useful to mark places at which a pause of a lesser or greater length should be made in reading. This definition is not altogether wrong, but punctuation has much higher objects in view. Points are necessary for marking the parts or sections into which sentences and paragraphs are divided, so that the exact meaning or sense may be apprehended, and perfect regularity preserved. The real use of points, therefore, is to cut off and separate single words, or groups of words, from each other. Sometimes the separation need only be slight, and for this the point called the *comma* , is sufficient. For instance, "Providence has, I think, displayed a tenderness for mankind." Here there is a comma before and after "I think," because these two words express something thrust into the sentence, which should be kept in some measure distinct. The *semicolon* ; is used to mark a more perfect separation of words. In general, it cuts a sentence into two or more parts, one of which has a reference to the other. Thus, "Economy is no disgrace; for it is better to live on a little than to outlive a great deal." Here the sentence is in two sections, the semicolon marking the boundary of separation. The *colon* : signifies a still wider separation in the words of a sentence; but its qualifications are so indistinct, and so liable to misconception, that in practice it is now almost entirely disused, and the *period* or full stop . is employed in its stead.

The other marks used in written language are as follows:—The *mark of interrogation* ?, which is put after words asking a question; the *mark of admiration* !, put after any exclamation of surprise, lamentation, or scorn; the *dash* —, which is sometimes employed instead of a semicolon, or for any kindred purpose; and the *parenthesis* ( ), for enclosing a word or portion of a sentence foreign to the tenor of the sense. Good writers endeavour to avoid requiring either parenthetic marks or dashes, both of which indicate irregularities of thought and expression.

CONCLUSION.

We have now explained the Etymology and Syntax of the English tongue, so far as our limits permit; and, in drawing to a close, we may be allowed to impress on our readers the value of the science which we have been endeavouring to expound. If they have intelligently gone along with us in our various remarks, they will not be surprised when we assert that this department of human knowledge, if skilfully cultivated, will be productive of very valuable results. To understand the grammar of a sentence, is nothing more or less than to understand its sense, and to see clearly how its various parts are connected; while in learning to recognise the different modifications that words undergo, and the different arrangements of which they are susceptible, to express difference of thought, we have exercised many of the mental faculties, and in so far laid the foundation of what is much wanted, a just system of Logic.

The sources whence the student will derive effectual aid in the prosecution of this interesting subject, we have already pointed out incidentally; but let no one lament too much though he should not have access to them. Rather let him, by additional thought on his own part, make up for the deficiency, and he may rest assured that, by accustoming himself to mark the different modes of expression he meets with in reputable authors, *a system of grammar will evolve itself*, which will be all the more valued—if we may not say valuable—that it has been wrought out by his own exertions, and not received by tradition or passively from the hands of another. Following this plan, the real method of induction, he will either reproduce the rules which we have set before him, or else see their erroneousness. So that, in either case, we shall deserve well of him; for, if we are right in any thing, we shall have served as a guide to him; and in those points where we have erred, we shall have put him on the way to find out our errors. We know very well that the pupil cannot see with our eyes, and we have, therefore, only endeavoured to direct his attention to such objects as he may see with his own. So far as he sees, he should believe, and no farther. To dogmatize is the method of a grammatist, but our ambition has been to act the part of a philosophical grammarian, and, as such, we cannot conclude without warning our readers never to forget that words in themselves are nothing, and that they are only valuable in so far as they are the symbols of ideas. Beautifully and justly has Johnson said, "Words are the daughters of earth, and things only are the sons of heaven." Language is but a vehicle of thought, or, at best, its instrument, and to view it as an "end unto itself," is the vain humour of a pedant. Let none be so taken up with words as to forget solid things.

—•—

COMMON ERRORS CORRECTED

The remaining space of the present article could scarcely, we think, be better employed than in enumerating some examples of the most common errors in the pronunciation and selection of words. In every part of the country there are some peculiar vices of speech, which have been handed down from one generation to another, and are generally so inveterate in most minds, from the effect of early habit, that no cultivation which the mind may receive in mature life altogether obliterates them. For any one who has occasion to mix in refined society to be thus liable at every moment to the use of some barbarism of speech, is a misfortune of some magnitude; for nothing tends so much to convey a mean impression of his education and habits of life. The most beautiful young female, who, silent, appears a kind of divinity, is reduced at once to common earth when we hear a few inelegant words fall from her mouth. Coleridge somewhere tells that he was once much prepossessed in favour of an individual whom he met at a dinner-table, and who appeared a dignified and respectable person, until, some kind of fruit being introduced, he heard him exclaim, "Oh, them's the jockies for me!" Words are the exponents of conditions of mind, and, when mean ones are used, we unavoidably suppose the condition of mind to be mean.

ERRORS IN PRONUNCIATION.

The interchange of *w* for *v* and *v* for *w*, and the putting of the sound of *h* before words where it is inappropriate, and taking it away where it ought to be. *Examples*—Vill you vait to get some vine and wictuals? An 'ard boiled *hegg*.

The sound *k* instead of *g* at the ends of words. *Examples*—Somethin*k*, nothin*k*.

The addition of *r* at the ends of words ending in vowels. *Examples*—Idear, windor, Elizar.

Changing the termination *en* or *ain* into *ing*; as gar*ding* for garden, fount*ing* for fountain.

UNGRAMMATICAL FORMS.

Between you and *I*, there is a great want of conscientiousness in most partisans. *Correction*—Between you and me, &c.

I am not so proud as *him*. *Cor.*—As he.

You will do it better than *her*. *Cor.*—Than she.

May thou as well as me, be meek, patient, and forgiving. *Cor.*—As well as I, &c.

While the house *was being* built. *Cor.*—While the house was in the course of being built.

He *don't* go to town to-day. *Cor.*—He does not go to town to-day.

I *rather think* he is out of town. *Cor.*—I believe he is out of town.

I *had better* go myself. *Cor.*—It were better that I should go myself.

I *had oblige* to go. *Cor.*—I was obliged to go.

John is tall in comparison *to* James. *Cor.*—John is tall in comparison with James.

He is a *very rising* man. *Cor.*—He is rising very rapidly.

She *readied* a dish for us. *Cor.*—She cooked, or prepared, a dish for us.

She was a *superior* woman, or, She was a *most superior* woman. *Cor.*—Superior can only be used with regard to something else which is at the same time expressed; thus, She was a woman much superior to the generality of her sex.

Short-lived, long-lived. *Cor.*—Short-lifed, long-lifed.

The *then* Earl of Winchelsea; the *then* Mrs. Bennet. *Cor.*—The Earl of Winchelsea of that time; the Mrs. Bennet then living.

He *lays* asleep in the cabin. *Cor.*—He lies asleep in the cabin.

His health was *drank*. *Cor.*—His health was drunk. The dinner was all *eat* up. *Cor.*—The dinner was all eaten up.

I went to table and *eat* very heartily. *Cor.*—I went to table and ate very heartily.

A *couple of shillings*. *Cor.*—Couple can only be properly applied to objects in connection; as, a married couple, a couple of pointers.

John, James, and Robert, were sober workmen, the *latter* particularly so. *Cor.*—The last particularly so (the objects enumerated being more than two).

The Manchester Guardian is a *well-advertised* paper—meaning a paper which usually contains many advertisements. *Cor.*—The Manchester Guardian usually contains many advertisements, or—enjoys a large share of the patronage of advertisers.

I could not give him credit, *without* he changes his behaviour. *Cor.*—I could not give him credit, unless he changes his behaviour.

I will go, *except* I should be ill. *Cor.*—Unless I should be ill.

I saw them all, *unless* two or three. *Cor.*—I saw them all, except two or three.

I took some cream *into* a bowl. *Cor.*—I took some cream in a bowl.

I am going *for* to do it. *Cor.*—I am going to do it.

He was a devoted *antiquarian* all his days. *Cor.*—He was a devoted antiquary all his days. (*Antiquarian* is the adjective.)

James is going to be a *medical* man. *Cor.*—James is going to be a physician, surgeon, or medical practitioner.

He is *oftener* wrong than right. *Cor.*—He is more frequently wrong than right.

I have *no right* to pay this tax. I have *no right* to be distressed by that man's conduct. *Cor.*—I am under no obligation to pay this tax. I am not obliged to suffer from that man's conduct.

You will be *necessitated* to submit. *Cor.*—You will be obliged to submit.

Don't talk of *those* sort of things to me. *Cor.*—Don't talk of that sort of things to me. *Sort of things* is a mean and objectionable expression. "Things of that kind" is more elegant as well as correct.

The castle is seated *by* the Garonne. *Cor.*—The castle is seated beside the Garonne.

Lord Byron was born *at* London. There have been destructive fires *at* Edinburgh. *Cor.*—Lord Byron was born in London. There have been destructive fires in Edinburgh. (*At* is only proper with respect to a small town.)

I met him *on* the street. *Cor.*—I met him in the street.

I don't know, but I will inquire *at* my friend. *Cor.*—Of my friend.

Oh, I *will* fall, and nobody *shall* help me. *Cor.*—Oh, I shall fall, and nobody will help me.

I have been *to* London, and am now going *for* Liverpool. *Cor.*—I have been in London, and am now going to Liverpool.

They were some distance from home when the accident happened. *Cor.*—At some distance, &c.

He lives opposite the Royal Exchange. *Cor.*—Opposite to, &c.

The performance was approved *of* by all who understood it. *Cor.*—The performance was approved by all.

They attacked Northumberland's house, whom they put to death. *Cor.*—They attacked the house of Northumberland (or the Duke of Northumberland), whom they put to death.

It is true what he says, but it is not applicable to the point. *Cor.*—What he says is true, &c.

Together with the national debt, the greatest national advantages are *also* transmitted to succeeding generations. *Cor.*—*Also* is superfluous.

Failing in his effort, he *again* repeated it. *Cor.*—*Again* is superfluous.

He is *no way* thy inferior, and in this instance is *no ways* to blame. *Cor.*—He is in no wise thy inferior, and in this instance is not at all to blame.

He charged me with want of resolution, in which he was greatly mistaken. *Cor.*—He charged me with want of resolution, but in this censure he was greatly mistaken.

No *less* than two hundred scholars have been educated in that school. *Cor.*—No fewer, &c.

It is above a year since the time that I left school. *Cor.*—It is more than a year since I left school.

He was guilty of such atrocious conduct, that he was deserted by his friends for good and all. *Cor.*—He was guilty of conduct so atrocious, that he was entirely deserted by his friends.

OBSOLETE, AWKWARD, AND MEAN FORMS.

I had *as lief* do it myself as persuade another to do it. *Cor.*—I would as readily, &c.

He convinced his opponent by *sheer dint* of argument. *Cor.*—Entirely by force of argument.

He is *not a whit* better than those whom he so liberally condemns. *Cor.*—He is not in any degree, &c.

He *stands upon the bond*, and will not abate *a jot* of his claim. *Cor.*—He insists on the strict terms of the bond, and will not in the least abate his claim.

Good satin, *I take it*, is considerably superior to common silk. *Cor.*—I presume.

Politics too often *sets men by the ears*. When they *come to words*, and *fall out*, reason is generally lost sight of. I should not wonder but on this occasion there might be *broken heads going*. *Cor.*—Politics too often causes quarrels. When men enter into controversy and differ violently, reason is generally lost sight of. I should not wonder but on this occasion they might commit some violence on each other.

We shall have a *regular break-up* in the ministry. *Cor.*—We shall have a dissolution of the ministry.

He was very dexterous in *smelling out* the designs of his neighbours. *Cor.*—In penetrating, &c.

He is a *thorough-paced* knave. *Cor.*—He is a great knave.

Heretofore Hannibal had carried all before him; *wherefore* he had become very proud, listening to no advice *whatsoever*; *whereas* Scipio invariably took counsel from the most sagacious of his officers.—The words in Italics are all obsolete and objectionable.

He *wist* not what to do. *Cor.*—He knew not what to do.

He little *wots* of the storm that is brewing. *Cor.*—He is not aware, &c.

Topsy-turvy, *pell-mell*, *hurly-burly*, having a *month's mind* for a thing, *currying favour* with a person, *dancing attendance* on customers.—All objectionable, from their meanness.

We are *at one* on the slave question.

I happen to have a little leisure *upon my hands*.

He might have perceived it with *half an eye*.

We should always be glad to *put ourselves about* for our neighbours. *Cor.*—To put ourselves to a little inconvenience.

My father *left* this morning by the mail. *Cor.*—My father went away this morning, &c. "When are you to *leave?*" is, in like manner, vicious. The place or thing left should always be stated.

Slang phrases of all kinds should be received warily. The least objectionable are those which merely suggest comical ideas; those which tend to present light and jocular views of moral error are particularly detestable. It will be the aim of a well-bred and judicious person to make his discourse neither too nice and formal, nor too loose and homely, but as far as possible to preserve a medium between the select language employed in literature, and the familiar and perhaps temporary phraseology which prevails in ordinary society.

LOGIC.

INTRODUCTORY

It is generally observable that some men form clearer and more rational ideas upon most subjects than others. In a miscellaneous company, should any complicated question arise, a considerable number of the party will probably be found to treat it in a confused or partial manner, so as to have no effect in convincing each other; but after a great deal of wrangling, and perhaps some anger, it may be that some one who has not as yet opened his mouth, rises up and sets the whole matter in so clear a light, showing so well the whole of its bearings, that all the consequences likely to arise from what is involved in it, that the storm is silenced at once—all, or at least a large portion, of the company, being convinced that a correct and just view of the matter has at length been placed before them. Such is exactly the history of many questions that come before deliberative assemblies: all is confusion, until some leader stands up and gives a more than usually comprehensive and lucid view of the case, which carries the conviction of so many, that clear resolutions are formed, a measure is arranged, and the business of the house is allowed to advance. What is it that enables particular men thus to make all appear order where others could bring forth nothing but confusion? It is simply their possessing minds which, seeing many parts of a subject at once, detect the order in which they lie, the bearing they have upon each other, the truth of this, the fallacy of that, what effect such a thing will have, how far there is justice in such another thing, and so forth; while others, when called to consider such a subject, are, to use a common phrase, quite at sea in it, seeing nothing of it but some of its external parts, which they may fasten upon and discuss till they are tired, without ever advancing one step towards a wise conclusion.

It has been found, by attentive observation, that the mind in all these operations goes through certain defined courses, leading either to truth or error. It has, we may say, certain established modes of action, which are natural to it, and which must accordingly have characterized it always. To all of these modes of action appropriate terms have been given, in order that they may be recognisable—just as such words as noun, verb, case, tense, have been given to certain forms of speech which are the same in all languages. The operations of the mind, as far as reasoning is concerned, have thus been reduced into a science; in other words, methodically described as a part of the great scheme of nature. Logic is the name applied to this science.

The use of this science is easily shown. It is readily allowed that many men reason very clearly, in ordinary circumstances, without having been much instructed. They enjoy a natural sagacity which enables them to take a pretty large view of most subjects, and to consider their various parts with a good deal of precision. The same power enables them to steer clear of the ordinary sources of error. This class of men would be the first, in an early state of society, to make advances towards Logic as a scientific system. But even these men are obviously liable to derive great advantage, in their reasoning processes, from a knowledge of distinct terms for those processes, as well as for all the kinds and modes of error which lie along their way. The *thing* and the *term* together, once implanted in their minds, they know in an instant what to embrace and what to avoid on their own part, and also how to detect and render apparent the error in others, when it occurs. It is clear that, under favour of such knowledge, argument must be greatly facilitated, and much tedious contention avoided. With those who are not naturally powerful or clear reasoners, the same knowledge is calculated to be of infinitely greater use. We may fairly presume that, if such men were so well acquainted with the science of logic, that of any course their minds were taking they could say at once to themselves whether it was one of a legitimate kind, or one notorious for leading to error, they would be enabled, almost mechanically, to keep in right intellectual paths.

Thus Logic is, in the first place, a science, or the description of a department of nature. In the second place, it becomes an art, or means of teaching right modes of reasoning. For its value in the latter character, we have a good argument in the preface to the masterly work of Archbishop Whately. "Many," he says, "who allow the use of systematic principles in other things, are accustomed to cry up common sense as the sufficient and only safe guide in reasoning. Now, by common sense is meant, I apprehend (when the term is used with any distinct meaning), an exercise of the judgment unaided by art or any system of rules—such an exercise as we must necessarily employ in numberless cases of daily occurrence, which, having no established principles to guide us—no line of procedure, as it were, distinctly chalked out—we must needs act on the best extemporaneous conjectures we can form. He who is eminently skilful in doing this, is said to possess a superior degree of common sense. But that common sense is only our *second-best* guide—that the rules of art, if judiciously framed, are always desirable when they can be had—is an assertion for the truth of which I may appeal to the testimony of mankind in general; which is so much the more valuable, inasmuch as it may be accounted the testimony of *adversaries*. For the generality have a strong predilection in favour of common sense, except in those points in which they respectively possess the knowledge of a system of rules; but in those points they deride any one who trusts to unaided common sense. A sailor, for example, will perhaps despise the pretensions of medical men, and prefer treating a disease by common sense; but he would ridicule the proposal of navigating a ship by common sense, without regard to the maxims of nautical art. A physician, again, will perhaps contemn systems of political economy, of logic, or metaphysics, and insist on the superior wisdom of trusting to common sense in such matters; but he would never approve of trusting to common sense in the treatment of diseases. Neither, again, would the architect recommend a reliance on common sense alone in building, nor the musician in music, to the neglect of those systems of rules which, in their respective arts, have been deduced from scientific reasoning, aided by experience. And the induction might be extended to every department of practice. Since, therefore, each gives the preference to unassisted common sense only in those cases where he himself has nothing else to trust to, and invariably resorts to the rules of art wherever he possesses the knowledge of them, it is plain that mankind universally bear their testimony, though unconsciously and often unwillingly, to the preference of systematic knowledge to conjectural judgments."

INVESTIGATION.

Investigation, or the art of inquiring into the nature of causes and their operation, is a leading characteristic of reason, and may be defined as one of the essential distinctions between man and the lower animals. Investigation implies three things—*Observation*, *Hypothesis*, and *Experiment*. Observation is the act of noticing circumstances evident to the senses, for the purpose of acquiring a knowledge respecting them and their causes. Hypothesis is a supposition or conjecture relating to the cause of an effect. Experiment is putting in operation, or trying what will be the result of certain supposed causes.

The first step in the process, it will be perceived, is to *observe*. Powers of observation lie at the foundation of all excellence in art or science. All men who have attained eminence in literature have been close observers. They have noticed circumstances and treasured remembrances which common minds would have neglected. The late Sir Walter Scott observed all that passed under his eye; no expression escaped him, if it bore on the illustration of character. Reasoning from the first efforts of observation may be exemplified as follows:—

An agriculturist *observed* that a certain spot in one of his fields produced more grass than any other portion. He recollected that a certain quantity of rubbish had lain for some time on that spot; and *supposed* that the rubbish had been the cause of the greater fertility. To ascertain whether his *hypothesis* or conjecture was correct, he covered another spot with sand, but no such effect followed. He inferred, therefore, that the mere covering of the spot had not been the cause. He then *supposed* that some portion of the rubbish had possessed peculiar qualities, the nature of which he wished to discover. A portion of each ingredient of the rubbish was therefore deposited in separate places; and after some time it was found that in one of the places a similar degree of fertility prevailed. This *experiment* determined his hypothesis. He acquired a knowledge of what ingredient is useful in conferring fertility. This may be called following out a train of reasoning on observed circumstances to its proper results.

POWER, CAUSE, AND EFFECT.

In Logic, *Power* is the relation of circumstances to each other in time. *Cause* is the invariable antecedent or thing going before. *Effect* is the immediate invariable consequent, or the change produced by power. No effect can take place without a cause.

There are immediate or proximate causes, and also remote or final causes. It is of great importance that these should not be confounded with each other: neglect on this point has led to all manner of superstitions and errors. First, of proximate causes: When we pour water on salt, the salt melts. Water is therefore the *cause* of the melting; in other words, water possesses the *power* of causing salt to melt. The melting is the *effect*. Again: Atmospheric air is necessary for the growth of plants; it is one of the essential causes of the vegetation. Such are instances of the action of *immediate* causes, quite undeniable, for they have been determined by experiment. But the existence of immediate causes does not preclude the existence of remote causes. Thus, a remote cause of vegetable growth from atmospheric air is the nature of the air, and a more remote cause still, is the Being who made the air—the Great First Cause of all created things. Pursuing an inquiry of this kind is called tracing events or circumstances to their final causes—going back, step by step, till we reach, as we must invariably do, that Being who not only designed but sustains all by his Providence.

The Sign.—We must guard against the error of confounding signs with causes. Smoke accompanies the combustion of moist wood. The smoke is not the *cause* of the combustion; it is only a *sign* that there is combustion. The falling of mercury in the barometer does not cause rain; it is only a sign the atmosphere is in that condition which is likely to lead to rain.

Imaginary Causes.—In determining what are the causes of events, it is of importance, in the first place, to ascertain that the supposed causes exist. A king once called a number of men of science around him, and said, "How should it be, that when I fit up a balance with two scales, each of which bears a basin of water of equal weight, and I put a live fish into the basin in one of the scales, that scale does not preponderate?" The cause of this seeming wonder was immediately sought for, and created some little altercation, till one of the men, more ready-witted than the others, said boldly out that he disputed the fact; and the king, laughing, owned that he was in the right, and that his question was a joke. Here we have an instance of trying to discover the cause of a thing which was not founded in truth. It is clear that causes assigned for any such unproved and improbable circumstances must be imaginary.

Imaginary causes may also be such as persons are willing to consider true without investigation. A storm rises at sea and wrecks several vessels. Witches raise storms. An aged and poor woman is residing in a lonely cottage at no great distance on the shore. That old woman is a witch. She caused the storm which wrecked the vessels. Here we have a train of reasoning, such as has sent hundreds of aged females to the stake, but which rests on no solid foundation. Before proceeding to accuse the woman of witchcraft, it would be necessary to settle whether there were such beings as witches at all. Having proved this, which would be impossible, the next step would consist in determining whether this old woman, in particular, was a witch. And, last of all, whether she actually was concerned in raising the storm in question.

Confounding Cause with Effect.—Causes and effects are sometimes mistaken for each other, for want of a close examination of facts. It is not unusual to hear a person say that a shower brings a change of wind, whereas the wind is the cause of the shower. The appearance of small-pox on the outer surface of the body is by ignorant persons supposed to be the cause of the illness in that disease, whereas the external marks are an effect of an internal cause. The richness of certain soils is not an effect of the flourishing of certain vegetables upon them, but the cause of the flourishing. Much money circulating in a country is not the *cause* but the *effect* of wealth. In common speech, the mistaking of effect for cause is called "putting the cart before the horse."

Induction.

Having established the reality of a cause, and that, if certain circumstances be given, certain results will follow, we have furnished the mind with a sufficient degree of experience to know that when the same cause and circumstances are again produced, the same consequences will ensue. This is drawing an inference from ascertained truths, and in Logic is known by the term *induction*, which signifies the bringing in of valid conclusions. We have learned, by indisputable experience, that when a spark of fire falls on gunpowder, the gunpowder will explode. Therefore, when we see a spark is about to fall on any quantity of gunpowder near us, we infer, and justly, that an explosion will be the consequence.

Thus, induction is an inference from facts that have been established by observation, hypothesis, and experiment. If the observation has been defective, or not sufficiently extensive, the subsequent hypothesis will, in all probability, be defective also, and we may arrive at wrong conclusions. Should a traveller, on visiting a foreign country, see only a few people, and these have red hair, he would not be warranted, on returning home, to say that all the people of that country were red-haired. His induction would not be fair; it would be founded on limited observation, and liable to be disputed by others better acquainted with the country.

In some subjects, it is much easier to draw a just inference than in others; but in all cases, judgment and caution are required. A physician saw a case of fever last year; he saw another last month; and when he sees a third similar case, he infers that another person is about to have the same fever. The skill of the physician consists in judging whether he has examined a sufficient number of cases of fever to justify such a conclusion.

General Principles.

In reference to inanimate substances and the lower animals, two or three cases are generally sufficient to justify conclusions; but, in regard to mankind, who differ so much from one another, and are under the influence of so many external and various circumstances, a very extensive collection of facts is necessary. When a person draws conclusions from a large array of facts, he is said to deduce *general principles*, and these are often of great importance in regulating social life. Pains-taking men, by collecting a record of all the deaths which occur year after year in a country, and the ages of the persons at death, are able to form a correct inference as to the number per hundred out of the population who will die per annum, and also the ratio of deaths as respects the ages of the individuals. This affords an instance of fair induction. If the facts had been collected only from a single town or parish, and only for one or two years, the inference would have rested on too narrow a foundation, and consequently would not have been fair. The rules to be observed in deducing general principles are—1st, that the cases be true; and, 2d, that the facts be universal.

Theory.

A theory is a precise system of rules, intended to explain certain facts. The theory, to be correct, must rest on rules founded on a rigorous induction of things true or probable. In some instances, in forming theories, we require to take truths as being proved, although we cannot actually measure these truths by the evidence of the senses. The Newtonian theory of the planetary system, as sustained by contending forces, explains the phenomena and movements of the heavenly bodies, including our earth. But this theory, after all, is only conjectural. For instance, it is stated that all bodies let fall on the surface of our earth are attracted by gravitation in the direction of its centre; and that, if a body could get to the centre, there it would remain, even though unsupported by any tangible object. Now nobody ever was at the centre of the earth to see that this would be the case. We can only, in this as in many other cases in which personal experience is limited, accept of the reasonable inferences of learned men, founded on their examination of a wide array of facts, and reconcilable with all known phenomena. Hence, experience cannot stand in opposition to well-established theory. Without theory or general principles, experience is but a feeble guide.

ANALYSIS AND SYNTHESIS.

Analysis is taking any subject, first as a whole, and then taking it to pieces and viewing each part separately; in other words, proceeding from the complex to the simple. *Synthesis* is the reverse of this, and implies taking, first the separate parts, and after treating each individually, proceeding to the whole in combination.

When a chemist takes a quantity of mineral water for the purpose of discovering its ingredients, he separates the different elements, and is thus said to analyze the contents of the water. When, knowing the different ingredients, he forms each artificially, and puts them together to form a whole, he may be said to proceed synthetically. We may speak of the British constitution as a whole, and then analyze its component parts to prove the truth of our assertions; or we may first speak of each part separately, and then refer to them all in a united form. When a clergyman illustrates a doctrine by separate texts, he treats his subject analytically; when he reassembles the texts or heads of his discourse into an aggregate form, he treats the subject synthetically. The analysis and synthesis must agree. The same conclusion must be arrived at in both cases.

In delineating human character, general notions are resolved into individual parts. We begin with the more conspicuous traits of the character, and gradually descend to the more hidden principles of action and passion, and we may afterwards present the character synthetically, with a unity of appearance. In all subjects the mind follows the same plan. Analysis should be carried to that point at which the truth of the general principle we wish to find is ascertained.

Philosophical Arrangement.—The memory derives aid from philosophical arrangement; because knowledge so arranged is easily applied to use, in the same manner as goods put up in small parcels are more readily and advantageously handled than if their contents were lying in a state of confusion. It enables us also to ascertain the truths which may be deduced from general principles. For instance, lives are insured by fair inferences from philosophically arranged facts.

DISCOVERY AND INVENTION.

Discovery is finding out something already existing. *Invention* expresses the analogies of objects considered as means in reference to a particular end. Finding out the polarity of the magnet was a *discovery*; but the application of that discovery to the purposes of navigation was an *invention*. The mechanical powers are beautiful instances of invention. The lower animals do not invent; they betake themselves to the shelter of rocks during a storm, but they are never found to construct a building for shelter. Newton is said to have *discovered* the binomial theorem, because he only brought to light a truth formerly unknown; but he is said to have *invented* the method of fluxions, because he contrived a new method of *discovering* truth.

Invention facilitated.—Invention is facilitated by referring particular truths to general principles, or concentrating the attention to one subject.

ART AND SCIENCE.

Art is a knowledge convertible to practical purposes. *Science* is a knowledge of the principles of art. The object of art is to produce certain effects by the action of bodies upon each other; that of the latter is to ascertain the uniform relations of substances. All art must be founded upon science, because art implies knowledge acquired. The man who prescribes for disease, without having made a *fair induction*, is a mere empiric.

Difference of the Sciences.—The sciences differ only in their matter, or the nature of their truths. In the physical sciences, the relations we trace are uniform. Polarity, or turning towards the north, is a universal property of the magnet. But in those sciences in which we have to deal with the powers of living bodies, or mental operations, the true relations are not only difficult to discover, but even after we know them we may frequently be disappointed in the result we wish to produce. New causes intervene which sometimes elude observation. The constitutions and habits of human beings are different. A motive which influences one person fails to influence another.

But, by extensive observation, we can trace a remarkable uniformity in the great operations of nature. The changes of the moon seem to be irregular to one whose observation is limited. Human life is *uncertain* as regards individuals, but *certain* as regards a number. Men, too, are possessed of certain uniform principles, which can be acted upon by certain moral truths, when they are brought into circumstances necessary for the due operation of those truths.

The Object of all Science.—It is the object of all science to ascertain facts, and to trace their relations. We know, for example, that a certain substance is a medicine, and we know that it acts upon the skin. These are two facts. With this knowledge, if nothing more can be ascertained, we must be satisfied. It is sufficient for all practical purposes.

EVIDENCE.

Demonstrative evidence is employed about all subjects which can be expressed by numbers; but the subjects of moral evidence are matters of fact.

Proof.—The term *proof* should not be confined to demonstration; because a proposition for which sufficient probable evidence has been advanced is considered to be *fairly proved*. It cannot be *demonstrated* that the Romans had been in this island; but it is *proved* by the testimony of historians, the Roman camps and roads, the remains of Roman buildings, the coins, urns, &c.

Two kinds of Moral Evidence.—The two kinds of moral evidence are *Experience* and *Testimony.* We have the evidence of certainty for personal experience.

In reference to things that are various, as the direction of the wind and the effects of medicine, conclusions are drawn from general experience by collecting all those instances in which we have found them to exist in one way, and all those in which we have perceived them to exist in another, and then determining the ratio which those instances bear to each other. Thus if the number of instances in which a certain fruit had proved harmless were equal to those in which it had proved hurtful, it would be *uncertain* whether it would hurt a person that was going to eat of it. If more had been hurt by it than not, it would *probably* hurt him; if very few who had eaten of it escaped injury, it is *highly probable* that it would hurt him.

Testimony.—*Direct* testimony is that which is professedly given. *Incidental* testimony is that which is casually introduced on one subject in the course of an evidence delivered on another. The latter has greater weight than the former, because it is less susceptible of deliberate intention to deceive.

When all the persons through whom the information passes are known, the testimony is *remote;* but when they are not known, the evidence is termed *report.*

Mixed Evidence.

Mixed testimony is that by which we learn from others the general conclusions which they have drawn. It is termed *mixed*, because it possesses partly the nature of *personal observation*, and partly the nature of *testimony.* The *degree* of evidence to be attributed to mixed subjects depends, 1st, On the nature of the subject—some subjects are capable of more accurate observation than others; 2d, On the character of the observer—his *ability* must be considered in scientific subjects—his *honesty* in common matters; 3d, On the number of our informers—*several persons* are less likely to be mistaken in the conclusions they have drawn than *one person.*

A thing believed by all men, as far as we can know, is a matter of *general notoriety.*

Tradition is the relation of a fact or event which was not committed to writing by any person who observed it, but was communicated from one to another for a certain period of time. It is very uncertain, because the defects of memory are supplied by invention.

Internal Evidence.

The preceding species of evidence are termed *external*, because they are drawn from some external source. The following are named *internal*, because they arise from the subjects themselves:—

Analogical.—When it is inferred from the resemblance which the subject in question bears to some other known subject, that they are likely to produce similar effects, the evidence is termed *analogical.* From the resemblance which a disease in a certain patient bears to other diseases which he has observed, the physician ascertains its nature, and prescribes for its cure. The credit due to this species of evidence is ascertained by finding whether the resemblance holds good in regard to the point under consideration.

Presumptions.—*Positive* proof is the evidence of men on oath, or of writings or records. *Presumptions* are *probable inferences.* These inferences are of greater or less weight according as it is more or less probable that the facts established would not have existed unless the fact which is inferred had existed also. Thus, James was found dead, with a bleeding wound, in a house; Thomas was observed running out of the house, and there was no other person found on the spot; *therefore, he was the murderer.*

The Degree of Probability.—The *degree of probability* is calculated as follows:—Of 100 persons who had eaten of a certain fruit, 75 were hurt by it; and of every 16 who had eaten of it, 4 died. Hence the probability of safety in eating of it is $\frac{1}{4}$, and the probability of surviving the eating of it is $\frac{3}{4}$.

DIRECT AND INDIRECT BELIEF.

Belief is ascent produced by apparent credibility. It is *direct* when a proposition, without regard to any former proposition, is admitted; but *indirect* when a proposition is admitted in consequence of the admission of some former proposition.

The *intuitive* principles of belief are—1st, A conviction of our own existence; 2d, A confidence in the evidence of our senses; 3d, In our mental operations; 4th In our mental identity; 5th, In the conformity of th operations of nature.

In judging of the credibility of a statement, we must often extend our views beyond *our own experience.* The King of Siam would not believe that water froze in Britain, because he had never seen water become solid. If the king had proceeded upon the knowledge which he had acquired of the properties of bodies, he would have recollected that he had seen various fluids rendered solid by the abstraction of heat, and hence inferred that water might become solid in a low temperature.

TRUTH.

Truth is that which admits of proof. It may be proved to be true by the evidence of the senses, by investigation, hypothesis, and experiment, or by a fair train of induction founded on these preliminaries. Some persons are so incredulous, that they will believe in the truth of nothing which they cannot prove by the evidence of the senses and a certain degree of experience. But, under the head of *theory*, we have seen that it is perfectly reasonable to accept of inferences founded on the investigation and experience of others, provided the inferences are reconcilable with known phenomena.

Too great credulity is as erroneous as too great incredulity. A person may make himself ridiculous by believing even that which the senses seem to prove to be true. An ignorant person sees a juggler, as he thinks, catch a bullet fired from a gun, and believes that the juggler actually performed this feat; whereas the bullet is not fired at all, but is held in the juggler's hand. To judge of truth, therefore, the mind must be cultivated, the experience extensive, and the induction just. In Logic, Truth is said to be the agreement of propositions with the notions concerning which an affirmation is made. Truth does not exist unless the terms employed are understood in the same sense by the speaker and the person addressed. The chief causes that preven the discovery of truth are—1st, *Ambiguous language*; 2d *Hasty inductions*; 3d, *Prejudice*

GENERALIZATION.

Generalization is that process by which the mind arrives at a whole class, expressed by a *general* term. It may be defined as the notion of partial resemblance. A horse, a sheep, and a stag, are named *quadrupeds*, because *they resemble one another in having four legs*, though they differ in many other respects.

A marble, an apple, an orange, agree in *form*—they are *round*: but the first is hard, the second is pulpy, and the third is fragrant.

India-rubber, steel, air, the gases, are *elastic*, that is, they have the power to resume their former shape when the force that diminished it is withdrawn.

Generalization, then, is *tracing certain points of resemblance*. Abstraction is fixing the mind on the point of resemblance in one body. Generalization implies *three* things: 1st, An object that gives rise to the notion of resemblance in the mind; 2d, The rise of that notion in the mind; and, 3d, The name to express that notion of partial resemblance.

ANALYSIS OF TERMS.

A *general term* expresses a notion of *partial similarity*. Thus, the general term *quadruped* expresses the partial notion of resemblance that is felt when we regard a horse, sheep, stag, &c.

To *analyze* a general term is to mention every notion which it embraces.

Passion embraces two notions: that of displeasure and haste.

Peevishness is transferring displeasure from the guilty to the innocent.

Manslaughter is killing accidentally, or without malice.

Murder is killing with malice aforethought.

The analysis of complex terms is indispensable to accuracy of thought. Many hot disputes arise from men not being able to analyze the language they employ. A gentleman lately related the following anecdote to show that Sheridan was a wit. Sheridan was walking one day with a friend, when he observed a person coming towards him who was very affected in his pronunciation. As soon as he met Sheridan, he asked him if he had seen a certain great curosity which was then exhibiting. Sheridan walked on, and his friend observed, "That gentleman does murder the English language." "Not so bad," answered Sheridan, "he has only knocked an i (eye) out." Some of the company who heard this anecdote related, pronounced it witty, others affirmed that there was no wit in it. They disputed more than two hours, and seemed then farther from agreement than when they began. Fortunately, just as they were about to part, a gentleman requested to know whether all the disputants would admit that *a feeling of light mirth, occasioned by the unexpected discovery of resemblance with difference*, constituted *wit*. All agreed that it did. He then asked them if there was not in this instance a resemblance in the sound—i—eye, with a difference in the meaning—i, a letter of the alphabet. To this, too, all assented, and wondered how they could possibly have disputed so long about a matter that was so simple.

Importance of General Terms.—The progress of society is greatly owing to the introduction of general terms. The process of study is abridged more and more in proportion as the truths to be acquired increase in number. Hence the elementary truths of science, which were at one time occult, become the subjects of common education. A short period employed at the present time, under a skilful teacher, will carry the student beyond the conclusions which limited the inquiries of those who were deservedly reputed eminent philosophers an age or two ago.

Men are apt to fall into two great extremes. The one arises from too minute an attention to *particulars*, the other from habits of *generalization* carried to an excess. When theoretical knowledge and practical skill are happily combined in the same person, then the intellectual power of man appears in its full perfection.

PREDICABLES.

A term is said to be *common* when it belongs to a whole class alike; as, Horses are *quadrupeds*.

The horse is a *quadruped*. A term is named a *predicable* when it may be affirmed of the class, or of any one of the class.

Predicables have been reduced to *five* classes—*genus, species, difference, property, accident.*

The *genus* expresses the common part of the essence of several objects.

The *specific* expresses that which is essential to the notion of an object.

The *difference* expresses the distinguishing part, or characteristic.

The *property* expresses what belongs to every individual of the species.

The *accident* expresses what belongs to some individuals only of the species.

The following are examples of predicables:—

Man is an *animal*. Animal is the *genus*.

Man is a *rational being*. Rational is the *difference*.

Man *possesses the property of speech*. The *property*.

Man is *tall, learned, ignorant, &c. Accidents.*

Rational being, or animal, is the *species*. The species with the difference is equivalent to the *genus*.

The qualities necessary to the existence of a subject constitute its *essence*.

Man is also distinguished from other animals by the *capacity of religion, making exchanges, using fire to dress his food.*

A logical or universal whole is termed a genus when its parts are also wholes or species; as *man, beast, bird, fish, insect*, are *species of animal*.

A whole is termed a *species* when its parts are individuals; as *John, James, &c.*, are *men*.

A genus that is not considered as a species of any thing is termed the *summum* or the *highest genus*.

The *proximum genus* is the *lowest genus* that can be predicated of a subject.

Man is an animal. Here *animal* is a *genus* in relation to *man*. An animal is a substance. *Animal* is a *species* in relation to *substance*. *Genus* and *species* are only notions of resemblance. We may, therefore, generalize differently, and refer the same individual to any of several different species, and the same species to several genera, as suits our purpose.

Man may be classed *politically, physiologically, theoretically*, or *geographically*; as—

The man is a farmer, a merchant, a manufacturer, &c.

The man is a negro, a white man, &c.

The man is a pagan, a Christian, a Mohammedan, &c.

The man is a European, an American, an African, &c.

And the *property* of an object may appear differently to different men; for the notion which is most important in reference to one art may not be regarded so in another. The sailor considers *polarity* the property of the magnet; but those manufacturers who use magnets for shielding their faces in grinding needles, fix on the notion of attraction.

The predicables are *relative*, because the same notion or quality may be considered in various relations. Thus

Red is a *genus* in relation to *scarlet*.

Red is a *property* in relation to *blood*.

Red is the *difference* in relation to a *rose*.

Red is an *accident* in relation to a *cup*.

The term *species* in natural history is applied to animals which "resemble one another as much as those of the same stock do." Hence it is said that the African elephant is of the same species as the Asiatic one

DIVISION.

Logical divison is the distinct enumeration of several things by one common name. The *highest genus* is the *whole*, the *species* is the *parts* into which it is divided. Thus,

An *oak* is a *tree*. An *elm* is a *tree*. A *fir* is a *tree*.

Physical division is separating the constituent parts of any thing; but in a *logical* division each of the parts expresses the *difference* as well as the general notion. A tree is divided physically into *trunk*, *branches*, *leaves*, &c.

The rules of division are *three*:—

1. Each of the parts, or any of them less than the whole, must contain less than the thing divided. To divide bird into *vertebrated*, *wading*, *rapacious*, would violate this rule, for all birds are vertebrated.

2. All the parts together must be exactly equal to the thing divided. To divide bird into the *sparrow tribe*, *rapacious*, and *wading*, would be erroneous, because some birds are *climbing*, &c.

3. The members must not be contained in one another. Book cannot be divided into *quarto*, *French*, *Latin*, for the same book may be both quarto and French.

The principle of division with which we begin must be kept in view. To divide book partly according to size, partly according to language, would be a *cross division*. One mode of dividing may be most suitable for one purpose, and another mode for another. A bookseller would divide book into octavo, quarto, &c.; but a philologist would divide book into Latin, French, &c.

Classification.—In classifying, we separate objects according to certain differences, or continue to generalize until a difference can no longer be found. In classification, one act of generalization follows another. Thus, according to Linnæus, animals that suckle their young form the class *mammalia*; birds form a second class; amphibious animals a third class; fishes a fourth; insects a fifth; worms a sixth. The mammalia are classified into *seven orders*. Each order is divided into *four genera*. Each genus has *different species*, of which there are *many varieties*. Cuvier classifies thus: Individual, species, kind, family, order, class, division.

DEFINITIONS.

Definition is fixing in a single word or phrase the particular circumstance of resemblance of various objects. A sheep is a ruminating animal; it resembles those animals which chew their food twice. The attribute which we obtain, common to all the objects, is the definition. The proximate genus with the specific difference is the logical definition. *Rational animal* is the logical definition of man.

Definitions are divided into *nominal* and *real*; because the object in view may be either to explain the *meaning* of the term or the *nature* of the thing.

The *nominal* explains the *meaning* of the term; as, decalogue, the ten commandments. The *real* defintion explains the nature of the thing; as, gold is that metal which is yellow, fusible, malleable, heavy, precious, &c.

And real definitions have been divided into *physical*, *accidental*, and *logicol* because a definition may be employed to enumerate the *properties* and *accidents*, or the *physical* or *metaphysical parts* of the essence.

An accidental definition or description enumerates the properties and accidents; as, Bonaparte was a native of Corsica, who was conquered at Waterloo.

The *nominal* and *real* definitions are the same in all strict sciences; because in them the meaning of the word and the nature of the thing are the same. Gold may possess many qualities not implied in the meaning of the term; but all the properties of a triangle, or of a circle, may be deduced from its definition.

Such terms, too, as virtue, vice, obligation, right, &c., are capable of a real definition as well as of a logical; and the nominal definition coincides with the real. "Virtue is that benevolence which springs from love to God and man."

Rules for Definition.

The rules for definition are *three*:—

1. The definition must be adequate. To define *fish* as an animal that has an air-bladder, is too narrow, for many fish have not an air-bladder.

2. The definition must be plainer than the thing defined. Dr. Johnson's definition of *network* is not so.

3. The definition must be neither too brief nor too prolix. When it is tautological, we are left to suppose what is not true. Circumstances must not be introduced which are true generally, but not always; because accidental circumstances may be mistaken for real. Clouds are *gloomy vapours*. This definition is true only in certain circumstances.

Importance of Definition.

1. To guard our meaning against mistake, we must define the terms we employ, if we do not use them in their common acceptation. If we employ, without definition, the term *virtue* to express *fortitude*, some persons may suppose that we mean *justice*.

2. We must understand the terms used by others in the sense in which they define them; and if a definition has not been given, we must understand them according to common use.

3. We must distinguish *verbal* from *real* differences. John affirms that the ancient Germans were *savages*. James denies the assertion. They dispute long and violently. They are asked to define the term *savage*. John defines it, "a person unacquainted with agriculture." James defines it, "an illiterate person." Hence the dispute is *verbal*, for James admits all that John contends for. John does not include in his definition the notion illiterate. James does not deny that the ancient Germans were unacquainted with agriculture. If he had denied this, the dispute would have been *real*. The one would have denied that which the other affirmed to be true.

PROPOSITION.

A *proposition* is an act of judgment expressed in language. Judgment is the notion of relation which arises upon the perception or conception of two or more objects, or of two or more affections of our mind. We perceive the distant mountain, we consider its relation in position to the hill that is nearer. A notion of relation arises in the mind; the hill is judged to be nearer than the mountain.

Every proposition expresses the relation of a whole to its parts. Snow is white, cold, &c.; that is, each of those qualities forms a part of the subject snow.

Terms of a Proposition.

Every proposition has *two* terms: the *subject*, or that which is spoken of; and the *predicate*, or that which is said of the subject.

Subject.	Copula.	Predicate.
Snow	is	white
Snow	is not	black.

The *copula* affirms or denies the *predicate* of the *subject*.

It is probable that some ships have been lost. *That some ships have been lost* is the subject; *probable* is the predicate. Kings reign. *Kings* is the subject; (are) *reigning* is the predicate.

When the predicate is emphatic, it is placed before the subject; as, *Great* is Diana of the Ephesians.

A Qualified Subject or Predicate.

The man is wise who speaks little. The subject is not *man* only, but man limited by the words *who speaks little*; *wise* is the predicate.

The sailor is happy in having reached the shore. The predicate is not *happy*, but *happy* limited or qualified by the words *in having reached the shore*.

Compound Propositions.

In *compound* propositions there is either more than one subject or *one* predicate.

Life and death are in his hand. *Life* and *death* are the two subjects. Holy and reverend is his name. *Holy* and *reverend* are the two predicates.

Compound propositions are distinguished by the language in which they are clothed. Life *and* death are in his hand, is named a *conjunctive* or *copulative* proposition; because *and* is a copulative conjunction.

Neither Cæsar *nor* Pompey loved his country, is equivalent to—Cæsar did not love; Pompey did not love. A conjunctive proposition is false when one or both of the propositions into which it is resolvable is false. Virtue and riches are necessary to salvation. Virtue is necessary to salvation, but riches are not.

Disjunctive Propositions.

It is *either* day *or* night, is resolvable into four propositions. 1. It is day. 2. It is not night. 3. It is night. 4. It is not day. A disjunctive is false when it does not contain the true member or proposition. It is *either* summer or winter. It may be spring or autumn.

Comparative and Causal Propositions.

A comparative proposition is false when the higher degree is false, or the positive is not true in both propositions, as, Riches are *better than* virtue.

A causal proposition is also false when either of the propositions is false, or the cause is falsely assigned; as, All events are necessary, *because* they were decreed by fate; Tamerlane was cruel, *because* he was born under Scorpio.

Definitive and Conditional Propositions.

A definitive is false when any of the propositions is false; as, Cæsar was put to death in the 610th year of Rome, by those whose lives he spared when conquered. Cæsar was put to death in the 710th year of Rome.

If this man is sick, he has a fever. This proposition is false; it is not true that whoever is sick has a fever.

The Property of a Proposition.

Propositions are divided, according to their *property*, into *true* and *false*.

Propositions are divided, according to their *substance*, into categorical and hypothetical.

Propositions are divided, according to their *quality*, into affirmative and negative.

Propositions are divided, according to their *quantity*, into universal and particular, or partial.

A categorical proposition is a *simple* proposition; as, Snow is white.

A hypothetical proposition is either a *disjunctive* or a *conditional*.

The following may be taken as illustrations:—

Dogs are *rational*. The *property* of the proposition. It is *false*.

Dogs are *faithful*. The *substance* of the proposition. It is *categorical*.

Horses are *quadrupeds*. The quantity of the subject. It is *universal*.

Horses are quadrupeds. The quantity of the predicate. It is *partial*; because there are other quadrupeds than horses.

Horses are quadrupeds, is *universal*; because all horses are quadrupeds.

Some men are not virtuous, is partial; because the sign *some* indicates that the proposition is particular.

Circles are round, is *indefinite*; because the sign *all* is not expressed.

Opposition of Propositions.

Two propositions are said to be opposed to each other, when, having the same subject and predicate, they differ in quantity or quality, or both.

A universal negative and a universal affirmative are termed *contraries*; as, *All* horses are quadrupeds; *no* horse is rational.

A universal affirmative and a particular affirmative are termed *subalterns*, and also a universal negative and a particular negative; as, *All* horses are quadrupeds; *some* horses are quadrupeds, *No* horse is rational; *some* horses are not rational.

A particular affirmative and a particular negative, are termed *subcontraries*; as, Some horses are black; some horses are not black.

A universal affirmative and a particular negative, or a universal negative and a particular affirmative, are termed *contradictories*; as, *All* horses are quadrupeds; *some* horses are not black: *No* horse is rational; *some* horses are black.

Contraries differ in *quality*. Subalterns differ in *quantity*. Subcontraries differ in *quality*. Contradictories differ in both *quantity* and *quality*.

Contraries cannot be both true; for if it is true that *all* men are mortal, it must be false that *no* man is mortal. Subcontraries cannot be both false; for it must either be true that some men are white, or that some men are not white.

Subalterns may be both true or both false. *All* men are liable to mistakes, *Some* men are liable to mistakes, are both *true*. *No* man is liable to mistakes, *Some* men are not liable to mistakes, are both *false*.

In contradictories, if the one is true the other is false, and *vice versa*. If it is *true* that *some* men are not white, it is *false* that *all* men are white.

Conversion of Propositions.

A proposition is said to be converted when its terms are transposed; as, *Some cowards* are *boasters*; *some boasters* are *cowards*.

A universal negative and a particular affirmative are converted simply; as, *No* Christian is *impious*; *no impious man* is a *Christian*.

In converting a universal affirmative, we must limit its *quantity*; as, *All* birds are *animals*; *some* animals are birds.

In converting a particular negative, we must regard it as a particular affirmative; as, *Some* members of the university are not learned; *some not learned* are members of the university.

REASONING.

Reason is a series of consecutive judgments, and *reasoning* is a series of related propositions, or a continued analysis of our thought. Thus, Man is fallible; he who is fallible may err; he who may err ought not to wonder at others differing from him in opinion; therefore, man ought not to wonder at others differing from him in opinion. The last proposition is contained in the first as much as of the intervening propositions; but the relation between the first proposition and the last is not seen till the unfolding of proposition after proposition.

Logical Inference.

Logical inference is of *two* kinds: it proceeds either from the parts to the whole, or from the whole to the parts. Thus, A cow, a deer, a sheep, ruminate; a cow, a deer, a sheep, represent all horned animals; therefore, all horned animals ruminate. This is *inductive* reasoning.

Deductive reasoning is proceeding from the whole to the parts; as, All horned animals ruminate; a cow is a horned animal; therefore a cow ruminates.

All horned animals is the *class* or *whole*; the parts are, a cow, a deer, a sheep; what is affirmed of the *whole* may be affirmed of *each of the parts*, or of all the parts. The rule for *inductive* reasoning is—What is affirmed of the *parts* may be affirmed of the *whole*. The property which belongs to the *parts* is admitted to belong to the *whole*, or *class*.

What is denied of the *whole* may be denied of the *parts*.

Analysis of Reasoning.

Every *conclusion* is deduced from other *two propositions*, termed *premises*; as—Premiss 1, or *major* proposition, *All* horned animals ruminate; Premiss 2, or *minor* proposition, A sheep is a horned animal; *Conclusion*, Therefore, a sheep ruminates. *Sheep* is named the *minor* term, because it is less extensive than *ruminating*, which is therefore termed the *major*. Horned animals is the *middle* or *mean* term, or *proof*. It is also the *whole*.

In the major proposition we find the *middle* and *major* terms; and in the minor proposition, the middle and minor terms.

The third proposition is named the conclusion, because it *concludes*, or *shuts up in one*, the major and minor propositions. The first two propositions are termed the *premises*, because they *premise*, or go *before*, the conclusion.

Enthymeme.

Enthymeme is reasoning from signs (language) or probabilities, because it has one of the premises suppressed. Thus, He is an industrious man; therefore, he will acquire wealth. The *major* proposition is here suppressed—Every industrious man acquires wealth, which is false. Therefore, the conclusion is only probable—he *may* acquire wealth. All good men are happy; therefore, John is happy. The minor premiss, John is a good man, is suppressed.

Hypothetical Reasoning.

A disjunctive proposition states an alternative, or implies that some one of the categorical propositions is true. Wealth must *either* be spent *or* hoarded; it is not hoarded; therefore, it is spent. The reason is not conclusive, because a proposition or member is wanting; for wealth may be neither spent nor hoarded; it may be laid out or employed in producing more wealth.

Dilemma.

The *dilemma* is a complex conditional reasoning, in which either one of the *antecedents* must be admitted, or one of the *consequents* must be denied.

If Eschines joined in the public rejoicings, he is inconsistent; if he did not join, he is unpatriotic; but he either joined or did not join; therefore (one of the consequents must follow), he is either inconsistent or unpatriotic.

We speak of the *horns* of a dilemma, because the name implies a taking hold of both ways; if a person is not caught by the one antecedent or consequent, he must be caught by the other.

If it is spring, you are to blame for not sowing; if it is autumn, you are to blame for not reaping; but it is either spring or autumn; therefore, you are to blame for either not sowing or not reaping. It is not conclusive. The enumeration of the parts is not complete; it may be summer or winter.

Sorites.

The *sorites* consists of a number of dependent propositions, in which the predicate of every preceding proposition becomes the subject of every succeeding proposition, till the subject of the first is found to agree in the conclusion with the predicate of the last. Thus, A miser covets much; he that covets much wants much; he that wants much is miserable; therefore, a miser is miserable. There are here as many acts of reasoning as there are intermediate propositions.

Figure.

The *figures* of reasoning are only *different forms* of stating it. We have seen that the same act of reasoning may be expressed either *categorically* or *hypothetically*. It will now be shown that the same act of reasoning may be expressed in each of the *four* figures.

First Figure.

No lover of pleasure is a true philosopher;
The Epicureans were lovers of pleasure;
They were not true philosophers.

Second Figure.

No true philosopher is a lover of pleasure;
The Epicureans were lovers of pleasure;
They were not true philosophers.

Third Figure.

No lover of pleasure is a true philosopher;
Lovers of pleasure were Epicureans;
The Epicureans were not true philosophers.

Fourth Figure.

No true philosopher is a lover of pleasure;
Lovers of pleasure were Epicureans;
The Epicureans were not true philosophers.

In the first figure, the middle term is the subject and the predicate of the minor. In the second figure, the middle term is the predicate of both premises. In the third figure, the middle term is the subject of both premises. In the fourth figure, the middle term is the predicate of the major, and the subject of the minor. The fourth is the opposite of the first, and the third of the second. The first figure is used when we are reasoning with a person who wishes instruction; the second in proving to one who objects; the third in showing that a universal conclusion has been drawn when a partial conclusion is the legitimate one.

Reductio ad Impossibile.

In *reductio ad impossibile* or *ad absurdum*, it is proved, not that the original conclusion is true, but that an absurdity would follow from the supposition of its being false. Thus, All gold is yellow; some metal is not yellow; some metal is not gold. If this conclusion is not true, the contradictory—All metal is yellow, must be true: All gold is yellow; All metal is gold; all metal is yellow. The major premiss is true, being originally granted; therefore the falsity must be in the minor premiss, which is the contradictory of the original conclusion; therefore the original conclusion must be true.

Fallacy.

Fallacy is false or inconclusive reasoning. When the fallacy is in the form of expression, it is termed *formal*. Otherwise it is named *material*.

Money is wealth; corn is not money; therefore it is not wealth. Whatever is affirmed or denied of the *whole* may be affirmed or denied of any of the parts. But here nothing is mentioned as belonging to the class, money; corn is excluded from it. Now, though we may affirm of *gold* or *silver*, or of any part of the term *money*, what was affirmed of the class itself, we are not authorized to deny that what was affirmed of it can be affirmed of nothing else. The following is a similar fallacy:—Horses are animals; sheep are not horses; therefore, sheep are not animals. Sheep are animals as well as horses: corn is wealth as well as money. The terms *animal* and *wealth* have been used *partially* in the premises, but *universally* in the conclusion.

Fallacy of Equivocation.—In this fallacy, the middle term is used in two senses, or there are *two* classes, not *one*. Thus, Wicked men abound in repentance; therefore they abound in what is good.

This act of reasoning or fallacy is analyzed as follows:
Repentance is a good thing;

Wicked men abound in repentance;
They abound in what is good.

In the major premiss *repentance* signifies *genuine sorrow*, but in the minor it signifies *regret arising from pain or loss*.

Fallacy of Division and Composition.—5 is *one* number; 3 and 2 are 5; therefore, 3 and 2 are *one* number. 3 and 2 are two numbers; 5 is 3 and 2; therefore, 5 is two numbers. The former is the fallacy of *division*, because the middle term 5, is used *collectively* in the major premiss, but dividedly, 3 and 2, in the minor. The fallacy of *composition* is the reverse. In both there are *two* wholes or classes.

The miracle of curing the man sick of the palsy might have been the result of chance; therefore, all miracles might have been the result of chance. This is an instance of the fallacy of *composition*.

Fallacy of Accidents.—In this fallacy, the middle term is used simply in one of the premises, but conjoined with certain accidents in the other; as, What we eat grew in the fields; loaves of bread are what we eat; therefore, loaves of bread grew in the fields. In the major premiss *we eat* is taken *simply*, but in the minor it is taken with its accidents, *baked*, *cooked*, &c.

A certain medicine, when taken improperly, hurts; therefore it is a bad medicine. It is bad when taken with its accidents, that is, *improperly*.

Reasoning in a Circle.

This occurs when a person pretends to determine the truth of a proposition by instancing the conclusion. The English language, by being composed of words from the Saxon and Latin languages, admits of this fallacy to a great extent. A person says, A thing is *hateful*. Why is it hateful? Because it is *odious*. Now, *hateful* and *odious* mean the same thing; *odious* being a Latin synonym for the Saxon word *hateful*. Reasoning in this way is just as bad as saying a thing is hateful because it is hateful, or it is true because it is true. Why did you go to such a place? says one man to another; Because I went, is the reply. This is no answer at all.

Whately gives an instance of this fallacy in the following sentiment. "To allow every man an unbounded freedom of speech must always be, on the whole, advantageous to the state; for it is highly conducive to the interests of the community, that each individual should enjoy liberty, perfectly unlimited, of expressing his sentiments." This kind of rant often passes for sound reasoning.

Petitio Principii.

When any one reasons on the supposition of a fact which is neither proved nor granted, he is said to *beg the question*, or, in the language of Logic, to resort to the *petitio principii*. A proposition cannot be proved to be true from something which is equally uncertain and disputed.

Self-Contradiction.

Some persons advance arguments which bear their own contradiction, and therefore come to nothing. A partisan will be heard to say, "The removal of the laws which prevent the free importation of foreign corn would injure the home agriculturists; but it is well known, from the most ample investigation, that foreign countries possess so little overplus of corn, or the means of sending it, that any expectation of supplies from abroad is little better than a delusion." Here the second proposition, in effect, contradicts the first. This fallacious kind of reasoning is only surpassed by the following legal *jeu d'esprit*:—"There are three points in this case," says the defendant's counsel. "In the first place, we contend that the kettle was cracked when we borrowed it; secondly that it was whole when we returned it; and, thirdly, that we never had it at all."

Ignoratio Elenchi.

Ignoratio elenchi, or irrelevant conclusion, is when various kinds of propositions are substituted, according to the occasion, for the one that ought to be proved. The fine arts please the imagination, and adorn and polish life. But the fine arts are the parents of luxury. This does not prove the original conclusion, namely, that the fine arts are a frivolous amusement; besides, it mistakes the effect for the cause. The fine arts are the offspring of wealth, not the parent of luxury, for they can be encouraged only by a people who possess as much wealth, at least, as enables them to devote a portion of their time to the cultivation of the mind.

Argumentum ad Hominem.

This signifies the argument directed point blank to the person spoken to, or a reference to something in the person's own condition which proves the truth of the argument. There is a fine instance of the legitimate use of the *argumentum ad hominem* in Luke's Gospel, chap. xiv. v. 5. The Pharisees, affecting to be scandalized by Christ doing works of mercy on the Sabbath, he addressed them as follows:—"Which of you shall have an ass or an ox fallen into a pit, and will not straightway pull him out on the Sabbath day?" This direct appeal was unanswerable.

The *argumentum ad hominem* is always used fairly when the conclusion established is not considered general but particular; that is to say, when it applies to the conduct or principles of the person reasoned with, not with the principles of all mankind. No man is entitled to have his argument overturned by the doings of others.

Fallacies of the Feelings.

The feelings may be said to be always lying in wait to set aside the efforts of judgment. The class of fallacies of this nature are intimately connected with interest, caprice, self-esteem, envy, jealousy, disputation, complaisance, outward appearance, long-sounding words, inferring the motive from the effect, authority, manner, awe of rank, fear, &c. Bacon terms the fallacies or prejudices which militate against the discovery of truth *idols*, because men are apt to pay homage to them instead of regarding truth. He classes them as follows:—

The 1st class are called Idols of the *Tribe*, because they are common to the whole race or *tribe* of mankind; the 2d are termed Idols of the *Den*, because every man has his own particular den or character; the 3d class, Idols of the *Market*, because they are accommodated to *common notions*; and the 4th, Idols of the *Theatre*, because many systems of philosophy are but *stage-plays*, which exhibit nothing but *theatrical worlds* or *visionary hypotheses*.

The first class are those prejudices which men entertain from their early notions, and from a love of hypothesis. Thus an old woman who may have recommended some nostrum, which has been successful in curing one disease, will consider it a remedy for all other diseases.

The second are those prejudices which arise from habits of thinking, the dispositions or the passions of men. A theologian who is of a violent temper, will represent the Deity as implacable. The pedantic mathematician, who reasons on a subject, will not be convinced by probable conclusive reasoning, because it is not demonstrative.

The third are those which arise from the relations of human society, from the condition of men, from their different stations. The man of wit laughs at the philosopher of whose speculations he is ignorant.

The fourth are those prejudices which men entertain upon the authority of others. The zealous abettor of some favourite theory will never listen to any arguments against it.

The following are illustrations of these various fallacies, drawn from different circumstances.

Of Caprice.—There are persons who will not admit that those individuals whom they happen to dislike are in any respect worthy of esteem. They seem to reason thus:—I like that man; therefore, he is the best person in the world. I dislike that one; therefore, he is a worthless fellow.

Of Self-Love and Self-Conceit.—Some individuals regard all men as irrational who differ from them in opinion: all who do not agree with them are opinionative. I am a man of common sense; therefore, it is so. I have a right to be displeased with you for not succumbing.

Of Envy and Jealousy.—Some men contradict with a mean malignity those of whom they are jealous. Their envy of a person begets hatred of his opinions. I did not say that; therefore, it is false. I did not write that article; therefore, it is contemptible.

Of Disputation.—Disputation, or maintaining an assertion for the sake of contradiction, renders conviction difficult, if not impossible. When some disputants find that a position is not to be defended, they trust to equivocation; some affect contempt or modesty, so reproach themselves in order to get rid of an adversary; others defend themselves with the only weapons they can use to advantage—the strength of their voice and lungs.

Of Interest.—A difference of judgment not unfrequently proceeds from interested motives. I am a native of this country: therefore, I must believe that every interesting event recorded in its early history actually occurred. My interest is apparently damaged by a certain public measure; therefore, I must oppose it. I have nothing to do with the effect which it may have on the country generally.

Of Complaisance.—Some persons either commend what is reprehensible, or more than is just, and therefore delude those that are so commended, and wrong those that really merit praise.

Of Outward Appearance.—There are some individuals who overrate the value of whatever at once captivates the senses; and who undervalue whatever requires observation and thought to be duly appreciated. The colours of the painting are beautiful; therefore, the design is admirable. That is a fine-looking man. What a fine orator! What a good man he is!

Of Sounding Words.—There are individuals who never discover the false statements and the invalid reasoning which are found in some tastelessly decorated productions. The figures set them a-gazing; the periods tickle their ear; and the sound of the words allures them to thoughts so frivolous that a child would reject them, if expressed in suitable language.

Of Inferring the Motive from the Effect.—There are not a few men who regard every change of opinion as a sign of fickleness; who distinguish neither fortunate from prudent, nor unfortunate from vicious. He has changed his opinions in regard to popular education; therefore, he is a mere weathercock. He did not pay that respect to Mr. A. which was expected; therefore, he is proud and vain. He is of the same opinion in regard to geology as Mr. C.; therefore, he is doubtless as heretical in his opinions. Nay, he is unquestionably an atheist, and something worse.

Of Authority and Manner.—Some men test the truth of an assertion by authority which they have been led accidentally to revere. There are others, again, who are disposed to test it by the manner in which it is propounded. Their reasoning, tacitly and involuntarily, is—This is the opinion of Mr. A., the leader of my party; it is therefore correct; I have no need whatever to examine it. T. is a man of no fortune—what is his opinion worth? The speaker had a fine showy manner; it was quite impossible to hear him without reasoning correctly, and feeling rightly. How completely he demolished his opponents! His very manner showed that he despised them all. It was quite sufficient that he proved a part only of what he was to prove, for he left his audience to infer the rest. It may be true that he imputed to his opponents certain sentiments which they utterly repudiate; but his authority and manner made good the imputation. That many such sophisms as the above are frequently to be met with, must occur to every sound observer who mixes with the world.

Dogmatizing.

This is but a branch of the above. When a person utters his own opinions, and endeavours to force them on his hearers, right or wrong, he is said to *dogmatize*, that is, lay down his dogmas or opinions in an improper manner. Few things are more common than this fallacious mode of disputation, which clearly originates in excessive self-esteem. What I say is right, for I have studied the subject, and I am a man of common sense. Persons of this turn of mind are always hurt at any one thinking differently from them, and look upon it as a kind of personal insult, for it amounts to calling in question their judgment.

Confusion of Ideas.

Fallacies in reasoning often lurk under a confusion of ideas, and to produce this confusion is often the object of cunning and dishonest arguers. A tricky man went into the shop of a rather simple-minded woman, and asked for a penny loaf and a penny glass of gin. The articles being given, he drank the gin, and addressed the woman as follows:—"On second thoughts, I will not take the bread; therefore, I just give it back in payment for the gin." The woman, somewhat perplexed, answered, "But you did not pay me for the bread." "Well," said the man, "I have not taken it." "But where is the payment for the gin?" "My good woman," replied the man, "haven't I told you already that I have given back the penny loaf for it." This piece of sophistry so confused the ideas of the poor woman, that she allowed the villain to depart.

Very simple questions may in this manner be made to assume an air of extraordinary difficulty. A herring and a half for three halfpence, how many for elevenpence? is a jocular question, which has perplexed many at first sight.

Suppressio Veri.

Suppressio veri, or the suppression of the truth, is a common and dishonest method of reasoning on a question. The thing is done in various ways. A person under examination by a committee of the House of Commons respecting education, is asked if he thinks it right to give "special religious instruction in schools?" He answers that "he would not give special but general religious education in schools." An opponent sees this answer in print, and in order to injure the reputation of the respondent, he says that Mr. So-and-So "declares that he would not give religious education in schools." Here the truth is suppressed; the word *special* has been left out. This is called *garbling* a sentence to suit a bad purpose.

The following is an analogous mode of procedure. A statistical writer, after making an elaborate investigation, publishes a statement of facts and figures to show that a particular corporation is in a state of insolvency. His inferences, which are quite fair, are met, not by an analysis and disproval of his statement, but by an exposure of an error in his calculations, to the extent of three shillings and sixpence! This trifling error is thereupon made to form the foundation of a train of reasoning tending to show that the writer of the statement is ignorant of arithmetic, that he is rash in judgment, and altogether wrong in his calculations. This species of dishonest reasoning is common among the warm adherents of party. A person is openly accused in an assembly of being concerned in appropriating the public money. Another rises to refute the calumny; says the accused is a most estimable individual—he is a good father and an exemplary husband; but not one word as to the actual merits of the question; and by this clap trap appeal to feelings and the force of language, all inquiry on the subject is prevented.

Professional spite, also, sometimes takes this form of equivocation. Instead of meeting the truth of any statement respecting the qualification of a rival, some point is dragged forward in reply, with which the argument has nothing to do. "That man is an excellent lawyer," says A. B does not meet this with a denial or approval, but answers—"Did you hear he was once a bankrupt?" or, "that he was brought up on charity?" or makes some other observation equally aside from the question.

Logical Analysis.

In analyzing a train of reasoning—1. Begin with the concluding assertion; 2. Trace the reasoning backwards, and observe how that assertion is proved; 3. The assertion will be a conclusion, and the proof of it a premiss; 4. Ascertain whether the reasoning thus obtained is conclusive; 5. Pursue with each premiss the same plan, until you arrive at the premises with which the whole commences.

Any train of reasoning, therefore, should contain leading or major premises, and subordinate or minor premises. In some instances, it may be found that every step backwards in the reasoning is correct, till we arrive at the final or major premises, which rest on no solid foundation. Unfair arguers are apt to set a plain person off his guard by making him grant certain premises. The Socratic method of arguing was of this nature. The opponent was asked question after question, or, in other words, to give up point after point, till he was lost in a labyrinth, and then he was at the mercy of his enemy.

In Smith's Wealth of Nations, in the chapter on the Division of Labour, we are afforded an example of fair analysis. The concluding assertion is—The division of labour increases wealth. The proofs advanced in support of the assertion are—1st, Because it increases the dexterity of the workman; 2d, It saves time; 3d, It gives rise to invention. And then those proofs are proved—Because the man who confines his attention chiefly to one department of labour works with more dexterity than one who prosecutes different sorts of labour. He who is constantly engaged at one kind of labour, does not lose time in passing from one sort of work to another. Useful inventions have generally been made by those individuals who had occasion to give their attention chiefly to their own sort of employment. The major premiss of the conclusions respectively are—Whatever increases dexterity increases wealth. Whatever saves time increases wealth. Whatever gives rise to invention increases wealth.

Ultimate Conclusion.

The Division of Labour increases Wealth.

Proved by—Major Premiss.

Whatever promotes dexterity increases wealth.
Whatever saves time increases wealth.
Whatever gives rise to invention increases wealth.
Whatever enables one man, &c.

Minor Premiss

The division of labour promotes dexterity.
The division of labour saves time.
The division of labour gives rise to invention.
The division of labour enables one man, &c.

Each of these minor premises is proved by an induction of particular facts.

The division of labour is the division of it into a number of branches or departments. Labour means, 1st, Employment; 2d, The act of labouring; 3d, The result of labour. Wealth is that which is necessary, useful, or agreeable to man, and also *exchangeable.*

Analogy.

Analogy is a consistent reference of one thing to another; and a want of this consistency leads to serious errors in reasoning; thus, it may be said—Birds swallow small stones to aid digestion, therefore men should do so too. No Christian minister ought to marry, because St. Paul recommends celibacy. Wealth demoralizes a nation, because it demoralizes some individuals. Here the proofs are inconsistent or untrue. There is not such a degree of resemblance between the stomach of a bird and that of a man, as warrants us to affirm of the one what was affirmed of the other. St. Paul dissuaded the Christian ministers of his time from marrying, because their families would have been persecuted; but the families of clergymen in our time have no such thing to fear. Wealth has not the same effect on a nation that it has on an individual. It may render some individuals proud, indolent, and prone to luxury; but a wealthy nation is industrious, and by no means comparatively proud.

DOCTRINE OF SYLLOGISMS.—SOPHISTRY.

From the preceding definition of propositions and predicables, it will appear that from *truth* nothing can really follow but what is true; whensoever, therefore, we find a false conclusion drawn from premises which seem to be true, there must be some fault in the deduction or inference, or else one of the premises is not true in the sense in which it is used in the argument. When an argument carries the face of truth with it, and yet leads us into a mistake, it is a *sophism.*

It being of importance that every thing like sophistry or a semblance of truth without the reality, should be avoided in processes of reasoning, we shall, at the risk of a little recapitulation, explain the fundamental grounds of reasoning, according to the doctrine of syllogisms.

When unable to judge of the truth or falsehood of a proposition in an immediate manner, by the mere contemplation of its subject and predicate, we are constrained to use a medium, and to compare each of them with some third idea. The three parts so formed are a *syllogism.* For example, we take the following, given by Watts:—

Our Creator must be worshipped;
God is our Creator;
Therefore, God must be worshipped.

Here it may be observed that the third term or conclusion rests on a foundation afforded by the two preceding. To ensure truth in the conclusion, the premises, major and minor, must be true, and strictly agree. We have another example, as follows:—

Every wicked man is truly miserable;
All tyrants are wicked men;
Therefore, all tyrants are truly miserable.

In forming syllogisms, great care requires to be taken to construct them in such a manner that the first and second terms are analogous, and not a mere play of words. Previous to the method of reasoning from an induction from established facts, introduced by Bacon, it was usual to reason sophistically from premises presumedly true, and consequently the most false conclusions were arrived at. The logic in vogue was that of the ancient Greek philosopher Aristotle, which it was a species of heresy to deny. "Men were everywhere taught to believe in *matter, form,* and *privation,* as the origin of all things; that the heavens were self-existent, incorruptible and unchangeable; and that all the stars were whirled round the earth in solid orbs! Aristotle's works were the great text-book of knowledge, and his logic was the only weapon of truth. Men's minds, instead of simply studying nature, were in an endless ferment about occult qualities and imaginary essences; little was talked of but *intention* and *remission*, *proportion* and *degree*, *infinity*, *formality*, *quiddity*, *individuality*, and innumerable other abstract notions. The Latin tongue, which was employed by these scholastics, was converted into a barbarous jargon, which a Roman would not have understood; and in the end, the most sectarian bitterness was produced, sometimes ending in bloody contests. In the midst of these disputes, Aristotle was still the grand authority. Christians, Jews, and Mohammedans, united in professing assent to the great lawgiver of human opinions: not Europe alone, but also Africa and Asia acknowledged his dominion; and while his Greek originals were studied at Paris, translations were read in Persia and Samarcand. The rage for disputation which now began to prevail in consequence of the spread of this philosophy, induced the council of Lateran, under Pope Innocent III., to proclaim a prohibition of the use of the physics and metaphysics of Aristotle; but, awful as were then the thunders of the Vatican, they were not mighty enough to dethrone him from that despotism over men's minds which, by long custom, had now rendered itself almost omnipotent."* It was reserved for Lord Bacon to break the mighty power of Aristotle's philosophy, and to substitute that which is now in use.† The errors of the sophists, which it may be advantageous to examine, were of two leading orders. The fault, in the first instance, may reside in the *expressed argument*, or syllogism, in which the conclusion does not follow from the premises it is apparently involved in; or secondly, it may lurk in the *concealed process of thought*, dexterously suggested by the sophist, by means of which false premises are regarded as proved, and a false though logically legitimate conclusion is of course necessitated; or in which a conclusion, likewise logically fair, and probably true as matter of fact, but irrelevant, or only partially relevant to the point at issue, is admitted as applicable and decisive. In the one class the link is wanting which should bind the inference to the previous positions; in the other, that is absent which should connect either with the real subject of dispute. A sophism, then, which is inseparable from the form of the expression, may perhaps with propriety be styled *syllogistic;* while one attaching to the subject-matter may fall to be treated as *extra-syllogistic*. It is obviously as respects the latter sort that the common mind is most open to deception; and it must at the same time be allowed that logic is here, where her aid is most essential, able to lend it but in scanty measure. The candid will, however, remember that even the meanest modicum of such service is of value, and will not quarrel with an art for failure where absolute success is plainly unattainable.

First, then, of *syllogistic fallacies;* which, indeed, by excessive generalization, might be comprised under the other class, since they are resolvable into the impression that the same or similar terms are always representative of the same or similar ideas. It is much more convenient, however, to consider them separately.

Errors of this description may proceed, in the first instance, *from confounding allied meanings of the same term*. Sometimes a word is used both in its primary and in a transitive sense. An instance in point occurs in Mr. Burke's Essay on Taste, prefixed to his celebrated disquisition on the Sublime and Beautiful. "It may perhaps appear," he observes, "that there is no material distinction between the *wit and the judgment*, as they both seem to result from different operations of the same faculty of comparing. But, in reality, whether they are or are not dependent on the same power of the mind, they differ so very materially in many respects, that a perfect union of *wit and judgment* is one of the rarest things in the world." The words *wit* and *judgment* have each, in the above passage, two distinct significations—the powers thus denominated respectively, and the products of both in peculiarly lively exercise. The inference, of course, does not hold, and the objection it is intended to meet remains unanswered.

Sometimes a metaphorical sense is slipped in, in place of the literal. We have heard that a popular orator thus managed to turn to his own account the misfortune of a rival, absent, it seems, from delicate health. "The gentlemen has said he cannot venture himself in such an atmosphere, but this is the atmosphere in which I delight to breathe." With an excited crowd, this flimsy artifice, we believe, succeeded in procuring for a stout pair of lungs the applause due to distinguished patriotism.

Occasionally, the extension of a term is changed. Thus Hume, in his Essay on Miracles, argues as if what is granted of ordinary were true of universal *experience*. Because events of this order have not come under the observation of most persons, it is concluded that they could never have come under the observation of any. A little ambiguity has sometimes arisen from the vague application of *authority*. Referring to the writer last named, in his capacity of historian, we may think fit to pronounce him an excellent authority; but unless the term be expressly guarded, we may be represented as intimating our approval of his ethical and metaphysical speculations. By *prophet* we usually understand a person supernaturally commissioned to foretell events; in the works of Mr. Carlyle, he is simply a man of commanding genius and vast practical power. *Mystery*, formerly meaning simply a thing unknown, now denotes invariably a thing that cannot be known. The notion popularly attached to *wealth* differs widely from the use of the term by writers on political economy; and much

---

* Account of Lord Bacon's *Novum Organon*, in Library of Useful Knowledge.

† Francis Bacon, created Baron Verulam, who rose to the rank of Lord Chancellor of England in the reign of James I., obtained the highest reputation as a philosophical writer. In 1620, appeared his chief production in a complete form, "The *Novum Organon*, or New Method of Studying the Sciences," in which he pointed out the way in which we should begin and carry on our pursuit of knowledge in order to arrive at *truth*. The principles he laid down were to ascertain facts in the first place, and then to reason upon them towards conclusions—a mode which may now appear very obvious, and even unavoidable, but which was nevertheless unknown till explained by him. To come to particulars, Bacon tells us—

I. That the ultimate aim of philosophical investigation is to bring the course of events as much as possible under our own control, in order that we may turn it to our own advantage.

II. That as each event depends upon a certain combination of circumstances which precede it, and constitute its cause, it is evident we shall be able to command the event whenever we have it in our power to produce that combination of circumstances out of the means which nature has placed within our reach.

III. That the means of producing many events which we little dream of, are actually placed within our reach; and that nothing prevents us from using those means, but our inability to select them from the crowd of other circumstances by which they are disguised and surrounded.

IV. That therefore we should endeavour, by diligent observation, to find out what circumstances are essential, and what extraneous, to the production of each event; and its real cause being stripped free from all the perplexing concomitants which occur in nature, we shall perceive at once whether we can command the circumstances that compose it or not. This, in short, is to generalize; and having done so, we shall sometimes discover that objects, which of all others appeared the most useless, remote, and inapplicable to our purpose, possess the very properties we are in search of. Nature stands ready to minister to our designs, if we have only the sagacity to disentangle its operations from one another, to refer each event to its real source, and to trace the powers and qualities of objects into their most abstract form.

In pursuing the dictates of this noble philosophy, man is no longer impatient and ridiculous. He calmly vanquishes the barriers which oppose his wishes—he eludes the causes of pain—he widens the range of enjoyment—and, at the same time, feels the dignity of intellect, which, like a magician's talisman, has made all things bow before his feet.

practical mischief has resulted from the belief that a country is prosperous just in proportion as it amasses specie. In these cases and the like, serious mistakes have been generated, and risen to the rank of established and unimpeachable principles, through sheer inattention to the variations of terms. The more closely, indeed, the shades of meaning blend with each other, the more nearly like the similarity that subsists between them, the greater becomes the difficulty of detecting the fraud. Beyond a certain point, indeed, of difference, the most obtuse intellect will refuse to be imposed on. It is absurd, therefore, in an enumeration of fallacies, to assign a place to a glaring play upon words. Though the pun may puzzle, it can never mislead. "He who is most hungry eats most; he who eats least is most hungry; therefore, he who eats least eats most." We immediately discover that *eats* in the first member of the syllogism is equivalent to *will eat*, while in the second it stands for *has eaten*; and the apparent contradiction is solved and laughed over.

A second class of errors in reasoning, belonging to the same general order, may arise *from the oversight of certain differences between related terms*. It is often, for example, taken for granted that words springing from a common root only vary among themselves as parts of speech, whereas, in fact, the radical meaning may have become considerably modified. *Schemer* denotes an artful, truckling, unprincipled individual—qualities which it would be most unfair to ascribe to every man that chanced to be the author of a *scheme*. The two terms are related to each other, but a *devout* man is not therefore a *devotee*. In some instances, however, the derivative and primitive differ too plainly for either to become available for the purposes of sophistry. A mind that would fail to detect the transition from *art* to *artful*, from *pity* to *pitiful*, and the like, must be under the influence of principles of association no less peculiar than those which led the Laird of Ellangowan, in Guy Mannering, to give justice imbodiment in a justice of the peace.

To this head we would also refer the disingenuous use of *pseudo-synonymes*—that is, terms corresponding generally, but not alike expressive of the required shade of distinction. To *murder*, and to *put to death*, both indicate agency with a similar result; but the former phrase determines that agency to be criminal, while the latter affixes no such character to it. Many, under the impression that the terms are perfectly equivalent and interchangeable, might be induced to ascribe to *sour* substances the recognised properties of *bitter*. It is unnecessary to multiply examples.

Let us now review briefly the more frequent and more dangerous species of fallacies which we have ventured to denominate *extra-syllogistic*. The fault here was described as attaching, not to the expressed process of argument, but to the concomitant process of thought.

Sophisms, ranging under this general category, are all traceable to two sources, the first of which is the *assumption of doubtful premises*. This error appears in a great variety of forms.

Accidental coincidence is often assumed as sufficient to establish efficient connection. Two events happen nearly at the same time; therefore one is supposed the cause, and the other the effect. Of this sort of false reasoning, we remember a notable instance in Prideaux. Cambyses was mortally wounded by his sword piercing his body in the same part in which he had stabbed the sacred bull of the Egyptians. In narrating this incident, the dean expresses his concurrence in their superstitious inference, observing that the mode of the king's death was probably designed to mark the divine displeasure against his act of violence, as an insult offered to the cause of religion in general. On the same error are based the fictions of astrology. The fate of individuals and of nations has been thought to be bound up in the movements and conjunctions of the stars; and so simple an event as the appearance of a comet has ere now frightened Europe into penitence. Virgil, in his first Georgic, bids the farmer confide in those indications of the weather afforded by the aspect of the sun, since that luminary's obscuration gave faithful warning of the impending doom of Cæsar. On the same principle, the decline of the Roman power was early ascribed to the spread of Christianity. All our popular superstitions are to be similarly explained; those, for instance, which interpret as infallible preludes of death or discord, the chirping of an insect, the howling of a dog, or the spilling of a little salt.

Closely allied to the preceding fallacy is that which consists in the *assumption of a hypothetical cause*. At this stumbling-block we find the father of logic himself tripping. "All the heavenly bodies," says Aristotle, in his physics, "must move in circles, because a circle is the most perfect of all figures." The reason here assigned for a position, now known to be at variance with existing phenomena, is neither appreciable in itself nor applicable to the question. Des Cartes's hypothesis of animal spirits [illegible] Hartley's theory of vibrations, both framed to ex[illegible] transmission of sensible impressions from the [illegible] of the nerves to the brain, are both referable [illegible] source of error—the supposition, nam[illegible] en a *possible* cause has been assigned, the [illegible] been discovered.

What is [illegible] *tions, is frequently assumed to be true absolutely* [illegible] Deleterious drugs are always to be rejected; opium is a deleterious drug; therefore, opium is always to be rejected." It is plain, that a maxim which holds good, generally, of persons in health, is not applicable especially to cases of disease. This sophism appears, perhaps, more frequently in the interrogative than in the categorical form. The object of the disingenuous disputant, then, is to extort from his adversary an unconditional answer to a question so put as to require it to be qualified. When the query is advanced in a bold, triumphant tone, with its real complexity dexterously disguised, a timid and inexperienced debater will be easily silenced by this expedient. The question, for example, "Is war detestable, or is it not?" cannot be answered directly and unconditionally. If we choose the affirmative, we concede the criminality of even defensive war; if we prefer the negative, we are dealt with as the advocates of aggressive. We must explain and qualify, if we would avoid either horn of the dilemma, at the risk, indeed, of being accused by our opponent of a wish to shuffle and prevaricate, and perplex the discussion. To this head, most cases of defective parallel may conveniently be referred.

Again: *We may assume, as exhaustive of all the alternatives of a given case, what embraces only a portion of them.* Thus, in one of Lucian's Dialogues of the Dead, Menippus chooses to take for granted that the misery of Tantalus only arises from fear that he may *die* of thirst; and proceeds, accordingly, in sarcastic vein, to prove the apprehension groundless. "You say you are punished with thirst; but why is that dreadful to you? For I see no region besides this Hades, nor any second death in another quarter." Thus, too, the celebrated sophistical puzzle respecting motion. "Whatever body is in motion must move either in the place where it is, or in some place where it is not; neither of these alternatives is possible; therefore, there is no such thing as motion." Here it is assumed, that there is no such third alternative as is conveyed by the prepositions *from* and *to*, the others involving manifestly a contradiction in terms.

Next may be mentioned the error of assuming that what is true of a whole is true of a part. Critics, on this principle, have conceived themselves bound to vindicate, or puff into beauties, even the most flagrant

faults of standard writers; and have seldom struck the medium between unqualified censure and extravagant praise. How often are meritorious individuals subjected to the odium, attaching, perhaps justly, to the majority of a class to which they chance to belong! How often are salutary institutions and customs neglected or decried, just because they have a common origin with others that are noxious and blameworthy! To reverse the illustration: How often are particular periods characterized as enlightened and prosperous, simply from a partial survey of the aspect of affairs! Take the era of Elizabeth. "There was, perhaps, a learned and vigorous monarch, and there were Cecils and Walsinghams, and Shakspeare's and Spensers, and Sidneys and Raleighs, with many other powerful thinkers and actors, to render it the proudest age of our national glory. And we thoughtlessly admit on our imagination this splendid exhibition as in some measure involving or implying the *collective state of the people* in that age."* And how much pernicious error has, in like manner, resulted from admitting the impression that every wise man has been always wise, every great man always great, and every good man always good.

It may be assumed that a position must be false because of certain consequences supposed to follow from it. These consequences may not follow. The truth of Galileo's astronomical theory did not infer the falsehood of the Scriptures, but merely the falsehood of the received interpretation of them. Or they may follow, and the position still be tenable. To have alleged that Galileo's theory was inconsistent with the Ptolemaic system of the universe, would have been true, but nugatory.

The above is not offered as a complete list of all the cases which we think resolvable into the fallacy of assumption, but merely as an index to its more common varieties. An adroit sophist will sometimes, without recourse to any other disguise than that of well-feigned perplexity, palm upon us, wholly unsuspicious of deception, a statement which, but for this artifice, had been the first to be tested.

The fallacy of *irrelevant conclusions* appears in two shapes.

First, A position may be proved, *altogether different from that which ought to be established*, although the sophist designs it to be mistaken for the other. Thus, Horne Tooke, in the Diversions of Purley, would have us infer the falsity of our common notions respecting the first principles of morals, by showing that the terms *right, just, true*, only point, if their etymology be consulted, to what is *ordered, commanded, trowed.* But to prove this is by no means tantamount to proving that there are no such things as immutable morality and eternal truth. Byron is reported to have said that "he had met with so many whose conduct differed from the principles they professed, and who seemed to profess those principles either because they were paid to do so, or from some other motive which an intimate acquaintance with their character would enable one to detect—that altogether he had seen few, if any, whom he could rely upon as truly and conscientiously believing the Scriptures."† Was not this conclusion intended to be taken as equivalent to another—namely, that there *were* few persons in the world sincerely entertaining these convictions?

Secondly, The proof of *part* of a position may be substituted for proof of the *whole.* Thus, if an insufficient argument, accompanied by several valid ones, be detached from the rest, and refuted singly, the sophist may plausibly insinuate that he has done enough to destroy the entire body of evidence. Or, again, to prove that certain inconveniences attach to a particular system, or that certain defects adhere to a particular institution, may with many minds pass as equivalent to the position that the system should be abandoned and the institution abolished. Instances of such artifices must occur readily to every one.

RHETORIC.

Rhetoric, in the sense used by logicians, is the faculty of perceiving and employing what is best adapted to persuasion, and is therefore the adaptation of Logic to oratory. The object of the rhetorician is to *convince* and *persuade:* the former comprehends *instruction* and *conviction;* the latter *exhortation*, or the *influencing of the will.*

We confine ourselves to the following leading points in persuasive oratory.

Persuasion.

Persuasion, or influencing the will, depends on *proof* and *exhortation;* the former *proves* the expediency of the means proposed, and the latter *excites* men to adopt these means by representing the end as desirable. *Proof* is necessary, because the *judgment must be convinced;* and *exhortation* is also necessary, because the *feelings must be influenced.* To make one *believe*, it suffices to *convince;* but to make one *act*, it is necessary to show that the action will gratify some feeling in one's mind. It is, therefore, as necessary for the orator to *awaken those feelings* which will lead to action, as to satisfy the understanding that the conduct to which he would persuade will *tend to gratify the emotions* that are raised.

The Address to the Understanding.

The address to the understanding may be *direct*, because it is under the immediate control of the will; but the address to the *feelings* must be *indirect*, because they are not under the same control. The emotion of anger or gratitude is not to be raised in the mind by *thinking about it*, but by filling the mind with such thoughts as are calculated to produce a change in the feelings. We can produce a change in the circulation of the blood by *taking a medicine that will affect it;* but we cannot produce a change in it by merely *willing.*

Some speakers fail to persuade by only showing the audience how they ought to feel, and telling them that they ought to feel. They speak only to the *reason* of their hearers. Some speakers fail to persuade by *only proving;* others by *only exhorting.*

Improper Motives.—Refutation.

Some orators excite improper motives, because they strive to excite certain emotions when circumstances do not require them. There is not unfrequently a want of skill shown in attempting to allay an improper feeling that has been excited in the audience. An improper feeling is to be allayed by exciting an opposite one. If hatred is to be allayed, then the audience must be led to dwell upon a subject which kindles benevolence.

A string of vague abuse has often the effect of a train of sound reasoning, because the *excited feelings* of the hearers blind their judgment, and cause them to lose sight of the conclusion to be proved.

In arguing, a respondent should begin by refuting the objections of his opponent, when the audience has received them favourably.

When the objections to be refuted are *ridiculous, indirect* or *ironical* refutation should be employed.

Onus Probandi, or Burden of Proof.

The *burden of proof* rests with him who would dispute any point in favour of which there is a presumption. The burden of proof rests now with him who would disprove the principle of gravitation or any other generally allowed truth.

Treating a Proposition.

Propositions may generally be treated in *four* parts

* Foster's Essay on Popular Ignorance.
† Moore's Byron, vol. vi.

the Exordium or Introduction; the Narration or Exposition; the Division; the Conclusion.

In the Introduction, such topics are to be introduced as tend to render the hearers attentive and docile, and to raise the hope of something interesting.

The Narration is an explicit declaration of the subject of discourse, and ought to terminate in the proposition to be explained

The Division ought to exhaust the subject, and not comprehend any thing besides. See Division.

In the Conclusion it is generally proper to begin with a brief recapitulation of the articles discussed, and to end with an address to the affections.

Some writers treat a proposition as follows:—1. The Introduction. 2. They explain the terms of the proposition, show what is granted and what disputed on each side, and then state the point of controversy. 3. They examine objections, and establish their own proposition. 4. They refute objections, and expose fallacies. 5. They make some observations naturally suggested by the subject.

Example.—Enthusiasm is a species of madness.

1. This is a term which is seldom understood by those who use it most frequently. It may, therefore, be useful to show what enthusiasm is.

2. Some derive it from *en thusia* (Greek), *in sacrifice*, because many of the enthusiasts of old were affected in a violent manner during the time of sacrifice. At this day different persons understand it in different senses, quite inconsistent with each other. It is here used to express a sort of madness arising from some falsely imagined divine influence.

3. There are various kinds of enthusiasm. Some enthusiasts imagine that they have gifts which they do not possess; some think to obtain the end without using the means; others think that some things are owing to divine interposition, which really are not.

4. It is a kind of madness to suppose that we have the gifts which we do not possess; for our premises are false, though our reasoning may be conclusive. Some men are misled by pride and a warm imagination to ascribe to the Deity certain impulses which are altogether unworthy of him. The man who imagines himself the peculiar favourite of Heaven, is fortifying himself against the advice of man and the grace of God.

5. Let us beware that we do not run with the common herd of enthusiasts, fancying that we are Christians when we are not; hoping to gain the end without using the means. Let us make use of every means which are conducive to our intellectual and moral improvement, and then we may expect a daily growth in that holy religion, which never can truly be termed enthusiasm.

CONCLUDING OBSERVATIONS.

The preceding definitions of the modes of reasoning, and their application to persuasive oratory, may be of use in directing the comparatively unlearned how to detect fallacies in the arguments of opponents, and what methods may be best employed to sift and arrive at the truth. We should, however, fail in our duty, if we did not add, that, without the habit of clearly arranging our ideas, and acquiring the power of grasping a subject both in its details and general features, the mere instrumental part of logic will not be of essential service in reasoning. An observation of the following rules is recommended by Watt, as serviceable in these respects:—

"I. Rule.—Accustom yourselves to clear and distinct ideas, to evident propositions, to strong and convincing arguments. Converse much with those friends, and those books, and those parts of learning, where you meet with the greatest clearness of thought and force of reasoning. The mathematical sciences, and particularly arithmetic, geometry, and mechanics, abound with these advantages: and if there were nothing valuable in them for the uses of human life, yet the very speculative parts of this sort of learning are well worth our study; for by perpetual examples they teach us to conceive with clearness, to connect our ideas and propositions in train of dependence, to reason with strength and demonstration, and to distinguish between truth and falsehood. Something of these sciences should be studied by every man who pretends to learning, and that (as Mr. Locke expresses it) not so much to make us mathematicians, as to make us reasonable creatures.

We should gain such a familiarity with evidence of perception and force of reasoning, and get such a habit of discerning clear truth, that the mind may be soon offended with obscurity and confusion: then we shall (as it were) naturally and with ease restrain our minds from rash judgment, before we attain just evidence of the proposition which is offered to us; and we shall with the same ease, and (as it were) naturally, seize and embrace every truth that is proposed with just evidence.

This habit of conceiving clearly, of judging justly, and of reasoning well, is not to be attained merely by the happiness of constitution, the brightness of genius, the best natural parts, or the best collection of logical precepts. It is custom and practice that must form and establish this habit. We must apply ourselves to it till we perform all this readily, and without reflecting on rules. A coherent thinker or a strict reasoner is not to be made at once by a set of rules, any more than a good painter or musician may be formed extempore by an excellent lecture on music or painting. It is of infinite importance, therefore, in our younger years, to be taught both the value and the practice of conceiving clearly and reasoning right; for when we are grown to the middle of life, or past it, it is no wonder that we should not learn good reasoning, any more than an ignorant clown should not be able to learn fine language, dancing, or a courtly behaviour, when his rustic airs have grown up with him till the age of forty.

For want of this care, some persons of rank and education dwell all their days among obscure ideas; they conceive and judge always in confusion, they take weak arguments for demonstration, they are led away with the disguises and shadows of truth. Now, if such persons happen to have a bright imagination, a volubility of speech, and a copiousness of language, they not only impose many errors upon their own understandings, but they stamp the image of their own mistakes upon their neighbours also, and spread their errors abroad.

It is a matter of just lamentation and pity to consider the weakness of the common multitude of mankind in this respect, how they receive any thing into their assent upon the most trifling grounds. True reasoning hath very little share in forming their opinions. They resist the most convincing arguments by an obstinate adherence to their prejudices, and believe the most improbable things with the greatest assurance. They talk of the abstrusest mysteries, and determine upon them with the utmost confidence, and without just evidence either from reason or revelation. A confused heap of dark and inconsistent ideas makes up a good part of their knowledge in matters of philosophy as well as religion, having never been taught the use and value of clear and just reasoning.

Yet it must be still confessed that there are some mysteries in religion, both natural and revealed, as well as some abstruse points in philosophy, wherein the wise as well as the unwise must be content with obscure ideas. There are several things, especially relating to the invisible world, which are unsearchable in our present state, and therefore we must believe what revelation plainly dictates, though the ideas may be obscure. Reason itself demands this of us; but we should seek for the brightest evidence both of ideas and of the connection of them, wheresoever it is attainable.

II. Rule.—Enlarge your general acquaintance with things daily, in order to attain a rich furniture of topics, or middle terms, whereby those propositions which occur may be either proved or disproved; but especially meditate and inquire with great diligence and exactness into the nature, properties, circumstances, and relations of the particular subject about which you judge or argue. Consider its causes, effects, consequences, adjuncts, opposites, signs, &c., so far as is needful to your present purpose. You should survey the question round about, and on all sides, and extend your views, as far as possible, to every thing that has a connection with it. This practice has many advantages in it, as—

1. It will be a means to suggest to your mind proper topics for argument about any proposition that relates to the same subject.

2. It will enable you, with greater readiness and justness of thought, to give an answer to any sudden question upon that subject, whether it arise in your own mind or be proposed by others.

3. This will instruct you to give a plainer and speedier solution of any difficulties that may attend the theme of your discourse, and to refute the objections of those who have espoused a contrary opinion.

4. By such a large survey of the whole subject in all its properties and relations, you will be better secured from inconsistencies, that is, from asserting or denying any thing in one place which contradicts what you have asserted or denied in another; and to attain these ends, an extensiveness of understanding and a large memory are of an unspeakable service.

One would be ready to wonder sometimes how easily great and wise and learned men are led into assertions in some parts of the same treatise, which are found to be scarce consistent with what they have asserted in other places; but the true reason is the narrowness of the mind of man, that it cannot take in all the innumerable properties and relations of one subject with a single view; and therefore, whilst they are intent on one particular part of their theme, they bend all their force of thought to prove or disprove some proposition that relates to that part, without a sufficient attention to the consequences which may flow from it, and which may unhappily affect another part of the same subject; and by this means they are sometimes led to say things which are inconsistent. In such a case, the great dealers in dispute and controversy take pleasure to cast nonsense and self-contradiction on their antagonist, with huge and hateful reproaches. For my part, I rather choose to pity human nature, whose necessary narrowness of understanding exposes us all to some degrees of this frailty. But the most extensive survey possible of our whole subject is the best remedy against it. It is our judging and arguing upon a partial view of things that exposes us to mistakes, and pushes us into absurdities, or at least to the very borders of them.

III. Rule.—In searching the knowledge of things, always keep the precise point of the present question in your eye. Take heed that you add nothing to it while you are arguing, nor omit any part of it. Watch carefully lest any new ideas slide in, to mingle themselves either with the subject or predicate. See that the question is not altered by the ambiguity of any word taken in different senses, nor let any secret prejudices of your own, or the sophistical arts of others, cheat your understanding by changing the question, or shuffling in any thing else in its room.

And for this end it is useful to keep the precise matter of inquiry as simple as may be, and disengaged from a complication of ideas which do not necessarily belong to it. By admitting a complication of ideas, and taking too many things at once into one question, the mind is sometimes dazzled and bewildered, and the truth is lost in such a variety and confusion of ideas; whereas, by limiting and narrowing the question, you take a fuller survey of the whole of it.

By keeping the single point of inquiry in our constant view, we shall be secured from sudden, rash, and impertinent responses and determinations, which some have obtruded instead of solutions and solid answers, before they perfectly know the questions.

IV. Rule.—When you have exactly considered the precise points of inquiry, or what is unknown in the question, then consider what and how much you know already of this question, or of the ideas and terms of which it is composed. It is by a comparison of the known and unknown parts of the question together, that you may find what reference the part known hath unto, or what connection it hath with, the thing that is sought; those ideas whereby the known and unknown parts of the question are connected, will furnish you with middle terms or arguments whereby the thing proposed may be proved or disproved.

In this part of your work, namely, comparing ideas together, take due time, and be not too hasty to come to a determination, especially in points of importance. Some men, when they see a little agreement or disagreement between ideas, presume a great deal, and so jump into the conclusion. This is a short way to fancy, opinion, and conceit; but a most unsafe and uncertain way to true knowledge and wisdom.

V. Rule.—In choosing your middle terms or arguments to prove any question, always take such topics as are surest and least fallible, and which carry the greatest evidence and strength with them. Be not so solicitous about the number as the weight of your arguments, especially in proving any proposition which admits of natural certainty or of complete demonstration. Many times we do injury to a cause by dwelling upon trifling arguments. We amuse our hearers with uncertainties, by multiplying the number of feeble reasonings, before we mention those which are more substantial, conclusive, and convincing. And too often we yield up our own assent to mere probable arguments, where certain proofs may be obtained.

VI. Rule.—Prove your conclusion (as far as possible) by some propositions that are in themselves more plain, evident, and certain, than the conclusion; or at least such as are more known and more intelligible to the person whom you would convince. If we neglect this rule, we shall endeavour to enlighten that which is obscure by something equally or more obscure, and to confirm that which is doubtful by something equally or more uncertain. Common sense dictates to all men, that it is impossible to establish any truth, and to convince others of it, but by something that is better known to them than that truth is.

VII. Rule.—Labour, in all your arguings, to enlighten the understanding, as well as to conquer and captivate the judgment. Argue in such a manner as may give a natural, distinct, and solid knowledge of things to your hearers, as well as to force their assent by a mere proof of the question. Now, to attain this end, the chief topic or medium of your demonstration should be fetched, as much as possible, from the nature of the thing to be proved, or from those things which are most naturally connected with it.

VIII. Rule.—Though arguments should give light to the subject, as well as constrain the assent, yet you must learn to distinguish well between an explication and an argument; and neither impose upon yourselves, nor suffer yourselves to be imposed upon by others, by mistaking a mere illustration for a convincing reason.

Axioms themselves, or self-evident propositions, may want an explication or illustration, though they are not to be proved by reasoning.

Similitudes and allusions have oftentimes a very happy influence to explain some difficult truth, and to render the idea of it familiar and easy. Where the resemblance is just and accurate, the influence of a simile may pro used so far as to show the possibility of the thing in question; but similitudes must not be taken as a solid proof of the truth or existence of those things to which they have a resemblance. A too great deference paid to similitudes, and an utter rejection of them, seem to be two extremes, and ought to be avoided. Locke, even in his inquiries after truth, makes great use of similes for illustration, and is very happy in the invention of them, though he warns us lest we mistake them for conclusive arguments.

Yet let it be noted here, that a parable or a similitude used by any author, may give a sufficient proof of the true sense and meaning of that author, provided that we draw not this similitude beyond the scope and design for which it was brought; as when our Saviour affirms, Rev. iii. 3, 'I will come to thee as a thief:' this will plainly prove that he describes the unexpectedness of his appearance, though it will by no means be drawn to signify any injustice in his design.

IX. Rule.—In your whole course of reasoning, keep your mind sincerely intent on the pursuit of truth, and follow solid argument wheresoever it leads you. Let not a party spirit, nor any passion or prejudice whatsoever, stop or avert the current of your reasoning in quest of true knowledge.

When you are inquiring, therefore, into any subject, maintain a due regard to the arguments and objections on both sides of a question: consider, compare, and balance them well before you determine for one side. It is a frequent but a very faulty practice, to hunt after arguments only to make good one side of a question, and entirely to neglect and refuse those which favour the other side. If we have not given a due weight to arguments on both sides, we do but wilfully misguide our judgment, and abuse our reason, by forbidding its search after truth. When we espouse opinions by a secret bias on the mind through the influences of fear, hope, honour, credit, interest, or any other prejudice, and then seek arguments only to support those opinions, we have neither done our duty to God nor to ourselves; and it is a matter of mere chance if we stumble upon truth in our ways to ease and preferment. The power of reasoning was given us by our Maker for this very end, to pursue truth; and we abuse one of his richest gifts, if we basely yield it up to be led astray by any of the meaner powers of nature, or the perishing interests of this life."

[WORKS ON LOGIC.]

Within a few years many works have appeared, purporting to treat of the powers and of the operations of the mind, though few of them attempt to present a system of Logic fit for those who would study it as a science, unincumbered with scholastic subtleties and useless distinctions. Most of the treatises which, until of late years, were in common use, had been formed on the mode of ancient systems, and contained of useful information little more than a description of the syllogism and a few general principles of demonstrative reasoning. Collard and Condillac simplified and improved the science of Logic, and all the subjects which properly fall within its precincts were amply discussed by Doctor Richard Kirwan, in "An Essay on the Elements, Principles, and different Modes of Reasoning." Prolixity and a fondness for detail, however, obscure the merits of this author. We may speak in high terms of the concise and admirable work of Dr. Hedge, of Harvard University, whose Elements of Logic is perhaps better than any other fitted for general use. Another valuable work, bearing the same title, has been issued by Dr. Whately, archbishop of Dublin: it is more comprehensive than that of Dr. Hedge, and may be confidently recommended to those desirous of acquiring an accurate knowledge of the principles of this important science.

The student should not confine himself to either of the above works however, but should read in connection and with reference to them, Locke's Essays on the Understanding, Reid's Essays on the Intellectual Powers, Stewart's Elements of the Philosophy of the Mind, Upham's Mental Philosophy, Campbell's Philosophy of Rhetoric, Gambier's Introduction to Moral Evidence, Beattie's Essay on Truth, Scott's Elements of Intellectual Philosophy, and the works on the subject by Watt & Kirwan.—*Am. Ed.*]

EDUCATION.

Till within the last few years, the idea commonly entertained with respect to general elementary education comprehended only certain branches of instruction familiarly known by the terms, *reading, writing, and arithmetic.* A "liberal" education added ancient and modern languages and mathematics. Such formed the entire round of accomplishments which were supposed, with the accident-directed moral training of the domestic circle, to be sufficient to fit the youth, of even the highest classes, for entering upon the varied duties of life. Nor was this scanty education thought requisite for all. A vast class was allowed to exist without the least tincture of school learning of any kind, as not being supposed to require any knowledge beyond that which immediately fitted them for the laborious duties by which they earned their bread.

The active period which has elapsed since the conclusion of the last war (1815), has been distinguished by nothing more than by the enlargement of our ordinary ideas with respect to education. It may be said to be now universally acknowledged that all—all, from the peer to the peasant—ought to be educated, however there may still be differences of opinion as to the *means* of educating, and what education should *consist of.* It is also generally admitted that *reading, writing, and arithmetic*, even when effectually taught, constitute but a branch of education, being merely instrumentary accomplishments, the acquirement and cultivation of which tend in a certain degree to improve the intellect. The study of the ancient classical languages, while still admitted by candid persons to be also a means of improving the intellect, is now no longer upheld, excepting by a few, as the grand instrument of liberal education, the character in which it was generally regarded a few years ago. It is now seen that this study gives to the youth of the middle and upper classes but a portion, and, in many instances, the least requisite portion, of what they should know on entering the world. The old elements of education may therefore be said to have sunk from their former character of all-sufficiency, and to have now taken their place as only parts of a complete education.

PRINCIPLES OF EDUCATION.

The primary meaning of the term *educate*, from the Latin *educare*, to lead or bring out, does not ill express the first great principle of the science. It may be held to assume that the human being is naturally in a comparatively rude and inert condition, and that external forces must be applied to draw forth his faculties into their full activity and power, and bring them to their highest degree of refinement and nicety of application. This is, in reality, a large part of the business of education, taking even the widest view of its purposes. A full definition would further include the regulation and discipline of those moral feelings on which our actions are mainly dependent, and also the communication of such parts of knowledge as the circumstances and prospects of individuals may render necessary.

Before correct views can be entertained with regard to education, or proper steps can be taken for working it out in practice, it is obvious that a distinct notion ought to be attained as to the character of the being to be educated. Man is this being; but the question "what is man?" is one to which science does not yet enable us to give an answer which all would acknowledge as right. For this reason it is totally impossible for any writer to present a theory of education which would be generally received as a perfect science. The subject must needs partake of the obscurity and uncertainty which as yet rest upon at least the mental character of man; and it will only advance in clearness and precision, in proportion as progress is made in a correct system of mental philosophy.

While fully acknowledging the difficulty under which every candid writer on education must lie, the present would humbly endeavour to make the nearest approach to a correct system which his views of the natural character of the human being will admit of. He considers the race as exhibiting a definite mental constitution, in all its parts harmonizing with the surrounding universe. He considers this constitution as embracing a variety of faculties, for sensation and action, which it is the business of the educator to awaken, strengthen, and regulate, so that each person may arrive at the best condition of which his character is susceptible, and most thoroughly fulfil the design of his being in all its various respects. He views, in the first place, the faculties of the physical frame as requiring to be duly exercised, so as to bring them to the utmost limit of their native power and health. Of the mental system, he views those faculties which constitute the intellectual powers as requiring to be drawn out, exercised, and instructed, so that they may operate readily and efficiently for all the various purposes which they are designed to serve; and those, again, which constitute the moral feelings as calling for the exertion upon them of all external moral influences—at the head of which stands the revealed will of God with regard to human destiny—in order that the best possible state of feeling may be attained with regard both to the affairs of the present and to a future state of existence. Upon these views of man's character a scheme of education may be founded, which rational persons, as yet unprepossessed by other notions, will, he thinks, generally acknowledge as accordant with common sense, however unprepared they may be to trace it to its foundation. He will, therefore, without further preface, proceed to describe such a scheme, adopting the appropriate divisions into *physical, moral,* and *intellectual*, and combining, as far as his space permits, practical directions with what may be called the philosophy of the subject.

PHYSICAL EDUCATION.

The object of physical education is to ensure, as far as possible, that sound and vigorous frame of body which, while all must feel it to be one of the greatest of blessings, appears to be an essential concomitant of a sound condition of the mind itself. Physical education comes into operation before any other department, for one of its first concerns is to take care that the human being shall be brought into the world in the enjoyment of a perfect organization. The mother is here the educator. She is required, during pregnancy, to order her life, with respect to food, dress, and all other habits, according to certain rules, found to be conducive to the welfare of her future offspring. Judicious medical men recommend, that, at this time, the food taken should not greatly differ from what is taken at other times. The dress should be loose and easy. Moderate exercise should be regularly, as far as possible, indulged in; and it is of the greatest consequence of all, that, while ordinary duties are attended to, a quiet, cheerful, and easy state of mind should be maintained. Departure from these rules, indulgence in late or otherwise irregular hours, and exposure to the excitements produced by violent passions, or the frivolities of fashionable life, are calculated to occasion deplorable effects on the being yet to be brought into the world.

Infancy.—The physical education of an infant involves simply the means of keeping it in health. For this purpose nature has made one signal provision, in the tenderness which she has infused into the female heart—a feeling which insures an unfailing kindness towards the young. But something besides kindness is required to rear children successfully. It is necessary that those who have the duty of nursing the young, whether mothers or substitutes for mothers, should have some knowledge of the physiology of the infant body, or at least be acquainted with the rules of management which result from such a knowledge. The sad effects of ignorance on this subject are sufficiently conspicuous, for we cannot doubt that, of the great mortality of the young (four-tenths of them dying under five years of age), much is owing to erroneous methods pursued in the nursery.

Here the leading rules only can be indicated. An infant should never be plunged into cold water, or exposed in any other way to cold, because, the circulation being comparatively languid in the infant subject, he can less endure cold than grown-up persons; and an attempt to produce hardiness may only undermine health. It is of the greatest consequence that an infant should be kept constantly clean and dry, that its hours be early and regular, and itself be as far as possible habituated to a periodic recurrence of all its wants. The mother's milk is the most appropriate food; next, that of a nurse about the same time confined; next, cow's milk warmed and diluted. Farinaceous or any other kind of solid food, is unsuitable to the stomach of an infant under six months old. A child ought, if possible, to be nursed about eight months, and somewhat longer if weakly, or when the period of eight months terminates in the dead of winter. After weaning, the food should be farinaceous—that is, of substances composed of grain, potatoes, arrow-root, &c. Animal food should be avoided till the period of infancy may be considered as nearly at an end, and even then it should be of the tenderest fibre, and administered in very simple forms and moderate quantities.

The food and general habits of the nurse are of great and direct importance. The child is immediately dependent in all respects upon the person who suckles it; thrives with that person, and also declines with her; suffers when she suffers, and is well when she is well. So remarkably is this the case, that an act so simple on her part as the taking of a hasty draught of cold water, will probably give the infant a stomach-ache within two hours. It is therefore of the greatest consequence to the welfare of the young that those from whom they draw their sustenance should observe all the rules proper to their condition. A nurse should live a quiet but not inactive life, using simple wholesome diet, avoiding stimulating drinks, and preserving, as far as possible, a cheerful mind. Fermented liquors, as porter and ale, are only to be resorted to when her strength would otherwise sink under exhaustion of her system. In fair health, a light beer is perhaps the most suitable beverage.

For the due development of the muscular system of an infant, its dress should sit light and easy upon its person and its limbs should be allowed free play on all possible occasions. The restless movements of an infant, the tossing about of its head, arms, and limbs, are to be considered as merely impulses of nature, directing it to exercise, and consequently strengthen, its muscular system. These movements should therefore be rather encouraged than repressed. Care should be taken that it is not too soon allowed to bear its own weight, as the natural consequence is bending the as yet soft bones of the legs, which may thus become deformed for life. Whenever a child of proper age is unable to bear its own weight, or walk without this effect following, we may be sure that its general health is defective: and it is a more immediate and pressing duty to take measures for remedying this defect, than to attempt to keep the limbs straight by mechanical appliances.

The general health of an infant may be described, in a word, as to be secured (supposing a good constitution at first) by food appropriate to its organs, warmth, cleanliness, regularity in sleep and other wants, a well-aired nursery, and occasional walks out of doors, protection from all injuries through the medium of the nurse and otherwise, and the muscular exercise of which its system is capable.(1)*

Childhood, Youth, and Manhood.—Physical education ought to be continued till the body is brought to the utmost degree of perfection, in all its functions, of which it is capable. The improvement of all the systems and functions of the body may be called the *education* of these systems and functions; hence recent writers on the subject speak of the education of the skin, the education of the lungs, of the digestive organs, of the muscular frame, of the brain.

In a subsequent article of this work, that on the Preservation of Health, most of the matters which fall under Physical Education are carefully treated. By reverting to that paper, the reader will find of how much importance must be the formation of habits of bodily cleanliness, seeing that the skin is a system which only can have a healthy function when it is thoroughly free from impurities, and that nothing is more indispensable for general soundness than the particular health of this part of our frame. In the same paper, the value of a due supply of pure air for the health of the respiratory organs is insisted on; as also the proper regulation of the appetite for food. The education of the muscular system implies a competent knowledge of the structure, attachment, and conditions of action, of the muscles; the operation of arterial blood and nervous influence on the muscles, and other matters, for which we refer to our article entitled Account of the Human Body.

Under this branch of physical education falls all the science of exercise—walking, riding, running, leaping, swinging, skating, dancing, fencing, cricket, ball-play, &c. The importance of these to health, in the full development of the muscles and improvement of the frame, has long been known, and by some nations steadily practised. The perfect forms of the Greeks and Persians were the result of this branch of education receiving a large share of national attention. Ample provision for such exercises should be made in all seminaries of education, infant and more advanced. What are strictly called gymnastics, are more violent and trying than any we have mentioned, consisting of climbing poles, leaping bars, swinging by the hands, and maintaining difficult positions. These require much caution in the watchful educator, and should not be allowed in slender and weakly boys. They ought not to be overdone by any youth whatever, seeing that, even in the robust, strains and ruptures have been occasioned by them.

MORAL EDUCATION.

The training of our moral nature for the due performance of our part as members of society, is that branch of education which the great majority of those who have reflected on the subject consider as by far the most important. It is a great mistake to suppose that this is a

* The numbers introduced in this manner refer to volumes of *Chambers's Educational Course*, according to a list (as far as published) given at the close of the section "Intellectual Education." It will be understood that the volume referred to either treats that department of the theory and practice of education fully, or is a school book in which the subject is embodied.

branch which the advocates of improvements in education have generally overlooked. As far as we have observed, all but a small sect of this class of philanthropists acknowledge its paramountcy. This is the part of education which, in a national system, would call for the most attention, because, while degrees of intellectual attainment are proper for different classes of men, there is no class of whom it can be said, that a *right and perfect moral development* is not of the utmost consequence both to themselves and the society of which they form a part. Besides such a benefit, that of an acquaintance with the mere elements of literature sinks into insignificance. There is no need, however, to exalt any department of education at the expense of another. It may be true, that intellectual development is not expressly moral development; but it must be clear to every candid person, that the refinement and expansion of mind obtained from intellectual culture, are favourable to the moral nature. A thinking man is not on that account likely to be the less a virtuous man; else, much of our common observations of life must be a delusion. We would therefore say, let no department of education be considered as calling for exclusive or disproportionate cultivation; but let all go on in harmony together.

Moral education can have no definition from us but the development and regimen of the moral nature of those who are to be educated. Of the perplexity which attends this part of our being, it is unnecessary to speak. Let us only see if we can settle upon any principles by which it may be beneficially affected. It appears to include a variety of native feelings, of various strength and tendency to activity in every different person, yet all of them liable to be acted upon by appropriate external means, to good as well as to evil. In a mind totally untrained, the good dispositions are not without some energy; but, generally, where there is a want of regulation of the feelings, and of certain principles to which the character of emotions and actions may be referred as to a standard, the moral being is a scene of deplorable confusion—the more so, of course, in instances where there is a considerable natural endowment of the inferior feelings. We have then the coarse, sensual, and selfish conduct which has been the mark of the rude throughout all ages. On the other hand, we cannot doubt that many natures, not originally of a high cast, thrown under influences which tended to check the less worthy tendencies, to strengthen the good, and to induce regularity over all, must have been thereby enabled to pass through life in a creditable manner, if not with some higher result less open to observation.

One principle thus strikes us at the outset as of very great consequence, namely, the circumstances, or, so to speak, the moral atmosphere, in which the being to be educated is placed. It is but matter of every-day observation, that a child reared amidst gross scenes, where no restraint is imposed upon any of the feelings by those around him, will prove, in all likelihood, a very different being from one brought up amidst virtuous and gentle people. Such a difference, we cannot doubt, would exist even where no attempt had been made by the latter parties to fashion the moral character of the young creature committed to their charge. It is exactly a difference of this nature which exists between the youths native to the vale of the Missouri (or those of the not less savage classes which social circumstances produce in most great cities) and those of civilized countries in general: circumstances decide the one set to be barbarians, and the other to be tolerably well-behaved persons. This *education of circumstances*, though so powerful, is unfortunately not always within the command of well-meaning parents. Individuals are here generally able to do little of themselves, if the persons by whom they are necessarily surrounded be not of the character that is desirable. Thus, it often happens that a poor though well-disposed man is obliged to live in a part of a city where his children can only breathe moral contamination; and we can scarcely imagine a greater hardship. Yet these are just reasons why every effort should be made to promote a universal improvement of society; and it must rarely happen that some arrangements cannot be made, of a character likely to operate favourably on the young persons who are the objects of care.

We would here impress the importance of removing *temptation* as much as possible out of the way of young persons. There is a notion amongst some, that a little temptation is not amiss, as a means of training the young to withstand greater assaults. But this is, we are convinced, an ill-founded doctrine, and most fatal policy. It is of the nature of every one of our feelings to be awakened into activity by the presentation of its appropriate object; and it is the equally natural result, that the frequent activity promotes the power and the tendency to activity of those feelings. By presenting, then, what are called temptations, we are taking a direct means of educating and strengthening the inclinations towards error. On the contrary, a feeling, allowed to lie dormant, loses in power, and becomes always less and less liable to act. There is perhaps a confusion of ideas at the bottom of the objectionable theory. The true plan seems to be to remove all actual temptation, but to give the intellect and the moral feelings proper warning against all such dangers, and thus prepare them for resistance when the time of unavoidable trial arrives. We would say, then, do not allow the young to see or touch evil things, or even to be in company where such things are to be spoken lightly of, from an idea that they are thus to be hardened against temptation. Be content to inspire a salutary horror of such things by your own report, if you only are so fortunate as to be able to keep your young charge exempt from positive contact with what is discommendable. An error may of course be committed in speaking too strongly against what you disapprove of, in which case, the young person no sooner discovers the exaggeration, than, from a principle of contradiction, he is inclined to embrace the vice. But discretion will save from this mistake. Upon the whole, it may be set down as a most important rule in education, to reduce temptation to the smallest possible bounds.

Nearly connected with the education of circumstances is the *education of example*. Here personal conduct in the educating party is all in all. Children are remarkably disposed to imitation. They imitate instinctively, without having necessarily any discrimination of the character of the act which they are imitating. The general nature of their conduct is therefore ruled very much by the nature of the conduct presented to their observation. So much is this the case, that, if a child be carefully watched, he will be observed to contract a tendency to scolding and beating, from that very discipline by which, most erroneously, an endeavour is made to correct his errors. It must obviously, then, be of the greatest importance that the demeanour and general actions of the educator, and of the family in which a child is reared, should be models of all that is proper. Just the more amiable and correct in all respects that this conduct is, so will the young be the more likely to form those habits which their best friends could wish. We will not pause to consider the effect which a positively vicious course of life is calculated to have on such of the young as witness it. The kind of bad example which we have here a chance of helping to abolish, is that which shows itself in acts far within the circle of positive vice. Such are the use of offensive and uncivil language, wranglings, domineering, low and sordid habits of all kinds. If parents and the other grown-up members of a family do not restrain themselves from all such acts in the presence of children, there cannot be a doubt that the children will likewise be addicted to them. It may be a somewhat startling doctrine, but we nevertheless declare our full conviction that there is not the least need for ever using, in the presence of or towards children, any language which might not be addressed by a well-bred person to a perfect equal. All ordering, dragooning, scolding, and, much more, all violence, exerted for the purpose of managing or punishing a child, are unmitigated errors and evils. A child has feelings to be wounded and roused up into contradiction by harsh usage, as well as any grown-up person; and it is well known that such means are not serviceable for gaining any end with our fellow-creatures. A civil request, if reasonable, will succeed with a child as with a man. Gentle and respectful language gain as much upon an uncorrupted child's nature as upon a man's. Such treatment can have no chance of *spoiling* a young person: it will only promote his being made a rational, well-bred being, instead of a wrangler or tyrant.

The *preceptive part* of moral education, though the lowest in power, is not to be overlooked. A good maxim or a sound advice, well-timed, and made thoroughly intelligible and thoroughly acceptable, will rarely fail to have a good effect. Even supposing it to be little regarded at the time, it may remain in the memory, and come into play on some future occasion, when perhaps more necessary than now. In such moral seeds, there is a vitality like that of the seeds of plants, which may have been buried too deep for germination for thousands of years, and yet, when placed in the proper circumstances, visited by sap and heat, will send up as goodly specimens of their kind as if they had been shed from a parent stem of last year's growth. It will therefore be proper, from time to time, to inculcate moral lessons, appropriate to the capacity of the child. This may be done directly, by giving good maxims to be learned by heart; but it will be done better by means of narratives showing the virtues in action. This is because a child much more readily apprehends a series of incidents than an abstract truth. It will also be well to allow the simple narration, in the first place, to be received into his mind, and then to allow himself, if possible, to make out the moral. Call his own moral feelings, as far as may be, into judgment upon the case, and only tell him whether he is right or wrong, till he fully comprehends it in all its bearings. Thus his own good feelings, as well as his judgment, are brought into exercise, and thus a far deeper impression is made than if the whole case, including the moral, were merely related to him.(8)* It is a duty of preceptive education to warn against and check evil, as well as to inculcate good. When any thing wrong is done, we but imperfectly correct it by saying, "Don't do that," or inflicting censure or punishment. It is necessary that we should convince the understanding and move the feelings of the child to a sense of the impropriety of his conduct. This may be done by mild argument and illustration, calling upon himself ultimately to say whether such conduct is commendable or not, and whether it ought to be repeated or avoided. He thus becomes judge upon his own case, and is forced to condemn himself, where, if condemned by others, his opposive feelings might have only presented resistance and defiance. At some schools, including those for infants, it has been found possible to impress such lessons by means of a kind of trial, the school-fellows being the jury. The case is stated to the assembled children: they are asked to say if such conduct is right or wrong. They invariably give a sound decision, and the effect is most powerful. Obdurate natures, to which a reprimand from master or parent would at the moment be as nothing or worse, are found unable to resist the force of the *public opinion of their own society*—as is every day found to be the case with grown-up people, such being, in fact, a law of human nature.

Circumstances, example, precept, are all inferior in effect to *Training*, which is more particularly the novel feature of modern education. This principle may be said to have its natural basis in the law of habit. It is indicated in the text, "Train up a child in the way he should go, and when he is old he will not depart from it;" and in the maxim, "Just as the twig is bent, the tree is inclined." We are so constituted, that, when accustomed to do any thing, we do it almost without the governance of our will or judgment. We do it easily, and generally well. If accustomed, for instance, to a particular class of intellectual operations, we acquire a facility in going through them, which generally strikes others with wonder. If accustomed to the exercise of a particular class of feelings, be they good or bad, they in time awake in us unprompted, and we become their almost passive instruments. To habituate the feelings to the exercise and regulation which is productive of the best results, is moral training.

The feelings are of very various character. Proceeding upon Dr. Gall's description of them, which seems to us to be the best, we find the first class described as selfish, yet necessary for the preservation of the individual and the species; others directed to objects apart from self, yet as liable also to misdirection and abuse. It is altogether a strangely mingled web, yet not without a certain definiteness of constitutional arrangement and of purpose. Here it may be at once admitted, as a fact not less clear from philosophical inquiry than from revelation, that perfection in the complicated operations of our moral nature is not to be looked for. But it is equally certain that there are influences which may act advantageously in regulating, directing, and harmonizing these operations.

The selfish or lower feelings are the first in the individual to call for attention, and they may therefore be first treated in this place. That early developed instinct which regards food, is so liable to be over-indulged by a mistaken kindness, that we feel particularly called upon to give a warning with regard to it. The unavoidable effect of such over-indulgence is to produce pampering and fastidious habits, equally degrading to the moral as they are dangerous to the physical system. The food of the young should never be otherwise than simple, if we were merely to regard their health; still more should it be so, if we would preserve in them manly and hardy habits. On the rare occasions when a little treat is afforded, care should of course be taken that it is of a nature in all respects harmless. Comfits should be few and far between, if ever given at all; and rewards and punishments should never have reference to edible things. As to liquor of any kind, such as men are themselves but too much accustomed to indulge in, certainly one drop should never enter the lips of a young person on any pretext whatever. There are few sights more distressing to a reflecting mind, than that of parents handing the so fatal wine-cup to their children. The quantity of food given to the young should never be stinted from penurious or ascetic motives; but it is very certain that great errors are committed in giving too much and too frequently. Eating is altogether much a matter of habit, and that with regard to quantity as well as quality. The amount actually required for the efficient support of the system is, under natural circumstances, not great: it is generally much exceeded. There is therefore room for a judicious restriction, within the range of common practice. It is but a result of the general law, that a systematic moderation

* The Moral Class-Book, here referred to, supplies a variety of narratives showing the virtues in action, together with a selection of moral maxims from Scripture and other sources.

at this period of life will lead to an easily maintained temperance in future days, and thus be productive of the greatest blessings.

The combative and destructive dispositions of children are also early manifested. The great activity of these faculties in boys is particularly remarkable, being shown as much in a wild spirit of adventure, for innocent objects, but often leading into danger, as in any direct form of violence. The superabundant vitality of this period of life seems to be a cause, or at least a necessary accompaniment, of the energy of these faculties. No peril intimidates; little compunction is felt in dealing with either man or beast. In all this there is no doubt a good end in view; but it still remains for the educator to regulate these dispositions. The *contendative* spirit may be directed to the overcoming of difficult tasks, the taking of energetic exercise, and the visiting of places and objects the examination of which may be useful. The other feeling, instead of being allowed to show itself in rage, passion, and resentment, to inflict pain on harmless animals, to torture or oppress companions, or take delight in defacing or destroying inanimate and perhaps ornamental or useful objects, may be trained to reserve actual manifestations of its energy for objects clearly noxious. It is to be lamented that education, as heretofore and still in many places conducted, rather tends to foster than to regulate or moderate this propensity. The old notion that to be able to fight is essential to a youth, still, we fear, in some measure guides directors of education, at least so far as to induce their taking little pains to prevent scenes of outrage where only youthful good humour and kindness should prevail. The oppressive system of fagging is also still, to the disgrace of our age, allowed in some of our public seminaries. It is well, no doubt, that he who is to find life a thorny and difficult path, should not enter it with too gentle or timid dispositions; but surely it is not impossible to draw a distinction between quarrels, blows, and tyranny, and the encouragement of a spirit sufficiently manly and energetic for all the common needs of our life.

The first object of the educator with regard to these feelings, ought to be to impress the lesson that their exercise is good or bad just as they have good or bad objects in view—that they must, in all cases, be under the guidance of the moral sentiments and judgment. The pupils should be trained to check every impulse of these feelings which they are conscious has not a legitimate object in view, and only to allow them any freedom when careful reflection has satisfied them that such a course is entitled to the entire sanction of the moral law. Particular regard should be paid to the suppression of the spirit of wanton cruelty, of malice, of revenge, of uncharitableness. And one important means of working out these ends will be to allow no example of harshness, cruelty, or quarrelsomeness, ever to appear before the eyes of the young. It is very desirable that those who conduct schools in which the children of the humbler classes are educated, should address themselves particularly to the formation of habits favourable to humanity. Large sections of the humbler classes, particularly those who have any thing to do with animals, are habitually cruel. Much might be done to mitigate this distressing characteristic, by carefully impressing at school the wickedness involved in every description of cruelty to animals.

The secretive disposition calls for a large share of attention from those who would bring up a child well. This tendency of our nature appears to have a legitimate operation in dictating such a reserve as may be necessary for the restraint of our ordinary feelings, where their expression would be disagreeable or mischievous; but it is liable to great abuse, and particularly amongst the young. The first impulse of all unregulated minds, young and old, is to conceal the truth, if such expedient seem calculated to save them any harm or inconvenience. It is only when the greater evil of lying is thoroughly understood, that this tendency ceases. It becomes, therefore, of great consequence to check the first instances that are observed in the young of a disposition to conceal the truth for selfish or base purposes, and to seek to establish principles and habits of a contrary character. For this end nothing is so necessary as a mild and just treatment of children under all circumstances, seeing that when severity or injustice is to be apprehended, a direct and far too great temptation is given for secretive conduct.

It is difficult to legislate between the evils of blabbing, and the equally notorious evils of a habitual system of conspiring for the concealment of truths which conscientiousness would direct being told. There can be little doubt that the "*don't tell*" practices of the nursery and school are calculated to implant and foster the seeds of disingenuousness in the youthful mind. Yet it is not less true, that to encourage a tale-bearing habit would be destructive to all manly and honourable feeling. Here caution, judgment, and a careful discrimination of cases, must be the chief guides of the educator. We would, for our part, deem it a duty to lean as much as possible to the principle of having the truth told at all hazards. The educator may do much by a rigid system of inspection, and omitting no opportunity of breaking up all confederacies against the truth. As he never will allow *shirking*, if he can help it, so also he will never, on his own part, be guilty of the meanness of *winking*. The more open and candid his own conduct in all his relations towards his pupils, the better will it be for them. There exists a school on improved principles, where the most lively mutual confidence exists between the masters and their pupils, and on the part of the pupils towards each other, with the best effects on all hands. Honour is thus so habitually observed, that the desks containing the little property, letters, &c., of the pupils, need no locks. There is much evil in families from children being brought up in non-confidential habits with their parents and with each other. The family parlour and table should be a scene where all can unfold their ordinary thoughts, without fear of censure or ridicule. It is the best means of insuring that the young people will act with the concurrence of their parents, when they come to take any of the more serious steps of life.

The acquisitive feeling requires much more educational care than it has usually received. We need not detain the reader with an exposition of the legitimate use of this faculty, which prompts man to accumulate and store up the goods of life, for regular instead of precarious use. To this impulse capital owes its existence, without which there could be no civilization. The Author of our being has stamped importance on this faculty, by the strength of the propensity. None more requires modification, regulation, and right direction. It is often too strong for conscientiousness, and is the source of by far the largest amount of crime. But, besides this, it is even with the honest too much manifested in abuse. Its objects are made the paramount pursuit of life, and in its intense selfishness it withers to dust every generous and kindly feeling of the heart. In a commercial country, like our own, it deeply degrades a large proportion of the community, and leads to much individual and social suffering.

These evils are the consequences of the natural strength of this feeling, the absence of regulating education, and the presence of positive mis-education. Selfish and exclusive appropriation of desirable things, either to eat or hoard, is a lesson taught the youngest, both by precept and example; and there is none more easily learned. Here bribery operates, till infant morality becomes mere matter of barter, and good conduct and attentive study are estimated by the infant merchant by what they will thing. Perhaps we err in so soon introducing children to the use of money; it is at least desirable that they should not be accustomed too soon, or at any time, to an engrossing sense of its value and importance. It is well to accustom them to take care of any thing that is their own, but not to set too great store by their little possessions, or to be too exclusive in the use of them. A habit of scrupulous regard to the distinction between *mine* and *thine*, is one which cannot be too early formed, at the same time that they are accustomed to make a generous use of whatever is their own.

Self-esteem and love of praise or approbation are early awakened feelings, and the more call for regulation that they are so liable to be called into exercise by the procedure of education itself. Here it is particularly important to keep in mind what are the legitimate uses of these feelings. A well regulated self-esteem obviously gives that confidence in ourselves and our powers which is necessary for all our efforts in life; while a moderate regard to the opinions of others is useful in prompting to such efforts, and in restraining us from many displays of caprice and absurdity to which we should otherwise be liable. It will of course be well to encourage these feelings, as far as they tend to give necessary confidence, and to maintain a decent regard for character in the world, but no further. Their vices, pride and vanity, too much reliance upon self, and too abject a regard to the world's opinion, are to be sedulously guarded against. In the procedure of education, they are so readily available as means of stimulating to exertion and encouraging good (that is, not troublesome) behaviour, that it is not surprising that they are so extensively made use of for those purposes. The whole system of place-taking, prizes, medals, &c., is founded on them. It cannot be doubted that educators are thus guilty, in many instances, of fostering invidious and even destructive feelings in those under their charge; the whole system is unquestionably a selfish one. Feeling strongly these objections, some modern educationists advocate the entire abolition of all marks of *emulatively comparative* proficiency or good behaviour at school, retaining only an accurate register of individual advancement, to enable the pupil to mark his own progress. Theoretically this is right; and we may hope that, when education is fully organized on a right footing and supported by an improved adult society, the whole system of competition, including every kind of rewards and punishments, will be dispensed with. Meanwhile we must leave educators to act on these points according to their best discretion, only strongly recommending them to dispense as far as possible with all these inferior, and, to a certain extent, degrading and corrupting influences.

Cautiousness—a feeling intended, in its right direction, to prompt to foresight and the avoidance of unnecessary dangers, but, in its excess, pusillanimity and cowardice—calls for a careful treatment. Among unthinking persons, it is mere sport to frighten children with narratives, objects, and exclamations, calculated to inspire terror. Thus their imaginations are filled with bugbears, which harass them constantly, and make it the severest punishment to be left at any time alone, or to be in the dark. In cases where a predisposition exists, the most serious consequences sometimes flow from this irrational treatment. An enlightened educator never allows an ideal terror of any kind to enter the mind of his child or pupil. As the feeling may be strong or weak in the particular case, he seeks to moderate or to foster it, giving encouragement and stimulus if it be defective, and prompting to caution if it be otherwise. He carefully impresses the lesson that danger and hazard may be laudably encountered for a good object, but that it is folly to undertake the least risk when no end is to be gained by it. For example, he would approve of his pupil perilling his own life to save a friend from drowning, but not of his going across a lake thinly frozen, merely to show his courage.

The selfish feelings appear in a natural subordination to those which are usually called "higher," and sometimes, by excellence, "the moral sentiments." These are what mainly give the characteristic, "goodness," to an individual, and so rule the social machine, that general movements are usually of a virtuous character, and vice is obliged to remain in nooks and corners, or put on the garb of virtue when she appears. It is to the proper training and regulation of this class of feelings that the educator chiefly looks for the result he aims at—namely, the right formation of character.

Conscientiousness, the conscience, the moral sense, or by whatever other name it is called, is that innate feeling which gives the disposition to follow right and avoid wrong in all circumstances. To bring this feeling into its full force, it is necessary to train it with the aid of intellect to lend it discrimination. The pupil must be accustomed to observe its rules, as to the property of others, their reputation, their comfort, and happiness, the right decision of every question in which their interests are concerned, and also with regard to the truth in all things. He thus becomes fixed in equitable, disinterested, and ingenuous habits, beyond all the powers of ordinary temptation. It will be no exercise to this sentiment, to tell the young to avoid certain acts, because they are mean and only practised by the vile, or because they will procure universal odium. That is an appeal to love of approbation, not to conscientiousness, to the development of which it will be rather unfavourable than otherwise. To fortify conscientiousness against what is wrong, we must directly address itself, by an endeavour to show the actual unjustness or baseness of any particular course of conduct, or the integrity and purity of the opposite; taking care to induce an act positively conscientious on all possible occasions, as in the acting upon a sentiment do the means of improving it chiefly lie.

So, also, with benevolence. We must not content ourselves with presenting ideal pictures of the distresses of our fellow-creatures to the minds of the young, thinking that to excite their commiseration is enough. We must endeavour to induce them to perform *acts* of kindness and charity—we must endeavour to make them give, from their own means, or at some expense of self-denial, succour to the unfortunate; and for this reason it will be proper that they are occasionally brought to witness cases of actual suffering, and made to administer relief with their own hands. It was a beautiful old custom of Christian princes and princesses, to have a number of poor persons occasionally brought before them, that they might administer to their relief and comfort by washing their feet with their own hands. It was its least good effect to humble rank to the level of mortality: the better one was to give activity to the sentiment of benevolence, too apt in such persons to become dormant, from their very elevation above all spheres in which human suffering exists. Benevolence is also to be shown in what is called an obliging disposition, a readiness to sacrifice ourselves and take some trouble whenever our doing so can at all promote the happiness of our fellow-creatures. It is likewise shown in mercy towards the weak, including animals, and in a forgiving placable temper. "Teach your children never to wound a person's feelings because he is poor, because he is deformed, because he is unfortunate, because he holds an humble station in life, because he is poorly clad, because he is weak in body and mind, because he is awkward, or because the God of nature has bestowed upon him a darker skin than theirs."*

Justice and kindness to others have a worthy associate

* Goodrich's Fireside Education.

in respect or veneration for others who are of superior worth, and for superior objects in general, including the objects of religious faith. This is also a native sentiment of the mind, and one which sends a beautiful light throughout the world. The scoffing and undervaluing propensity is its opposite, a disposition rarely found associated with estimable qualities. The sentiment of veneration is that on which all social grades depend; it is the spirit of subordination itself. It is a folly when exercised with regard to mere artificial rank unattended by worthy qualities; but with regard to persons elevated either by their native good qualities, or the function which has been intrusted to them to execute, it is as much due as is our pity and succour for the unfortunate. It is *perhaps* this feeling which chiefly gives a regard for the feelings of others; for we must think our fellow-creatures of some consequence, before we will be disposed to go out of our way on their account. The feeling, therefore, eminently deserves the care of the educator; but great pains must be taken to give it a right direction. We must teach the young to discriminate judiciously as to objects really entitled to their reverence. It may here be remarked, that the feeling of veneration is one which may prove of great importance in certain contingencies to which the educator is liable. When a child has been indulged or mis-trained to such an extent that he defies all the reins to which he has been accustomed, it will generally be found that removing him to a new scene, and into the charge of individuals who, whether from their character or from the force of novelty, excite the veneration of the young delinquent, is attended with a good effect, which it only requires firmness, discretion, and kindness in the new teacher to follow up, for a complete reformation.

The above may be said to be the natural means of cultivating and forming the moral character of those intrusted to our hands. And these natural means are of great consequence, and entitled to all the respect we can give them; for they are in reality means of divine appointment, designed to serve in the great work of mutual improvement. But the most powerful means of modifying human character is that other revelation which has come to us in a more direct manner, and which is fully disclosed in the pages of Scripture. As soon as this can be made intelligible to the young, it should be imparted, not under those rudely familiar circumstances which too often attend religious education in the school-room and at home, where the child is conscious of little besides a struggle to commit certain texts and dogmas to memory, but in the quiet of confidential converse, when the thoughts are called home, and the soul is open to awe, love, hope, and all the gentler emotions of our nature. Then may we hope to convey some just impressions of the grand yet tender relation in which man stands to his Creator, his destiny on earth, and the appointments for the future. Then only may we hope to impart just feelings with regard to the inscrutable scheme on which the weal or wo of an eternity depends. It is obvious that, if we succeed in these things, we must awaken in the moral nature a self-sustaining influence infinitely more powerful than precept, example, training, and all the other natural machinery of a moral education. Yet it should never be lost sight of, that neither means will singly be operative. Upon a mind which has been left rude and unregulated, the efforts which ultimately take the name of religious education can make little impression. The words which have been learned will probably remain only as words, without producing any real religious feeling, much less any improvement of conduct. Indeed, both the morals and the intellect must be cultivated to a considerable extent, before religion can be any thing but a passing sound. There must be a prepared intellect to understand it, and prepared moral feelings to give it a reverential reception, and entertain its behests in the spirit due to them, not to speak of acting upon its precepts.

To recapitulate—the moral nurture of the young is to be accomplished by a variety of means: first, by placing them in a pure moral atmosphere, presenting what is good and nothing evil of human conduct before their sight, familiarizing them with every sound precept, and giving their various feelings due regulation, exercise, and training; next, by imbuing them, under the circumstances most calculated to be effective, with those religious truths which so infinitely transcend all others in importance. In order to impress our lessons still more pointedly, we beg to add some express directions, which we think may be advantageously followed in the management of the young, more particularly those at the infant stage.

Anticipate and prevent fretfulness and ill-temper, by keeping the child in good health, ease, and comfort. Never quiet with giving to eat, or by bribing in any way, still less by opiates. For the first few months avoid loud and harsh sounds in the hearing of children, or violent lights in their sight: address them in soft tones; do nothing to frighten them; and never jerk or roughly handle them. Avoid angry words and violence both to a child and in its presence, by which means a naturally violent child will be trained to gentleness. Moderate any propensity of a child, such as anger, violence, greediness for food, cunning, &c., which appears too active. Show him no example of these. Let the mother be, and let her select servants, such as she wishes the child to be. The youngest child is affected by the conduct of those in whose arms he lives. Cultivate and express benevolence and cheerfulness; in such an atmosphere a child must become benevolent and cheerful. Let a mother *feel as she ought*, and she will *look as she feels*. Much of a child's earliest moral training is by looks and gestures. When necessary, exhibit firmness and authority, always with perfect temper, composure, and self-possession. Never give the child that which it cries for; and avoid being too ready in answering children's demands, else they become impatient of refusal, and selfish. When the child is most violent, the mother should be most calm and silent. Out-screaming a screaming child is as useless as it is mischievous. Steady denial of the object screamed for is the best cure for screaming. In such contests, witnesses should withdraw, and leave mother and child alone. A child is very ready to look round and attract the aid of *foreign* sympathy in its little rebellions. Never promise to give when the child leaves off crying: let the crying be the reason for *not* giving. Constant warnings, reproofs, threats, and entreaties—as, *let that alone—be quiet—how naughty you are*, &c., all uttered in haste and irritation, are most pernicious. No fixed or definite moral improvement, but the reverse, results from this too common practice. Watch destructiveness, shown in fly and insect killing, and smashing and breaking, quarrelling, striking, &c. Never encourage revenge. Never allow a child to witness the killing of animals. Counterwork secretiveness by exposing its manœuvres. Regulate notions of property—one's own and another's. Never strike a child, and never teach it to strike again. Never tell a child to beat or threaten any animal or object. Corporal correction may be avoided by judicious substitutes. Set an example of cleanliness, order, punctuality, delicacy, politeness, and proper ease of manner. This is better than *teaching manners*, as it is called. Inculcate early, and manifest in yourself, a delicate regard for the rights of others and their feelings, in contrast with selfish vanity, arrogance, and exclusive attention to one's own ease, comfort, and gratification. Prevent all indelicacies and slovenly habits at table—touching the utensils, stretching for what is wanted, sitting awkwardly, &c. Study early to gain a child's confidence by judicious sympathy in its joys and sorrows. Have no concealment with it.

govern by love, and not by fear: the contrast between children governed by the one and the others is truly instructive. Never forget that kindness is power with man and beast. *The Arab never strikes his horse.* Cultivate truth, justice, and candour in the child, and manifest them in yourself. With a child whose firmness is apt to run into obstinacy, never contend; in doing so, you aggravate the feeling by manifesting the same feeling in yourself, and by further showing your combativeness, exciting the child's opposition. Divert the child from the object, and put in activity its benevolence, justice, and reason. Never frighten to obtain a child's obedience: threats of hobgoblins, and all false terrors, are most injurious in their direct effects, and, being generally discovered to be falsehoods, operate most immorally.

We beg to conclude the section with the following remarks from Dr. Combe's excellent manual for the management of infancy:—"It is a common and pernicious error in modern education, that the passions and moral emotions implanted in the human mind are the results of intellectual cultivation; that intellectual discipline will suffice to regulate them. Under this mistaken notion, parents are often disappointed and displeased with a child, when, after a full explanation of the impropriety of the feeling or passion, it still, on the recurrence of the temptation, gives way to it as much as before. I have known a father, under this false impression, lecture, and threaten, and punish his child, and take every way to correct it but the right one. Fortunately for mankind, however, morality and religion have a much more solid foundation than a mere deduction from an erring intellect. They are based on feelings implanted in the very nature of man, and which mere intellectual cultivation or neglect can neither generate nor destroy; and their real strength and authority will not be fully recognised, till they are cherished and developed in strict accordance with their natural constitution. Like the external senses, they must be habitually exercised upon their appropriate objects—in worshipping the true God, and in doing justice, and loving mercy—before they can attain their proper influence over the character, and their true authority in regulating human conduct. From almost the first hour of existence, this principle should be systematically acted upon, and the utmost care be taken to secure at all times a healthy moral atmosphere for the young. To do perfect justice to the infant, there is required, on the part of the mother, a combination of cheerful activity, good sense, knowledge, readiness of resource, and unfailing kindness and impartiality, which is not often to be met with. But by aiming at a high standard, we shall make a nearer approximation to what is required, than if we rest satisfied in indifference with whatever occurs. It is lamentable to reflect how numerous are those mothers, who, from indolence or other causes, leave the entire control of their offspring to an unqualified attendant, and even themselves give way to expressions of anger or caprice, which cannot fail to act injuriously upon the infant mind. Let us, then, not deceive ourselves, but ever bear in mind, that what we desire our children to become, we must endeavour to be before them. If we wish them to grow up kind, gentle, affectionate, upright, and true, we must habitually exhibit the same qualities as regulating principles in our conduct, because these qualities act as so many stimuli to the respective faculties in the child. If we cannot restrain our own passions, but at one time overwhelm the young with kindness and at another surprise and confound them by our caprice or deceit, we may with as much reason expect to gather grapes from thistles, or figs from thorns, as to develop moral purity and simplicity of character in them. It is vain to argue that, because the infant intellect is feeble, it cannot detect the inconsistency which we practise. The feelings and reasoning faculties being perfectly distinct from each other, may, and sometimes do, act independently; and the feelings at once condemn, although the judgment may be unable to assign a reason for doing so. Here is another of the many admirable proofs which we meet with in the animal economy of the harmony and beauty which pervade all the works of God, and which render it impossible to pursue a right course, without also doing collateral good, or to pursue a wrong course without producing collateral evil. If the mother, for example, controls her own temper for the sake of her child, and endeavours systematically to seek the guidance of her higher and pure feelings in her general conduct, the good which results is not limited to the consequent improvement of the child. She herself becomes healthier and happier, and every day adds to the pleasure of success. If the mother, on the other hand, gives way to fits of passion, selfishness, caprice, and injustice, the evil is by no means limited to the suffering which she brings upon herself. Her child also suffers, both in disposition and in happiness; and while the mother secures, in the one case, the love and regard of all who come into communication with her, she rouses, in the other, only their fear or dislike."

INTELLECTUAL EDUCATION.

By intellectual education we hold it to be implied that the human intellect, originally a mere instrument ready to be exerted, requires, for the full development of its powers, and subsequently, for the ready use of those powers, the application of certain external stimuli, and the force and regulation of a certain discipline; also, that the intellect, besides being thus improved in its own character and energies, requires to be possessed of certain knowledge and certain accomplishments, in order to a proper performance of the various duties of life. We shall not stop to make a nice investigation as to the various powers of the intellect and their modes of acting, but at once assume that, with senses serving as media for the access of impressions from the external world, it includes powers which can take cognisance of things, or perceive, and powers which can compare things, and trace their connection in cause and effect (reflecting); these having various modes of action recognised, as memory, association, &c.; and that these various media, powers, and modes of operation, may all be improved by use and exercise.

Intellectual education properly begins with the first symptoms of consciousness in the infant—the first indications that the senses and internal observing powers, the germs of which exist in the youngest infant, are beginning to act.

The senses require the earliest attention of the nurse. Sight, hearing, and touch, are, in a very short time after birth, in obvious activity; but they require at first to be very delicately treated. Exposure to bright lights and sudden loud sounds, has produced blindness and deafness for life. Both senses should be brought on gradually. These, as well as touch, should then be judiciously exercised upon their own objects, placed at different and increasing audible and visible distances, till at great distances objects can be seen and slight sounds heard. Objects should also be touched blindfold, and discriminated. Smell and taste are improvable by similar means. It would form an extremely interesting occupation to an intelligent nurse, for many a moment of ennui which she now endures, in her care of an infant, to exercise its senses on their appropriate objects. When nothing is done, or when the child is shut up in a small room with no range of vision, not only is no progress made, but there is great danger of short-sightedness being either induced or aggravated.

Leaving the external senses, and advancing to the internal faculties of the mind—the powers of feeling, observing, and thinking—we may remark that the brain, which is as much the instrument of these powers as the eyes and ears are of their respective external senses, is at birth, and for some time after it, too imperfect and delicate in its substance for active manifestation. The desire of food, and sensibility to bodily pain, alone appear, and are, indeed, all that are then necessary. But the more delicate the brain, the more delicately ought it to be treated; for an injury to it may produce idiocy or imbecility for life. In the exercise and cultivation of the intellectual organs, it has been found, from experience, that great caution is required. It is here that the brain is most apt to be overworked; and it is here that that premature activity, called *precocity*, appears. Under the head Precocity, Mrs. Barwell gives the following emphatic counsel:—"When a child appears to be over-*intelligent*, or too *clever* or *wise* for its age, this is a symptom of unnatural development of the brain; it is a kind of disease, which often ends fatally. Avoid, therefore, exercising the child's *ability*; treat it as an animal, with nutritive food, muscular out-door exercise, and plenty of sleep; and do this, and *this only*, for some years." We allude to the subject of precocity thus early, in treating of intellectual training, because its indications often appear in very early infancy, and erroneous treatment cannot be too soon avoided.

Before two years of age, much important intellectual education is going on. It is not the education of books; it is gradual introduction to surrounding objects. How early the eyes are used to gaze at, and the hands stretched out to grasp and become familiar with, every thing presented or observed, need not be here insisted on. A judicious nurse will direct this impulse of nature and much assist this self-education, so that the earliest impressions may be made by such objects as form the materials of existence, and their qualities, never to be effaced in after life; while the observing faculties will have a healthier growth, by means of an easy and pleasingly directed exercise. Modern educationists have often complained of a prevalent want, in people of all ages, of what may be called *observativeness*—the power or rather habit of noticing what is before and around us. Multitudes pass through life, of whom it may be said that they have missed four objects in five which came in their way. This could be met in early infancy by taking the proper means of establishing habits of observation. "Look here;" "see this;" "feel that;" "weigh the other thing;" "what beautiful colours;" "smell that flower," should be the simple and constant lessons of the nurse; and she would find both the intellect and dispositions of the child improved by such exercise. The contrast, in after life, between children so trained, and those who never observe any thing, would be both striking and instructive.(1)

From Two to Six Years of Age.—Intellectually prepared by the nurse up to the point at which we have arrived—when the child has reached the age of two years, and when, if it can by any means be so arranged, he or she should join an infant-school—the intellectual education will, so to speak, take a more scholastic form. The lessons will be somewhat more systematic, and suited for the simultaneous attention of numbers. But still the caution will never be lost sight of, that, from two to six, the intellectual exercises should be light and attractive, and never long continued at one time; air, exercise, and play, regularly alternating with instruction. The paramount object at that period of life, let it never be forgotten, is *moral* training; to which object companions of the same age, in considerable number, are as essential as light is to the exercise of the eyes, or air to that of the lungs. Benevolence, truth, justice, honesty, attachment, all imply companions. Although, at that age, the intellectual training is secondary, when compared with the moral, yet without tasking the infant faculties, without giving to the pursuits any character less attractive than regulated play, a great degree of intellectual acquisition and improvement may be realized.

The introduction which the child has received in the nursery to the material world, will form a stage in his progress for the more systematic teaching from two to six years of age. *Objects* will still be the *material* of his studies; but they will be so arranged and classed as to conduct him through a complete knowledge of the external features, qualities, and uses—short of their chemical composition—of nearly all the objects with which ordinary life is conversant;—simple objects, parts of objects, objects natural and artificial, mineral, vegetable, animal, with their parts, conditions, differences, agreements, manufacture, and abstract qualities, and classification of objects by resemblances and differences. In these exercises several hundred useful ideas may be imparted; all of them made real by the connection of each with some material type.

Simultaneously and incidentally, the words expressing the objects and their qualities, &c., will be given, and, in connection with the object, will never be forgotten. Incidentally, too, the word will be exhibited printed, and so *read* as well as pronounced, and likewise spelled. The letters of the alphabet will be separately taught as objects. This learning of things and words together will be found beneficial as to both. When the senses are explained, which we assume has been done, the exercise will be easy and improving which connects the objects with each sense, or with several at a time; in other words, whether the pupil has seen, heard, touched, smelled, tasted, or weighed, the object or its quality. Thus, without a task, almost insensibly, and as it were at play, the child, in four years, will have attained a sum of knowledge of great extent and value, which will form the basis of an enlarged mind in after life, and prepare for the future acquisitions of science and philosophy. The rule should be rigidly observed, that no object in nature or art should ever be spoken of to a child without an endeavour being made to present it to him either in reality, model, or drawing, and this practice should be continued till the object has become familiar to him.

Between two and six, besides the acquisition of knowledge of objects, much elementary knowledge may be gradually, easily, and almost insensibly, imparted;—the simpler geography—arithmetic by means of Wilderspin's ball-frame, or *arithmeticon*—the pence-table—weights and measures—letters, syllables, words, lessons on pictures of animals, &c.—lessons on maxims moral and prudential—anecdotes and stories with a moral and improving tendency, told elliptically, that is, by words being left out for the children to supply, &c. At this age the vocal powers and musical ear should be exercised, which is both amusing and instructive to the children; many of the lessons may be sung. Much knowledge of common and useful things, connected with life and manners, may be communicated at this age, with an impression that will never be effaced. Lessons, too, connected with exercise in the practice, may be given on the benefits of cleanliness, ventilation, temperance, with all the evil effects of their contraries; while prejudices, fallacies, tyrannies, cruelties, unfairnesses, selfishnesses, bad habits, &c., all of which operate so mischievously on society, may be met by anticipation in lessons and counter-practice, so as to be avoided in after life. It is plain that the moral and intellectual training must proceed hand in hand.(2)

From Six to Fourteen Years of Age.—In a rightly arranged and complete course of elementary intellectual education, it is presumed that the period from two to six years of age has been spent in an infant-school. The effect which such a preparation has in facilitating the subsequent operations of the teacher is so great, that every effort should be made to give children the advantage of it.

From six to fourteen is the period of the elementary schools. This is the time during which children, besides having their moral education carried on efficiently, are to be introduced to those branches of instruction which are necessary for the business of life—a process which includes within itself the exercise and development of the intellectual faculties, and the formation of habits of intellectual application and taste.

The two great questions are, what is to be taught; and how are we to teach it? Mother tongue—the power of reading it, acquaintance with its grammatical structure, and with the exact meanings of its words, and the power of composing it with fluency and elegance—is certainly entitled to the first attention. There are three modes of teaching it. First, the old practice of instructing children in it by rote, without regarding whether they ever thoroughly comprehend a single syllable of it, or are ultimately able to make the least use of it. Second, what is called the Explanatory Method, practised in the Edinburgh Sessional School and many other seminaries, whereby it is at least secured that the pupils have some synonym for every term that comes under their notice, so as to give some reason to believe that they understand it. Third, the Exhibitory Method, which adds to other expedients that of showing, in all possible cases, the objects referred to in lessons, or at least presenting drawings of them on a black board or otherwise. Considering how little the young are prepared for the abstract, and how eagerly, under a natural impulse, they grasp at the tangible, we need scarcely say that the last method appears to us as one of which advantage should be taken as far as possible.

The first step may be a regular series of lessons on the consonants, single and compound, as they occur both at the beginnings and ends of words. In the selection of monosyllabic words for this purpose, care should be taken, for obvious reasons, to avoid such as refer to coarse and mean ideas. The powers of single vowels being thus also taught, it will be proper next to advance to words in which double vowels or digraphs are exemplified; and so on, as in the work here referred to.(3) The lessons for practice should consist of sentences of such a nature as to admit of amusing explanation and illustration by sketches on the black board, and by sensible objects.

1. *Names of things* will perhaps be best explained by showing the object itself, or its picture, and by asking the children to tell what they know *about* the object. Their own simple definitions are very often the best.

2. *Names of qualities*, by requesting children to name objects that *have* the quality. For example, to explain *deep*—"Tell me any thing that is *deep*." The following have been named—"The sea, a well, a coal-pit, a canal."

3. *Names of actions*, by performing the action named, or describing it by some interesting anecdote, so as to show practically the meaning of the word.

These suggestions may by some be considered trifling and childish, but a proper trial is requested, and the result will show whether children make more real improvement by the above simple and obvious expedients, or by etymological erudities and dictionary definitions.(4)

Grammar will incidentally accompany the reading, in the form of parsing. By what is called the *incidental method* much advantage is gained; knowledge of an object and its qualities is obtained: its name is pronounced, written down, and read; while its description is read and parsed; all which exercises, instead of impeding, actually aid and facilitate each other. A judicious extension of the incidental method may be made one of the most important means of advancing popular education. Learning to spell orally columns of a book, is a waste of time and an irksome labour. We spell only when we write; and the power is really not attained by the old school exercise of spelling, but by reading; the words become familiar to the eye as *specific forms*. No one who reads much can remain a bad orthographer; and no one writes much who has not previously read much more.

Simple Lessons in Reading.—The child may now make a step forward in the art of reading and spelling, and be prepared for more methodical intellectual culture. At the same time, in order to *amuse*, and induce reading for *the pleasure it communicates*, the subjects of the lessons should be of that species of narrative which delights the infant mind, bearing, in each case, a reference to the perceptions of the pupil, or tending to encourage in him a love of the beautiful in nature. Instead of the old unprofitable reading and spelling in schools, the improved plan of instruction in English consists of—First, Correct reading, dividing and spelling of words; meaning by spelling, not the laborious and useless committal to memory of whole columns of spelled words, but, 1, naming letters singly by their powers, grouping them into syllables, and these again into words, so as to *read* a language; 2, putting down letters on paper, in proper number, order, &c., so as to produce a combination expressive of sound, and thus *write* a language. Spelling is acquired by constant practice in reading, writing from dictation, copying pieces from good authors, composing and correcting original essays, and performing systematic grammatical exercises. Second, Understanding what is read—proved by searching examination, and illustratively aided by real objects. What is called the elliptical method is here much used, the child supplying the omitted words, and receiving, according to the skill and information of the teacher, much collateral information. Very simple ideas only ought to be called up, and such matters alluded to as may be supposed to interest and encourage the dawning faculties. We cannot too earnestly recommend the practice of illustration by pictures and sensible objects. The *black board* and chalk should be in constant use, and every teacher should qualify himself to draw ready off-hand sketches. The rudest outline done on the spot excites more interest than the finest engraving. The lessons themselves, in detail, are given in the work here referred to.(5) The curiosity of young persons is necessarily first excited by the things which lie most immediately around them, and the circumstances and procedure of familiar life. These are the subjects of their earliest inquiries, and it is extremely desirable that clear, distinct, and correct explanations of them should be invariably given. Most parents of intelligent and well-regulated minds take care that such should be the nature of the answers given to the first inquiries of children; but it is needless to point out, that many persons who have children under their care, either possess not the ability, or have not the necessary leisure, or will not be at the pains, to give correct and satisfactory answers. Lessons should be given which aim strictly at an explanation of *external appearances* in the natural and social world. *Principles* are for subsequent study. The subjects may be such as the following:—Of God and the works of creation; of animated creatures; of mankind; of the country; processes of husbandry; inanimate objects of all common kinds.(6)

In elementary education, after some progress has been made in the power of reading, the different conditions of a child at about seven, and at from ten to fourteen years of age, suggest the necessity of two series or courses of instruction—one of a simple, primer-like character, the other more advanced, but both going over nearly the same ground. This is the more necessary, as so many children are taken from school about ten years of age. In the construction of a series of schoolbooks, already more than once quoted, we have proceeded so far upon this arrangement, most of the volumes of the advanced course being foreshadowed in that which may be called the *preliminary*. We observe the same arrangement on the present occasion.

Preliminary.

Introduction to Geography.—The pupil having, in the infant school, had some instruction in the simplest elements of geography, may, in his seventh or eighth year, pursue the study more regularly. Lessons may now be given which will suit those whose education allows but a small portion of time for geography—lessons calculated to impress a fair measure of that most useful knowledge even on the future manual labourer. These need not give copious lists of localities, capes, bays, districts, and towns, it being presumed that the learner has maps before him on which he will be exercised. He cannot, moreover, be introduced too early to the GLOBE, for the spherical as well as relative position of its great divisions, with their latitude and longitude. Proportion should also be impressed upon him; this is apt to be confused by maps of different sizes. The relative situation of countries need not be much adverted to, that being best learned on the maps. The chief attention should be devoted to the *characters, physical and political, of the countries*. The plan should be followed of treating, generally, in the first place, of the plants, animals, and races of men, in the different regions; and, in the second, of the most important particulars peculiar to each country, which cannot be brought under general heads. With the maps and globe always before the pupil, much useful information may by this method be conveyed.(9)

Writing.—This is entirely an art, to be acquired by practice, with the assistance, first of a skilled teacher, to train to the mode of sitting, of holding the pen, &c.; and, second, of suitable exemplars of the various kinds of writing. A free and bold practice with chalk upon a black board would probably form a good introduction to the art of writing. It was by such means, under the guidance of his father, that the celebrated Porson acquired that accomplishment of singularly elegant writing, for which he was scarcely less remarkable than for his extraordinary attainments in classical literature.

Introduction to Arithmetic.—The simplest elements of arithmetic are presumed also to have been taught in the infant school, by means of the instrument called *Arithmeticon*. In this early school period, it may be pursued by means of regular exercises wrought upon slates, according to the rules presented in an appropriate book. An active teacher may also do much for this part of school education by conducting mental exercises, or exercises in which no sensible figures are used. It is found an excellent discipline for giving habits of attention and concentration.

Introduction to English Composition.—The pupil may be, at this early period, introduced to English composition. We recommend the modern plan of teaching the rules last. Let the pupil successively compose and write down nouns; then their qualities, or adjectives; then the action or change, or verbs. He has been a *composer* from the moment he began as a child to prattle. Let him go on, and he will insensibly infer the essential laws of language, by his own experience and his teacher's hints, more rationally and more thoroughly than from a system of grammatical rules, necessarily dry, irksome, and repulsive. In giving these lessons on composition, the following suggestions will be attended to:—1. It is suggested that, previously to a pupil's entering on composition, he should spend a few weeks in copying, with great accuracy, short pieces in prose from some good author. This will give the habit of neatness and exactness in the use of points, capitals, &c., and, if carefully managed, will form an excellent preliminary exercise. 2. Each pupil should be provided with a quantity of common paper for the scroll copy, an exercise-book for transcribing, and this text-book. 3. Let the teacher place fifteen or twenty familiar objects on a table or desk before the class, and request the pupils to comply with the direction in the first lesson, by writing on the spot the names of the articles; and so on with the other lessons, in order. 4. When the lists are finished, they should be exchanged, and each pupil should correct the spelling, &c., of his neighbour's work. 5. This done, the papers may be returned to their owners, for the purpose of their reviewing the criticisms; and all should be encouraged to protest against false corrections. 6. The teacher should then pass round the class, deciding disputed points, explaining the ground of each decision, questioning the pupils, and allowing them freely to question him. 7. The scroll-copy, thus corrected, should be taken home by its owner, neatly transcribed into the exercise-book, which, duly dated, should be handed to the teacher next day. 8. The teacher may then mark the errors in the transcript, asking the pupils to show the cause of each correction. 9. The exercise-book should then be returned to the owner, with a *number* (in the teacher's handwriting) indicating the rank of the exercise. 10. At the end of each lesson, the pupils should be questioned on the parts of speech employed, meaning of words, knowledge gained, &c. 11. The pupils should use *black* ink in writing the exercise, and *red* in correcting. The teacher's criticisms, remarks, and numbers, should be in *blue* ink. These distinctions, though apparently trifling, will be found important. 12. Three or four lessons may be given weekly, according to circumstances. Less than half an hour will suffice for writing each exercise, and little more than that time will be required for correction. The lessons will proceed from objects to qualities and actions, each embracing a very wide field of exercise. The derivation of words from other languages, or ETYMOLOGY, both simple and compound, may, at the same time, be an incidental exercise. (10)

Introduction to the Sciences. The pupil has hitherto been conversant with the *external* features of objects, and the ordinary uses to which they are put. At the age of nine or ten he may be gradually introduced to philosophical *principles*—to a connected and systematic view of nature, the most obvious parts of which it is composed, and the laws by which it is governed. The subjects will be—the extent of the material world; the stars, the solar system, the earth as a planet, the moon, eclipses, masses of matter—their attractions and motions; the earth—its general superficial features, its structure; the soil, the atmosphere, heat, light, electricity, and magnetism; evaporation, clouds, rain, frost, ice, snow, the winds; elements of matter—their combinations; the vegetable creation; animal creation; man—his general character and history, his bodily nature, his mental nature.(7)

Rudiments of Music.—About this stage of education, the pupil may be introduced to the principles and rules of vocal music. This is invariably a branch of education in several continental countries, and is attracting marked attention in Britain. In the infant school we have already recommended simple singing by the ear; the pupil may now not only study musical rules, but learn to sing from notes.*

* We are far from being satisfied with the means yet practised for teaching vocal music in schools. Very encouraging progress is making in London by Mr. Hullah, under the eye of Dr. Kay, the able and excellent Secretary of the Committee of Privy-Council, sanctioned by the Committee. The method employed by Mr. Hullah is the synthetic method of M. Wilhem's work, published in Paris under the sanction of the Minister of Public Instruction. The method is successfully practised in the school for teachers at Battersea, established and almost exclusively supported by Dr. Kay; and a singing school for teachers, on that method, approved by the committee, has been established in Exeter Hall. The committee have published the first part of a Manual; and one of their minutes devotes eleven octavo pages to a minute description of the organization of singing schools on the Wilhem method. We much approve of the system, and trust it may lead to the universal introduction of good vocal music into education

Advanced

Geography. A year or two after the pupil has mastered the Geographical Primer, he may proceed to study geography in a more enlarged and generally informing manner. Taking England as the first of a series of countries, he will study its situation, extent, division, and general detail of localities; after which will come its physical geography, including superficial features, climate, soil, and vegetable productions, minerals, animals, natural curiosities; next, its historical geography, including remarkable events, antiquities; its political geography, including its civil state, revenue, army and navy, and ecclesiastical state; its social geography, including its national character, language, literature, arts and sciences, manufactures and commerce. In thus studying the geography of particular countries, a constant reference to maps is necessary. By having these sufficiently large, and the natural features strongly marked, as in the series here referred to (26), a whole class can learn at once.

Arithmetic and Grammar.—These branches are now pursued on more comprehensive plans, and with a deeper investigation of principles. In connection with the former stands book-keeping; with the latter, etymology and composition—all of which will now be thoroughly mastered, as technicalities of the greatest importance for the business of life.

Drawing.—This is an art, of the same character as writing, less imperatively necessary, but yet entitled to more attention than is generally paid to it. Its elements may be acquired by all, and are calculated to be useful in many circumstances throughout life. These may be taught by the use of chalk upon a black board. The objects should be the simplest delineations of common things, beginning with practice in straight and curved lines, and proceeding to a paling, a wall, a gate, a guide-post, a house, a rustic bridge, utensils, tools, and implements, flowers, patterns, and animals. On the black board, the chalk, compasses, and rule, may be employed; on the slate, only the hand and eye should be used at this stage of the young pupil's progress. Deeper lines will show foregrounds—lighter, backgrounds; and thus the first notions may be given of aërial perspective. By rendering universal some instruction in drawing of common objects, real talent, where it exists, will never be concealed; while much pleasure will be derived from efforts far short of those of the higher order of genius.(11)

The pupil will in due time advance to the elements of drawing and perspective, and the art of sketching from nature.(12) Terms in the art of perspective should be explained to him, and figures delineated, which are nothing more than the simple geometrical diagrams. The sector, visual rays, points of sight, all the rules of perspective, should be plainly and intelligibly laid down. Black-lead pencil drawing, characters of foliage, light and shade, and tinting; styles and modes of treatment in sketching from nature, both landscapes and figures, with the rules for arrangement and effect, should all be made plain to and practised by the pupil, the teacher guiding his efforts. We may remark here, and the observation is of general application, that the teacher must keep in mind that the intellectual powers are bestowed on different individuals in different degrees; and such differences must be allowed for. It will soon be seen whether the pupil possesses powerfully the drawing or pictorial faculties. If he does not, he should never be pushed beyond the simplest elements of the art. The same is true of other branches of study.

Natural or Mechanical Philosophy.—The pupil, now advancing to his eleventh and twelfth year, may proceed to the elements of mechanical philosophy, by custom, though too extensively, called *natural philosophy* or *physics*: seeing that, under that denomination, chemistry and even natural history have as good a claim to be ranked. It is a question whether this branch of physical science, or chemistry, should be studied first. We think they may, in their elements, proceed together; but if singly, it seems rather more natural to attend to the more visible and tangible properties and powers of matter, unchanged in its substance, than to those that require a change in the constitution of matter, often its destructive analysis, to ascertain its composition. All should be familiar with the laws of matter and motion—with matter's impenetrability, extension, figure, divisibility, inertia, attraction, cohesion, capillary attraction, chemical attraction, magnetic attraction, gravitation, repulsion, heat, evaporation, contraction, ignition, density, specific gravity, compressibility, elasticity, dilatability; with motion and forces, weight in falling bodies, centre of gravity, pendulum, centrifugal force, projectiles, action and reaction, motion in elastic bodies, reflected motion, composition of motion and of forces.(15)

Mechanics and Machinery.—The pupil, after having attained a competent knowledge of the above particulars, may proceed to study the mechanical powers, and their philosophy—the lever pulley, and inclined plane, which are the primary mechanical powers; while from the lever and inclined plane come the other three, or secondary mechanical powers—the wheel and axle from the lever, and the wedge and the screw from the inclined plane. The combinations of mechanical powers, friction, human labour, horse-power, draught, water-power, and steam power, and all the science of machinery, will naturally follow.(16)

Hydrostatics, Hydraulics, and Pneumatics, will next in order engage the pupil's attention; and he should not be suffered to proceed without having mastered, by the test of strict and searching examination, the previous subjects, which form a series.

When he has become familiar with the mechanics of solids, he will proceed to the study of the laws of fluids, including the aëriform fluids. The hydrostatical part embraces pressure of water, levels, specific gravity, fluid support, &c. Under hydraulics—the hydraulic press, aqueducts, fountains, friction betwen fluids and solids, action of water in rivers, waves, change of temperature, &c.

Under pneumatics are comprised—the atmosphere, laws of air, pressure of air, the air-pump, pressure of air on solids and liquids, on mercury; the barometer, pumps, siphons, steam, latent heat, winds, sea and land breezes, ventilation, diving-bell, buoyant property of aëriform fluids, balloons.(17)

Optics, Acoustics, and Astronomy, will complete a course of natural philosophy.

Chemistry.—It will now be time to lay a foundation for the pupil's future progress in chemical science, and at the same time impart to him a practical knowledge of the chemical laws and operations which are at work around him in daily life.(14) Such are respiration, combustion, heat, light, water, poisonous gases; these are all matters upon which comfort, health, and life itself, may depend. The teacher should begin with showing experiments, and should be possessed of a museum of substances and chemical agents, with an apparatus.

Animal Physiology.—The important purpose served by including this subject in juvenile education, is the preservation of health, not its restoration when lost; the *prevention* of disease, not its *cure*, with which last the ignorant cannot be trusted. It ought to be impressed as a maxim, that although we ought not to be our own doctors, we need not be our own destroyers. We ourselves can bear testimony to the successful and gratifying introduction of this study in a Scottish parish school in Falkirk, under the care of Mr. Downie; and to the interest taken by the pupils of both sexes, from nine to twelve years of age, in the lessons, which are illustrated, as they ought always to be, by diagrams.(13)

Mental Philosophy.—This is a department of science which it is the fashion of our age to overlook. Yet what can be more important than a knowledge of that wonderful power by which we think and act, and which more especially connects us with the things above and beyond this humble and transitory scene? No serviceable manual as yet exists for imparting a knowledge of mind in schools; but an intelligent master has it in his power to do much by oral instruction.

Mathematics.—This important branch of study cannot be omitted in elementary education. In its widest sense, it is that science which treats of measurable quantity, in magnitude and in number. *Geometry* is the branch of mathematics which treats of that species of quantity called magnitude, both theoretically and practically. Theoretical geometry investigates the relations and properties of magnitudes in three dimensions—as lines, surfaces, and solids. Although magnitudes have no *material* existence, they may be represented by diagrams. That branch of geometry which relates to magnitudes described on a plane, is called Plane Geometry. This requires six elementary books—a book on the quadrature and rectification of the circle, a book on geometrical maxima and minima, an exposition of the method of geometrical analysis, and an additional second and fifth book. The basis of the first six books should be the *Elements of Euclid*, as given in the very correct edition by Simpson, with the improved fifth book by Playfair, and the other improvements of the latter geometrician contained in his original edition of Euclid's *Elements*. The pupil will proceed with the definitions, postulates, and axioms.(18) Solid and spherical geometry and conic sections (19) will next engage the pupil; and, finally, the elements of algebra.(20)

Elocution may be the next pursuit of the pupil. In this branch of study, the subjects of articulation, inflection, modulation, and the measure of speech, will be familiarly explained.(25)

History, &c.—History and biography are important branches of information, of which it is well to acquire the elements at school. The history of the mother country, its literature, and great men, has the most immediate claim upon attention, after which come the histories of the countries to which geographical and political circumstances, or any other cause, have given importance in our estimation.(21 22 23 24)

Natural History.—As a study for the last two years of the fourteen, ought to be reserved natural history, which is better understood, and more beneficially acquired, after than before the study of the elements of chemistry and mechanical philosophy. The pupil, in this branch, will learn to distinguish the animal, vegetable, and mineral kingdoms; the atmosphere and its phenomena; the winds, the ocean with its tides and currents; the discoveries of geology; the nature of animals and plants, &c.

Political Economy.—A pupil who has entered his fourteenth year, with his mind stored with the knowledge and strengthened by the exercise of the education we have described, should be introduced to the elementary principles of political economy. Society suffers in its vital interests from the prevalence of ignorance and prejudice in this great field of speculation and action.

Logic.—The elements of logic appear to us to form the appropriate conclusion to our practical elementary course from six to fourteen. All that precedes it is knowledge, and as such chiefly addressed to the *knowing* faculties of the mind. But man has also *reflecting* faculties; and it constitutes the chief end and object of our knowledge to furnish these with materials for their exercise, which is called reasoning. This, the highest operation of mind, is regulated by laws in the nature of things, which right reason both discovers and obeys. These laws systematized constitute the science, practically the art, of logic. The pupil, while he masters its principles, should be well exercised in their application.

Religion.—The first principles of religion are understood to have been imparted under the circumstances indicated in our section on moral education. In a school-course, due provision must be made to carry out this all-important department. Looking only to what the principles of education ask from us on this point, we would direct, first, the continuation of the method formerly described; next, daily scripture reading; next, a subjection of the individual pupils to the agency of the ordinary means of diffusing religious knowledge and maintaining religious impressions.*

Languages.—Though it is a great error to regard the acquirement of one or two ancient languages, and a school study of a few of the books written in them, as constituting a liberal education, unquestionably a liberal education ought to include that acquirement and that study. The commencement of a classical course, as it is called, may be made during the latter part of the elementary period; but it should mainly be postponed till after fourteen, when the comparative ripeness of the mind enables a pupil to acquire more of this kind of knowledge, and that more effectually, in one year, than in three or four at an earlier stage. The study of the classical languages is a special education, required by those whose occupations are to be of a philosophical or literary character. In an expressly literary education, they would always form a conspicuous element. And the refining effect which the admirable productions of the Grecian and Roman writers is calculated to have upon the minds of all must be at once admitted. The abuse of these languages in education has been solely in their being made the sum and substance of all education, and, though in a less degree, in their being taught at a period of life when it is impossible to experience their softening and improving influence.

MECHANISM FOR EDUCATION.

The mechanism for education may be said to be of two kinds—that which is furnished in the family circle, and that which is furnished by public establishments.

The mother is an educator of nature's appointment, and the first. To her falls the duty of securing the sound organization of the infant as far as it can be done by obedience to nature's rules before and after his birth. She has the duty of drawing his senses and intellectual faculties into that gentle exercise which gives them vivacity without being attended by danger, and that of establishing the basis of regular and correct moral habits. For all these purposes she is in a position of great influence; for her infant, accustomed to look chiefly and

most immediately to her for protection, kindness, and every comfort, is unavoidably disposed to pay to her that veneration on which genuine influence depends. She is, as has been well said, the DEITY of the child, and nothing but a sad misuse of her own feelings can prevent her from being all-powerful over him for the regulation of the whole economy of his being, at least during the first two or three years of his life.

So far as moral education depends, as we have shown, on moral atmosphere, and the influence of immediate example, the importance of home as a part of the mechanism of education must be acknowledged. Before the period of school attendance, home is all in all: thereafter, it still continues to bear a great share in the duty. The formation of moral habits, and the development of religious feelings, will depend much on what is done in these respects in the family circle. Parents may even serve as aids to the business of school, to a degree of which they have in general little conception. First, they may do much in the way of enforcing and providing for that important requisite, regular attendance. Second, they may strengthen the hands of the teacher by paying him proper respect. Compared with these objects, the mere superintendence of lessons given out to be learned at home, is, though itself important, a trifle. There is a tendency in parents to be over-easy in the admission of excuses for attending school; and they often take away their children for a considerable time, for reasons affecting their own conveniency and pleasure. It is also not uncommon for them to look down upon teachers, and speak of them, and even to them, in no very respectful terms. All these are errors of a fatal character, seeing that they weaken the school mechanism in some of its most important requisites.

A child becomes a fit subject for the education of public establishments at two years of age. From this age till six, he should, if possible, attend an infant-school.

The *infant-school*, although a modern invention, is a part of educational mechanism which is now generally approved of throughout Europe, being in vogue not only in Britain, France, Holland, and Germany, but even in Italy. It is, when rightly constituted, only a nursery upon a large scale—a place where infants may be reared in company instead of being kept in solitude—where they may be reared in pure and well regulated circumstances, instead of being exposed to the contaminations of a public street. It is peculiarly essential for the children of the poorer classes, who are otherwise so liable to become a mere infantine *canaille;* but it might be well for children of every grade to be brought up in infant-schools, as society is essential to the working out of many of the problems of education.

An infant-school should generally be calculated for about 100, or not more than 140 pupils, of both sexes. Two teachers, male and female (if possible, a man and his wife), are required, the one to superintend the boys, and the other the girls. The school should be well ventilated, and fitted up with a long gallery containing six or seven tiers of seats, and divided into two departments for the various sexes, the younger children being disposed on the lowest forms. The walls should be furnished with drawings of natural and other objects; and a black board and arithmetic-ball frame should likewise be provided. A piece of play-ground is so essential, that no establishment without one is entitled to be considered as an infant-school. It should have flower-borders, which the children are trained to respect, and places of convenience where cleanly and delicate habits are inculcated. A circular swing is required for the amusement and to promote the physical health of the children; and it will be well to have a quantity of wooden prisms, of the form of bricks, with which they may engage in the building of houses, towers, and other structures, according to fancy.

The intellectual education of an infant school is limited to the learning of little hymns and knowledge rhymes, the study of simple geometrical forms, and of the merest elements of arithmetic, exercises upon narrative passages of Scripture, the properties of objects, the characters of animals, the names of countries and cities, &c. In some, reading and grammar have been introduced to satisfy prejudiced parents; but these are departures from the right character of the institution. Most of the lessons are metrical, and sung to simple airs. The moral department, confessedly the chief, consists in the learning of good precepts, scriptural and otherwise, the fostering of kindly, and gentle, and the restraint of angry and malevolent feelings, the formation of conscientious, polite, and delicate habits. It is remarkable how far a good infant-school teacher can accomplish these objects, and how quickly any new pupil is brought into harmony with the spirit of the place.

An infant-school teacher requires a union of qualifications which is not often attainable. He should possess a gentle and affectionate character, with an unlimited patience, yet have that intellectual activity and vivacity which are necessary for sustaining attention in young children. He must both be a well-informed man and capable of making what he knows intelligible to those who know nothing: he must both be firm and discreet in management, and possessed of manners of almost infantine playfulness. A knowledge of music and a good voice are among the qualifications which he requires.

The elementary schools following upon the infant seminaries (where these exist, or, otherwise, being the first schools), are different in different countries, not only in the materials and modes of instruction, but in the extent to which they carry on pupils. In Britain, they are generally in a state considerably inferior to what is found in Holland and Prussia. In a rightly constituted system, there would be two seminaries between the infant-school and the university, the first or primary school being devoted to those branches of instruction in which all should participate, and the second or secondary school affording continued and more advanced instruction to those destined for professions and for the more important places in society, and as such being preparatory to the university. The parish-school and the grammar school of a small Scottish burgh may be considered as an arrangement approaching to what is required in this respect.

The primary school is applicable to the ages between six and ten or eleven. In a country under a national system of education, one would be required for every group of population above a thousand in number, as the attendance would then probably be from a hundred to a hundred and fifty. Reading, grammar, arithmetic, the elements of geography, history, and science, and moral training, would form the chief features of the business of a primary school. And to this extent all should be educated. It follows that infant and primary schools ought to be special subjects of state provision and care. Society is expressly interested in seeing all children trained and instructed thus far, that they may become a moral and intelligent population. So strongly is this regarded in Prussia, that education, up to the point in question, is enforced by law. Certainly, it is at least well to encourage parents, by all means consistent with the spirit of a free country, to have their children educated to this extent. While the state, then, regulates the education of infant and primary schools, the state should also furnish it gratuitously, or all but gratuitously, thus removing all difficulty which may be felt by indigent individuals, the very class whose children are apt to become most dangerous if left uneducated. It has often been objected to the idea of gratuitous education, that what is obtained for nothing is not valued; but the education furnished by the state (or, as an alternative, by local assessment) would not be really gratuitous. Every parent would know that he contributed to the fund by which the school was supported, and that this was much the same thing as paying fees.

In order to ensure a supply of well-qualified teachers, as well as for the sake of uniformity of methods, the infant and primary schools would each require district normal schools. Teaching is an art. It is one of considerable nicety, requiring both natural and acquired gifts of no ordinary kind. Without a due apprenticeship to it, no man can be expected to satisfy the demands of the modern educationist. There is a large amount of detail, both in the methods of procedure and in the material of instruction, which a candidate for this employment must have thoroughly mastered before he can duly teach. There is also an aptness and facility for the duty which nothing but practice can give. For all of these reasons, schools for the training of teachers, or normal schools [so called from *norma* (Latin), a rule,] are indispensable. We have not room here to enter fully into the details of a well-constituted normal school of any kind, but may pause for a moment to indicate the important principle, that it is not sufficient for a young man to sit by, observing the procedure of a well-conducted school; he must enter personally into the business, and be accustomed to act as teacher himself, in order to attain the right qualifications.

We have considered the infant and primary schools as comprehending the education required by all the children of a state, and as therefore calling for state support and regulation. For this reason, we have indicated a conclusion to the primary school period somewhat later than what is practically the case in schools answering more or less to this description. Generally, the primary school period may be said to end at nine years of age, at which time a boy, for example, is considered as fitted to commence a classical course in a higher school. While the material of intellectual education remains generally as it is, this arrangement will be appropriate; but if we consider some branches of general knowledge as necessary for all, we must postpone the conclusion of the primary period to ten or eleven. At that age, the children of the humbler classes would be fitted to commence the active life to which they are usually destined, while others would be equally ready to go forward into advanced schools.

The secondary school—answering to the grammar schools and academies of Britain, the colleges and *pensions* of France, the gymnasia of Switzerland and the German states—is the first school appropriate chiefly to the middle and upper classes. As its benefits are not universal, it should be supported solely by those who take advantage of its instructions, although the state may extend to it protection and regulation. The higher intelligence required of the middle and upper classes, and the special education required for the professions which many of these classes are called to follow, constitute the necessity for secondary schools. They are introductory to a university course for those who are to follow law, medicine, divinity, or any of those other occupations which are now rising into the same rank with the "professions;" those otherwise destined here obtain that comparatively liberal education which is required in the middle walks of life. The course of instruction proper to a secondary school corresponds with what has been pointed out in the preceding section as the advanced department of intellectual education. It may here be proper to remark, that, when we speak of certain classes of the community attending this advanced order of schools, we do not mean that these are to be conducted on exclusive principles. Let their fees be as moderate as possible, and let all who can afford attend. In such circumstances, it would often happen that children of the humbler classes, who showed an aptitude for a superior education, would obtain it, and be thereby enabled to make an advance in life suitable to their faculties.

Religious instruction is presumed, as formerly indicated, to be imparted, throughout the whole period of elementary education, in schools. Here a difficulty as to arrangement unfortunately arises from the various views which are taken on doctrinal points. The teaching of doctrine according to the views of any one denomination, necessarily precludes from the school where it is done, the children of those who dissent from the views in question. On the other hand, if doctrine be excluded, those who are most eager for the inculcation of particular doctrines or for the maintenance of particular religious institutions, are offended. To obviate the difficulty as far as possible, a particular arrangement has been made in Holland, in the Irish national schools, and some others; Scripture reading is there confined to such parts as include no controverted doctrines, and to a general reference to the Bible on preceptive points, and all else is taught to the pupils, at extra hours, by their particular pastors. It is thus thought possible to teach religion as efficiently as by any other plan, while the school is allowed to be a common good to all classes of the community, and a means of bringing up the children of religious parties in harmony together.

INDUSTRIAL EDUCATION.

The mingling of industrial arts with education, is an idea of modern times. One of the first examples of it, by which general attention was attracted, originated at Hofwyl in Switzerland, in 1806, under the care of a man of fortune still living, M. de Fellenberg. Here the object was to teach farming on improved principles, while general education was conducted on an almost incidental plan, at intervals, by the superior of the establishment. Schools of this kind have since been planted in other parts of the continent, and in the United Kingdom. Latterly, industrial education has been extended from agriculture to handicrafts.

As a specimen of a purely "agricultural school," we select that of Templemoyle, near Londonderry, which appears to be conducted in an efficient manner. Established in 1827 by the North-West of Ireland Agricultural Society, for the purpose of giving young men "a plain English education and a knowledge of the principles and practice of agriculture," it lately contained sixty-six pupils, for each of whom a small payment was made. The superiors are a teaching farmer and a schoolmaster, beneath whom is a matron to superintend the domestic establishment.

"At half-past five the pupils rise, arrange their rooms, say their prayers, and, in two divisions, which alternate on different days, are engaged until eight in study or in work; half the pupils are with the farmer, and half under the schoolmaster, except on extraordinary occasions, when the services of all are required for the farm, or the season releases them from their agricultural duties. At eight they breakfast, and are free until nine; work and attend school in alternate divisions, from nine until one. Dine at one, and have recreation until two. From two to six, are at work and in school alternately. From six to seven, sup and have recreation. From seven to nine, prepare the lessons for the next day, have prayers, and retire at nine. On Sundays they attend their respective places of worship, and occupy a part of the remainder of the day in religious reading.

"The intellectual instruction consists in spelling, reading, grammar, geography, arithmetic, writing, and book-keeping, with some elementary and practical geometry and trigonometry. The farmer gives lectures also in the evening upon the theory of agriculture. It is intended to introduce lectures on botany and agricultural chemistry.

"The practice includes all the operations of farming, under the different approved systems; the rearing of cattle, the management of a dairy, and, in general, the incidental as well as the direct occupations of the farmer or agricultural labourer. The head farmer, or agricultural master, is expected to explain the principles of the work in which the pupils are engaged, and to take opportunities for incidental instruction. The operations which he is specially called upon, in the regulations of the committee, to teach, are, ploughing and the setting of the plough, the use of farming instruments in general, the qualities of stock and modes of recognising them, the treatment and management of dairy and farming stock, the making and repairing of fences, the rotation of crops and those best adapted to different varieties of soils, the modes of draining, reclaiming, and improving lands, and the most recent inventions and improvements in agricultural implements. The farmer takes those who are sufficiently advanced in knowledge and age to be benefited thereby, to the fairs, to assist in the sale of the products of the farm and stock.

"The pupils are divided, for work, into sections, each of which has its monitor, or chief, and consists of eight or ten boys. The head monitor, or superintendent, has the control of them, in the absence of the master, and arranges with him the distribution of their time, takes an account of the stock, and of the products of the labour, and advises with the master in regard to the farm, in such a way as to prepare himself for actual superintendence. This place is occupied by the elder pupils in rotation.

"The farm consists of one hundred and thirty-three acres,* of which one hundred and twenty-five are arable land. It is worked so as to present examples of the most approved rotation of crops, the fields embraced in the same series of shifts lying adjacent to one another. The whole is drained by underground drains, according to the Scottish system, and is well enclosed with different fences as specimens, and trials of the various kinds."†

Industrial village schools are well exemplified in that of Ealing, about five miles from London, established by a benevolent lady. The principles held in view in establishing this seminary were, that the children should early acquire habits of patient industry; that they should be acquainted with the value of labour, and know the connection between it and property; that they should have intelligence, skill, and an acquaintance with the objects by which they are surrounded; that the higher sentiments, the social and moral part of their being, should receive a full development. The industrial occupation is gardening, pursued in a piece of ground connected with the school. "It is divided, one portion being reserved for the use of the school, another being subdivided into small gardens for the boys. The pupils work in the first under monitors, and receive a compensation in proportion to the useful results of their labour. The second they hire at fixed rates, and dispose of the produce as they please, always receiving, however, the market price for it from the school, if they choose to dispose of it there. The younger children are not allowed to undertake gardens on their own account, but work for others or for the establishment. Partnerships are sometimes formed among them for the more advantageous cultivation of larger pieces of ground. An account current with each pupil is kept, in which he is charged with the rent of his ground, and the seeds and plants which he has purchased from the stock, and credited with the produce which he has sold to the school."*

In-door occupations are less desirable in alternation with school instruction than these healthy out-of-door labours, but must have the effect of training to steady and persevering habits, not to speak of the actual skill conferred by them. As an example of a school in which such occupations are pursued, we select that of the Royal Military Asylum at Chelsea, where 600 children of non-commissioned officers are reared. Those above eleven are here taught handicrafts, about four hours a-day of three days of the week being thus devoted. "Rather less than a hundred boys work as tailors; fifty each day alternately: about the same number are employed in a similar manner, as shoemakers, capmakers, and in covering and repairing their old school-books; besides which, there are two sets or companies of knitters and of shirt-makers, and others who are engaged as porters, gardeners, kitchen-work, &c. Every thing is done by those who work at the trades except the cutting-out. This branch, requiring more experience, is managed by the old regimental shoemakers, tailors, &c., who, with aged sergeants and corporals, and their wives, manage the concerns of the institution. The system of monitors and teachers to overlook the other boys at work is generally adopted; while, in addition to the various branches of industry mentioned, the school furnishes a company of drummers and fifers, and an excellent band of music; the players necessarily devoting a considerable part of their time to the practice of their instruments."† Though there are some defects, the asylum is allowed to be "an evidence that a greater degree of progress may be made in reading, writing, and arithmetic, and in other branches of learning, than is attained in the great majority of schools, and yet that the boys may be taught music, gymnastic exercises, and various useful trades; thus improving their health, increasing their means of enjoyment, and promoting their future interests, much more effectually than by the prevailing methods."‡

Industrial education is practised with marked success in various institutions for the reform of young criminals, as in Parkhurst Penitentiary, Isle of Wight, and the Warwick County Asylum; in several for the refuge of destitute persons, as in that at Hoxton, and the Guernsey Hospital; and in various schools for orphan and pauper children under the New Poor-Law Act, of which that at Norwood is a most interesting example. It is not as an *improvement*, which may or may not be adopted, that industrial education is here to be advocated: it is called for as something *absolutely necessary*, to counteract an inherent tendency of all asylums for the maintenance and education of children to become monastic institutions. The children are kept apart from external nature. From human society, and from many or most of the common operations of life. They come out as helpless nearly as they went in. Industrial education presents itself as almost the only conceivable means of fitting such children for entering the world in any thing like the same condition as other children. It is not essential that any one child be made a proficient in any one art; the great end is to make them generally acquainted with the arts of life, and to prepare them by habits of industry for earning their own bread when they grow up. From the attention which the Poor-Law Commissioners are giving to the subject, we have no doubt that in a short time we shall see the whole or the forty-five thousand orphan and pauper

---

* A plot of the ground, as surveyed by the pupils, and drawn by one of the number, was presented to me, showing the details of the arrangement, and the classification of its parts. The construction of this drawing was one of the practical exercises of the class.

children of England educated in this wholesome manner. In the late reports of the commissioners there are some excellent hints thrown out. Different arrangements are recommended for different districts. It is suggested, that in an agricultural district there ought to be a large garden which the children should be taught to cultivate, in order to become acquainted with those duties which they will probably be called to perform when they are sent out into the world. They should also be taught to erect sheds or outhouses, to make wheelbarrows and other simple utensils, and to fashion desks and forms for the school. Thus, as farm-servants, they will be able to execute a number of little jobs in carpentry, which would otherwise require the interference of the proper tradesman. To enable them to contribute to their own personal comfort and that of their household, without an expenditure of their earnings, they should be taught to make and mend their own clothes and shoes, to plait straw hats, to make straw mattresses, and whitewash walls. In a manufacturing district, the employments should bear a similar relation to the trades of the neighbourhood, and in or near a seaport, the arts connected with maritime life should be taught. Such, in brief, are the views of the Commissioners respecting the boys: they recommend that the girls should be trained to the household duties of cooking, cleaning, and washing clothes, sewing and knitting, by having to perform those duties as far as required in the workhouse. It is worthy of remark, that in the Marylebone charity for girls, this plan has been for many years acted upon with excellent results. There the girls are accustomed to make their own beds, to clean their own knives, forks, and shoes, and to be scrupulously clean in their dress. "Their chief employment is needle-work; but they are employed in rotation to scour the school-rooms, the play-rooms, and the washing-rooms, the tables, forms, and stairs, as well as to prepare and remove the meals of the rest of the scholars, and to wait upon the domestic superintendent and officers."*

The reporter of these circumstances adds, and we fully concur in his sentiments—"The value of charities of this description is too obvious to require particular comment. By establishing *good habits*, they doubtless accomplish more than can ever be effected by mere precept; and they not only tend to make useful servants, but provident, neat, and intelligent wives and mothers. If it were possible to engraft some part of such a system on the national and other schools, these advantages would become generally diffused, and the consequence would be a great increase in the comfort of the houses of the poor, and an accompanying contentment, productive of the best results on the character, among young married men of the working-classes, whom the extravagance or mismanagement of untidy and ignorant partners often drives to alehouses, and other resorts of idleness and dissipation."

* Quarterly Journal of Education, i. 287

DRAWING AND PERSPECTIVE.

Drawing is an imitative art, by which the forms, positions and relations of objects are represented on a flat surface. The faculties employed in this as in other imitative arts, are possessed in a certain degree by all persons. Some possess these faculties in so high a degree, as to become fitted to exercise them as a profession, for the gratification of mankind at large. In others, they are manifested so moderately, that a protracted effort to make such persons become tolerable draughtsmen would only be labour thrown away. The majority, however, are so far endowed, as to be able, when instructed, to delineate any simple object, and to enjoy much pleasure from higher delineations produced by others.

The practice of elementary drawing at school, hitherto greatly overlooked, is calculated to produce the most beneficial results. As regards those who possess the faculties for design in a high degree of excellence, early practice will awaken those faculties, and, furnishing them with stimulants to progress, secure the benefit of their ultimate exercise for the community. Lesser degrees of excellence will also be developed—such as would in vain perhaps essay excellence in the higher walks of art, but might become of incalculable value in connection with certain branches of manufacture.

As a means of elevating tastes and desires, and thereby embellishing what might be otherwise a routine of commonplace existence, drawing appears in its most interesting light. The person who has acquired a knowledge of botany feels a new pleasure in examining the parts of a hitherto unseen plant; he who has acquired a knowledge of geology is interested in passing along a road, the side of which displays a deep section of rock, or from which he may view various granitic elevations; he who has acquainted himself with the principles of machinery experiences an enjoyment in contemplating the intricacies of some great engine, which another knows nothing of; and in the same manner he who has studied the art of drawing discovers a source of new and innocent gratification in the innumerable forms and tints of external nature. Things formerly passed with a careless eye and a vacant mind, then assume a character which arrests attention and awakens thought. Those faculties of the mind which perceive and appreciate the figure, colour, and arrangements of objects, and trace in all a natural and appropriate beauty, spring up from a dormancy which might have otherwise known no interruption; a new association of our mysterious being with the physical world around us is practically established; and the value of existence becomes by just so much enhanced. Not surely that it is desirable that an absorbing interest should be created in all minds respecting the outward aspect of nature, to the neglect of the more serious affairs of life. All that can be contended for is, that as many as possible should be rendered capable of looking with pleasure, instead of indifference, upon the beauties of nature, so that they may realize the benefit of this part of the intellectual and sentimental powers which have been conferred upon them; a portion of their nature which, like others, may be abused, but, in its moderate use, is not only a source of innocent pleasure, but may become the means of anticipating and supplanting many pursuits of a less worthy character. Nor, while the art is perhaps chiefly acquired with these views, may it be without some results of a more directly useful kind. In many situations—when wandering in our own, or roaming in foreign countries—we may see objects of which we would be glad to carry away some memorandum, and of which the slightest pencil sketch would be sufficient to awaken a recollection at any other time. And yet, for want of a few elementary lessons in drawing, many of even those who travel for the purpose of informing the public, are unable to commemorate such objects, or, at the best, can give only a few scratches, which a professional artist has afterwards to fashion into shape—a shape, of course, in which correct representation is not to be looked for. In this point of view, drawing takes its place, as a useful art, by the side of writing, being, like it, a means of description, and one which may occasionally be even more serviceable than that art, though certainly not capable of so general an application.

Referring to the volumes on Drawing in our EDUCATIONAL COURSE for a methodic series of instructions, our design on the present occasion is to present a popular view of what may be done by comparatively unlearned persons to acquire a knowledge of the art, including perspective, which is the foundation of all pictorial delineation. It will be understood, then, that in all our observations we address ourselves directly to the pupil.

DRAWING.

Drawing is effected by various materials, as chalk, black-lead, or coloured pencils, Indian ink, &c. Drawings of a simple kind are made principally on white paper or Bristol board, but also sometimes on tinted papers, in which case the lighter parts are brought out by white crayons. Commence a study of the art by acquiring ease of hand, and in fact learn what the hand can do by its different evolutions. For this purpose, drawing lines with chalk on a black board is perhaps the best exercise. Either, therefore, on a board with chalk, or on paper with a pencil, learn to make drawings of lines, straight, curved, or a modification of either. Observe how much more beautiful is the appearance and effect of a curve in comparison with a straight line, and how nature delights in this waving of forms, of which we have examples in the bending of boughs in trees, the serpentine winding of rivers, and the curvilinear forms of animals.

You may begin the drawing of objects by copying other drawings; but this species of exercise can only make you familiar with the manner in which lines answer the purpose of representation. To be master of the art, you must throw aside all drawings or copies, and learn to draw by your own ingenuity from tangible objects in nature and art. In this study, the hand is taught to obey the conceptions of the mind. When, for example, we see a chair standing on the floor, we observe its shape or figure, its line of back, seat, legs, and all other parts about it. We then take a pencil, and bending the mind intensely on the form of the chair, try to define all the lines of the object on the paper or board. The more perfectly that the hand can obey the direction of the mind, while bent in thought on the object, so will the drawing be more true in all its details.

The pupil, therefore, must be taught to call up the whole power of his mind respecting the appearance of an object, when he wishes to represent it by a drawing. On this, indeed, may be said to rest the fundamental principle of delineation in all its branches. No one can possibly attain even a mediocrity in the art, who does not, less or more, possess this power of recalling images to the mind, and of training his hand to act in strict conjunction with its dictates. The hand is only the instrument employed by the imitative faculty, and can do nothing useful without the strong concurrence of the will. Accomplishment in penmanship, and every other art in which design or figure is an element, is founded on this fundamental basis.

In these elementary lessons an idea of perspective will be unconsciously gained. It will be noticed that strong outlines mark the objects or parts of objects nearest the eye or in the foreground; while, to make parts retire, or have an appearance of being at a greater distance, the lines must be made light, and the representations smaller. It is a matter of first consequence to bring out effects on a broad scale, not by repeated small markings, but by a comparatively few bold lines of greater and lesser thickness. You will observe that an object may be represented in two ways—first, by mere outlines describing its figure; and, second, by introducing strong shades among the outlines. Take, for illustration, figure 1. Here the blades of a plant are re-

Fig. 1.

presented by a few thin and thick lines properly disposed, and by a little shading being thrown in to bring out the effect.

Fig. 2.

A just idea of the value of lights and shades may be said to be the beginning of all excellence in pictorial delineation; and you are recommended to lose no opportunity of acquiring it. The most simple objects afford examples. In fig. 2 we have a group of this nature, being a stone, a piece of broken wood, and the leaves of a tall grassy plant, such as may be observed in a field or by the roadside.

Mr. D. R. Hay, in his excellent work, "The Laws of Harmonious colouring," has the following practical observations on the method to be followed by young men in gaining a knowledge of drawing, with reference to patterns, decorations, and ornamental designs:—"The course of study I am about to point out is within the reach of all—even those in the most humble situations of life. They will find it of easy acquirement, and a source of continual enjoyment, in the improved medium through which it will lead them to view the most ordinary productions of nature. She shall be their instructor; for all that I can pretend to do is to point out to them a practical mode of receiving her lessons. To the uninitiated I therefore address myself; and let them not be dissuaded from beginning, by having no predilection for the study—the more they persevere the more they will love it.

"In the first place, your attempts ought to be of the most simple nature, and on as large a scale as you can conveniently adopt: therefore, begin by procuring a black painted board or slate of from two to three feet square, and with white chalk practise the drawing of squares, circles, and ovals, without any guide to your hand. You may make yourself copies of these figures by the ordinary rules. When you are tolerably perfect at these, upon the proper combination of which depends all linear harmony, you may practise in the same way triangles, hexagons, octagons, and such other figures as arise from the various combinations of the straight line. Next, by your circular and oval lines, you may form crescents, circular and flattened volutes, regular undulations, and other figures, which arise out of their various combinations, first making an accurate copy to yourself of each figure by measurement, and continuing to practise until you can form it by the eye with perfect ease. Avoid forming your figures by little bits at a time; do each line as much as possible by one sweep of the hand. When you find yourself pretty perfect in this kind of practice, I would recommend you at once to draw from nature. You may take for your first subject a cabbage leaf, the larger the better, and persevere in copying it, full size, until you can represent it accurately in outline, with its principal fibres. You may then vary your practice by other simple subjects of a similar kind, until you find you can do them all with ease.

"Before endeavouring to draw more than one leaf at a time, you must know a little of perspective. The most simple mode by which you will attain such knowledge of this art as will be most useful for your present purpose, is to hang a circular object, such as a hoop, between you and the window; set it a-moving gently round, recede a little from it, and you will find that, as one side of it retires and the other comes forward, the circle which it describes becomes narrower and narrower, until it disappears altogether, and leaves nothing but a dark line, as if a stick instead of a hoop were hanging before you. I recommend you to do this between you and the window, because the hoop will appear like a dark line, and you will thereby be better able to mark the change that takes place in the shape of the circle. Fix it in various positions, and draw from it, and observe that it is a different figure from an oval. You may now hang up your cabbage leaf, or that of any other large and well-developed vegetable, and you will observe the same change in its figure as it turns round. Make an outline of its shape while its front is half turned from you, then bring it from between you and the light, and place it where the light will fall upon it, with its face half turned from you, as when it hung before the window. Take your outline, and within it draw the principal fibres as you see them. To do this properly, will require a great deal of practice, but it will pave the way to your being able to draw the most complete groups of flowers and foliage that can be placed before you. You may now hang before you a small branch of any tree or plant, with two or more leaves upon it—the larger the leaves are the better—and endeavour to make outlines of them, varying their shape according to their perspective, as already described; be particular on this point, for a great deal depends upon it.

"You may now lay aside your chalk and slate, and provide yourself with a few sheets of common cartridge-paper, and some pieces of common charcoal—that made from lime-tree is the best. Stretch a whole sheet of your cartridge-paper upon your board by a wafer or a little paste at each corner. Place before you a cabbage, cauliflower, stalk of dock-blades, or any such large vegetable, and they will be more picturesque if the outer leaves are hanging loose. Copy these carefully in outline, using your charcoal gently, that any inaccuracy may be easily dusted off. A large thistle with its foliage is likewise an excellent example, but more difficult. Indeed you cannot go wrong in your choice—hemlock, fern, nettle, are all worthy of your study. From these the richest and most effective of Gothic ornaments were taken by our forefathers. The more you study such subjects, the more beauty and grace you will find in their forms."

When a considerable advance has been made in the elementary department of drawing, it will be proper to go on to the higher stage of perspective drawing, in exact accordance with the rules on the subject. For this you will require the following

Requisites for Drawing.—Among the various articles required in systematic drawing, the first place may be given to a wooden board of convenient size, or about two feet in length by eighteen inches in breadth; it should be perfectly smooth and perfectly squared. On this board the paper on which the drawing is to be executed should be properly fastened. This is done by damping the surface of the paper with a wet sponge, and after it has fully expanded, fastening it down with a little thin glue round the edges; it should be laid on the board evenly, and left to dry in the air.

The next requisite is a flat rule called a T-square; this is a thin straight-edge, or rule, attached at right angles to a short piece of wood much thicker, so that when the cross-piece is moved along any side of the board, the rule will project across the paper, and by its edge pencil lines may be drawn straight from left to right and from top to bottom. To test the accuracy of the square, let other lines be made from the opposite sides of the board; and if they agree with the former lines, by being parallel to each other, all is right. On this the correctness of the drawings will materially depend.

To these must be added a pair of compasses—an instrument so well known, that it is only necessary to remark, that the points should be just so sharp as to hold on the paper without piercing it. The compasses should be held lightly by two fingers and the thumb, and moved with the least pressure which the operation may require.

These simple implements will be sufficient, until a knowledge of the art suggests the necessity for a case of mathematical instruments.

Paper may be purchased of all qualities; for early practice, it is sufficient for it to be what is called *hard*, that is, able to endure being written upon with pen and ink.

Black-lead pencils are of various qualities: a soft pencil gives off the lead too freely, and will not retain its point; a hard pencil wounds the surface of the paper, and cannot be easily obliterated; therefore the medium pencil is best for drawing perspective. The wood should be carefully cut from its point, and the lead sharpened by being gently rubbed on a file, which produces a better point than can be formed with a knife.

Indian-rubber, or a clean crumb of bread, to take out lines incorrectly drawn, is also necessary.

Every student of drawing is supposed to be acquainted with the form of acute, obtuse, and right angles, circles, ellipses, and other simple mathematical figures, and therefore we need occupy no time here in describing them: those who wish to refresh their memory on these matters are referred to our article GEOMETRY.

PERSPECTIVE DRAWING.

The study of perspective is commenced by acquiring a knowledge of certain principles, and the technical appellations by which they are described. The first thing which you will attend to is the existence in all correct perspective drawings of a *horizontal line*. The horizontal line is always the height of the spectator's eye, and, of course, fields or hills may be above this imaginary line in a picture. In the following diagrams, the horizontal line is always marked H. There is a certain point on the horizontal line to which the eye is directed; this is called the *point of sight*, and in the following diagrams is marked P.

As noticed in our article OPTICS, the apparent magnitude of any object is influenced by its distance from the eye; if near, the object seems large, if remote, it is small. It is, then, a most important principle in perspective drawing, to regulate the size of the objects marked according to the distance at which we wish them to appear. We have a good example of this gradual diminution of objects as they recede from the eye, in the manner in which a long avenue of trees seems to close in a point at its further extremity. It would be possible for a person, unskilled in the rules of perspective, and merely by the general directions already given, to give a representation on paper of the manner in which objects thus seem to diminish, as, for example, a row of posts; but as mathematical science gives exact rules on the subject, no one need trust to chance, but appeal to principles of unerring accuracy. We crave attention to these principles, which we illustrate by certain lines in the diagrams which follow.

Figure 3 represents a quadrangular drawing, of which AB is the base. Across the picture, at rather more than

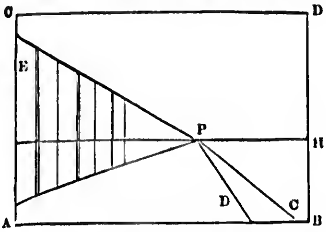

Fig. 3.

a third of the height, is a line H, representing the horizontal line. On the horizontal line, a point at P is the point of sight, and to this point all objects are diminished in proportion as they approach it. Thus, a road represented by the two lines CD tapers to a point at P, and a row of posts E diminish towards the same centre of observation.

The horizontal line, which, it will be perceived, regulates some important points in pictorial delineation, may be placed high or low at pleasure; but it is generally regulated in its elevation by the nature of the subject to be drawn. If placed high up, it leaves too small a proportion of sky, and produces what is called a bird's-eye view; if placed near the base, unless the scene be mountainous, the proportion of sky will be too great. In general, the horizontal line should be drawn at about one-third of the height of the picture. The point of sight may also be fixed at pleasure; but its best situation is removed from the centre towards one of the sides; if directly in the centre, the perspective would have too formal an effect.

When an object having angles, as a box, stands on a base parallel to the horizon, and two of its sides or surfaces can be seen, that which is farthest from the eye will recede according to the situation of the point of sight. Place a box as in fig. 4, immediately in front of the eye; AB is its bottom or base, and EF is the farther edge of its top. AB, the base, being parallel to the horizontal line H, the point of sight will be at P, and the visual rays from the upper corners of the box will centre in P, because the eye is in front, and above the object. Any alteration of the position of the box, or the eye, will consequently require a corresponding arrangement of the laws of perspective.

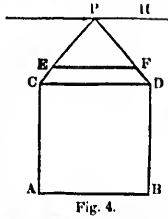

Fig. 4.

Place the box toward the farther side of the table, immediately in front, and lower the eye till the horizontal line is one-third down the box, when the top will be lost sight of; there let the eye be fixed, by resting the chin on any convenient object, and the front, or only one side of the box, will be seen. Then let the box be moved to the left, in a straight line, the position of the eye being retained, and a second side of the box will come into sight; its receding lines or visual rays will then be centered in the altered point of sight, and the side in front will retain its form, because its base is parallel with the horizon. When this experiment has been made, and the situations of the box and the eye have been considered—presuming the box to have been a cube—proceed to ascertain the mode of representing this object according to the rules of perspective, referring to the natural appearance of the box occasionally, the more effectually to fix the mutual resemblances in the mind. Fig. 5 will show the process by which all the particulars may be demonstrated. Presuming the paper is fastened down on the drawing-board, the T-square and pencil ready, commence thus: Apply the T-square and draw the base line AB, and also the boundary of the picture CD. Then draw the horizontal line H across the paper; this may be fixed at pleasure, but parallel to AB. Then find the half of the base AB, and draw a perpendicular beneath the picture to O, and on it place the profiled angle of 60 degrees, just at that distance which, by continuing the sides of the angle, they will intersect the extremities of the base, and together form an equilateral triangle, as AOB: this must be strictly attended to. Now, as before observed, the point of sight is better when removed from the centre of the picture; and taking a station to the right, by a horizontal line from O to S, this becomes the station whence the picture is seen, and the point of sight is therefore found by the perpendicular line from S to P on the horizontal line. Now, as a vanishing point is required to determine the width of the receding side of the box, the profiled angle of 90 degrees is to be placed at S on the perpendicular PS, and the side line continued until it intersects the horizontal line at V, which fixes the vanishing point: this also must be strictly attended to. It will be observed that the angle at S is one of 45 degrees, being the half of the profiled angle of 90.

We now call attention to the situation of the eye, which is always on a level with the horizontal line; therefore, the true position of S is immediately in front of P, or, as if the perspective lines beneath the picture could be raised up to the level of S, and fixed at that distance from the picture, to show the true situation of the eye when viewing the object. The front square shape of the box may then be drawn in, occupying less than half the base of the picture, in order to show the perspective, as at fig. 3; then, from the nearest perpendicular of the box draw the visual rays from the top and the bottom of the square to P, which give the diminutions. Now, a line drawn from the corner of the box near A to the vanishing point V, will intersect the diminishing line, which gave the receding base of the box at L; and a perpendicular line from L to K on this intersection, will give the true representation of the square box as seen in perspective. If this were a cube of glass, the farther sides would be seen, as shown by the finer lines in the diagram.

Repeat this study in different sizes, referring to the natural appearance of the box, in order to feel, as well as see, the coincidence between that and the object produced by the rules of linear perspective. It is of importance that this diagram should be thoroughly understood, because many of the rules employed in it are frequently required.

The boundary of a picture, or the plane, may be of any proportions. The base is marked in fig. 3, AB. The perpendicular, from the middle of this base line, assists in finding the situation for the angle of 60 degrees O, the width of the base, measured from the extremities to the perpendicular O, forming an equilateral triangle

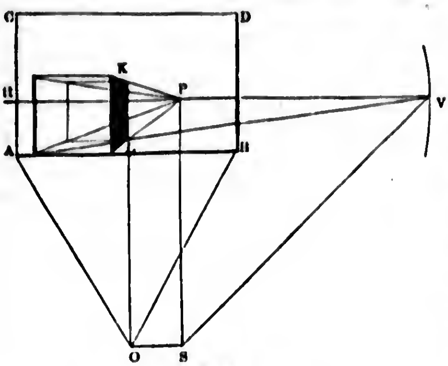

Fig. 5.

as AOB. This is a rule, whatever may be the size of the picture; it also shows the proper distance at which a picture should be viewed. This expanse of vision, at an angle of 60 degrees, is marked in the diagram O, and places the point of sight in the middle of the picture, which is very often objectionable; therefore, a line parallel with the base is drawn from O, and on this line the better station is taken, which is marked in the diagram S. Now, the horizontal line H having been taken at pleasure, a perpendicular drawn into it from S will give the point of sight at P, into which the visual rays are drawn that regulate the receding side of the object. The vanishing point V is entirely distinct from the point of sight, of which there can be but one; but vanishing points may be numerous. This, marked in the diagram V, is of great consequence, for by it is determined the proper width of the object, by the line which intersects the visual ray from the base of the box A to V, as at L; and here the perpendicular to K, which intersects the upper visual ray, completes the perspective form of the object.

No objects better exemplify rules in perspective than articles of household furniture, such as boxes, chairs, tables, and chests of drawers. We direct your attention to the following illustrations: Fig. 6 exhibits a parlour chair and a footstool. Observe that the chair stands with the corner of its seat nearest to the spectator, the point of sight being in the middle of the picture. The receding sides of the chair have their respective parts regulated by diagonals to their vanishing points. The footstool stands on a line parallel to the base, and therefore its visual rays tend to the point of sight in the centre of the picture. These may prepare the mind of the student to consider, that objects, when differently situated, have each their vanishing points regulated by the angle at which they are viewed.

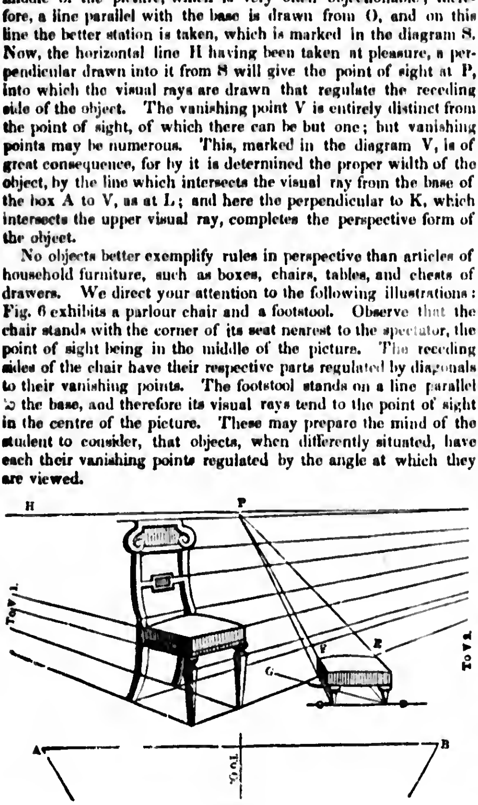

Fig. 6.

We recommend you, on all occasions, to draw the horizontal line so far on either side, that it will be intersected by the diagonals, which are to be drawn at an angle of 90 degrees from the station, into the horizontal line, where they determine the vanishing points. These are only indicated in the diagrams by the direction of those lines, and the words "to V 1" or "to V 2."

In fig. 6, the base line AB is drawn, its centre determined, and the perpendicular drawn to O; the angle of 60 degrees is taken in agreement with the base line, making an equilateral triangle, and the point of sight P is fixed on the horizontal line H. The vanishing points are found by the angle of 90 degrees at O, projected on either side to V 1 on the left, and V 2 on the right, as before described. All the diminutions of corresponding ornaments on the back and front legs of the chair are drawn to V 2, while the side of the chair is regulated by V 1. The footstool is placed parallel to the base on the line CD, and its diminution regulated by the rays EP and FP. The diagonal G from the leg of the footstool D, to the vanishing point V 1, would determine the square of the stool, or the position of the farther leg, at the point where it intersected the ray CP.

Fig. 7 shows the perspective lines required to represent a writing-desk placed diagonally on a table which stands on the base line. The base of the picture is drawn as AB, the centre is taken, and a perpendicular drawn to O, for the angle of 60 degrees. The horizontal line is drawn at H. The parallel is drawn from O to S, and there the perpendicular to the horizontal line fixes the point of sight at P. Then the angle of 90 degrees is taken at S, and the sides being projected to the horizontal line, gives the vanishing points V 1 on the left, and V 2 on the right. Now, the table being seen in front, or on the base line, the visual rays from the legs and the top are drawn to the point of sight P. The table being supposed to be a parallelogram, its side, seen in perspective, will be about half its width seen in front; therefore let half the space seen in front be set off from the leg on the right; and the diagonal from that half to V 1 will give the diminution of the side of the table, where it intersects the ray from the front leg to the point of sight P, at R. A parallel line from this to the ray from the other front leg will give the situation T for the most distant leg. The writing-desk being presented with its corner towards the spectator, both sides will require their receding points, which are determined by the vanishing points V 1 and V 2. Such familiar objects should be drawn, by which the more readily to fix in the mind of the student the leading principles of linear perspective.

It will be seen that, when an object has its base line parallel to the horizon, the point of sight is in the picture, and that it is arranged in agreement with the [illegible] under which the object is viewed. [illegible] object which has four sides, [illegible] those sides be immediately in front of the eye, the visual rays will be hidden, because the point of sight is in or behind the object. It will also be seen, that if the object be moved on either side, or the point of sight be altered by a change of station, the visual rays determine the receding side of the object immediately on a second side being seen.

If the base line of an object be removed from its parallel to the base line of a picture, the angle under which the object is viewed becomes altered in strict conformity with its changed po-sides, the particulars of which the student may ascertain by placing an object in the various positions.

Suppose a chest of drawers, or a cube, to be placed and seen as in fig. 3, and while the nearest corner is to act as a pivot, the end near A. to be moved so as to cause a space between the base line of the

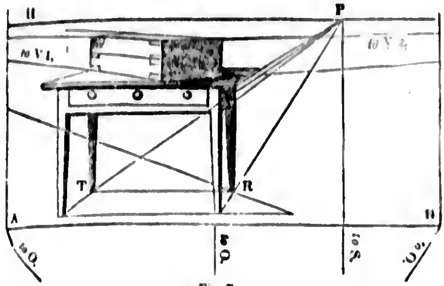

Fig. 7.

object at that end and the fixed base line of the picture, the angle of vision would require that the base and top lines of the object should have their vanishing points. The object could be moved thus in different directions till that which in the diagram is the receding side would become the front, and each position would require a diagram; but the student is presumed to have become acquainted with the fact, that, at each pause in the movement of his object on its pivot, there will be exhibited a diminution on one side, proportionate to the increase of the other side; until, by continuing these rotatory movements of the object, that side which was at first presented obliquely, becomes the front, and its base parallel to the base of the picture. The original front of the object, by the revolving movements, will have been lost or hidden, exactly in proportion as the receding side advanced to the front. Thus the vanishing point extended as the advancing side became more evident, just in proportion as the receding side diminished. Make these experiments, and observe, on the first change of position deviating from a parallel with the base of the picture, that the vanishing point V 1 was required, and so far removed on the horizontal line on the left, as perhaps to require an angle of 80 degrees at the station, while V 2 on the right would then require an angle of 10 degrees. Any subsequent change of position in the object will alter the angles for the respective vanishing points, and these together always making an angle of 90 degrees.

Fig. 8 shows the method by which the situations of windows may be properly drawn in the representation of a house, seen obliquely. Draw the base line AB: find the angle of 60 degrees on the perpendicular from the centre, and mark the station S: determine the horizontal line H, and the point of sight on it, perpendicular to S: find the angle of ninety degrees, and draw the lines to the vanishing points V 1 and V 2: draw the nearest perpendicular of the house C, and fix where the nearest windows are placed, also their height and width, DE: draw these diagonals to the vanishing point V 2; they regulate the diminution of the heights of all the

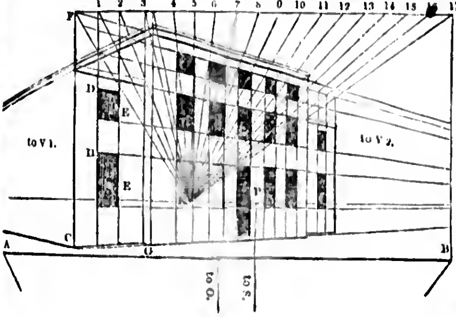

Fig. 8.

windows: draw also the cornice and the base lines; then draw a fine line F parallel to the horizon, and touching the perpendicular C; then, with the compasses, take the measure of the space between the perpendicular C, which is the corner of the house, and the edge of the window D, and mark it on the line F as at 1; then take the width of the window E, and mark it as at 2. It is better to have a second pair of compasses to prevent mistake in the alternate alteration that is required, or the space for the windows may be marked with the point of a needle on a piece of writing-paper, and then marked off carefully on the line F; then the compasses will mark the space between the windows only. The small projection which separates the centre from the wings must be noticed, as at G; then the space with compasses 4, then the window 5, then the space 6, then the window 7, then the space 8, then the window 9, then the space 10, then the window 11, then the space 12, then the window 13, then the space 14. This being the further extremity of the centre of the house, the corresponding projection to G must be noticed, as being so much of the next space hidden behind the projecting centre; it will therefore be marked 15, then the window 16, then the space 17. These compose the spaces and widths of the windows as seen in the front of the house: and it must be mentioned, that the points which have been made on the line F, must be perfectly true on the line, or the truth of the diminution will be impaired. Now, assume a point about the middle of the house, on the horizontal line, as at K, and draw diagonals from all the points made on the line F into the point K, observing that the point of the pencil runs into both at every line. A needle may be placed at K, against which the straight-edge may be pressed, to assist in drawing the diagram correctly. Now, the diagonals which regulated the diminution in the height of these widows, as drawn to V 2, will be intersected by the radii drawn from the point K into the marks on the line F, and those intersections will show the diminution of width according to the laws of linear perspective.

As this diagram may be crowded with lines, you are recommended to examine the intersections carefully, and mark the forms of the windows with a hard pencil, and then draw in all the perpendiculars as regulated by the radii on the diagonal lines. If in this state of the diagram there should appear any confusion, it will be far better to commence another; and the larger the drawing is, the less risk is there of disappointment. The side of the building, that is, the wing and the portion of the centre seen above, with the little projection at G, are drawn by diagonals to the vanishing point V 1.

You are advised not to pass this diagram without having obtained a perfect knowledge of the principles by which the diminutions are regulated. Difficult as this may appear, it ought by all means to be attempted, for it cannot be too strongly impressed on the mind, that no perfection in drawing, no delicacy in finishing, nor boldness of effect, can atone for deficiency in perspective. When a little progress has been made in this, so that the judgment is prepared to understand the arrangements which objects must undergo to be correctly represented on a flat surface, a scene in nature can be sketched without any material difficulty.

Fig. 9 represents a method by which archways are put into perspective.

The base AB, the horizontal line H, and the point of sight P, are determined as in the preceding diagrams. In this it will be seen, that, if the point P had been retained in the centre of the subject, the sides of each respective arch would have been alike; to obviate this, P is placed a little to the left of of the centre.

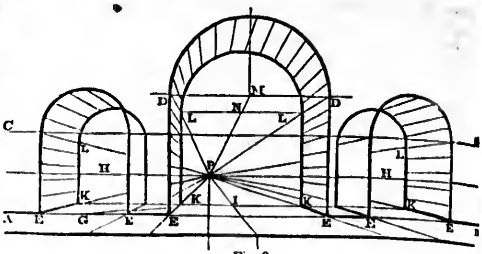

Fig. 9.

This is a subject which may often be met with, and you are advised to study such objects in nature, be they of one or more arches; ever remembering that the station must be preserved with the head towards the point of sight; the eyes only are to be turned from one part to another. You will thus practically learn the distance at which to take a station for such studies. If it be taken too near, too little of the subject will be seen. If it be taken too far off, then there will be more expansion than is required, and the subject will not show the minutiæ.

Suppose such an object as fig. 9 to be in front of the draughtsman: the piers between the arches should be sketched as perpendicularly as possible, and the arches turned by hand: then the depth of the receding sides, as nearly as the judgment may direct, and as much of the masonry as may point out the perspective of the subject: then, while all is fresh in the memory, attach the sketch to the drawing-board, and by the T-square draw the base AB, the horizontal line H, the point of sight P, and the vanishing point V 2; then, by the T-square, correct all the perpendiculars and horizontals; draw the line CC, which is the chord of the smaller arcs, and DD, which is the chord of the large arc, and observe that the perpendiculars intersect the line C and those at the centre arc at D: then find the centre for the arc M, and describe it correctly from one perpendicular into the other: do the same from their centres to the smaller arcs; and thus the superficies of the subject will be defined: then draw the visual rays from the base of all the perpendiculars E, and from the intersections on CC and DD, to the point of sight P, which give the receding lines for the visible sides of the archways. If the piers be square, a line drawn from the base of the perpendicular of the centre archway E, to the vanishing point V 2, will give the perspective width of the receding parts. If the piers be one square in front, and two squares deep, mark off a square to the left of the perpendicular, as at G; and a diagonal drawn thence to V 2 will give the receding depth where it intersects the visual ray EP at K. At this intersection draw the horizontal line I; and where this intersects the visual rays at EP, as at K, raise the perpendiculars till they intersect the visual rays CP and DP, as at LL. Thus will the receding sides of the archway be determined. To find the arc at the farther end of the subject, draw the horizontals LL; and the visual ray MP, where these intersect at N, is the centre on which the arch may be described. The smaller arches are to be found by a similar process.

Now, the correcting of such a sketch by the application of the rules of perspective, will show where the eye and hand have failed in giving a faithful representation of the object. Therefore, again visit the spot, taking a station strictly in agreement with that in the drawing, and compare the corrected lines with those which nature will present. Let all be rigidly examined, and the result will not fail to be satisfactory.

We recommend that every opportunity should be taken to sketch such subjects from nature; they furnish excellent studies for linear perspective, and one such study would convey more information than the copying of a dozen drawings or diagrams.

SKETCHING FROM NATURE.

Having acquired a certain facility of hand, and mastered the principles of perspective, you may proceed to the more agreeable study of sketching from natural scenery. At first, do not attempt any difficult or complex subject. Select some assemblage of ordinary objects, such as may be thought agreeable in themselves, and likely to be represented with ease and satisfaction. The scene selected should not contain more than three or four objects of different kinds—such as a cottage, one or two trees, and a small rustic paling, with perhaps the addition of a little glimpse of background. You will observe that an artist rarely ever takes an object in its broadest and most regular form: he never represents a house, for instance, as if he had taken up his position right in front of it, as an architect would do; nor would he paint a row of trees at a right angle to his own position, seeing that the effect of such representations would be tame and formal. He endeavours to catch the careless grace of nature, as she appears to casual observation. A house, particularly, should always be viewed from a point a little aside from the front, so as to bring in as many of its angularities as possible. A group of natural objects should be represented as if the draughtsman had just by chance got his eye upon it; and yet the selection of a point from which this effect may be obtained must be a matter of study. For an early lesson in sketching from nature, it is enough that the objects be outlined; to fill in details, and give the full effect of light and shade, must be left to a future period in the career of a young artist.

As an example of the scenes which may be selected for early sketches from nature, fig. 10 is given, being simply a cottage backed by a few trees, and having some broken ground in front, while a glimpse of the sea is obtained at the side of the picture. The station of the draughtsman is here at S, in order that the cottage may not appear to have been viewed formally, and that the trees behind may give to the scene its neat pyramidal form, while the broken grounds in front communicate boldness of character, and the straight line of the sea at P (which is the horizontal line) affords a pleasing contrast to the other lines of the drawing.

It will be remarked that the cottage stands on a line parallel to the base AB, the point of sight P is perpendicular to the station S; consequently, the rays that regulate the side of the chimney, the upper and under lines of the roof, and the window on that side of the cottage, all centre in P.

Provided with a sketch-book, (measuring perhaps 10 inches long by 7 inches broad,) the first thing to be done is to select a station from which the drawing is to be executed. A difficulty may present itself respecting the size of the proposed drawing; but the dimensions may be determined in a very simple man-

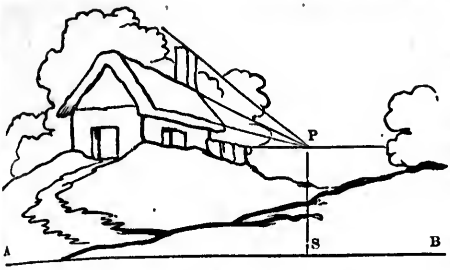

Fig. 10.

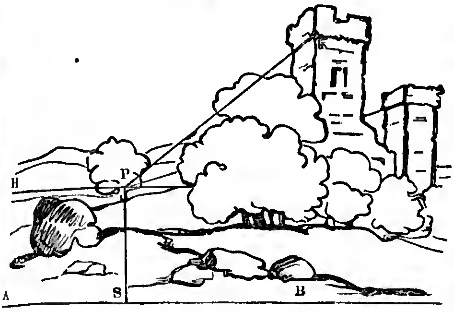

Fig. 11.

ner. Hold up the sketch-book in front, with one eye closed, and the space in the scene covered by the book is that which may be drawn; of course, the farther off the book is held, the less of the subject will be covered. When the extent of the scene is arranged, the book may be gently lowered, and a few dots made on the top margin, merely to point out the relative situations of particular features, as the width of the cottage, and the trees. Then, remembering to preserve the station, mark the point of sight on the distant horizon. Do not be in haste, but judge of the relative distances of the most prominent parts, such, for instance as the gable end of the cottage and its length, and tenderly mark them on the places to be so occupied. When these or more dots for guides have been placed, examine their relative distances, and compare them with the objects, by holding the sketch-book out in front so as to see the agreement between them over the margin. To arrange these particulars well at first, will save much trouble in obliterating falsely drawn lines. Be careful in sketching to preserve the perpendiculars of walls and chimney; that is, by placing them at right angles with the base line, which is now the lower edge of the sketch-book.

To prevent the hand from injuring the sketch as it proceeds, commence on the left and proceed to the right. Endeavour to sketch the lines with a lightness of hand, or with what is called freedom, the effect of which is very distinct from lines drawn by a straight-edge: let them be rather broken, or a little wavy, yet having the general appearance of straightness. Let the masses of foliage be sketched with the same ease and confidence that the capital letter E, or the flourish of the D, are made in writing. Sketch the grounds, in their different undulations, rather more angularly, or as if ruggedly dashed in, and strengthen the lines where separation of parts seem to be required.

In examining the objects of which a scene like the foregoing is composed, you will observe that the lines for the cottage have one character, the lines for the trees another, and the lines for the ground a third character, which detach the objects from each other. A simple outline of these three forms is sufficient to be aimed at, for the introduction of more markings or separations would only tend to confuse early studies.

If the lines, on a first attempt, be not all which could be expected, they furnish a proof that the mind is in advance of the hand, and should operate as a stimulus to exertion. In a few studies you may discover, that, by beginning with a cut point to the pencil, it gradually wears away, and gives an increasing thickness of line; this is often very advantageous, for, as the sketching advances to the foreground, the bolder lines of the pencil contribute to the separation of parts, to regulate distances, and give a more spirited effect to the subject. You will also discover, after a little practice, that, by a gentle twist of the pencil, a fresh point or surface will come in contact with the paper, and with it a finer line may be drawn. Occasionally, by pressing harder on the pencil, an increase of power will be communicated to such parts as may require separation or additional spirit, as on the rude line which forms the foreground in fig. 10, and gradually on the pathway to the cottage door.

Suppose a scene to consist of two or more plans, as the remains of a castle on an irregular surface, with a mass of trees in front, and near it, as the principal or leading feature of the scene, an arm of the sea, and remote hills forming the background or distance, and a rude foreground. We shall suppose that a scene of this nature, as represented in fig. 11, can be conveniently visited. Commence by selecting a station that will present a variety of forms or opposition of character, such as lofty objects contrasted by small objects, which will prevent the appearance of equal heights or parallels, and also prevent the scene from being crowded or closed up. The castle toward one side of the picture, and the distance on the other, so as to form an irregular diagonal mass, are in better relief than if the building with the trees were more in the middle of the subject. The opposition of angular to circular forms produces a pleasing effect in a sketch, and should be observed. If the perpendiculars of a ruin be broken, the general appearance must be that of standing upright; for however mutilated towers or walls may be, there will still be evidences of their having been properly constructed. When these particulars shall have been considered, proceed to arrange the situation of the principal mass, by dotting on the edge of the sketch-book; and by faintly indicating the forms determine the horizontal line, observing that hills may appear far above; in fig. 11, it is at H on the extremity of the water, the station is at S, and consequently the point of sight at P, into which are drawn the visual rays, or lines which regulate the receding sides of the towers. These and the perpendiculars being arranged, they may be boldly sketched in, and the trees freely marked, in a character partaking of the semicircular; the fewer markings the better, for it is the useless separation of parts composing a mass that destroys the breadth and boldness of a sketch. The distant hills may be tenderly indicated with a fine point, and the foreground may be coarsely defined with a broad-pointed pencil, in order to detach it from the parts more distant. Here and there an additional spot or touch of the bold pencil may be given, to assist in preserving the gradations of distance.

The same object in nature will often present many excellent subjects for the sketch-book; even moving to a distance of fifty yards may present a scene of increased interest. Do not therefore fail to take advantage of such stations, and sketch an outline from each, in order to exercise the judgment by comparing the subject afterwards. It is also useful to ascertain how nearly the eye has determined the truth, by applying the rules of linear perspective to every sketch at the earliest convenience. Many advantages arise from two or three students sketching the same scenes in company, for various valuable remarks are thereby elicited, tending to the mutual benefit of the party. The sketch-book should be preserved complete, as containing records of advance in judgment and correctness of delineation.

In drawing from nature, as in penmanship, every person may be said to possess a *manner* of his own. Some draw stiffly, and others with remarkable freedom. You are recommended to catch the tone of those who form their sketches in a bold and free style, but by no means imitate any one. Your object ought to be to draw scenes with *natural truth and beauty*, regardless of all *mannerisms*. At first you can scarcely avoid drawing with a certain degree of formal stiffness, but animated by a desire to excel, and exercising taste and judgment, your practice will improve, and your sketches will not fail to meet with approbation. Whatever be the difficulties you encounter, others whose works you admire were at the outset equally embarrassed; for rest assured that in most cases in which great proficiency has been attained in the art of delineation, no small degree of trouble has been endured, and many failures have taken place, before the artist was finally successful.

Drawing Foliage.—To draw correctly the various kinds of trees, with their respective characters of foliage, requires the most careful study and frequent exercise from nature. In an elaborate work on Landscape Drawing, published by Leigh, London, the following remarks occur on the characters of foliage:—"When a tree is near the eye, the leaves are distinctly separated from each other; their particular form, the insertion of their stems into the branch, the perfection of their local colour, are all apparent. Remove this object to the second plan, the foliage assumes masses, retaining the character, but the tone is altered; the separation of parts is no longer evident, yet it is recognised as the object previously inspected. Remove it still farther from the eye, the masses assume a uniform tone, relieved by indications of light and shade, softened by the intervention of atmosphere. Remove this object still more distant, it is rendered indistinct, and forms a portion of the mass of light or shade in which it may be situated. Nature presents these appearances to every inquiring eye, and the mode of representing them must depend on the perseverance of those who delight in transcribing them into their sketch-books." This is so just, that the student might imagine the tree first inspected retiring gradually into indistinctness, and displaying, as it receded, the due portions of aërial effect. It also teaches how tenderly the outline must be expressed in extreme distance, how much more evident the marking may appear in the mid-distance, how much more defined the form becomes by light, shade, and markings, on the second plan, and how distinct the expression of character and power of touch ought to be, as they approach the eye or the foreground.

Fig. 12. The willow has been represented by perpendicular markings, terminating in a point, to give the idea of its pendant foliage. A broad mass of light is usually preserved, and an increase of markings is given to one side of each subdivision of foliage, with considerable power of characteristic markings on the shade-side of the tree, besides an occasional repetition of touch for effect.

The fir has been represented by short angular markings connected with each other, much like the zig-zag scratch with a pen to obliterate an incorrect word. These markings are continued in agreement with the projections of the branches, are repeated with increased power on the shade-side of the tree, and a few slight markings are given on the extremities, and beneath the masses, to indicate folinge on the farther side of the tree.

The elm has been represented by escalops in a semicircular direction, so distributed as to give the idea of thick foliage; the masses are separated by detached markings, indicating the same character, and their rotundity given by repetitions, with occasional increase of power. A few dots on the extremities will relieve the harshness of the outline, where the escalops are too evident or regular.

The oak has been represented, as in fig. 13, by a character which partakes of angular and broken circular markings, intermingled with dots and sharp touches. The lighter parts are pencilled tenderly, and the shade portions are repeated upon, with additional power given by sharp angular markings.

We mention these varieties for the purpose of showing that foliage is not to be represented by distinctly pourtraying every leaf, but by a bold grouping and superficial outlining; the purpose being served by merely a general representation. Suppose a tree is to be selected for placing in the foreground of a drawing, where its peculiarities are required to be displayed. Let the growth of the branches be observed; a straight line is rarely to be seen, nor do they spring from each other with uniformity; there is usually an undulating line, often graceful, or a wild luxuriance, ever pleasing, in these supports to the foliage. Let the effect of the leaves which may compose a principal mass be indicated, not the outline of a leaf or

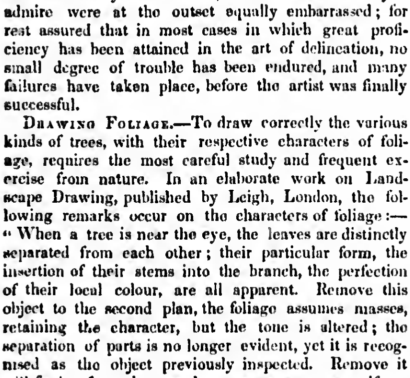

Fig. 12.

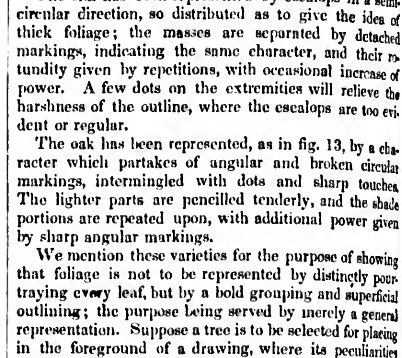

Fig. 13.

leaves, which would prove labour in vain, but what is seen as much by the imagination as the eye—that is, not the detail, but the effect. If too much regularity appear, destroy it by projecting a touch or two on the extremities, and attack any formality by additional markings, in conformity with the character adopted. Oftentimes the mere waving of the pencil, or a powerful repetition with the broad point, will not only remove a monotonous appearance, but communicate characteristic spirit and effect.

Experience has shown, that, while students could sketch the extremities of various branches of trees with good effect, they have felt embarrassed in giving a corresponding correctness to the mass, or masses of foliage, belonging to the same tree. This has arisen from not having duly considered that each mass required to be treated as a centre, from which the character should be spread towards its respective boundary, with such discrimination as to obviate all appearances of formality, and then, by the introduction of repetitions of markings and touches, to arrange the separate parts, so as to preserve but one central mass, however it might be situated. A few trials, with the observance of these particulars, will remove the difficulty. Sometimes the hues of nature in their variety may at a future time be added. The light and shade in Indian-ink cannot be thus used as a basis, because under colour it is injurious to transparency. The light and shade in bistre is rich in mass, powerful in touch, and susceptible of giving transparency, with a high degree of finish. Either may be adopted, as the succeeding hints will apply to one as well as the other. Cakes of Indian-ink, of bistre, or of neutral tint, may be had of the venders of colours for artists. They should be free from grit; and when they were well ground, and duly incorporated with gum and white sugar-candy, they will deposit no sediment.

Flower-Drawing.—In connection with the drawing of foliage and trees, we should particularly recommend the practice of flower-drawing. At first you may copy drawings or prints of flowers, with a view to catching the mode of delineation in groups; nature, however, in this, as in every thing else, must be your true school, and to that we direct your attention. We press this advice in a particular manner on young mechanics who are studying ornamental design with regard to their profession. No doubt, examples of ancient and modern ornament are of great value in this branch of drawing; but, as Mr. Hay justly remarks in his work on Colouring, "flowers are your best practice, as you will now have obtained freedom of execution. To those who have gained a facility in copying the beautiful forms which prevail in the vegetable kingdom, and who have had such instructions in the use of water-colours as may enable them to copy individual flowers with ease, I would recommend the acquirement of a thorough knowledge of the laws of harmonious colouring. They will then be able to group and arrange flowers in the most agreeable and effective manner in regard to colour, as their previous experience must have taught them to accomplish in combination of form.

"Dr. Ure says, that 'the modes in which taste is cultivated at Lyons deserve particular study and imitation in this country. Among the weavers of the place, the children, and all persons busied in devising patterns, much attention is devoted to every thing in any way connected with the beautiful, either in figure or colour. Weavers may be seen in their holiday leisure gathering flowers, and grouping them in the most engaging combinations. They are continually suggesting new designs to their employers, and are thus the fruitful source of elegant patterns.' Hence the French flower-patterns are remarkably free from incongruities, being copied from nature with scientific precision.

"All these facilities for the improvement of our fancy manufactures are within the reach of the most humble. The pursuit of such a course of study as I have endeavoured to point out, would not only augment their sources of innocent pleasure, but lead them to other instructive pursuits. The youth, in searching for the most graceful and picturesque plants in nature's most profuse and wildest productions, would be naturally led to commence the study of botany, for he would then have some interest in the inquiry. And it may be easily imagined with what avidity the more advanced would add to his knowledge of that pleasing science, or the gratification he would derive from the study and practice of horticulture.

"I need scarcely (continues this writer) point out the advantages to be derived from the cultivation of flowers by those engaged in designing ornamental patterns. The productions of a well-managed flower-garden to such would be, in my opinion, of more real utility, as objects of study, than the contents of the Louvre. In those productions of nature they will find the most exquisite beauty and elegance of form, and, even in single flowers, the most perfect combinations of colouring.

"In saying that the study of such subjects is of more utility to the ornamental designer than that of those great works of art which have been the admiration of ages, I do not mean to undervalue the benefit that any one, and especially the artist, may derive from studying works of this description. I am aware that 'the eye has its principle of correspondence with what is just, beautiful, and elegant, and that it acquires, like the ear, an habitual delicacy, and answers, with the same provisions, to the finest impressions. Being therefore versed in the works of the best masters, it soon learns to distinguish true impressions from false, and grace from affectation.' I have therefore not the least doubt that those who have risen to some degree of eminence as ornamental designers, would reap great benefit in attaining a knowledge of the various styles and subtleties of colouring, by carefully studying and copying, in masses of colour alone, the best works of art to which they can get access, and applying these arrangements to the particular figures of their patterns."

LIGHT AND SHADE—TINTING.

In every scene, during the presence of light, some parts fall immediately under the effect of the light, while others are thrown into shade. In art, advantage is taken of this mixture of light and dark parts, not only for the facility with which it enables the draughtsman to separate the parts of a scene, but for the agreeable effects which may be produced by the judicious association and distribution of the light and shade. In the representation of a round object, it is only by a careful disposition of the light upon the convex part, and the truth of the attendant reflected light and shadow, that the appearance of roundness is communicated. The means by which the effect of light and shade are to be produced by tints, are now to be described. First, with regard to the preparatory steps in the process.

Provide the best *hard* drawing-paper, which may be had of various size and substance. For subjects in which minute and fine delineation is required, the paper should be smooth on the surface; but when the subject is of a rural character, in which all the shagginess of nature is to be introduced, the paper should be of a rough description, for roughness of surface in such a case will assist in giving truth to the representation. Drawing-papers have frequently a greasiness of surface, which prevents a tint from being spread with evenness; the slightest infusion of gall into the water with which the tint is made, will remedy the defect; or the surface of the paper may be sponged with the gall and water before fastening it on the drawing-board.

A few camel-hair pencils must be provided; say two *flat inch tins*, to distribute a tint over a large space; two *swan-quills*, to wash in smaller spaces; and two *hen* *quills*, to pick in minute parts. The qualities of these denominations of hair-pencils are various. A bad one is far worse than a bad pen; with this it may be possible to write, but with a bad pencil every effort will be foiled. A proof of the quality may be made in the following manner, prior to purchase: When dipped in water, if it spring into a line with the quill, and retain its point, select it; if it spread into two or more points, reject it; and observe, that it is not requisite for a pencil to be touched two or three times on the edge of a vessel containing water, nor to be passed between the lips, since these might give a point to a bad one. Provide also a few small delf saucers, in which to mix the tints, and two cups or glasses, to contain water; one to be preserved pure, and the other in which the pencils are to be washed.

The tints may be made according to taste: from Indian-ink, a black; bistre, a brown; or neutral tint, a gray: they are alike capable of communicating smoothness and spirit. With reference to further advancement in the art, it is proper to state, that the light and shade of a landscape in the neutral tint, is a basis on which the hues of nature in their variety may at a future time be added. The light and shade in bistre is rich in mass, powerful in touch, and susceptible of giving transparency with a high degree of finish.

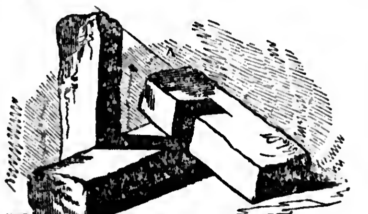

Fig. 14.

It may be observed, that the relief of an object depends on the just arrangement of the light, the due management of the half-tint and shade, with the proper introduction of the shadow.

Fig. 14 represents three rude stones full in the light, the line A showing the direction in which it falls. The shade-side of two, and the end of the third, show a play of light toward the lower parts, which is to be observed in nature. The shadow is marked stronger beneath, while that which is cast on the inclined stone is strongest at the base of the upright stone, and becomes lighter as it falls on the varying surfaces of the others.

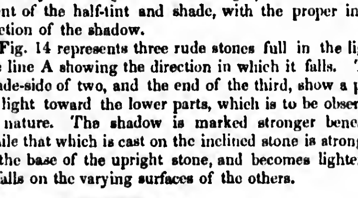

Fig. 15.

Fig. 15 represents an acorn dislodged from its cup. The illumination is from the left, and falls on the rotundity of the acorn, the greatest light being on the most prominent part. In this case, a slight portion of half-tint is placed along the upper edge, while the under side gradually approaches through half-tint to shade, and then softens into reflected light on the lower edge, which contributes to the character of smooth roundness, the power of the shadow beneath assisting in giving effect to the object. The light operates in the same manner on the cup, being cast on the advancing part of the hollow; its shade is cast on the receding part opposed to the light, on the same principle that the exterior of the cup is treated, while the shadow relieves the half-tint, as in the previous instance. These plain and circular objects are introduced to call the student's attention to such natural objects, in which it may be there observed how admirably the lights and shades are intermingled with half-tints, so as to obviate all harshness or violent opposition, while the shadows give a due effect, harmonizing the whole, and rendering the minutiæ worthy of the closest investigation.

Suppose you have made a sketch of such an object, at least six times the size of fig. 14, and that it is fastened down on the drawing-board; a few small saucers, and two vessels containing pure water, on the right hand near the pencils, with the window on the left, so that the sunshine does not fall on the drawing-board: Let a tint be made, according to the previous directions, from either of the cakes before mentioned, and of any strength the student may think proper. Mix it well with the pencil to be used, and always let that be rather larger than might seem to be required—say, a swan-quill. The pencil is properly charged for use when it has been stirred into the tint and gently touched, or passed two or three times on the edge of the saucer. This must be done carefully, because, if the pencil contain too much tint, there is a difficulty in spreading it neatly, and the edges will be hard. If the pencil contain too small a quantity, it will be impossible to spread the tint. If the space be large, it will require a little experience to keep the pencil equally charged with the tint.

Whatever may be the tint chosen, it must be washed over all the parts which do not receive the light. Thus, with the pencil charged with tint, as before described, commence at the top of the perpendicular stone, fill in the form, and proceed by slow motions downwards, so as to keep the floating or lower edge of the tint constantly being acted upon by the pencil, while it is distributing the tint neatly to the shapes required. The pencil must not be returned to repair omissions, as that would destroy the evenness of tint; the parts should be washed in with correctness at the first. The pencil may then be carried across the shadow to the shade of the flat stone and its shadow on the ground, with attention to the edges; then the upper surface of the diagonally-placed stone, with its shade and shadow. If these spaces be well washed in, they will appear of one uniform power of tint. When it is perfectly dry, strengthen the tint in the saucer by an addition of colour from the cake: this increase of power to the tint must be judged of by experience in its application over the tint first washed in. If the subject be examined, it will appear to consist of three gradations of tint; that which has been spread is the first, as on the upper surface of the diagonally-placed stone; the second gradation of tint appears on all the other shaded parts; and the third gradation is confined to the shadows. It may be noticed, that, if too much colour is added to the first tint, it would produce a harsh effect; and if too little is added, the effect would be deficient: in either case, the due gradation would not be observed. Experiments may be made on a piece of paper, till the proper strength of the tint has been ascertained; it may then be applied to the shades and shadows as before, but omitting the upper surface of the diagonal stone. When this is perfectly dry, the tint must be again strengthened to the third gradation of power, with the same precautions as before; and with it wash in the shadows, keeping the edges of this tint rather within the boundaries of the preceding.

Mass, Half-Tint, and Shade.—Suppose such a scene as fig. 11 to have been sketched, and you are disposed to give effect to the outline by a few tints. Consider under what circumstances of light it has been seen in nature, or under what circumstances it might be seen. Imagine it an evening effect, the sun having descended behind the broad mass formed by the castle and trees; these, on different broken surfaces, constituting the second plan; beyond which is a mid-distance, terminating in water and remote hills; the foreground composed of a rude mass, with rock and bushes interspersed. With this outline you are presumed to be familiar, and will perceive that, by placing the light behind the principal objects, an opposition will be established that must give a character to the whole. Thus, the principal will be in half-tint; the light brightest behind the castle, and gradually subdued along the distance; the foreground powerful, so as to relieve the half-tint of the principal, and oppose the distance; thus the gradations or keeping will be preserved, and effect given to the subject.

Attempt the subject first on a small scale to become acquainted with the process, and afterwards on one much larger, for improvement. With the first gradation of tint, as in the preceding cases, commence at the top of the tower, and proceed downwards by slow movements, so as to preserve the outline, sweeping the pencil round the masses of foliage, and covering all the second plan; continue the wash over the foreground, except the edge where the pieces of rock are situated; these may be omitted, to relieve the mass from the second plan. When the tint is dry, make the second gradation of strength, and wash over again the trees and the ground on which they are situated. Then begin on the left on the foreground, and wash over the mass till within a little of the lights which were left untouched with the first wash. In these lights, and in repetitions of wash towards them, be careful not to let any perpendicular shapes appear; any promiscuous irregularity of form will better express ruggedness of surface. When this is dry, reduce a little of the first tint with water, and wash it in the distant hills; then reduce the tint yet more, and with it wash in the space for the sky. As this may represent clouds, an even tint is not of material consequence; the pencil, therefore, should have less tint in it than usual. Begin at the angle on the left hand, and wash over the space, leaving such parts untouched as fancy may select, occasionally touching the extreme point of the pencil in the pure water, so that the tint may become still weaker as it approaches the part just above the castle. If this be well done, whatever may be the forms left untouched in the sky, the appearance will be that of a light or tender tint, getting gradually weaker in a diagonal direction towards the chief light behind the castle.

In this state the drawing would exhibit some effect, and might receive any additional washes or touches that may be suggested by the taste or the judgment of the student. After obtaining a knowledge of the distribution of the tints in their gradations, let the subject be drawn again considerably larger, and now investigate the general principle which regulates the proposed effect, and reflect on each particular part of the process, so as to comprehend the motive for every application of tint. When the tints are washed in, let the drawing be placed at some distance, where it can all be seen at once, without the surrounding objects interfering with the view. At this due removal which is regulated by the size of the drawing, the gradations of distance, and the keeping, will more clearly show their correctness or inaccuracy. If the drawing be large, the flat tints on the second plan will tamely express masses of foliage, or the union of many trees; and the castle will require some characteristic markings. The black-lead pencil may be used upon the tint to indicate a variety of form on the building, or to separate the mass into trees of various heights, and these will serve as guides for the introduction of repetition of wash or touch. This proceeding implies finish, and may be carried to the extent dictated by the judgment of the student; but it must ever be borne in mind, that breadth of effect is injured by every addition that disturbs a mass. Variety may be introduced, so as to attack a monotonous space or mass, without destroying it. Whenever it appears that more is required to complete the drawing, and the improvement is not suggested by a glance, desist immediately; put the drawing aside, and engage in something else. In a few days, on recurring to the subject, it will be seen with a fresh eye; new ideas will arise; a little will be added, or a little power will be reduced, so as to effect an improvement which no straining of the faculties in the former instance could have produced. A drawing may thus be subjected to frequent revision, and retouched as an advance in taste shall direct.

Suppose such a subject as fig. 10 be sketched, for the purpose of study, in breadth of light, the opposite of the last effect: let a tint be made less powerful than the first gradation—such a tint as might represent clouds that were not gloomy—and with it wash over the space for the sky, preserving the forms of the trees, and softening off the tint in a diagonal direction, so as to leave the light along the horizon, with the greatest breadth on the right. When dry, repeat a few washes on the angle towards the left and along the top, so as to produce a gradation of power from the top to the horizon, and it will give the effect of retiring or keeping. If the tint has not been washed in with evenness, endeavour to convert any conspicuous form into a cloud, by picking or filling in on its edges a corresponding tint, so as to make it form part of another more appropriate shape. Then, with that power of tint, considered as the first gradation, commence at a part not so high as the gable of the cottage, upon the trees, with an irregular form, distinct from a straight line, and continue the tint over the trees beneath, to the line of ground on which the cottage stands. Begin again at the lower part of the base beneath the cottage, and wash in the tint up to where the ground line before mentioned joins the boundary of the subject, and continue to wash in the tint, in agreement with the form of an indicated path to the cottage door, and so across to the mass of foreground and bush on the right. When all is perfectly dry, make the second gradation of power in tint, and wash over the lower portion of the trees close to the cottage, with the space before washed in, observing not to let it approach the edges of the previously washed tint, lest the shapes should appear harsh, particularly on the bush opposed to the light horizon. It must be observed, that the power which was required to separate masses in outline, ceases to be proper on the application of tint, as there is no decided outline in nature. With the tint of the second gradation, wash in the door, the window, the shade of the roof with its shadow, and the shade side of the chimney. Then, with the third gradation of power, wash in the foreground and the lower part of the bush, with the precautions before mentioned. When dry, place the drawing at a due distance, according to its size; and observe, if the effect be that of a cottage in a mass of light, that the gable end cannot properly receive the same degree of illumination as the roof and the side where the window is; it will therefore be proper to wash over it a tint that will keep it in its place. You must reflect, that, as the light is concentrated, by the illumination from the right being poured upon the cottage, its relieving mass of half-tint will be lighter than on other occasions; therefore, a tint lighter than the clouds will be sufficient to detach it from the brighter side, without destroying the mass of light in which the cottage is placed. As in the case of the preceding subject, any repetition of wash or touch that may seem to be required should be added, being careful to preserve the intended effect. A little practice will teach that the trees should be diversified with tender tints, so as not to destroy the mass of light; that the distant sea should be washed with a tint to relieve it from the horizon; that the ground on which the cottage stands may be broken or enriched with characteristic forms; and that the foreground may be touched with a power that shall judiciously detach it from the second plan.

In the examination of drawings, during the progress of retouching, if a part appear too light, or another part too dark, so as to produce the effect of *spottiness*, cover such part with the fingers, and imagine the appearance with any proposed alteration; if an improvement be suggested, at once adopt it, and examine again; always paying attention to preservation of the masses, on which both simplicity and effect depend. A drawing should be ascertained to have *one principal light*, while the subordinate lights diminish in brilliancy, in proportion as they are removed from the principal. Masses of shade should decrease in power of tint, conformable to their degrees of remoteness. These are essential to keeping and effect. Making-out or marking more than the respective distances require, touches which are inappropriate, or harshness of any description, are all departures from the principles of the art, and deviations from natural appearances. Although effects may be observed in nature at variance with these rules—such, for instance, as light scattered equally on the foreground and the mid-distance, or the whole scene being beneath a glare of sunshine, or in shade by the clouded state of the atmosphere—yet these are effects unsuited for pictorial delineation, because they are deficient in what constitutes beauty and attraction in the art.

You may have observed how essential a sky is in giving effect to a drawing. The great variety of forms, lights, half-tints, and shades, the storm, the distant falling shower, and other incidental effects, which the atmosphere presents to the view, should always be regarded with attention, not only because advantage may be taken of such diversity for powerful contrast, but because a well arranged sky is a beautiful portion of a landscape. The repetition of tender washes over each other may be justified only in the endeavour to obtain that tenderness and delicacy of tints which are conducive to faithful representation of clouds; for continuing to wash the same tint in successive applications, will produce an effect that is termed *woolly*, from its being deficient in that *sharpness* or spirit which is obtained by a few decided tints applied in just gradations. These varieties may be adapted to the nature of the scene, and may, by their judicious contrasts of form and tint, contribute very materially to the general effect of a subject, as in a stormy sky, bright horizons, and beams of light. The effect of moonlight may readily be given by strong tints, softened off in the circular direction of the moon, and repeated till the gradation is obtained; then give a wash over the whole sky. *Take out* the clouds to a half-tint by dabbing, and *take out* the moon to the clean paper, with crumbs of bread. A few catching lights on the clouds near the moon may be *taken out*, but made less bright than the moon.

HUMAN FIGURES.

A knowledge of drawing the human figure is to be gained by a careful study of the outlines of the different parts composing the trunk, limbs and members. All such integral portions of the human figure, if time and other circumstances permit, may be first studied from casts conveniently placed on the table, so as to give a facility to the hand in this department of sketching.* It must, however, be borne in mind, that exercises of this nature, under the guidance of a master, do not obviate the necessity for studying the human figure from life neither do they supersede the acquisition of a knowledge of figure-drawing on a small scale, for the purpose of ornamenting and giving effect to a scene from nature. The introduction of human figures is of considerable utility in drawing a landscape, in order to serve as a scale by which a spectator may know the probable measurements of objects near which the figures are situated; figures also give animation to a scene, and, by the touches of light or of dark which they justifiably offer, communicate valuable relief to a mass, or assist in the keeping of the subject.

There are several well-known rules with respect to the drawing of human figures; they are as follows.—

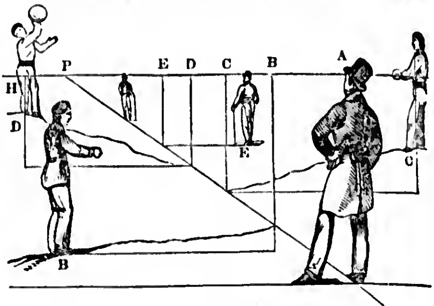

Fig. 16.

The height of a figure should be eight times that of its head; half its height is at the lower part of the body; a quarter of its height is at the knee. This division of the human figure can readily be put on the memory by the following method: Draw a perpendicular line, then divide it into eight equal parts; give one for the head, and, placing dots at each part in succession, give a second part for the breast, a third part for the centre of the abdomen, a fourth part for the lower portion of the body, a fifth part for the midway of the thigh, a sixth part just beneath the knee, a seventh part just beneath the calf of the leg, and the eighth part to the sole of the foot. The shoulders are two heads in width; the elbow is a head and a half from the shoulder; and the arm, with straightened fingers, is three heads and a half from the shoulder; that is, the fingers will reach down to the fifth division of the perpendicular. The measurements of the human figure, according to the highest standards of art, are exceedingly minute; but such are not necessary where a mere sketch of the form is required to enliven a landscape.

Fig. 16 exhibits the mode of ascertaining the heights of figures, wherever they may be placed in a scene, according to the rules of perspective. A is a figure on the base line; the eyes determine the height of the horizontal line H. Draw the visual rays from the head and feet of the figure A to the point of sight P, and the receding diminutions are determined, supposing the space to be a level surface. Where the situation of a figure is below the visual rays, as B, draw a parallel line from the feet of the figure towards the ray, and raise the perpendicular line B. Now, the measurement between the visual rays at B is the height of the figure required. When the situations of figures are above the rays, as at C and D, draw the parallels and the perpendiculars to their intersections beneath the elevations, and the measurements between the visual rays at C and D will give the respective heights of the figures required. The figure E being on a level with the base, a parallel line drawn from the lower ray will determine the height of a figure so situated.

* Stucco casts of figures and their subordinate parts may be had from different manufacturers of models of this description in London, Edinburgh, and other large towns.

PHOTOGENIC DRAWING.

Representations of landscape scenery have for many years been made by mechanical means, with the aid of the *camera lucida*, a species of box provided with a mirror and lens, in which the representations fall, and are therefrom copied by an attending artist into his sketch-book. The idea of fixing representations of this nature on the surface on which they fall, so as to save the trouble of copying, appears to have been entertained by ingenious men both in France and England; and at length the possibility of doing so was made known at Paris in the month of January, 1839. The discoverer was M. Daguerre, aided, however, by one or two other persons; and he was rewarded by the French government for making known the process which he pursued in the art, which was henceforth called Daguerreotype Drawing, or, as frequently, Photogenic Drawing (that is, drawing by the action of light).

The material on which photogenic drawing is performed is a thin and perfectly smoothed piece of copper coated with silver, and its preparation is a matter of extreme delicacy, for the surface must be rendered sensitive to the faintest shadows thrown upon it. Having been properly prepared by means of a spirit-lamp and the fumes of iodine, to give the silvered face a golden tinge, the plate is placed in the camera, a darkened box, and the focus adjusted. The camera being set in a position to catch the reflection of the object upon which the sun is shining, the aperture is opened, and the process of catching and retaining the reflection goes on of itself. A few minutes generally serve to give the representation. When taken from the camera, nothing is visible on the plate, and it must instantly, without any light being allowed to fall upon it, be placed in a box, and then subjected to fumes from mercury acted upon by a spirit-lamp. The formerly invisible figures are now developed. The next operation is to fix the images, by removing the coating of iodine, on which the light would still act. A saturated solution of common salt, filtered and warmed, or, what is better, a weak solution of hyposulphite of soda, not heated, some cold distilled water, and some warm distilled water, with two (sheet copper) troughs, are the chief materials required in this process. The plate, when removed from the mercurial box, is freed from the board attached to it, and plunged into one of the troughs, containing cold distilled water, care being taken not to touch the centre of the plate. It is again *immediately* removed, and plunged into the saline solution in the other trough, and, being laid there face upwards, is stirred about by means of a little copper-wire hook. The yellow tinge now leaves the plate; and when this is seen to have taken place, the plate is placed on an inclined plane (of japanned white iron), and distilled water, hot, but not boiling, poured freely over it. All these operations are but the work of a minute or two; and when the last is finished, the plate must be dried rapidly by blowing on it, and moving it in the air, else stains will be left on the drawing. After this, the drawing cannot be washed out; but rubbing, or the continued action of vapours, would destroy it.

In order to preserve the sketches from vanishing, a glass is put closely over them, and they are framed. When finished in a perfect way, the design on the plate is exquisitely beautiful, and though impressions of it cannot be multiplied as from a graven plate, it is in a perfect state for the engraver to copy, and he can do this with far more ease and correctness than in the case of ordinary drawings. There are no colours in the sketches. They show only a neutral tint, or dull shades relieved by lighter parts. And all, as a matter of course, are the *reverse* of the original. There are now several able practitioners of the art in London; and in Edinburgh, some very beautiful specimens of photogenic drawing of street scenes have been effected by Mr. Howe, miniature painter.

Various attempts have been made to adapt photogenic drawing to the sketching of miniature portraits from life; but, though likenesses are obtained, they have a dull, leaden hue, and the countenance has a death-like, unpleasant appearance. Besides, as the slightest movement of the head, while sitting, or even the winking of the eyes, causes derangement in the action of the sun's rays, all representations from life have less or more a *muzzy* or confused appearance. We have seen miniature likenesses taken on paper prepared for the purpose, instead of plates, but they wanted the liveliness and force of likenesses executed with the pencil. To all appearance, photogenic drawing will be limited in its utility to the taking of representations of buildings, or scenes in still nature, to be afterwards copied at leisure; the perfect faithfulness of the delineation being altogether unapproachable by artistic skill.

STUDY OF PAINTING AND SCULPTURE.

Drawing with black-lead pencils, chalk, or crayons, and Indian ink, constitute the first steps in a study of the fine arts. The more advanced studies refer to drawing in water-colours, paintings in oil-colours, and sculpture—three separate branches, individually followed as professions. It is not our intention to offer any instructions in these advanced departments of art, but to say only a few words as to the manner in which they are performed, and the advantages derivable from a contemplation of their varied products.

Drawings in water-colours are executed on thick hard paper, the outlines being lightly sketched with black-lead pencil. The colours are prepared in small oblong cakes; when required, a portion is rubbed down with water in a small saucer, and applied with a camel-hair pencil. Great care is necessary in laying on the respective colours; for the nature of the material wrought upon, and the transparency of the tints, prevent that freedom in rubbing out or obliterating one colour by another, which may be resorted to in oil-painting. For directions how to proceed, we refer to a small and accessible work on Water-Colour Drawing, by Mr. John Clark. (W. S. Orr & Co., London.)

Oil-paintings are executed on a variety of materials, but chiefly canvas, stretched on a frame; less frequently on wood, copper, and slate. The canvas or other material requires to be prepared with a coat of paint, to give it a smooth surface, and to prevent the absorption of the colours afterwards laid on. The colours are ground and prepared with fine nut, poppy, or linseed oil, and are ordinarily purchased by painters in bladder-bags, in a state ready for use. For convenience in using, a small portion of each colour required in the piece is placed on a thin oval board, called a *pallet*, which is held in the left hand, by passing the thumb through a hole at one extremity; the canvas frame is generally placed on a stand, called an *easel*, in front of the artist, and the colours are applied with brushes of fine elastic hair. The colours being opaque, the painter has the opportunity of retouching his work, by putting one colour over another, when the previous colour has been thoroughly dried. Oil-paintings are sometimes executed on walls and the roofs of buildings; but paintings of water-colours on walls are the most ancient. These, known by the name of *fresco* painting, are done while the surface of the plaster is moist, and admit of no retouching when the plaster dries. Specimens of fresco painting have been found in Herculaneum and Egypt, still, after thousands of years, maintaining their brilliant colouring.

The greater number of sculptures, ancient and modern, are executed in single blocks of white marble; a few are in bronze. A sculptor commences by drawing his design on paper; when satisfied with this, he pro-seeds to form a model of his proposed figure in moist clay, supporting it partly by irons and frame-work. Having, as he thinks, brought his model to perfection as respects attitude and surface, it is ready to form a copy to work from; but as it is a perishable material, he takes a cast from it in plaster, and this cast serves as a mould for a fac-simile model in plaster of Paris. The plaster cast being hard and durable, it is used as the permanent copy by the different workmen. The first operative employed on it, by means of a machine, takes off the rougher parts of the marble, and gradually diminishes the block in the required directions. The next is an able assistant, who brings the figure still nearer in form to the copy; and it lastly passes under the hands of the sculptor, who gives that tasteful finish and spirit which the nature of the subject requires. Statues in bronze are cast in moulds taken from finished models.

With respect to the advantages derivable from a contemplation of the higher objects of art, they may be defined as the education of the eye and of taste, which is of particular importance to the draughtsman.

Addressing ourselves again to the pupil—you will observe that nature, though truthful, is not always consistently beautiful or graceful. We see living human figures less or more deformed, some tall and slender, others short and ungainly, and a third class out of proportion in the different parts of their person. Now, to set about copying figures possessing any of these defects, would be absurd; and you must in all cases endeavour to imitate only what is allowed to be nearest to perfection. Taking mankind in the gross, exceedingly few individuals come up to any thing like a perfect standard. Fashions of dressing and habits of living, independently of original defects of form, conspire to throw the figure out of just proportion; so that a perfect man or woman, as respects bodily form and carriage, is practically out of the reach of all ordinary students. In London and elsewhere, there are *life* academies, in which draughtsmen study from the best-formed living figures that can be hired to exhibit themselves; and studies of this kind are indispensable for all who design following out the higher walks of art. Studies from sculptured figures are, nevertheless, desirable, because these are formed upon the highest ideality of grace, beauty, and perfection; and a contemplation of their exquisite proportions is believed to refine and discipline the tastes of the student. It is on this account that we append the present observations on this branch of the art.

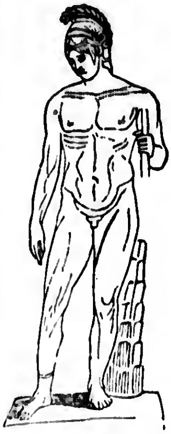
The figures which afford a recognised standard of perfection, are for the most part works of ancient Grecian art. The period in which the highest conceptions of personal perfection were formed, was during the administration of Pericles (about 440 years before the Christian era.) In this age flourished Phidias, the greatest sculptor of ancient or modern times, who raised art from a comparatively rude to a very high condition. With him commenced what is called the *ideal style* of sculpture, in other words, a style aiming at an exalted conception of simple truth and grace. The religion of the Greeks, which was the idolizing of deified heroes and heroines, offered the utmost scope for these lofty conceptions. His masterpieces were the figures of Pallas Athene and Jupiter, his Venus Urania, his Nemesis in the temple at Marathon, and his Amazon. He taught a number of others, among whom Alcamenes of Attica, and Agoracrites of Paros, were his favourite pupils. Both these sculptors executed several works which attained a high reputation. A contemporary was the famed Myron of Eleutheris in Bœotia, who represented highly finished athletic forms. His Runner, his Slinger, and his Pancratists, are celebrated. His ideal of Hercules completed this class of forms. His Heifer and his Sea-monster, are famous among his animal forms. But one thing was wanting to this great sculptor—grace of expression; in

Apollo Belvidere.

this he was surpassed by a rival sculptor, who adopted the undulating line of beauty, and first expressed the sinews and veins with accuracy. He created the ideal of Apollo in the position of an archer, who had just shot the serpent Python—the figure indicating in its expression a placid satisfaction and assurance of victory. This splendid work of art was found at Antium, the modern Capo d'Anzo, at the end of the fifteenth century. It was purchased by Pope Julius II., then a cardinal, and placed in that part of the Vatican called the Belvidere, whence it has been commonly named the Apollo Belvidere. The fore part of the right arm and the left hand, which had been destroyed, were restored by Angelo du Montorsoli, a pupil of Michael Angelo. The ease of the attitude and excellent proportions of the figure are universally admired. Our small outline engraving affords but an imperfect idea of the majestic original.

After the ideal style of Phidias and his disciples, succeeded the period in Grecian art distinguished for the *beautiful*. Praxiteles and Scopas were the great leaders of this improved style, in which beauty was united with grace. The most celebrated works of Scopas are his furious Bacchante—the head bending backwards, uniting the highest beauty with Bacchanalian frenzy; his Cupid, his Venus, and his Achilles, who is placed in a mournful attitude, contemplating as if lamenting the loss of his friend Patroclus. Praxiteles, the most feeling of all sculptors, created the perfect ideals of Diana and of Bacchus; the latter being designed by him as a contrast to the satyrs and fauns, whose figures express rudeness and licentiousness. The figure of Bacchus was soft and tender, without being effeminate, and expressed perpetual gayety and sport. He effected, also, the admired statue of a Satyr, and the ideal of Eros, or Cupid, which was that of a playful boy. Praxiteles was the first to represent Venus entirely naked, thus giving to the world a new ideal of the goddess. His most celebrated works are his Venus of Cos and of Cnidos; the former covered from the hip downwards, the latter entirely naked, holding her garment with her left hand over the bath. The group of Niobe is also ascribed to this master.

To the epoch which followed that of Praxiteles is usually ascribed the statue of Venus, styled the Venus de Medicis, from having been placed in the gallery of the Medici at Florence, after its discovery at Tivoli in 1695. It is of pure white marble, and measures, according to one authority, 4 feet 11 inches, and according to another 5 feet 2 inches, in stature. Some small portions have been restored. It is not ascertained who was the sculp-



Achilles.

Venus de Medicis.

tor of this exquisitely designed figure. The pedestal exhibits the name of Cleomenes; but the inscription is modern. It has been the object of the artist to represent Venus either as just coming from the bath, on the point of dressing herself, taken by surprise, and full of modesty, or as appearing before Paris for his judgment in the contest with Juno and Minerva for the prize of beauty. By many, the countenance is thought unintellectual, or at least unexpressive. The graceful waving lines of the body have never been surpassed: and, taken in different points of view, they offer a most advantageous study for ideal grace and beauty.

In this latter age, appeared Lysippus of Sicyon, Euthycrates, Apollodorus, and others, among whom stand pre-eminent Polydorus, father and sons, of Rhodes, who formed the celebrated group of Laocoon. A number of great works of this era were executed by Greek sculptors at Rome, to whom we are indebted for many busts of distinguished Romans.

Among the numerous ancient sculptures, which, like those already mentioned, have survived until modern times, and been preserved in museums, may be mentioned the following, as useful studies: The Dying Gladiator, a naked manly figure, reclining on his shield, his weapon broken, and expiring from a mortal wound in the side. The Three Graces, a group of female figures in different attitudes, calculated to show the symmetry of the form in various positions. Antinous, the figure of a graceful youth, in a simple attitude, expressive of melancholy, and executed with great correctness of proportion. Adonis, a figure somewhat more slender and elegant. Venus Genetrix, a figure draped, and possessing a noble simplicity of expression: the drapery, hanging in the most elegant folds, is in itself a study. Cleopatra, meditating in a reclining position. Laocoon, a group of figures, above referred to, consisting of a father and his two sons, struggling in the folds of serpents, and strongly characteristic of the distraction and suffering which may be conceived to be endured in that dreadful situation. Hercules, a figure expressive of robust muscular strength.

After a lapse of nearly ten centuries, the art of sculpture was revived in Italy, and thence spread to France and other modern nations. Germany has latterly produced various sculptors of eminence; among these may be mentioned Dannecker of Stuttgard, and Tieck of Berlin. Dannecker has executed, in pure white marble, a figure of Ariadne seated on a tigress, in an attitude of inexpressible elegance, and equal to the works of ancient art. It is contained in a private museum at Frankfort on the Maine. Thorwaldsen, a Danish sculptor, has likewise produced several works of striking grandeur and beauty; not the least imposing of his designs is the colossal figure of a lion carved in the solid rock at Lucerne in Switzerland. The animal is supposed to be dying from the effects of a wound from a spear, and reclining over a shield emblazoned with fleurs de lis: it is a monument emblematic of the fidelity of the Swiss Guards who perished in defending their master Louis XVI., on the 10th of August, 1792, from the brutality of the Parisian mob.

Canova, an Italian (born 1757, died 1822), has been justly esteemed the restorer of the graceful and lovely in sculpture. All his works display a surprising degree of softness and delicacy, and will form admirable studies to the young artist. His Cupid; Psyche, standing half dressed, with a butterfly; the repentant Magdalene; Hebe, smiling and animated; a Venus, partially draped; Beneficence (several figures); Graces rising from the bath—are only a few of the works by which Canova gained his great reputation. Modern sculpture has likewise been distinguished by various works executed in England, by Flaxman, Chantrey, Westmacott, Baily, and others. Modern art has almost reached the ancient in the figure of Eve at the Fountain, which is conceived in a style of pure simplicity and grace, with somewhat more intellectuality in the features than is generally to be found in the Grecian sculpture of female figures.

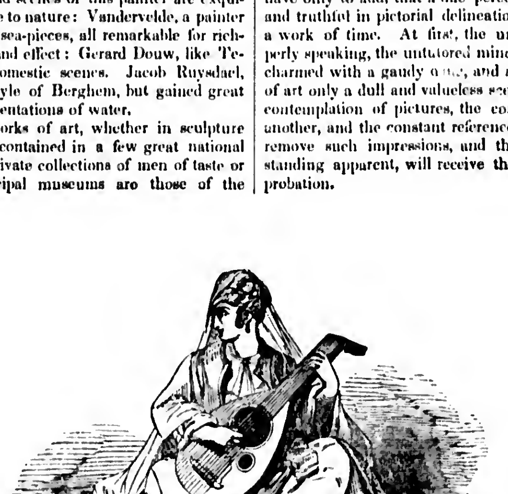
Eve at the Fountain.

Besides studying the manifold graces of ancient and modern sculpture, with the view of improving the taste in reference to figures, you are recommended to study the styles and compositions of the more celebrated painters, as nothing could be more suitable for imparting correct ideas respecting drawing, disposal of groups of objects, and colouring. Another great benefit will consist in making you feel your own deficiency, and how much you require to attain by diligent study. Painting, you will learn, has, since the revival of art, taken the character of *schools*, or peculiar styles, each of which has had its leaders and followers; for example, there is the Florentine school, commenced by Michael Angelo Buonarotti (born 1474, died 1564), who delighted in representations of the grand and terrible. The Roman school, of whom Raphael (1483–1520) was the head. The great characteristics of this school are, truthful representations of nature, a just expression of the passions, a chaste nobleness of design, and correctness of drawing. The Venetian school, headed by Titian (1477–1576), the characteristics of which were the harmony of colours, delicacy of tints, and a judicious contrast of light and shade. This school was improved by Corregio and Tintoretto. The German school, led by Albert Durer (1471–1528) and Holbein. The second Lombard school, distinguished by the works of the three Caracci (1555–1609). The French school, founded by Nicholas Poussin (1594–1665), Vouet, and Charles Le Brun. The Flemish school was founded by Peter Paul Rubens (1577-1640), whose design is dignified, his drawing of anatomy and perspective correct, and his colouring brilliant. The only objection to some of his figures is, that they are too heavy; and certainly they want the grace of those of Raphael. The Dutch school, ct which the most prominent painter is Rembrandt (1606-1668), is less distinguished for taste than the faithful adherence to nature.

The works of the eminent masters in these various schools were chiefly scriptural and historical; and scenes of a miscellaneous kind, embracing landscapes, figures, animals, sea-pieces, architecture, and other subjects, were painted by contemporary artists, who followed no particuar school. Among these great masters may be named Claude Gelee of Lorraine (1600-1682), whose landscapes are exceedingly beautiful, his colouring delicate, his tints tender, and his lights and shades unrivalled; Salvator Rosa (1615-1674), whose taste was for the wild, rugged, and romantic aspects of nature; Gaspar Poussin (1613-1675), whose pictures are grand, and remarkably true to nature. The sixteenth and seventeenth centuries produced the following masters, all of whose works are esteemed:—Paul Veronese, Guido, Carlo Muratti, and Spagniolletto—historical; Murillo (Spanish)—figures; Hobbima—landscape; Canaletti—buildings; and De Wit—the interior of churches. Vernet, a Frenchman of the eighteenth century, was celebrated for his sea-pieces and figures. In the course of the seventeenth century, Holland produced, but cannot be said to have encouraged, many distinguished painters. Among these are included David Teniers, celebrated for his representations of domestic and familiar scenes: Paul Potter, renowned for his cattle pieces, the most remarkable of which is his picture of a bull; it is contained in the royal museum at the Hague, and valued at £5000: Philip Wouvermans, noted for his landscapes, beautiful skies, and scenes with groups of figures hunting, or otherwise engaged in field sports: Berghem, also noted for his landscapes, his foliage, cattle finely drawn and coloured; the woodland scenes of this painter are exquisitely finished and true to nature: Vandervelde, a painter of naval victories and sea-pieces, all remarkable for richness of composition and effect: Gerard Douw, like Teniers, famed for his domestic scenes. Jacob Ruysdael, who painted in the style of Berghem, but gained great celebrity for his representations of water.

All the eminent works of art, whether in sculpture or painting, are now contained in a few great national museums, or in the private collections of men of taste or opulence. The principal museums are those of the Vatican at Rome, the Gallery of the Medici at Florence, the royal galleries at Munich (now the head school of painting and other fine arts in Germany), the Louvre at Paris, the British Museum and National Gallery in London, and the Royal Museum at the Hague. If at all within the means of young men desirous of pursuing professions in which taste in drawing is requisite, we strongly recommend them to visit the museum of the Louvre, which is rich in ancient sculpture and modern paintings; the sight of the many fine works of art in Paris would scarcely fail to inspire a high degree of refined taste. If unable to accomplish this desirable object, we advise you to pay occasional visits to any private collection to which you can gain admission, and also to exhibitions and museums open to the public. Among recent works of English art, generally accessible, the historical pieces of Haydon and Hilton, the historical and pathetic pieces of Allan, the grand architectural idealities of Martin, the church and other architecture of Roberts, the landscapes of Gainsborough, Calcott, Mulready, Thompson, and the Nasmyths, the animals of Landseer, the sea-views of Stanfield, Turner, and Williams, and the faithful delineations of humble life by Wilkie, and many other works of art which might be mentioned, will afford much pure pleasure and instruction, and show what can be accomplished by a cultivated observation, and a persevering desire to excel.

In the course of your observations you will learn, that in the delineation of human figures great care requires to be paid to historical costume and the fashion of artificial objects represented. A person who lived in the eighteenth century, for instance, should not be dressed as an ancient Roman; nor should the interior of a house of the fifteenth be decorated like one of the sixteenth century. On this account, every student of the fine arts requires to be well instructed in history, archaiology, and other branches of learning. With respect to statues, it is so important to give an easy and graceful effect, that a departure from exact costume is allowable, so far as to place a loose garment over or about the person. We have only to add, that a due perception of the beautiful and truthful in pictorial delineation must be in all cases a work of time. At first, the unpractised eye, or, properly speaking, the untutored mind, will perhaps be most charmed with a gaudy one, and see in the finest work of art only a dull and valueless scene. But the repeated contemplation of pictures, the comparison of one with another, and the constant reference to actual nature, will remove such impressions, and the work of true merit standing apparent, will receive the highest meed of approbation.



ARITHMETIC—ALGEBRA.

In the present and succeeding article, an attempt is made to convey to the comparatively unlearned mind some knowledge of Mathematical science, both as regards measurement by numbers (Arithmetic) and measurement of dimensions (Geometry). The sketch we offer of each is necessarily brief and imperfect; but our end will be gained if we afford that amount of information on the subject which is generally possessed by persons of moderately well-cultivated intellect.—*Ed.*

A recognition of the value of *numbers* is coeval with the dawn of mental cultivation in every community; but considerable progress must be made before methods of reckoning are reduced to a regular system, and a notation adopted to express large or complex quantities. An inability to reckon beyond a few numbers is always a proof of mental obscurity; and in this state various savage nations have been discovered by travellers. Some are found to be able to count as far as five, the digits of the hand most likely familiarizing them with that number; but any further quantity is either said to consist of so many fives, or is expressed by the more convenient phrase, "a great many." Among the North American Indians, any great number which the mind is incapable of distinctly recognising and naming is figuratively described by comparing it to the leaves of the forest; and in the same manner, the untutored Negro of Africa would define any quantity of vast amount by pointing to a handful of sand of the desert.

On the first advance of any early people towards civilization, it would be found impossible to give a separate name to each separate number which they had occasion to describe. It would therefore be necessary to consider large numbers as only multiplications of certain smaller ones, and to name them accordingly. This is, no doubt, what gave rise to classes of numbers, which are different in different countries. For instance, the Chinese count by *twos;* the ancient Mexicans reckoned by *fours.* Some counted by *fives*, a number which the fingers would always be ready to suggest. The Hebrews, from an early period, reckoned by *tens*, which would also be an obvious mode, from the number of the fingers of the two hands, as well as of the toes of the two feet. The Greeks adopted this plan; from the Greeks it came to the Romans, and by them was spread over a large part of the world.

NOTATION.

The representation of numbers by written signs is an art generally believed to have taken its rise after the formation of alphabets. One of the earliest sets of written signs of numbers of which we have any notice, is certainly the series of letters of the Hebrew alphabet which was used by that people—Aleph, beth, gimel, daleth, he, vau, zain, cheth, teth, standing respectively for the numbers one, two, three, four, five, six, seven, eight, nine. The Greeks directly adopted this plan from the Hebrews, forming their numbers thus:—1 alpha, 2 beta, 3 gamma, 4 delta, 5 epsilon—here having no letter corresponding with the Hebrew *vau*, they put in the words *επισημον βαυ* to denote six; after which they proceed with 7 zeta, 8 eta, &c. Before adopting this plan, they had indicated one by iota ι, probably because it was the smallest of their letters, five by Π (P) being the first letter of *pente*, five; ten by Δ (D) being the initial of *deka*, ten. After having for some time adopted the Hebrew plan, they divided their alphabet into three classes; the first ten letters expressing the numbers from one to ten, while twenty, thirty, forty, and so on up to a hundred, were signified by the next *nine*, ninety being expressed by a figure formed for the purpose, and resembling the Arabic 5 inverted. The remaining seven letters expressed 200, 300, 400, 500, 600, 700, 800; and for 900 there was another inverted figure. Larger numbers were represented by letters accented in various ways.

The Romans, from an early period, had a plan of expressing numbers, which seems to have been at first independent of the alphabet. The following clear account of it was given a few years ago by Professor Playfair:—"To denote one, a simple upright stroke was assumed |; and the repetition of this expressed two, three, &c. Two cross strokes X marked the next step in the scale of enumeration, or ten; and that symbol was repeated to signify twenty, thirty, &c. Three strokes, or an open square [, were employed to denote the hundred, or the third stage of enumeration; and four interwoven strokes M, sometimes incurved ⅭⅠↃ, or even divided CIↃ, expressed a thousand. Such are all the characters absolutely required in a very limited system of numeration. The necessary repetition of them, however, as often occasionally as nine times, was soon found to be tedious and perplexing. Reduced or curtailed marks were therefore employed to express the intermediate multiples of five; and this improvement must have taken place at a very early period. Thus, five itself was denoted by the upper half V, and sometimes the under half Λ, of the character X for ten; L, or the half of [, the mark for a hundred, came to represent fifty; and the incurved symbol ⅭⅠↃ, or CIↃ, for a thousand was put into IↃ, to express five hundred.

These important contractions having been adopted, another convenient abbreviation was introduced. To avoid the frequent repetition of a mark, it was prefixed to the principal character, and denoted the effect by counting backwards. Thus, instead of four strokes, it seemed preferable to write |V; for eight and nine, the symbols were ||X and |X; and ninety was expressed by X[. This mode of reckoning by the defect was peculiar to the Romans, and has evidently affected the composition of their numerical terms. Instead of *octodecem* [eight and ten—for eighteen], and *novemdecem* [nine and ten—for nineteen], it was held more elegant, in the Latin language, to use *undeviginti* [one from twenty], and *duodeviginti* [two from twenty].

But the alphabetical characters now lent their aid to numeration. The uniform broad strokes were dismissed, and those letters which most resembled the several combinations were adopted in their place. The marks for one, five, ten, and fifty, were respectively supplied by the letters I, V, X, and L. The symbol for a hundred was aptly denoted by C, which had originally a square shape, and happened, besides, to be the initial of the very word *centum*. The letter D was very generally assumed as a near approximation to the symbol for five hundred; and M not only represented the angular character for a thousand, but was likewise, though perhaps accidentally, the first letter of the word *mille*."—*Edin. Rev.* xviii. 193.

The Hebrew, improved Grecian, and Roman numerals, were perhaps sufficient to express any single number with tolerable precision; but it is easy to see that they must have been nearly unfitted for use in the process of arithmetic. The Greeks certainly contrived to overcome many obstacles in the business of calculation, and even could express fractions—though, from a practice of adding from left to right, and ignorance of the plan of *carrying* tens to the higher places, their problems were at all times awkward and complicated. The Romans, however, careless of old inconveniences, were still more awkwardly situated than the Greeks. Let any reader just suppose, for instance, even so simple a question as the amount of XLVIII added to XXXIV! It is evident that placing the figures below each other, as we do with the Arabic numerals, would serve little to facilitate such a calculation. In fact, the Romans were obliged, where mental calculation would not serve, to resort to a mechanical process for performing problems in arithmetic. A box of pebbles called *loculus*, and a board called *abacus*, constituted their means of calculation; and of these every schoolboy, and many other persons, possessed a set. The word calculation claims no higher descent than from *calculus*, a stone or pebble. The board was divided from the right to the left hand by upright columns, on which the pebbles were placed, to denote units, tens, hundreds, thousands, &c. The labour of counting and arranging the pebbles was afterwards sensibly abridged by drawing across the board a horizontal line, above which each single pebble had the power of five. In the progress of luxury, *tali*, or dies made of ivory, were used instead of pebbles; and afterwards the whole system was made more convenient by substituting beads strung on parallel threads, or pegs stuck along grooves; methods of calculation still used in Russia and China, and found convenient in certain departments of Roman Catholic devotion, and in several familiar games in more civilized countries. With such instruments, problems in addition and subtraction would not be very difficult; but those in multiplication and division, not to speak of the more compound rules, must have been extremely tedious and irksome. So disagreeable, indeed, was the whole labour, that the Romans generally left it to slaves and professional calculators.

The numerals now in use, with the mode of causing them by peculiar situation to express any number, and whereby the processes of arithmetic have been rendered so highly convenient, have heretofore been supposed to be of Indian origin, transmitted through the Persians to the Arabs, and by them introduced into Europe in the tenth century, when the Moors invaded and became masters of Spain. Such in reality appears to have been in a great measure the true history of the transmission of these numerals; but as it has been lately found that the ancient hieroglyphical inscriptions of Egypt contain several of them, learned men are now agreed that they originated in that early seat of knowledge, between which and India there exists more points of resemblance, and more traces of intercourse, than is generally supposed. In the eleventh century, Gerbert, a Benedictine monk of Fleury, and who afterwards ascended the papal throne under the designation of Sylvester II., travelled into Spain, and studied for several years the sciences there cultivated by the Moors. Among other acquisitions, he gained from that singular people a knowledge of what are now called the *Arabic numerals*, and of the mode of arithmetic founded on them, which he forthwith disclosed to the Christian world, by whom at first his learning caused him to be accused of an alliance with evil spirits. The knowledge of this new arithmetic was about the same time extended, in consequence of the intercourse which the Crusaders opened between Europe and the East. For a long time, however, it made a very slow and obscure progress. The characters themselves appear to have been long considered in Europe as dark and mysterious. Deriving their whole efficacy from the use made of the cipher, so called from the Arabic word *tsaphara*, denoting *empty* or *void*, this term came afterwards to express, in general, any secret mark. Hence, in more troublous times than the present, a mode of writing was practised, by means of marks previously concerted, and called *writing in cipher*. The Arabic characters occur in some arithmetical tracts composed in England during the thirteenth and fourteenth centuries, particularly in a work by John of Halifax, or De Sacrobosco; but another century elapsed before they were generally adopted. They do not appear to have settled into their present forms till about the time of the invention of printing.

It would be impossible to calculate, even by their own transcendent powers, the service which the Arabic numerals have rendered to mankind.

NUMERATION.

The Arabic numerals take the following well-known forms:—1, 2, 3, 4, 5, 6, 7, 8, 9, 0. The first nine of these, called *digits* or digital numbers, represent, each, one of the numbers between *one* and *nine*, and when thus employed to represent single numbers, they are considered as *units*. The last (0), called a *nought*, nothing or cipher, is in reality, taken by itself, expressive of an absence of number, or nothing; but, in connection with other numbers, it becomes expressive of number in a very remarkable manner.

The valuable peculiarity of the Arabic notation is the enlargement and variety of values which can be given to the figures by associating them. The number ten is expressed by 1 and 0 put together—thus, 10; and all the numbers from this up to a hundred can be expressed in like manner by the association of two figures—thus, twenty, 20; thirty, 30; eighty-five, 85; ninety-nine, 99. These are called decimal numbers, from *decem*, Latin for ten. The numbers between a hundred and nine hundred and ninety-nine inclusive, are in like manner expressed by three figures—thus, a hundred, 100; five hundred, 500; eight hundred and eighty-five, 885; nine hundred and ninety-nine, 999. Four figures express thousands; five, tens of thousands; six, hundreds of thousands; seven, millions; and so forth. Each figure, in short, put to the left hand of another, or of several others, multiplies that one or more numbers by ten. Or if to any set of figures a nought (0) be added towards the right hand, that addition multiplies the number by ten; thus, 999, with 0 added, becomes 9990, nine thousand nine hundred and ninety. Thus it will be seen that, in notation, the *rank* or place of any figure in a number is what determines the value which it bears. The figure third from the right hand is always one of the hundreds; that which stands seventh always expresses millions; and so on. And whenever a new figure is added towards the right, each of the former set obtains, as it were, a promotion, or is made to express ten times its former value.

1,	2	3	4	5	6	7,	8	9	0
Thousands of millions.	Hundreds of millions.	Tens of millions	Millions.	Hundreds of thousands.	Tens of thousands.	Thousands.	Hundreds.	Tens.	Units.

A large number is thus expressed in the Arabic numerals, every set of three from the right to the left hand being divided by a comma for the sake of distinctness.

The above number is therefore one thousand two hundred and thirty-four millions, five hundred and sixty-seven thousands, eight hundred and ninety. Higher numbers are expressed differently in France and England. In the former country, the tenth figure expresses billions, from which there is an advance to tens of billions, hundreds of billions, trillions, &c. In our country, the eleventh figure expresses ten thousands of millions, the next hundreds of thousands of millions, the next billions, &c. The two plans will be clearly apprehended from the following arrangement:—

ENGLISH METHOD.	FRENCH METHOD.
Units.	Units.
Tens.	Tens.
Hundreds.	Hundreds.
Thousands	Thousands.
Tens of thousands.	Tens of thousands
Hundreds of thousands.	Hundreds of thousands.
Millions.	Millions.
Tens of millions.	Tens of millions.
Hundreds of millions.	Hundreds of millions.
Thousands of millions.	Billions.
Ten thousands of millions.	Tens of Billions.
Hundreds of thousands of millions.	Hundreds of Billions.
Billions.	Trillions.
Tens of billions.	Tens of trillions.
Hundreds of billions, &c.	Hundreds of trillions, &c.

SIMPLE OR ABSTRACT NUMBERS.

There are four elementary departments in arithmetic—Addition, Multiplication, Subtraction, and Division.

Addition.

Addition is the adding or summing up of several numbers, for the purpose of finding their united amount. We add numbers together when we say, 1 and 1 make 2; 2 and 2 make 4; and so on. The method of writing numbers in addition, is to place the figures under one another, so that units will stand under units, tens under tens, hundreds under hundreds, &c. Suppose we wish to add together the following numbers—27, 5, 536, 352, and 275; we range them in columns one under the other, as in the margin, and draw a line under the whole. Beginning at the lowest figure of the right-hand column, we say 5 and 2 are 7—7 and 6 are 13—13 and 5 are 18—18 and 7 are 25; that is, 2 tens and 5 units. We now write the 5 below the line of units, and carry or add the 2 tens, or 20, to the lowest figure of the next column. In carrying this 20, we let the cipher go, it being implied by the position or rank of the first figure, and take only the 2; we therefore proceed thus—2 and 7 are 9—9 and 5 are 14—14 and 3 are 17—17 and 2 are 19. Writing down the 9, we proceed with the third column, carrying 1, thus—1 and 2 are 3—3 and 3 are 6—6 and 5 are 11. No more figures remaining to be added, both these figures are now put down, and the amount or sum of them all is found to be 1195. Following this plan, any quantity of numbers may be summed up. Should the amount of any column be in three figures, still only the last or right-hand figure is to be put down, and the other two carried to the next column. For example, if the amount of a column be 127, put down the 7 and carry the other two figures, which are 12; if it be 234, put down the 4 and carry 23.

```

   5
 536
 352
 275
----
1195
```

For the sake of brevity in literature, addition is often denoted by the figure of a cross, of this shape +. Thus, 7+6 means 7 added to 6; and in order to express the sum resulting, the sign =, which means *equal to*, is employed, as 7 + 6 = 13; that is, 7 and 6 are equal to 13.

Multiplication.

Multiplication is a short method of addition under certain circumstances. If we wish to ascertain the amount of twelve times the number 57, instead of setting down twelve rows of 57, and adding them together, we adopt a shorter plan by which we come to the same conclusion. For ascertaining the amount of all simple numbers as far as 12 times 12, young persons commit to memory the following Multiplication Table, a knowledge of which is of great value, and saves much trouble in after-life:—

1	2	3	4	5	6	7	8	9	10	11	12
2	4	6	8	10	12	14	16	18	20	22	24
3	6	9	12	15	18	21	24	27	30	33	36
4	8	12	16	20	24	28	32	36	40	44	48
5	10	15	20	25	30	35	40	45	50	55	60
6	12	18	24	30	36	42	48	54	60	66	72
7	14	21	28	35	42	49	56	63	70	77	84
8	16	24	32	40	48	56	64	72	80	88	96
9	18	27	36	45	54	63	72	81	90	99	108
10	20	30	40	50	60	70	80	90	100	110	120
11	22	33	44	55	66	77	88	99	110	121	132
12	24	36	48	60	72	84	96	108	120	132	144

This table is so well known, that it is almost superfluous to explain that, when any number in the top row is multiplied by any number in the left-hand side row, the amount is found in the compartment or square beneath the one and opposite the other. Thus, 2 times 2 are 4, 5 times 6 are 30; 12 times 12 are 144.

The multiplying of numbers beyond 12 times 12 is usually effected by a process of calculation in written figures. The rule is to write down the number to be multiplied, called the *multiplicand*; then place under it, on the right-hand side, the number which is to be the *multiplier*, and draw a line under them. For example, to find the amount of 9 times 27, we set down the figures thus—

```
 27 (Multiplicand.)
  9 (Multiplier.)
---
243 (Product.)
```

Beginning with the right-hand figure, we say 9 times 7 are 63; and putting down 3 we carry 6, and say 9 times 2 are 18, and 6 which was carried makes 24; and writing down these figures next the 3, the product is found to be 243.

When the multiplier consists of two or more figures, place it so that its right-hand figure comes exactly under the right-hand figure of the multiplicand; for instance, to multiply 5463 by 34, we proceed as here shown. Here the number is multiplied, first by the 4, the product of which being written down, we proceed to multiply by 3, and the amount produced is placed below the other, but one place further to the left. A line is then drawn, and the two products added together, bringing out the result of 185742.

```
  5463
    34
------
 21852
16389
------
185742
```

We may, in this manner, multiply by three, four, five, or any number of figures, always placing the product of one figure below the other, but shifting a place further to the left in each line. An example is here given in the multiplying of 76843 by 4563.

```
      76843
       4563
-----------
    230,529
  4,610,58
 38,421,5
307,372
-----------
350,634,609
```

Multiplication is denoted by a cross of this shape ×: thus, 3 × 8 = 24, signifies, that by multiplying 8 by 3, the product is 24. A number which is produced by the multiplication of two other numbers, as 30 by 5 and 6, leaving nothing over, is called a *composite* number. The 5 and 6, called the *factors* (that is, workers or agents), are said to be the *component parts* of 30, and 30 is also said to be a multiple of either of these numbers. The equal parts into which a number can be reduced, as the twos in thirty, are called its aliquot parts. A number which cannot be produced by the multiplication of two other numbers, is called a *prime number*. When the multiplicand and multiplier are the same, that is, when a number is multiplied by itself once, the product is called the *square* of that number: 144 is the square of 12.

Subtraction.

Subtraction is the deducting of a smaller number from a greater, to find what remains, or the difference between them. We subtract when we say, take 3 from 5, and 2 remains. To ascertain what remains, after taking 325 from 537, we proceed by writing the one under the other as here indicated, and then subtracting. Commencing at 5, the right-hand figure of the lower and smaller number, we say, 5 from 7, and 2 remains; setting down the 2, we say next, 2 from 3, and 1 remains; and setting down the 1, we say, 3 from 5 and 2 remains; total remainder, 212

```
537
325
---
212
```

To subtract a number of a higher value, involving the *carrying* of figures and supplying of tens, we proceed as in the margin. Commencing as before, we find that 5 cannot be subtracted from 2, and therefore supply or lend 10 to the 2, making it 12; then we say, 5 from 12, and 7 remains. Setting down the 7, we take 1, being the decimal figure of the number which was borrowed, and give it to the 1,

```
8432
6815
----
1617
```

making it 2, and taking 2 from 3, we find that 1 remains Setting down the 1, we go to the 8, and finding it cannot be taken from the 4 above it, we lend 10 to the 4, making it 14, and then we say, 8 from 14, and 6 remains. In the same manner as before, adding the first figure of the borrowed number (1) to the 6, we say, 7 from 8, and 1 remains; thus the total remainder is found to be 1617. From these explanations, which apply to all calculations in subtraction, it will be observed, that when the upper figure is less than the figure directly under it, 10 is to be added, and for this *one* is carried or added to the next under figure.

Subtraction is denoted by a small horizontal line, thus — between two figures; as, for example, 9 — 5 = 4, which means, 5 subtracted from 9, and 4 remains.

Division.

Division is that process by which we discover how often one number may be contained in another, or by which we divide a given number into any proposed number of equal parts. By the aid of the Multiplication Table, we can ascertain without writing figures how many times any number is contained in another, as far as 144, or 12 times 12; beyond this point notation is employed. There are two modes of working questions in division, one long and the other short. Let it be required to divide 69 by 3: according to the long method, write the figures 69 as annexed, with a line at each side, and the divisor, or 3, on the left. The question is wrought out by examining how many times 3 is in 6, and finding it to be 2 times, we place 2 on the right side; then, placing 6 below 6, we draw a line and bring down the 9, and proceed with it in the same manner. The quotient is found to be 23.

```
3)69(23
  6
  —
   9
   9
```

But we take a more difficult question—the division of 7958 by 6. In commencing we find that there is only one 6 in 7, and 1 over; we therefore place the 6 below the 7, and subtract it, in order to bring out the 1. The 1 being written, we bring down the 9 to it, and this makes 19. There being 3 times 6 in 18, we place the 3 to the product (which in division is called the *quotient*, literally, How many times?) and 18 below the 19, leaving 1 over as before. To this 1 we bring down the 5, and trying how many sixes there are in 15, it appears there are only 2. We place 2 to the quotient, and 12 below the 15. This leaves 3 over, and bringing down 8 to the 3, we have 38, in which there are 6 sixes. Six sixes make 36; therefore, placing 6 to the quotient, and 36 below the 38, we find that there are 2 over. Here the account terminates, it being found that there are 1326 sixes in 7958, with a remainder of 2 over. In this question, 6 is called the *divisor*; the 7958 is the *dividend*, and 1326 is the *quotient*.

```

Skilful arithmeticians never adopt this long method of division; they pursue a plan of working out part of the question in the mind, called short division. They would, for example, treat the above question as here shown. The over number of 1 from the 7 is carried in the mind to the 9, making 19; the 1 from 19 is in the same manner carried to the 5; and the 3 from it is carried to the 8, leaving the overplus of 2.

```
6)7958
  ————
  1326–2
```

Division is denoted by the following character ÷; thus, 75 ÷ 25, signifies that 75 is to be divided by 25.

These explanations conclude the subject of simple or abstract numbers. On the substructure of the few rules in Addition, Multiplication, Subtraction, and Division, which we have given, whether in reference to whole numbers or fractions, every kind of conventional arithmetic is erected, because these rules are founded in immutable truths. Mankind may change their denominations of money, weights, and measures, but they can make no alteration in the doctrine of *abstract* numbers. That 2 and 2 are equal to 4, is a truth yesterday, to-day, and for ever; but as to how many pence are in a shilling, or how many inches in a foot, these are altogether matters of arbitrary arrangement, and the treatment of them forms an inferior department of arithmetical study, taking a different form in different countries: this *local* arithmetic, as we may call it, is comprehended in the term

COMPOUND NUMBERS OR QUANTITIES.

The calculation of the value of any number of articles, or a summation of values, in relation to money, would be comparatively simple, if the scale of money were constructed on a principle of decimals, or advancing by tens —as, for example, 10 farthings one penny, 10 pence 1 shilling, 10 shillings 1 pound. By making both weights and measures on the same plan, as, 10 ounces 1 pound, 10 pounds one stone, 10 stones 1 hundredweight; 10 inches 1 foot, 10 feet 1 yard, &c., ordinary calculations would be rendered exceedingly easy. Thus, if an ounce cost 1d., a pound would cost 1s., and a hundredweight would cost 100s. or £10; or, reversing the question, if we were asked £10 per hundredweight for any article, we should know in an instant that it was at the rate of 1d. an ounce. In short, the greater number of arithmetical calculations would be accomplished by little more than a momentary reflection, without the aid of pen or pencil.

This very convenient system of decimal arithmetic is established in France and Belgium, and it is there carried to a most enviable degree of perfection: as, for example, in money reckoning, the *franc* (equal to our 10d.) is the standard coin of account, and is divided into 100 parts called *centimes*. There is an equal simplicity in the money reckoning of the North American Union, in which the dollar (equal to our 4s. 3d.) is divided into 100 centimes; but as weights and measures are not on the same decimal scale, the advantage is of comparatively small moment.

In the United Kingdom, the pound or sovereign is the standard in money. It consists of a series of inferior coins, advancing irregularly from a farthing upwards; as, 2 farthings 1 halfpenny, 2 halfpence or 4 farthings 1 penny, 12 pence 1 shilling, 20 shillings 1 pound. While, therefore, the French compute values in money by francs and centimes, and the Americans by dollars and centimes, we compute by pounds, shillings, and pence; and to ascertain the value of irregular quantities in these irregular denominations of money, there is a complex set of rules to be obeyed; indeed, it may be said that the principal part of the time usually spent by youth at school on arithmetic, is consumed in learning to work questions in this arbitrary and local department of the science. We have only room to give a few examples in this species of computation.

L is the initial letter of the Latin word *libra*, a pound, and is used to denote pounds; *s* from the Latin word *solidus*, for shillings; and *d* from *denarius*, for pence: £ *s. d.* are therefore respectively placed over columns of pounds, shillings, and pence. The mark for a halfpenny is ½, for a farthing ¼, and for three farthings ¾. To find the number of farthings, pence, and shillings, in any number of pounds, we multiply by 20, which brings the pounds into shillings; next by 12, which brings the shillings into pence; and lastly by 4, which brings the pence into farthings, as, for example, Required the number of farthings in £5—we proceed as in the margin. The result is observed to be 4800 farthings.

```
   £5
   20

 1200
    4
 ————
 4800
```

Compound Addition.

In ordinary transactions of business, and making up of accounts, Compound Addition, that is, the addition of moneys, is principally required. In the margin is an account of sums to be reckoned up. The first thing done is to add together the halfpence and farthings on the right-hand side; and in doing so we throw all into farthings. Thus, 2 and 1 are 3, and 3 are 6, and 2 are 8, and 2 are 10. Ten farthings are 2 pence, and 2 farthings, or one halfpenny, over. We set down ½ for the halfpenny, and carry the 2 to the pence column; this being added, we find there are 31 pence, which make 2 shillings and 7 pence. We write down the 7, and carry the two shillings to the shillings column; adding them to the under figure at the right-hand side, we reckon up thus—2 and 2 are 4, and 5 are 9, and 7 are 16, and 4 are 20, and 2 are 22; we put down 2 aside, and carrying 2 to the second row of the shillings column, we find, on summing it up, that it amounts to 7; this 7 and the 2 set aside make 72 shillings, that is, £3, 12s.; 12, therefore, is written down under the shillings column, and the 3 pounds are carried to the pounds column, which is added up as in Simple Addition, making 320. Thus, the sum-total is £320, 12s. 7½d. All accounts in Compound Addition, referring to British money, are performed in the same manner. We recommend young persons to acquire facility in writing; and it will save much time if they learn to sum up the columns by a glance of the eye, without naming the numbers; for instance, instead of saying 2 and 2 are 4, and 5 are 9, and 7 are 16, and 4 are 20, and 2 are 22, acquire the knack of summing the figures in the mind, thus—2, 4, 5, 9, 16, 20, 22.

£31	12	7½
73	14	8½
69	17	5¾
87	15	6¼
57	12	3½
£320	12	7½

Compound Multiplication.

Questions in Compound Multiplication are determined in the following manner:—Having written down the number to be multiplied, place the multiplier under the lowest denomination, and proceed as in this example. We wish to multiply the sum of £37, 16s. 8¾d. by 6. We begin by multiplying the farthings by the 6; this makes 18 farthings, or 4½d. Setting down the ½, we carry the 4 to the pence, saying 6 times 8 are 48, and 4 are 52, which is equal to 4 shillings and 4 pence. Setting down the 4 pence, we carry the 4 shillings onwards, and multiplying 16 by 6 find 96, which, added to the 4 shillings, gives 100. This is equal to £5, so we set down 0, and carry the 5 to the 37. The amount is 227. The answer of the question is therefore £227, 0s. 4½d.

£37	16	8¾
		6
£227	0	4½

Compound Subtraction.

Compound Subtraction is performed as in the following question:—If we take £27, 17s. 8¾d. from £36, 14s. 5½d., how much remains? The first thing we are called on to do, is to take 3 farthings from 2 farthings or ½d., and as this cannot be done, we borrow a penny, or 4 farthings, and adding these to the 2 farthings, we have 6. We now take 3 from 6, and find that 3 remains, which is therefore written down. It is now necessary to account for the borrowed penny, and a means of doing this would be to consider the pence of the upper line of figures as so much less, or 4d. instead of 5d. It is found, however, to be the most convenient plan to add 1 to the pence of the lower line, which comes to the same thing. Adding 1 to 8, in this case, we have 9 to subtract from 5. As this cannot be done, we borrow 1s., which is 12d., and adding that 12 to the 5 makes 17, from which taking 9, there will remain 8, which is placed under the pence. The borrowed 1s. is also repaid by adding 1 to the 17, making thus 18 to be taken from 14; but as we cannot do this either, we borrow £1, which is 20s. Adding 20s. to 14 makes 34; then 18 from 34 leaves 16. This is placed under the shillings, and 1 is carried to the lower amount of pounds, which are then subtracted as in Simple Subtraction; thus, 1 to 7 is 8; 8 from 6, cannot, but 8 from 16, there remains 8; carry 1 to 2 is 3, and 3 from 3, nothing remains. Total sum remaining, £8, 16s. 8¾d.

£36	14	5½
27	17	8¾
£8	16	8¾

Compound Division.

Compound Division is performed as follows:—We wish to divide £87, 14s. 9¾d. into 7 equal parts. Dividing 87 by 7, as in Simple Division, the answer is 12, and 3 remain, that is, 3 pounds are over. We set down the 12, and taking the 3 which is over, we reduce it to its equivalent in shillings, that is 60; we then add the 60 to 14, making 74, which being divided by 7 gives 10 shillings, and 4 shillings over. Setting down the 10, we carry forward the 4; 4 shillings are 48 pence, which, added to 9, makes 57. This divided by 7 gives 8 and 1 penny over; a penny is 4 farthings; add to these the 3 in the dividend, thus making 7; 7 divided by 7 gives 1, that is ¼d. The sum desired, then, is £12, 10s. 8¼d.

£	s.	d.
7)87	14	9¾
12	10	8¼

If the divisor is a composite number—the product of two numbers individually not exceeding 12—we can divide first by one and then by the other, as follows: Divide £376, 11s. 1½d. by 63: 63 is a composite number; its component parts are 7 and 9 (seven nines are 63). The given amount, therefore, is first divided by 7, and the quotient, £53, 15s. 10½d., is divided by 9. The result is the same as if the original sum had been divided by 63. £5, 19s. 6½d. is the quotient.

£	s.	d.
7)376	11	1½
9)53	15	10½
5	19	6½

When the divisor is a prime number above 12, the work is in every respect similar to the former; but it is performed by long division, as in the annexed example:—Divide £484, 19s. 7¾d. by 73. The amount being written down as in long division of simple numbers, the pounds are first divided by 73: the answer is 6. The remainder 46 is reduced to shillings by multiplying by 20, and the 19s. in the sum we are dividing being taken in, makes together 939s., which, divided by 73, gives 12, and 63 of a remainder. These 63 shillings are now reduced to pence by being multiplied by 12, and the 7 being taken in, makes 763; this, divided by 73, gives 10, and 33 over, which, being reduced to farthings by being multiplied by 4, and the three taken in, makes 135; and this, divided by 73, gives one, and 62 over. The whole answer is £6, 12s. 10¼d. and a fraction $\frac{62}{73}$ over.

British Weights and Measures.

The working of accounts in weights and measures, as respects addition, multiplication, subtraction, or division, proceeds on principles similar to those which have now been explained. The only real difference is that, for example, in reduction, instead of multiplying by 20, by 12, and by 4, to reduce a sum to farthings, if the question refer to ordinary weights we multiply to bring out the number of hundredweights, 112 for pounds, and 16 for ounces. Suppose we wish to know how many ounces are in 15 tons: we multiply 15 by 20, and the result is 300, that is, 300 hundredweights; a hundred weight is 112 pounds, so we now multiply 300 by

112, and the result is 33,600 pounds; this multiplied by 16, the number of ounces in a pound, gives 537,600 ounces. In the addition of quantities, each denomination is set down in its own column, as in money, and the summation is made also as we add money, with the difference, that we carry forward ounces, pounds, or whatever it may be, to the next column. The mark *cwt.* is usually employed to indicate hundredweights, *lb.* pounds, and *oz.* ounces.

The following are the principal tables of weights and measures established by law in the United Kingdom, and hence called *imperial*. That which is entitled *avoirdupois weight* is the table in use for all ordinary purposes:—

I.—MEASURE OF LENGTH.

Inches.						
12	1 Foot.					
36	3	1 Yard.				
198	16½	5½	1 Pole or Perch.			
7,920	660	220	40	1 Furlong.		
63,360	5280	1760	320	8	1 Mile	

The hand = 4 inches; the English ell = 45 inches; the pace = 5 feet; and the fathom = 6 feet. The geographical degree = 20 nautical leagues, or 69,121 miles. In land measure, the chain of 100 links = 66 feet.

II.—MEASURE OF SURFACE.

Sq. Inches.					
144	1 Sq. Foot.				
1,296	9	1 Sq. Yard.			
39,204	272¼	30¼	1 Sq. Pole.		
1,568,160	10,890	1210	40	1 Rood.	
6,272,640	43,560	4840	160	4	1 Acre.

And 640 acres make 1 square mile.

III.—MEASURES OF CAPACITY.

1. *Solidity.*

1728 cubic inches = 1 cubic foot.
27 cubic feet = 1 cubic yard.
The ton measurement = 8 barrel bulk, or 40 cubic feet.

2. *Measure for Liquids, Corn, and Dry Goods.*

Cubic Inches.	Wat. lbs. av.						
8·665	5/16	1 Gill.					
34·659	1¼	4	1 Pint.				
69·318	2½	8	2	1 Quart.			
277·274	10	32	8	4	1 Gal.		
554·548	20	64	16	8	2	1 Peck.	
2218·19	80	256	64	32	8	4	
17745·5	640	2048	512	256	64	32	

4 pecks = 1 bushel; 8 bushels = 1 quarter.

The peck, bushel, and quarter, are used for dry goods only. There are, besides, the coom = 4 bushels, the wey or load = 5 quarters; and the last = 2 loads or 16 quarters.

According to the system introduced January 1, 1826, the imperial gallon contains 277,274 cubic inches, or 10 lbs. avoirdupois of distilled water at 62° Fahrenheit, the barometer being at 30 inches. Heaped measures (formerly used for dry goods) were abolished in 1835.

IV.—MEASURES OF WEIGHT.

1. *Avoirdupois.*

Troy Grains.						
27·34375	1 Drachm.					
437·5	16	1 Ounce.				
7000	256	16	1 Lb.			
98000	3,584	224	14	1 Stone.		
196000	7,168	448	28	2	1 Qr.	
784000	28,672	1,792	112	8	4	1 Cwt.
15680000	573,440	35,840	2240	160	80	20 — 1 Ton.

FLOUR WEIGHT.—1 Peck = 14 pounds; 1 boll = 140 pounds; 1 sack = 280 pounds, or 2½ cwt.; 1 barrel = 196 lbs.

2. *Troy Weight.*

Grains.			
24	1 Pennyweight.		
480	20	1 Ounce.	
5760	240	12	1 Pound.

This weight is used in weighing gold, silver, platina, &c. The fineness of gold is expressed in carats and grains, the pound or other weight being divided into 24 carats, and the carat into 4 grains. Thus the carat pound is the 24th part of the troy pound, or 10 dwts., and the carat grain the 96th part, or 60 troy grains.

In Beer Measure, the barrel contains 4 firkins, or 36 gallons; and the hogshead 1½ barrel or 54 gallons.

In Wine Measure, besides the gallon and its subdivisions, various denominations are used, as the butt, pipe, &c.; but these are now to be considered rather as the names of casks than as expressing any definite number of gallons. The *standard gauges* in trades are as follows:—Pipe of port, 115 imp. galls.; pipe of Lisbon, 117 do.; pipe of Cape or Madeira, 92 do.; pipe of Teneriffe, 100 do.; butt of sherry, 108 do.; hogshead of claret, 46 do.; aum of hock, 30 do.

Herrings are measured by the barrel of 26⅔, or cran of 37½ gallons.

Apothecaries' Weight.—20 troy grains make 1 scruple, 3 scruples make 1 drachm, and 8 drachms make 1 ounce. The ounce and pound are the same as in troy weight. This weight is used in medical prescriptions only.

The Scottish acre, formerly a standard in Scotland, and now abolished, consisted of 54937·15 imperial square feet; 23 Scots acres were very nearly equal to 29 imperial acres. The Scottish *choppin* was very nearly the English wine quart, and the *mutchkin* was rather more than the English pint. Previous to the Union with England, the Scottish money pound was equal to one shilling and eightpence English. Hence £100 Scots was equal to the sum of £8, 6s. 8d. in our present money.

French Weights and Measures.

As French weights and measures are now frequently referred to in literature, we think it proper to offer the following particulars on the subject.

The French system of weights and measures is established on a principle much more simple and unerring than that in use in England—the former is of universal application, the latter can never be any thing but local. The French unity of length and weight is based on an invariable dimension of the terrestrial globe, which is recognisable in all countries. It is independent of all extrinsic notions, such as gravity and the arbitrary subdivisions of duration, an advantage which the length of a seconds pendulum certainly does not present. The admeasurement of a fourth of the earth's meridian—an ideal circle going round the globe from pole to pole at right angles with the equator—constitutes the basis of the French system. The length of this fourth of the meridian is divided into 10,000,000 parts: a single ten-millionth part is the *metre*, or the unity of long measure. (A metre is equal to 39⅜ British inches.)

A square, measuring on each side 10 metres, forms the *are*, or the unity of the mensuration of surface. (40½ ares are nearly equal to one British acre.)

A cube, measuring on each of its sides one metre, constitutes the *stère*: used for dry measure.

A cube, measuring on each of its sides the tenth part of a metre, is the unity of volume. A vessel gauging such a cube, is the unity of liquid measures, and is called the *litre*. (A litre is equal to about a pint and three quarters, or nearly a quart, British measure.)

The weight of a cube of water, measuring on each of its sides the 100th part of a metre, is the unity of weight, and is called the *gramme*. A thousand grammes of pure water at its greatest density (about 40° of Fahrenheit's thermometer), are of course equivalent to the litre. (A thousand grammes, forming 1 kilogramme, weigh about 2¼ pounds British.)

These unities being often too great or too small for common use, they constitute the basis of new unities on the simple decimal principle. The names of these new unities are formed from Greek and Latin words. If to express multiplication of the original unity, Greek is used; if to express division of the original unity, Latin is used, or words slightly modified from it. The Greek words are *deka*, for ten, *hecto* a hundred, *kilo*, a thousand, and *myria* ten thousand. The Latin words are *decem* for ten, *centum* a hundred, and *mille* a thousand. These various words are placed before, or prefixed to, the principal unity. Thus, the *decametre* is equal to ten metres, and the *decimetre* is the tenth part of a metre; the *hectolitre* is equal to 100 litres, and the *centilitre* is the hundredth part of a litre; the *kilogramme* is equal to a thousand grammes, and the *milligramme* is, the thousandth part of a gramme.

The connection between these weights and measures will now be clearly seen. The *are* is the square decametre; the *litre* is the cubic decimetre; and the kilogramme is the weight of a litre of pure water at its maximum density.

The currency of the country being assimilated by decimal reckoning to the weights and measures, it may be safely averred that the whole world cannot produce a more simple and immutable plan of calculation than that now in use in France and in Belgium.

FRACTIONS.

Hitherto we have spoken only of whole numbers which in arithmetic are called *integers*. We have now to treat of fractions, or the parts into which integers may be broken. The more ordinary fractions of any single article or number are a half, third, quarter, &c.; but a number admits of being divided into any quantity of equal parts. All such fractions are called *vulgar fractions*, from their being common. It is the practice to write vulgar fractions with two or more small figures, one above the other, with a line between, as follows:— $\frac{1}{2}$ (one-half), $\frac{1}{3}$ (one-third), $\frac{1}{4}$ (one-fourth or quarter), $\frac{1}{8}$ (one-eighth), $\frac{4}{5}$ (four-fifths), $\frac{9}{10}$ (nine-tenths), and so on. In these and all other instances, the upper number is called the *numerator*, the lower the *denominator*.

It may happen that it is necessary to add together different fractions to make up whole numbers. In working all such questions, we must, in the first place, bring all the fractions into one kind; if we have to add $\frac{1}{2}$, $\frac{1}{4}$ and $\frac{1}{8}$ together, we make all into eighths, and see how many eighths we have got; thus, $\frac{1}{2}$ is $\frac{4}{8}$; then $\frac{1}{4}$ is $\frac{2}{8}$, that is 2 and 4, which make 6, and $\frac{1}{8}$ makes a total of $\frac{7}{8}$. The same plan is to be pursued in the subtraction of vulgar fractions.

It is necessary sometimes to speak of the tenths, hundredths, or thousandths of a number, and for this arithmetic has provided a system of *decimal fractions*. Where great exactness of expression is required, decimals are indispensable. It has been already shown that, in writing common numbers, the value of a figure increases by ten times as we proceed from right to left; in other words, we ascend by tens. Now, there is nothing to prevent us in the same manner descending by tens from unity. This is done by decimal fractions. We place a dot after unity, or the unit figure, which dot cuts off the whole number from its fractional tenths; thus 120·3 means 120 and 3-tenths of a whole; if we write 120·31, the meaning is 120 and 31-hundredths of a whole, that is, 31 parts in 100 into which a whole is supposed to be divided. If we go on adding a figure to the right, we make the fraction into thousands; as for instance, 120·315, which signifies 120 and 315 out of a thousand parts.

Tables of specific gravities, population, mortality, and many matters of statistics, are greatly made up of decimal fractions, and therefore it is proper that all should comprehend the principle on which they are designed. In many cases, it would answer the purpose to write the fractions as vulgar fractions; but there is a great advantage in reducing all broken parts to the decimal notation, for it allows of adding up columns of decimals all of the same denomination. Their great excellence, indeed, consists in the uniformity which they give to calculation, and the easy methods which, by these means, they present of pursuing fractional numbers to any degree of minuteness.

The method of reducing a vulgar to a decimal fraction is a simple question in division. For instance, to reduce $\frac{3}{4}$ to a decimal, we take the 3, and putting two ciphers after it, divide by 4, thus— $\frac{4)300}{\cdot 75}$; therefore, .75 is the decimal, or, what is the same thing, 75-hundredth parts of a whole are equal to the three quarters of a whole.

SERIES AND RATIOS OF NUMBERS.

A *series* of numbers is a succession of numbers that increase or decrease according to some law. Of the two kinds of series usually treated of in arithmetic, the simpler is one whose terms increase or decrease by some constant number called the *common difference*. This common difference or rate of increase is only *one*, when we say, 4, 5, 6, 7, 8; it is *two*, when we say 7, 9, 11, 13; and *four*, when we say 6, 10, 14, 18, and so on. Every advancement of this nature, by which the same number is added at every step, is called *arithmetical progression*. There is a different species of advancement, by which the last number is always multiplied by a given number, thus causing the series to mount rapidly up. Suppose 4 is the multiplier, and we begin at 2, the progression will be as follows:—2, 8, 32, 128, 512, 2048, and so on. It is here observed, that multiplying the 2 by 4 we have 8; multiplying the 8 by 4, we have 32; and multiplying the 32 by 4, we have 128, &c., till at the fifth remove we attain 2048. This kind of advancement of numbers is called *geometrical progression*. The very great difference between the two kinds of progression is exemplified in the following two lines, the number 3 being added in the one case and being used as the multiplier in the other:—

5, 8, 11, 14, 17,—Arithmetical Progression.
5, 15, 45, 135, 405,—Geometrical Progression.

In the case of arithmetical progression, as above or in any other manner exemplified, it may be noticed that the amount of the first and last term is always the same as twice the amount of the middle term; thus, 5 and 17 being 22, are equal to twice 11, or 22. The cause of this is, that as the numbers increase or decrease in equal degrees, the last number is just as much more as the first is less than the number in the middle; and the two being added, the amount must consequently be double the central number. The same rule holds good with respect to any two numbers at equal distances from the number in the middle. If the series be an even number, and do not possess a middle term, then the two terms nearest the middle (called the mean terms) must be added together; thus in the natural series from 1 to 24, 12 and 13 are the two nearest the middle, and one being added to the other makes 25, the sum of the first and last term.

In geometrical progression, each term is a factor of all the numbers or terms that follow, and a product of all that go before, so that there is an harmonious ratio pervading the whole. Each term bears an exact proportion to its predecessor, because the multiplier is the same. Supposing, as above, the multiplier to be 3, the term 15 is proportionally greater than 5, as 45 is greater than 15. In the technical language of arithmetic, as 15 is to 5, so is 45 to 15. To save words, such a proposition is written with dots, thus—15 : 5 :: 45 : 15. The two dots mean *is to*, and four dots mean *so is*. The same formula is applicable to any series of proportional terms, though not in continued proportion to each other.

In order to discover the ratio between any two terms, we divide the largest by the least, and the quotient is the ratio: 45 divided by 15 gives 3 as the ratio. By thus ascertaining the ratio of two terms, we are furnished with the means of arriving at the ratio of other terms. We cannot do better than explain the method of working out this principle in the ratio of numbers, by giving the following passages from the admirable *Lessons on Arithmetic*, by Mr. T. Smith of Liverpool. Taking the four regularly advancing terms, 15, 45, 405, and 1215, he proceeds—"Suppose that we had only the first three, and that it were our wish to find the fourth, which term bears the same proportion to the third as the second does to the first. The thing we have first to do, is to discover the ratio between the first and second terms, in order to do which, as before shown, we divide the larger by the smaller, and this gives us the ratio 3, with which, by multiplying the third term, we produce the fourth; or, let the three terms be these, 405, 1215, 5, and let it be our wish to find a fourth which shall bear the same relation to the 15 as 1215 does to 405. We divide and multiply as before, and the fourth term is produced. And in this manner, having *two* numbers, or two quantities of any kind, bearing a certain proportion towards each other, and a *third*, to which we would find a number or quantity that should bear a like proportion, in this manner do we proceed, and thus easily may we find the number we require."

Referring to the discovered ratio of 45 to 15 to be 3, or the fifteenth part—"Now (continues this author), what would have been the consequence had we multiplied the third term (405) by the whole, instead of by a fifteenth part of the second? The consequence would have been, that we should have had a term or number fifteen times larger than that required. But this would be a matter of no difficulty; for it would be set right at once and our purpose gained, by dividing the over-large product by 15. Let us write this process down: $405 \times 45 = 18225$, and $18225 \div 15 = 1215$,—which 1215 bears the same proportion to 405 as does 45 to 15. And this is the rule, when the terms are properly placed—*Multiplying the second and third terms together, and dividing the product by the first*: this avoids all the difficulties arising from the occurrence of fractions in the course of the process, and gives us, in all cases, any proportional terms we may require."

Rule of Three.

On the principle now explained, we can, in any affairs of business, ascertain the amount of an unknown quantity, by knowing the amount of other three quantities, which, with the unknown quantity, bear a proportional relation. The word *quantity* is here used, but any *sum of money* is also meant.

Let it be remembered, that the *ratio* of one number to another is the number of times that the former contains the latter; for example, the ratio of 6 to 3 is 2, that of 12 to 4 is 3, and that of 8 to 12 is $\frac{2}{3}$. When two numbers have the same ratio as other two, they constitute a *proportion*. Thus, the ratio of 8 to 6 is the same as that of 12 to 9, and the equality of these two ratios is represented thus:—

$$8:6 = 12:9, \text{ or } 8:6::12:9.$$

The following is the rule for stating and working questions:—Make that term which is of the same kind as the answer sought, the *second* or *middle* term. Consider, from the nature of the question, whether the answer should be more or less than this term; if *more*, make the *smaller* of the other two terms the *first*, and the *greater* the *third*; if the answer should be *less* than the middle term, make the *greater* of the two terms the *first*, and the *smaller* the *third*; then multiply the second and third terms together, and divide the result by the first term. The quotient found will be the answer to the question, and it will be found to bear the same proportion to the third term as the second does to the first. Suppose the question be this: If 3 lbs. of tea cost 9s., how many pounds may be purchased for 21s.?—state the terms, with the larger sum last. Should the question, however, be the reverse—If 7 lbs. of tea cost 31s., how much may be purchased for 3s.?—then the sum to be ascertained is less, and is put last. Suppose another plain example: If 10 men can execute a piece of work in 8 days, how long will 4 men take to do the same?

```
9 : 3 :: 21
          3
       9)63
       7 lbs.

21 : 7 :: 3
          7
      21)21
       1 lb.

4 : 8 :: 10
          8
       4)80
       20 days.
```

Such is the principle of working Rule of Three questions, whatever be their apparent complexity. If either the first or third term, or both, include fractional parts, they must be reduced to the denomination of the fractions before working: thus, if one be reduced to shillings, the other must be made shillings also; if to pence, both must be pence, and so on. If the middle term be also a compound quantity, it may either be reduced to its lowest term, before multiplying and dividing by the other terms, or you may multiply and divide by Compound Division and Multiplication.

If the middle term be reduced to its lowest term, the answer will be in that denomination to which it was reduced; thus, if it were brought to farthings, the answer would be in farthings; if to ounces, the answer would be in ounces.

Example.—If 2 cwts. 1 qr. 7 lbs. sugar cost £8, 14s. 4d., what will 14 cwts. 3 qrs. cost?

```
cwt. qr. lb.     L.  s.  d.     cwt. qr. lb.

```

Here, in order to make the first term a simple number, it is reduced to its lowest term, namely, pounds. The third term is therefore reduced to pounds also, that both may be alike. The second or middle term is reduced to its lowest term, pence. After multiplying and dividing, according to rule, the quotient is 13343 pence, which are brought to shillings and pounds. The remainder, 147, being further reduced to farthings, and divided by the first term, gives 2 farthings. The answer is £55, 11s. 11½d. $\frac{70}{259}$.

The following is a kind of question which often occurs in business:—A person is unable to pay his debts. He owes to A, £540, to B, £260, to C, £200, being in all £1000. On examining his affairs, it is found that he possesses property only to the value of £370. How, then, is this to be divided proportionally among the three creditors, so that each may receive a fair share? The way to arrive at an answer, is to work out each creditor's share as a distinct account. Thus, first, as to A's share:—The answer is £199 16s. Following a similar calculation, we find that B will receive £96, 4s., and C, £74. Another method of computation would consist in ascertaining how many shillings per pound the effects would yield. In this case we state the terms as annexed.—Answer 7s. 4¾d. ⅕, or a fraction more than seven shillings and fourpence three farthings in the pound. By allotting this rate of dividend to each creditor, their respective shares would be liquidated as above. Instead of dividing 7400 by 1000, the same result will be found if 74 be divided by 10.

Questions in arithmetic arise in which a sixth term is required, bearing a proportion to five terms already known. This, which involves what is called *Double Rule of Three*, is exemplified as follows:—If I give 16 men £45 for 28 days' work, what must I give, at the same rate, to 20 men for 35 days' work? The answer, according to the plan of working here shown, is £70, 6s. 3d.

Practice and Mental Arithmetic.

Under these names are comprehended short practical methods of working arithmetical questions, partly or wholly by the mind, or by the jotting of a few figures. Ordinary business questions are seldom solved by the Rule of Three, and principally by Practice or Mental Arithmetic. The kind of questions most commonly occurring are computations of the aggregate value of a certain number of articles at a certain price, and the adding of the whole together to find the sum-total. The plan usually adopted is to calculate the value of any number of articles by the nearest round sum, and then to apply the difference. For instance, a lady is buying a gown from a haberdasher; she has received 15 yards at 5½d. per yard; the haberdasher tells her in an instant she has to pay 6s. 10½d. He knows it is so by saying internally to himself—15 yards at 6d. would be 7s. 6d. then, if I take 15 halfpence, that is, 7½d., from the 7s. 6d., I find that 6s. 10½d. will remain.

Another principle followed in this practical arithmetic is to work by aliquot parts. By remembering that a penny is the 12th of a shilling, or the 240th of a pound; that 6s. 8d. is the third of a pound; that 3s. 4d. is the sixth of a pound, and so on, we are able to save much of the ordinary figuring. As an illustration, let it be required to find the value of 3567 articles at 3s. 4d. each. By the usual rules of arithmetic, this question would be performed by multiplying the 3567 by 40 (there being 40 pence in 3s. 4d.), and then dividing by 12 to bring it into shillings, and by 20 to bring it into pounds. The practical method is much shorter; 3s. 4d. being the sixth of a pound, if we divide 3567 by 6, we at once obtain the amount, thus—

```
6)3567
 £594, 10s.
```

Interest.

Interest is an allowance for the use of money, paid by the borrower to the lender. The amount of allowance on £100 is called the *rate of interest*. The amount of money lent is styled the *principal*. In the United Kingdom, it is customary to reckon the interest at a certain rate per hundred pounds per annum, or for the whole year. The hundred pounds, for shortness, is called *cent.*, a contraction of *centum* (Latin), a hundred. If the money is lent for a less term than a year, then it becomes a question in arithmetic what is the proportion of interest chargeable. According to the existing laws (1842), £5 per cent. is the highest legal interest that is chargeable on money lent in any other form than by a bill or promissory note. The interest, commonly called *discount*, that may be taken for advances on bills or promissory notes, is left unlimited. In general, it varies from about 4 to 6 per cent., according to the state of the money market or trustworthiness of the borrower. £5, being equal to 100 shillings, the interest on £1 for a year at 5 per cent. is consequently 1s.; and if the interest be £2, 10s., or 2½ per cent., the charge will of course be 6d. per £1. This is so very simple a matter of calculation, that interests of 5 or 2½ per cent. per annum may in most instances be calculated mentally, or at least with a few figures. When the interest is 3, 3½, 4, or 4½ per cent., and for a less period than a year, the calculation is more complex, and will require to be wrought as a question in Rule of Three, or the amount may be determined by an appeal to Interest Tables.

The following is an example of the mode of working a question of interest for a whole year. What is the amount of interest payable on £649, at 4½ per £100 or per cent. per annum?

```

```

Interest on broken periods is not calculated by calendar months, but for days—the exact number of days from the day of lending to the day of paying; and therefore the calculation of the number of days is an important preliminary in the transaction. Bankers and merchants, to save the trouble of calculation, appeal to a table which shows the number of days from one day to another in the different months of the year.

When the period consists of less than a year (365 days), multiply the principal by the number of days, and by twice the rate, and divide by 73000. (We get this 73000 by multiplying 365 by 2 and by 100.) For example —What is the interest of £235, 10s. for 28 days, at 3 per cent. per annum? Here, for convenience, we begin by multiplying by 7 and by 4, instead of 28. The 6 is twice the interest, 3.

	£	s.		
	235	10		
		7		
	1648	10		
		4		
	6594	0		
		6	s.	d.
73000)	39564	0	(10	$10\frac{134}{1825}$
	20			
	791280			
	730000			
	61280			
	12			
	735360			
	730000			
	$\frac{5360}{73000} = \frac{134}{1825}$			

When partial payments are made, it is necessary to deduct them from the principal, care being taken not to confuse principal with interest. The following is a rule to follow in such a case:—Calculate the interest on the principal up to the time at which the first partial payment is made, and add it to the principal; from this sum subtract the money paid, and the remainder is a new principal; compute the interest on this principal from the time of the first payment up to the time of the second payment, add it to the latter principal; from the sum subtract the second sum paid, and the remainder is again a new principal; and continue this process till the last payment.

MENSURATION.

Mensuration refers to the measurement of objects, and is of three kinds—*lineal*, or measuring by mere length; *superficial*, which respects breadth as well as length; and *solid*, which includes, length, breadth, and thickness. In the United Kingdom, the foot of twelve inches is the common standard of measurement. A draper measures cloth with a rod of three feet or one yard, and workmen usually measure the dimensions of walls, or the superficies of apartments, by a ribbon marked in feet and inches. In common usage, the inch is divided into eighths and sixteenths.

As lineal measurement requires no explanation, we pass to a consideration of superficial measurement, or that of both length and breadth. A *superficial foot*, which is the basis of this kind of measurement, is either a square of a foot in length and a foot in breadth, in other words, a foot each way, or it is any dimension in which the length multiplied by the breadth will form a foot. For example, the surface of a piece of wood, 2 feet in length and 6 inches in breadth, is a superficial foot. A superficial foot is generally called a square foot, and is a superficies consisting of 12 times 12, or 144 square inches. Sometimes the term *square feet* is confounded with that of *feet square*, which is quite a different thing. A piece of cloth said to measure six square feet, consists of six squares of a foot each; but a piece said to measure *six feet square* would be six feet along each side, and comprise thirty-six squares of a foot each. Inattention to these distinctions has often led to awkward errors and disputes.

The method of finding the superficial contents of any oblong surface, is to multiply the length by the breadth; but other points require attention in the calculation. To arrive at exactness, the inch is reckoned to contain 12 seconds or parts each second contains 12 thirds, and each third contains 12 fourths. Feet multiplied by feet, give feet; feet multiplied by inches, give inches; feet multiplied by seconds, give seconds; inches multiplied by inches, give seconds; inches multiplied by seconds, give thirds; seconds multiplied by seconds, give fourths. *Rule* for working questions—1. Write the multiplier under the multiplicand, feet under feet, inches under inches, seconds under seconds, &c. 2. Multiply each denomination of the length by the feet of the breadth, beginning at the lowest, and place each product under that denomination of the multiplicand from which it arises, always carrying 1 for every 12. 3 Multiply by the inches, and set each product one place farther to the right hand. 4. Multiply by the seconds or parts, and set each product another place toward the right hand. 5. Proceed in this manner with all the rest of the denominations, and their sum will be the answer.

Example.—Multiply 6 feet 3 inches by 3 feet 2 inches. In working, we begin by multiplying the 3 inches by 3, and then the 6 feet also by the same 3 below it; this gives 18 feet 9 inches. This makes 18, 9. We now multiply by the 2 inches, placing the 6 one remove to a side. By then multiplying the 6 by 2, we have 12 inches or 1 foot, and setting down the 1 below the 18, we add up. The answer is 19 feet, 9 inches, and six seconds. Questions of this kind may also be wrought by decimals.

Ft	in.	
6	3	
3	2	
18	9	
1	0	6
19	9	6

To measure the *solid* contents of an object, a different process is pursued. Suppose we take a piece of wood measuring a square foot, and cover it with dice, each die an inch square and an inch high, the wood will be covered with exactly 144 dice. Let us now put a second layer of dice on the first, and the number will be doubled, or 288 dice; and if we thus go on adding layer above layer till we have 12 layers, the number of dice will be finally 12 times 144, or 1728 dice; in other words, we shall have formed a cube consisting of 1728 solid inches. Such is solid measure.

Solid measure is computed arithmetically, by multiplying the length by the breadth, and the product by the thickness. Civil engineers, who require to calculate the solid contents of masses of earth, with a view to excavation, resort to this simple rule; it is likewise followed by builders in reference to walls, plumbers to cisterns, and other artificers. The following is a question not unlikely to occur. Required the contents of a cistern 9 yards 2 feet in length, 6 yards 2 feet in breadth, and 4 yards 2 feet in depth. Analyze these dimensions—9 yards 2 feet are 29 feet; 6 yards 2 feet are 20 feet. Multiply the 29 by 20, and then multiply by 14 (14 feet being equal to 4 yards 2 feet); next divide by 27, which is the number of solid feet in a solid yard. The question is thus wrought in the margin. The answer is seen to be 300 yards 20 feet.

EVOLUTION.

The extraction or discovery of the square and cube roots of numbers, forms a department of arithmetic called *Evolution*, and is useful in some kinds of measurement. In the following table, the squares, cubes, and fourth and fifth powers of the nine units are given. The square of any number, it will be observed, is gained by multiplying the number by itself; the cube, by multiplying the square by the number; the biquadratic by multiplying the cube by the number; and the sursolid by multiplying the biquadratic by the number:—

Root, or 1st power, -	1	2	3	4	5	6	7	8	9
Square, or 2d power,	1	4	9	16	25	36	49	64	81
Cube, or 3d power, -	1	8	27	64	125	216	343	512	729
Biquad., or 4th power,	1	16	81	256	625	1296	2401	4096	6561
Sursolid, or 5th power,	1	32	243	1024	3125	7776	16807	32768	59049

The powers of numbers are usually expressed by adding a small figure to them; thus, 3^2 signifies the second power or square of 3, that is, $3 \times 3 = 9$; 3^3 signifies the third power or cube of 3, or $3 \times 3 \times 3 = 27$. The small figure thus added is called an *index* or *exponent*, because it indicates or exposes to view the powers of the quantity to which it is affixed. The square root of any small quantity may easily be ascertained by means of the multiplication table; for instance, 6 is at once seen to be the square root of 36, because $6 \times 6 = 36$; but when larger numbers occur, it is requisite to have recourse to another process.

Supposing it were required to find the length of the side of a square which contains 59,049 square inches on its surface, it is evident that it cannot at once occur to the mind what number, by being multiplied into itself, produces this quantity. It is therefore requisite to find the square of one part of the number, and then the square of the other part. To effect this, the whole number is divided into parts, by a dot being placed over each alternate figure, beginning at the unit. The reason for thus separating it into periods of two figures each, is because the square of a single figure never consists of more than two places, the square of a number of two figures of not more than four places, &c.

After the whole number has been thus divided, the root whose square comes nearest to the first period must be placed in the quotient, and its square subtracted from the first period. Thus, 5 being the first period, 2, as being the root of 4, is placed in the quotient, and the square of 2 ($2 \times 2 = 4$) is subtracted from 5, because 5 here forms the first period. The next period (90) is then annexed to the remainder for a new dividend. The root is doubled for a divisor, and after ascertaining how often it is contained in the dividend, omitting its last figure, the result (4) is placed both in the quotient and also in the unit's place of the divisor; the whole number (44) thus formed, must be multiplied by 4, and the product must be subtracted from the dividend. The same process must be repeated until there is no remainder, and the quotient will contain the root sought, which in this case is 243.

The rule for extracting the cube root is equally tedious, and indeed almost too complex for practical purposes. The methods of extracting the roots of higher powers are so complicated, that they are usually omitted in arithmetical works. The 4th, or biquadratic root, may be ascertained by extracting the square root twice, because it is the square root of the square root. The 6th root is the square root of the cube root, or the cube root of the square root.

The 8th root, being the square root of the biquadratic root, may be found by extracting the square root three times. In the same way the 9th root may be called the cube root of the cube root, and may be found by extracting the cube root twice. But the common arithmetical operations furnish no method of obtaining the 5th, 7th, 10th, 13th, 14th, 15th, 17th, 19th, 20th, and most other roots; and this part of arithmetic continued, therefore, involved in practical difficulties, until the invention of logarithms.

LOGARITHMS.

Logarithms (from two Greek words, signifying the number of the ratios or proportions) is a branch of arithmetic of comparatively modern invention, the discoverer having been John Napier of Merchiston, near Edinburgh, in the early part of the seventeenth century. The principles upon which logarithms are founded, may perhaps be rendered familiar by the following illustration:—Supposing that 1 is the first term of a geometrical progression, and that the ratio or multiplier is 2, the terms stand in the following manner:—

1	is the first term.	
2	..	ratio.
4	..	square of the ratio.
8	..	cube of the ratio.
16	..	4th power of the ratio.
32	..	5th power of the ratio.
64	..	6th power of the ratio.

All this might, however, have been conveyed far more concisely by substituting signs for words, thus—

1	..	2^0
2		2^1
4	.	2^2
8	.	2^3
16	..	2^4
32	.	2^5
64	..	2^6

It is evident that this might have been expressed still more concisely by omitting the number signifying the ratio (2) throughout, retaining only the indices or exponents, they alone being sufficient to indicate the degree of power to which the ratio is raised in each term. Exponents thus placed in order, opposite to a series of numbers in geometrical progression, are, as we have said, called Logarithms, or, literally, *number of the ratio*.

The most tedious sums in multiplication can, by means of logarithms, be solved simply by addition. For instance, if it were required to multiply 256 by 32, it would merely be requisite to add the logarithms standing opposite to those two numbers—their sum (13) stands opposite the product required, namely, 8192:—

Num.			Log.	Num.			Log.
1	..	..	0	128	..	..	7
2	..	..	1	256	..	..	8
4	..	..	2	512	..	..	9
8	..	..	3	1024	..	..	10
16	..	..	4	2048	..	..	11
32	..	..	5	4096	..	..	12
64	..	..	6	8192	..	..	13

Again, to multiply 128 by 16, we take the 7th + 4th, or 11th power of 2, because 128 is the 7th and 16 the 4th power of 2; opposite to the sum of 7 and 4 (11) is 2048, equal to the result of the multiplication of the two numbers. This also affords a quick and easy method of dividing one number by another; thus, if it be required to divide 4096 by 16, it is only requisite to ascertain the difference between the logarithm of these two numbers, which in this case being 8, the figure opposite to 8 is the required quotient, indicating how often 16 is contained in 4096, namely, 256 times.

The indices or exponents, 1, 2, 3, 4, &c., might, however, denote the powers of any other number or ratio. Every different ratio or geometrical progression gives a different system of logarithms. Soon after the invention of logarithms by Lord Napier, it occurred to Briggs, then professor of geometry at Oxford, that a system whose base or ratio is 10 is preferable to all others, on account of its being analogous to the general method of notation. In A. D. 1624, Briggs published the tables of logarithms which are now in common use. In this system, 10 being the ratio or multiplier, the terms may be thus expressed—

1	10	100	1000	100,000,	&c.
10^0	10^1	10^2	10^3	10^4	&c.

The exponents, 1, 2, 3, 4, are, as was shown in the previous table, the logarithms of the opposite numbers, and might therefore have been written in the following manner:—

1	10	100	1000	100,000,	&c.
0	1	2	3	4	&c.

The logarithms of all intermediate numbers, such as those between 1 and 10, 10 and 100, &c., are found by ascertaining the geometrical mean proportion between any two numbers, and likewise the corresponding arithmetical means between the indices of those numbers. In every system, 0 is the logarithm of 1. Hence, the logarithm of any number between 1 and 10 must be less than a whole number, and therefore a decimal fraction; and the logarithm of any number between 10 and 100 must be one with a fraction. In the same way, the logarithm of any number between 100 and 1000 must be 2 and a fraction, and so on, through the rest of the series. The integers, 0, 1, 2, 3, &c., to the left of the decimals it logarithms, are called the *characteristics* of those logarithms. Thus, 0 is the characteristic of all numbers between 1 and 10; 1 is the characteristic of all between 10 and 100; 2 that of all between 100 and 1000, &c. In tables of logarithms the characteristics are generally omitted.

The method of using a table of logarithms is the following:—To ascertain, in the most common tables, the logarithm of a number less than 10,000, it is merely necessary to find the first three figures of the number in the left-hand column, and the fourth figure in the horizontal line at the top; then opposite to the former and under the latter is the required logarithm. If the given number consists of five figures, find, as before, the logarithm belonging to the first four figures; the difference between it and the next logarithm may be ascertained from the margin; this difference is to be multiplied by the fifth figure of the given number, and one figure cut off from the right of the product; and the other figures of this product being added to the preceding logarithm and the index 3 prefixed, the sum will be the required logarithm.

The process of finding the natural number of any given logarithm is precisely the converse of that just described. The given logarithm must be sought in the table, and against it, in the left-hand column, will be found the natural number. It has already been shown that tables of logarithms afford an easy method of finding the product in multiplication, and the quotients in division, by means of simple addition and subtraction. Logarithms are equally applicable to the solution of questions in proportion or the rule of three, it being merely requisite to add the logarithms of the second and third terms together, and from the sum to subtract the logarithm of the first; the remainder is the logarithm of the fourth term.

A number may, by means of logarithms, be raised to any required power, by multiplying the logarithm of the number by the index of the power. Thus to square any number, multiply its logarithm by 2; to cube a number, multiply its logarithm by 3; and so on.

To extract the root of any given number, the logarithm of the number must be divided by the proposed index, and the quotient is the logarithm of the required root. Thus, to find the square root of 169, it is only necessary to divide its logarithm, which is 2·2278867 by 2; opposite to the quotient will be found the number 13, which is the square root of 169, because $13 \times 13 = 169$.

ALGEBRA.

We have seen that logarithmic tables may be used as a substitute for many lengthened operations in arithmetic. It is evident that the value of all methods of computation lies in their brevity. Algebra must be considered as one of the most important departments of mathematical science, on account of the extreme rapidity and certainty with which it enables us to determine the most involved and intricate questions. The term *algebra* is of Arabic origin, and has a reference to the resolution and composition of quantities. In the manner in which it is applied, it embodies a method of performing calculations by means of various signs and abbreviations, which are used instead of words and phrases, so that it may be called the system of symbols. Although it is a science of calculation, yet its operations must not be confounded with those of arithmetic. All calculations in arithmetic refer to some particular individual question, whereas those of algebra refer to a whole class of questions. One great advantage in algebra is, that all the steps of any particular course of reasoning are, by means of symbols, placed at once before the eye; so that the mind, being unimpeded in its operations, proceeds uninterruptedly from one step of reasoning to another, until the solution of the question is attained.

Symbols are used to represent not only the known, but also the unknown quantities. The present custom is to represent all known quantities by the first letters of the alphabet, as a, b, c, &c., and the unknown quantities by the last letters, x, y, z.

The symbols used in arithmetic to denote addition, subtraction, &c., belong properly to algebra. Thus the sign $+$ *plus*, denotes that one quantity is to be added to another, and is called the positive or additive sign; all numbers to which it is prefixed are called *positive*. The sign $-$ *minus*, denotes that one quantity is to be subtracted from another; it is called the negative or subtractive sign, and all quantities to which it is prefixed are called *negative*. If neither $+$ nor $-$ be prefixed to a quantity, then the sign $+$ *plus* is understood.

The general sign to denote that one number is to be multiplied by another, is $\times$; but it often occurs that one letter has to be multiplied by another, and this is represented by placing those letters one after the other, generally according to the order in which they stand in the alphabet; thus a multiplied by b, is expressed by ab. The multiplication of quantities consisting of more than one term, as for instance $a + b$ by $c + d$, may be represented by any one of the following methods:—$\overline{a+b} \times \overline{c+d}$, or $\overline{a+b}.\overline{c+d}$, or $(a+b)(c+d)$. The bar drawn over $a + b$ and $c + d$, which in the two first examples marks them as distinct quantities, is called a *vinculum*, but brackets or parentheses for the same purpose, as in the last example, are now in more frequent use.

When a letter is multiplied by any given number, it is usual to prefix that number to the letter. Thus, twice a, three times b, four times c, six times x, &c., are expressed thus: $2a$, $3b$, $4c$, $6x$; and the numbers 2, 3, 4, 6, thus prefixed, are called the *coefficients* of the letters before which they stand.

The sign $\div$ between two numbers shows, as in arithmetic, that the former of those numbers is to be divided by the latter; thus $a \div b$, means that a is to be divided by b. It is, however, more usual to place the number to be divided above that by which it is to be divided, with a small line between, in the form of a fraction; thus $\frac{a}{b}$ denotes that a is divided by b.

It has been shown in Arithmetic that the powers of quantities are denoted by a small figure, called the exponent or index of the power. Thus, $a \times a$, or the square of a, is expressed by a^2; $b \times b \times b$, or the cube of b, is expressed by b^3, &c. The cube of $a + b$, or of $(a + b)(a + b)$ is expressed thus: $(a + b)^3$.

The roots of quantities are represented by the sign $\surd$ with the proper index affixed; thus $\sqrt[2]{a}$, or, more simply, $\sqrt{a}$, expresses the square root of a; $\sqrt[3]{a}$ the cube root of a; $\sqrt[4]{a + b}$ represents the 4th or biquadratic root of $a + b$. Fractional indices are also frequently used to denote the roots of quantities, thus:

$a^{\frac{1}{2}}$ is the square root of a.
$a^{\frac{1}{3}}$ is the cube root of a.
$a^{\frac{1}{4}}$ is the 4th root of a &c.

Again, $a^{\frac{2}{3}}$ is the cube root of a^2, or of the square of a.
$a^{\frac{3}{2}}$ is the square root of a^3, or of the cube of a.
$a^{\frac{2}{5}}$ is the 5th root of a^2.

When two or more letters or quantities are connected together by signs, the combination is called an algebraic expression, and each letter or quantity is called a *term*.

Quantities of one term are called simple quantities; as a, $2a$, $3b$, &c.

A quantity of two terms, as $b + c$, is called a *binomial*.

When a binomial expresses the difference between two quantities, it is called a *residual*, as $a - b$.

A quantity consisting of 3, 4, or many terms, are called respectively *trinomials*, *quadrinomials*, *multinomials*.

The sign $=$ placed between two quantities shows, as in arithmetic, the *equality* of those quantities.

When quantities are connected by this sign, the expression is called an *equation*: thus, $2+4=6$, is an equation, as also, $a+b=c-f$.

The symbol $>$ or $<$ is called that of *inequality*, it being placed between two quantities, of which one is greater than another; the open part of the symbol is always turned towards the greater quantity: thus, $a>b$ denotes a to be greater than b; and $c<d$ denotes d to be greater than c. The sign of difference is $\backsim$, only used when it is uncertain which of two quantities is the greater; thus $e \backsim f$ denotes the difference between e and f when it is uncertain which is the greater.

The word *therefore*, or *consequently*, often occurring in algebraical reasoning, the symbol $\therefore$ has been chosen to represent it: thus, the sentence "Therefore $a+b$ is equal to $c+d$," is thus expressed in algebra, $\therefore a+b=c+d$.

Like quantities are such as consist of the same letter or letters, or power of letters: thus, $6\,a$ and $2\,a$ are like quantities, and also $4\,abc$ and $9\,abc$. *Unlike* quantities are such as consist of different letters: as, $4a$, $5b$, $6\,ax^2$, $4\,cd$, which are all unlike quantities.

Addition.

The operation of addition in arithmetic consists, as has been shown, simply in joining or adding several quantities together: thus, $4+8+7+6=25$. This same process is always used in algebra, whenever *like* quantities with *like* signs are required to be added: thus, $2\,a+3\,a+6\,a=11\,a$; and $-7\,b-4\,b-6\,b=-17\,b$. But as it often happens that like quantities which are to be added together have unlike signs, addition has in algebra a far more extended signification than in arithmetic. Thus, to add $7\,a+4\,a$ to $8\,a-3\,a$, it is evident that, after $7\,a+4\,a+8\,a$ have been added according to the usual method, $3\,a$ must be subtracted. Hence the general rule for the addition of *like* quantities with *unlike* signs is to add first the coefficients of the positive terms, and then to add those of the negative terms; the less sum must be subtracted from the greater, and to this difference the sign of the greater must be annexed, with the common letter or letters. Thus, let it be required to add $7\,a-3\,a+4\,a+5\,a-6\,a-2\,a$ and $9\,a$; $25\,a$ will be found the sum of the positive terms, and $11\,a$ that of the negative; $11\,a$ being the less number, must therefore be subtracted from $25\,a$, the greater, leaving a remainder of $14\,a$, which is the required amount. The reason of this mode of procedure may be shown by a simple illustration:—As a letter may represent any quantity, let a represent £5; and suppose that a gentleman has in one bank $7\,a$, or seven five pounds; in another bank $4\,a$, and in another $9\,a$, or nine five pounds: let us suppose, too, that his tailor's bill is $6\,a$, or six five pounds; his baker's $3\,a$, or three five pounds; and his butcher's $2\,a$, or two five pounds; it is evident that, to ascertain how much money is really his own, he must first compute the whole value of his property dispersed in the different banks, then the amount of the bills of his creditors, and then find the difference between the two sums by subtracting the less from the greater. When the aggregate of the positive terms is equal to that of the negative ones, the sum of the two quantities will be equal to 0: thus if a man possesses £2000, and owes £2000, it is evident that when his debts have been deducted from his property, nothing will remain. Unlike quantities can only be added by collecting them in one line, and prefixing the proper sign of each; thus, the sum of $3\,a+2\,b+4\,c-2\,d$ can only be rendered $3\,a+2\,b+4\,c-2\,d$; this will be evident by reflecting that different letters in the same algebraical expression always represent different quantities, which cannot of course be added into one sum unless their precise value be known. Thus, the addition of a and b cannot be represented by $2\,a$ or $2\,b$, because that would imply that a is equal to b, which it is not necessarily; neither could it be represented by ab, because ab denotes the multiplication of the two quantities; the only method then of expressing these sums is thus, $a+b$. When like and unlike quantities are mixed together, as in the following example, the like quantities must first be collected together according to the method above described, and all unlike quantities must be annexed in order:—

$$\begin{array}{rrrr} & 9\,a & +\ 5\,xy & -\ 8\,ay \\ - & 8\,xy & -\ 10\,x & +\ 2\,xy \\ & 3\,x & -\ 7\,ay & -\ 5\,x \\ & 5\,ax & -\ 6\,ax & +\ 11\,y \\ - & xy & -\ 4\,a & +\ 9\,ax \\ & 2\,ay & +\ 12\,x & -\ 2\,a \\ - & 10\,y & -\ 3\,xy & +\ 13\,ay \\ \hline & 3\,a & -\ 8\,ax & -\ 5\,xy+y \end{array}$$

Subtraction.

When two like quantities, having like signs, are to be subtracted the one from the other, the process is precisely the same as that already described in arithmetic: thus, $3\,a$ subtracted from $7\,a$, leaves as a remainder $4\,a$. From $8\,a+5\,a$ take $6\,a+2\,a$, and the remainder will be $2\,a+3\,a$, or $5\,a$.

But supposing it were required to subtract $6\,a-4\,a$ from $9\,a$, it is evident that some other process must be adopted; because, if $6\,a$ be subtracted from $9\,a$, the proposed operation will not be performed; for it is not $6\,a$, but $6\,a-4\,a$, that is, $2\,a$, which is required to be subtracted from $9\,a$; $6\,a$ subtracted from $9\,a$ leaves $3\,a$, which is $4\,a$ less than would result from subtracting $2\,a$ from $9\,a$; but if to $3\,a$ we add the other term, namely, $4\,a$, the sum will be the remainder sought, because $3\,a+4\,a=7\,a$; and if $2\,a$ be subtracted from $9\,a$, which is just the same question in another form, for $6\,a-4\,a$ is $=2\,a$, the remainder is just $7\,a$ as before. So, if $a-b$ is to be subtracted from c, the remainder would be $c-a+b$, and for the same reason. It may therefore be given as a general rule, that all the signs of a quantity which is required to be subtracted from another, must be changed: thus, when $4\,x-3\,y$ is subtracted from $7\,a+5\,b$, the remainder is written thus, $7\,a+5\,b-4\,x+3\,y$.

When like quantities are to be subtracted from each other, it is usual to place them in two rows, the one above the other; the signs of the quantities to be subtracted must, for the reason above adduced, be conceived to be changed; and the several quantities must be added, as shown in the following examples:—

$$\begin{array}{rl} \text{From} & 5\,ax+7\,xy-2\,y \\ \text{Take} & 3\,y+3\,ax-6\,xy \\ \hline \text{Remainder,} & 2\,ax+13\,xy-5\,y \end{array}$$

Multiplication.

The multiplication of two quantities is performed by multiplying, as in arithmetic, the coefficients of the quantities, and then prefixing the proper sign and annexing letters: thus, the product of $3\,a$, multiplied by $5\,b$, is $15\,ab$, and $7\,a\times 4\,ab=28\,ab^2b$.

When the signs of both quantities are alike, the sign $+$ is to be prefixed; but when unlike, the sign $-$ must be prefixed, which may be thus shown at one view:—

1. $+$ multiplied by $+$ produces $+$
2. $-$ multiplied by $-$ produces $+$
3. $+$ multiplied by $-$ produces $-$
4. $-$ multiplied by $+$ produces $-$

Hence the technical rule generally given is, that "like numbers produce *plus* $+$, and unlike produce *minus* $-$." This, however, is not perfectly true when more than two quantities are to be successively multiplied; because although the product of an even number of negative quantities is positive, yet the product of an odd number of negative quantities is always negative; thus,

$$-a\times -b\times -d=-abd$$
$$\text{and } -a\times -b\times -d\times -c=abde.$$

When the same letter occurs in both quantities, the indices must be added; thus, $a^2 \times a^3 = aaaaa = a^5$. In the multiplication of compound quantities, it is usual to commence from the left-hand figure; the multiplication, for instance, of $8ab - 4ac + x$ by $2a$, is thus performed:—

$$\begin{array}{l} 8ab - 4ac + x \\ 2a \\ \hline 16a^2b - 8a^2c + 2ax \end{array}$$

To multiply two compound quantities, each term of the one must, as in arithmetic, be multiplied by each term of the other; these particular or partial products must be added according to the rules of addition, and their sum will give the whole product, as shown in the following instance:—

$$\begin{array}{lr} \text{Multiply} & 3a + 8b \\ \text{By} & a - b \\ \hline & 3a^2 + 8ab \\ & -3ab - 8b^2 \\ \hline \text{Product,} & 3a^2 + 5ab - 8b^2 \end{array}$$

Division.

The operations of division being in algebra, as in arithmetic, merely the converse of those of multiplication, the same rules respecting signs apply in both. Thus, $6ab^2$, divided by $2b$, is equal to $3ab$,

$$\text{And } -8cx^2 \div 4x, \text{ or } -\frac{8cx^2}{4x} = -2cx$$

In division, all letters common to both quantities must be omitted in the quotient; and when the same letters occur in both with different indices, the index of the letter in the divisor must be subtracted from that in the dividend; thus,

$$abx \div ab, \text{ or } \frac{abx}{ab} = x: \text{ and}$$

$$6a^5 \div 2a^3 \text{ or } \frac{6a^5}{2a^3} = 3a^2$$

When the exponent of any letter in the divisor exceeds that of the same letter in the dividend, the latter exponent must be subtracted from the former, and the quotient will be in the form of a fraction; thus,

$$-12a^3x^2 \div 8ax^5 = -\frac{12a^3x^2}{8ax^5} = -\frac{3a^2}{2x^3}$$

When the number to be divided is a compound quantity, and the divisor a simple one, then each term of the dividend must be divided separately, and the result will be the answer; thus,

$$\frac{6a + 24ab + 8a^2 + 12ac}{2a} = 3 + 12b + 4a + 6c$$

When the divisor and dividend are both compound quantities, the rule is the same as that of long division in arithmetic. When there is a remainder, it must be made the numerator of a fraction, under which the divisor must be put as the denominator; this fraction must then be placed in the quotient, as in arithmetic. The compound quantities must, however, be previously arranged in a particular way, namely, according to the descending powers of some letter, as of b in the following example; and this letter is called the *leading* quantity. The following is an example of the division of compound quantities:—

$$\begin{array}{l} b - x)\; b^3 - 3b^2x + 3bx^2 - x^3\; (b^2 - 2bx + x^2 \\ \quad\quad\; b^3 - b^2x \\ \hline \quad\quad\; * - 2b^2x + 3bx^2 \\ \quad\quad\;\;\;\, - 2b^2x + 2bx^2 \\ \hline \quad\quad\quad\quad * \quad\;\; bx^2 - x^3 \\ \quad\quad\quad\quad\quad\;\;\; bx^2 - x^3 \\ \hline \quad\quad\quad\quad\quad * \end{array}$$

Fractions.

The rules regulating the management of fractions in algebra are similar to those in arithmetic.

A mixed quantity is reduced to a fraction by multiplying the whole or integral part by the denominator of the fraction, and annexing the numerator with its proper sign to the product; the former denominator, if placed under this sum, will give the required fraction. Thus, the mixed quantity $2x + \frac{5ab}{6c}$ may be thus reduced to a fraction: $2x \times 6c = 12cx$, and as $5ab$ must be added to form the numerator, and the former denominator be retained, the required fraction is the following: $\frac{12cx + 5ab}{6c}$. An operation exactly the reverse of this would of course be requisite, were it proposed to reduce a fraction to a mixed quantity. Thus, the fraction $\frac{12cx + 5ab}{6c}$ may be reduced to a mixed number by dividing the numerator by the denominator; the numerator of the fractional part must be formed by that term which is not divisible without a remainder; the following is therefore the required mixed quantity: $2a + \frac{5ab}{6c}$. A fraction is reduced to its lowest terms, in algebra as in arithmetic, by dividing the numerator and denominator by any quantity capable of dividing them both without leaving a remainder. Thus, in the fraction $\frac{10a^3 + 20ab + 5a^2}{35a^2}$, it is evident that the coefficient of every term can be divided by 5, and as the letter a enters into every term, $5a$ may be called the greatest common measure of this fraction, because it can divide both the numerator and the denominator. The numerator, $(10a^3 + 20ab + 5a^2) \div 5a = 2a^2 + 4b + a$; and the denominator, $35a^2 \div 5a = 7a$; hence the fraction, in its lowest terms, is $\frac{2a^2 + 4b + a}{7a}$. Sometimes the greatest common measure of two quantities is not so obvious as in the example just adduced, in which case recourse must be had to the following operation:—The quantity, the exponent of whose leading letter in the first term is not less than that in the other, must first be divided by the other; the divisor must then be divided by the remainder; each successive remainder is made the divisor of the last divisor, until nothing remains; when the divisor last used will be the greatest common measure. Quantities which have no common measure or divisor except 1, are called *incommensurable*; thus, 7, 5, 3, and 11, are incommensurable quantities, and are also said to be *prime* to each other. When fractions are required either to be added or to be subtracted, they must necessarily be first reduced to a common denominator, which is effected by multiplying each numerator by every denominator but its own, to produce new numerators, and all the denominators together for the common denominators. The new numerators can then be either added or subtracted according as the case may require, and the new denominator must be left unchanged. Multiplication of fractions is performed by multiplying all the numerators together for a new numerator, and their denominators together for a new denominator; it is then usual to reduce the resulting fraction to its lowest terms. Division of fractions is effected by multiplying the dividend by the reciprocal of the divisor. The reciprocal of any quantity is unity, or 1 divided by that quantity, or simply that quantity inverted: thus, the reciprocal of a or $\frac{a}{1}$ is $\frac{1}{a}$, and the reciprocal of $\frac{a}{b}$ is $\frac{b}{a}$: therefore, to divide a fraction as $\frac{8a^2}{2}$ by $\frac{4a}{5}$ the dividend [illegible] must be multiplied by the reciprocal of $\frac{4a}{5}$, which is $\frac{5}{4a}$; therefore, $\frac{8a^2}{4} \times \frac{5}{4a} = \frac{40a^2}{16a}$; this last fraction, divided by its greatest common measure $8a$, is the fraction required, namely, $\frac{5a}{2}$.

Involution and Evolution.

The raising of a quantity to any required power is called involution, and is performed by multiplying the quantity into itself as often as it is indicated by the given power. When the quantity has no index, it is only necessary to place the given power above it, in order merely to indicate the power: thus, the 4th power of a is a^4, and the cube or 3d power of $a + b$ is $(a + b)^3$.

When the quantity has an index, that index must be multiplied by the given power; thus, the fourth power of a^2 is a^8, because $2 \times 4 = 8$. If the quantity required to be raised be a fraction, both the numerator and the denominator must be multiplied by the given power: thus, the square of $\frac{a^2}{d^3}$ is $\frac{a^4}{d^6}$. When the sign of the quantity is +, then all the powers to which it can be raised must be +; if —, then all the even powers will be +, and all the odd powers —. Thus $x \times x = x^2$; $-a \times -a = +a^2$; $-a \times -a \times -a = -a^3$.

A compound quantity, that is, one consisting of more than one term, is raised to any given power by multiplying it into itself the number of times denoted by the power. This is done according to the method already described in multiplication. Thus, the square of $x + 4y$, is thus found:

$$\begin{array}{rl} \text{Multiply} & x + 4y \\ \text{By} & x + 4y \\ \hline & x^2 + 4xy \\ & \qquad\; 4xy + 16y^2 \\ \hline \text{Square} = & x^2 + 8xy + 16y^2 \end{array}$$

The operations of evolution are the reverse of those of involution, being designed to discover the square root, cube root, &c., of any given quantity. The roots of numerical coefficients are found as in arithmetic: thus, the square root of $49a^2$, is $7a$, because $7 \times 7 = 49$. The index of the given quantity must be divided by 2 for the square root, by 3 for the cube root, by 4 for the 4th root, &c.: thus, the cube root of a^6 is a^2.

The square root of compound quantities may be extracted by a method very similar to that described in arithmetic, and of which an example was there given. The cube root may likewise be extracted by a similar process.

Irrational Quantities, or Surds.

Some numbers have no exact root; for instance, no number multiplied into itself can produce 5. The roots of such quantities are expressed by fractional indices, or by the sign $\surd$, which is called the radical sign, from the Latin *radix*, a root: thus, the square root of 5, and the cube root of $(a + b)^2$, may be expressed either by $\sqrt{5}$, $\sqrt[3]{(a+b)^2}$, or by $5^{\frac{1}{2}}$, $(a+b)^{\frac{2}{3}}$.

The approximate value of such quantities can be ascertained to any required degree of exactness by the common rules for extracting roots: thus, the square root of 2 is 1 and an indefinite number of decimals; but as the exact value can never be determined, the name of *irrational* is given to such quantities, to distinguish them from all numbers whatever, whether whole or fractional, of which the value can be found, and which are therefore termed *rational*. Irrational numbers are generally called *surds*, from the Latin *surdus*, deaf or senseless.

Equations.

When two quantities are equal to each other, the algebraical expression denoting their equality is called an *equation*. Thus, $x - 2 = 4 + 3$ is an equation, denoting that if 2 be deducted from some unknown quantity represented by x, the remainder will be equal to $4 + 3$, that is, to 7; therefore, the value of x in this equation is evidently $7 + 2$, or 9.

The doctrine of equations constitutes by far the most important part of algebra, it being one of the principal objects of mathematics to reduce all questions to the form of equations, and then to ascertain the value of the unknown quantities by means of their relations to other quantities of which the value is known.

Many problems, which are now quickly and readily determined by being reduced to equations, used formerly to be solved by tedious and intricate arithmetical rules; and they may still be found in old treatises on arithmetic, arranged under the titles of Double and Single Position, False Position, Allegation, &c. Equations receive different names, according to the highest power of the unknown quantities contained in them. An equation is said to be *simple*, or of the *first degree*, when it contains only the first power of the unknown quantity: thus, $x \times b = 35a - 2$ is a simple equation, the unknown quantity being represented by x, as it generally is in other equations, and the known quantities by the other letters and figures. $x^2 + 4 = 8a$, is a *quadratic* equation, because x, the unknown quantity, is raised to the second power. $x^3 = a + 3b$ is a *cubic* equation, the unknown quantity being raised to the third power. $x^4 - a = 25c$ is a *biquadratic* equation, because x is raised to the 4th power. If equations contain unknown quantities raised to the 5th, 6th, or higher powers, they are denominated accordingly.

The quantities of which an equation is composed, are called its *terms*; and the parts that stand on the right and left of the sign =, are called the *members* or *sides* of the equation.

When it is desired to determine any question that may arise respecting the values of some unknown quantity by means of an equation, two distinct steps or operations are requisite; the first step consists in translating the question from the colloquial language of common life into the peculiar analytical language of the science. The second step consists in finding, by given rules, the answer to the question, or in other words, the solution of the equation. Expertness and facility in performing the former operation cannot be produced by any set of rules; in this, as in many other processes, practice is the best teacher. Every new question requires a new process of reasoning; the conditions of the question must be well considered, and all the operations, whether of addition, subtraction, &c., which are required to be performed on the quantities which it contains, are to be represented by the algebraic signs of +, —, &c.: the whole problem must be written down as if these operations had been already performed, and as if the unknown quantities were discovered, which can be done very briefly by substituting the first letters of the alphabet for the known quantities, and the last letters for the unknown, prefixing to each the signs of addition, multiplication, &c., which may be denoted in the question. Thus, suppose a farmer wished to divide £1, 15s. between his two sons, allowing 9s. more to the elder than to the younger, what would each receive? To express this question in algebraic language, the share of the younger son may be represented by x, and then that of the elder son will be $x + 9$. The steps of reasoning by which this question may be solved, are the following:—The share of the elder + the share of the younger is £1, 15s., equal to 35s. therefore, $x + 9 + x = 35$, or $2x + 9 = 35$ ∴ $2x = 35 - 9$, or $2x = 26$ ∴ x (share of the younger son)

$x = \frac{26}{2} = 13$, and $x + 9$ (the share of the elder son) $= 13 + 9 = 22$.

The second operation in determining a question may be said to consist in contrivances to get x, or the unknown quantity, to stand alone on one side of the equation, without destroying the equality or balance between the two sides; because, in such an equation, for instance, as the following, $x = 4 + 2$, the value of x is at once seen; if 6 were to be put in the place of x, the question would be said to be *fulfilled*, because then it would stand thus, $6 = 6$; therefore, 6 is the *root* or solution of the equation, $x = 4 + 2$. In some questions, the unknown quantity is so much involved with known quantities, that it is often a difficult, although always a highly interesting process, to separate it from them. Many rules for effecting this are given in most algebraical treatises, but they may all be comprised in one general observation, namely, that any operation, whether of addition, subtraction, &c., may be performed on one side of an equation, provided only that the very same operation be performed on the other side, so as not to destroy their equality. Thus, in the equation $x + 5 = 12$, it is evident that, if 5 could be removed from the left to the right side of the equation, x would stand alone, and its value at once be ascertained; it having been already stated that any operation may be performed on one side of the equation, provided only the same operation be performed on the other, it follows that 5 may be subtracted from the left side, if subtracted likewise from the right; therefore, $x + 5 - 5 = 12 - 5$; but $5 - 5$ being equal to 0, the equation would more properly be expressed thus, $x = 12 - 5$; that is to say, the value of x is 7. Again, in the equation, $x - 10 = 27$, add 10 to each side of the equation; then, $x - 10 + 10 = 27 + 10$; but $-10 + 10 = 0$; therefore, $x = 27 + 10$. When the same quantity is thus subtracted from both sides of an equation, or added to both sides, the operation is technically, though perhaps incorrectly, termed, "*transposing* quantities from one side of an equation to the other."

The reason why the same operation performed upon both sides of an equation does not alter their equality, is simply because "if equal quantities be added to, or subtracted from, equal quantities, the value of the quantities will still be equal." To illustrate this, supposing a wine-merchant has 2 casks of wine, each cask containing 36 gallons, it is evident that, if he draws off the same number of gallons from each cask, the quantity of gallons remaining in each cask will still be equal; so, if he were to replace the same number of gallons of wine in each cask, the number of gallons contained in each would still be equal to each other. For the same reason, if the two sides of an equation were either multiplied or divided by the same number, their equality to each other would still remain; in the equation $3x = 27$, the value of x may be discovered by dividing both sides of the equation by its coefficient 3; thus, $\frac{3x}{3} = \frac{27}{3}$; but $\frac{3x}{3} = x$, and $\frac{27}{3} = 9$; $\therefore x = 9$. In the same way, if the unknown quantity in an equation is required to be divided by some known quantity, each side of the equation may be multiplied by the divisor; thus, in the equation $\frac{x}{4} = 32$, if each member be multiplied by 4, the result will be $x = 32 \times 4 = 128$. This is technically called clearing an equation of fractions.

On Simple Equations Containing two or more Unknown Quantities.

It may be given as a general rule, that when a question arises as to the value of two or more unknown quantities, each of these quantities must be represented by one of the last letters of the alphabet, and as many separate equations must be deduced from the question as there are unknown quantities. A group of equations of this kind is called a *system of simultaneous equations*.

If it be required to solve a system of two simple equations, containing two unknown quantities, the most natural method seems to be to determine first the value of one of the unknown quantities by means of both the equations. Then, as "things which are equal to the same thing are equal to each other," it follows that the two sets of numbers or letters in the two equations, which have been ascertained to be equal to the value of x, will also be equal to each other, and may be reduced to an equation, which will contain only one unknown quantity. This process is technically called *elimination*. Let it, for instance, be required to find the length of two planks of wood: the length of both planks together is 20 feet, and one plank is 8 feet longer than the other plank. This is evidently a question involving two unknown quantities, namely, the length of each of the two planks of wood. To translate this question into algebraical language, call the longer plank x, and the shorter plank y, then the facts above mentioned may be thus stated: $x + y = 20$, and $x - y = 8$. The value of x may be ascertained by means of both the equations, in the following manner:—

The first equation gives $x = 20 - y$
And the second, $x = 8 + y$

The two values of x, thus ascertained, must form a new equation, thus:

$$20 - y = 8 + y$$
$$20 = 8 + 2y$$

So that it is evident from this last equation that $2y$ is equal to 12, because $20 - 8 = 12$; therefore $y = 6$, and $20 - 6 = 14$. The length of both the planks is thus ascertained, the longer being 14 feet in length, and the shorter 6 feet.

This problem is not only given as an example of *elimination*, but also as an illustration of the general theorem, that "the greater of two numbers is equal to half their sum, *plus* half their difference; and that the less number is equal to half the sum, *minus* half the difference." Thus the above question might have been solved in the following manner:

$$\frac{20}{2} + \frac{8}{2} = 14, \text{ and } \frac{20}{2} - \frac{8}{2} = 6$$

The following is the method of demonstrating this curious theorem algebraically:—Let a and b be any two numbers of which a is the greater, and let their sum be represented by s, and their difference by d;

Then, $a + b = s$
and $a - b = d$

$$2a = s + d$$
$$\text{and} \quad a = \frac{s}{2} + \frac{d}{2}$$
$$\text{Also, } 2b = s - d$$
$$\text{and} \quad b = \frac{s}{2} - \frac{d}{2}$$

Quadratic Equations.

A quadratic equation literally means a *squared equation*, the term being derived from the Latin *quadratus*, squared; a quadratic equation, therefore, is merely an equation in which the unknown quantity is squared or raised to the second power. Quadratic equations are often called equations of two dimensions, or of the second degree, because all equations are classed according to the index of the highest power of the unknown quantities contained in them.

There are two kinds of quadratic equations, namely, pure and affected. *Pure* quadratic equations are those in which the first power of the unknown quantity does not appear: there is not the least difficulty in solving such equations, because all that is requisite is to obtain the value of the square according to the rules for solving simple equations, and then, by extracting the square root of both sides of the equation, to ascertain the value of the unknown quantity. For instance, let it be required to find the value of x in the equation $x^2 + 4 = 29$. By deducting 4 from each side of the equation, the value of x^2 is at once seen to be as follows: $x^2 = 29 - 4 = 25$; the square root of both sides of this equation will evidently give the value of x, thus, $x = \sqrt{25} = 5$. *Adfected* or *affected* quadratic equations are such as contain not only the square, but also the first power of the unknown quantities.

There are two methods of solving quadratic equations; we are indebted to the Hindoos for one of these methods, of which a full account is given in a very curious Hindoo work entitled *Bija Ganita*. The other method was discovered by the early Italian algebraists. The principle upon which both methods are founded is the following. It is evident that in an adfected equation, as for instance, $ax^2 + bx = d$, the first number, $ax^2 + bx$, is not a complete square; it is, however, necessary for the solution of the equation that the first side should be so modified as to be made a complete square, and that, by corresponding additions, multiplications, &c., the equality of the second side should not be lost; then, by extracting the square root of each side, the equation will be reduced to one of the first degree, which may be solved by the common process.

The following illustration from Bridge will perhaps tend more to simplify the subject, and show its practical utility, than any mere abstract rules which might be advanced. A person bought cloth for £33, 15s., which he sold again at £2, 8s. per piece, and gained by the bargain as much as one piece cost him. Required the number of pieces.

Let x = the number of pieces, £33, 15s. $\times$ 20 = 675; therefore, $\frac{675}{x}$ = the number of shillings each piece cost, and 48 x is equal to the number of shillings for which he sold the *whole*, because £2, 8s, or 48 shillings was the price he obtained for each piece. Therefore, $48x - 675$ was what he gained by the bargain. Hence, by the question, $48x - 675 = \frac{675}{x}$. This equation, after having been submitted to the usual operations of transposition and division which have been already described, assumes the form of

$$x^2 - \frac{225}{16}x = \frac{225}{16}.$$

The next step is to complete the square; this is done by adding to each side of the equation *the square of half the coefficient of the second term.*

$$x^2 - \frac{225}{16}x + \left(\frac{225}{32}\right)^2 = \frac{225}{16} + \frac{50625}{1024} = \frac{65025}{1024}$$

then, extracting the square root,

$$x - \frac{225}{32} = \frac{225}{32} \text{ and } x = \frac{480}{32} = 15.$$

Therefore, 15 pieces of cloth was the quantity sold.

It is often requisite, for the more easy solution of equations, to change them into other equations of a different form, but of equal value; and this is technically termed Transformation. Our limits will not permit us to enter on any explanation of this rule, or of the rules farther advanced in the science, as Permutations, Undetermined Coefficients, Binomial Theorem, Exponential Equations, &c. To those who desire to possess a thorough knowledge of algebra, we refer to the complete and accessible treatise of Mr. Bell, in Chambers's Educational Course.

GEOMETRY.

GEOMETRY (from two Greek works signifying the *earth*, and *to measure*) is that branch of mathematical science which is devoted to the consideration of form and size, and may therefore be said to be the best and surest guide to the study of all sciences in which ideas of dimension or space are involved. Almost all the knowledge required by navigators, architects, surveyors, engineers, and opticians, in their respective occupations, is deduced from geometry and other branches of mathematics. All works of art are constructed according to the rules which geometry involves, and we find the same laws observed in the works of nature. The study of mathematics, generally, is also of great importance in cultivating habits of exact reasoning; and in this respect it forms a useful auxiliary to logic. As will be observed from even the short sketch which we are able to present, the steps of reasoning from given and exact premises are clear and undeniable, and the results satisfactory. All subjects, it is true, are not susceptible of being brought to the test of mathematical analysis; but, to one acquainted with the process, no fantastic speculations or loose points in any argument will be accepted as proved truths, or passed over without an attempt at refutation.

It has been frequently asserted, though apparently with little truth, that geometry was first cultivated in Egypt, in reference to the measurement of the land. Thales of Miletus, who lived about 600 B. C., is among the first concerning whose attainments in mathematical knowledge we have any authentic information. About two centuries later, the Platonic school was founded, which event is one of the most memorable epochs in the history of geometry. Its founder, Plato, made several important discoveries in mathematics, which he considered the chief of sciences. A celebrated school, in which great improvement was made in geometry, was established about 300 B. C. To this school the celebrated Euclid belonged. After this period, geometrical science, like all general knowledge, gradually declined, and such continued to be the case until about a century after, when it revived among the Arabians.

About the beginning of the fifteenth century, geometry, as well as all other departments of knowledge, became more generally cultivated. In modern times, Kepler, Galileo, Tacquet, Pascal, Descartes, Huygens of Holland, our own Newton, Maclaurin, Lagrange, and many others, have enlarged the bounds of mathematical science, and have brought it to bear upon subjects which, in former ages, were considered to be beyond the grasp of the human mind

As improved by the labours of mathematicians, geometrical science now includes the following leading departments:—Plane Geometry, the basis of which is the Six Books of Euclid's Elements; Solid and Spherical Geometry, Spherical Trigonometry, the Projections of the Sphere, Perpendicular Projection, Linear Perspective, and Conic Sections. But to these main branches of the science there are added Practical Mathematics, which may be defined as an elaboration of the abstract doctrines and rules of general mathematics, in application to many matters of a practical nature in the business of life. For example, among the branches of practical Mathematics, we find Practical Geometry, Trigonometry, Measurement of Heights and Distances, Levelling, Mensuration of Surfaces, Mensuration of Solids, Land-Surveying, Calculations of Strength of Materials, Gauging, Projectiles, Fortification, Astronomical Problems, Navigation, Dialling, &c. In such a limited space as the present sheet, it would be altogether impossible to present even a mere outline of these numerous branches of general and practical mathematics; and all we propose to do is to offer a sketch of a few leading features of the science, in order to show what is meant by various terms in common use, and also to incite the reader to a regular course of study.

DEFINITION OF TERMS AND FIGURES.

In common language, the extremity of any sharp instrument, such as an awl, a pencil, or a penknife, is called a point. A small mark or dot made with such an instrument on wood or paper would also be called a point; but if examined with a magnifying glass, it would appear an irregular spot, having length and breadth. A *geometrical point*, on the contrary, has neither length nor breadth, and may be called an imaginary dot.

The extremities or ends of lines are always considered to be points; and when the two lines intersect, that is, cross each other, the intersection is called a point.

The definition always given in geometry of a *line* is, that it is *length without breadth*. It is therefore evident that a true geometrical line cannot be constructed; for however finely a line may be drawn, it will be always found to have some breadth; this will at once appear by examining it through a microscope.

In practical geometry, it is necessary to draw points and lines; but it is impossible to approach to mathematical exactness unless they be drawn as finely as possible, always bearing in mind that such lines and points are merely *symbols* of the true geometrical lines and points.

A *superficies* or *surface* has only length and breadth, and is bounded by lines. By the word surface is generally understood the outside of any thing; as, for instance, the exterior of the lid or of the sides of a box. It is also used in geometry to convey the very same idea, always supposing that it has no thickness.

A geometrical surface, like a line and a point, cannot be constructed. The thinnest sheet of paper is not a superficies but a solid, having the three kinds of bulk, technically called dimensions, which are possessed by a solid body, namely, length, breadth, and thickness.

Solids are bounded by surfaces. Geometry considers the dimensions of space as abstracted or separated from any solid body which might occupy that space: a body always occupies a space exactly equal to itself in magnitude. This will be better understood by imagining a cast to be taken of some solid body: when the body is removed, a cavity remains, and we can reason concerning the dimensions of that cavity, knowing that it is of the same length, breadth, and thickness, as the solid body from which it was cast. In this way, we reason concerning the dimensions of any given space, and with the same precision as if geometrical lines, surfaces, and solids, were really drawn in that space; and it is the business of theoretical geometry to examine the properties and relations of these forms or magnitudes. We learn from practical geometry how to form representations of the ideas thus acquired. Therefore, the common meaning usually attached to the words *point line, surface* and *solid*, is admissible in practical geometry; the object of this branch of science being to show how to draw upon paper, or construct in wood or metal, correct representations of those forms or magnitudes which are conceived to exist in space.

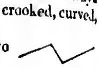
As there are three kinds of magnitudes, lines, surfaces, and solids, it follows that the natural division of the science of geometry is into three primary departments; namely, 1. Geometry of Lines; 2. Geometry of Surfaces; 3. Geometry of Solids, or Solid Geometry. The term *Plane Geometry*, however, is usually applied to the geometry of straight lines, rectilineal figures, and circles described on a plane.

Lines are named by two letters placed one at each extremity. Thus, the line drawn here is named the line A B.

A B

It is obvious that lines can be drawn in different ways and in various directions. A line can be crooked, curved, mixed, convex, concave, or straight.

1. A *crooked* line is composed of two or more straight lines.



2. A line, of which no part is a straight line, is called a *curve line*, a *curved line*, or *curve*.

3. A *mixed line* is a line composed of straight and curved lines.

4. A *convex* or *concave* line is such that it cannot be cut by a straight line in more than two points; the *concavity* of the intercepted portion is turned towards the straight line, and the *convexity* from it.

A straight line is in geometry called a *right* line, from the Latin *rectus*, straight. If two lines are such, that when any two points in the one touch or coincide with two points in the other, the whole of the lines coincide, each of them is called a *straight* or *right* line. Thus, a line which has been carefully ruled on a sheet of paper, will be found to coincide with the edge of a ruler.

A straight line, therefore, may be said to lie evenly between its extreme points. If a straight line, as A B, turn round like an axis, its two extremities A and B remaining in the same position, any other point of it, at C, will also remain in the same position.

A C B

Any point in a line is called a *point of section*, and the two parts into which it divides the line are called *segments*. Thus, the point C in the above line A B is a point of section, and A C, B C, are segments.

It is evident that two straight lines cannot enclose a space; and that two straight lines cannot have a common segment, or cannot coincide in part without coinciding altogether.

A surface may be concave, like the inside of a basin; convex, like the exterior of a ball; or plane, like the top of a flat table. A plane superficies, or, as it is commonly called, a *plane*, is considered to be perfectly even, so that if any two points are taken in it, the straight line joining them lies wholly in that surface. This cannot, perhaps, be better illustrated than by placing two flat panes of glass the one above the other. If the two surfaces coincide exactly in every part, they may be said to form a geometrical plane; and it is upon a plane equally flat and even that all geometrical lines and figures in plane geometry are supposed to be drawn.

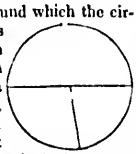
The Circle.

A figure is a part of space enclosed by one or more boundaries; if these boundaries are superficies, it is called a *solid*, and if lines, it is called a *plane* figure, in plane geometry.

The space contained within the boundary of a plane figure is called its *surface*; and the quantity of surface, in reference to that of some other figure with which it is compared, is called its *area*.

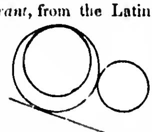
The circle is one of those figures which are most used in the arts and in practical geometry, and therefore claims particular attention. When a line is made to turn round one of its ends or extremities which remains fixed, the extremity which is carried round the other traces a line which is in every part equally distant from the point where the other end is fixed. The line thus traced is a *circle*, and is frequently termed the *circumference*, from the Latin *circum*, round, and *ferens*, carrying.

A pair of compasses are generally used in practical geometry to describe a circle. They consist of two straight and equal legs, generally of brass or iron, and always pointed at the bottom. Their upper extremities are joined together by a rivet or joint, so that they can be opened or closed at pleasure. In order to draw a circle, one end must be firmly fixed, and the other, after being opened proportionately to the required size of the circle, must be made to turn completely round, and a pencil or pen being attached to it, the trace of the circle is left upon the paper. The point in which one of the legs of the compasses is fixed, and round which the circle is described, is called its *centre*, as A. A straight line, as B, drawn from the centre to the circumference of a circle, is called a *radius*, which is a Latin word literally signifying a ray, and of which the plural is radii. A common wheel affords one of the most familiar examples of a circle. The axle is the *centre*, and the spokes are *radii*, while the outer rim of the wheel may be called the *circumference*. It is evident that all the spokes are of equal length; and this is invariably the case with the radii of every circle. A straight line, drawn through the centre of a circle, and terminated at each extremity by the circumference, is called *diameter*, from the Greek *dia*, through, and *metreo*, I measure.



An *arc* of a circle is any part of the circumference; the *chord* of an arc is a straight line joining its extremities. These two words come from the Latin words *arcus*, a bow, and *chorda*, a string, because, as is shown by the annexed figure, a geometrical arc with its chord closely resembles a bow to which a string has been attached for the purpose of shooting. A rainbow is a beautiful example of an arc. A *semicircle* is a segment, having a diameter for its chord, and therefore is just half of a circle.

When a chord is lengthened, and made to extend beyond the boundaries of a circle, it is said to *cut* the circle, and is therefore called a *secant*, from the Latin *secans*, cutting. A straight line A B, which lies wholly *outside* the circle, meeting it only in one point, is called a *tangent*, from the Latin, *tangens*, touching, because it is said to touch the circle in the point C. If the line A B were to remain fixed, and if the circle C D E were made to revolve round a point in its centre, in the same way, for instance, as a fly-wheel turns it would be found that no part of the line A B would be touched by the circle, except the one point C. This property of the circle has been turned to account in various ways. Thus, the grindstone used for sharpening knives is a circle made to revolve on its centre; the blade of the knife is held as a *tangent* to this circle; and, therefore, each time that the grindstone is turned round, it rubs against the blade, producing a finer edge, and giving it a polished appearance.



Circles are said to *touch* one another, when they meet but do not cut one another. Circles that touch one another, as the circle C D E and F G H in the last figure, are called tangent circles.

The point in which a tangent and a curve, or two tangent circles, meet, is called a *point of contact*. When of two tangent circles one is within the other, the contact is said to be *internal*; but when the one is without the other, the contact is said to be *external*. (See figure.) Tangent circles are very frequently applied to useful purposes, in various arts and manufactures. The wheels of a watch are merely so many tangent circles. When by means of the mainspring one of the circles is made to revolve, its motion causes the wheel which touches it to move also, and the motion of that tangent circle causes the wheel which touches it to move likewise; and in this way motion is transmitted or carried through the watch. It will be observed, on examining the inside of a watch, that the circumference of each wheel is indented or toothed; when the watch is going, the teeth of one wheel enters into the indentations of the other, and thus the one wheel is carried round by the other.

Concentric circles are circles within circles, having the same centre. A stone thrown into water produces a familiar instance of concentric circles; the waves at first rush in to supply the place of that portion of water which was displaced by the stone, and then by rapidly flowing back, several circles are formed, one within the other, on the surface of the water; and though these circles are of very various sizes, some being large and others small, yet the spot in which the stone fell is alike the centre of all, and therefore they are called *concentric* circles.

Circles that have not the same centre are called *eccentric*, in reference to each other from the Latin *ex*, out of, and *centrum*, centre. A point which is not the centre of a circle may also be called eccentric in reference to that circle.

Circles are called *equal* when their radii are equal in length, because it necessarily follows that the circumference is also equal: thus, the two wheels of a gig are obviously equal circles, and the spokes or *radii* of one are equal to those of the other.

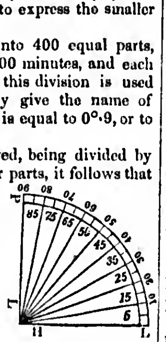
The circle, as we shall hereafter have occasion to show, is of much importance in many operations of practical geometry, and is therefore divided into 360 equal parts, called *degrees*. It would, however, have been possible to have divided the circle into any other number of degrees; the reason why the number 360 was originally fixed upon, is the following. During the early ages of astronomy, the sun was supposed to perform an annual revolution round the earth, while the earth remained perfectly stationary. The first astronomers taught that the orbit or path in which they imagined the sun to move, was a circle, and that the period which elapsed from the moment of his leaving one point in this circle until he returned to it again, was precisely 360 days. Accordingly all circles were divided into 360 degrees.

When it was discovered that the earth moves round the sun, and that she performs an entire revolution, not in 360 days, but in 365 days, 6 hours, 48 minutes, 48 seconds, it was not thought advisable to alter the division of the circle which had previously been established, because the number 360 is found of great convenience in all lengthened calculations, there being many numbers by which it can be divided without a remainder, as 1, 2, 3, 4, 5, 6, 8, 9, 10, 12, 15, 20, &c.

Each of the 360 degrees is subdivided into 60 minutes, and each minute into 60 seconds. The degree is marked thus (°); the minute (′); the second (″); so that, to express 14 degrees, 7 minutes, 5 seconds, we have only to write 14° 7′ 5″. Sometimes the second is again divided into sixty equal parts, called tierces, or thirds, which division is expressed by the sign (‴); but more frequently decimals are used to express the smaller divisions.

The French divide the circle into 400 equal parts, called degrees; each degree into 100 minutes, and each minute into 100 seconds. When this division is used by English writers, they generally give the name of *grades* to the degrees. One grade is equal to 0°·9, or to 54′, or to 3240″.

A circle, as we have just observed, being divided by mathematicians into 360 degrees or parts, it follows that the quarter of a circle includes 90 degrees. Taking, then, a quarter of a circle, and marking it as in the adjoining figure, H L is the horizontal line, and P L the perpendicular line ascending from it. Any line drawn from the centre to any point of the circumference defines the degree of inclination, or slope off the horizontal. Thus, a line ascending from the centre to the 10th degree, is called an inclination or angle of ten degrees; a line ascending to the 45th degree is called an inclination or angle of forty-five degrees; and so on with all the other degrees to the 90th. In this manner a standard of comparison has been established for defining the various slopes or inclinations in planes.

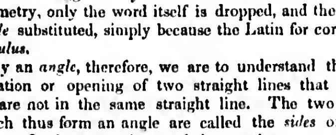


Angles.

Every one is familiar with the meaning of the word *corner:* we are accustomed to call those parts of a room in which the walls meet, the "*corners* of the room," and in the same way, the sharp point in which two sides or edges of a table meet, is also called a corner. The very same idea suggested by the word *corner* is admitted into geometry, only the word itself is dropped, and the word *angle* substituted, simply because the Latin for corner is *angulus*.

By an *angle*, therefore, we are to understand the inclination or opening of two straight lines that meet, but are not in the same straight line. The two lines which thus form an angle are called the *sides* of that angle. In the above figure of the quadrant, or quarter circle, we have an example of a right angle in the corner formed by the junction of the horizontal and upright lines.

An angle which is greater than a right angle, or more than 90° (as O), is called an *obtuse angle*, from the Latin *obtusus*, blunt, because the vertex or angular point has a blunt appearance.

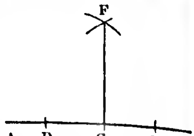


An angle which is less than a right angle, or less than 90° (as A), is called an *acute angle*, from the Latin, *acutus*, sharp, from the vertex being sharp-pointed. The number of degrees by which an obtuse angle exceeds, or by which an acute angle is less than a right angle, is called the *complement* of the angle.

The two lines which form a right angle are said to be *perpendicular* to each other; therefore, whenever a perpendicular is raised either on the ground or on paper, a right angle is formed. Thus, the walls of houses and of all architectural edifices are perpendicular, and form right angles with the ground on which they are built; and when the perpendicular is departed from, as in the Leaning Tower of Pisa, the eye is offended, and an apprehension of danger excited in the mind. It is not, however, essential that a perpendicular line should be vertical, that is to say, in the same direction as a weight falls when suspended by a string: a perpendicular may be in an inclined or even in a horizontal position, provided only that it form an angle of 90 degrees with the line to which it is perpendicular. It is so often requisite in practical geometry to erect a perpendicular, that an instrument called a Carpenter's Square has been invented for the purpose. It consists merely of two flat rulers placed at right angles to each other. As, however, instruments of this description are often made with great inaccuracy, and as it is not, besides, always possible in certain situations to have one at hand, the following methods of raising a perpendicular on a given line and from a given point will be found very useful.

Let A B be the given line, and C the given point.

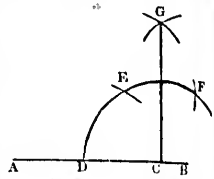
Case 1.—When the point is near the middle of the line.



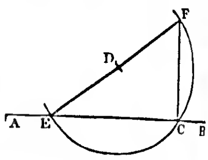
On each side of C lay off equal distances C D, C E; and from D and E as centres, with any radius, describe arcs intersecting in F; draw C F, and this is the required perpendicular.

Case 2.—When the point is near one of the extremities of the line.

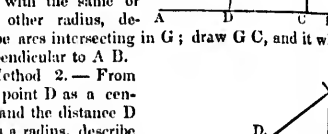
Method 1.—From C as a centre, with any radius, describe the arc D E F, and from D lay off the same radius to E, and from E to F; then from E and F as centres, with the same or any other radius, describe arcs intersecting in G; draw G C, and it will be perpendicular to A B.



Method 2.—From any point D as a centre, and the distance D C as a radius, describe an arc E C F, cutting A B in E and C; draw E D, and produce it to cut the arc in F; then draw F C, and it is the perpendicular.

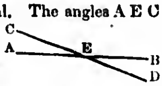


The angles made by a straight line falling on another straight line, are either two right angles, or are together



equal to two right angles. The first of the annexed figures presents an example of two right angles being formed by the meeting of two straight lines. In the second figure it is evident that the angle A C D contains exactly as many degrees more than a right angle as the angle D C B contains less than a right angle; therefore the two angles are together equal to two right angles. Each of these angles is said to be the *supplement* of the other, from the Latin *suppleo*, "I fill up what is deficient," because the numerical value of each angle is exactly what the other wants of 180 degrees, which is the sum of two right angles. Equal angles have therefore invariably equal supplements; and it is scarcely necessary to add, that all angles having equal supplements must be equal.

From this it follows, that when two straight lines cross, the opposite angles are equal. The angles A E C and D E B are called *vertical angles*, because they are opposite to each other; they are evidently equal, simply because they have



equal supplements, as will at once be seen by a careful examination of the figure. The same is true of the angles C E B and A E D. It is manifest from this, that if two straight lines cut one another, the angles which they make at the point of their intersection are together equal to four right angles. Hence, all the angles made by any number of lines meeting in one point are together equal to four right angles.

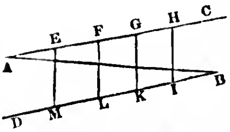
Parallel Lines.

We are surrounded by familiar examples of lines which always preserve the same distance from each other. The ruts made in a muddy road by the wheels of a cart, the iron bars called *rails* of a railroad, upon which the wheels of the steam-carriages run, the five lines upon which the characters of music are drawn, the strings of a harp and of a violin, are all so many instances of lines which are always equidistant from each other; and which, even if prolonged to an infinite extent in the same direction, could never meet. Such lines are in geometry called *parallels*, from the Greek words *para*, beside, and *allelon*, each other.

As the distance between any two parallel lines is always equal at every point, it follows that perpendiculars drawn between such lines must also be equal. Thus, in architecture, the columns which support the upper part of a building are made of equal height, because the roof which they support is parallel with the ground from which they are erected. From the fact that parallel lines cut other lines proportionally, results a mode of dividing a given line into any number of given parts.

Let A B be the given line, and let the number of equal parts be five.

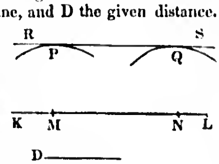
Method 1.—Draw a line A C through A at any inclination to A B, and through B draw another line B D parallel to A C; take any distance A E, and lay



it off four times on A C, forming the equal parts A E, E F, F G, G H; lay off the same distance four times on B D in the same manner; draw the lines H I, G K, F L, and E M, and they will divide A B into five equal parts. or AB, A H, and B M, are cut proportionally.

In this figure, the lines A C and B D being parallel, the parallel lines E M, F L, &c., are equal; and by them the straight line A B is divided into equal parts. In practical geometry, the method of drawing a line parallel to a given line, and at a given distance from it, depends on the fact that the parallel lines are everywhere equidistant, and is the following:—

Let K L be the given line, and D the given distance. From any two points M and N in K L as centres, and a radius equal to D, describe the arcs P and Q; draw a line R S to touch these arcs, that is to be a common tangent to them; and R S is the required line parallel to A B.



Triangles

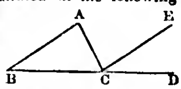
The triangle is one of the most useful figures in geometry; all figures which are bounded by straight lines are capable of being resolved or divided into triangles. A triangle has three sides, and also, as its name imports three angles.

A triangle (as E) in which the three sides are equal is called *equilateral*, from the Latin *æquus*, equal, and *latus*, a side. Such a triangle is also called *equiangular*, (from *æquus*, equal, and *angulus*, corner), because when the sides of a triangle are equal, the angles likewise are invariably equal.

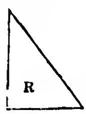
A triangle (as I) having two equal sides, is called *isosceles*, from the Greek *isos*, equal, and *skelos*, leg.

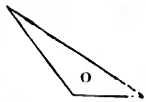
In a *scalene* triangle (as S) the three sides are of unequal length. The word *scalene* literally means unequal, being derived either from *skazo*, to limp, or from *skalenos*, unequal.

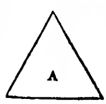
One of the most important properties of triangles is, that the three angles are together equal to two right angles. This fact is demonstrated in the following manner:—Draw a triangle as A B C, and extend one of its sides (B C) as far as D. The obtuse angle thus formed (A C D), is called an *exterior* angle, because it is outside the triangle. From the point C draw a straight line to E, parallel to the line A B. It is an established fact, that all alternate angles formed by a straight line cutting two parallel lines, are equal; the angles B A C, A C E, are alternate, because they are formed by the straight line A C, cutting the two parallel lines A B and C E, and are therefore equal. It is evident that the angles A B C and E C D are equal, because the line A B, which forms a side of one angle, is parallel to the line C E, which forms a side of the other; and the other side of each angle is made by the same line, namely, B D; and an angle being the inclination of one line to another, it is obvious that whenever, as in this case, the inclination of the lines is equal, the angles likewise must be equal. Having now proved that the obtuse exterior angle A C D is equal to the two interior and opposite angles C A B, A B C, we have merely to add A C B, the only remaining angle of the triangle, to the angle A C D; and the angles A C D, A C B, will be found equal to the three angles C B A, B A C, A C B · but the angles A C D, A C B, are equal to two right angles, because, as has been already stated, the angles made by one straight line falling upon another, are either two right angles, or are together equal to two right angles; therefore, the angles C B A, B A C, A C B, are equal to two right angles, or 180 degrees.



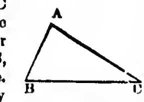
There are several very useful conclusions to be deduced from this property of triangles. 1. There can only be one right angle in a triangle; for, if one angle is 90 degrees, the other angles can only be together equal to 90 degrees; one must be the complement of the other, or what the other wants of 90 degrees. A triangle which has a right angle is called a *right-angled* triangle, as R. The side opposite the righ angle is called the *hypotenuse*. 2. It is equally obvious that a triangle cannot contain more than one obtuse angle. Fig. O is an *obtuse-angled* triangle. 3. All the angles of a triangle may be acute, as A, which is called an *acute-angled* triangle. 4. When two angles of a triangle are known, or even the sum of those angles, the third may be easily discovered; for, if the sum of two angles be deducted from 180 degrees, the remainder must be the number of degrees of which the third angle consists.





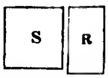


Another property of triangles is, that the greater angle of every triangle has the greater side opposite to it. In the annexed triangle, the angle ABC is greater than the angle BCA. The side AC, being opposite to the larger angle, is longer than the side AB, which is opposite to the smaller angle. There is a kind of natural geometry in the mind even of an uneducated person, according to which he acts without much reflection. Supposing that an untaught peasant had to ascend to the summit of a mountain, he would not commence his ascent from a point where the mountain forms the greatest angle with the ground, and is therefore most precipitous; he would, on the contrary, take the more circuitous road along the opposite side of the mountain, as if he were aware of the property of triangles which has been last mentioned, namely that the largest angles are subtended by the longest sides.

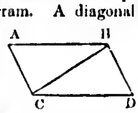


Quadrilateral Figures.

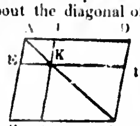
Quadrilateral, or literally four-sided figures, are sometimes called *quadrangles*, because they have four angles; they may be divided into two classes—1. Those in which all the opposite sides are parallel; and, 2. Those in which all the opposite sides are not parallel. Those belonging to the first class are called *parallelograms*, and may be further subdivided into two divisions—namely, those which contain four right angles, and to which the generic name of *rectangle* has consequently been applied; and, secondly, those which do not contain any right angles, two of the angles being obtuse and two acute. A square is the most useful of quadrilateral figures. Having four right angles, it is called a *rectangle*; and all the sides are of equal length. The figure S is a square. The annexed figure R may be called with equal propriety a parallelogram, a rectangle, or an oblong; it will be observed that its sides are not all equal, its length being greater than its breadth. In speaking of a rectangle, it is often found convenient to name it by the lines which compose its base and height, and it is called the rectangle under or contained by these lines. A *rhombus*, or *lozenge*, and a *rhomboid*, form the second division of the first class; because although the sides are parallel, the angles are not right angles. A rhombus has all its sides equal, as B. In a rhomboid, the opposite sides only are equal, as P, the length being either greater than the breadth, or *vice versa*. A *trapezoid* has only two sides parallel, as D. When the sides of a trapezoid that are not parallel are equal, it is sometimes called a *trapezium*, from the Greek word *trapeza*, a table.

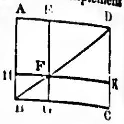


A *diagonal* is a straight line drawn between two opposite angular points of a parallelogram. A diagonal bisects a parallelogram, that is, divides it into two equal parts; thus, let ACDB be a parallelogram, of which BC is a diagonal; the opposite sides and angles of the figure are equal to one another, and the diagonal BC bisects it.



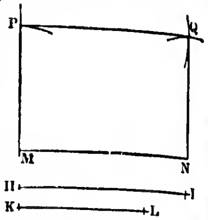
From this it immediately follows, that the complements of the parallelograms, which are about the diagonal of any parallelogram, are equal to one another. It has been shown, that the literal meaning of the term complement is *to fill up*; the application of this term to parallelograms will be understood by carefully comparing the following explanation with the annexed figure. Let ABCD be a parallelogram, of which the diagonal is AC; let EH, FG, be the parallelograms about AC, that is, through which AC passes, and BK, KD, the other parallelograms which make up the whole figure ABCD, which are therefore called the complements. The complement BK is equal to the complement KD. The two complements, joined to any of the parallelograms about a diagonal, form what is called a *gnomon*. Thus the parallelogram HG, together with the complements AF, FC, is the gnomon, which is more briefly expressed by the letters AGK, or EHC, which are placed at the opposite angles of the parallelograms which make the gnomon.





When it is required to describe a rectangle, of which the length and breadth are to be respectively equal to two given lines, the following operation is necessary:—

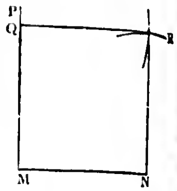
Draw a line MN equal to HI, and draw MP perpendicular to MN, and equal to KL; from P as a centre, with a radius equal to MN, describe an arc at Q; and from N as a centre, with a radius equal to MP, describe an arc cutting the former in Q; draw PQ, NQ; and MQ is the required rectangle.



A square may, for practical purposes, be described in the following manner on any given line.

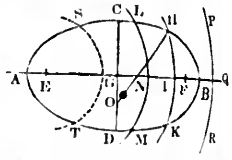
Let MN be the given line.

From M draw MP perpendicular to MN, and from MP cut off a part MQ equal to MN; then from Q and N as centres, with a radius equal to MN, describe arcs intersecting in R; draw QR, and NR, and MR* is the required square.



Ellipse.

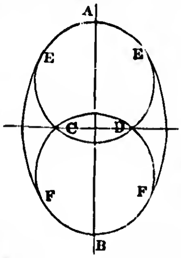
An *ellipse*, or oval, is geometrically constructed as follows, by means of a pair of compasses. Let AB be the major axis or transverse; draw a line bisecting it perpendicularly (which is done by describing from A and B as centres, with any radius, arcs cutting each other in C and D, and then joining C and D), and make GC, GD, each equal to half the minor axis or conjugate; then CD is the minor axis. From C as a centre, with half the major axis AG as a radius, cut AB in E and F, and these points are the foci. Produce AB to Q, till EQ becomes equal to AB; and from E as a centre, with EQ as a radius, describe the arc PQR, and it will be a species of directrix to the ellipse. From the same centre E, with any distance FI, describe the arc HIK, and with IQ, the distance of this arc from PQR, as a radius, and F as a centre, cut the arc HIK in H and K, and these are two points in the curve. Similarly, from E as a centre describe another arc LM; and with the distance of this arc from PQR as a radius, and F as a centre, cut the arc LM



* Quadrilateral figures are concisely named by the letters at two opposite angular points

in L and M, and these are also two points in the curve. Find the other two points S and T in exactly the same manner. Having thus found a sufficient number of points in the curve, join them all carefully, and the ellipse will thus be constructed.

An ellipse may be constructed by the following method, which will be considered sufficiently exact for many practical purposes:—On a given line, as AB, describe two circles of such diameter as may best accord with the required proportions. Whatever size be taken, let the foot of the compasses be placed so as to describe the elongated parts of the figure true on the perpendicular line AB. Then draw a horizontal line so that it intersects the parts C and D, where the circles cut each other. Now, the width of the oval may have



been previously determined; if so, it must regulate the expansion of the compasses, and determine whether the foot shall be placed on the line CD, equidistant from the centre, so as to describe the segment, that it may unite with the lines of the circles on either side, forming a continuous line, as at EE and FF; that is, in such a manner as to form the oval figure as if made by one operation.

Polygons.—Inscribed and Circumscribed Figures.

A plane figure enclosed by more than four straight lines, is called a *polygon*, from the Greek words *polus*, many, and *gonia*, an angle; because, when a figure has many sides, it has necessarily a corresponding number of angles. A regular polygon has all its sides equal, and also all its angles; an irregular polygon has its sides or angles, or both, unequal. A polygon of five sides is called a *pentagon*; of six, a *hexagon*; of seven, a *heptagon*; of eight, an *octagon*; of nine, a *nonagon*; of ten, a *decagon*; of eleven, an *undecagon*; of twelve, a *dodecagon*; and of fifteen, a *quindecagon* or *pentedecagon*. Figures which have more than twelve sides are called polygons of 13, 14, 15, 16, 17 sides, &c.

The centre of a regular polygon is a point equally distant from its sides or angular points. The *apothem* is a perpendicular drawn from the centre to any one of the sides, and analogous to the radius of a circle.

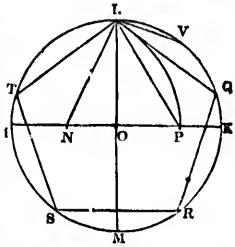
The whole boundary of any figure is called its *perimeter*, from *peri*, around, and *metreo*, I measure. The perimeter of a polygon is, in fact, what the circumference is in a circle, for by it the figure is enclosed. In practical geometry, the usual method adopted for obtaining regular polygons is, in the first place, to draw a circle about equal in size to the required size of the polygon; then the circumference is divided into as many equal parts as the polygon is to have sides; all that then remains to complete the figure is to draw straight lines or chords between each two points of division, and these lines will form the sides of the polygon.

Figures constructed according to this method are said to be *inscribed in* a circle, and all the angles of the inscribed figure will always be found to be upon the circumference of the circle. A reguler pentagon may, by the following process, be inscribed in a circle:—

Let SLR be the given circle.

Draw two perpendicular diameters, IK LM; bisect the radius OI in N; from N as a centre, with NL as a radius, cut OK in P; with radius LP, and centre L, cut the circumference in Q; join LQ, and other four chords equal to it being drawn in succession in the circle, the required polygon will be formed.

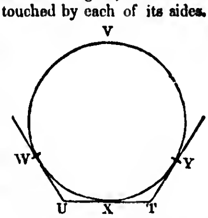
A regular decagon may be inscribed in a circle by a little extension of the same process:—



Let SLR be as before the given circle.

Find a side LQ of the inscribed regular pentagon; bisect the arc LQ in V, and the chord LV being drawn, it is a side of the regular decagon; and ten chords equal to it being successively placed in the circle, will form the polygon.

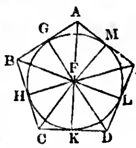
Sometimes a figure is described about a given circle, and is then said to be a circumscribed figure, the circumference of the circle being touched by each of its sides. In practical geometry, the method of describing a regular polygon about a circle is the following:—



Let WVY be the given circle.

Find the angular points of the corresponding inscribed polygon of the same number of sides; let W, X, Y, be three of these angular points; through these points draw the tangents WU, UT; TY; and UT is a side of the required polygon; in the same manner the other sides are found, and the circumscribing polygon is thus described.

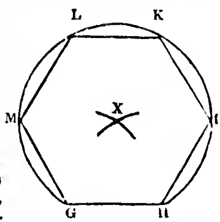
In this manner, the regular pentagon in the adjoining figure is described about the circle; H, K, L, M, and G, being the angular points of the inscribed regular pentagon, and tangents through these points being drawn, the circumscribing regular pentagon is formed.



Practical geometry affords a short and easy method of constructing a regular hexagon upon a given line.

Let GH be the given line.

From G and H as centres, with the radius GH, describe arcs intersecting in X, and this point is the centre of the circumscribing circle; hence, with the radius GH, from the centre X, describe a circle, and apply GH six times along the circumference, and GHKL is the required hexagon.



Another fact relating to the properties of regular figures, and which is of some importance in several of the mechanical arts, is, that there are only three regular figures which can cover a surface completely, so as to leave no intervening interstices; these figures are the square, the equilateral triangle, and the hexagon: we have a familiar example of the fact that squares can completely cover a surface, in a common chess-board—the sides of each square coincide exactly with the sides of the adjoining squares, and no part of the board between the squares is left uncovered. The reason of this is, that all the angles made by any number of lines meeting in one point, are together equal to four right angles, or to 360 degrees; and that, therefore, if it be required to lay any number of figures together, so that the sides may be joined, and that no space may intervene between, it is a necessary condition that the angles contained between their sides be some aliquot part of 360, else their angular points cannot all meet in one point, neither can the surface be covered exactly. The angles of squares being right angles, or angles of 90°, it is obvious that four squares can completely cover any plane surface which is proportionable to their size, because $90 \times 4 = 360$. Six equilateral triangles can be joined without leaving any interstices, because the number of degrees contained in each of their angles is 60, and $60 \times 6 = 360$. Three hexagons can also be placed contiguous to each other, because 120, the number of degrees contained in each of their angles, multiplied by 3, produces 360; but no other figures could by any means be thus placed without leaving interstices; and it is useful to bear this in mind, because in mosaic work, inlaying, paving, and some kinds of ornamental painting, it is often requisite to cover a surface with some regular figure. We sometimes see octagons laid near each other in painted floors, &c., and there is always an empty space between them; but this empty space is a perfect square, because the number of degrees in each angle is 135, and as two angles only meet in one point, the sum of both, $135 + 135$, being equal to 270, there are evidently 90° required to make up the required number 360; and 90° are, as we have shown, contained in the angle of a square.

The honeycombs of a bee-hive afford a familiar illustration of the fact just explained, with respect to the figures which can cover a surface. Of the only three regular figures which can entirely fill up any given space, the bees have selected the hexagon; but here the question arises, Why were the little mathematicians led to choose the hexagon in preference to the square? The reason is cogent and philosophical: the object of the bees was not only to fit in their habitations closely together, so that labour and wax might be saved, and that each little cell might be strengthened by the immediate juxtaposition of other cells, but also to render the interior of each cell as large and commodious as possible; because the young ones are lodged in these cells, and besides, the honey which is to supply the whole hive with food during the winter is stored away in them. Had the square or the equilateral triangle been chosen, the angles of the cell would in that case have certainly been farther from the centre, but the sides would have come nearer to it; for just in proportion to the number of sides is the length of the apothem. When a figure has but few sides, the apothem is comparatively short; and, other things being equal, it increases in length according as the sides are more numerous. The longer the apothem, the farther the sides recede from the centre; therefore, it is clear that a figure of many sides circumscribes a larger space than a figure of equal perimeter, which has fewer sides. This is one of the reasons why a circular form is given to domestic utensils, such as ewers, bottles, casks, culinary vessels, &c., and also to water-pipes, and to the pipes used for conveying gas. A circle is merely a polygon of an infinite number of sides; on account of the infinite smallness of its sides, it is free from all angular projections, and having more sides than any other polygon, it can, with a given perimeter, according to the principle just laid down, enclose the largest possible space. It follows from this, that if, from a given quantity of materials, a vessel is constructed having a circular form, that vessel will be found capable of receiving a larger volume of contents than another vessel wrought into any other form out of the same given quantity of materials would be able to contain. This principle is one of very extensive application, and is constantly acted upon in architecture and in many of the arts.

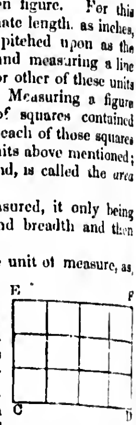
The capacity of a circle, as, for instance, a circular tube, is greatly increased by only a small addition to its diameter, because the increase is all round. The increase of capacity is in the ratio of the squares of the diameter: a tube 8 inches in diameter has four times the capacity of one which is 4 inches in diameter; one 16 inches in diameter has four times the capacity of one 8 inches in diameter; and so on.

MENSURATION OF PLANE FIGURES.

It is often requisite, for many practical purposes, to ascertain the exact size of a given figure. For this purpose certain lines of a determinate length, as inches, feet, yards, miles, &c., have been pitched upon as the *units of measure* or *lineal units;* and measuring a line consists in finding how often one or other of these units of measure is contained therein. Measuring a figure consists in finding the number of squares contained within its boundaries, the sides of each of those squares being equal to one of the lineal units above mentioned; the number of squares, when found, is called the *area* or *superficial content* of the figure.

A rectangle is very easily measured, it only being requisite to ascertain its length and breadth and then to multiply the one by the other.

If CE is a rectangle, and M the unit of measure, as, for example, a foot; and if the base CD contains M 4 times, and the side DE contains it 3 times, the number of squares described on M that are contained in CE is just $= 4 \times 3 = 12$ square feet. For by laying off parts on CD, DE, equal to M, and drawing through the points of division lines parallel to the sides of the figure, it will evidently be divided into 3 rows of squares, each containing 4 squares; that is, $3 \times 4 = 12$ squares or square feet.



If the side CD contained $4\frac{1}{2}$ inches, and DE 3 inches, it would similarly be found that the number of square inches in the figure would be $= 4\frac{1}{2} \times 3 = \frac{9}{2} \times 3 = 13\frac{1}{2}$ square inches; or $4{\cdot}5 \times 3 = 13{\cdot}5$ square inches; and whatever is the length of the sides, the area is found always in the same manner.

The area of a square is at once known by multiplying one of the sides by itself; thus, supposing one side of a square table to measure 4 feet, then 4 multiplied by 4 gives the whole number of square feet contained in the table, namely, 16.

It is demonstrated by Euclid, that parallelograms upon the same base and between the same parallels are equal to each other; from this it follows that the area of a rhombus and a rhomboid can be ascertained by the same easy process adopted for measuring rectangles, namely, by multiplying the length by the perpendicular height or breadth. The area of a triangle is also found in the same way, the base being multiplied by the perpendicular height; but only half the product denotes the content of the triangle, because a triangle is exactly the half of a parallelogram of the same base and altitude.

The area of any quadrilateral may be found by the same method: a diagonal being drawn from two of its opposite angles, it will be divided into two triangles, and by computing as above the area of each triangle, and then adding their areas together, their sum will indicate the whole extent of area comprised within the quadrilateral. The area of a trapezoid is generally found by multiplying half the sum of the two parallel sides by the perpendicular distance between them: the area of a trapezium may likewise be found in the same way. When it is desired to ascertain the area of an irregular polygon, diagonals must be drawn between the opposite angles; this will divide the figure into quadrilaterals or trapezoids, and triangles, and the area of each these must be found separately, according to the above rules; all these areas added together will give the whole superficial content of the polygon.

The area of a regular polygon is found by adding all the sides together, and then multiplying the sum by the apothem: half the product will be equal to the r . The reason of this is, that every regular polygon y be divided into as many equal triangles as it has s, and as the area of a triangle is equal to half the product produced by the multiplication of the base by the perpendicular, so the total amount of all the triangles forming a polygon may be found by multiplying the sides of the polygon, which are the bases of the respective triangles, by half the apothem; because the apothem, as before explained, is only a perpendicular drawn from the centre of the polygon to the middle of one of the sides, and is therefore equal to the perpendicular height of each triangle; half the product, as in the case of a single triangle, therefore, gives the required area.

The rule for finding the area of a polygon leads to that for finding the area of a circle; because, as before observed, a circle may, by approximation, be considered as a regular polygon with an infinite number of infinitely small sides. As the area of a polygon is obtained by the multiplication of its perimeter by its apothem, so it may naturally be inferred that the multiplication of the circumference of a circle by its radius will be the means of discovering the area of the circle. But here a difficulty arises; it is evident that the radius and circumference cannot be multiplied until the exact length of each be known: there is no difficulty of this kind in the measurement of polygons, because their sides, being straight lines, can easily be measured; the radius of a circle, being also a straight line can be measured with equal facility; but how are we to ascertain the length of the circumference? This question has occupied the attention of philosophers from age to age, and was never solved to the entire satisfaction of any till about a century ago. Innumerable attempts have been made to discover what ratio a circumference bears to its diameter. Archimedes, one of the Greek geometricians, who lived more than two thousand years ago, assigned the ratio to be as 7 to 22; nearer ratios have been discovered since his time. A Dutch mathematician carried the ratio to 36 figures, and this was at the time considered so important a discovery, that it was engraved on his tombstone at Leyden. Others subsequently extended the ratio still further; and in a French work published about 1719 A. D., it was carried to no less than 128 figures. The ratio 3·1416 is sufficiently accurate for all common purposes. When very great accuracy is required, the ratio 3·14159 may be used instead of 3.1416. Sometimes the ratio 3.1415926536 is taken, but such a high degree of accuracy is seldom required. The general rule for finding the length of the circumference of a circle is to multiply the diameter by the ratio, and the product is the circumference; or to add the stant logarithm 0·4971509 to that of the diameter, and the sum is the logarithm of the circumference.

THE CONSTRUCTION OF SCALES.—PROPORTION.

In practical geometry, scales of various kinds are used for the construction of figures. Scales are lines with divisions of various kinds marked upon them, according as they are to be used for measuring lines or angles. The name of *scales* is given to lines so divided, because the Latin word for ladder is *scala*, and the divisions are equidistant like the steps of a ladder. A line so divided is for the same reason said to be *graduated*, this word being derived from the Latin *gradus*, a step.

The *values* of the magnitudes of lines or angles are numbers representing the number of times that some unit of the same kind is contained in them.

The *unit of measure* for lines is some line of given length, as a foot, a yard, a mile, and so on.

The unit of measure for angles is, as we have already shown, the ninetieth part of a right angle.

The method of constructing a scale of equal parts is the following:—

Lay off a number of equal divisions, AB, BC, CD, &c., and AE, and divide AE into 10 equal parts.

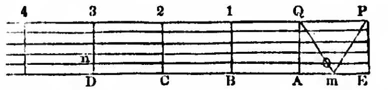
When a large division, as AB, represents 10, each of the small divisions in AE will represent 1. When each of the large divisions represents 100, each of the small divisions in AE represents 10. Hence, on the latter supposition, the distance from C to *n* is 230; and on the former supposition, it is 23.

If the large divisions represent units, the small ones on AE represent tenths, that is, each of them is $\frac{1}{10}$, or ·1. On this supposition, the distance C*n* is 2·3.

To construct a plane diagonal scale

1. A diagonal scale for two figures.

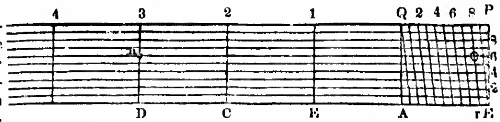
Draw five lines parallel to DE, and equidistant, and



lay off the equal divisions AE, AB, BC, CD, &., and make EP, AQ, B1, C2, &c., perpendicular to DE. Find *m* the middle of AE, and draw the lines Q*m*, *m*P.

The mode of using this scale is evident from the last If the large divisions denote tens, then from *n* to *o* is evidently 34.

2. A diagonal scale for three figures.



Draw ten lines parallel to DE, and equidistant. Lay off the equal parts AB, BC, CD, &c., and AE, and draw EP, AQ, 1, C2, ... &c., perpendicular to DE. Divide QP, into 10 equal parts. Join the 1st 2d, 3d, ... divisions on QP with the 2d, 3d, 4th, ... divisions on AE respectively.

If the divisions on AD each represent 100, each of those on QP will represent 10. Thus from 3 on AD to 8 QP is 380; but by moving the points of the compasses down to the fourth line, and extending them from *n* to *o*, the number will be 384. For the distance of 8 on QP from Q is 80, and of *r* from A is 90; and hence that of *o* from the line AQ is 84.

When the divisions on AD denote tens, those on QP denote units; and from *n* to *o* would then represent $38\frac{4}{10}$ or 30·4.

When the numbers representing the lengths of the sides of any figure would give lines of an inconvenient size taken from the scale, the numbers may be all multiplied or all divided by such a number as will adapt the lengths of the lines to the required dimensions of the figure.

Scales, by enabling us to ascertain the length of lines and magnitudes of figures, are very useful in the investigation of the doctrine of proportion. The import of the term proportion has already been sufficiently dwelt upon in arithmetic; and the reader has only to apply the ideas there developed to lines and to figures.

To prevent any misapprehension on the subject, it is well to understand clearly the distinction between the term *equal* and *similar* figures. Equal figures are those which are precisely the same in every respect, being of the same size and of the same form. Similar figures are those which are precisely of the same form or shape, but of different sizes; the angles of two similar figures are equal, and the homologous sides, that is, the sides which lie in the same relative position in each figure, are proportional.

There is always a difficulty in the demonstration of the doctrine of proportion, on account of the frequent occurrence of incommensurable quantities, that is to say, quantities which have no common measure; the subject is however rendered clear by the higher branches of mathematics.

The applications of the doctrine of proportion are very numerous and important, for it is the very foundation of many arithmetical, algebraical, and trigonometrical operations. It furnishes rules for taking plans in architecture and surveying: a map, whether of an estate or of a country, is merely a proportional representation on a small scale of the exact outline of a district. Sculpture and painting, usually numbered among the fine arts, are really wholly dependent upon the mathematical doctrine of proportion; a statue or bust, for instance, is either equal to some given figure, and is then familiarly termed "large as life," or else it is a similar figure proportionably larger or smaller than the given figure, according as it is constructed on a larger or a smaller scale. In the same way, landscape paintings are merely delineations of the prominent forms in natural scenery, all of which are represented in proportion on a smaller scale; and the value of the painting in a great measure depends on the mathematical exactness of these proportions.

ANALYSIS OF EUCLID'S ELEMENTS.

It is one of the most remarkable facts in the history of science, that, while the great majority of ancient scientific treatises have been altogether cast aside, and their place supplied by more recent productions, destined in their turn to be as entirely superseded by others of still more recent date, yet that one book has weathered every ebb and flow of popular opinion, and still holds as high, if not a higher, place in the public estimation, as when first given to the world. This work was written more than 2000 years ago; and it is surely scarcely necessary to add, that Euclid was the author, or perhaps rather the compiler, of this extraordinary production. There are thirteen books extant written by Euclid, and hence called *Euclid's Elements*. The fourteenth and fifteenth books are supposed to have been added by Hysicles of Alexandria, about 170 A. D. The method of reasoning pursued throughout these Elements, and adopted by all mathematicians, is the following:—In the first place, certain definitions, postulates, and axioms, are laid down, which form the entire basis of all mathematical science. Perhaps it might be advisable to make a few observations on the exact meaning of these terms before we proceed farther.

By a *definition*, is merely meant an explanation or a description of the characteristic properties of the object defined; the assertion, for instance, that "an isosceles triangle is that which has only two sides equal," is a definition, because it conveys to an unlearned person an idea of the meaning of the term isosceles.

A *postulate* is something that is allowed to be done, or to be *imagined* to be done. The postulates given by Euclid are the following:—

1. A line may be drawn from any one point to any other point.
2. A line may be produced (that is, continued or lengthened) at pleasure to any length.
3. A circle may be described about any centre, and at any distance, or with any radius. It will be evident, from a careful examination of these postulates, that when necessary to prove any process of reasoning, it is permitted to draw a line to the moon, and another from the moon to a star, or to any point in the heavens; and although it is of course impossible really to draw such lines, yet by these postulates we are permitted to *imagine* them to be so drawn. It is also evident, that by these postulates we are permitted the use of two instruments in mathematical reasoning, namely the ruler and the compasses.

Mascheroni, an Italian mathematician, endeavouring to render the narrow basis upon which geometry is upreared still more narrow, suggested a method of performing all mathematical problems by the aid of compasses alone, dispensing altogether with straight lines and the ruler: an account of this plan may be seen in a celebrated work published by Mascheroni about A. D. 1797, entitled *Geometria del Compassa* (Geometry of the Compasses).

An *axiom* is a statement of some simple fact which is self-evident, or requires no proof; thus, the 9th axiom is an assertion that the whole is greater than its part. It is impossible to doubt a statement like this; even a child is prepared to admit its truth; for who is not aware that a whole mass of stone, for instance, is greater than any fragment that may be broken off it? and every day's observation is equally confirmatory of all the other axioms, which, as propounded by Euclid in the first book, are the following:

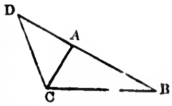
1. Things which are equal to the same thing, are equal to one another.
2. If equals be added to equals, the whole are equal.
3. If equals be taken from equals, the remainders are equal.
4. If equals be added to unequals, the wholes are unequal.
5. If equals be taken from unequals, the remainders are unequal.
6. Things which are double of the same, are equal to one another.
7. Things which are halves of the same, are equal to one another.
8. Magnitudes which coincide with one another, that is, which exactly fill the same space, are equal to one another.
9. The whole is greater than its part.
10. All right angles are equal to one another
11. Two straight lines cannot be drawn through the same point, parallel to the same straight line, without coinciding with one another.
12. It is possible for another figure to exist, equal in every respect to any given figure.

Geometrical facts and suppositions are, by Euclid and all other mathematicians, couched in a form of expression called a *proposition*. There are three kinds of propositions, *theorems*, *problems*, and *lemmas*. A *theorem* is a statement of some truth or class of truths; but as, with the single exception of the axioms, no bare assertion or statement is admitted into geometry unless fully corroborated by proofs, a theorem requires to be demonstrated. There is no way of proving the truth of a theorem, except by reference to some truth or truths already established by previous theorems; which again must have been demonstrated by some preceding theorems; and thus we are led back from theorem to theorem, until we arrive at the foundation upon which they are all found to rest, namely, the definitions and axioms.

A *problem* either proposes something to be effected, as the construction of a figure, or it is a question which ought to be solved; in either case it requires something *to be done*, and therefore depends entirely upon the postulates for its solution. After the *solution* has been stated, its sufficiency for performing all the required conditions still remains to be proved.

A *lemma* is a theorem which properly belongs to some other part of geometry, but which, from the close connection which subsists between all the branches of mathematical science, is often fitly introduced to explain some difficulty which would otherwise arise in the demonstration of the succeeding theorems or problems. As lemmas rather disturb the continuous order of a subject, they are never used by good mathematicians except when absolutely requisite.

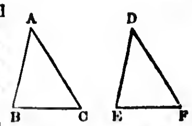
Having now explained the meaning of the terms used in geometrical reasoning, the following observations on the nature of that reasoning, and the method pursued by Euclid and others, will be readily understood:—A proposition is first stated in general terms: take, for instance, the 20th proposition—"Any two sides of a triangle are together greater than the third side." This is but bare assertion: to advance a step farther, Euclid places the figure referred to, namely, a triangle, before the student, and tells him that, in the annexed triangle, namely, ABC, any two sides of it together are greater than the third side; that is to say, the sides BA, AC, are together greater than the one side BC; the sides AB, BC, are greater than AC; and BC, CA, are greater than AB. This is certainly calling off the attention from a mere general observation, and confining it for a time to the examination of one individual case; it is also demanding the assent of the perceptive faculties; for the moment that the eye lights upon the triangle ABC the mind is immediately ready to acknowledge that two of the sides are together greater than only one of its sides: yet the matter cannot rest here. Euclid knew, as well as any of our modern philosophers, that there are *two* primary principles in the human intellect: the eye sees and conveys its impressions directly to the perceptive or observing faculties; but information thus acquired ought to be immediately brought under cognisance of those faculties which enable us to trace the cause as well as the effect, and to compare the relation of things. Euclid, therefore, subjected every proposition he advanced to a double kind of proof, by addressing *both* the sets of faculties which compose the human intellect: perhaps this may alone be sufficient to account for the fact, that his work has from age to age been used as the text-book of elementary geometry, while other works, because less truly philosophical, have engrossed public attention for a moment, and have then sunk into oblivion.



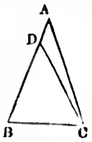
A brief analysis of the several books composing what is called Euclid's Elements, may not be unacceptable to the unlearned reader. The first three propositions in Book I. are problems, and show the several methods of describing an equilateral triangle, of drawing a straight line equal to a given straight line from a given point, and of cutting off from the greater of two given straight lines a part equal to the less. The fourth proposition is the first theorem which occurs in Euclid, and requires to be examined a little in detail, because, in connection with the 8th proposition, it forms the foundation of all that is advanced respecting the comparison of triangles. This important theorem, as stated by Euclid, is as follows:—

If two triangles have two sides of the one equal to two sides of the other, each to each, and have likewise the angles contained by those sides equal to one another, their bases or third sides shall be equal, and the two triangles shall be equal, and their other angles shall be equal, each to each, namely, those to which the equal sides are opposite. Or, if two sides and the contained angle of one triangle be respectively equal to those of another, the triangles are equal in every respect.

Let ABC, DEF, be two triangles, which have the two sides AB, AC, equal to the two sides DE, DF, each to each, namely, AB to DE, and AC to DF, and the angle BAC equal to the angle EDF; the base BC shall be equal to the base EF, and the triangle ABC to the triangle DEF; and the other angles, to which the equal sides are opposite, shall be equal, each to each namely, the angle ABC to the angle DEF, and the angle ACB to DFE. The method adopted for demonstrating this theorem, as well as that contained in the 8th proposition, is a peculiar species of demonstration which has received the name of super-position: it is in reality the same method pursued by tailors and dressmakers when they wish to satisfy themselves as to whether a piece of cloth has been cut correctly from a given pattern; they place their original pattern and the piece of cloth or silk together, the one behind the other, and carefully observe whether the edges of one project beyond those of the other; but if they both coincide in every point, the tailor knows that his cloth has been correctly cut according to the pattern. In the same way, Euclid requires the triangle ABC to be applied to, or placed exactly over, the triangle DEF, so that the point A may be on D, and the straight line AB upon DE, the point B shall coincide with the point E, because AB is equal to DE; and AB coinciding with DE, AC shall coincide with DF, because the angle BAC is equal to the angle EDF; wherefore, also, the point C shall coincide with the point F, because AC is equal to DF; but the point B coincides with the point E, wherefore the base BC shall coincide with the base EF, and shall be equal to it. Therefore, also, the whole triangle ABC shall coincide with the whole triangle DEF, and be equal to it; and the remaining angles of the one shall coincide with the remaining angles of the other, and be equal to them; namely, the angle ABC to the angle DEF, and the angle ACB to the angle DFE. The postulates do not permit one triangle to be cut out and placed over the other, therefore Euclid only *imagines* what would be the result supposing this were to be done. This theorem depends entirely upon the 8th axiom, being, in point of fact, merely what a logician would call the converse of it; for in the 8th axiom it is stated, that magnitudes which coincide with one another, that is, which exactly fill the same space, are equal to one another; and in this theorem, in order to prove them equal, it is proved that they coincide.



The demonstration of the 6th proposition is the first instance in Euclid of a species of reasoning termed by logicians *indirect*, or a *reductio ad absurdum*, and which consists in proving a theorem to be true by showing that an absurdity would follow from supposing it false. The theorem here advanced is, that if two angles of a triangle be equal to one another, the sides which subtend, or are opposite to, those angles, shall also be equal to one another, and it is demonstrated by the following indirect mode of reasoning:—Let ABC be a triangle, having the angle ABC equal to the angle ACB, the side AB is also equal to the side AC. For if AB be not equal to AC, one of them was greater than the other. Let AB be the greater, and from it cut off DB equal to AC, the less, and join DC, therefore, because in the triangles DBC, ACB, DB is equal to AC, and BC common to both; the two sides DB, BC, are equal to the two AC, CB, each to each; but the angle DBC is also equal to the angle ACB; therefore, the base DC of the one is equal to the base AB of the other, and the triangle DBC is equal to the triangle ACB, the less to the greater, which is absurd. Therefore, AB is not unequal to AC; that is, it is equal to it.



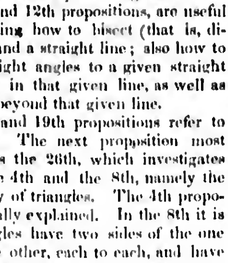
The corollary or inference drawn from this is, that all triangles having equal angles have also equal sides.

The 7th proposition affords another specimen of that kind of indirect demonstration, which logicians call a dilemma. It is stated in the proposition, that, upon the same base, and on the same side of it, there cannot be two triangles that have their sides which are terminated in one extremity of the base equal to one another, and likewise those which are terminated in the other extremity equal to one another. This is proved by examining separately every possible position in which two equal triangles can be imagined to be placed so as to have but one base: it is evident that if they *could* be so placed, the vertex of one triangle must be either without, within, or on one side of the other triangle: each of these suppositions is examined separately, and each proved to be impossible; the reader is thus brought into a dilemma, having no alternative but to admit the truth stated in the theorem. There are many instances in which this species of demonstration is used by Euclid.

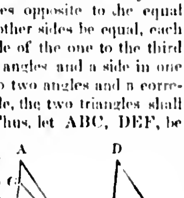
The 8th proposition refers to equal triangles.

The 9th, 10th, 11th, and 12th propositions, are useful practical problems, showing how to bisect (that is, divide in two) an angle and a straight line; also how to draw a straight line at right angles to a given straight line, from a given point in that given line, as well as from a point without or beyond that given line.

The 16th, 17th, 18th, and 19th propositions refer to the angles of triangles. The next proposition most worthy of examination is the 26th, which investigates the same subject as the 4th and the 8th, namely the conditions of the equality of triangles. The 4th proposition has already been fully explained. In the 8th it is proved that if two triangles have two sides of the one equal to two sides of the other, each to each, and have likewise their bases equal, the angle which is contained by the two sides of the one shall be equal to the angle contained by the two sides of the other; or if the three sides of one triangle be respectively equal to those of another, the triangles are equal in every respect. Thus, let ABC, DEF, be two triangles having the two sides AB, AC, equal to the two sides DE, DF, each to each, namely, AB to DE, and AC to DF; and also the base BC equal to the base EF; the angle BAC is equal to the angle EDF, and the angles at B and C of the triangle ABC are respectively equal to those at E and F of the triangle DEF.



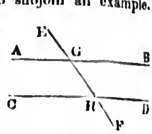
The 26th proposition gives still further information on this useful subject. It shows that if two triangles have two angles of the one equal to two angles of the other, each to each, and one side equal to one side, namely, either the sides adjacent to the equal angles, or the sides opposite to the equal angles in each, then shall the other sides be equal, each to each, and also the third angle of the one to the third angle of the other; or, if two angles and a side in one triangle be respectively equal to two angles and a corresponding side in another triangle, the two triangles shall be equal in every respect. Thus, let ABC, DEF, be two triangles which have the angles ABC, BCA, respectively equal to DEF, EFD; namely, ABC to DEF, and BCA to EFD; also one side equal to one side; and first, let those sides be equal which are adjacent to the angles that are equal in the two triangles, namely, BC to EF; the other sides shall be equal each to each, namely, AB to DE, and AC to DF; and the third angle BAC to the third angle EDF.



This little group of theorems is found very useful in the arts, for it is often requisite to have some rule by which to be able at once to determine whether two given triangles are exactly equal to each other; and if such rules were firmly engraven in the mind of every mechanic, there is no doubt but that there would be far less expenditure of time, labour, and money.

In the 27th proposition, the investigation of the properties of parallel lines is commenced, and this subject is continued through the 28th, 29th, 30th, and 31st propositions, until suddenly broken off by the introduction of one of the most remarkable propositions in the whole book, namely, the 32d, in which it is shown that the three interior angles of a triangle are together equal to two right angles. This important fact has already been examined, and therefore we have only to add that it was discovered by Pythagoras, a philosopher of Samos, about 500 B. C. The doctrine of parallel lines must not be dismissed hastily, for, with the exception perhaps of proportion, no other part of elementary geometry has created so much perplexity and discussion. The first two theorems relating to parallel lines are very simple and easily demonstrated; for the 27th theorem only affirms, that if a straight line falling upon two other straight lines makes the alternate angles equal to one another, these two straight lines shall be parallel. The 28th theorem is equally easy of demonstration, as it merely assumes that if a straight line falling upon two other straight lines makes the exterior angle equal to the interior and opposite angle upon the same side of the line, or makes the interior angles upon the same side together equal to two right angles, the two straight lines shall be parallel to one another. To make this more clear, it may be as well to subjoin an example.

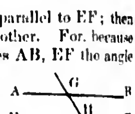
Let the straight line EF, which falls upon the two straight lines AB, CD, make the exterior angle EGB equal to the interior and opposite angle GHD upon the same side; or make the interior angles on the same side, BGH, GHD, together equal to two right angles; AB is parallel to CD.



But the 29th proposition assumes the converse of this, namely, if a straight line fall upon two parallel straight lines, it makes the alternate angles equal to one another; and the exterior angle equal to the interior and opposite upon the same side; and likewise the two interior angles upon the same side together equal to two right angles. Now, the assertion contained in this theorem is both easy of comprehension and evident to the senses; the difficulty lies in subjecting it to that rigorous demonstration to which all theorems must be brought before they can be received as mathematical truths. Euclid has endeavoured to prove it by means of a *reductio ad absurdum*, but this species of demonstration is for many reasons never adopted by good mathematicians, when it is possible to prove the truth of a statement by any other process of reasoning. Almost every succeeding mathematician has devised some particular method of his own to elucidate the doctrine of parallel lines, but no one has ever yet fully succeeded in effecting the required demonstration.

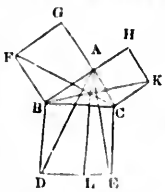
The 30th proposition shows that straight lines which are parallel to the same straight line are parallel to one another. The following demonstration of this fact is founded upon the truths previously advanced in the 29th and 27th propositions:—

Let the two lines AB, CD, be parallel to EF; then AB and CD are parallel to one another. For, because GHK cuts the parallel straight lines AB, EF the angle AGH is equal to the angle GHF. Again, because the straight line GK cuts the parallel straight lines EF, CD, the angle GHF is equal to the angle GKD; and it was shown



that the angle AGK is equal to the angle GHF; therefore, also AGK is equal to GKD, and they are alternate angles; therefore AB is parallel to CD.

The 33d proposition resumes the chain of demonstration, which was suddenly interrupted by the insertion of the famous 32d proposition, and continues the investigation of the properties of parallel lines. This subject naturally leads to the examination of parallelograms; and indeed it may be said, that almost all the succeeding propositions in the first book are devoted to the investigation of parallelograms, and the relation subsisting between the properties of parallelograms and those of triangles. In proposition 35, for instance, it is alleged that parallelograms upon the same base and between the same parallels, are equal to each other; in proposition 37, the same fact is affirmed with respect to triangles, namely, that triangles upon the same base and between the same parallels, are equal. Propositions 36 and 38 are the converse of the preceding. The most celebrated, however, of the succeeding theorems, and the most striking, perhaps, in the whole range of geometrical science, is the 47th proposition. We subjoin the theorem and the example given, and refer those who are curious as to the method of demonstration, to Euclid himself. In any right-angled triangle, the square which is described upon the sides subtending the right angle, is equal to the squares described upon the sides which contain the right angle. Let ABC be a right-angled triangle, having the right angle BAC; the square, described upon the side BC is equal to the squares described upon BA, AC; that is, the square BE is equal to the two squares BG and CH. Pythagoras had also the honour of discovering this important truth. It is related, that immediately upon the discovery, he was so transported with joy at the value of the truth, and with gratitude at being permitted to reveal it to the human race, that he sacrificed a whole hecatomb, that is to say, a hundred oxen, as a testimony of his thankfulness. This story is entirely fabulous; yet something may be gained even from a fable; and from this fictitious narration we learn, that the truth now unfolded in the 47th proposition was held in the highest estimation, not only by the discoverer, but by the ancients who invented the fable and who transmitted it to posterity.



Having now examined Euclid's method of reasoning, and the various forms of logical arguments employed by him, and adopted by others in demonstrations, it now only remains to glance rapidly at the contents of the other books.

In the second book, the properties of rectangles and squares formed under given lines, constitute the principal subject of investigation. All the demonstrations in this book are very simple; many of them consist chiefly in proving that the figure drawn is really composed of the rectangles alluded to in the proposition; and most of the demonstrations are founded upon the self-evident principle, that the whole is equal to all its parts taken together. The first three propositions show the theory of common mathematical multiplication, and also that of the mensuration of rectangles in practical geometry, already explained. The 4th may be called a geometrical demonstration of the rule laid down for extracting the square root of two terms in arithmetic and algebra. The 5th. 6th, 7th, and 8th propositions show the principles upon which some useful operations in algebra are conducted; all the remaining propositions of this book are of great value in trigonometry.

The third book is devoted entirely to the investigation of the circle, and of various lines considered with reference to the circle, and drawn within or without its circumference. The properties of tangents and of tangent circles are fully considered; and also the relation between angles which are made at the circumference and those made at the centre. This book is of great use in various mechanical arts; it is also the foundation of practical geometry, the circle being very frequently used in the construction of complicated figures.

The fourth book may be considered as a continuation of the third, as it treats of such figures as cannot be easily drawn without the circle. It explains the method of describing regular polygons in and about circles; and conversely, to describe circles in and about regular polygons.

The fifth and sixth books may be considered together, being both devoted to the same subject, namely, the doctrine of proportion. The fifth book is introductory to the sixth, for it lays down abstract theorems relative to proportion; and the sixth book shows the application of these theorems to geometry. Every branch of mathematical science is more or less dependent upon the demonstrations contained in these two books.

The seventh, eighth, ninth, and tenth books are never put into the hands of students, being of very little use in any part of mathematics. The doctrine of proportion is more or less dwelt upon in all these four books; and they also treat of the greatest common measure of any two numbers, of square and cube numbers, and of incommensurable quantities. The main, if not the only, object of Euclid, in writing these four books, seems to have been to settle the intricate question of incommensurables.

The remaining books of Euclid are entirely devoted to the examination of solids, and to the investigation of their properties and relations.

SOLID GEOMETRY.

It has been already observed, that all bodies having length, breadth, and thickness, such as wood, timber, &c., are called solids; and that the investigation of the properties and relations of the various figures assumed by such bodies, is the object of solid geometry.

The boundaries of solids are surfaces. Those solids which are bounded by plane surfaces are called *polyhedrons*, from the Greek words *polus*, many, and *edra*, a seat. The planes which contain a polyhedron are called its *sides* or *faces*; the lines bounding its sides are termed its *edges*: and the inclination of any two of the planes is called a *dihedral* angle.

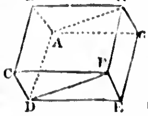
The meaning of parallel lines having been already explained, it is only necessary to say that the word parallel has the same signification when applied to planes as when applied to lines. *Parallel planes*, like parallel lines, would never meet, even if lengthened to any extent. The ceiling and the floor of a room are parallel planes.

A *solid* angle is formed by three or more plane angles meeting in the same point. The corner of a box, for instance, is a solid angle formed by the junction of three angles, namely, the plane angle terminating one side of the upper or under surface of the box, and the two plane angles belonging to its two sides.

The generic name of *prism* is given to all polyhedrons contained between two opposite, parallel, and equal polygons, connected together by parallelograms. The common bricks used in masonry are familiar examples of one species of prism; the little optical instrument used for showing the colours of rays of light, is another kind of prism—it is a glass, bounded by two equal and parallel triangular ends, and three equal and similar sides. The two ends of prisms are generally called the *terminating planes*, and one of them is called the *base*. The edges of the sides are called the *lateral edges*, and those of the terminating planes are called the *terminating edges*

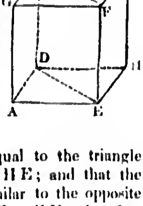
Prisms may be right or oblique, regular or irregular. In *right* prisms, the lateral edges are perpendicular to the base; in *oblique* prisms the sides are in an oblique position with respect to the base. A right prism having regular polygons for its terminating planes, is said to be *regular*; an *irregular* prism is one in which the ends are irregular polygons. The line joining the centre of the terminating planes of a regular prism is called the *prismatic axis*, and the *altitude* or *height* of the prism is equal to the length of this line.

The parallelograms which form the sides of prisms, are always equal in number to the sides of the base, and prisms are classed accordingly. The prisms which have a triangular base are called *triangular* prisms, those which have a quadrangular base are called *quadrilateral* prisms. *Hexagonal* prisms are those having a hexagon for their bases; and *polygonal* prisms are those of which the base is a polygon. The parallelopiped and the cube are two quadrangular prisms, which, being of great importance in the arts, require special attention. The *parallelopiped* is bounded by six four-sided figures, of which every opposite two are parallel. It is called rectangular when its base is a rectangle; and when these six planes are all rectangles placed perpendicularly to each other, it is said to be right, and oblique when the planes are inclined to each other. We can scarcely look round us without seeing rectangular parallelopipedons. Beams of timber, hewn stones, the box of a gardener's wheel-barrow, the bodies of carts, are almost invariably rectangular parallelopipedons; and this form is generally given to houses and to rooms. It is one of the propositions of the 11th book of Euclid, that if a solid be contained by six planes, two and two of which are parallel, the opposite planes are similar and equal parallelograms; thus, let the solid C D G H (which is a parallelopiped), be contained by the parallel planes A C, G F; B G, C E; F B, A E; its opposite planes are similar and equal parallelograms.



Parallelopipeds, when cut by a plane passing through the diagonals of two of the opposite planes, are formed into two equal triangular prisms.

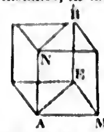
Let A B be a solid parallelopiped, and D E, C F, the diagonals of the opposite parallelograms, A H, G B, namely, those which are drawn betwixt the equal angles in each; and because C D, F E, are each of them parallel to G A, though not in the same plane with it, C D, F E, are parallel; wherefore the diagonals C F, D E, are in the plane in which the parallels are, and are themselves parallels; and the plane C D E F shall cut the solid A B into two equal parts.

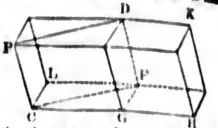


Because the triangle C G F is equal to the triangle C B F, and the triangle D A E to D H E; and that the parallelogram C A is equal and similar to the opposite one, B F; and the parallelogram G E to C H; therefore the planes which contain the prisms C A E, C B E, are equal and similar, each to each; and they are also equally inclined to one another, because the planes A C, E B, are parallel, as also A F and B D, and they are cut by the plane C E; therefore the prism C A E is equal to the prism C B E, and the solid A B is cut into two equal prisms by the plane C D E F.

Def.—The *insisting* straight lines of a parallelopiped, mentioned in the following propositions, are the sides of the parallelograms betwixt the base and the plane parallel to it.

Parallelopipeds are equal when they are upon equal bases and of the same altitude. This fact is very evident, and is constantly acted upon when the solids are right; for instance, in making book-shelves, each shelf is made



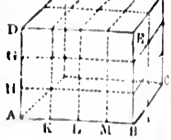


equal to the others—that is, it is made equally long and equally broad, and has the same altitude or thickness. Solid parallelopipeds which have the same altitude, are to one another as their bases; thus, let A B, C D, be solid parallelopipeds of the same altitude; they are to one another as their bases—that is, as the base A E is to the base C F, so is the solid A B to the solid C D.

Whatever can be proved respecting the properties of parallelopipeds, is equally true with respect to those of cubes, because a cube is merely a parallelopiped with square sides. The dice used by gamblers are cubes; and tables, footstools, and rooms often receive a cubic form. Just as the unit of measure for plane surfaces is a square, so the *unit of measure for solids* is a cube, and the length of each side of the cube is an inch, a foot, a yard, or any other lineal unit which may be fixed. To measure the solidity of a solid, is to ascertain how many cubic inches, or cubic feet, &c., are contained therein. The solidity of a parallelopiped is found by multiplying the length by the breadth, and the product by the height; the result gives the number of cubes contained within the figure.

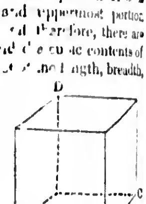
Let l, b, and h, be the length, breadth, or thickness, and the height, and v the volume or solid content, then $v = lbh$.

Let A F be a right rectangular parallelopiped. Let its length A B be 4 lineal units, as 4 inches, its thickness B C 2 inches, and its height A D 3 inches. The solid can evidently be divided into three equal portions by planes through G and H, parallel to the base A C; and into four equal portions by means of planes through K, L, M, parallel to the side B F; and into two equal portions by a plane through I, parallel to B D. Each of the small cubes into which the solid is now divided, is a cubic inch; the number of cubic inches in the lowest portion B C is 4×2, or 8, and in the second and uppermost portion there are as many; and in them all therefore, there are $4 \times 2 \times 3$, or 24—That is, to find the cubic contents of the solid, find the continued product of length, breadth, and height.



The solidity of a cube is found by multiplying the side by itself, and that product again by itself; or, literally, by raising the side to the third power

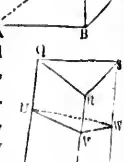
Let e = an edge of a cube; then $v = e^3$.



The reason of the rule is evident, since a cube is just a parallelopiped whose length, breadth, and height, are equal.

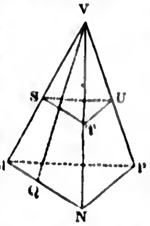
The solidity of all prisms, or of any parallelopiped, may be found by multiplying the area of the base by the height.

Let b denote the base, and h the height; then $v = bh$.



A pyramid is an angular solid, which has a polygon for its base, and triangles for its sides or faces; these sides all meet in one point, and form a solid angle, which is called the vertex of the pyramid. Pyramids, like prisms, may be either regular or irregular

When the base of a pyramid is regular, the line joining its vertex or summit is called its *axis*, and when the axis is perpendicular to the base, it is then a *regular* pyramid. They are also said to be triangular, quadrilateral, polygonal, &c., according as the base is a triangle, a quadrilateral, a polygon, &c. The pyramids of Egypt are quadrilateral, having square bases and four similar and equal triangular sides. An obelisk is also a pyramid, and has a square base and triangular sides; but the height is very great in proportion to the extent of the base. The solidity of a pyramid is found by multiplying the area of the base by the perpendicular height, and one-third of the product is the answer: $v = \frac{1}{3}bh$.

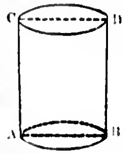


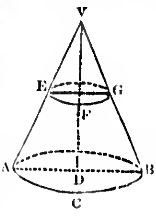
Example.—Find the solidity of a rectangular pyramid, the length and breadth of its base being 6 and 4 feet, and its altitude 20 feet, $v = \frac{1}{3}bh = \frac{1}{3} \times 6 \times 4 \times 20 = 160$ cubic feet.

By a regular solid is meant a solid bounded by regular plane figures, and its solid angles equal; that is to say, a solid in which all the sides are equiangular and equilateral. It has been proved that there can be only five regular solids; these are often called Platonic bodies, because Plato was the first who investigated their properties. The names of these five regular solids are the following: and it will be observed that these names are formed by prefixing the Greek numeral indicating the number of sides to the termination *hedron*, from *edra* (Greek), a seat, that is, a side.

The *tetrahedron* is a regular triangular pyramid, whose sides are equilateral triangles. The *hexahedron* is a cube. The *octahedron* is contained by eight equilateral triangles. The *dodecahedron* is contained by twelve regular pentagons. The *icosahedron* is contained by twenty equilateral triangles. Each side of a regular solid, except the tetrahedron, has an opposite face parallel to it, and the edges of these faces are also respectively parallel.

A cylinder differs from a prism in having a circular instead of a rectilineal base; it is contained between two equal and parallel circles and a convex surface. The line joining the centres of the two circles is called the *axis*. When the axis is perpendicular to the plane of the bases, the cylinder is said to be *right*. Steam-boilers, the shafts of circular pillars, the stone of a common garden roller, the barrel of a gun, and many other familiar objects, are cylinders. Combinations of cylinders are also very frequently used in the arts; telescopes and opera-glasses, for instance, are merely cylinders fitted one within the other, and of which circular lenses form the base. The solidity of a cylinder is found in the same way as that of a prism, namely, by multiplying the area of the base by the perpendicular height. This rule is founded upon the theorem that a cylinder and a parallelopiped, having equal bases and altitudes, are equal to one another. A cone, like a cylinder, has a circular base, but it terminates in a point like a pyramid; sugar-loaves are made in the form of cones. The annexed figure is a cone. A B is the base, V is the vertex, and the straight line V D joining the vertex and the centre of the base is called the axis. A frustum of a solid is a portion contained between the base and a plane parallel to it; thus, the portion E G A B is a frustum of the cone. When the axis of a cone is perpendicular to its base, it is called a *right* cone.





Other cones are said to be *oblique*. A right cone may be described by the revolution of a right-angled triangle about one of the sides of the right angle. It is proved that if a cone and a cylinder have the same base and the same altitude, the cone is equal to the third part of the cylinder. From this fact results the method usually adopted for ascertaining the solidity of a cone. The area of the base is multiplied by the altitude, which, as before shown, is the rule for finding the solidity of a cylinder; one-third of the result, therefore, gives the solidity of the cone.

SPHERICAL GEOMETRY.

A *sphere* or *globe* is a solid having one continued curved surface, and which is conceived to be generated by the revolution of a semicircle about its diameter: balloons and cricket-balls are spheres.

Spherical geometry consists in the investigation of the properties of spheres.

Every point on the surface of a sphere is equally distant from a point in the middle of the sphere called its centre; any line drawn from the centre to the circumference is called a *radius*, and any line drawn through the centre, and terminated at both extremities by the circumference, is termed a *diameter*. When the diameter is perpendicular to the plane of a circle of the sphere, it is termed an axis, and the extremities of the axis are called the poles. Circles of the sphere, whose planes pass through the centre, dividing the sphere into two equal parts, are called *great* circles, and all others are *small* circles. By the distance of two points on the surface of a sphere, is meant an arc of a great circle intercepted between them.

A *spherical angle* is that formed on the surface of the sphere by arcs of two great circles meeting at the angular point, and is measured by the inclination of the planes of the circles.

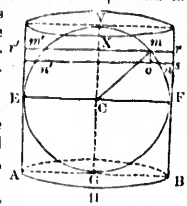
A *spherical triangle* is a figure formed on the surface of the sphere by arcs of three great circles, called its *sides*, each of which is less than a semicircle.

A *quadrangular triangle* is that of which one of the sides is a quadrant.

A *lunary surface* is a part of the surface of the sphere, contained by the halves of two great circles.

A *segment* of a sphere is a part cut off by a plane.

There are several methods of finding the contents or solidity of a sphere; perhaps the most simple and the most easy to be remembered is the following: Find, by the rules previously given, the solidity of the circumscribing cylinder, as E A B F, which is a cylinder equal in diameter and height to the diameter of the sphere; two-thirds of it will be the volume of the sphere, because a sphere is proved to be equal to two-thirds of its circumscribing cylinder.



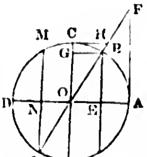
The exterior extent of surface, or convex superficies of a sphere, may be ascertained by multiplying the diameter of the sphere by its circumference. Thus, in a globe of 20 inches diameter, and 62·832 circumference, the convex superficies is 1256·64 inches, because $62{\cdot}832 \times 20 = 1256{\cdot}64$. Also, the surface of any zone of the sphere, as *mnn'm'*, is exactly equal to the surface of the corresponding zone of the cylinder *rss'r'*.

Spherical geometry is of great importance in several of the arts and physical sciences, and more especially in astronomy and navigation.

TRIGONOMETRY—LAND-SURVEYING.

Trigonometry signifies literally the art of measuring triangles, but with the progress of science the meaning of the word has been much extended. Trigonometry is divided into plane and spherical, according as it is directed to the investigation of plane or of spherical triangles.

A fixed relation subsists beetwen certain lines drawn in and immediately round a circle; and it is upon this relation that trigonometry is founded. Most of these lines, such as tangents, secants, arcs, chords, &c., have already been mentioned; it only remains to add, that the sign of an arc is a straight line, drawn from one extremity of the arc perpendicular to the radius passing through the other extremity, or, it is in fact the half of the chord of double the arc. The sine, tangent, and secant, of the complement of an arc, are called cosine, cotangent, and cosecant of that arc. This will be better understood by carefully examining the annexed figure, which is a representation of the various trigonometrical lines.



B C is the complement of the arc A B; B M D is the supplement of A B; angle B O C is the complement of A O B, and B O D is the supplement of A O B; B E is the sine of A B; A F is the tangent of A B; O F is the secant of A B; so B G is the sine of B C, or the cosine of A B; C H is the tangent of B C, or the cotangent of A B; and O H is the secant of B C, or the cosecant of A B.

The following rules for computation are useful in right-angled trigonometry, that is, in computing the sides and angles of right-angled triangles.

I. When two sides are given, to find an angle.

¶ Make a given side radius, then the side made radius is to the other given side as radius to the trigonometrical name of the latter side.¶

II. When one of the three sides and an angle are given, to find a side.

¶ Make any side radius, then the trigonometrical name of the given side is to that of the required side as the given side to the required side.¶

Although in this case any side may be made radius, it is preferable to make one of the sides concerned radius, that is, either the given or the required side, as this introduces the radius as a term of the proportion, and its logarithm being 10, it simplifies the calculation.

III. When the two sides are given, to find the hypotenuse.

¶ The sum of the squares of the two given sides is equal to the square of the hypotenuse.¶

IV. When the hypotenuse and a side are given, to find the other side.

¶ The difference between the squares of the hypotenuse and the given side is equal to the square of the required side. Or, the product of the sum and difference of the hypotenuse and a side, is equal to the square of the other side.¶

When the square of a side is known, its square root gives the value of the side.

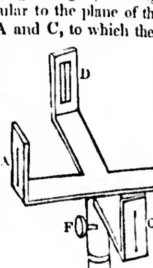
The first two rules are sufficient for the solution of all the problems in right-angled trigonometry; but the last two may sometimes be conveniently employed.

Trigonometry is one of the most useful departments in mathematical science. Its application to practical purposes are very extensive, and it is of great importance in navigation, engineering, and, as we shall immediately see, in land-surveying.

Land-surveying is the method of measuring and computing the area of any small portion of the earth's surface, as a field, a farm, an estate, or district of moderate extent. There are three distinct operations in the art of land-surveying, all of which require the surveyor to possess a competent knowledge of arithmetic, algebra, and geometry. In the first place, the several lines and angles must be measured; secondly, they must be protracted or laid down on paper, so as to form a plan or map of the district; and, thirdly, the whole area of the district must be computed by means of the foregoing operations. In performing the first operation, the most useful instrument is the chain called *Gunter's chain*, from the name of the inventor, the Rev. Edmund Gunter, who lived about two hundred years ago. It is 22 yards or 66 feet long, and is composed of 100 equal links, the length of each being 7·92 inches. At every tenth link is a mark made of brass. An acre consists of 10 square chains, or 100,000 square links. There are 80 chains in a mile, and 640 acres in a square mile.

Iron pins, about two feet long, called *arrows*, with red handles, or pieces of red cloth, attached to them, are used for sticking in the ground at the end of each chain length, when measuring in the field. Ten of them are commonly used.

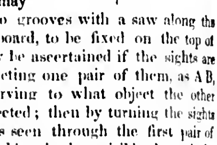
In measuring land with the chain, two persons are required, one at each end of the chain; the one who walks first is, for the sake of distinction, called the leader, and the other the follower. Lines measured perpendicularly to chain lines, to the angular points, and other points of the boundary of a field, such as to crooked hedges, brooks, &c., are called *offsets*. The cross-staff is used in measuring offsets: it consists of two bars of brass placed at right angles, with sights at their extremities, perpendicular to the plane of the bars. There are narrow slits at A and C, to which the eye is applied, and wider openings at B and D, with a fine wire fixed vertically in the middle of them. The cross is supported on a staff E, about 4½ feet high, which at the lower end is pointed and shod with brass, so that it can easily be stuck in the ground. The sights are placed on the top of the staff, and fixed to any position by a screw F.



A simple cross-staff may be made by cutting two grooves with a saw along the diagonals of a square board, to be fixed on the top of the staff. It can easily be ascertained if the sights are at right angles, by directing one pair of them, as A B, to one object, and observing to what object the other pair, C D, are then directed; then by turning the sights till the second object is seen through the first pair of sights A B, if the first object is then visible through the second pair of sights, and is exactly in apparent coincidence with the wire, the sights are at right angles; if not, they must be adjusted.

An instrument not less important in surveying is the theodolite. This useful instrument, fixed on the top of a tripod, consists of two graduated circles perpendicular to each other, one of which is fixed in a horizontal and the other in a vertical plane, and is used for measuring horizontal and vertical angles.

In the figure of the theodolite here presented, H R S represents an oblique view of the horizontal circle, and *mQn* a direct view of the vertical one, which extends to little more than a semicircle. The vertical circle is movable about an imaginary axis, coinciding with the radius O Q, which, produced passes through the centre C of the horizontal circle. On the vertical circle is fixed a telescope W, furnished with a spirit-level I, the tele-

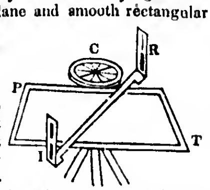


scope is connected with a movable radius O A, in contact with the opposite side of the vertical circle; and this radius is fixed to a vernier *o*, movable, by means of a screw, along the limb of the circle. When the centre *o* of the vernier coincides with the middle division Q of the circle, the axis of the telescope is then horizontal, and the instrument thus serves also as a spirit-level. A vernier to the horizontal circle is attached to the vertical circle at *e*, and is movable with it.

To measure a horizontal angle subtended at the instrument by the horizontal distance of two objects: Direct the telescope to one of the objects, and observe the number of degrees at *e* on the horizontal circle; then, while this circle remains fixed by means of a clamping screw, turn the vertical circle till the other object is visible through the telescope, and in apparent coincidence with the intersection of the cross wires, and note the number of degrees on the horizontal circle at *e*; then the difference between this and the former number is the required horizontal angle.

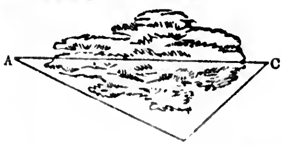
To measure a vertical angle: Direct the telescope to the object whose angle of elevation is required; then the arc, intercepted between Q and *o*, is the required angle. An *angle of depression* is similarly measured.

A plane table is frequently used in surveying. This instrument consists of a plane and smooth rectangular board fitted in a movable frame of wood, which fixes the paper on the table P T, in the adjoining figure. The centre of the table below is fixed to a tripod, having at the top a ball-and-socket joint, so that the table may be fixed in any required position. The table is fixed in a horizontal position by means of two spirit-levels lying in different directions, or by placing a ball on the table, and observing the position of it in which the ball remains at rest. The edges of one side of the frame are divided into equal parts, for the purpose of drawing on the paper lines parallel or perpendicular to the edges of the frame; and the edges of the other side are divided into degrees corresponding to a central point on the board for the purpose of measuring angles.



A magnetic compass box, C, is fixed to one side of the table for determining the bearings of stations and other objects, and for the purpose of fixing the table in the same *relative* position in different stations. There is also an index-rule of brass I R, fitted with a telescope or sights, one edge of which, called the *fiducial* edge, is in the same plane with the sights, and by which lines are drawn on the paper to represent the direction of any object observed through the sights. This rule is graduated to serve as a scale of equal parts.

A principle of measuring by triangles, which is alike common to land-surveying and the trigonometrical surveys of engineers, may be comprehended from the following figure. We wish to find the distance between two objects that are either invisible from each other, or inaccessible in a straight line from each other.



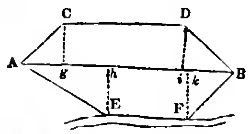
Let A and C be the two objects inaccessible in a straight line from each other, on account of a marsh. Measure two lines A B, B C, to the objects and the contained angle B. In a triangle A B C, two sides, A B, B C, and the contained angle B, are known; hence A C may be found.

Such a problem as the above is common in measuring heights and distances; and it will be understood, that the principle of throwing the area of any given field or set of fields into triangular spaces, is that pursued in all processes of land-measurement. In most instances, fields are irregular in form; their outlines being often bent, with a greater width at one place than another. In such cases, after measuring the areas of the triangles, the odd pieces at the sides require to be measured, and their aggregate area added to the whole. We may illustrate the process of surveying as follows:—

The angular points of the large triangles or polygons, into which a field is to be divided for the purpose of taking its dimensions, are called *stations*, and are denoted by the mark $\odot$; thus $\odot_1$ is the first station; $\odot_2$ the second; and so on. The lines joining the stations, and which are measured by the chain, are called *chain lines*, or *station lines*.

‖ Divide the field into triangles, or into triang'‍s and quadrilaterals, the principal triangles or quadrilaterals occupying the great body of the field, and the rest of it containing secondary triangles and trapezoids formed by offsets from the chain lines. Measure the base and height, or else the three sides of each of the principal triangles, then calculate their areas by the rules in Mensuration of Surfaces, and also the offset spaces, and the sum of all the areas will be that of the entire field.‖

Example 1.—Find the contents of the adjoining field from these measurements, A being the first and B the second station.



On chain line.	Offsets.
$Ag = 150$	$gC = 141$ to left.
$Ah = 323$	$hE = 180$ to right.
$Ai = 597$	$iD = 167$ to left.
$Ak = 624$	$kF = 172$ to right.
$AB = 769$	

The double of the areas of the component triangles and trapezoids are found, in order that there may be only one division by 2, namely, that of their sum.

$gi = Ai - Ag = 447$, $iB = AB - Ai = 172$, and $hk = Ak - Ah = 301$, $Bk = AB - Ak = 145$.

Twice the area of the

triangle $AgC = Ag \cdot gC = 150 \times 141$	$=$	21150
trapezoid $CgiD = gi\ (Cg + Di) = 447 \times (151 + 167)$	$=$	137676
triangle $DiB = Bi \cdot iD = 172 \times 167$	$=$	28724
triangle $AhE = Ah \cdot hE = 323 \times 180$	$=$	58140
trapezoid $hEFk = hk\ (hE + kF) = 301\ (180 + 172)$	$=$	105952
triangle $BkF\,F = Bk \cdot kF = 145 \times 172$	$=$	24940
Twice area	$=$	376582

And area $= 188291 = 1$ acre, 3 roods, 21·26 poles.

These admeasurements, instead of being written out as above, are generally registered in a tabular form. A field-book, which is used to enter these measurements, is divided into three columns. The different distances on the chain line are written down in the middle column, and in the right and left-hand columns the offsets are inserted, with any remarks that may be made. The measurements on the chain lines are written in order upwards in the middle column, the first being written at the foot of the column, as the surveyor can thus more conveniently compare the measurements with the imaginary lines in the field.

In surveying a whole country by trigonometrical measurement, or in engineering plans for canals, railways, and roads, it is necessary to make allowance for the earth's convexity in all the calculations of levels. The degree of convexity, or departure from a true level, is reckoned to be about 7 inches and 9-10ths in the space of a mile. (See article HYDROSTATICS.) In land-measuring, the scale of operations is ordinarily too limited to require any such allowance for difference of levels.

We have now, as far as our limits would permit, presented an outline of the methods pursued in land-surveying; and to those who design following out the study of this, as well as other branches of theoretic and practical mathematics, we recommend a regular course of instruction from Mr. Bell's excellent treatises in Chambers's Educational Course—works so cheap as to be within every one's reach.

POPULAR STATISTICS.

INTRODUCTORY.

STATISTICS is a science of comparatively late date, but it is one which promises to be of considerable service to mankind. Whatever can be ascertained by *taking down numbers and instances, and making summaries of them*, may be said to be a proper object for this science. It is generally applied to such matters as the amount of population, the rate of mortality, the progress of commerce and manufactures, and the increase or diminution of crime. The benefit of coming to correct reckonings about these matters must be obvious; but we shall cite one instance to make it quite clear. From accounts which have been kept of the burials in England for the last fifty years, it appears that the rate of mortality (or number who die yearly in comparison with the whole population) diminished regularly down to 1831, but has since then been a little on the rise, showing that the condition of the people at large (mortality depending on condition) was improving till that time, but has since been slightly declining. When such a fact as this is ascertained, statesmen are put on the alert to discover, and, if possible, remove the causes. Thus, it is seen, a nation may be much benefited by taking a census, and the keeping of a correct register of deaths. The value of statistical operations, then, is manifest. Statistics may be said to be the account-book of a nation, for ascertaining the state of its affairs. One which keeps no statistical records may be said to be like a merchant who does business without keeping a ledger or ever coming to a balance.

Statistics bears in like manner upon many of the interests of private life. Of this we trust to be able to give some notable instances in the sequel.

It is one of its least utilities that it tends to substitute real and distinct knowledge in many matters for vague and general impressions. There are many things which, to the uninstructed mind, can only be mentioned to create a feeling of doubt—for example, the comparative likelihood of life in men and women. Ask an uninstructed person whether women or men in general live longest, and, at the best, he will only be able to answer from some obscure notion in his mind, the result of a few observations which he has happened to make. Statistics has ascertained, though only within the last fourteen years, that female life is *better*, that is, of longer duration, than male. Here is a thing which no individual could ascertain for himself, and about which all was doubt for hundreds and thousands of years, settled at last by statistics. We have now the satisfaction of knowing the fact distinctly, instead of only conjecturing, and perhaps wrangling about it.

On some of these vague questions, proverbial wisdom is found to have made a conclusion for itself. For example, this oracle has long been clear, that an open winter is the most fatal to life, and that more die of surfeit than of want. Statistics finds both of these, and many like conclusions, to be exactly the reverse of the truth. It has here corrected decided error, which is better still than giving distinct knowledge where formerly there was only doubt. It is observable of almost all such proverbial notions, that they appear to have proceeded upon a principle of contradiction or paradox, the contradiction being generally to what is the most likely conclusion of the mind upon the subject. For instance, want seems at first sight a more deadly thing than over-abundance; but then it is also found, if we pause and look narrowly, that it is possible also to die of cholic and of pampering. The clownish oracle has the same wish to be novel, original, and striking, which is the bane of so much philosophy, and it decides that the most mischief is done by the less obvious evil. To put an end to such modes of judging, by adducing the undeniable testimony of figures, is, we humbly submit, a worthy service, and this service is rendered by statistics.

There is one other service which statistics has rendered, of a more remarkable though perhaps less directly useful kind than the above. Almost all the occurrences which depend on the human will happen irregularly as to time, as far as an individual is concerned. A man commits some particular crime which he is not likely ever again to commit in his life—for instance, an assault with violence. It was, to all human apprehension, the merest chance which brought him into the circumstances which provoked or prompted him to commit the offence. Yet, strange to say, there is no offence so accidental as to individuals, or so unlikely to occur above once in an ordinary man's lifetime, but what statistics finds it to occur, with the greatest regularity, in a certain range of individuals and a certain range of time. The returns of a particular crime, in such a country as England or France, are nearly the same for each successive year. In all classes of occurrences which appear occasional as to individuals, the same uniformity is observed when we go to sufficiently large numbers: even in the number of letters put into the post-office without addresses, there is a precise uniformity, if we take the office of a large city, and reckon year against year. Thus to find an order in the most casual of things, even in the wayward and fleeting movements of the mind, affords highly interesting matter for reflection.

Statistical science has its quicksands and difficulties as well as its triumphs. Often, when an extensive range of facts has been accumulated, all, as is thought, tending to confirm a certain view, there may still be room to contend that they lead to directly opposite conclusions, or that they show the presence of totally opposite causes from those presumed to exist. There is a tendency in those who pursue the science, to make inferences in accordance with their own prejudices, or to seek only for facts by which these are favoured. Such errors are particularly likely to be made in subjects where many causes are presumedly involved, and which are so extensive that it is difficult to command a general view of them. As an example, we have only to remind the reader of the various notions which are usually entertained as to the causes of any distress which may take place throughout the country. The higher class of statisticians usually, however, are cautious in drawing inferences and tracing causes, believing it to be their best course, in all doubtful cases, to restrict themselves to the collection of facts.

BIRTHS.

Proportion of the Sexes.

Many millions of observationa have been made upon births in the various countries of Europe, from which one uniform result appears, that about 21 boys are born for 20 girls. The proportion in different states is here stated:—

STATES AND PROVINCES.	Males to 100 Females.
Russia	108·91
The Province of Milan	107·61
Mecklenburg	107·07
France	106·55
Belgium and Holland	106·44
Brandenburg and Pomerania	106·27
Kingdom of the Two Sicilies	106·18
Austrian Monarchy	106·10
Silesia and Saxony	106·05
Prussian States (*en masse*)	105·94
Westphalia and Grand Dutchy of the Rhine	105·86
Kingdom of Wurtemburg	105·69
Eastern Prussia and Dutchy of Posen	105·66
Kingdom of Bohemia	105·38
Great Britain	104·75
Sweden	104·62
Average for Europe	106·

Further inquiries have shown some curious modifications of the law which seems to preside over this part of the natural economy of the world. In illegitimate births, the over proportion of boys is somewhat less, nearly approximating in some countries to a par with the number of girls. There is also a less over-proportion of boys from marriages in which the husband is the younger party, and where both are extremely young.*

The average fruitfulness of marriages is not clearly ascertained, in consequence of imperfect registrations; but it is considered by Mr. M'Culloch to be in England in the ratio of 4·2 children to each marriage.

Legitimate and Illegitimate Births.

The proportion of illegitimate to legitimate births is a point of great importance in political economy as well as morality, for illegitimate children are generally a burden to the state, and have an inferior chance of growing up useful citizens. It is also a fact ascertained by statistics, in opp[illegible] to common ideas, that such children have generally less of the elements of health and vitality than other children. The proportion of illegitimate to other births is—for France, 1 to 12·5; Prussia, 1 to 13·1; England, 1 to 14; Sweden, 1 to 14·6; the preponderance of morality thus appearing in favour of the two latter countries. In cities the proportions are strikingly different. In Paris, for 28 legitimate there are 10 illegitimate births; in other and stricter terms, the latter are in proportion to the former as to 2·84. In Stockholm, from the report of a recent traveller, the proportion is 1 to 2·3; that is, nearly a third of the children born in that northern capital are illegitimate. In Berlin, the proportion has risen since 1790, from 1 to 9 to 1 to 6.

Still Births.

The proportion of dead-born to live-born children is found in European cities to be about 1 in 20, but in the country not above half that amount; showing apparently that rural life is most favourable to the health of women during pregnancy, and to successful parturition. It is worthy of remark, that more male than female children are still-born; the proportion in Western Flanders has been found as 14 to 10, and the same result appears in some other countries. At Gottingen, in 100 births, 3 were of legitimate and 15 of illegitimate children.

Effects of Scarcity.

Times of scarcity and privation tend to reduce the number of marriages, and also of births, though generally not immediately. The great scarcity which occurred in England at the commencement of the present century, occasioned a diminution in the number of marriages to the extent of about 18 per cent., as compared with the previous years of abundance. In the Netherlands, wheat was at 9·56 florins per hectolitre, in 1816, and the births in the year 1818 had sunk, from a previous higher number (195,362 in 1815), to 183,706: in 1819, wheat had fallen to 3·72 florins per hectolitre, and the births, two years thereafter, rose to 210,359.

MARRIAGES.

The number of marriages per annum, in proportion to the population, and the ages at which marriages take place in both sexes, form interesting subjects of inquiry.

In England and Wales, the number of marriages registered was 111,481 in 1837–8; 121,083 in 1838–9; and 124,329 in 1839–40. The number is believed to have been less in the first of these years than it otherwise would have been, in consequence of a popular error which induced parties to hurry on their nuptials before the commencement of the operation of the registration act. Taking the two latter years against each other, we find an increase of 3216 marriages upon the latter; but this is liable to a reduction of 1700 on account of the increase of population; so that, on the same number of people in 1838–9 and 1839–40, there was an increase of marriages, strictly, of about 1500. While there was thus an increase upon the whole country, the greater portion of the manufacturing districts in the west of England, where at this time commercial difficulties existed, showed a *decrease*, amounting in some districts to 6 per cent.; in Manchester and Salford to no less than 12 per cent.

In England and Wales, the proportion of marriages to the whole population seems to have been diminished during the last fifty years. It is calculated that, in the period 1796–1800, there was 1 marriage annually to every 123 persons; in the period 1816–1820, 1 for every 127 persons; in the period 1826–30, 1 for every 128 persons. This seems to be nearly its present proportion.

Some years ago, Mr. Finlaison made a calculation of the ages of women at the time of their marriage from an assemblage of 878 cases, which was too small for very satisfactory results. Enlarging the number to 1000 for the sake of arithmetical distinctness, he found the following to be the various ages at marriage:—

* "In France, it was observed a few years ago, that out of 6,705,778 persons born, legitimate and illegitimate, there are 3,458,965 males and 3,246,813 females, or nearly 16 males to every 15 females. Out of 460,391 illegitimate children, there are 235,951 males, 224,440 females. From these data it follows that, in France, for every 100,000 legitimate female children, there will be 106,534 legitimate males; but for every 100,000 illegitimate females, there will be born only 105,128 illegitimate males; so that the probability of a child about to be born being a female is greater if it is illegitimate than if it is legitimate."—*Babbage*

Age.		Age.	
14 to 15	32	28 to 29	45
16 .. 17	101	30 .. 31	18
18 .. 19	219	32 .. 33	14

22 .. 25	101	36 .. 37	2
26 .. 27	60	38 .. 39	1

A calculation upon which more dependence may be placed was made by the registrar-general, upon the basis of 10,019 marriages which occurred in different parts of England in 1838–9, reducing the proportions to 10,000. The following table gives the results:—

Ages.	Men.			Women.			1818-9.	
	Bachelors.	Widowers.	Total.	Spinsters.	Widows.	Total.	Men.	Women.
15 and under 20	229	..	229	1315	1	1316	327	1416

Totals	8832	1187	10,019	9238	781	10,019	10,000	10,000

According to this table, the average age of marriage in England is—for men, 27·4 years; for women, 25·5 years. It presents, upon the whole, a favourable view of the prudence of the English people as to marriage. Only 2·3 per cent. men, and 13 per cent. women, are wedded under the age of 20. About one-half of both sexes are married between 20 and 26. Only about three-fourths of a per cent. of first marriages are contracted by either men or women after the age of 44.

It seems to be clearly ascertained, that the tendency of the sexes to marriage is liable to be modified by a number of conditions. Above a certain point in education, comfort of circumstances, and respectability of position, the tendency diminishes, and we see men and women of the middle and upper classes living contentedly in celibacy, from a dread of the increased expenses of matrimonial life. Below that point the tendency increases, from opposite causes. It is observably more powerful amidst a dense operative population than among a scattered one, and it reaches its extreme in the half-destitute class, however otherwise circumstanced. Statistics afford us some information respecting two widely separated parts of the earth, one of which is remarkable for early and numerous, and the other for rare and long-delayed marriages—Glasgow and the parish of Montreux in Switzerland. In Glasgow, the marriages were, in 1830, in the proportion of 1 to 112 of the population; and this ratio rises much higher in unusually prosperous years, as, for instance, in 1825, when it was 1 in 84. Montreux is too small a district to afford basis for a calculation of this kind; but the people, who are all small labouring proprietors, are remarkable for postponing marriage to a late age, the average ages of men and women being 30 and 26·75 respectively. In Montreux, the births are as 1 to 46 of the population, and the deaths as 1 in 75, both uncommonly low proportions. Those of Glasgow will be found very different. It seems incontestable, indeed, that a multiplication of marriages in most situations is attended by an increase of mortality, and particularly an increase in the mortality of the young. We trust we may here venture upon a few general remarks with respect to marriage among the industrious orders.

It is a familiar saying among the industrious orders, that the mouth never comes without the meat for it; by which they encourage themselves to marry, or console themselves when, having married, they find their family increasing upon them more rapidly than they can well see how they are to provide for it. This fallacy has been in some measure brought to the test of figures. Dr. James Philips Kay, an assistant Poor-Law Commissioner, instituted in the year 1838 an inquiry into the actual income of agricultural labourers in the counties of Norfolk and Suffolk. Returns to the circulars which he issued for this purpose enabled him to make the following abstract of the annual earnings of 539 families:—

	Average annual income.		
36 single men	£25	1	4¼
64 married men, with no children at home	30	12	10¼
136 married men, with 2 7-8ths children, all under 10 years of age	32	13	2
120 married men, with 3 7-10ths children, 1 of whom above 10 years	35	9	0¼
92 married men, with 4 9-10ths children, 2 of whom above 10 years	40	10	1
44 married men, with 5¼ children, 3 of whom above 10 years	45	11	9¼
15 married men, with 7 children, 4 of whom above 10 years	50	18	6
1 married man, with 5 children above 10 years	42	13	0
1 married man, with 6 children above 10 years	52	0	0

The first question suggested by this table is—how much of the increased income of the men with families was owing to their working more steadily, from a sense of their families being dependent upon them? and how much to the earnings of their wives and children flowing into the common stock? This does not directly appear, but the returns afford means of arriving pretty near the truth by calculation. Out of the 539 male heads of families, 475 earned annually by day-work £7382, 5s. 2d., which gives the average annual earnings of each man by this means at £15, 10s. 10d., or within a fraction of 6s. a week. The earnings by task-work are specified in 350 cases, and amount in all to £5018, 17s. 7d., which gives the average earnings of each man by this means at £14, 6s. 10d. annually, or 5s. 6d. a week. There are enumerated at least 286 cases in which the labourer obtained earnings in both ways; but it would give too high an average to add the two sums together. We are enabled to approach to the truth in another direction, by deducting the amount of earnings said to be made by women and children from the average income of the families. The sum of all the annual earnings of all the families (counting each single man as a family), in the table given above, is £19,129, 16s. 5d.; and this gives an average annual income of £35, 10s. The men are stated to have earned on an average £5, 3s. by harvest-work, in addition to their regular wages; the average earnings of wives are about £2, 12s. 7d.; of children able to work, £8, 1s. 11d.; and the value of gleanings by the younger children is £1, 1s. 10d. Deducting these sums from the average family income, leaves £17, 4s. 4d. for the average annual earnings of the man by ordinary task and day *wage*; and this, when we take into consideration the number of men, and the amount earned in the year by these routine kinds of labour, seems not an improbable estimate. This £17, 4s. 4d. added to the £5, 8s. of harvest wages, gives £25, 12s. 4d. as the average annual earnings of a man (7s. 3d. per week), or only 13s. more than the average earnings of the unmarried men; from which we infer, that *the additional income of the married men is derived from the labour of their wives and children.*

Deducting the earnings of the unmarried men from the whole amount, and dividing the remainder by the number of married men, we get an average of £36, 7s. 2d. for the annual earnings of each married man and his family. But whereas the £25, 1s. 4½d. is allotted exclusively to the maintenance of one person only, the income of £36, 7s. 2d. has to provide for an average of 5·5 persons. Unless the married man can support a wife and 3·5 children upon £11, 5s. 9½d. per annum, he must dispense with luxuries, comforts, it may be conveniences, in which the unmarried man can indulge. And the average income is raised to this height by taking into account those families which, having three, four, five, and six children above ten years of age, have an average income of about £45 per annum. To reach this highest grade, even they must have passed through years of greater pinching, when their children were growing old enough to take care of themselves and earn a little. The mill through which they have been ground may be conceived by taking into account these facts. The average annual earnings of a wife with no children were £3, 8s. 9d.; of a wife with $2\frac{7}{8}$ children under 10 years of age, £2, 9s. 10½d.; of a wife with $3\frac{7}{10}$ children, one above 10, £2, 11s. 7¼d.; of a wife with $4\frac{9}{10}$ children, two above 10, £2, 5s. 7½d.; of a wife with $5\frac{3}{4}$ children, three above 10, £2, 19s. 1d.; of a wife with 7 children, four above 10, £2, 3s. 10d. From which it appears, that a woman with a family is only able to earn about two-thirds of what a woman without that incumbrance can earn. The earnings of the children, also, fall to be taken into account. In families with $2\frac{7}{8}$ children, none of whom were above 10 years of age, the average annual earnings of each child were 15s. 3¼d.; in families with $3\frac{7}{10}$ children, one of them above 10, the average earnings of each child were £1, 1s. 9½d.; in families with $4\frac{9}{10}$ children, two above 10, the average earnings of each child were £1, 13s.; in families with $5\frac{3}{4}$ children, three above 10, the average earnings of each child were £2, 2s. 5½d.; in families with 7 children, four above 10, the average earnings of each child were £2, 17s. 8d. An additional head of income must, in strict accuracy, be mentioned—the value of corn gleaned by the children. As might be expected, the amount increases with the number of children; but as the age of the latter does not much affect their ability to glean, the increase is very gradual, and of small amount.

VALUE OF CORN GLEANED.

Families.	Average annual amount to each family.
46 with no children - - - - -	£0 17 10¼
110 with 2 7-8ths, all the children under 10	0 18 7¼
97 with 3 7-10ths, one child above 10 -	1 0 6¼
85 with 4 9-10ths, two children above 10	1 5 6¼
37 with 5 3-4ths, three children above 10	1 9 6¼
13 with 7, four children above 10 - -	1 6 9¼

These figures demonstrate that the married labourers incurred in general an additional amount of expenditure, which their additional income by no means compensated. The *kind* of expense incurred by the married men, as well as the amount, is different—child-bed outlay, education of children, and the increased chances of sickness as the numbers of a family increase. It must be remarked, too, that the cases selected to illustrate this point, are, in so far as the unskilled labourers of the country are concerned, favourably circumstanced. Of the 539 families enumerated, 397 had gardens (averaging $19\frac{1}{7}$ rods); 136 had some fuel free of charge; 259 had each a pig; and 20 each a donkey. The average of their house-rent (£3, 11s. 4½d.) did not rise above the average level throughout the country; while in a rural district provisions are cheaper than in towns. Above all, the engrossment of their parents' attention by labour was not so dangerous for the children as in densely populated towns, where, when left at all to themselves, they are in constant danger of falling in with instructors in crime, and are placed in a situation where greater opportunities present greater temptation. If, then, among individuals who, for the class to which they belong, may be considered in easy circumstances, marriage be a step which must render increased exertions and self-denial necessary, what must it be for those who are in more difficult circumstances? Let the experience of a committee appointed in Glasgow, in 1837, to afford relief to the industrious poor in a season of severe pressure, answer the question. Out of 3072 adult males who applied for relief and were furnished with work, 2273 were married. The number of the children of those married applicants was 6302, or nearly 3 children to each family. No less than 532 of those married men were under 30 years of age; of the children, 3994, or nearly two-thirds, were under 10 years of age. Of the 2273 married men, 2171 were weavers; and the account given by Mr. Charles Baird, in a paper read before the Statistical Society of London, in February, 1838, of the condition of that class even in times of no extraordinary pressure, may serve to show with what prospects they had rushed upon the hazardous responsibilities of marriage:—"The great bulk of the weavers in Glasgow and its suburbs are in extreme poverty. Their wages which, even in 1819, were as low as 12s. gross, or 10s. 8d. net (the deductions being for loom-rent, winding, &c.), now average only 8s. 4d. gross, or 7s. net per week; and even for this miserable pittance they are obliged to work from 14 to 16 hours per day. Their houses, which are generally in the suburbs, are of the poorest description, barely furnished, and the food and clothing of the inmates, as might be expected, not only of the plainest description, but also quite inadequate." It is apparent, that they who, in the best of times, can barely procure a subsistence by 14 or 16 hours of daily toil, must, by the slightest and shortest stagnation of trade, be reduced to destitution, and, under such circumstances, to incur the charge of a family is madness.

This is a consideration which has of late been much urged upon the poorer classes—not always, it is to be feared, in the most judicious manner. Leaving out of view that the deductions of Malthus, whose disciples have been the most busy in giving this kind of advice, are based upon statistics remarkable both for vagueness and inaccuracy, and tainted by the polemical bias of his mind when he first published them, the form in which they have generally been submitted is of all others the least calculated to make an impression upon uneducated minds. Abstract reasoning, geometrical and arithmetical ratios, convey no tangible ideas calculated to influence their conduct; and the subordinate discussions into which some of these philosophers are fond of diverging, repel by inspiring disgust. Advice may be sound, however, although it be given in an uncouth form and by unamiable persons. In regard to improvident marriages, the industrious poor would do well to consider.

Marriage has its attractions, and, what is more, its moral advantages. It is the only institution which reconciles with the stability and good order of society one of the strongest impulses of our nature. If it add in some degree to a man's expenditure, it repays him by conferring blessings unattainable without it The un married man is isolated; the married man, if ordinarily well conducted, has a permanent hold on the affections of a portion of his fellow-creatures. A judicious selection of a helpmate ensures him comforts at home which no price could otherwise secure for him. If he act wisely, he will find his family affections the best of moral teachers. The state of marriage is honourable, and is desirable. And now let us turn to the considerations which every man, properly desirous of entering such a state, ought to weigh duly beforehand:—It is mainly by her domestic industry that he ought to expect his wife to contribute to his comfort—by her judicious aid in making what he earns go as far as possible. She may at first have some time to spare for earning, but when a family comes upon her, that, and the household together, will take up by far the greatest part of her time. Children must for a time be a mere draft upon his industry. Great and just complaints have been raised of the extreme labour exacted from infants in factories. Granting that the employers of such infants are culpable—what are their parents? The father who allows his child to be precociously employed in labour beyond its powers, calculated to destroy it physically and morally, and render all its future life one long disease, is consenting to the crime. There is no legal press-gang to sweep children into factories. A conscientious man, who contemplates marriage, will take these facts into consideration, and ask himself whether his position and prospects are such as entitle him to expect to be able to support a wife and children as they ought to be supported for a number of years. He must estimate the possible earnings of his wife at a very low figure—as something that may at times enable them to indulge in an extra luxury, but not as contributing to the necessary household expenses. He ought to assume that his children, before their eighth year, will earn nothing, and that for some years after their earnings will amount to a mere trifle. The sources of his income being thus ascertained, he must next look his expenses fairly in the face. It is a duty he owes to himself and society to aim at procuring for himself a sufficient allowance of nourishing food, comfortable clothing, the means of preserving cleanliness, so requisite to health, and weather-tight, well ventilated lodgings, with the necessary fuel. The same comforts which he aims at for himself, he becomes bound to procure for her whose time after their union ought to be mainly directed to caring for the comforts of him and his children. And for those children, he is bound, by every natural feeling, to provide while they are unable to provide for themselves, in such a manner that they shall start upon life with hale constitutions and a fair elementary education. From his knowledge of his own expenses as a bachelor, and from what he can learn of the expenses of his married neighbours, he can form a tolerably near estimate of what marriage is likely to cost him. He must take it for granted that unforeseen accidents are more likely to occur in a family consisting of two, three, or four, than in a family consisting of one; and on this account ought not to venture on the married state unless he or his intended has some little stock of sparings laid up in the event of contingencies. This being provided for, he must next take into account whether his earnings can cover the certain steady outlay of a family, and deposit a trifle at intervals in the savings' bank; and whether there is a fair prospect of their continuing to increase, and at least not to fall off. If every prospect is favourable, he may take the step; if not, he incurs the almost certain danger of reducing himself and his family to a state of destitution—of increasing by his rash act the number of sufferers in society—of adding to the number of that class which is at once miserable in itself and the cause of misery to others. When we ask all who have not a reasonable prospect of being able to rear and instruct a healthy family to abstain from marriage, we only ask of them to consult their own happiness; the benefit of their abstinence will be reaped by society at large as well as themselves, the bad effects of their rashness will be felt by society as well as themselves, but the deepest, bitterest dregs of the harsh draught will fall to be drained by them. We only ask them to submit to a necessity which it is in vain to struggle against. If they ask why they are to deny themselves a gratification which they see others indulge in, the answer is, for the same reason that they forego many other pleasures they may wish for but cannot earn by honest industry. Marriage is a fruitful source of happiness when judiciously set about; but, like all other goods of this life, it must be earned, and those who are not in a condition to earn it (whether for want of employment or want of ability), ought in conscience to forego it. To rush blindly upon the cost of marriage, without forethought, encouraging their rashness by such groundless remarks as, "When God sends mouths he sends meat," is not even to snatch a pleasure they have not had it in their power to earn, for such inconsiderate matches have more of a curse in them than of a blessing. A bachelor state may be less happy than a good marriage, but it is better than a rash one, which precipitates all parties into destitution.

It is the more necessary to impress the importance of the lesson, "Learn to abstain," because it is the more difficult to practise, on account of the strength of the impulse to be overcome, and the weakness of those subjected to it, from its reaching its intensest power at an age when the judgment is yet immatured and experience empty; and also because rash marriages are the great promoters of a destitute, and consequently a demoralized and unhealthy population; and because the man who has taught himself, by struggling against inclination, to make his instincts bend to his reason in this matter, has strengthened himself to resist almost any other temptation. It is men (and women too) who know how to earn and how to practise self-denial—who know what it is to appreciate pleasures, but are able to reconcile themselves to abstinence—in whom inclination and will are under the control of judgment and reflection—who constitute the sound and useful portion of society. In proportion as this class preponderates, will it be possible to keep the healthiness and morality of the community at a high average.

DEATHS.

A human being born with a sound constitution is calculated to live seventy years or upwards, under favourable circumstances; but, as we well know, all of us are surrounded more or less by circumstances unfavourable to life, by which, practically, our term of years is liable to be greatly shortened. Existence, as to duration, is proverbially the most uncertain of all things, and this because, from ignorance, incautiousness, and accidents, life is constantly coming into collision with the conditions calculated to destroy it. The conditions unfavourable to life come into operation, we have seen, before the human being has seen the light. They continue in operation throughout the whole of its appointed period; so that, out of any large number born, a certain proportion die in the first year, a certain proportion in the second, the third, and so on, until all are gone—only a certain comparatively small number attaining the full age which nature promises to some [illegible] maintained in favourable circumstances.

The conditions necessary for healthy and protracted existence are [illegible] of Almighty wisdom; they are briefly enumerated in the article PRESERVATION OF HEALTH, to which we refer. They vary in different countries, according to climate, civilization, and political arrangements; and, as necessarily follows, are different in the same country in different ages.

Table of Mortality for England.

During the eighteen years from 1813 to 1830 there were registered as buried in England and Wales 3,938,496 persons, of whom 1,942,301, were females. The ages of all these persons were, as far as possible, ascertained and stated; so that it was possible by these means to ascertain the rate of mortality at the different ages, for that period, and in that country. The table consequently formed is here given.

Age.	Males.	Females.	Both Sexes.	Age.	Males.	Females.	Both Sexes.	Age.	Males	Females.	Both Sexes.
Under One Year.	436,046	341,137	778,033	40	16,209	17,304	33,513	80	20,666	24,951	45,617
1	130,426	127,017	266,441	41	10,083	10,906	20,989	81	13,146	14,279	27,425
2	78,114	75,900	154,014	42	13,423	14,073	27,506	82	15,523	17,582	33,105

37	11,873	13,409	25,282	77	21,012	21,845	42,857	119	1	0	1
38	12,519	14,268	26,787	78	19,595	21,030	40,625	120	2	1	3
39	11,167	12,611	23,778	79	15,576	16,433	32,009	124	1	0	1

It appears from this table, as it has done from others constructed in other countries, that, while the births of males to females is about 21 to 20, the deaths are in an opposite relation; that is to say, female life in general is of longest duration.

Mortality at Various Ages, and Expectation of Life.

The great mortality of the early periods of life is very remarkable. One-fifth of the whole of the children born in England and Wales appear from the above table to die in their first year. (A Belgian table represents no less than a tenth of the entire mortality as taking place in the *first month of life.*) The disproportion between the deaths of males and females, appears also to be greatest under the fourth year; a fact which confirms the common remark as to its being more difficult to rear boys than girls, and which, it may further be observed, is in harmony with the disproportion of still births.

From a table of mortality, a calculation is easily made with regard to the probable duration of the life of any person. The calculation is made, with regard to any particular age, by adding up, in a table of mortality, all the deaths after that age, and dividing the sum by the numbers living at that age. The quotient is the *expectation of life* of a person of that age. A table of the expectation of life, for service in life assurance and annuity business, is formed by doing this with regard to every age, and putting the whole in proper succession. We here present such a document, formed from the above mortality table, but only showing the expectation at every fifth year; joined to which is a similar table formed from the Million Tontine of 1695, and indicating very clearly the improvement of life in England during the last hundred years.

Age.	Million Tontine. of 1695.		Parish Registers. 1813–1830.

Diseases.

Of the specific causes of mortality, it is difficult to procure anywhere a proper estimate, on account of the imperfection of most systems of registration, and particularly the want of precision and uniformity in naming various diseases. The system of registration recently established in England, is conducted upon enlightened principles, and appears to have hitherto been managed with great regard to correctness. It has enabled its able director, Mr. Farr, to draw up very minute and comparatively satisfactory tables of the fatality of diseases in England and Wales for several recent years. The registered deaths of 1838 were 342,529, of which 175,044 were of males, and 167,485 of females. The causes of death were assigned in 330,559 instances: assuming that the other cases might be distributed proportionally among the assigned causes, a table was constructed, of which the following is a summary:—

No.	Diseases.	Males.	Females.
1	Epidemic, Endemic, and Contagious Diseases,	20·300	20·716
	Including *Small-pox*,	5·125	4·710
	Including *Typhus*,	5·500	5·861
2.	Diseases of the Nervous System,	16·034	13·999
3.	Diseases of the Respiratory Organs,	27·118	27·850
	Including *Phthisis*,	16·033	19·101
4.	Diseases of the Organs of Circulation,	1·205	·915
5.	Diseases of the Digestive Organs,	5·960	5·709
6.	Diseases of the Urinary Organs,	·793	·193
7.	Diseases of the Organs of Generation,	·006	2·008
8.	Diseases of the Organs of Locomotion,	·647	·623
9.	Diseases of the Integumentary System,	·153	·099
10.	Of Uncertain Seat,	12·974	13·805
11.	Old Age,	9·637	11·928
12	Deaths by Violence,	5·107	2·127

The healthy occupations of the country make a difference in its favour in the general mortality; but this appears larger than it really is, in consequence of the flocking of the worn-out and miserable to large towns, and the occasional resort of sick persons thither for the sake of medical attendance, in the course of which life is in many instances cut short. In 1838, out of equal numbers in town and country, the deaths in the former appeared to be 101,019, and in the latter only 70,410. The average of life in the country would thus seem to be 50, and in the city 37; but if the above modifying causes are taken into account, the disproportion must be deemed considerably less. As might be expected, diseases are of different fatality in country and in town. Taking similar amounts of population in each, Mr. Farr found that, for 1·00 in the counties, there were, in the cities, "by asthma, 3·80; erysipelas, 2·71; convulsions and teething, 2·57; cephalitis and hydrocephalus, 2·41; hydrophobia, 2·37; pneumonia, bronchitis, and pleurisy, 1·99; delirium tremens, 1·98; typhus, 1·88; small-pox, 1·73; heart-disease, 1·73; childbirth, 1·63; syphilis, 1·59; rheumatism, 1·58; gout 1·55; hernia, 1·48; purpura, 1·46; sudden deaths, 1·45; liver disease, 1·45; hepatitis, 1·35; tetanus, 1·32. The excess of mortality in cities was of less amount in the following cases:—By consumption, 1·24; croup, 1·23; violent deaths, 1·17; stone, 1·11; mortification, 1·10; malformations, 1·07; apoplexy 1·07; hæmorrhage, 1·02." Of some other diseases, the fatality was greatest in the counties. The "mortality to 1·00 in the counties was, in the cities, by paralysis, ·99; dropsy, ·99; jaundice, ·99; diabetes, ·97; cancer, ·92; hydrothorax, ·88; hæmatemesis, ·79; debility (frequently premature birth), ·75; atrophy, ·75; scrofula, ·16."

London is, upon the whole, healthy for a large city, the annual mortality being 1 in 42 of the population, a proportion very little above that of England and Wales (1 in 44·5). But the general healthiness of London is in some measure deceptive. It contains districts and kinds of population widely different; and the effects of wealth, spacious accommodations, and comparative cleanliness at the west end and in the suburbs, makes up in a summary for the opposite conditions of the eastern parts. This is rendered clear by the following statement:—

	Annual Deaths per cent.	Or
Whitechapel	3·866	1 in 26
St. George's, Southwark	3·297	1 .. 30
Bermondsey	3·121	1 .. 32
St. Pancras	2·018	1 .. 40
Camberwell	1·925	1 .. 52
Hackney	1·826	1 .. 54

It is to be observed that all these results rest, not upon the population as actually known, but as computed hypothetically from the census of 1831. Their accuracy, of course, cannot be entirely depended on, but they may be received as good approximations. The effect of crowding is shown by a table, exhibiting the mortality, and the number of square yards of space to each person in three groups of metropolitan districts.

	Square yards to each Person.	Annual Mortality.	Mortality from Typhus alone.
1st group of ten districts,	35	34·28	349
2d	119	27·6	181
3d	180	22·0	131

Hence we see that typhus is nearly three times as fatal in the first or crowded group as in the third or open one.

Glasgow is believed to stand lowest among British cities in point of health, and for some years its unhealthiness seems to have been steadily on the increase. In 1821, the rate of mortality was 1 in 39 and a fraction; in 1831, it was 1 in 30 and a fraction; in 1838, 1 in 26 and a fraction. In 1821, the deaths of children under ten years of age in this city were 1 in 75; in 1839, they were a little under 1 in 48. The extreme mortality of Glasgow is readily accounted for by the existence of a vast horde of miserable people in the meaner and closer parts of the city. Mr. Symons, an English gentleman who had taken pains to make himself personally acquainted with the subject, states as follows:—"It is my firm belief that penury, dirt, misery, drunkenness, disease and crime, culminate in Glasgow to a pitch unparalleled in Great Britain." This class becomes a focus of typhus fever and other pestilential disorders, which emanate from it to the rest of the inhabitants, and generally prove very fatal. In 1839, the deaths from typhus fever alone reached 2180. It may be remarked that statistical science, which has been cultivated to an unusual degree in Glasgow, gives an unfavourable view of the city in a number of respects. In the five years previous to 1831, the average births in Glasgow were 1 to 29·47 of the population; the burials 1 to 30·91; and the marriages 1 to 105; the respective average numbers for entire England during the same period being 1 to 37, 1 to 54, and 1 to 129. It thus appears that there are in Glasgow more marriages, more births, and *more deaths*, than in the country generally. In the parish of Montreux, where the births are 1 to 46 of the population, nineteen out of twenty complete the first year of life, and very nearly four-fifths of those baptized have been observed to live to receive the sacrament of communion.

A similar correspondence between many marriages, many births, and many deaths, is shown in the returns from Liverpool, as appears from the following passage in Dr. W. C. Taylor's work, *England in the Nineteenth Century*:—"The site of Liverpool is low, and we regret that, upon examining the returns of the population for 1841, and comparing them with those of the births, marriages, and deaths, we should have found such a startling result—a result not so surprising to us as it would be had we not seen some of the older returns. In 1662, the baptisms were 30, and burials 30: 1700, as above, the former 131, the burials 125; in 1800, the baptisms 3033, burials, 3157. The births registered in 1839, when a close approximation to correctness in the returns took place, were 7128, deaths 7437; in 1840, with a population of 223,054, the returns showed 9990 deaths to 9925 births. We then went farther, and made calculations upon a basis every way favourable, for we applied to the Population Returns of 1841 the Registrar-General's return of births and deaths for 1840 in Liverpool, consequently we applied them to nearly the tenth part of a clear increase more than we ought, and the result, compared with the totality of England exclusively of Wales, made from a table in which the decimal surplus population was deducted from England alone, gives the following figures:—

	Births to Population.	Deaths to Population.	Marriages to Population.	Births to Marr.
Population of all England reduced to June 30, 1840, 14,707,751	1 to 31·07	1 to 44·45	1 to 125·29	4·03
Liverpool, 22[illegible],	1 .. 22·47	1 .. 22·82	1 .. 60·0	2·6

Here are startling anomalies," remarks Dr. Taylor; "double the deaths and marriages, and little more than half the number of births [to a marriage], averaged in the totality of England."

Effect of Seasons.

Seasons affect mortality very considerably. We have already adverted to the popular notion that a mild winter is the most fatal to life, and mentioned that it is the reverse of the fact. Severe weather, in reality, affects life to a much greater extent, particularly in some classes of ailments, than could be supposed likely. One table, prepared from the Belgian registers, shows a surprisingly gradual decline of mortality as the spring and summer advance, and then an equally gradual increase towards the middle of winter, the influence being rather more marked in country than in town.

Months—1815 to 1816.	Deaths.	
	Town.	Country.
January	59,892	116,129
February	58,967	114,758
March	51,277	111,241
April	51,818	107,264
May	48,911	94,718
June	46,607	84,461
July	45,212	77,555
August	47,032	78,802
September	50,491	85,131
October	51,649	89,541
November	52,908	90,585
December	55,631	98,705
Average	51,700	95,822

In 1838, the weather at the commencement of the year was more than usually cold, and in certain classes of diseases the mortality of that year in the metropolis for the different seasons was as follows:—

Causes of Death.	Winter.	Spring.	Summer.	Autumn.
Paralysis	234	181	135	187
Apoplexy	299	241	201	246
Asthma	760	225	97	331
Hydrothorax	90	73	43	79
Bronchitis, pleurisy, pneumonia	1699	870	545	1154
Influenza	31	19	3	11
Diseases of the heart, &c.	273	150	177	211
Diabetes	12	4	1	6
Dropsy	501	427	375	465
Mortification	84	50	35	56
Sudden deaths	216	165	105	140
Old age	1383	969	778	941

The disproportion, it will be observed, was greatest in diseases of the respiratory system.

Effects of Wealth and Civilization.

The progress of wealth and civilization takes a prominent place among the conditi[ons] [ei]ther causing or accompanying a reduction of mo[rtality].

The number of deaths th[at] [oc]curred in the city of London in 1697, was 21,000; a [c]entury later, in 1797, the [numb]er was only 17,000, notwithstanding the increase of the population. About the middle of last century, the annual mortality in the same city was as high as 1 in 20; in 1830, it was 1 in 41. Of course, in the metropolis of a great nation, an increase in the number of inhabitants is not necessarily a proof that the indigenous population is increasing; but the average of deaths being in London 1 for every 41 inhabitants in 1830, and the average of *registered* baptisms (everywhere in this country less than that of births, and most of all in London), being in the same year 1 in every 31, we know that, independent of the increase from immigration, the population of London has been steadily augmenting. The statistics of the city of Amsterdam present a remarkable contrast to this picture. In 1727, the annual average of mortality was 1 death for every 27 inhabitants; and the average for the twelve years preceding 1832 was the same. During these twelve years, too, the average number of deaths in a year was 7336; the annual average number of births only 7282. If during that period the population of Amsterdam did not positively decrease, it must have been kept up by immigration.

There is another point of difference in the career of these two cities for a century back. Whilst the wealth of London has been increasing almost in a geometrical ratio, the commerce of Amsterdam, and with it the opulence of the city, has been diminishing. Here, then, we have two striking examples of an increase in the mean value of life attendant upon augmented wealth, and, at the least, a stationary condition of that mean value attendant upon a diminution of commercial prosperity. The analogy is marked, and not surprising, between the fortunes of communities and individuals: in both cases, opulence (that is, the comforts of which opulence gives command) has a tendency to improve the general health and prolong life. This, however, is taking but a superficial view of the question; to enable us to turn such knowledge to account, we must go more closely to work, and examine in what manner the beneficial change is produced. If we do this, there are facts established by the statistical inquiries which have of late years been made in Europe (although the science of statistics can scarcely be considered as far advanced beyond its mere infancy), which will show us that the increased wealth of a community is rather an attendant upon its increased health than a cause. They are both mutually causes and consequences—both the results of advancing civilization, and both contributing to carry on that civilization to a yet higher pitch. A recapitulation of some of the most striking circumstances either attendant upon, or productive of, the increasing health of a community, will be found fraught with useful practical lessons.

The ascertained facts regarding the rate of mortality in our own country, since the commencement of the reign of George III., invite to investigation. "The annual number of burials," says Mr. Rickman, in the preface to the Population Returns of 1830, "as collected in pursuance of the population acts, authorizes a satisfactory inference of diminished mortality in England; the average number of burials not differing materially from the year 1780 to the year 1815; the first five years of th[e] [per]iod, the last five years, and the whole period of thirty-[si]x years, giving the same average result of 193,000 registered burials, the population having increased 3,300,000 in the mean time." It appears from a subsequent part of the preface, that the annual mortality in 1780, as near as could be ascertained, was 1 in 34 or 35 of the population, that in 1820 it was 1 in 49. On the other hand, the same authority states—"The mortality of the inhabitants of England appears to have sunk to its *minimum* in the decade preceding the population abstract of 1821; and since that time it seems to have risen as fast as it descended after the year 1800. The census of 1841 gives one death annually for every 44·5 persons." The wealth of England has, however, continued to increase; and this shows the necessity of inquiring into the minute details of our social system during the period of increasing and diminishing healthiness, in order to see what has caused both.

In general terms, it may be remarked that the commencement of the diminished ratio of mortality is nearly contemporaneous with those inventions which contributed to give such an increased power to the productive industry of the nation. The Duke of Bridgewater and Brindley constructed the Worsley and Manchester Canal between 1758–60, and the Liverpool and Manchester Canal between 1762–67. In 1769, the connection between Boulton and Watt for bringing into play the patent obtained by the latter for improvements in the steam-engine, was formed. In 1775, the partners obtained from Parliament a further extension of the patent, which shows that they were then only beginning to reap the advantage of the improvements. Arkwright obtained the first patent for his spinning machinery in 1769, and his second patent in 1775. His first water-mill was erected in 1771; but five years elapsed before he began to derive any profit from it. The influence of these improvements was, from the first, of the most marked kind, and it ramified over the whole country.

By means of these inventions, conveniences and luxuries were brought within the reach of incomes which previously could not afford them; and the extraordinary cheapness and goodness of British manufactures, with such advantages, so increased the demand for them in foreign markets that the manufacturers found the supply of labour insufficient. The national wealth was not only increased, it was diffused through all classes of society. Increased incomes, the spirit of rivalry, prompted all classes, the labouring class as well as others, to live more comfortably; better clothed, housed, and fed, men became liable to fewer diseases.

From the middle of the eighteenth century, a stimulus had been given to the popular intellect, and the English were becoming a reading nation. The great inventors were themselves chiefly members of the middle and humbler classes, and the earliest of the great manufacturers were so likewise. Sunday-schools, book-clubs, and the diffusion of newspapers, were perhaps amongst the most serviceable means of enlightening the people of England during the reign of George III. At last came Joseph Lancaster with his cheap apparatus for the elementary education of the masses. When we find such circumstances accompanying the diminution of mortality in England, we cannot refrain from supposing them in some measure connected.

We deem it, then, tolerably clear that the great promoters of the health of individuals are—increased affluence, relieving the mind from despondency or harassing care, and furnishing the means of cherishing the body; and increased intelligence, teaching how to derive the most advantage from this affluence, and laying the foundation of habits of judicious self-control; and that the great promoter of the health of communities is the extension of these advantages to as many of the individuals or classes composing them as possible. The possession of affluence, and the intelligence requisite to acquire, retain, and use it aright, is the main distinction between what are called civilized and savage men. In the common practice of sinking the individual in the class—speaking of nations as resembling or contrasted with nations, we are apt to overlook the fact, that every civilized nation is not necessarily composed exclusively of civilized human beings. In every nation, even in our own, there are many who grow up, live, and die, unreflecting creatures of impulse, scrambling day after day to snatch a precarious livelihood—now gorged, more often starved—ignorant of responsibility to God or man—in short, as complete savages as are to be found among the woods of America or in the bush of New Holland. The detrimental influence of a numerous class of this kind being left in any society is not confined to itself. Its existence does not merely lower the average of virtue and comfort in a country by diminishing the ratio its sum bears to the total of the whole population; the contagion extends to the civilized or comfortable classes, who are by proximity brought into contact with it. From the squalid dens in which this class congregates, emanate contagious diseases that penetrate into the dwellings of the wealthy. Its numbers compose what an eminent statist has aptly called "the dangerous classes of large cities;" the ranks of our thieves and housebreakers are perennially recruited from among them. They constitute, in times of domestic contention, the brute instrument of the wicked of the *civilized* class. They are a chronic disease in the social body; and a nation is healthy in proportion as they are diminished in number, or become humanized by a participation in the comforts of their more favoured brethren.

The advantages which society has derived from augmented wealth and extended education, may be distributed under three classes, according as they proceed from greater facility of procuring physical comforts owing to their greater abundance, or from the greater power of contributing to their own enjoyment by regulating their moral conduct, which men derive from intellectual cultivation, or from the union of both these causes. We proceed to illustrate, by some statistical details, the mode of operation in each of these three classes.

The advantages which the whole community derive from an increase of wealth, and its source, more efficient application of industry to the natural wealth of the country, are of two kinds—those in which all participate, even those who do not exert themselves; and those of which individuals acquire a share by their personal exertions. Of the first kind are the benefits resulting from drainage in town and country. The stimulus given by the inventions adverted to at the outset has extended to agriculture; and the efforts which have been made to render land which was not productive, or productive of little, more fertile, have indirectly contributed to promote the public health. The draining of the fen counties on the east coast of England has banished a class of diseases which were most destructive in these districts. The fevers of Essex used to be inferior in virulence, but scarcely inferior in frequency, to those of the Pontine marshes. With the drainage of the marshes of that county these fevers have disappeared. "The intermittents," says Mr. Rickman, "which, heretofore, under the name of ague, infested the country very extensively (especially the fen districts), are no longer spoken of." In the time of Richardson the novelist, as we learn from his published correspondence, the scourge visited periodically even those families which were in easy circumstances. The change for the better is of course most manifest in the positively unhealthy districts, but it is experienced in the diminution of chronic rheumatisms, wherever surface drainage and underground drainage have extended. The exertions of the more wealthy classes in large towns, to promote by sewers and other aids of public cleanliness their own health and comfort, has in like manner indirectly tended to promote the health and comfort of all classes. There are nooks and corners in London, inhabited exclusively by the poor, which are still badly enough off in this respect; but we do not, even in them, find "the kennels running blood two days in every week," as Dr. Johnson has left on record was the case in Southwark in his day; nor do we find "pigs bred and fed in the houses or back-sides of paved streets," routed out in droves by the constables in the fashionable parishes of St. George's, Hanover Square, as was the case in 1761.

The advantages which each individual must acquire for himself by his own exertions, are superior household accommodation, clothing, and food.

Previous to the impetus given to national industry in the early part of the reign of George III., the following are the rates of wages which the labouring classes of England had it in their power to earn per week: *Men* —In the iron-works at Rotherham, 10s.; in the cutlery and plating trades at Sheffield, 13s. 6d.; in the cloth manufactures at Wakefield, 10s.; the colliers in that neighbourhood, 11s.; in the manufacture of cloth at Leeds, 8s. 3d.; at the alum works at Ayton, in Cheshire, 7s. 6d.; in the lead mines at Fremington, in Yorkshire, 7s. 6d., the colliers of Newcastle, 15s. 6d.; in the manufacture of cottons and checks at Carlisle, 9s.; in the manufacture of stockings, cottons, and linsey-woolseys, in the tanneries at Kendal, 9s. 5d.; in the making of pins and shoes at Warrington, 8s. 7d.; in the manufacture of fustians, checks, hats, and small-wares at Manchester, 7s. 3d.; in the potteries at Burslem, in Staffordshire, 9s. 6d.; in the manufacture of piece-goods at Witney, in Oxfordshire, 11s.; making carpets at Wilton, in Wiltshire, 11s.; pins in Gloucestershire, 11s.; says and burying-crape at Sudbury, 7s. 6d.; says and calimancoes in Suffolk, 5s. 9.; flannels and linseys at Salisbury, 8s. *Women*—In the lace manufacture at Bedford, 4s. 6d.; in the cloth manufacture at Leeds, 3s.; in the lead mines at Fremington, 6s.; in the Kendal manufactories, 3s. 3d; in making pins and shoes at Warrington, 4s. 6d.; making shoes and hats at Newcastle, 4s. 6d. *Children*—In the porcelain and glove manufactures at Worcester, 2s. 6d.; of shoes and hats at Newcastle, 1s.; boys in the potteries at Rotherham, 3s.; boys and girls in the Fremington lead mines, 3s. 3d.; children at Kendal, 2s.; children at Manchester, 3s. 5d. The medium rate of the wages of manufacturing labour was—in the east of England, 6s. 6d.; in the south, 9s. 4d.; in the west, 11s. The medium rate of agricultural wages was 8s. in the eastern counties; 6s. in the southern; and 5s. 10d. in the western districts. These rates were ascertained by Arthur Young in his tours of 1768 and 1770. Young estimates the population of England and Wales, in 1770, at 8,500,000: of these he gives 2,800,000 as the number engaged in agriculture—the landlords, with their families and dependants, amounting to 800,000; and the number engaged in manufactures, 3,000,000. This, on a rude estimate, would give the numbers of the population depending upon the wages of labour for subsistence, of that time, less than four millions. He estimates the non-industrious poor at 500,000.

The information given by Mr. Jellinger Symons in his "Arts and Artisans at Home and Abroad," published in 1839, enables us to contrast with Young's statements the capability of earning possessed by the labouring classes of England in our own day. *Men.*—In Manchester, a spinner can earn from 20s. to 25s. a week; a man in the card-room, 14s. 6d. to 17s.; a weaver by power, from 13s. to 16s.; by hand, from 7s. to 15s.; dressers earn from 28s. to 30s.; and mechanics, from 24s. to 26s. The wages at Sheffield vary from 25s. to 35s., and often amount to 40s., for workmen in the skilled departments; in the iron-works of the Birmingham district, wages average from 20s. to 30s. for the common labourers; in the Leeds flax-mills, men earn from 17s. to 19s. a week; in the Gloucestershire cloth-factories, from 12s. to 14s. In other trades, the average wages per week throughout England are—iron-founders, 28s. to 30s.; machine-makers, 26s. to 30s.; sawyers, 24s. to 28s.; carpenters, 20s. to 25s.: stone-masons, 18s. to 22s.; bricklayers, 17s. to 20s.; spadesmen, 10s. to 15s.; porters, 14s. to 16s.; colliers, 3s. 6d. a day; stocking weavers in Leicester, 8s. 3d. per week. *Women* earn per week, at Manchester, as spinners, 10s. to 15s.; in the card-room, 9s. to 9s. 6d.; weavers by power, 8s. to 12s.; by hand, 6s. to 12s.; in the Leeds flax-mills, 5s. 6d. to 6s. 6d.; in the Gloucestershire cloth-factories, 4s. to 5s. Children can earn in the Manchester factories, from 1s. 6d. (scavengers) to 7s. a week; in the Leeds flax-mills (when nine or ten years old), 3s. 6d. to 4s. "Agricultural wages," says Mr. Symons, "in England vary so little, and are so well known, that I need hardly do more than state, that in the Coteswold districts, for instance, a shepherd receives 10s. weekly; a carter, the same; day-labourers, 8s. in summer, and 6s. in winter; in addition to which, they earn 3 guineas at harvest time, which will pay their rent. Women receive 6d. a day in winter, and 8d. in summer, and 1s. in time of hay and harvest. Perhaps these are the lowest wages paid in any district in England. From 8s. 6d. to 10s. 6d. will be throughout the average wages of the great bulk of adult male agricultural labourers of England. These rates of wages are taken at a period when the remuneration of labour is retrograding in a marked manner. Even under this state of affairs, however, they show that the increase of national wealth has at least given individuals of the labouring class the command of a greater money income.

The labourer's power of commanding the comforts of life can only be partially known from a statement of his earnings: attention must be paid to what these earnings can purchase. The principal expenditure of the labourer, as already stated, is in house-rent, clothing, and articles of domestic consumption. By the improvements of machinery, all classes are enabled to procure better clothing at a lower price than they formerly paid for an inferior article. The extent to which this change has been carried, may be inferred from one or two facts regarding our manufactures. In 1787, when the mule-jenny first came into common use in Bolton, Paisley, and Glasgow, the manufacturers paid for their fine yarn at the rate of 20 guineas per lb.; the same quality of yarn has of late been sold at from 14s. to 16s. a lb. The cotton twist, which sold in 1786 for £1, 18s. per lb., is sold now for 3s. The process of reduction in the price of manufactured goods is still going on, and in the linen as well as in the cotton trade. Canvass, No. 27, an article, the quality and dimensions of which do not vary, which sold in 1814 at 30s. a piece, had fallen in 1833 to 18s. In the woollen manufactures, a great reduction of price, compared with quality, has also taken place. The consequence is apparent in the style of dress adopted by the working-classes of Great Britain, so different from what prevails on the continent, and did formerly prevail here. As to houses, every person who has attained to middle age must have remarked the improvement in many districts of the accommodation of the labouring classes in this respect; and yet the money rental seems to have remained nearly stationary. Young states the house-rent of the working man to have been in his time—at Leeds, £2; Wakefield, £2, 5s.; Newcastle, £2, 12s. 6d.; Hatfield, £2, 15s.; North Mines in Middlesex, £3, 10s.; Kensington as high as £5. In 1839, the average rental of a labourer's cottage in the country near Penzance was about £3; in the town, £5; in the county of Rutland, £1, £1, 10s., and £2. In Suffolk, in 1838, the house-rent of 539 labourers' families averaged £3, 11s. per family; in Northumberland, the average rent of a labourer's cottage was estimated at £2, 10s. Even the price of provisions, which is generally supposed to have been so much lower in former times, has not increased, if it has increased, so much as is supposed. The average prices of butcher meat, beer, cheese, milk, and butter, throughout the kingdom, do not materially differ now from what they were in 1760; bread is dearer, but improved in quality, and potatoes are much cheaper. Tea, coffee, sugar, and pepper, have been much reduced in price; and now, instead of scarcely ever appearing in the weekly bills of the labourer, are standing articles of his expenditure.

This improvement in the quality of the accommodations procurable by a moderate income must always be kept in view, when comparing what a man can earn now with what he could earn formerly.

It would, however, convey a false impression of the amount of social advantage at any time derived in Great Britain from the great increase in the productive powers of industry, were we to leave unnoticed the large and increasing class which has never yet been reached by these benefits. Even in the most busy marts of industry, numbers are to be found, and these not always entirely unable or unwilling to work, who are in a state bordering upon destitution. We have a remarkable example of this class in the city of Limerick, where a large district is in a manner given up to them. In England, it is to be observed, the mean value of life among the more comfortable portion of the working-classes is now as high as that of the middle classes in last century: this appears from comparing the experience of the Amicable Insurance Office, established in 1706 for the benefit of the middle classes, with the table of mortality collected by the Society for the Diffusion of Useful Knowledge, which embraces the history, as to mortality, of 24,323 years of life among the labouring classes from all parts of England, from 1823 to 1828. In Limerick, on the contrary, while the deaths in the three tontine societies there founded in 1807, 1811, and 1814, and with lives injudiciously selected, show respectively one death annually in 108, 81, and 182 persons, the annual mortality among the poor is 1 in 19. This is not all. "The frightful excess of epidemic and endemic diseases among the poor of Limerick may be gathered from the following fact, that while the per-centage proportion of this class to the whole number of deaths in England and Wales in 1838, was under 20 (19·8); in the metropolis and Leeds, 26·1 and 26 respectively; in Manchester, 23·2; in Birmingham, 20; and in Liverpool, 19·8; it is in Limerick not less than 40, or nearly five times as great as the proportion of deaths from diseases of the respiratory system, to which, among a healthy population, it ought to be nearly equal."* Among the families of this class who came under the notice of Dr. Griffin—"Out of 66 who had more than 10 children born alive, 13, or one-fifth, had lost 11 or more of those children; and the aggregate mortality of those families was 159, or 12 each, which, if distributed among the same number of families who had the greatest number of children born alive, amounts to 79 per cent., and was probably higher." He adds—"It has been remarked that production is often most rapid among a population in extreme wretchedness; and I strongly suspect that this is a consequence of the high mortality which occurs in such circumstances. It is the character of any influence which tends greatly to depress the powers of life, that it always bears heaviest on the tenderness of infancy and the feebleness of age. Now, as I find that the poor nurse their own children, there is generally an interval of about two years between the birth of one child and that of the next; but if a child dies early on the breast, this interval will be much shorter, and if this occurs often, there will be a certain number born, as it were, *for the purpose of dying*."

Effects of Increased Wealth and Knowledge in Combination.

Some results from the combined influence of increased wealth and knowledge may now be adverted to. It is to be observed, that the rich could at all times command many comforts favourable to life; but it is only when knowledge suggests a right employment of the means afforded by opulence, and opulence on the other hand exists to avail itself of the aid of knowledge, that the full benefit of the conditions we have been reviewing can be said to be realized. The following illustration may make our meaning more clear.—

It is commonly believed that there is more danger to life from lithotomy than from amputation; but statistical inquiry shows that death more frequently follows the latter than the former operation. The results of 640 cases of amputation of legs and arms, in hospitals and private practice, in France, Germany, United States, and Great Britain, were in 150 cases fatal—a ratio of 23½ per cent. It is to be kept in view, however, that the mortality in cases of amputation very frequently arises from the injury or disease on account of which the operation is resorted to; whereas the mortality from lithotomy is almost invariably the direct effect of the operation alone—the surgeon having it in his power, in the latter case, to choose a time when the patient is in the best condition to endure the suffering, which he can rarely do in case of amputation. When we reflect upon the intimate acquaintance with the human frame, and the confidence in his own skill, which the surgeon can only acquire by dexterity, the result of much practice and the traditional experiments of his predecessors, we are able to form some idea of the importance of knowledge in alleviating the miseries of humanity. And when we add the consideration of the cost of instruments, medicines, and the time and trouble requisite to form a good surgeon, we are able to form some idea of the extent to which stored-up capital is a necessary prerequisite to men having been able (in the first instances at least) to give and receive this alleviation.

Another example of the benefit of the co-operation of increased national wealth with increased knowledge, is the diminished risk of life in cases of child-birth. It may appear that we are wandering from the consideration of wealth, seeing that the examples we are about to subjoin are selected from the returns of lying-in hospitals—the only trustworthy statistics on this point. But it must be kept in mind, that a nation must be wealthy before it can support such institutions; that the improvement so marked in the case of the poor, must be *a fortiori* greater in those who can afford continued watching and the best assistance; and that the affluent classes must have enjoyed the benefit before it could be extended to the poor. The process by which a share in this and other privileges of the rich has been extended to the poor, is a question for after investigation. With this explanation, we submit the following quotation from M. Quetelet's Treatise on Man, to show the mortality of women in child-birth, and their children:—

"According to Willan, the mortality in the great lying-in hospital in London, into which about 5000 women were annually admitted, was,

			Of mothers.	Of children.
From 1749 to 1758,	-	-	1 in 42	1 in 15
" 1759 " 1768,	-	-	1 " 50	1 " 20
" 1769 " 1778,	-	-	1 " 53	1 " 4[illegible]
" 1779 " 1788,	-	-	1 " 60	1 " 41
" 1789 " 1798,	-	-	1 " 288	1 " 77

According to Casper, the mortality of confined women at Berlin has been—from 1758 to 1763, 1 in 95, from 1764 to 1774, 1 in 82; from 1785 to 1794, 1 in 141; and from 1819 to 1822, 1 in 152."

The same author supplies us with an estimate of the sanitary influence of vaccination:—"In most civilized countries, there are enactments on vaccination, of greater or less severity, which are enforced with proportionate rigour. According to Casper and several other savans who have written on the ravages caused by the small-pox, it would appear that formerly generations were decimated by this scourge, that is to say, one-tenth of the human race died from it. Duvillard has found—1st,

* "Wherever the absolute mortality is low, the number of deaths in the epidemic class is less than the number in the pulmonary class, and, on the contrary, wherever the deaths in the first class exceed or equal those, it may be affirmed that the absolute mortality [illegible]."—*Appendix to First Report of Registrar General*, 8th edition, p. 111

That in the natural state, of 100 individuals of 30 years of age, scarcely four individuals have escaped an attack of small-pox; 2d, That two-thirds of all infants are attacked by it sooner or later; 3d, That small-pox, in the early years after birth, destroys, on an average, one out of every three who are affected with it; 4th, And one dies out of every seven or eight affected, at whatever age it may be. Such was the state of things before the discovery of vaccination; it has since been much ameliorated. However, in 1817, 745 persons died in Paris of small-pox; in 1818, 993; and in 1822, the number was as many as 1084. Also, at St. Petersburg, in 1821, 408 deaths took place from it; and at Vienna, 238 in 1822; whilst in London, in that year, there were 712. Prussia has been much better dealt with than other countries: during the two years 1820 and 1821, taken together, only 1 in 7204 persons died; whilst France lost 1 in 4216 the last two years. The following are the data of Berlin for almost half a century:—From 1782 to 1791 inclusive, 4453 deaths; from 1702 to 1801, 4999 deaths; from 1802 to 1811, 2955; from 1812 to 1822, 555. The number of deaths for the last period, which is extremely small in comparison with the preceding years, would be still less, if the deaths for 1814 and 1815 were subtracted, during which time vaccination was neglected. Indeed, these two years had 411 deaths from it; so that during the remaining there was only 114. But we should fall into a serious error, as M. Villermé has said, if we counted as gain to the population all those individuals who had been vaccinated, and not carried off by the small-pox. 'An epidemic, or any other malady against which we endeavour to secure ourselves,' says M. Villermé, 'indeed suppresses one cause of death; but from that circumstance the probability of dying from some other disease becomes greater. In other words, by closing one of the gates of death, we open the others wider, so that more persons pass through these latter; which is not saying that mortality should be equally rapid. Consequently, vaccination, and every preservative against epidemic disease, or any disease whatever, does not increase the population of old Europe *directly*, but, what is still better, it alleviates the lot of those whom it snatches from the chance of the small-pox, it diminishes the number of the blind, it preserves the native beauty of the person, and increases the average duration of life.'"

This will scarcely be called an exaggerated estimate of the advantages resulting from the discovery of vaccination. In the three examples which have been adduced, the reader may see how far knowledge and affluence combined, have served as preservatives against tangible dangers. But in so far as the affluent classes are concerned, this is but a small portion of the benefits they have conferred. The habits generated in these classes by the advancement of knowledge, at a time of increased diffusion of knowledge, have been favourable to a general healthy condition of the individual system, alike calculated to ward off the attacks of disease and to baffle them when they are incurred. Any person whose memory can carry him back for forty years, and who has had opportunities of observing, may remember the deficient ventilation, the small rooms, and the number of inmates in each room, which characterized even the houses of the landed gentry. In towns, the evil was still greater. But it would require to carry the retrospect still farther back—to the time when Rousseau in France, and Davy and Edgeworth in England, commenced their crusades against unhealthy absurdities in the dress and manner of living of the wealthier classes—to imagine the whole amount of the improvement which has been effected in this respect. The improved taste of the wealthier classes has contributed to improve their morals; and, in return, the better regulation of their conduct has tended to improve their general health. The practice of deep drinking, which universally prevailed, has almost ceased to exist among the affluent classes. Literary and scientific pursuits, if they do not always guard against low debauchery, save many from it, and enable still more to recover, after yielding for a time to temptation. An interesting paper, published by M. Benoiston de Châteauneuf, entitled "On the Duration of Life in the Rich and in the Poor," corroborates these views. The author has made, on the one hand, an abstract of the deaths of 1600 persons of the highest rank, among whom are 157 sovereigns and princes; on the other hand, he has taken, from the civil registers of Paris, the deaths of 2000 persons in the 12th arrondissement, which contains a population of workmen of all kinds—ragmen, sweepers, delvers, day-labourers, &c., a class subjected to pain, anxiety, and hard labour, who live in want and die in hospitals. Out of these materials he has constructed a table showing the per centage of mortality among the two classes at different ages, and has added a column indicating the per centage among the middle or easy classes. He found that, between 25 and 30, the deaths per cent. were—among the rich, 0; among the common class, 1·41; among the poor, 2·22: from 50 to 55—among the rich, 1·81; among the common class, 2·68; among the poor, 2·58; from 75 to 80—among the rich, 8·09; among the common class, 10·32; among the poor, 14·59. At this last age the column showing the deaths among the poor stops for want of materials—they had all died off; the column showing the deaths of the common class extends to the age of 90; that of the rich to 95. The same conclusion is indicated by contrasting the annual mortality shown by the annual average of deaths among the English middle classes who have insured their lives with the Equitable Society, and the annual average among the negro slaves. Among the former, it was only 1 in 81·5 from 1800 to 1820; whereas it has been calculated that one negro slave dies annually out of 5 or 6.

Some facts would almost seem to show, that the education enjoyed by the more affluent classes—the cultivation their minds received, partly from direct tuition, partly from their social circumstances—gave the mind an increased power of vitality. An officer of high rank in the service of a German state made this remark to the writer, when speaking of the disastrous retreat from Moscow, in which he had taken a part. The officers, he said, uniformly stood out longer than the privates, although the previous habits of both parties had led him to expect the reverse. Literary men, and artists who have attained to any thing like a competence, are also a long-lived generation. The remark has often been made, of the greater facility with which young men, belonging to the class vaguely called "gentlemen," generally attain to superior adroitness in athletic exercises. Whenever a party of Etonians are pitted at cricket or running against a party of lads of a lower class, the difference is at once perceptible. Again, the facility with which the young men educated at Oxford and Cambridge—unapt though the system of education pursued in these two great seminaries be to prepare them for the real business of life—work their way into the routine of legal or diplomatic business, is well known. There is something in the strengthening influence of good and delicate feeding, clothing, and lodging, combined with exercise of the physical and mental faculties, sufficient to strengthen, not to exhaust, persevered in for generations, that ennobles the race of the human animal, just as careful grooming and crossing the breed judiciously ennobles the horse. What is here spoken of, is not the power of such a process to confer genius, or true nobility of disposition; but to bring out in perfection all the average commonplace qualities of the human being. In any country, a superiority of this kind is discernible in the dominant *caste;* and as mere human animals, there is no country in the world that can produce a race equal to the young gentry of England.

Limits to the Effects of Wealth.

The limits to this favourable condition of the affluent classes in England, are to be sought partly in deficient knowledge and deficient habits of self-control; partly in a redundancy of numbers compared with property, which affects them in common with all other classes, though not exactly to the same extent. The deficiency of knowledge may be detected in several noxious practices still persevered in, such as tight-lacing on the part of the fair sex. The want of proper habits of self-control is a more deeply rooted evil, inasmuch as it has its root in a physical fact too much overlooked by reasoners upon morals. When named, it will be found to be a very commonplace fact: it is, that every successive generation begins the world with as little experience as that which preceded it. Every one of us starts from as mere a state of ignorant barbarism as the child of the savage. We are forewarned of much by the instruction of those who have been taught by their own experience, or the experience of those who went before them; but there is much of which it seems impossible to forewarn us. The passions are fully developed before the reflecting powers; and every individual seems destined to experience a period of his existence in which imagination and passion are strongly and thrillingly awakened, while the guiding power of reason is yet dormant. This is the most dangerous, as it is perhaps the most pleasant, period of life; and it is one which is most dangerous with regard to that very class which is so highly favoured in other respects. Penury, or the necessity of daily labour, may restrain the less affluent classes at this period of life; but the younger branches of the affluent class have no such substitute for the control of reason; and in proportion as their general healthiness is higher, so their passions are developed, it may be, with greater intensity. It is at this period that many of the more favoured class make shipwreck of their health, incurring diseases which cling to them through life, if they do not bring it to a premature close.

The influence of economical circumstances upon the affluent classes, in regard to their moral and physical welfare, is quite as striking as their influence on the less fortunate classes, though somewhat different in kind. The anxiety occasioned to the upper classes by the prospect or actual pressure of pecuniary embarrassment, is of a much more harassing and exhausting kind than what is suffered by the poor. Pride, and all the other secondary feelings, with ranging imagination, add to their torments; and their occupations generally demanding a steady exercise of the faculties of combination and investigation, and keeping their minds continually on the stretch even in the time of prosperity—this addition renders their burden more than they can bear, and the whole man breaks down beneath the weight. Excessive mental exertion, even under the most favourable circumstances, is known to be productive of fatal effects. Ev[illegible] children of affluent and fortunate parents have been sacrificed to the vanity which was gratified by their displays of precocious talent. The cupidity which grows upon men struggling to maintain their place in society, increases this evil by forcing on the acquirements of children, in the hope of seeing them able, at a comparatively early age, to provide for themselves. Casper of Berlin published, in 1834, a tabular statement of his observations on the sanatory tendency of various occupations, which serves to throw some light on this intricate question:—

Of 100 theologians, there have attained the age of 70 and upwards	43
Agriculturists and foresters,	40
Superintendents,	35
Commercial and industrious men,	35
Military men,	32
Subalterns,	32
Advocates,	29
Artists,	28
Teachers, professors,	27
Physicians,	24

That physicians should stand lowest in this scale of vitality, is not, considering their exposure to contagion, to be wondered at; and the high grade of theologians is equally intelligible, from their certain though moderate income, and the equanimity favoured by their pursuits. It is, however, startling at first view to find the average duration of life among commercial men so little elevated above that of military men, in a table constructed in a country where war had raged at no remote period. The last fact seems to establish that the agitation of mind produced by mercantile uncertainties and difficulties is scarcely a less destructive agent than the sword.

There is perhaps a point in the development of national wealth and civilization, at which mortality shows a tendency to increase. Such an idea is naturally awakened when we learn that the mortality of England is now greater than it was some years ago. The proportion of deaths to persons in the decade 1821-31, was 1 to 49; that of the decade 1831-41, has, as already stated, been found from the population returns to be 1 to 44.5.

EDUCATION.

The statistics of education have an obvious value in their connection with many questions regarding the civilization of countries.

It is clear, however, that the state and amount of education in a country is a highly complex question; for, first, there may be much education of a poor and inadequate kind; and, second, there may be conditions favourable to education in some countries, and not in others—as, for instance, the natural character of the people, the tendency of the political and social institutions, and the direction which the energy of the people chiefly takes, as towards war, commerce, or art. The numbers at school are also liable to be affected by the ratio of the increase of population; for, where there is a rapid increase of people, there is always a greater than usual proportion of the young.

Prussia, where the most perfect of all national systems of education exists, as far as organization is concerned, contained, according to a census taken some years ago, 12,726,823 inhabitants, of whom 4,767,072 were under fifteen years of age. It is reckoned that, out of 100 children from one to fourteen years of age complete, there are 43 of full seven and upwards—the legal age for attendance at school in Prussia. This would give 2,043,030 children in Prussia liable by law to attend school. It was found, in point of fact, that 2,021,421 did attend, being only a shortcoming of 21,609, a small enough allowance for contingencies. Thus, if we were to take Prussia as a criterion for old states, where the population does not advance rapidly and consider the years between 7 and 15 as those proper for school attendance, we should conclude that about *one-sixth* of the whole population of such a country should be at school.

Most of the German states make an approach to the organization of the Prussian system; and we find that in Austria there was, a few years ago, one school for every 275 families. But the object of the governments in supporting education in Prussia and Germany generally, is said to be of a narrow kind—a species of drill, for the purpose of conferring the accomplishments of reading, writing, and arithmetic, and to train the young to a subserviency to the government itself.

Education was in a low state in France till the revo ration of the Bourbon family, since which time it has become a government object, and made a rapid advance. The elementary schools instructed 737,369 pupils in 1815; in 1828, this number was raised to 1,500,000; being *one-twentieth* of the population. It is calculated that one-third of the people of France are unable to read or write.

In England and Wales, in 1818, there was 4167 endowed schools, 14,282 unendowed schools, and 5162 Sunday-schools, educating in all 644,000 children, or *one-sixteenth* of the population. Of 11,000 parishes, 3500, or nearly a third, had no school whatever. Since then, the number of both schools and scholars has been greatly increased. In 1833, the following returns were made to parliament:—

Attending infant schools,	89,005
.. daily schools,	1,276,947
Total,	1,365,952
Attending Sunday-schools (supposed to be an exaggerated statement),	1,548,890

Probably from a tenth to an eighth of the people of England and Wales are now receiving school instruction.

The registration of marriages, by which the parties are required to sign their names on being united, has supplied within the last few years a means of testing the proportion of those ignorant of writing throughout England and Wales. Of the 121,083 couples married during the year ending June 30, 1839, there were 40,587 men, and 58,959 women, who, being unable to write their names, were obliged to sign by marks. The proportion of men unable to write was thus 33, of women 49 per cent.; medium, 41. The number unable to write was least in the metropolis, and, next to it, in the northern counties; and greatest in Lancashire, Bedfordshire, Monmouthshire, and Wales. The trustworthiness of this test was confirmed by the registration of the ensuing year, when, amongst the 124,339 married couples, 41,812 men, and 62,523 women, were found to sign with marks; and the proportion in the various districts was also nearly the same. It is to be remarked, that a large portion of the married couples recorded in these years must have consisted of persons who passed their educational years in times when the means of instruction in reading and writing were much less extended than they now are. Ten years hence, the proportion of both men and women attesting the marriage-register with "marks" will probably be much diminished.

Scotland, unlike England, possesses a national system of education, there being a legally endowed school in every parish, under the care of the clergy. Returns to parliament in 1831 gave the following view of education in Scotland:—

	Schools.	Pupils.
Parochial,	1047	68,293
Private,	3995	154,160
Total,	5042	222,453

The whole emoluments of the teachers of the parochial schools was £55,339, being at an average an income of £15, 11s. 9¼d. to each. The aggregate sum was composed of—endowments, £29,642; fees, £20,117; other emoluments, £1979. Taking 68,293 as the number of pupils in the parochial schools (it was, however, the *greatest* attendance), each costs the public 15s. 7¼d. per annum. In the same year, the Sabbath School Union for Scotland taught 63,326 children.

The proportion of children taught *out of* the parochial system was unexpectedly great. It was greatest in certain counties, as follows:

	Parochial schools.	Private Schools.
[illegible]shire,	32	190
Aberdeenshire,	91	317
Lanarkshire,	72	352

—and there was no county, except Peebles, where the parochial schools were the most numerous. Only one-fifth of the teachers and one-fourth of the scholars were under the parochial system. It is also to be remarked, that some of the schools returned as parochial, were merely under the care and patronage of parochial clergymen, by whom they had been established. The returns were considered as not quite complete, and the number attending school in Scotland in 1834 was *computed* as being more probably 323,154, the proportions in the two different classes of schools being nearly the same.

Notwithstanding the political agitations and poverty which have long depressed Ireland in many respects below the level of the sister kingdoms, it has certainly for many years been above at least England with respect to the elementary instruction of its people. The ability to read and write is observably much more diffused in Ireland than in England; and it is often remarked with surprise, of Irish peasants of the humblest appearance, that they possess an acquaintance with the classics and the elements of Geometry.* Till 1831, education in Ireland was chiefly left to private enterprise and the efforts of a few religious societies: the government in that year established a Board for National Education, which has since been a channel for the application of a considerable amount of public money to this purpose. Various enumerations give the children attending public schools in Ireland for different periods, as follows:—

	Protestants.	Catholics.	Total.
In 1808,	45,590	116,977	162,567
.. 1821,	..	..	394,813
.. 1824–6,	142,169	408,285	560,549†

In 1835, a return to the Commissioners of the Education Board gave a computed total of children attending school in Ireland at 633,946, the population being at the same time computed at 7,954,100; so that the proportion under school instruction appeared to be about 1 for every 12·5 inhabitants. Since then, the national system has made great advances. The following table, drawn up from the eight reports of the Commissioners, shows the progress down to December 31, 1841:—

Reports to the Commissioners of Education.	Number of Schools in actual operation.	Number of Children on the Roll.
No. 1. (1834),	789	107,042
.. 2. (1835),	1106	145,521
.. 3. (1836),	1181	153,707
.. 4. (1837),	1300	166,929
.. 5. (1838),	1384	169,548
.. 6. (1839),	1581	192,971
.. 7. (1840),	1978	232,560
.. 8. (1841),	2337	281,849

Number of schools in actual operation on the 31st December, 1841,	2,337
Number of school-houses in progress of erection on the 31st December, 1841,	382
Total number of national schools on the 31st December, 1841,	2,719
Number of children in attendance upon the 2337 schools in operation,	281,849
Expected attendance upon the 382 building schools	48,356
Total number of children in actual attendance, and expected attendance,	330,205

SUMMARY OF THE FOREGOING.

Schools in operation.			Schools Building		
Ulster,	1005	91,700	Ulster,	103	10,166
Munster,	482	75,772	Munster,	113	13,907
Leinster,	642	88,258	Leinster,	81	10,754
Connaught,	208	26,119	Connaught,	85	13,529
	2337	281,849		382	48,356

* Of an edition of Euclid published by the editors of the present work, by far the largest portion of copies is sold in Ireland. Mr. Bicheno, in a report on the Poor-Law, asks, "Where in England could the ordnance surveyors find persons among the *lowest class* to calculate the sides and areas of their triangles, at a halfpenny a triangle, as they do in Ireland, and plenty of them?"

† In this sum is included 10,026 whose persuasion was not ascertained.

To which are to be added eight vested schools not included in the above, making the total number of schools on the 31st December, 1841, 2727.

The Irish national system at first met with great opposition, in consequence of religious party-spirit; but this obstacle is gradually giving way. The Presbyterian Church in Ireland has 300 schools in connection with the national board, and the Irish Society is stated to be about to form a similar connection with respect to about 60 schools under its charge. About 20 Poor-Law Schools have recently come under the superintendence of the board. It may here be mentioned, that at a great proportion of the elementary schools in Ireland, one penny a week is paid by each pupil for education.

Education is actively conducted in America, and it is calculated that about a sixth of the population are at school. In most of the states schools are supported by a tax on property, and the superintendence is intrusted to committees of the rate-payers. In those of New England, the schools are as one to every two hundred of the inhabitants—a proportion, perhaps, exceeded in no part of the world.

In surveying the statistics of education, we must keep in mind a few considerations by which the character and effects of education are liable to be much affected. Education is not certain to produce *good* effects, but only those which its directors contemplate and seek to bring about. It is a means of conferring certain accomplishments upon the mind, and modifying it to certain ends, inclinations, and habits of thinking and feeling. Its efficacy, even where well directed, is liable to be greatly modified by the character of the people amongst whom it is operating: for instance, a European people of good stock, and amongst whom all refining social agencies have long been at work, will show better results with a certain apparatus of school instruction, than a people newly emerged from barbarism. Above all, our expectations of moral results must be governed by the degree in which the moral department of education is attended to. Intellectual education gives only aptitude and information; it requires a training of the moral being to produce good conduct. We shall say more on this subject under the head "Crime."

It has been seen that Prussia stands at the head of all the countries adverted to, with respect to the proportion of the population attending school. It is excelled in this respect by the United States of America, where, it is computed, there is a school for every 200 souls. England and Scotland have probably a ninth of their inhabitants at school—a considerably smaller proportion. But reckonings of schools and scholars are only a means of ascertaining a portion of educational influences. It cannot be doubted that, besides all the benefits, such as they are, of school learning, the youth of this country enjoy an immense advantage in the influence which the free institutions, the humanity, and the tone of mind resulting from an old-established civilization, must exercise upon them. In a national system of education, the central government should possess but a slight, if any influence, and the business of both arranging and supporting should be left as much as possible in the hands of the people themselves. We beg to submit the following general views on this subject:

Any thing done by government, as the organ of society, to promote universal education, must be based upon the actual state of educational efforts in the country. The people must everywhere be encouraged, invited, stimulated, to take a portion of the task of education into their own hands. With communities, as with individuals, education cannot be a one-sided matter, in which the instructor arouses the pupil; there must be exertion on the part of the latter also. The mistake of some governments, especially the Prussian, has been to hold the people as entirely passive: they have *drilled* rather than *educated*. Almost every thing that has been hitherto done in Great Britain to promote education has been the result of private enterprise: even the majority of endowed schools are the fruits of private enthusiasm in the cause of education. A paper by Mr. Long, in the second volume of the Journal of the Central Society of Education, estimates the annual income of endowments in England, for purposes of education, at £1,500,000; and shows the want of a proper power, invested in some individual or body, for the purpose of assisting, directing, and correcting all who are intrusted with the management of such charity property. Educational amateurs may be deficient in skill, but funds left to support schools require some one to administer them, and to adapt the mode of dispensing them to the perpetually altering circumstances of society. A table of the mechanics' institutions and other popular associations in England for promoting and diffusing science and literature, has been published in the Statistical Journal. It is defective, but it shows approximatively what has been done by private effort for the higher education of the people. The total number of societies is stated to be 112; of 91 of these the annual income has been ascertained, and it amounts to £36,793, 14s. This is a slender provision for the intellectual wants of the adults of England, and what is more, its influence is limited, in a great measure, to those who, strictly speaking, do not belong to the working classes. In the Glasgow Mechanics' Institution, a majority of the attendants on the lectures are shopmen, individuals employed in warehouses, and even some students—the middle classes. Of the operatives who attend, the *mechanics* form a considerable proportion. The Mechanics' Institution of Liverpool, one of the most flourishing institutions of the empire, is, both in its elementary schools and its lectures for adults, frequented and supported almost, if not quite, exclusively by the middle classes. The facts mentioned seem to justify these conclusions:—That national education requires the operation of government only as public trustee, and of the people themselves, trying to procure the kind of education their wants prompt them to seek; that the duty of government is to insist that education shall be universal, and to provide such superintendence and means of general control as are necessary for enforcing this precept; that the duty of the people, in their respective districts, is to carry into effect the general directions of government. The business of government is to see that the necessary funds are provided, the necessary establishments for training teachers and pupils kept up, and the attendance of children enforced. The business of the people is to appoint teachers, and to take precautions for their discharging their duties conscientiously. The details of tuition are best left to the teachers, care being taken that they are previously educated for their profession. Success in teaching depends, in a great measure, upon the enthusiasm and ability of the teacher; and the most successful method is that which is best adapted to the peculiar character of the teacher. Some teach more efficiently by one method, others by another. The public judge most correctly of a teacher's ability by looking at results—at the kind of scholars he turns out. Some such organization of the whole country for educational purposes, as is indicated in these general terms, would, by giving a controlling power to government, ensure equal diffusion of education; by leaving to the people the appointment of teachers, and by leaving, to a certain extent, to individuals the choice of what should be taught, would keep alive the interest which men take in their own handiwork; and by leaving the methods to the choice of well-trained teachers, would give scope for progressive improvements being effected in the art of education by those who were practically acquainted with it. The importance of leaving a certain latitude of choice to individuals (parents, or the more advanced young men and women), is apparent from the experience of the Glasgow Mechanics' Institution. The most uniformly successful classes have been those of mechanics (or natural philosophy) and chemistry; and a large proportion of the operatives who attended them have been engineers, and others engaged in processes which are best conducted by those who understand something of their principles. Human beings are most easily seduced to undergo the toil of learning (for though to pick up fragments of information be agreeable, to devote the continuous attention necessary to understand a subject thoroughly is at first a task) by the conviction that what they are learning can be turned to profitable account. Having learned one subject thoroughly, they acquire a liking for the effort, and are more easily induced to extend their researches. It is good not to attempt too much at first. Get every one to learn something that may benefit them in their occupations: none who have learned this thoroughly, be it what it may, will stop there.

CRIME.

Crime is the result of various causes—as, first, the natural or original disposition of the culprit; second, the moral atmosphere in which he has lived; and, third, the temptations placed before him. Generally, all of these causes are more or less concerned in crime, so that it becomes a very complex question. When we apply statistics to the investigation of crime, we are met by the further difficulty, that only a certain portion of the whole of the offences committed are known to us, and that the proportion known must vary in different countries according to the efficiency of the legal apparatus applied to the detection of crime. Statistics has, nevertheless, afforded some curious and valuable knowledge on the subject.

The number of persons annually committed or bailed to take their trial in England and Wales, has for a number of years past been on the increase; but chiefly, it is believed, in consequence of the increased efficiency of the laws. For the five years before 1839, it was 22,174 on an average; in 1840, it was 27,187. The last sum was an increase of 45 per cent. on the number for 1830, which was 18,657. It is important to observe, that these are not summaries of the whole offences of their respective years. There is, besides, a larger number of offences, which are tried summarily before magistrates. For example, in 1837, in addition to 17,090 persons convicted upon regular trial, there were 59,374 summary convictions.

By far the greater proportion of English crimes are against property. Taking the average of the five years before 1839 (22,174), it appears that 84·5 per cent. were thefts and frauds, the small proportion of 7 per cent. of these being accompanied by violence. Of offences against property and person, in which malice was involved, as murder, maiming, arson, and injuries to cattle, there were about 6 per cent. A class called sexual offences gave 2, and offences against the state, in which was included coining, 6½ per cent.

The counties in which committals are year after year fewest, are those of Wales, the four northern ones, Cornwall, and Derby; those in which they are most numerous, are Middlesex, Essex, and Warwick.

There are some crimes which women are not, from various causes, liable to commit; but the gentler does not appear to be the honester sex; for the proportion of female to male committals for theft without violence, is as 84 to 73 per cent., a difference of one-sixth against females.

In the inquiries which have been made with regard to the age of offenders, wonderfully uniform results have been found, as will appear from the following table, giving the centesimal proportion at each period of life:—

	1836.	1837.	1838.	Greatest Difference.
Under 12 years	1·84	1·52	1·53	0·32
From 12 to 16	9·71	0·72	0·92	0·21
„ 17 „ 21	20·03	20·23	20·13	0·20
„ 22 „ 30	31·42	31·74	31·24	0·50
„ 31 „ 40	14·43	14·56	14·75	0·32
„ 41 „ 50	6·76	6·65	7·02	0·37
„ 51 „ 60	3·33	3·24	3·00	0·33
Above 60	1·40	1·55	1·58	0·18
Not ascertained	2·08	1·79	1·78	0·30
Total	100·0	100·0	100·0	

The large proportion at the periods of adolescence and youth must be considered as strictly owing to a greater tendency to crime for the proportions of human beings at those ages to the whole population are different, the persons from 16 to 20 being as 10 per cent., and those from 20 to 30 as 15 per cent., of the entire nation. It is calculated that amongst the persons living in England and Wales, from 17 to 21 years of age, there is one committal for 232; while from 41 to 50 there is one for 941; and above 60 one for 3391 individuals. We thus see how great an influence the strong and unregulated feelings of youth exercise in inducing criminality.

The connection of education or non-education, and of poverty, with crime, has excited much attention during the last few years. It is abundantly clear that some school learning may exist where the moral department of education has been neglected, or where the temptations to error may be very great. The education of mere reading and writing may only supply the means of committing a crime—as forgery—instead of tending to restrain from it. Yet it certainly does appear that criminals are generally uneducated in all ordinary respects. Mr. Rawson, Secretary of the Statistical Society of London, has found that, of every 100 offenders in England and Wales, 35·4 per cent. could neither read nor write; 54·2 per cent. could read and write imperfectly; 10 could read and write well; and only ·4, or less than a half per cent. had received a good education. In Scotland, out of 8907 offenders, 20·2 per cent. could neither read nor write; 59·2 could read and write imperfectly; 18·2 per cent. could read and write well; and 2·4 had received a superior education.

Mr. Bentley, author of a History and Directory for Worcestershire, has shown the relation of non-education to crime in a different way. It appears from his tables, that the six English counties having the greatest proportion of schools are Cumberland, Durham, Middlesex, Northumberland, Rutland, and Westmoreland, in which the schools are one for every 727 inhabitants, and the criminal offenders one for every 1156 inhabitants. The six counties that have the smallest proportion of schools are Chester, Dorset, Hereford, Lancaster, Northampton, and Somerset, in which the schools are one for every 1540 inhabitants, and the criminal offenders one for every 528; that is, out of a people having twice the number of schools, there is not in proportion half so many criminals as where the schools are deficient. A comparison of the number of schools in the six most criminal, and the six least criminal, of the English counties, leads to the same conclusion. In Essex, Gloucester, Hertford, Chester, Somerset, and Warwick, we find one criminal offender in the lists of government for every 499 inhabitants, and only one school for every 1069 inhabitants; on the other hand, in Cornwall, Cumberland, Derby, Durham, Northumberland, and Westmoreland, we have only one criminal to every 1309 inhabitants, while we have one school for every 839 inhabitants. In other words, there are six counties in England which have nearly three times the amount of crime found in six other counties; and the counties in which the least crime is found have one-fourth more schools than the counties in which crime abounds.

The different distribution of educational acquirements among the convicts of England and Scotland is striking and requires for elucidation some inquiry into the proportional diffusion of knowledge among the whole community in each country. Among the affluent classes it is much the same, but among the working-classes it is materially different. According to the factory returns, there exists a more widely diffused instruction in Scotland than in England: in the former country, out of 29,486 operatives, 95·8 per cent. could read, and 53 per cent. could write; while in the latter, out of 50,497 operatives, only 86 per cent. could read, and 43 per cent. could write. We have seen above, that, in proportion as education was diffused through the whole community, the proportion of criminals to the total of the population was diminished; and this holds good in Scotland. But the mere extension of intellectual education to individuals of a class in which improved economical circumstances and self-education in moral respects has not induced that moral sense shown to be elicited in civilized communities, does not raise these individuals to the same elevation in the moral scale that the same education would do under more favourable circumstances. To produce the full benefit of education, it is *the class*, not merely the *individual*, that must be educated. An educated individual, belonging to an uneducated class, either continues to associate contentedly with his original companions, and retains their comparatively low standard of morality, combined with the increased power lent him by education,—he has as feeble a restraint upon his conduct as they have, with much more power to do harm—or he attempts to associate with those above him in circumstances, though only equal in acquirements, and, failing in the attempt, sinks down to his former social level, soured against society, and prepared for any act of outrage. The petty pilferers are, for the most part, supplied by the destitute and uneducated class; the more daring and dangerous offenders by those who have moved in a more affluent sphere, and fallen from it by their imprudence or vices. The lesson read by the different degrees of education possessed by Scotch and English criminals, is the necessity of educating *classes* as well as individuals.

When we come to speak of educating classes, we are brought to the consideration of their economical condition. In Bristol, an inquiry into the educational statistics of the city showed that, out of nearly 10,000 adults, taken indiscriminately among the working-classes, 22·5 per cent could neither read nor write; 25·6 could read only; 51·9 could read or write. In a wretched part of the parish of Marylebone in London, it was found that 25 per cent. could neither read nor write, and 75 per cent. could either read, or read and write; and in two other portions of the same parish, inhabited principally by Irish labourers and their families, 49 per cent. could neither read nor write, and only 41 per cent. could read, or read and write. Among 1022 able-bodied and temporarily disabled paupers above the age of 16, the inmates of several union workhouses in Norfolk, Suffolk, and Kent, whose attainments were ascertained with precision, 46·5 per cent. could neither read nor write, 18 read imperfectly, 30·2 read decently, 5·3 read in a superior manner; and of the same, 66·4 could not write, 15·4 could write imperfectly, 16·9 write decently, and 1·3 write well. It thus appears, that poverty and want of education, as well as crime and want of education, go in company.

On the last point it is necessary to guard against a misconception. There may be a district poor in resources and with respect to the style of living of the inhabitants, and yet crime may not abound in it. The department of Creuse is one of the poorest in France, yet it presents the fewest crimes. M. Quetelet draws the important distinction, that a set of people living steadily on small means, but knowing no better, and contented with what they have, are not poor, in the sense in which a people are poor who, seeing wealth and luxury around them, and exposed to the severest sufferings from the occasional failure of employment, are thereby demoralized.

SOCIAL ECONOMICS OF THE INDUSTRIOUS ORDERS.

It is surely a deplorable feature in the condition of a large portion of the working-classes in this country, that they have little or no provision made against the necessities which arise to themselves or their families in the event of sickness, a failure of employment, or death. With some this is not the case, but it is the case with many; and the result is, that these persons have never more than a thin partition dividing them from the realms of want and dependence. The effect which this is calculated to have, need not be largely insisted on, for want and dependence are universally allowed to bring many evils. What is there to be expected from the moral nature of one who is every now and then obliged, perhaps, to ask for gratuitous medicine and medical attendance—to take bread from a parish officer or the managers of a charitable subscription—to trust to the pity of neighbours whenever any thing like an exigency arises in his family—in short, is, for the supply of a great part of his needs, a stipendiary upon his fellow-creatures? These things are evidently irreconcilable with true manly dignity, with political independence, and with an upright bearing in any of the relations of life. The destitution of such individuals is commiserated when it arises—every humane person who is himself above want, feels bound to contribute to its relief: the claim from suffering man to him who suffers in the smallest degree less, is irresistible. But while it is allowed that the need, when it does exist, must and ought to be relieved, all must likewise see that, in the effort to diminish one immediate and clamant evil, another is introduced. The working man is morally deteriorated by ceasing to be independent. Better, clearly, that this portion of the community were to place themselves, by efforts of their own, above all need for such degrading aid.

"But then the working-classes realize such small gains, that they can spare nothing for this purpose." This may be said; but it is at the best partially true. A great portion of the working-classes do most unquestionably, in ordinary times, realize enough to enable them to spare a little by way of provision for the future. Since many, most creditably to themselves, make such a provision, it may fairly be presumed that others, having the same wages, could do so also, if they were willing. We may still more confidently presume, that, when some with comparatively small wages are able to save, those who are better off could save also. Now, it often happens that the labourers of least skill, and who are least liberally remunerated, contribute as largely to savings' banks as their better paid brethren. Where this is the case, and the circumstances of the men are otherwise equal, we cannot doubt that the latter class make a less economical disposal of their income. Clearly, they have only to imitate the frugal conduct of the small-wage class, in order to have ample means for making the provisions in question. On this subject, from various causes, many erroneous notions prevail. When practical men are consulted, we hear of an afflicting number of instances in which the higher-waged workmen are considered as securing little if any more comfort to their families, than the other class, and perhaps not so much. We have heard masters of works declare that their men, at 25s. a week, did not, as a class, maintain their households, or educate their children, so well as those who had little more than half the sum. In a recent return from the Savings' Bank of Dundee, it appears that, while there is £1189 deposited by 108 male weavers, a class whose wages average 8s. weekly, and £425 by 36 hecklers, a class whose average wages are 12s., there is only £637 from 56 mechanics, men whose wages range from 18s. to 30s. Such facts, and we believe many of the like nature might be adduced, seem to prove that the working-classes have much more in their power for the promotion of their physical and moral well-being than is generally thought. Admitting fully that many are ground to the dust by poverty, we cannot doubt that a far larger proportion have all but the will to take the proper means for preserving their independence.

We do not profess here to inquire into the primary causes of the unendowed condition of the working-classes; but we can readily see various immediate ones, as intemperance and bad management of resources. The tavern bill of the whole operative class in the United Kingdom must be an enormous one. Of above thirty-one millions of gallons of spirits prepared in one recent year, and for which twenty millions of pounds sterling would be received, we cannot assume less than two-thirds to have been consumed by the working-classes. These classes probably expend in this way three times the whole cost of the religious establishment of the country. In Glasgow there is a tavern or spirit-shop for every fourteen families; and the sheriff calculates that not fewer than thirty thousand of the inhabitants go to bed drunk every Saturday night. In the parish of St. David's, in Dundee, while there are but 11 bakers' shops, there are 108 for the sale of liquors. In the parish of Lochwinnoch, in Renfrewshire, three or four times more money is spent in this way than is required for the support of religion and education. The value of ardent spirits consumed in the parish of Stevenston, in Ayrshire, with a population of 3681, exceeds the landed rental by £3836. These are startling facts, telling, if they tell any thing, that a large portion of the earnings of the working-classes is worse than thrown away. Now, though it is well, certainly, to compassionate and relieve the sufferings of all who need, we cannot but be equally sensible that it is proper to tell the plain truth, and say that for much of this suffering our countrymen have themselves to blame. There has been of late years a hollow kind of cajolery practised towards them, discreditable to all parties, and of a dangerous tendency. We dismiss this entirely, and conceive it to be both paying them a greater compliment and doing them a greater service, to tell them that the conduct of a large portion of their class is in many respects wrong, and to show them how it might be shaped somewhat better.

We propose therefore, in the present sheet, to treat of various arrangements or institutions which have been devised for the benefit of the industrious orders, with a view to their maintaining their independence, or avoiding some of the greater evils which beset them.

One of the most conspicuously valuable is

THE SAVINGS' BANK.

Previous to the commencement of the present century, such of the humbler classes as were given to saving had no proper place of deposit for their spare funds, which they were obliged, therefore, to keep in an unfructifying hoard in their own possession, exposed to the risk of loss, or had to consign to some neighbour, who, though thought safe, might turn out to be much the reverse. At the same time, in the want of a proper place for the deposit of spare money, those who might save, but did not, lacked one important requisite to their doing so. About 1805, it occurred to some benevolent minds that an important benefit would be conferred on these classes, if there were institutions of the character of banks, but on a modest scale, in which the poor could deposit the smallest sums they could, from time to time, spare, certain of being able to draw them forth when they pleased, with accumulated interest. Savings' banks were accordingly established, first in England, and afterwards in Scotland and Ireland, whence they quickly spread to America and France. They were generally conducted by associations of benevolent persons, who gave the security of their own credit for the accumulated sums, and held forth every temptation in the way of liberal interest, courtesy, and promptitude in management, to induce the working-classes to resort to them.

For some years, this joint-stock but still private security was found to be sufficient for the purpose; but, when it was understood that millions had found their way into savings' banks, it became apparent that something else was necessary in order to maintain the confidence which had at first been felt. The government was therefore induced to frame a variety of statutes for the better regulation of savings' banks, and one in particular by which its own security was given for the safe-keeping of the deposits. This was done under the guidance of the best intentions towards the industrious classes, who generally are depositors in savings' banks, and with as little interference as possible with private and local management.* A substantial benefit was also conferred, in the fixing of a rate of interest rather above the medium of what could be expected in a country under the particular circumstances of the United Kingdom with regard to capital.

By the above-mentioned acts, it is directed that *all* the funds deposited in National Security Savings' Banks must be paid into the Bank of England on account of government, and that the money so invested shall bear interest at the rate of £3, 16s. 0½d. per cent. per annum, *whatever may be the fluctuations in the value of the public funds during the term of investment.* Depositors are thus afforded the best of all securities, namely, that of the *whole British nation;* while the National Savings' Banks are enabled, after paying all charges upon their establishments, to give a considerably higher rate of interest than the ordinary banks, or even the greater part of private savings' banks, allow on deposits. The highest interest which the law allows the National Security Savings' Banks to pay, is 2½d. per cent. per diem, or £3, 8s. 5½d. per cent. per annum; the difference between this and the rate allowed on the money invested by them in government securities being reserved as a fund for the payment of the officials of the banks and other necessary expenses. The rate of interest which is generally paid by these banks, is 3⅓ per cent., or £3, 6s. 8d. per cent. per annum; and whatever is left, after defraying all charges, is allowed to accumulate as a surplus fund.

---

* Various rules are appointed by the legislature for the formation and management of savings' banks. An association of persons desirous of forming one in any place are enjoined first to frame a set of rules for the management, and to submit these to the approval of a barrister appointed by government, without whose certificate they cannot enjoy a legal status, or any of the advantages which the legislature has thought proper to hold out for the encouragement of such institutions. The present certifying barrister is John Tidd Pratt, Esq. A fee of one guinea is charged for the revision of the rules and certificate. The managers, trustees, and treasurer, must act gratuitously, the only paid officer being the actuary or clerk, who is obliged to give security for the money passing through his hands.

Deposits of from *one shilling* to *thirty pounds* may be received by these banks, but no individual depositor is allowed to lodge more than thirty pounds in one year, or than £150 in whole. Charitable and provident institutions may lodge funds to the amount of £100 in a single year, or £300 in all; and friendly societies are permitted to deposit the whole of their funds, whatever may be their amount. Compound interest is given on the sums lodged, the interest being added to the principal at the end of each year in some banks, and the end of each half-year in others, and interest afterwards allowed on the whole. Any depositor may receive, on demand, the money lodged by him, if it do not amount to a considerable sum; and even in that case it will be returned on a few days', or at most two or three weeks', notice. Practically, in Edinburgh at least, payment is always made on demand.

The wisest and most effectual provisions are made for insuring the proper management of the affairs of these banks. Each must have a certain number of trustees and managers, whose services are performed gratuitously, besides a treasurer, actuary, cashier, clerks, &c.; all of whom must give security, by bond, to such amount as the directors of the establishment may judge sufficient. No portion of the funds invested in government security can be withdrawn, except on the authority of an order signed by several of the trustees and managers. Detailed reports of the transactions of each bank must be periodically forwarded to the Commissioners for the Reduction of the National Debt, and also exhibited to the depositors at the bank office. It may be of use to add, that the money deposited is consigned daily to the safe custody of a bank, such as the Bank of Scotland, and is thence regularly transferred to the Bank of England. Any doubt, therefore, as to the *security* which is offered, would be quite absurd. When the perfect safety of the system is contrasted with the insecure practice of placing money at interest in the hands of private persons, as is unhappily too often done, no one in his senses would for a moment hesitate which mode of disposal he should prefer.

Under both the old and new systems, savings' banks have been highly successful in their object, and the money deposited in them reaches an amount which no one who regarded the habits of the working-classes thirty-five years ago could have anticipated. In 1840, the total sum was a trifle within *twenty-two millions.* In 1837, it was stated that the accumulations in the bank at Exeter alone, reached £800,000. At the same time Manchester and Liverpool respectively showed £280,000 and £345,000. In November, 1841, after existing five and a half years, the Edinburgh bank had accumulated £221,816: at the same period, after a somewhat briefer career, that of Glasgow showed a balance of deposits amounting to £173,204. In 1834, when the total accumulations in England (inclusive of Wales) amounted to £13,582,102, the number of depositors was 431,815, a very considerable proportion, it must be owned, of the whole population. The average deposit of each person was at that time £31, 4s. In Scotland, the average deposits are less, perhaps in consequence of the comparatively recent introduction of the national security system. At November, 1841, the depositors in Edinburgh were 18,961, giving an average of ten guineas to each; those in Glasgow were at the same time 13,239, giving to each an average of twelve pounds. We find ten guineas the average deposit at the Carluke Savings' Bank, a rural establishment.

The *kind of persons who deposit* is an important point; and here, we fear, some disappointment must be felt. We have already seen that the average amount of deposits at Dundee is little larger amongst workmen of high than amongst workmen of low wages. In that town, out of 464 male weavers in the parish of St. David's, with wages averaging 8s., 108 are depositors, or 1 in $4\frac{4}{17}$; of 181 flax-dressers, with wages averaging 12s., 36 are depositors, or 1 in 5; of 200 mechanics, with 20s. of average wages, 56 are depositors, or 1 in $3\frac{4}{7}$. The very small degree in which we thus see comparatively good wages favouring the saving principle, is surprising and lamentable. Another fact of a general character is not less striking. In many places, of the depositors in savings' banks, a majority are females. Female servants, in almost all places, form a conspicuous section. In the Dundee Savings' Bank, there were, a few years ago, 237 accounts in the names of female servants (aggregate deposits, £2235), while (and this is equally remarkable), out of the numerous class of factory female workers, only *one* had an account. It has also been stated, that, "a few years ago, in Perth, it was found, from its savings' bank, that the women of the 'Fair City' were laying up for the men, not the men for the women; that the young mechanics had forgot there were such things as want, or sickness, or age."* In the Edinburgh Savings' Bank, of the total number of accounts existing at November, 1841, the majority were by females, and generally by females isolated in society, and depending on their own exertions, as appears from the statements given below, in which the amount of balances and the average amount of each person's balance are also shown.

FEMALES.	No.	Amount of Balances. £	s.	d.	Average Amount. £	s.	d.

In Glasgow, the male depositors are a majority; but here the factory operatives are comparatively a small

* Tavern Bill of Dundee, p. 7.

section, numbering only 1282, while mechanics and artificers are 6774, notwithstanding the vast number of persons employed in factories in that city. The female domestics who deposit in the Glasgow Savings' Bank are 3862, and their aggregate accumulations are £22,378. With regard to this portion of the community, an interesting fact is mentioned in the report of the Edinburgh Savings' Bank for 1841. The five hundred accounts last opened by female servants in that bank, present the aggregate sum of £2313, 2s. 7d.; but the first five hundred opened by the same class, four or five years ago, show a total of no less than £11,921 10s. 4d. We here see, in a striking manner, how a [illegible] fund once begun by a person in humble circum[illegible], tends to mount up in the course of a few years.

It may be of service to many persons in the humbler walks of life, who are not much acquainted with business, to see an example of a savings' bank account: the following is one presumed to be formed by a man named John Smith, whose signature accordingly appears in the last column, as acknowledging the sums which he has withdrawn:—

SAVINGS' BANK in Account with ____________

No. ________

Date.	Deposited and Withdrawn	£	s.	d.	Manager's Signature.
1836.					
July 10,	Received Six Shillings,	0	6	0	George Rose.
August 12,	Received Nine Shillings,	0	9	0	J. T. Becher.
	Interest to November 20,	0	0	1½	
		0	15	1½	
November 23,	Paid Five Shillings and Three Halfpence,	0	5	1½	John Smith.
		0	10	0	
December 20,	Received Thirty-five Shillings,	1	15	0	George Rose.
1837.					
June 19,	Received Three Pounds,	3	0	0	J. T. Becher.
	Interest to November 20,	0	2	1½	
		5	7	2½	
December 1,	Paid Five Pounds, Seven Shillings, and Twopence Halfpenny,	5	7	2½	John Smith.

It is of still greater importance that a person who thinks of depositing should have a distinct idea of the benefit he is to derive in the way of interest. The interest usually given in savings' banks is at the rate of £3, 8s. 8d. per cent.; the difference between this and £3, 18s. 0½d., which the Commissioners of the National Debt allow, being, as already mentioned, reserved to pay expenses, &c. This being the interest allowed, any one may readily reckon how his money is to fructify, by supposing an addition of *one-thirtieth* being made to it at the end of every year. For instance, if he deposits fifteen shillings, and lets it lie for a year, he is then entitled to 15s. 6d. It is right that he should be fully aware that, in respect of interest, he is better off than the people of the middle and upper ranks who deposit in common banks; for not only does he get a higher per centage than is generally given by the banks, but he has the advantage of *compound interest*; that is to say, the interest due to him at the end of a year is silently, and without any trouble on his part, added to and considered as a part of the principal, on which interest is to be given in future. Thus, a common bank account and a savings' bank account, for the same sum, if left unattended to for a few years, would in the end come to a very different amount. In order that no one may be at a loss to calculate the interest he is to receive on a savings' bank deposit, we present the preceding table, which shows simple interest for a year on a variety of sums.

INTEREST TABLE, AT £3, 0s. 8d. PER CENT.

A prejudice exists in the minds of many working people, and is perhaps affected by others, against savings' banks, on the ground that, when a man is known to save, he is the more liable to have his wages reduced by his master, or to want work when there is any thing like a general failure of employment. Surely, there can be little foundation in fact for this notion. It is a general wish amongst masters that their working people should save, and many endeavour to bring this about by instituting savings' banks, and acting as managers. It is felt by every master, that a workman who has saved a little, is likely to be a much more steady and respectable person than one who has not. Indeed, as it has been justly observed, a receipt from a savings' bank is one of the best certificates of character which a working man can show. Let it also be considered, that, with a little capital in his possession, a workman stands in a much more independent position with regard to his master than he otherwise could do. We cannot doubt that in these considerations there is much more than a counterpoise to the visionary fear of having wages reduced, or employment withheld, in consequence of a bank deposit.

The following table was formed to show what a certain weekly contribution paid into the Windsor and Eton Savings' Bank would amount to in a certain term of years, interest being at £3, 8s. 5d. per cent. It is a highly instructive table, well worthy of being carefully studied by every individual of the industrious orders:—

	One Shilling per week.			One Shilling and Sixpence per week.			Two Shillings per week.			Three Shillings per week.			Four Shillings per week.			Five Shillings per week.

It would be difficult to over-estimate the importance of a little private hoard to a working man. It not only proves a succour in the evil day, but it tends to improve his whole moral nature. Wealth has been the subject of many bitter remarks to both the poet and the philosopher; but it is after all a greater friend to virtue than to vice. Often a very small amount of it, acquired by honest industry, will supply a modest pride that supports, if it is not in itself, moral efficacy. Doing well in this small way suggests and leads to doing well in other ways. The saver may prove the stay of a declining parent or other friend: he can do a better duty to his children; he can contribute to philanthropic objects which interest and bring out his finest feelings. It may even happen that, from less to more, and with no sacrifice of peace of mind, he is enabled by saving to rise into a higher grade in society. One of the best of the immediate effects of saving is, that, once fairly begun, it proves a preservative from many extravagances and vices. Temptations may present themselves; but the mind reverts to the fondly regarded little hoard in the savings' bank, and they are easily resisted. Hence, it is generally observed that, once a practice of saving has commenced, a great revolution takes place in the character. Irregularities and self-indulgences disappear, and steadiness, sobriety, and reflection take their place.

These views are, we feel assured, accordant with general experience; but it may nevertheless be well to quote one testimony from a practical quarter in support of them. The following passages are from a tract, published early in 1842, respecting an auxiliary to the Govan Savings' Bank, in Kerr and Company's Nailery:—

"Three years ago, nearly all the men in this work were seemingly constitutionally and hopelessly afflicted with *a spark in the throat*, and spent a very large portion of their wages on ardent spirits to quench it. As might have been expected under the circumstances, both their persons and dwellings presented standing proofs of their ruinous habits; and their employer was frequently annoyed by their suspension of labour to gratify their vitiated taste, at times when the hurried execution of orders rendered him most dependent upon them. However, by the exercise of a little kindly feeling towards them, matters began to assume a more pleasing aspect. By being regarded and spoken to in their sober intervals as rational and accountable beings, and having exhibited to them the advantages they were likely to derive from connecting themselves with the Total Abstinence Society and the Savings' Bank, one after another was cured of the long-existing malady, and not only took up a new position among his fellow-workers, as at once an advocate and an evidence of temperance and economy, but was enabled to provide himself and family with household comforts to which they had previously been strangers. With the view of cherishing such newly-formed habits, their employer afforded them the weekly opportunity of husbanding their spare earnings, by forming among them and conducting a little agency of the National Security Savings' Bank. The following summary of its transactions will show both the success of his labours, and the encouragement which the proprietors and managers of other public works are likely to enjoy in making similar efforts:—The nailery consists of three shops or hearths, each accommodating four workmen. Among the twelve persons employed in these shops, and two junior members of one of their families, there are nine open accounts; the number of deposits has been 351, and the amount deposited, including interest, £61, 15s. 10d. The number of repayments has been 31, and the amount repaid £36, 11s. 9d., so that the balance due at the 20th November, 1841, upon the nine open accounts, is £25, 4s. 1d., or about £2, 16s. each—a small average, certainly, in comparison with that of some other trades, but presenting a pleasing contrast to the situation in which matters stood at the commencement of the agency, when scarcely one of the workmen could, on a Wednesday or Thursday, muster a sixpence of his previous week's earnings. One observation must yet be made; they are now *not only more independent and comfortable, but stand much higher in the estimation of their employers.*"

THE FRIENDLY SOCIETY.

Savings, instead of being stored up in a bank, to be there constantly at command, may be disposed by a working man in a well-constituted friendly society, as a means of ensuring for himself certain contingent and fixed benefits. Friendly societies generally embrace several objects, as the securing of a weekly sum during sickness, and a pension after a certain age. They are based on the principle of mutual insurance; that is to say, members make payments, either at once or in small periodical sums, and thus constitute a fund, out of which such as happen to fall sick or to survive a certain age are supplied, the uncertainty attached to all individual concerns being lost in the certainty which attends calculations involving great numbers. In some respects, and for some cases, joining a friendly society may be better than becoming a depositor in a savings' bank. Sickness may come before the savings are considerable; or, if considerable, they may be melted away by a long-continued sickness; but, after the first weekly payment is made to a friendly society, the member is secure of succour, however long his illness may continue, besides, perhaps, other advantages. It is possible, on the other hand, that a difficulty may be experienced, in certain circumstances, in keeping up the weekly or other payments required to secure the benefits of friendly societies. Here, however, it may be said, there is no more than the usual uncertainty attached to all things. Assuredly, the arrangement of a rightly constituted friendly society furnishes a very considerable degree of security against some of the uncertainties of life.

It is to be regretted, of this excellent class of institutions, that many of them are founded upon erroneous principles, or rather upon no principles at all; and it often happens, therefore, that those who trust to them are disappointed, the funds falling short before all claims are satisfied. This was at one time not to be wondered at, as no proper calculations for friendly societies existed; but such is no longer the case, for sound calculations are now attainable. Nevertheless, there is still a vast number of obscure friendly societies, proceeding altogether at random, and by which the industrious classes are induced to misspend large sums. We trust that what we have now to state will be of some service in promoting the establishment of sound societies, and putting an end to such as are of a different kind.

One great mistake in the formation of friendly societies, is to assume that each member should pay an equal sum, whatever his age may be. This is unjust; for the younger members have a less chance of becoming burdensome to the funds than the middle-aged; and, indeed, there is a rising scale of probability of sickness throughout all the years of a man's life. The Highland Society found that, between twenty and thirty, men are liable at an average to be half a week indisposed per annum. Between thirty and forty, the average was about two-thirds of a week. At forty-six, it became a full week; at fifty-seven, two weeks; at seventy, eleven weeks. The Society, from taking unsuitable grounds for their calculations, made out the probabilities of sickness too low. In the following table, three sets of calculations are given, as to the proportion of sick out of one hundred at particular intervals of age:—

Ages.	Highland Society.	English Benefit Societies.	Mr. Edwards' Theoretical Table.
20 to 30,	1·11	1·54	1·72
30 .. 40,	1·42	1·83	2·30
40 .. 50,	1·97	2·58	3·10
50 .. 60,	3·60	4·42	4·54

The difference in the three columns is here of little consequence. They at least agree in representing *increase of years as attended by increased liability to sickness.* Now, a right friendly society is bound to advert to this circumstance. To admit all ages at an equal payment, is clearly making the younger members pay for the elder, who should have entered at an earlier age, and been paying all along.

Another great error in the constitution of benefit societies, is in making them for a year only. Many of the old friendly societies having ended in disappointment, in consequence of want of right calculations, or bad management, or peculation of the funds, the working-classes have contracted the notion that there is more safety in a yearly term. The immediate payments are also less than in a well-constituted friendly society. Yearly societies, as they are called, usually originate with some individual, often the keeper of a tavern, who advertises that a society will be formed in his house on a particular day. Applicants for admission pay one shilling as entry-money, which goes into the pocket of the originator of the scheme, by way of rent. The objects are generally threefold, namely, a fund for sickness and funeral expenses, a deposit fund, and a loan bank. Towards the first, there is perhaps a weekly payment of two-pence, or more if necessary, together with the interest arising from the loan of money to the members. Towards the deposit fund, there is a payment ranging generally from sixpence to two shillings, the accumulations being received back when the society closes. The money deposited is employed in making loans to such of the members as desire such accommodation, within the amount of their several entire deposits for the year, one penny per pound per month being charged by way of interest. The surplus, if any, of the twopences and interest, after sick and funeral money books, and other necessaries are paid, is divided among those members who may be clear of the books at the close of the society. Some such societies are formed by a spontaneous association of persons, who prefer renting a room for their meetings, and thus escape the temptations of a tavern; but none of them avoid the errors of an equality of payments for all ages, and the yearly dissolution. The youth of fifteen, who is not liable to half a week's sickness per annum, pays as much as the man of fifty-seven, who is liable to two weeks. Should sickness befall any one towards the close of the year, he is left, when the society dissolves, quite unprovided for, because he cannot enter another society in a state of sickness. Considered as a deposit for savings, the yearly society is strikingly inferior to the savings' bank, in as far as the depositor cannot take out money without paying an exorbitant rate of interest. Finally these societies are generally under the care of obscure persons, who can give no security for the funds placed in their hands, and who in many instances become bankrupt or abscond before the final reckoning. Yearly societies are, indeed, in all points of view, a most objectionable class of institutions, to which working people would never resort but for their ignorance and unwariness, and the temptations held out to allure them.

A well-constituted friendly society involves the principle of payments appropriate to particular ages, as no other plan can be considered equitable. It stands forth before the working-classes as a permanent institution, like the life-insurance societies of the middle and upper classes, and necessarily requires its members to consider the connection they form with it as an enduring one, because its grand aim is expressly to make provision at one period of life for contingencies which are to arise at another—youth, in short, to endow old age. By a yearly society, a man is left at last no better than he was at first, as far as that society is concerned; but the proper friendly society contemplates his enjoying a comfortable and independent old age from the results of his own well-bestowed earnings.

It is also essential to the character of a proper benefit society, that individuals be not admitted indiscriminately. To take in a person in bad health or of broken constitution, is unjust to the rest who are healthy, because he is obviously more likely to be a speedy burden to the funds. Here, as in life-assurance societies, it is necessary to admit members only upon a showing that they are of sound constitution and in the enjoyment of good health. And it may be well to grant no benefits until after the member has been a year in the society. By these means, men are induced to enter when they are hale and well, instead of postponing the step until they have a pressing need for assistance, when their endeavour to get into a benefit society is little else than a fraud.

Government has thought proper to interfere with its aid in the formation of friendly societies, though not compulsory. An association of persons forming one, has the means of ascertaining the soundness of its principles, and also entitles itself to deposit funds in savings' banks, with the government security and liberal interest, by submitting the proposed rules to the barrister appointed to certify them (at present John Tidd Pratt, Esq.), to whom a fee of a guinea is payable. Under the sanction of government, tables have been formed by a highly competent person, John Finlaison, Esq., Actuary of the National Debt, for the guidance of friendly societies; and these are easily to be had,* so that it is quite inexcusable to proceed upon random and unauthenticated data. Before quoting any of these tables, we shall endeavour to explain how they are formed.

We have an idea of a benefit society in its simplest form, if we suppose a hundred men, of exactly 33 years of age, to associate, and make such a payment at first as may be sure to afford each man that shall fall sick during the ensuing year one shilling a day during the term of his sickness. Taking (for the sake of illustration) the Scottish tables, we find that, among such a body of men, there will be about 66 weeks of illness in the course of the year. This, multiplied by 7, gives the whole sum required, £23, 2s., or a little more than 4s. 6d. each, which, less by a small sum for interest, will accordingly be the entry-money of each man. A society of individuals of different ages, each paying the sum which would in like manner be found proper to his age, would be quite as sound in principle as one on the above simple scheme. It is only a step further to equalize each man's annual payments over the whole period during which he undertakes to be a paying member.

We shall suppose that the superannuation allowance or pension is contemplated as commencing at 60 years of age. It is necessary to consult tables of mortality, in order to ascertain how many may be expected to reach that age, and how long each of these has a chance of surviving it. Having already treated of tables of mortality (see the article on LIFE-ASSURANCE, No. 46), we shall not say much on this subject. The table presented by the Highland Society, as proper for friendly societies, is a mean of the Northampton, Carlisle, and Swedish tables, and may be regarded as tolerably safe for both life-assurance and annuity schemes. It shows that, of 1005 persons of 21 years of age, no fewer than 528 reach the age of 60, 336 that of 70, and 127 that of 80; thus making it evident *how absurd it is for a working man to think that he has an extremely small chance of growing old, so as to need a provision.*

Another point for consideration is the rate at which the funds of the society may be improved. In most cases, we believe, it is best for such societies to rest content with taking advantage of the privilege which they enjoy by act of parliament, of depositing their money in the funds or the savings' banks, in which case they obtain for it (considering the half-yearly payment of interest) about £3, 17s. 6d. yearly.

34	12 19 10¾	0 1 4¼	54	24 13 11¾	0 5 1	75	29 13 8	

Proceeding upon these or nearly similar grounds of calculation, Mr. Finlaison formed the table which is given above, to show in one sum (and also in an equivalent monthly contribution, to cease at the age of 65), the value of an allowance of four shillings per week during sickness, from and after each age until 65, combined with an allowance or pension of 2s. per week, commencing payment at the age of 65; and further combined with a payment of four pounds whenever the death of the purchaser shall happen.

We would here call particular attention to a point of view in which savings' banks and friendly societies might be regarded as favourable to each other. It will be observed that, for the sum of about thirteen pounds at the age of thirty-four, a man can insure himself against absolute want under all future contingencies except deficient employment. Now, at that age, a prudent and careful man, who has begun early to frequent the savings' bank, may without difficulty have saved thirteen pounds. Let him draw his thirteen pounds from the savings' bank, and place it with the friendly society, and he is all but an independent man for life. This is a course highly worthy of the attention of domestic servants, who in the latter years of life are so often exposed to want.*

* See "Instructions for the Establishment of Friendly Societies." Printed by W. Clowes, London, for his Majesty's Stationery Office: 1835.

* Friendly societies and savings' banks sometimes appear as rival institutions, and their respective merits are keenly canvassed. Both have certainly their peculiar advantages. There is much in the consciousness of having a small fund stored up, and in the power of employing it for any particular purpose at pleasure; but it cannot be doubted that a reserve fund is a less efficient protection against contingencies, such as sickness and death itself, than connection with a sound friendly society. The difference is like that between taking one's risk of loss from fire, and paying in to an insurance office. "Whenever there is a contingency, the cheapest way of providing against it is by uniting with others, so that each man may subject himself to a small deprivation, in order that no man may be subjected to a great loss. He upon whom the contingency does not fall, does not get his money back again, nor does he get for it any visible or tangible benefit, but he obtains security against ruin, and consequent peace of mind. He upon whom the contingency does fall, gets all that those whom fortune has exempted from it have lost in hard money, and is thus enabled to sustain an event which would otherwise overwhelm him.

The individual depositor, not the contributor to a common fund, is really the speculator. If no sickness attacks him during his years of strength and activity, and he *dies* before he is past labour, he has been successful in his speculation; but if he fall sick at an early period, or if he live to old age, he is a great

The scheme of a right friendly society may be further illustrated by the actual arrangements of one of approved character, which happens to be well known to us. We allude to the Edinburgh School of Arts' Friendly Society, established about thirteen years ago. This society, although originating with certain of the members of and friends to the School of Arts (a species of mechanics' institution), and taking its name, is not otherwise connected with that institution, but is open to all persons, male and female, residing in Edinburgh. It has three separate funds or schemes—namely, a *Sickness Fund*, *Deferred Annuity Fund*, and a *Life Assurance Fund*. *One share* of the sickness fund entitles the member during sickness to 10s. a week for 52 weeks, 7s. 6d. a week for other 52 weeks, and 5s. a week for all future period of sickness until the age of 60 or 65, according to the age of superannuation fixed at entry; and thereafter his contributions cease, and he enters to the enjoyment of the *Deferred Annuity Fund*, one share of which entitles the member to an annuity of £8 a year, commencing at the age of 60 or 65, as fixed at his entry. One share of the *Life Assurance Fund* is a sum of £10 payable at the member's death. In this case, as in the others, the contributions cease at the age of 60 or 65.

The rates are calculated from the Highland Society's sickness table, increased by 50 per cent., which in this case may be considered as sufficient (seeing that only sound healthy men are admitted), and a mortality table compounded of the Northampton, Carlisle, and Swedish, assuming the rate of interest at 4 per cent. accumulated yearly; and the only charges for management are 2s. 6d. entry-money to each fund, and 1s. a year payable by each member of each fund.

The life assurance fund of this society stands apart from the other two, and may be entered independently. Its table being the only one we are acquainted with, which presents the advantages of life assurance to the humbler classes, we extract it. It is to be observed that females are admissible at one-sixth less charges. Half a crown of entry-money is charged.

Life Assurance Fund.

So that a person of the age of 25, for an entry-money of 7s. 6d., and the payment of 2s. 2d. a month until the age of 65—or £1, 5s. 9d. a year—may secure an allow-

loser: for his savings, with their accumulations, will support him but a short time in sickness; or even if he retain something in old age, after having provided for his occasional illness, the annuity which he can then purchase will be very inferior indeed to that which he would have obtained, if he had entitled himself to the benefit of the accumulated savings of all those who, having contributed for many years to a superannuation fund, had never reached an age to require it."—*Report of Committee on Friendly Societies*, 1825.

ance of 10s. a week during sickness for 52 weeks; 7s. 6d. a week for other 52 weeks; and 5s. a week during the whole remaining period of sickness, until the age of 65, an annuity of £8 a year during life after 65, and a sum of £10 at death.

Or, for 4s. 4d. a month, or £2, 11s. 6d. a year, double of those allowances.

At an examination of the society's transactions and funds in December, 1840, it was found that, after twelve years of business, when the deaths of unfree members, or persons who died in the first year of membership, were deducted, the mortality was within that allowed for the tables; and that all the three funds were in a good condition, each showing a surplus over what is necessary to make good the claims to which it was liable, when the value of the future contributions was taken into account against the value of the promised benefits.

For those who find occasion to go deeper into the subject of friendly societies, with a view to founding such institutions, we would recommend a careful perusal of the work which Mr. Charles Ansell prepared for the Society for the Diffusion of Useful Knowledge, and which was published by that society in 1835. Much benefit might also be derived from Mr. William Fraser's papers on Friendly Societies, published in Professor Jameson's Philosophical Journal in 1827.

THE LOAN SOCIETY.

The modern history of Scotland has proved that advances of money to persons of the trading class, made by the banks under prudent cautions with respect to security and the personal character of the borrowers, have a beneficial effect, supplying materials on which industry may work, and at once enabling many individuals to thrive, and giving a powerful impulse to the country at large. The well-cultivated face of our northern region bears powerful testimony to this fact. The institution called a Loan Society contemplates the same benefits to be conferred on an humbler portion of the trading class than those who resort to banks. By making small advances to such persons, it enables them to make little ventures in business which they could not otherwise have attempted, and often sends them forward upon a career which leads to their permanent advancement in life. The purchase of a cow or horse, of farm or mechanical implements, the discharge of rent, and the fitting out of a child for service or apprenticeship, are among the chief objects for which such loans are desired in the humbler walks of life. One might at first sight dread the effects of such anticipations of income; but, practically, the loan system, when rightly conducted, works well, and is productive of much good. "A loan fund," says a late writer, "is a savings' bank reversed, and even leads to the savings' bank, if well managed. For instance, I have before me now the case of a man who, though he has a family, is able to put by at least one shilling weekly. I might have urged him for ever to do so, but it would have been to no purpose. He came to me to borrow 30s. from the loan fund to buy corn to fatten his pig; he paid back this regularly at the rate of one shilling a week; and at the end of thirty weeks I said to him, 'Now, you have been owing me money, and have felt no inconvenience in paying it back; why should you not begin to make *me owe you?*' He had nothing to say to this, and is now a regular depositor in the ——— Savings' Bank through my hands."*

Loan societies are not institutions of yesterday; but, until a recent period, there were none upon an equitable or philanthropic footing. Government, sensible of the erroneous principles on which they were generally conducted, obtained an act in 1835 for their better regulation. By this statute certain benefits were held out to such loan societies as should be formed upon principles approved of by a revising barrister, and enrolled in conformity with the provisions of the act for benefit societies. The principal benefits offered were exemption from stamp-duty, and certain powers for recovery of loans. Enrolled loan societies were forbidden by this act to make loans of above fifteen pounds, or to make in any instance a second loan until the first should be paid off. A scheme of rules for a loan society conformable to law, is presented in the pamphlet quoted below.*

It seems here necessary to state, in the most explicit terms, that loan societies formed by interested individuals are entitled to no confidence, being almost universally usurious and oppressive in their modes of dealing and a source of great misery to the poor. There are about two hundred loan societies in London, and almost without exception they are of the same character as pawnbroking establishments.† On this subject we quote the following passages from a valuable communication which appeared in the *Times* newspaper:—"They generally originate with a knot of small tradesmen, who, having a surplus over the demands of their immediate business, find in them a profitable employment of their money. A capital of £500 has been known to start such a society—the paid-up capital eventually to be £2000 in shares of £5 each. It is very rare that the whole of the capital is at once paid down. Their rules in the outset describe the name and the constitution of the society; then follow the terms on which the shareholders have taken their shares, and the manner in which they are to receive a return for embarking money, which is the allowance of 4 per cent. interest per annum on the amount of subscription, while the balance of profit afterwards accruing is to be declared as a dividend. There are separate rules which apply to the borrowers from the society, which are called the 'borrowers' rules.' The general place of business is a public house; some few, but very few, are carried on in offices hired for the purpose. The borrower has, in the first instance, to call on the secretary, director, or treasurer, all of whom are allowed to sell (at a profit) what are termed 'application papers,' and purchase one (they are either 2d. or 3d. each), fill in the amount of the loan he requires, and leave it with the name of one or two sureties, according to the amount, for the inspection of the directors. He calls again, and has to pay 1s. for his security being inquired into, which goes into the pocket of the director whose turn it happens to be to look after the securities, the emolument of this office always going in rotation. He calls again, and is told whether or not his security is sufficient; if not, he gives another security and another shilling; if it is, he is told to call on a certain evening when the loans are made, and he will be attended to. Should he give half a dozen securities, and none prove acceptable, he pays his six shillings—for nothing is returned. When the evening arrives, he is called in his turn before the secretary, treasurer, and two directors, who form the authorized court for the conduct of the business. He is asked what amount he wishes to borrow. Perhaps it is £5 for six months; the first thing is to deduct 5 per cent. from the amount of the loan, 1s. for the book with the 'borrowers' rules,' in which will be made the entries of his weekly payments (for the loan is repaid in this manner), and the first week's instalment, and then in addition 1d. in part payment of the

† See "A Guide to nearly One Hundred Loan Societies." London: W. Strange.

rent of the office and 1d. towards the secretary's salary, both of which expenses he is obliged by the 'rules' to bear in common with the rest of the borrowers, weekly. Should he fail to keep up his weekly instalments, he is written to by the secretary calling upon him to pay, and for this letter he is charged 3d., a fee for the benefit of the secretary. If he does not pay due regard to this, he is, at the expiration of three weeks, summoned before the magistrates of the district, who, however, have shown a disinclination to enforce the payment of the extras, and have confined their decisions merely to the sum due to the society after the deduction of the legal interest. That these societies occasionally sustain losses there is no doubt, but they are trivial in comparison to the immense profits they make, as will be seen from the fact that one of them, upon a capital of £2000, was known to declare on the first half-year's business a dividend of 15 per cent., and on the second half-year a dividend of 18 per cent."

A proper loan society is a modest association of philanthropic persons, connected with some limited district, who wish to aid the meritorious poor of their neighbourhood with small advances of money, with or without the prospect of a small interest for their outlay. Anxious only for the good of their humble neighbours, they extend their aid on terms strictly equitable; while they guard against abuses of another kind, by making loans only where, from personal knowledge, they are assured that a good use will be made of the money. It is only in such circumstances that a loan society will do any good, as it is only under certain circumstances as to prudence and careful management that the Scotch system of banking, which loan societies resemble, is attended with the contemplated results.

As far as our information enables us to judge, the loan fund system is nowhere on a better footing than in Ireland. Private, irresponsible, and usurious, loan societies exist there, as elsewhere, but apparently in less proportion to those of a beneficial character. The extensive utility of loan funds in Ireland is owing to the establishment, by an act in 1836, of a central board of commissioners, with power to inspect the books of all societies formed under the act. In consequence of this statute, there are now from two to three hundred loan fund societies throughout Ireland, conducted on philanthropic principles, and said to be producing a great amount of good. In these societies, all profits, after paying clerk's salary and other unavoidable expenses, are applied to charitable purposes. It appears that in 1840, 215 such societies were circulating £1,164,046 among 463,750 borrowers, and that £15,477 of profit had been realized in three years.

Mr. S. C. Hall, in the agreeable work on Ireland published by him and his lady, gives the following account of the way in which one of these societies is usually constituted, and the manner in which the business is subsequently conducted:—"The resident gentry of some locality in which no loan society exists, perceive that such an institution is required, or would benefit the people in the district. A meeting is called, and as many as are inclined to become depositors state their intention of taking debentures from the new society, for which they receive interest, in some places five, and in others six per cent. One party is voted treasurer, another honorary secretary, and three or four others trustees. Rules for the government of the society are then drawn up, and it is imperative that each set of rules shall contain a provision that no manager or trustee shall directly or indirectly derive any profit from it. Another rule must ascertain the limit to which the managers shall be at liberty to go in expenses of management; and a third, that the treasurer shall become bound with solvent sureties in a reasonable amount for the faithful performance of his duties. These rules are then transmitted to the secretary in Dublin Castle, for the approval of the board, who make any alteration in them they may deem expedient; and the copy is then returned to the society, that three fair transcripts may be made and sent up for certification. On their reaching the secretary, he submits them to the certifying barrister, who, if they are in accordance with the acts, attaches his certification and signature that such is the case. One of these transcripts is then lodged in the office of the secretary to the board, another with the clerk of the peace of the county in which the society is situated, and the third is transmitted to the treasurer of the society, as a voucher that his society is entitled to the privileges conferred by the act.

The society is then in legal existence, and commences operations. A person is appointed clerk, and to him the intending borrowers apply for application papers, which are according to the form printed in the note,* and for each of which a penny or a halfpenny is generally charged.

This being filled up, and returned by the applicant, his solvency and general character, with those of his sureties, are considered, by one or two of the trustees in council met for the purpose, and if approved, the full loan applied for, or such portion of it as they may think proper to grant, is paid to the borrower, stopping, at the time the loan is issued, sixpence in the pound by way of interest. The borrower then receives a card, on which the amount lent to him is entered, and the instalments he pays are marked off. A duplicate of this, or a proper account of the transaction, is, of course, booked by the society. The borrower, and his sureties for him, bind themselves to repay the amount of the loan in twenty weeks, by instalments of one shilling in the pound per week. Thus, if a borrower applies for a loan of £5, which is approved, the society hands him £4, 17s. 6d., retaining two shillings and sixpence as interest. He then pays five shillings for twenty weeks, and the £5 is paid off. Should the borrower run into default, he subjects himself, in most societies, to a fine of one penny for the first week, and threepence for the second and every succeeding week, on each pound lent him; and should he remain two weeks in default, his sureties receive notice that they will be sued for the amount, together with the fines incurred; and unless the borrower comes in, this is immediately done. But in the very great majority of cases no such steps are necessary, the poor borrowers being generally very punctual in the repayments.

It has been objected by some, that the borrowers lose their time in repaying these instalments, but in practice

* APPLICATION FOR A LOAN FROM THE ——— LOAN SOCIETY.
Former Loan (if any) No.
Amount. £ Fines, *s.* *d.*

I, ——— ———, of ———, parish of ———, county of ———, of which the Petty Sessions are held at ———, and holding acres of land, request that I may be accommodated with pound shillings, according to the rules of the ——— Loan Fund, which I intend to employ in , and of which I solemnly declare that the whole is to be applied to my own use, and not divided with any other person.

——— ———

I certify that the above-named ——— ——— is personally known to me, and that I consider to be a solvent, honest, industrious person, and that I believe the above statement to be perfectly correct.

Given under my hand, this day of 184 .
Signed, ——— of ———.

[It is requested that no person will certify for an IMMORAL PERSON, or for one who does not live industriously in some calling.]

We whose names are hereunto subscribed, will guarantee the payment by a promissory note of £ , s., to the treasurer for the time being of the ——— Charitable Loan Society, applied for by ——— ———.

Given under our hand this day of

——— ——— of ———, of which the Petty Sessions are held at ———, possessed of property in ——— to the value of at least £

——— ——— of ———, of which the Petty Sessions are held at ———, possessed of property in ——— to the value of at least £

the personal attendance of the borrower or his sureties is seldom given. The instalments of a whole neighbourhood are frequently brought in by a child, or some old person, fit for no other employment, who goes, *per vicem*, for two or three town lands. 'Indeed,' remarks the Rev. Mr. Nixon, of Castle Town, 'it is quite delightful to see the confidence reposed by the borrowers in the persons who carry their instalments, and also the fidelity, and accuracy, nay, even the tact, that these latter evince in the discharge of the duty they have undertaken.' In some places the amount of interest charged is less than that above stated, and in others the fines are higher. There is no uniformity in these matters, nor have the central board any power of enforcing it, though it is evidently desirable."

Mr. Hall, adverting to the Third Report of the Loan Fund Board to Parliament, says—"It appears by this return—and the circumstance is so remarkable as to appear at first incredible—that out of an amount of £1,164,046 circulated in small loans among 463,750 individuals, so small an amount as £360, 18s. 8d. only should have been lost, or about ¼q. in the pound. We were very skeptical on this point, and consequently directed vigilant attention to the subject; when, what was our surprise to find that even this £360—this ¼q. in the pound—is considerably more than has been really lost, or left deficient by the poor borrowers! From the 'list of societies whose accounts show a loss on the transactions of the year 1840, after paying interest to depositors and expenses of management,' we took the first, namely, Mitchelstown, where the reported loss was £43, 2s. 6d., when we ascertained that this society lent during 1840, £5420 among 3070 borrowers, who paid £135, or sixpence in the pound, for its use, besides £11, 10s. 10d. for the price of their application papers and cards. The society paid in interest for money lent to it, and expenses of management, £190, 3s. 4d., and the difference between its receipts and disbursements constitutes this £43, 2s. 6d., not one penny of which was lost from defaulters. We are informed by a person in every way competent to judge, it is his firm belief that out of this £1,164,046 lent, not the odd £46, or not *one-tenth* of a farthing in the pound, was unpaid. This fact alone speaks volumes for the honesty of the people, and their appreciation of the benefit which the loan funds confer on them.

"It has been argued that this security from loss has arisen in consequence of the power which the law gives for the recovery of the loans; but the observation is equally applicable to societies more strictly private. For example, in New Ross a society has been established upwards of forty years, for the lending small sums to the poor; and the sum lost during the whole of that period is within five pounds. This fact we give upon the authority of the Rev. George Carr; we could adduce others equally strong, and we have no doubt might receive similar statements from nearly every institution of the kind in Ireland. We rejoice greatly at the opportunity thus supplied us of bearing out by unquestionable proofs our own opinions in favour of the honesty of the Irish peasant. It is indeed a subject upon which satisfactory evidence is especially necessary; for it has been too frequently and too generally questioned in England, where, upon this topic particularly, much prejudice prevails, and where it has been far too long the custom to

'Judge the many by the rascal few.'

"We therefore, from the very minute inquiries we have instituted, have no hesitation in arriving at the conclusion, that the loan funds in Ireland will speedily become, nay, are already, mighty engines either for good or evil, according as they may be worked and superintended Where properly managed, they cannot fail to exercise a vast influence on the moral and social condition of the people; where conducted carelessly, or by parties endeavouring to force business for their own gain, they may be indeed considered a moral pestilence, blighting the energies of the surrounding population, and fostering habits of improvidence or dishonesty."

THE ANNUITY.

The purchase of an annuity is a mode of providing for the latter part of life, which may be the most appropriate in some instances, especially where a person is unconnected with wife, children, or other near relatives, or where these have been otherwise provided for. When the case is different, such a mode of provision is liable to the charge of selfishness, in as far as it concentrates the benefit upon the purchaser alone; it has also been thought to tend to encourage improvident and careless habits, seeing that, once assured of a full provision for life, the need for further saving is in a great measure precluded.

There are numerous companies which grant annuities on the principle of making a profit by them; and sometimes this branch of business is carried on in connection with that of life-assurance. There are also associations of individuals for obtaining annuities and endowments to widows and other nominees on the mutual assurance principle, and one large class of these, at present flourishing in various parts of the United Kingdom, are said to be based on unsound calculations, and fraught with disappointment to those relying upon them. There is indeed one circumstance generally unfavourable to annuity business, namely, that the ordinary tables of mortality present views of the expectation of life somewhat below what is at present the truth in England. Hence, what makes life-assurance business everywhere so prosperous, is precisely that which tends to make annuity business a source of loss. It is obvious that, where individuals unite for annuities, and too low charges are made, those dying first will secure an over-proportion of the benefits, and leave those who come behind nothing but an empty purse.

With a view to encourage persons of the humbler classes to provide of themselves for their latter years, the government obtained an act (3 and 4 Will. IV. c. 14) to enable trustees of the legally established savings' banks to sell annuities of not less than four or more than twenty pounds, upon the security of the national credit. The same act provided that, in parishes where there was no savings' bar[illegible] society for granting such annuities might be form[illegible]vided that the rector or minister of the parish, [illegible]resident justice of peace, should be one of the trustees. Any person above fifteen years of age was entitled to purchase such an annuity, which might be to commence immediately, or at a future period of life, or for a limited term of years, at the pleasure of the party, and might be paid either in one sum or in half-yearly sums, convertible into quarterly by dividing the annuity, and commencing the two parts at different periods of the year. The whole arrangements of this act were dictated by the most considerate benevolence towards the classes designed to be benefited. To quote an authoritative document:—"Provisions are made for enabling the party to make his annual payments, or receiving the annuity, at any other society than the one at which the contract was originally entered into. Upon the death of the person on whose life the annuity depended, a sum equal to one-fourth part of the said annuity (over and above all half-yearly arrears thereof respectively) will be payable to the person or persons entitled to such annuity, or his, her, or their executors or administrators (as the case may be), provided such last-mentioned payment shall be claimed within *two years* after such decease, but not otherwise; provided also, that the fourth part of any expired life-annuity, payable under the provisions of the said act, will not be payable, nor be paid upon, or in respect of any *deferred life-annuity*, unless one half-yearly payment of such deferred life-annuity shall have been actually paid or become due at the time of the decease of the nominee. Independently of the advantages which are thus afforded to the industrious classes to obtain by small payments a certain provision in old age, or at any other stated period, *secured by government*, and of which they cannot be deprived on account of miscalculation, the tables of contributions have been so calculated, that *if the purchaser of a deferred life-annuity die before the time arrives at which the annuity is to commence, the whole of the money he has actually contributed will be returned, without any deduction, to his family.* And if it does not exceed £50, it is not necessary that probate or letters of administration should be taken out. But if he has left a will, or administration is taken out, no stamp or legacy duty is payable in respect of the sum so returnable, if the whole estate, &c., of the member is under £50; and again, *if a purchaser is incapable of continuing the payment of his yearly instalments, he may, at any time, upon giving three months' notice, receive back the value of the money he has paid.* No annuity granted will be subject or liable to any taxes, &c.; nor can the same be transferred or assigned, but must continue to be the property, or be received for the benefit, of the party by or for whom it was purchased; but in case of the bankruptcy or insolvency of the purchaser of an annuity, the same is to be repurchased by the commissioners at a valuation according to the tables upon which the annuity was originally granted, and the money will be paid to the assignee for the benefit of the creditors.

"From the above statement it will appear that any *deferred annuity*, purchased by annual or other payments, from a society established under the stat. 3d Will. IV. c. 14, will entitle the purchaser (if he live to the age at which the annuity is to commence) to receive an annuity equivalent to the value of all his payments, with the accumulation of compound interest; if he be unable to continue his yearly instalments, he may have back all the money he has paid, exclusive of interest; and if he die before the commencement of the annuity, his family will, in like manner, receive the whole of the contributions he may have actually made previous to his decease, exclusive of interest."

The tables on which the government annuities are granted have been formed, as might be expected, on the soundest principles, and are entitled to the greatest respect. They relate to four kinds of benefit—deferred annuities upon the continuance of single lives, immediate annuities upon the continuance of single lives, deferred annuities to continue for a certain term of years, and immediate annuities to continue for a certain term of years. The whole are presented in a brochure quoted below.* We have extracted only one specimen, namely, the terms of an annuity of £20, payable after twenty years from the time of its purchase—(See preceding table.)

BENEVOLENT PAWNBROKING.

The necessities of the humbler classes have given rise to the trade of pawnbroking, which, even when conducted, as it often is, by respectable persons, certainly forms a severe punishment upon the poor for their poverty. On this subject some exaggerated views have of late years gone abroad; but there can be no doubt that the poorest class, in pledging small articles for short periods—and the greater part of pawnbroking business appears to be of this kind—are subject to enormous extortions, calculated, most materially, to keep them in a depressed condition. It has been said that £3000 is annually lent by pawnbrokers in Ireland in one shilling loans, and that this sum actually produces to the lenders in a year not less than £19,500. To a poor person in want of a shilling for a week, it appears no great hardship to pay a penny for the loan of it; but when we consider that this is, in reality, borrowing money at 433⅓ per cent. per annum, the hardship of the case is presented in its true light. Nor is the licensed and ostensible trade of the pawnbroker the worst of the case. Wherever a large horde of very poor people is collected in our large towns, there rises an unlicensed and clandestine species of the trade, conducted upon principles still more ruinous to the needy. It has been shown that there are in Glasgow no fewer than seven hundred small unlicensed pawnbroking establishments, whose extortions from the poor infinitely exceed the legal rates to which the licensed traders are restricted. The saying of Solomon, that the destruction of the poor is their poverty, was never perhaps shown in a more striking light than in the losses which they endure in consequence of the necessity they are occasionally under of raising money by pledges.

On the continent, the system of lending upon pledges has been practised for several centuries upon a benevolent principle. The establishments where the business is carried on are called *Monts de Piété* (*mounts* being a term applied to heaps of money, while the word *piété* expresses the religious views in which the plan originated). In this case, an association of benevolent persons, possessing a little capital in common stock, are the pawnbrokers, and the objects they keep in view are to make the evil of pledging as light to the poor as possible, and to apply the profits to charitable purposes by which the poor will be benefited. Here there is no extortion, no punishment for poverty, and the poor, as a body, may be said to lose nothing. In France, some abuses have crept into the system; but these are not essential to it, and we have lately had experience nearer home how much good may be done by a well-conducted mont de piété.

The first establishment of the kind in the United Kingdom was set up at Limerick in 1837, through the exertions of a gentleman named Barrington, for the purpose of supplying funds to an hospital which he had founded out of his own fortune. The required capital was raised by debentures (or joint-stock shares) varying in amount from one to five hundred pounds each, upon

* "Instructions for the Formation of Parochial Societies for granting Government Annuities." London: Printed by W. Clowes and Son, for his Majesty's Stationery Office.

which interest was to be allowed at the rate of six per cent. These might be withdrawn at three months' notice, or money would be advanced upon them as pledges. Mr. Barrington described the following as the advantages proposed by his scheme:—

"1st, The raising a capital by small debentures at a certain interest, and lending it on a greater interest, and applying the profits to the purposes of charity.

"2dly, Receiving the debentures in pawn, thus giving to the depositors an advantage which they do not possess in the savings' bank.

"3dly, Lending money at interest to poor persons of unimpeachable character and industrious habits, on personal security, as is done by the loan-banks.

"4thly, Lending money on goods, as is now done by the ordinary pawnbrokers.

"5thly, In case of deserving objects, to restore the article, such as implements of trade pawned in the hour of *real* want, without interest or charge.

"6thly, Using every precaution against receiving stolen goods in pawn."

The plan meeting with a hearty approval, a capital of above fifteen thousand pounds was quickly subscribed, partly by the gentry, and partly by persons in the humbler walks of life. An active and intelligent person, who had himself been a pawnbroker, was placed at the head of the establishment, which had no sooner commenced business than it became largely supported. The following view of the transactions, from March, 1837, when it commenced, up to December, 1840, is given by Mr. and Mrs. Hall in their work on Ireland:—

Years.	Amount lent on Pledges.	Amount received for Released Articles.	Gross Profit.*
	£ s. d.	£ s. d.	£ s. d.
1837,	14,130 1 6¼	9,668 11 10¾	335 2 7¼
1838,	17,885 13 3¾	16,923 15 8¼	1074 18 4¼
1839,	21,091 7 8¼	20,727 19 6¼	1172 15 3¼
1840,	25,488 6 5¼	23,675 1 5¼	1357 13 11
Total,	78,595 0 0¼	71,005 8 7	3940 10 2¼

There is no charge for tickets at this establishment; consequently, if those pawns were pledged at a pawnbroker's, the poor would have to pay for each pawn a sum of one penny; if the amount borrowed amounted to 10s., twopence, if it amounted to 40s., fourpence: therefore (not at all taking into account the low rate of interest) the saving effected by the very poorest persons is most remarkable. For instance, say that

360,000	of those pledges were	*under* 10s., at 1d. each,	£1500 0 0
90,000	do.	*under* 40s., at 2d each,	750 0 0
10,895	do.	*over* 40s., at 4d. each,	181 11 8
Or a sum saved in four years on the bare item of tickets, to the very poorest people, of . .			£2431 11 8

If to this be added the saving in interest, we may safely calculate that nearly as much in addition is saved as the establishment is realizing, as the following table will show the difference in the rate of interest, for different sums, to 10s. and £1.

Sum Lent.	Mont de Piété Interest.	Pawnbroker's Interest.	Pawnbroker's *Total Charge* of Interest and Ticket.
£ s. d.	d.	d.	d.
0 1 0	0¼	0¼	1¼
0 2 0	0¼	1	2
0 3 0	0¼	1	2
0 4 0	1	1½	2½
0 5 0	1	1½	2½
0 6 0	1½	2	3
0 7 0	1½	2	3
0 8 0	1½	2½	3½
0 9 0	2	2½	3½
0 10 0	2	3	5
1 0 0	4	5	7

* Total number of pawns received since the establishment opened, to March 19, 1841, 460,895.

The Mont de Piété of Limerick having been attended with success, insomuch that it supports the hospital for the sick poor of the city, similar establishments have been opened at Belfast and Tandragee, and the example will doubtless be followed in time on this side of the Irish Channel. In September, 1840, at the meeting of the British Association at Glasgow, an interesting paper on the subject of the Irish establishments was read by Mr. H. J. Porter, from which we make the following extract:—

"At the close of the first nine months of the operations of the Tandragee Mont de Piété, I was able to show that the borrowers from the loan fund department, on personal security, had in their possession 1189 looms, of which 612 (more than half the number) were hired at 10s. per annum. One man had at that period one loom, for which he had paid £12 within the previous twenty-four years, without any other alteration than that which was necessary on the invention of the fly-shuttle; and, after having paid the price of four new looms in interest, he was not at that time the owner of one. Here, and in many similar cases, the mont de piété was the means of relieving the poor, and the owners of looms for hire began to find it difficult to let them out. One farmer proposed to sell his stock of looms to the institution, finding the hope of his gain drawing to a close but of course the proposal was rejected, as these old looms were incapable of producing as good a fabric as the new looms issued by the mont de piété.

"At the period of which I speak (first nine months of operation), above 2600 loans had been granted for the following purposes:—

For provisions . .	Loans, 550	amounting to	£1649
Materials for trade .	.. 138	..	402
Dealing	.. 194	..	661
Clothing	.. 41	..	81
Repairs of houses . .	.. 51	..	143
Yarn for weaving . .	.. 187	..	612
Looms	.. 131	..	449
To pay small debts .	.. 70	..	193
To buy cows . .	.. 504	..	2569
.. pigs . . .	.. 375	..	1223
Farming purposes, seed, &c.	.. 260	..	839
Rent	.. 77	..	252
Total	2608		£9070

"In order to form some idea of the benefit derived by these borrowers, I examined great numbers of them as they appeared, on the payment of the last weekly instalment. I ascertained pretty nearly the amount of money saved or realized by their having the advantage of ready money, and from these I formed an average estimate of the whole.

Oatmeal . .	£1100	Saving . . .	£309
Potatoes . .	550	.. . . .	338
Cows . .	2569	Profit . . .	124
Pigs . .	1223	.. . . .	160
Dealing . .	664	.. . . .	166
Total .	£6096	Total .	£336

"Had the mont de piété conferred no other benefit on the country than that derived by the peasantry, in procuring their summer provisions for ready money, that alone would amply repay the directors for all the labour bestowed on the working of the institution. What were the circumstances of these 550 families in bygone summers? Many of them found it difficult to procure credit, or obtain a sufficient supply of wholesome food for the maintenance of their families; idleness prevailed, sickness increased, and not unfrequently fields were mortgaged to more wealthy neighbours, who supplied the wretched holders of two or three acres of land with the required food at an exorbitant price. Others, whose credit was good, passed promissory notes, payable at harvest, and not unfrequently they were charged for meal 6s. or 8s. per cwt. more than the market price, independent of the expense of stamps; and it was no uncommon practice for a poor man, wanting the immediate use of a few pounds in money, to purchase oatmeal from a forestaller of provisions, while a third person would buy back the oatmeal from the poor man at a much less price than he was charged, hand him the money, and the oatmeal would never be delivered, but sold again by the forestaller to the next customer. The object of this transaction is evident. The value of a promissory note for provisions would be easily recoverable at the quarter-sessions, while one for cash, bearing usurious interest, would be likely to involve the forestaller in an open violation of the law. Thus were the poor on every side oppressed; the harvest time arrived, and the debts for summer provisions were generally first paid from the produce of the farm; too often were they unable to pay just demands of rent and other charges, while in few cases were they able to hold over their corn till the most favourable time arrived for bringing the produce of their farm to market.

"What, on the other hand, has been the experience of the last summer? Those 550 families borrowed, on moderate interest, from the mont de piété, £1640, and by habits of industry and increased diligence, their weekly instalments are paid; at harvest, instead of being deeply involved in debt, they owed nothing for their summer's food, and the produce of their land has in many cases been reserved for weeks, till the best price could be obtained; they are able not only to pay their rents, but to supply themselves and their children with better clothing. But other moral effects have followed. Halfpence and pence, which formerly were squandered in tobacco, snuff, and ardent spirits, are treasured up for the Monday morning's instalments, and the people are beginning to feel the value of small sums, and the truth of the old proverb, that, 'if you take care of the pennies, the shillings will take care of themselves.'

"Again, we find that £2569 has been borrowed for the purchase of cows. The benefit to the poorer classes in this particular is incalculable—the health arising from the possession of an abundant supply of milk; the improvement on their farms, by sowing green crops for the maintenance of their cows; the increased quantity of manure which is provided for the land—while it has been ascertained that in twenty weeks the generality of cows purchased have paid, by the produce of milk and butter sold, one-half of their own cost. Hundreds of families are now possessed of a cow each, and great numbers have already procured a second. As a proof of the saving habits which are promoted by this system, I may mention, that a respectable person has settled in this town, whose sole business is the purchase of butter and eggs for exportation; and he finds it frequently difficult to attend to the immense influx of persons who come to sell their produce to meet their weekly instalments. One poor woman borrowed a pound; she bought five hens for 4s. 2d.; she expended 15s. 10d. in clothing; and at the end of the twenty weeks her five hens had been the sole means of paying off her debt to the loan fund.

"But what is the testimony of the manufacturers in the neighbourhood? That the industry which is promoted by the necessity of those weekly instalments, and the punctuality of the weavers in returning their cloth, has already had the most beneficial effects.

"And how are persons in trade affected by the operations of the mont de piété? I have it from the best authority, that a great increase of business has been the result, and a greater degree of punctuality in meeting all engagements on the part of the poorer classes.

"One class alone are suffering from the effects of the mont de piété, and they are little deserving of compassion. Those who live by the destruction of others, both soul and body, are not to be commiserated—those who keep open houses for the drunkard—and when they have given a poor person as much whisky as they think he can pay for, or is able to consume, turn him out incapable of taking care of himself, and exposed to the risk of a watery grave in the next river or canal he meets—those are surely persons whose lack of business and prosperity is a blessing, and whose failure in trade must be held as a common good. I have undoubted authority for saying, that the temperance cause and the mont de piété are going hand-in-hand; and the twopence for the morning glass, or the shilling for the night's carousal, are now carefully saved to meet the weekly instalment.

"I might enlarge on the important benefits which this institution confers upon the working-class—above £1200 expended in the purchase of pigs, which are such a source of wealth to the Irish poor, being nearly fattened on the refuse from the tables of the owners."

We must be excused for adding one more anecdote from a report by Mr. Haynes of the Limerick establishment:—"A poor woman, when the institution first opened, was in the habit of pledging *every* morning her bed-tick for two shillings and sixpence, and releasing it every evening; this she did for the purpose of purchasing potatoes from the country people, and retailing them afterwards in small quantities, at a higher price, thereby endeavouring to support her family: for this loan she *daily paid the pawnbroker the sum of twopence.* When the mont de piété opened, she being only charged a halfpenny, saved three-halfpence daily, which eventually enabled her to raise a small stock-purse of ten shillings; and she now seldom, if ever, visits even that office."

THE PROVIDENT DISPENSARY.

On the subject of medical attendance, the working man, in ordinary circumstances, may well be at a loss how to act; for, on the one hand when he calls in a doctor on account of himself or his family, he is oppressed by the high charges for attendance and medicine; and on the other, if he resorts to a dispensary or hospital, he loses his independence. That these are evils of large amount, and widely prevalent, might easily be shown. In England, the ordinary medical practitioner charges for medicine only, but he gives much of that, and places a high price upon it. A working man, ill for three weeks, will find, on his recovery, a bill of thirty or forty shillings run up against him, either causing him to break up his little hoard in the savings' bank, or keeping him in embarrassment for the ensuing twelvemonth. Conducted as the medical profession is in that country, it is impossible, in short, for a poor man to have independent medical attendance which he means to pay, without the most serious pecuniary distress being entailed upon him. So severely is this felt, that the resort to medical charities has of late years been rapidly on the advance in England, both involving more individuals, and individuals of a better class than formerly. In 1821, when the population of Manchester was 158,000, the dispensary patients were 12,000. In 1831, when the population was 230,000, this class of patients had advanced to 41,000; an increase of fully two to one. It was calculated in the latter year that, of all the persons ill and requiring medical advice, the dispensary patients were a majority. Similar facts are stated with respect to Leeds and Birmingham. It would appear as if a wide-spread demoralization were going on throughout England from this cause. Dr. Holland, of Sheffield, has recently published a volume calling attention to the subject. He sets out by stating very broadly, as his opinion, that the character of the working-classes in Sheffield is at present undergoing a certain degree of deterioration, in consequence of so many charities, and particularly medical charities, being thrown open to them, the self-respect connected with independence being thus gradually worn away, and with it the virtues which have never yet been found to exist without it. The Infirmary, we are told, was established for the benefit of the poor and needful of all nations; but it never, our author argues, could have been designed for those who are able otherwise to obtain the desired aid. Now, however, the fact of being an operative is held as a sufficient claim

"The artisan never dreams of the possibility of rejection on the ground of being in full and regular employment, and being amply remunerated for his labour. He applies u[illegible] as naturally to the charity when he is sick, as to the tailor for the repair of his clothes, with this difference, that he would be perfectly astonished were any one to hint at the propriety of paying for the favours conferred by the former." Our author argues against the following classes, at least, having any right to the benefits of the institution: Single men in employment—married men with only young and small families—men with several children but high wages—men who have several sons and apprentices working along with them—servants in situations. All of these persons, excepting the last, must be able to provide medical attendance for themselves, if they economize their resources. He presents a hundred cases of applications, being those within the few weeks before the time when he was writing, and out of these he showe that there were fifteen young single men, all of whom but two had been in employment till the time of their illness, twelve at well-paid crafts, and one as a labourer. Eleven cases were of married persons without children; and thirty-two applicants were married, with only one or two children. In some of the latter instances, "the only child is a daughter eighteen or twenty years of age, who had never been allowed to go out to place, or to learn any business; in others, a son apprenticed to his father, and both in regular employment. In one instance, where the wife was the patient, the daughter was in a warehouse, and the son, a youth of fourteen years of age, was a day scholar in a respectable private academy in the town. The husband had received regularly twenty-four shillings a week for the last twenty years. Many of the thirty-two cases are even more flagrant instances of imposition on the charity."

Certainly in the whole number of applicants for relief, as far as our author has described them, we do not find that proportion of persons likely to be in necessitous circumstances, which might be expected. To support his views, he brings the testimony of the house-surgeon, who, in answer to queries put to him, says—"The character and appearance of the patients generally are very different from what they were fifteen or twenty years ago. The patients are much more respectably dressed, and in better circumstances. Many now, not from inability to walk, are conveyed to the house in hackney coaches. * * They apply for much more trivial ailments than formerly." The author speaks of females who come to the institution in elegant cloaks, shawls, and clogs. Not one half of the applicants have the appearance of indigence. "The frequency with which they apply for very trifling ailments, such as slight symptoms of indigestion, coughs, or occasional pain, or, indeed, for the removal of a disease which just perceptibly mars the beauty of the face or neck, is evidence that their situation in life is very remote from those circumstances which entitle them to the sympathy of the benevolent. *The really poor never apply for the relief of slight and unimportant complaints.*" Afterwards he adds—"In evidence of the trifling nature of many of the medical cases, we may state that one-half are often cured in ten days, and two-thirds in three weeks."

The results of his inquiries at the Dispensary are nearly the same. The great bulk of the applicants are either themselves artisans in the receipt of good wages, or the connections of such persons. They come in respectable apparel, and, when visited at their homes by the medical men, are found to possess every appearance of domestic comfort. Recommendations from subscribers to the institution are necessary to procure admission; but these are given, in seven cases out of ten, by persons who have no knowledge of the circumstances of the applicants. "A gentleman who, from his position in society, is often applied to, informs us that he always refuses, unless the individual bring a letter from his employer, stating that he is a necessitous object; and though promising to give a recommendation on this condition, *not one in twenty returns to receive it.*"

Facts still more remarkable are brought out by Dr. Holland. "The distresses of a community," he says (meaning such a community as that of Sheffield), "will be admitted to bear a strict relation to the state of trade. When this is extremly depressed, many hands are thrown out of employment. When the trade is good, the demand for labour is great; wages advance, and the blessings of plenty are universally experienced. The amount of misery or destitution cannot be the same in these very different circumstances. It cannot be a fixed quantity floating in society. The idea is preposterous; and yet, if the registered demand for charity be any criterion of the misery existing, there is indeed a quantity subject to scarcely any variation whatever.

"From midsummer 1835 to midsummer 1836, between which periods trade was better in this town than it had been known for years, the number of patients admitted on the books of the Infirmary was 3126.

"From midsummer 1836 to midsummer 1837, between which periods the trade was exceedingly depressed, the number was 3431, being an increase only of 305 patients.

"Between the former periods the number of patients on the books of the Dispensary was 2888.

"Between the latter periods, that is, from July 1836 to July 1837, the number was 2575, being less by 313 patients.

"According to these returns, there were *eight patients more during a prosperous state of trade, recipients of medical charity, than during the severe depression of it.*"

He elsewhere states that healthy seasons are marked by no diminution of the number of applicants. "We hesitate not to assert that, during the last twelve months, there has been less disease in this town and neighbourhood than has been known for many years, and yet during this period the demands on medical charities have increased."

As a remedy to these evils, some benevolent persons, with the co-operation of a few of the more liberal of the medical profession, have instituted what are called *Provident Dispensaries*, the main feature of which is, that the working man contributes a small sum weekly from his earnings, to entitle him to medical attendance and the requisite medicines, in the event of illness entering his household—the united contributions of a few hundred members being sufficient to engage a respectable physician, and defray all the other expenses. Such institutions have been tried with marked success at Coventry, Derby, and some other places. They are limited strictly to the class who are unable to fee medical attendants in the ordinary way, but who are yet anxious to keep themselves in all respects above the condition of paupers. Individuals wishing to belong to the provident dispensaries must join when in good health, as the object is in reality an "assurance" against sickness, and the provident character of the institution could not otherwise be maintained. One penny a week is paid for each adult of the family, and a halfpenny for each dependent child. Individuals of the more affluent classes contribute without the design of benefit for themselves, in order to encourage the institution, and from them, in general, the directing body is chosen—the only part of the arrangement which we cannot fully approve of. From the proceeds a medical man is feed, and medicines are provided; and it is remarkable that a thousand sick persons connected with a provident dispensary have been found to cost considerably less than a similar number of patients resorting to the medical charities.* The tendency of such institu-

* An Essay on Dispensaries. By P. H. Holland, Surgeon, Manchester: 1838.

tions to maintain the moral uprightness of the working-classes is obvious; and it is already proved that, wherever they have been planted, applications for parochial relief have been diminished. It is to be lamented that medical men have a prejudice against them, probably from no other cause than that small copper sums are concerned in supporting them. But surely it is better even for medical men that the humbler order of patients should pay something within their means, and that regularly, than only pay in a few instances, and in others either resort to charities or leave a large debt unliquidated.

Whatever may be the sentiments of the profession upon this point, it must be evident to all that, for the working-classes themselves, the provident dispensary is a most unexceptionable species of institution. It carries them over one great difficulty in their career with the preservation of their independence; it does more, for, being on the assurance principle, it encourages habits of foresight. Some other advantages presumedly incidental to it are thus stated by Mr. P. H. Holland, in the pamphlet above quoted:—"Assistance in sickness is much more easily accessible in provident than in honorary dispensaries. The patient need not lose time, or degrade himself, by running about to beg a recommendation, but applies at once for an attendance ticket, and puts himself under the care of the medical officer of his own choice; in fact, procures assistance just as readily as the richest of the land. Consequently, as I am informed by Mr. Nankivell, at the Coventry Dispensary, the cases being seen by the surgeons at the very outset, the probability of a successful result is much higher than in ordinary dispensaries: for instance, at Coventry, they have lost, out of 6094 patients attended, 92, or 1 in 66; at the Chorlton-upon-Medlock Dispensary, in the same period, out of 6438 patients admitted, 210 died, or 1 in 30·6. All who have had experience in ordinary dispensary practice, well know the advantages of getting the cases early; for, at present, very many patients, rather than undergo the trouble, unpleasantness, and painful sacrifice of honest pride, will not apply for a recommendation until they dare delay no longer; consequently, many cases are not under treatment until the only time at which it could be available is past, and it is this which renders dispensary practice so harassing.

"It is probable, nay certain, that the large number of patients, in proportion to the deaths, is in a great measure owing to the very easy access to a provident dispensary, causing many to apply on very trivial occasions; but who shall say how many of these trivial cases would have become serious, or even fatal, if neglected? But this partial explanation will not at all account for the very gratifying result which, by the following analysis of the reports of the Coventry Self-supporting Dispensary, I have elicited, namely, *that the average mortality among the members of that dispensary is considerably less than the average mortality of the country generally.* This is the more remarkable, as it is fair to presume that the sickly will be more ready to subscribe than those in robust health, and therefore we might have expected a mortality somewhat greater than the average. The mortality of a town like Coventry is about 1 in 50 per annum. The following table exhibits the number of members, upon the presumption that each on an average contributes at the rate of 3s. per annum, which must be very near the truth, as adult members pay one penny per week, and children a halfpenny, while any more than two in a family, below twelve years of age, are not charged.

Years.	Calculated Number of Members on the average of the whole year.	Patients Admitted.	Deaths.	Computed Number of Members to each Death.	Number of Cases to each Death.	Amount of Honorary Subscriptions and Donations for Expenses of the Establishment.	Amount of Members' Subscriptions, from which Fund the Drugs are paid for, and the remainder	Paid to the Surgeons.

Averages,	2670	1523	23	121	68	120 17 3¼	401 9 1	269 15 0

"The average annual mortality among 2676 of the population, taken promiscuously, would be about 53; whereas the mortality among the Coventry Dispensary patients has been only 23. We must not suppose that the dispensary is saving lives at the rate of thirty a year, for much of this difference of mortality must be attributed to 'the circumstance of the members of the institution consisting almost entirely of the most frugal, industrious, and prudent of the work-people.'* Something ought perhaps to be attributed to there being probably a disproportionate number of adult members. But if we are ever warranted in ascribing to medical means the saving of life, most surely are we so among the patients of a self-supporting dispensary, where the members have medical advice at the very outset of disease, more promptly perhaps than any other set of persons in the country.'"

MINOR ECONOMIC FUNDS.

The Hon. and Rev. S. G. Osborne, of Stoke Vicarage, Buckinghamshire, has published an account† of several small economic funds, which have been formed in his parish—a large agricultural one—for the benefit of the humbler classes, apparently in a great measure by the active and well-directed zeal of the author himself.

One of these is a *Coal Fund.* The poor in Mr. Osborne's district are generally ill off for coal during the winter months; and, when the weather is unusually severe, it is found necessary in many parishes to subscribe to obtain for them a portion of that domestic necessary. In Stoke parish, the poor are induced to commence in June paying one shilling a week each into the parson's hands, until twelve shillings have been paid. Coal is there generally from 1s. 1d. to 1s. 5d. a bushel; yet the managers of the fund undertake that each person shall have twelve bushels of coal delivered to him, during the course of winter, at his door, free of all charge (a sack of three bushels being given every three weeks four times). The extra money required is contributed by the benevolent people of the neighbourhood. Charity is here partially employed; but it is to be remembered that the benefit is conferred upon a class who might otherwise be entirely dependent in this respect. Mr. Osborne considers it a great matter that the poor are induced to contribute the larger share of the funds: their spirit of self-dependence is encouraged to that extent. The reverend manager of the fund endeavours to save a little in good years, in order to be the more able to succour the poor in bad ones. The poor complain of this, but he waits

* Letter from Mr. Nankivell.
† "Hints to the Charitable." Price One Shilling. T. & W. Boone, London.

patiently till a bad year comes to show them the good of the system. In the severe winter of 1837-8, he had £24 in hand. "We thought the severity of the season such an extreme case, that we ought to do something more than usual for the poor. Accordingly, we took a part of the balance, and bought 114 sacks of coal, some of which we gave away, but sold the greater part at the low price of sixpence a sack. The poor were thus taught the advantage of having saved this balance, and we had the satisfaction of affording a most seasonable relief, without begging for a single sixpence from any one." It may be presumed that the parties on the coal fund will be more careful of fuel thus obtained than of that which is given them for nothing. "They can look forward to the winter," says Mr. Osborne, "with one heavy care for it removed. When the winter comes, with little or any addition, the tired labourer may ever find a comfortable fire at home to spend his evenings by; he is not forced to go to the beer-shop to warm himself."

The *Wife's Friendly Society* is designed to enable married women of the poorest class to have a small fund which they can draw upon, to defray the expense of a proper medical attendant at their confinements, and furnish some of the comforts required on those occasions. Generally, this class of persons have no provision for such occasions, and the consequences are that they depend on charity, and sometimes suffer from the indifference which the midwives in that case employed are apt to feel where their care is not to be remunerated. A poor woman recommended to the Wife's Friendly Society pays 2d. weekly for a year to the treasurer (the vicar's wife), making 8s. 8d. in all. To this the society from charitable contributions adds 2s. 10d., making 11s. 6d. If she is confined that year, she gets an order for 10s., which serves as payment for her medical attendant. The remaining 1s. 6d. serves to furnish gruel and other little comforts—a small sum for such a purpose, but better than nothing. The person who recommended the member guarantees, that, after this payment is made, she will continue to pay her weekly twopence till the end of the year. Should no confinement take place, the money is spent on clothes.

In the case of the *Penny Clothing Fund*, the proportion of charitable contribution is greater than in any other of Mr. Osborne's schemes. The object is to encourage the poor to exert themselves to furnish decent clothing for their children. A benevolent person pitches upon some child belonging to a poor neighbour: the patron and the child each pay 1d. weekly into the fund, that is, 8s. 8d. annually. Some persons take two, three, or more children under their care. Mr. Osborne speaks of 150 in all in his parish being clothed by these means in one year. "The buying of the clothing is thus managed: a linen-draper attends with his shopman on a given day at the expiration of the year, with a large supply of all such articles of clothing as the poor most need for their children; the school-room is allotted to him as a shop for the day. In addition to the linen-draper we have a person over from a neighbouring market-town, whose business it is to deal in ready-made clothing and shoes for boys; he has a room adjoining the school for his shop. Each lady (these clubs are almost always wholly supported by the female sex) appears with the children she has put in, together with their parents; they are served in turn, and it is the lady's duty to see that they have their 8s. 8d. worth of goods. The pence are received from the children weekly at the school; from the persons putting them in, at the end of the year." Clothing for children being one of the things which the poor, amidst the various difficulties which beset them, are least apt to provide for, we can well believe that this fund does much more good than the practice of presenting blankets at Christmas—a blanket being an article which the parent couple feel the want of pressingly themselves, and are therefore eager to provide from their own means.

The *Endowment Society for Children* is the last of Mr. Osborne's parochial schemes which are different from those already developed in these pages. The object here is to make a provision, by small payments, in the course of a few years, for an event connected with a child which will make a small sum of money necessary—as, for instance, to put him (or her) out to service or apprentice him, or to furnish him with tools for his trade when his apprenticeship is expired. One shilling, one and sixpence, and two shillings, are the various sums received, and they may be for two, four, or six years. The principle is the same as in a savings' bank, but the money is devoted to a particular object, and that a very interesting one, and a stimulus to saving is added. The managers of this fund place the money collected in the savings' bank; in the event of the nominated child dying, another is taken, or the money given back.

For further information on these economic institutions, we refer to Mr. Osborne's little volume. It may be mentioned that he has published some other small pamphlets (T. and W. Boone, London) connected with the subject of this sheet, and all of which seem to us well worthy of the attention of those who aim at benefiting the poor by evoking their own best powers in their own behalf.

AGRICULTURE.

Agriculture may be defined as the art of disposing the soil in such a manner as to make it produce, in the greatest abundance and perfection, those vegetables which are useful to man and the animals depending on him for subsistence. The earth, in a state of nature, unless where it is chilled by an ungenial climate, possesses a certain degree of fertility, so as to produce plants more or less suitable for the subsistence of man and beast; but its spontaneous productions are small in amount compared with those which can be drawn from it by man's industry and intelligence, and those productions are not sure to be of the kind which are most needful. Savage nations usually rest content with the natural produce, and they are accordingly found to be few in proportion to the surface which they possess, and generally in the lowest state of misery. But wherever man has possessed any intelligence, he has applied himself to cultivate the earth, so as to make it capable of supporting in comparative comfort a larger amount of population.

The earliest efforts in agriculture appear to have everywhere been simple, and limited in their object. The surface was ploughed, the cereal grains (wheat, oats, &c.) were sown, and such a crop as nature gave was contentedly reaped. It cannot be said that, by such a system, more was done than merely to take advantage of the natural fertility, in order to raise farinaceous grains instead of the spontaneous herbage. Here, however, agriculture seems to have in every country taken its stand for many ages. It has only been in recent times that men anywhere thought of cultivating the soil under certain advantageous circumstances, having a reference to scientific principles, so as to *increase the natural productiveness*, and consequently render the earth capable of supporting an increased population.

The rise and progress of agriculture among us have unavoidably been much affected by the natural peculiarities of the country. Great Britain and Ireland are islands, having the vast expanse of the Atlantic on the west and German Ocean on the east, and lie within the 50th and 59th degrees of north latitude. Both from relative situation and latitude, therefore, they are exposed to a variable, and, upon the whole, ungenial climate. For about five months in the year, or from November till March, the ground is liable to be covered less or more with snow, or to be frozen in its surface; and herbage in either case is so scanty, that, unless for sheep, and not always for them either, the open ground does not afford nourishment for the stock of pasturing animals required in husbandry, or for the dairy and markets. In a word, vegetable food must be produced in sufficient variety and quantity during seven months of mild weather, to store up as a provision for the remaining five. This necessarily gives a peculiar character to the husbandry of the British islands, or of any other country similarly situated. Independently of the circumstance, the natural character of the soil throughout is far from being uniformly suitable for agriculture. Some land is good, some is of a medium quality, and a large proportion is positively bad, being in a state of nature no better than an unproductive morass or waste. Hence, under a poor system of agriculture, only the good land was cultivated, and a large section of the country was of no use to man or beast, farther than affording refuge to tribes of wild animals. In former times, live-stock were either kept on such a limited scale as to render their amount of winter provender easily attainable, or they were half starved for several months while the inclement season lasted.

The improvements which were in time effected to remedy these deficiencies, consisted of a series of moves, each depending on the other. Two things were desirable—to increase the extent of culturable soil for grain crops, and to raise sufficient food for cattle and horses all the year round. Now, these desirable points involved a thorough change in the practice of husbandry. How was it possible to break up and profitably cultivate indifferent soils, much of which had hitherto been considered beyond all hope of improvement, without an abundant supply of manure? and how could this manure be procured without keeping a large stock of cattle, for which there was evidently no means of subsistence? To overcome these difficulties, it was found necessary, in the first place, to introduce what are called green crops, that is, crops of artificial grasses, including clover, turnips, and other roots and plants; for, by having a proper supply of these substances, two important ends were gained—the support of cattle for manure, and the alternation of green with grain crops; thus at once enriching the land, and relieving it from the scourging obligation to raise corn crops successively. On these main points, then, along with plans for drawing off by artificial drainage the surplus water lodged in or upon the soil, hang the great agricultural improvements of modern times.

SOILS.—CHOICE OF FARMS.

The soil, or that earthy substance with which the dry land is in most parts covered, forms more particularly the material on which the agriculturist has to operate. An investigation of its various qualities is absolutely necessary for all who would conduct farming business in an enlightened and liberal manner.

The soil is mainly composed of particles which have been disengaged by various means in the course of time from the rocks on which it rests. In some instances, and more particularly on hills, it is composed in the main of pulverized materials from the rocks immediately beneath; but in many others, the pulverized matter has been washed down from high into low grounds, or transported by floods from great distances. The action of air and water on rocks in dissolving them, and the power of the latter element in transporting the disengaged particles, are the chief causes of the present arrangements of the soil.

Notwithstanding the different appearances which the earthy covering of the globe exhibits, it is composed almost entirely of four substances, formed by an original union of simple elementary matters. These four substances, washed at a former period from rocks, and called primitive earths, are *clay, sand, lime*, and *magnesia*. It is in the due combination of these that fertility consists. We shall describe them separately.

Clay.—Clay, or, as it is often called, alumine, or argillaceous earth, is easily distinguishable. It is a compact substance, which absorbs water slowly, and when moistened throughout, is soft, pliant, and exceedingly tough or tenacious. In its ordinary condition it is so close in texture as to prevent the penetration of the roots of plants, and therefore is a serious obstacle to vegetation. Clay is one of the most obdurate and worst kinds of soil upon which a farmer is called to operate. If it rest on a substratum of gravel, or friable rock, or sand, it admits of easy melioration; but this is seldom the case; it too frequently rests on a cold and still more compact dark clay, called *till*, which is so close that no water can sink through it.

A clayey soil may be meliorated by a due mixture of sand or any other light substance, which will serve to sheer down its articles and keep them apart from each other. All kinds of calcareous manures, ashes, and the loose dung swept from the streets of towns, peat, and farm-yard manure, are serviceable in mingling with clayey soils, and bringing them up to a proper state of fertility. When so improved, they are calculated to yield good crops of beans, wheat, oats, clover, and Swedish turnips. They likewise answer well for meadow lands or pasturage. Clay soils ought, if possible, to be ploughed up before winter sets in, in order to expose the furrows to the action of the frost, which mellows and brays down the tenacious clods.

Sand.—Sand or gravel, called sometimes silex, silica, siliceous matter, or earth of flints, is distinguished by properties of a totally opposite character from clay. It has little or no cohesion among its parts; is incapable of retaining moisture; and powerfully promotes putrefaction, but permits the gases to escape. Sand is thus a corrector of alumine. These two earths may indeed be classed among the contending elements, of which a union heightens their common virtues, and rectifies and subdues their respective defects.

The bulk of the soil, generally, is composed of sand, to the extent of from four to seven-eighths of the mass. Sir Humphry Davy observes that "the term sandy should never be applied to any soil that does not contain at least seven-eighths of sand;" also, that, "sandy soils which effervesce with acids should be called by the name of calcareous sandy soil, to distinguish them from those that are siliceous."

We are informed by Sir John Sinclair that "the best mode of improving the texture of a sandy soil, deficient in retentive or adhesive properties, is by a mixture of clay, marl, warp (the sediment of navigable rivers), sea-ooze, sea-shells, peat, or vegetable earth. Even light sandy soils are thus rendered retentive of moisture and manure. In some parts of Norfolk, the farmers have availed themselves of these auxiliaries for improving a sandy soil in an eminent degree. They have thus entirely changed the nature of the soil; and by the continuation of judicious management, have given a degree of fame to the husbandry of that district, far surpassing that of others naturally more fertile."—(*Code of Agriculture.*)

If the farmer of a sandy soil possess the means of giving it a top-dressing of brayed down or broken peat, he will find it to be attended with good effects: in general, the materials of improvement are obtained with little difficulty. When properly prepared, a sandy soil is one of the most valuable which can be worked. It will produce good crops of common turnips, potatoes, carrots, barley, rye, buck-wheat, peas, clover, and sainfoin and other grasses. It seldom possesses sufficient strength for wheat, beans, or flax.

Crops on sandy soils are easily injured by drought, as the moisture too readily evaporates from the open particles. This may be in some measure remedied by deep ploughing, which has the effect of preserving a due degree of moisture in the substratum, as a reservoir for the plants. To assist further in preserving the moisture in the soil, any small stones which lie on the surface should not be picked off. In rainy climates, or when the soil rests on retentive clay, such expedients may not be necessary.

Gravelly soils are similar in character to those which are sandy, and equally acquire the administration of materials to give tenacity to the mass, also a due supply of compost manure. Both sandy and gravelly soils should have frequent returns of grass crops.

Lime.—Lime, commonly called calcareous earth, is never found naturally in a pure state, but in combination with the acids—chiefly with the carbonic, for which it has so strong an affinity that it attracts it from the atmosphere. The burning of limestone is undertaken for no other purpose than to expel by heat this gas, and reduce the base to a caustic powder, in which state it has a strong tendency to absorb first moisture, and then the carbonic acid of which it had been deprived. Lime blends the qualities of clay and sand, occupying a middle place between the two. In its caustic state it is a powerful promoter of putrefaction, or decomposer of animal and vegetable matter, to which circumstance is owing, to a certain extent, its efficacy as a manure. Lime also helps to fix the carbonic acid which is generated by the fermentation of putrescent manures in the soil, or which floats in the air on the surface of the earth, and it freely imparts this gas, in union with water, for the nourishment of plants. Lime is therefore an exceedingly valuable ingredient to the farmer; and, accordingly, wherever agriculture is carried on with spirit, it is eagerly sought after, though it sometimes bears a very high price.

Magnesia.—Magnesia is a primitive earth found in some soils, but in a much smaller proportion than the above three. Its properties are nearly analogous to those of lime, but of doubtful value, and it is certainly injurious when mingled in large quantities with the other earths.

On analyzing the various soils and subsoils, they have been found to resolve themselves into one or more of the foregoing primitive earths; and their barrenness or fertility has in no small degree depended on the mixing and assorting of these ingredients. Some soils are called *loams;* a loam, however, is by no means a distinct body but is a combination of clay, sand, or calcareous matter. Some loams are denominated clayey, from the excess of argillaceous matter; others, open and light, from the preponderance of sand. In fact, these two original ingredients seem capable of being compounded in such an infinite variety of ways, as to give occasion to that diversified texture of soils met with in all countries and all situations.

Besides these four primitive earths, which constitute equally the soil and subsoil, the upper of these, or mould, contains the putrid relics of organized substances that have grown or decayed upon it, or have been conveyed thither in the progress of cultivation. The decomposition of these is the proximate cause of fertility; and the richness of soils bears reference to the relative quantities. The residual earth remaining after the process of dissolution, is extremely light in weight, and always of a blackish colour. It is owing to this that a garden, which has been under long-continued culture, approaches to a black shade, progressively deepening according to the abundance of this matter. In addition, nearly all soils are found to contain certain various chemical compounds, mineral salts, and metallic oxides; some of which are beneficial, others harmless, and a few injurious to vegetation, and which either pre-existed in the strata from which the surface has been formed, or have been carried to it by subterranean springs or by factitious causes.

The nature of soils is sometimes indicated by the kind of vegetables which they appear spontaneously to produce. This, however, is not a safe test of the nature of soils, or rather of what can be produced from them in a state of tillage; for the seeds of weeds which grow upon uncultivated ground may have floated to them from a distance on the winds, and vegetated where they have chanced to fall. All that can usually be expected from this kind of investigation is, whether the field be moist or dry—as, for instance, rushes will invariably indicate superabundant moisture and a necessity for draining. The *quantity* of herbage or plants produced in a state of nature will also serve as a test of the soil and its capacity for production. A surface which exhibits thin scanty herbage is a sure indication of poverty of soil, or a defect of moisture in the climate.

Choice and Size of Farms.

It has been justly observed by an eminent practical agriculturist, that too much can hardly be paid for a good soil, and that even a low rent will not make a bad farm profitable. The labour of cultivating a rich and a poor soil is nearly the same, while the latter requires more manure, and consequently is more expensive than the former, and the returns bear no proportion in value. It is a wise maxim in husbandry, of whatever nature the soil may be, that, like the cattle by which it is cultivated, it should always be kept in good condition, to enable it to do the work it is expected to perform. The ordinary height at which common grain crops can be raised in the British islands is from 600 to 800 feet; but in some situations, from particularly favourable circumstances, tolerable crops of barley and oats may be produced at a height of nearly 900 feet, and even higher. In proportion as the climate is improved by sheltering plantations and drainage, the height at which grain crops may be realized becomes the greater. In general, it is more appropriate to devote high grounds to sheep pasturage than to tillage; and a consideration of this circumstance will guide the selection and rent of land.

In making a choice of land for farming, let it be a rule to prefer a gently sloping surface, or level, to a hilly and irregular surface. The labour of working land of irregular surface is very great, independent of other disadvantages; and if taken, it should be at a proportionably low rental. If possible, select land that lies with an easy slope to the south; though, if well sheltered, the inclination in other directions is of little consequence. If the land require drainage, or be exposed to heavy rains, observe if there be sufficient inclination to carry off the water. If there be no lower point to which the water may be conveniently drawn, avoid the risk of taking the land, for this defect in its character will prove a frequent source of trouble and loss. In the case of dry calcareous soils, and in moderately rainy districts, the inclination of the surface and means of drainage are immaterial.

Land on the banks of a running stream is likely to be more salubrious for crops than that which is near sluggish brooks or dull sedgy lakes. From dull inert waters there arise, in certain conditions of the atmosphere, heavy pernicious vapours, which steal along the surface of the adjacent grounds, and tend to blight and otherwise injure the crops. These waters, also, are a fertile hotbed of insects. Running waters purify the air, and are of great advantage for cattle. See, however, that the land is not liable to be flooded in winter, for a contingency of that nature should cause a diminution in value.

Considerations respecting climate, soil, elevation, &c., are, however, of subordinate consequence in comparison with the very important matter of *distance from markets and roads*. A long carriage to market, particularly if the roads be indifferent, is one of the greatest drawbacks which the agriculturist can possibly encounter. We have a striking example of this in some parts of North America, where the finest lands, such as would bring an annual rent of £5 or £6 per acre in England, are not, for their entire proprietorship, worth as many shillings. Where bad roads interpose, a distance of a few miles is practically as bad as a distance of hundreds, or even thousands, of miles. The means of procuring an abundance of *labour*, at a reasonable rate, also forms an important matter of calculation for all persons before settling on a farm.

Farms vary considerably in size and mode of working. The first class which we may mention are small farms of from six to eight acres, conducted exclusively by the labour of a cottager, or, as he may be called, small farmer, and his family, and who, by dint of great personal exertion, and scarcely any outlay of money capital, fulfils the moderate expectation of realizing a plain livelihood, and, if he be a tenant, paying a rent to a landlord. The second class of farms, are those which are to be wrought on the most extended principles of rural economy, either by a tenant or proprietor, a large capital embarked, the best implements and machinery, hired labour, and the highest professional skill. Farms of this nature, when almost entirely laid out in tillage for grain crops, such as are common in Norfolk, Northumberland, East Lothian, and Berwickshire, range from 300 to 400 acres in extent, and are divided into eight or ten large fields, by carefully arranged thorn or stone fences. Some farms, however, where the soil is light, and cattle and sheep feeding is an object with the farmer, are as large as from 700 to 1000 acres. In those districts where the climate is moist, and attention is directed mainly to dairy husbandry, the farms are of more moderate size, being in general from 60 to 160 acres. Notwithstanding all that has been written on the practice of agriculture, it remains undetermined, by rigid examination of facts, whether small cottage farms, wrought by spade husbandry, or the large farms of capitalists, are most advantageous to the country—that is to say, which class produces the largest quantity of produce at the least expenditure of means, taking those means on both sides at their market value, and which can afford to pay the highest rent. It being, we think, very important that clear notions should prevail on this subject, we shall in the present article notice the routine of procedure on farms of the larger and more common class, and in that which follows proceed to an account of *cottage farming*, concluding with a few general observations on both.

A farm of the larger class, whether conducted by a tenant or a proprietor, may be described as a *factory* of agricultural produce, every part of the proceedings being conducted as in a factory of articles of trade, by ths employment of capital and the division of labour. The master farmer with his apparatus occupies a large establishment, such as we represent in the following cut. Such is the establishment, at least, common in Scotland. The whole, it will be observed, form a quadrangle, with the farmer's residence in front; feeding-houses for calves and cattle on the left; cattle-sheds in the rear, over which is a straw-room connected with the edifices behind for the thrashing-mill, for which steam or horse-power is employed; and on the right, stables, saddle-rooms, &c. In the centre are three fold-yards, open to cattle from the sheds behind, and into which straw may be thrown from the straw-room. The edifices on each side of the farm-

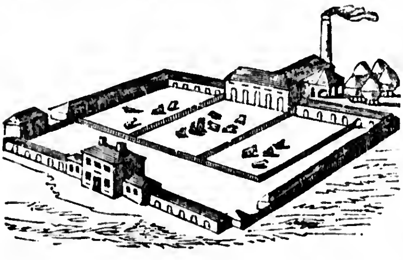

Fig. 1.

house in front are for cart-lodges, boiling food, lodges for unmarried male servants, or other purposes. A granary is supposed to be connected with the thrashing department.

If the farm be rented, it is superintended by the farmer himself, and this is the most common plan; but if kept in the hands of the proprietor, it is generally placed in the charge of a deputy, who is named factor or grieve. The farmer's family interfere very slightly with any of the arrangments. The whole of the labours of the field or in the farm establishment are performed by hired servants; and it is a leading principle in the economy of the farm to keep as few of these as possible.

It is found from experience that farms of this description cannot be conducted properly, for the legitimate advantage of either landlord or tenant, except a lease of considerable duration be granted; for if the tenant be at all times liable to be dispossessed at the mere will of the proprietor, he can have no interest in improving the land, and therefore cannot afford to pay a sum suitable to the actual capabilities of the ground. In all cases, for mutual comfort and pecuniary advantage, there ought to be a properly defined lease or contract for a term of years.

According to the modern practice of agriculture, the profits of a farm are frequently prospective; a number of years must sometimes elapse before the ground repays the farmer for his sunk capital, and his trouble in effecting improvement. The duration of a lease consequently depends on the nature and condition of the soil, as well as some other minor circumstances. It is understood that a long lease is a much greater stimulus to spirited farming than a low rent. If the lease be long, and the rent high, great exertion is used by the farmer; but if the lease be long, and the rent low, a slovenly mode of farming may in general be expected. It appears, from all experience on the subject in Scotland, that a lease should neither be too long nor too short, but of a fair moderate duration, as nineteen or twenty years. In Ireland it is customary to make the length of a lease depend on the contingency of two or three lives, one of which is the life of the landlord. But this is a clumsy and far from beneficial practice as respects the improvement of the land, and is not to be commended.

Furnished with a long lease; a capital of one, two, or three thousand pounds, according to circumstances; the best implements, and active servants, the agriculturist enters on a great undertaking, which demands all his energy and skill. He has to calculate rotations of crops; to procure manure at all hazards, either by purchase or by feeding cattle; if by the latter expedient, he has to attend fairs, to purchase cattle in a lean state, with the hope of selling them after being fatted by winter keep; and to provide for this winter keep, he must necessarily raise a sufficiency of turnips. The keeping up of fences, the attending of markets, and the general contrivance of ways and means, are also among his onerous round of duties. Let us now glance at what must be the nature of his proceedings in the ordinary culture of his possessions.

TILLAGE—FARM UTENSILS.

Tillage comprehends the ploughing, cleaning, and fallowing of the fields, with a view to their proper culture and improvement. The object of ploughing is to delve and turn over the soil in the ridges, to destroy the surface vegetation by burying it underground, where it rots and becomes a kind of manure; to bury the dung spread on the land; to form furrows for different purposes; and, generally speaking, to prepare the land for cropping. In old times ploughs were exceedingly clumsy in construction, and dragged with much difficulty. This great defect was at length removed by the invention of the swing plough, about seventy years since, by James Small, a Scottish ploughwright. Small's plough, which is an elegantly shaped instrument formed on scientific principles, was originally composed of wood and iron, and did not weigh altogether above seventy-six pounds; it was afterwards made of malleable iron, and of a light appearance; but latterly the practice of making it of wood and iron has again become pretty general. The chief merit of this plough consists in the fore part being formed in such a slender and tapering wedge-like manner, as to cut the land with the least possible resistance. The mould-board for turning over the furrow is beautifully curved from the point of the sock to the heel of the wrest, so that it turns over the mould with a small degree of friction and in the best manner.

A sketch is here presented, fig. 2, of the profile or side appearance of this valuable instrument. The degree

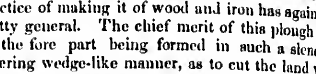

Fig. 2.

of bend in the mould-board is observed in Fig. 3, which represents the lower part or sole turned up to view. Small's plough, under different modifications, is adapted

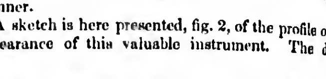

Fig 3.

for every species of tillage which the plough is required to perform. In its own proper form it is particularly well suited for light soils, and proceeds actively through the ground, cutting to a depth of from seven to nine inches; but it may be made to go much deeper, if additional power be attached to it. In Scotland, and other countries in which it has come into use, it is almost invariably drawn by two horses, yoked abreast, and is guided and tended only by the ploughman, the reins coming to each handle of the plough. Considerable skill is required to steady and guide this sharp instrument as it advances through the ground; but this is a point on which properly-bred ploughmen pride themselves, and does not form the subject of complaint.

Small's plough may be said to be the parent of all those modern improved ploughs which are strictly adapted to peculiar kinds of work. In its ordinary form it is not very well suited for ploughing up moor or heathy land from a state of nature, as the heath and other tough vegetable matter is liable to collect upon the coulter, and so choke and retard the instrument. To remedy this deficiency, Mr. Finlayson, an Ayrshire farmer, about twenty years ago contrived an instrument called the rid plough, a representation of which is given in Fig. 4. In

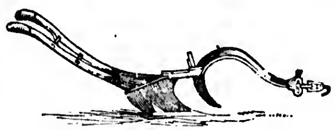

Fig. 4.

this plough the beam is curved so as to terminate in the coulter; and when the heathy matter collects, it is pushed up as the plough advances, and falls off, so as to rid or clear itself of all kinds of loose fibrous rubbish. The sock and mould-board are also so contrived as to cut and lay over the slice, without the power of its springing back to its old position.

There are various kinds of ploughs with one or two wheels, and adapted to particular purposes, but chiefly designed to suit an unskilful class of ploughmen. Wherever agriculture is in a backward condition, there are wheel-ploughs in use.

With Small's or Finlayson's plough, a skilful ploughman and a couple of active horses will make excellent work. The following are among Mr. Finlayson's directions to ploughmen :—"Nothing can be more beautiful than a field commodiously laid off, and neatly ploughed. There is even none of man's handiworks that can please the eye more, and at the same time show more of its unrivalled accuracy, than a lawn which presents ridges of the same width, with furrow-slices running in straight equidistant lines; and that, too, with such minute exactness as scarcely to be equalled by the gardener.

"It is not the man who makes the greatest ado with the horses who opens his ridges best, but more commonly he who goes steadily and directly forward himself, and keeps such a command, by the reins, as to prevent them from deviating far from the right path, yet without laying *too much stress to their precision*, or checking them suddenly from one side to the other; and he who can take a straight furrow at first, and continue so to the last, even on a ridge of fifteen feet, will finish with one, two, or three bouts less than one who is all along undoing, and overdoing, and that, too, independently of the ease to himself and his team, and the preference of the work in every respect.

"If broadcast ridges are of unequal breadth, bent, or zig-zag, the work cannot be so uniform, and in the turnings much time is lost, and harm done to the land which is ploughed, and with crooked drills there is a loss of ground, an unequal distribution of manure, if such has been applied, and the hoeings cannot be so effectually done where they are far distant, or done at all, without soddening the mould, and injuring the crop, where they are narrower.

"In fine, the grand criterion of ease and proficiency is that of the ploughman's walking between the stilts, and in the furrow, with a free step and erect body, for thus he is more convenient for himself, has the horses and the plough better at command, and increases not the friction by his weight; for thus *he cannot go*, excepting the horses and the plough are properly adjusted, and proceeding with the least possible obstruction, and thus, too, he is more graceful to look on, than when wriggling with one foot foremost, or moving as if part of his muscles were under the domination of violent spasmodic contraction.

"It would perhaps be impossible to give any thing like *a system of rules* for the most proper and convenient make, size, weight, turn, &c., of a plough for all the varieties of soil, or of diversity to be met with, even in the same ridge; neither shall I make the attempt; but a few rules may be laid down, and observed as axioms in all ordinary circumstances, viz:—

"1. The horses should be yoked as near to the plough as possible, without too much confining, or preventing them from taking a free step.

"2. When at work, they should be kept going at a good pace.

"3. The chains or theets should, from where they are suspended over the backs of the horses, point in a direction leading through the muzzle to the centre of the cutting surfaces of the coulter and share.

"4. The implement, when taking the form of the dimensions required, should stand upright, and glide onwards in the line of progression, without swerving in any particular way.

"5. The ploughman should walk with his body upright, and without using his force to one point, or showing appearance of inclination.

"The untamed and liveliest, or most forward horse, should be put in the furrow, and only bound back to the right or off theet of the land-horse, at or near the place where the backband joins it, at such length, when stretched at the width required, as to prevent his end of the beam, or double tree, from being before the other. And further, the heads of the two should be connected together by a small rope or chain, at the distance wanted, giving the furrow-horse power over the other, that is to say, if tender-mouthed, it must be fixed well up on his head, and in the rings of the bit or curb of the other, so that he may have the power of the head over that of the mouth of the land-horse."

Let the draught of the horses go in a direct line to the plough or swingle-trees; for if the line be in any way bent, a portion of the power will be lost. Sometimes in England as many as five horses are yoked to a plough, two and two, with one in front; and in most cases of this kind, the power of the foremost horses is partially thrown away, or probably distresses the hind pair of animals. It is not convenient to yoke four or five horses abreast, but it should be fully understood that in that manner they would exert their power to most advantage. Two horses will, in general, do more work yoked abreast to a plough, than four yoked before each other in single file; because some of the power of the foremost horses is always lost in its passage along the sides of the hind horses, and, in turning, the whole draught is imposed upon the hindmost in the row. Wherever the practice of yoking four horses in single file prevails, we recommend it to be discontinued as a waste of animal power, and in its stead to try the more efficacious plan of working the plough by only two horses abreast. Unless on very strong soils, or where a great depth is required, two horses with a well-made plough will be found amply sufficient. Where four horses must be employed, yoke them two and two abreast, and let the draught of the foremost pair proceed by a chain from their centre swingle-tree to the centre swingle-tree of the hindmost pair, thus passing between the hindmost and going in a direct line to the muzzle of the plough. By this means, the power of both pairs of horses goes unimpaired to the resisting object. Never, on any account, let the power of the foremost pair proceed by two chains along the sides of the hind horses to the outer ends of their swingle-trees, for this would only cause a needless expenditure of draught. In Scotland, where the economizing of animal power has been carefully studied, all ploughing whatsoever, be the land light or heavy, except when exerted on the subsoil, is performed with but two horses, and these invariably yoked abreast.

It is a well-known maxim in tillage, that clay or tenacious soils should never be ploughed when either too wet or too dry. When too wet, they are tough, and the clods difficult to break, and when too dry, the plough will scarcely penetrate the soil. In ploughing the first time for fallow or green crops, it is of importance to begin immediately after harvest, or as soon after wheat-sowing as possible, in order that strong tenacious soils may have the full benefit of the frost. On wet stiff soils frost acts as a most powerful agent in pulverizing the earth. It expands the moisture, which, requiring more space, puts the particles of earth out of their place, and renders the soil loose and friable. On such soils there is no rule of husbandry more essential than to open them as early as possible before the winter frosts set in. If left till spring, clay soils may be too wet for ploughing, or, if the season be dry, the earth, when turned up, will be in hard clods, very unfit for vegetation. Therefore, on farms having a proportion of clay and of light soils, it is necessary that the strong wet land should be ploughed first, providing the weather will allow.

Subsoil-ploughing is a new feature in husbandry. The object of it is to trench or loosen the soil beneath the ordinary ploughed surface, so as to allow of its gradual assimilation with the mould above, into which it may afterwards be brought. The process of subsoil-ploughing is effected by a powerful instrument, constructed according to the design of Mr. Smith of Deanston. As subsoil-ploughing, however, is intimately connected with the methods for improving waste land, we postpone any account of it till the article which follows the present on that subject. For an account of the proper steps to be taken to drain the land, if in a moist condition, we also refer to the same article.

The Harrow.—The plough leaves the land cut in longitudinal slices, and is therefore less intended to pulverize the soil than to turn up a fresh surface to the atmosphere. Another kind of instrument is required to break the upturned sward, reduce it to powder, and also to clear it of weeds or other foul substances. The harrow is the implement chiefly employed for this purpose, as well as for covering the seed. According to the diversity of soils, and the particular use to which the harrow is to be applied, its form undergoes considerable changes.

The harrow is a frame of wood, consisting of at least four bars lengthwise and crosswise, with iron teeth set on one side. Usually a pair of harrows is yoked and drawn together, as represented in fig. 5. The figure represents the most perfect implement of the kind, or such as is generally used in Berwickshire and the Lothians. The teeth are set only on the long bars; and the harrows are drawn at such an angle as to preserve the tracks of the teeth in separate lines, and at regular distances from each other. Strong heavy lands require heavier harrows than those of a light nature. In some cases the teeth of the harrow are of different lengths, those forming the front row being half an inch longer than the second, the second a little longer than the third, and so on diminishing backwards. In drilling crops, an implement called the drill-harrow is employed. A light single harrow is in most instances sufficient for drilling or harrowing over the young wheat in spring.

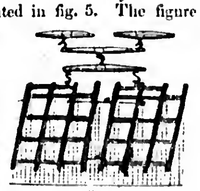

Fig. 5.

When the land is very foul, and calculated to choke the teeth of the harrow, a powerful instrument is now used, called Finlayson's patent harrow, or self-cleaning cultivator. It runs upon three wheels, one in front and two behind. The teeth are curved in such a manner as to bring up and disengage the couch or other weedy matter, the implement thus clearing itself as it advances. By means of a lever above, affecting the frame, the teeth can be depressed or raised, so as to work to any required depth.

The Grubber, &c.—In certain conditions of the ground, a harrow is incompetent to cut up and clear it of its under-surface weedy matter. In such cases, grubbers, eradicators, or scufflers, are used, according as circumstances require. The common Scotch grubber resembles a strong harrow frame, running upon four wheels, and guided like a plough. On the lower side of the frame are placed eleven long prongs, each of which terminates in a triangular sharp foot. On being dragged forward, the prongs scuttle the ground to a depth as great as that of the plough, effectually cutting the roots of weeds, and bringing all loose matter to the surface. The grubber, or scarifier, may be used to advantage in the following cases:—" 1. Barley and turnip land, after being once ploughed, may be made both clean and fine by its means, and the harrowings and subsequent ploughings are thereby rendered unnecessary. 2. Where lands have been ploughed in autumn, the objection to the sowing of spring crops on the winter furrow may be obviated by the use of the scarifier, as not only barley, but oats (if not grain after grass), beans, peas, and tares, may be sown without an additional ploughing. 3. Summer fallows may likewise be advantageously carried on with fewer ploughings, earlier in the season, and at less expense. 4. It may be effectually employed to forward operations in the preparation of land for potatoes or turnips, and afterwards for raising the potato crop; and, 5. Its utility in mixing lime or compost with the soil is of the highest importance, as it not only incorporates these manures more effectually than the plough, but never places them beyond the proper depth. Hence the scarifier or grubber is considered to be one of the greatest improvements in the culture of the soil that modern times can boast of."—(*Code of Agriculture.*)

Sowing Implements.—There are various machines for sowing grain, seed for turnips, &c., in drills, or rows, in the hollow of furrows, or ridges, or on a flat surface, as may be required. For sowing turnip-seed, a barrow on wheels, and pushed along by the hands, is generally used. For sowing grain, one of the best implements in use is

Morton's improved Grain Drill-Machine.—This machine, as represented in fig. 6, consists of a box or hopper supported on a frame with wheels, and is drawn by one horse, and guided behind by one man. The seed escapes from three conductors, the lower points of which act as coulters on the soil, making drills for the seed. In the inside of the box is an axle with projecting teeth, kept in motion by the axle of the machine, and preventing the seed from getting clogged. The seed passes into the conductors through holes, which can be made of any size by means of a sliding-board. The width of the coulters admits of being regulated by means of a screw and other apparatus; and five coulters may be used if necessary. A rod projects from the handle half

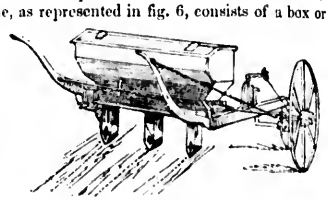

Fig. 6.

the breadth of the machine (not shown in the cut), to mark the ground, and by this mark the next advance of the machine is regulated.

There are other drill-sowing machines of greater breadth and size, likewise machines for dibbling beans; but they require no particular description. The rollers of wood or stone, employed to roll or press down the land which has been lately sown, are so common, that it will also be unnecessary to describe them.

Hoeing Implements.—The light implement called the hand-hoe is of use in cleaning turnips and other plants, but is altogether unsuitable for stirring the soil between the rows of extensive crops of turnips, potatoes, beans, &c. This heavy duty requires to be performed by animal labour by means of the horse-hoe. One of the best instruments of this kind is

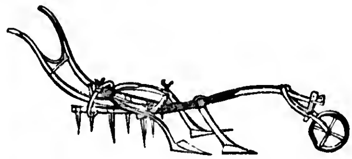

Fig. 7.

Wilkie's Horse-Hoe and Drill-Harrow.—This implement, a sketch of which is here presented (fig. 7), is guided and drawn like a plough. As soon as the infant plants appear above the surface, it is drawn betwixt the rows, thoroughly scuffling or cleaning the land from its numerous weeds. The depth to which its prongs and feathered feet go in the soil, is regulated by elevating or depressing the wheel in front. It likewise answers as a rake, by dragging along with it the heaps of destroyed weeds. Some horse-hoes are fitted with a movable mould-board at each side, by which the earth is heaped up on rows of plants; this is also done by a variety of the plough.

Weeding.

All lands are less or more infested with weeds, which are of no value either for ornament or use; on the contrary, they injure the crops by extracting the nourishment from the ground, and greatly impede cultivation by spreading their entangled roots beneath the surface. The manure deposited on the soil is destined exclusively for the support of what is meant to be raised, and every useless plant, therefore, which lives upon it, is so far noxious, and ought to be extirpated. Hence the common maxim, "A farmer should let nothing grow but his crops."

As prevention is always better than cure, the farmer should begin by preventing the growth of weeds. The seeds from which weeds spring are brought in some manner to the land from somewhere. Try to cut off this vicious produce at its source. Let all *bawks* or natural embankments forming boundaries to fields, be cleared of every species of weeds, such as thistles, docks, ragweed, rank grasses, &c., and let all road-sides near the fields be similarly cleared of their gay but unprofitable vegetation. If this were done generally over the country, a fertile source of foulness in land would be in a great measure destroyed. It is also desirable to sow clean seed for grain or other crops, and to use, if possible, those manures only which are free of the seeds of noxious vegetables.

Notwithstanding all ordinary precautions, lands, it is acknowledged, will develop a crop of weeds, because some seeds will lie uninjured for centuries in the soil, and the winds will waft others from great distances; such, in fact, is one of nature's provisions for covering the earth with vegetation. It has been ascertained that upwards of fifty different weeds infest arable lands, some of which are annuals, others biennials, but the principal part perennials, whose seeds will lie for a long period in the soil. The more common of these various weeds are the wild oat, the common thistle, dock, coltsfoot, ragweed, dent-de-leon, and chorlock or wild mustard, the latter particularly. To these is to be added that most tormenting weed, cough-grass or rack, which spreads its long cord-like roots beneath the surface, weaving the soil into a kind of matting. Annuals and biennials may be partially extirpated by a well-wrought summer fallow, or, if the soil be light, by the culture of potatoes or turnips, for the land in that case is well cleaned and dressed in spring, as well as hoed in summer. Hand-hoeing for this purpose is sometimes necessary. If, however, no ordinary process of teasing and cleaning the land extirpate the weeds, the more tedious and expensive operation of pulling must be resorted to. This will be absolutely necessary for the extirpation of chorlock, that flowering yellow weed which tinges the fields with its brilliant lustre in summer. When the crop is about a foot high, women or children should be employed in going carefully over the field, trampling down as little as possible, and pulling and carrying away in their aprons every stalk of the chorlock. The same thing may be done with the tall seeding-grass called the wild oat.

This process of weeding may be expensive, but it generally cleans the land, and repays itself by the increase of grain crop. According to experiments adduced by Sir John Sinclair, the increase of a wheat crop on a weeded over an unweeded land, was four and a half bushels per acre, and of other crops much more. "A six-acre field was sown with barley, in fine tilth, and well manured. The weeding, owing to a great abundance of chorlock, cost twelve shillings per acre. The produce of an unweeded acre was only thirteen bushels; of the weeded, twenty-eight bushels; difference in favour of weeding, fifteen bushels per acre, besides the land being so much cleaner for succeeding crops." With regard to oats:—"Six acres were sown with oats; one acre ploughed but once, and unmanured, produced only seventeen bushels. Other six acres, ploughed three times, manured and weeded, produced thirty-seven bushels. Ten bushels may be fairly attributed to the weeding, and the other ten to the manure." It is justly observed by the same authority, that however anxious farmers may be to have their lands *tithe-free*, it is of still greater importance to have them *weed-free*. There is much truth in the observation; for the agriculturist who suffers his lands to bear crops of weeds, pays dearly for his neglect in his diminished produce, and has the additional guilt of injuring his neighbours.

Dry and gravelly plains and hill-sides are frequently overrun with ferns, which occupy the space that ought either to be covered with good pasture or laid under the plough. The fern is so tenacious of life, and so firmly are its roots fixed in the soil, that repeated cutting, or the ordinary course of tillage, is unable to extirpate them. It has been mentioned as a good plan for eradicating ferns, that the land in which they grow should be partially flooded, or at least well moistened, by leading small surface water-channels across it.

Fallowing.

Fallowing signifies leaving the land for a certain time in a bare unproductive condition, during which it receives a rest from the labour of cropping, and is subjected to various processes of ploughing and harrowing, to pulverize the soil and destroy its noxious weeds. The value of fallowing for these purposes is a subject of considerable controversy; some ascribing to it numerous virtues, and others altogether condemning it, where green crops and good husbandry prevail. The truth seems to be, that fallowing is extremely useful for the purpose of working, pulverizing, cleaning, and otherwise improving, lands of a poor quality, after their first subjection to tillage; and that there its value rests.

The operations necessary for a well-wrought naked summer fallow commence after harvest. The first winter fallow ploughing is begun as soon as the hurry of harvest and wheat-sowing is over. If deferred till an advanced period of the season, and the weather sets in wet, the land becomes unfit for the operation. To prevent the bad consequences of too much rain at this period, that manner of ploughing and laying the ridges should be adopted which will best keep the land dry during the winter months, this being a most essential point. Strong retentive soils to which a summer fallow is more particularly applicable, should get an end-long ploughing, so deep as completely to turn up the soil from where it mingles with the subsoil or till.

When thoroughly pulverized, and freed from roots and weeds by the process just described, the fallow is ploughed end-long into gathered ridges, which are usually from fifteen to twenty feet broad. When the land is gathered into a furrow as deep as the soil will permit, the manure may be laid on. This is a very critical period; for if the weather becomes wet, the carting of the manure on fallow land of retentive wheat soils, is apt to poach and puddle it very much, by the pressure of the horses' feet and wheels of the carts. To prevent this as much as possible, the manure should be carried to the ground in single horse carts, with broad wheels, as they are less apt to poach the land than others. The manure is carted along the crown of the ridges, and is thrown out into heaps, of a size and at distances proportioned to the quantity intended to be applied; experienced workmen can generally measure both ground and manure accurately with the eye. People are now employed spreading the manure, and the plough immediately follows, in order that the dung may lie exposed as short a time as possible. The dung being covered, and the ridges raised, so as to admit the rain to run freely into the furrows, the land should remain untouched for a few weeks, that the manure may become decomposed. The period of decomposition is shortened, if the dung has been previously fermented.

The land may now be considered as ready to receive the seed furrow, which is generally given to it previous to the sowing. The ridge is again gathered; but as this ploughing is very slight, it does not raise the ridge much higher. Lime is frequently applied to fallow as well as dung, sometimes before the dung is laid, and sometimes after. In the first case, the lime is laid on just before the land is formed into ridges, and, if possible, a calm dry day should be selected for the purpose. After the lime is laid, the land should be immediately harrowed, to incorporate it with the soil. The second method is to lay the lime on just before the seed furrow is made; and if the ground be dry and the dung decomposed, this method will be found good.

The system we have described is referable to the heavier soils; when those of a lighter nature are to be fallowed, the cleaning process is not so difficult, and there is not the same risk from wet weather. If summer fallowing be judiciously conducted in the manner described, strong soils may carry repeated alternate crops of grain and pulse, without any intervening naked fallow, for perhaps six or eight years. But to preserve the beneficial effects of fallow on ordinary farm land, which is manured alone from its own produce, it is certainly the best and most economical plan to lay it down to grass with the crop immediately succeeding the fallow. Afterwards, successive crops of grain and pulse may be taken as its condition will allow, when broken up from lea previous to next fallow. Sir John Sinclair says: "It may be foretold of every farmer on a strong soil, in such a climate as Scotland, that his affluence and prosperity will always be in proportion to the excellent state of his fallows, every thing else being equally well conducted." Indeed, if fallowing is negligently or imperfectly performed, no land, however cheaply rented, can yield much profit to the farmer.

Farm Carts and Implements.

Two kinds of machines are in use for conveying produce to market and other purposes in husbandry—wagons and carts, and of these there are several varieties. Wagons with four wheels, and drawn by two or more horses, are acknowledged to be best adapted for conveying great loads to a great distance, and that is their principal merit. For all ordinary purposes connected with husbandry, the one horse cart with two wheels is preferable.

The Scotch cart, as it is called, is a most convenient and useful machine; and to add to its uses it may be rendered serviceable for carting hay or straw by placing a movable frame on its sides, as it is represented in figure 8.

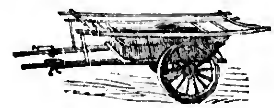

Figure 8.

The Scotch cart (without the frame) is suited for conveying any kind of material, dung, turnips, grain in sacks, &c., and usually carries from eighteen to twenty-two hundredweight, when drawn by only one horse; with a horse in trace, the weight may be augmented. In Scotland, all grain for market is carried in these one-horse carts, and to any distance. On such occasions one driver takes charge of two carts.

The following advantages of one-horse carts are enumerated in Loudon's Encyclopædia of Agriculture, the passage being apparently copied from a paper in the Annals of Agriculture, by Lord R. Seymour. "A horse, when he acts singly, will do half as much more work as when he acts in conjunction with another; that is to say, that two horses will, separately, do as much work as three conjunctively: this arises, in the first place, from the single horse being so near the load he draws; and, in the next place, from the point or line of draught being so much below his breast, it being usual to make the wheels of single-horse carts low. A horse harnessed singly has nothing but his load to contend with; whereas, when he draws in conjunction with another, he is generally embarrassed by some difference of rate, the horse behind or before him moving quicker or slower than himself; he is likewise frequently inconvenienced by the greater or less height of his neighbour: these considerations give a decided advantage to the single-horse cart. The very great ease with which a low cart is filled may be added; as a man may load it, with the help of a long-handled shovel or fork, by means of his hands only; whereas, in order to fill a higher cart, not only the man's back, but his arms and whole person, must be exerted." To these just observations it need only be added, that in many parts of England there is a wasteful expenditure in horse power, a couple of horses being often set to draw a clumsy wagon to market, containing a load which could with the greatest ease be drawn by one horse in a machine of less ponderous dimensions.

Every well-conducted farm establishment is now, or ought to be, provided with a variety of small but useful machines—for slicing turnips or potatoes, chopping hay or peas straw, bruising beans, peas, or oats, weighing-machine, &c., all which, of the newest construction, are to be seen at the establishments of agricultural implement makers. Utensils for cooking food for cattle, dairy utensils, and tools for manual labour, need not here be particularized.

There are now agricultural implement makers in cal towns both in England and Scotland; for a list of the newest implements and their prices, at some of these establishments, we refer to Jackson's Treatise on Agriculture, published in connection with Chambers's People's Editions.

MANURES.

By repeated cropping, the best soils become exhausted of their fertile properties, while naturally indifferent soils require the administration of certain qualities, before they will yield a due return to the labours of the husbandman. There are, no doubt, soils so naturally rich in some parts of the world, that, though used for twenty or more years in growing successive grain crops, they show no indications of impoverishment; yet even these must in time be exhausted, and therefore, in all circumstances, manures, or artificial fertilizers, require the consideration of the husbandman. In our own country they are of the first importance.

Manures are of two classes, both of which have distinctive characters, and perform different offices in the economy of vegetation. The first of these comprehends all animal and vegetable decomposing matter, and is principally employed in feeding the plant, augmenting its size, and sustaining the vital energy. The second operates more on the soil and decomposing matter than in directly contributing to the support of the vegetable. The first kind has been called animal and vegetable, and the second fossil, manures. Under this second class are ranked not only lime, marl, and gypsum, but sand, gravel, and clay, so that all the meliorations which are effected on soil by blending and compounding the original earths, are compressed within its limits.

The animal and vegetable manures, which are putrescent in their nature, are foremost in importance and dignity. They consist of certain elementary parts of animal and vegetable substances, elaborated by a natural chemical process in the course of the decomposition or decay of the bodies. The excrementitious matter, or dung of all animals, is no other than the remains of the vegetable or animal food which has been received into the stomach, undergone there a partial dissolution, and been thrown out as unserviceable for the further nutrition of the system. From this universal decay of organized matter, and its conversion into fluids and gases, it would seem that animal and vegetable substances, and excrementitious matter, are resolvable into each other, and are only different parts of the same original principles. The essential elements of them all are hydrogen, carbon, and oxygen, either alone, or in some cases united with nitrogen. Conveyed by liquids or moist substances into the ground, these elements are sought for as nourishment by the roots of plants, and so form the constituent principles of a new vegetation. Inasmuch as flesh consists of a greater concentration of these original elements than vegetables, the manure produced by carnivorous animals (man included) is always more strong in proportion to its bulk than that discharged by animals who live only on herbage. Experience fully proves that all animal and vegetable manures are but varieties of one kind of principles; their actual shape and appearance being of much less consequence than the degrees of strength in which these principles reside in them.

Whatever be the value of the elementary principles of manures, practically they are of no use as manure till they are disengaged by putrefaction. It may be further observed, that putrefaction is in every instance produced by the elementary principles being set at liberty either in a fluid or volatile state. If a quantity of stable dung be piled into a heap, and freely exposed to all varieties of weather, it soon heats and emits a stream of vapour, which is often visible as a cloud over it. These vapours, and also the odours sent forth, are gases escaping, and the heap is constantly diminishing in weight and volume; at the end of six months, if there have been alternate moisture and warmth, not above a fourth of the original essential material remains to be spread on the field; there may be in appearance nearly as much substance, but it is comparatively of little value—the real manure is gone, and what remains is little better than a mass of unputrefied rubbish.

It may be safely averred, that no principle connected with agriculture is so little understood or thought of as that which has been now mentioned. We therefore crave the most earnest attention to it by every reader of these pages. Generally speaking, the excrementitious matters thrown to the dung-hill are treated with perfect indifference as to the effects of exposure and drainage away in the form of liquids. It cannot be too strongly stated that this is a gross abuse in farming. The putrescent stream contains the very essence of the manure, and should either be scrupulously confined within the limits of the dung-hill, or conveyed to fresh vegetable or earthy matter, that it may impart its nutritive qualities.

A knowledge of this important truth has led to the practice of making compost dung-heaps, in which the valuable liquids and gases of different kinds of manure are absorbed by earth, or some other substance, and the whole brought into the condition of an active manure for the fields. Hitherto, it has been customary to speak of dung-hills, but there ought to be no such objects. The collection of manure from a farm-yard and offices should form a dung-*pit*, not a dung-*hill*; and the manner of making and managing the contents of this pit on the best principles is well worthy of our consideration.

Farm-yard Manure.—The situation of the dung-pit should be near the stables and cow-houses, and placed so low that all streams of urine from them should flow at once into it, so that nothing be lost. It may be three or four feet deep, and of a size proportionate to the stock of cattle usually kept by the farmer. It is not necessary that it should be built round with a wall, or have a perpendicular descent, as it may slope gently inwards, and deepen gradually towards the centre. It should, if possible, be covered by a roof, to prevent the action of the sun. If the bottom be found firm, impervious, and capable of containing the juices, no further trouble is requisite, and the work is complete; in many instances, however, it will be necessary first to puddle with clay, and then line the bottom with flag-stones. Into this pit, earth, with refuse straw, should be brought, and strewed over the bottom and sloping sides, to the thickness of from nine to twelve inches, and this will form an inferior layer to absorb all that portion of the liquid manure which naturally runs to the bottom. The pit is now prepared to receive all kinds of animal and vegetable manure, which, when brought, should be always laid evenly over the surface. In Scotland, such dung-pits are common, and in the course of accumulation, a young or wintering stock of cattle is allowed to go at large upon the whole; the animals being at the same time fed on a proper allowance of straw. Care is also taken to mix, in laying on, the dung brought from the cow-house, stable, and piggeries, so that the rich excrement of the well-fed animals may be incorporated with that of a poor description from others. It is likewise of the utmost importance, though too frequently neglected, to convey to the pit the entire liquid refuse of the farm-yard, provided the quantity be not so great as to make it advisable to have a separate pit for its reception.

It is customary to cart away the material of the dung-pit at convenient opportunities (usually during the frosts in winter), to a place in the fields, near where it is to be used, and there pile it up in a quadrangular heap of about four feet in height. Dung, carted out in this manner, is ready for the turnip husbandry in June, and the practice is otherwise convenient. It may, however, be stated, that for want of attention to principles already explained, such dung-heaps, by exposure for months to the weather, must lose some of their valuable properties. In every instance, the dung-heap in the fields should be placed in a hollow situation, with a substratum of earth, and should have a scattering of a few inches of earth over it, and around the sides, to keep in the volatile gases. When the dung-pit has been thus emptied, it may again be progressively filled as before; and when it is carted out in any of the spring months, it will be found necessary to turn it once, or oftener, for the purpose of accelerating the decomposition of the strawy part of the mass. It may be of use to know, however, that the dung required for fallows for wheat in autumn, may be less putrefied than that for turnip crops.

Liquid Manure, Bone-Dust, &c.—The urine of cattle is of great value as a manure, and this is so well known to the farmers of Belgium, that they use tanks for collecting the liquid from the cow-houses, and thence they pump it up, and pour it over the land at the proper season. When mixed with vegetable refuse, moss, or earth, it forms an excellent compost. It is deeply to be regretted that so little is known on this subject; and such is the carelessness of farmers and cottagers, that the urine from the cattle stalls is in most cases suffered to go completely to waste. The value of night-soil and human urine as manures is equally great, but both are much neglected in British agriculture. Without entering minutely into details on this point, it may be stated, that the offensive odour of all excrementitious matter may be neutralized by an intermixture of gypsum, or lime and earth, and in this state be used as most valuable manure. Bone-dust is now used as a highly nutritious manure on light soils; and it is reckoned that 100 bushels are equal to 40 cart-loads of farm-yard manure. Common sea-salt, when judiciously administered in moderate quantities on arable land at the time of fallowing, has been found of great value for its manuring and cleaning properties. It promotes fertility, is a remedy against smut and rust, preserves the seed from vermin, and is particularly useful in increasing the produce of grass lands.

Guano.—The sterile soils of South America are manured with a substance called guano, consisting of urate of ammonia and other ammoniacal salts, by the use of which a luxuriant vegetation and the richest crops are obtained. Guano is the excrement of sea-fowl, accumulated for centuries on the ground; being collected by the natives, it is now imported into Britain by merchants for the use of agriculturists. The increase of crops obtained by its application to land is said to be very remarkable. According to one authority, the crop of potatoes is increased forty times by it, and maize thirty times. This may be an exaggeration; but it is certain that guano contains ammoniacal salts in abundance, and other inorganic constituents which are indispensable for the development of plants. Like bone-dust, it is now sold by merchants in sea-port towns.

Lime.—Dry lime from the kiln is a powerfully exciting agent in agriculture. It possesses the power of decomposing animal and vegetable matter, and enters as an element into the fabric of plants; in certain cases it only alters the constitution of the soil. The great use of lime is to prepare newly broken-up land for successful cultivation. If moorish or waste soil is much infested with the tenacious roots of rushes, heaths, and other weeds which resist the mechanical action of the harrow, and yield slowly to putrefaction, the best mode is to till the ground, and allow it to lie in this state for twelve or eighteen months, or even two years, before applying the lime. It is then generally applied in autumn, and tilled in as soon as possible; but if not immediately tilled in, the soil with the lime on it should be harrowed, so that its decomposing effects may act as powerfully as possible upon the vegetable matter. After these operations, the land is sown two successive years with oats, without any fallowing but that described, and along with the second crop of oats some tenants sow it out in grass seeds for pasture. Others, after the first or second crop of oats, give the land a summer fallow for one season, or a green crop with manure. On the following season, another crop of oats is taken, along with which grass seeds are sown, and in this state is committed to pasture. In some cases, after tillage, the soil is allowed to lie for one, two, or more years, according to its nature, after which it is reduced to a complete state of pulverization by a well-wrought naked summer fallow. On the spring following it is limed, and the lime is well harrowed in along with grass seeds alone; and in the following season the land is committed to pasture. This, however, is a very expensive mode, and cannot be recommended to tenants whose lease is of a moderate length. It is decidedly the most enriching mode of laying down waste land with lime only for pasturage, as the energy which the lime communicated to the soil is not exhausted by grain crops.—(See article Improvement of Waste Lands.)

CROPPING.

Difference of crops successively on the same piece of land is essentially necessary in a right system of husbandry. Crops of the same kind have an exhausting effect, and experience proves that there must be a regular round or rotation, involving in particular a change from grain to green crops. A material use of green crops occasionally, is to weed and clean the land, for the land being in open furrows, may be trenched or hoed in such a way as to extirpate the weeds that spring up. Some lands become so foul, from negligent farming, that the only method of cleaning them is by putting them through a course of potato and turnip cropping.

Rotation on Clay Soils.—Clay soils are of various depths and fertility; and, like all others, differ materially according to the climate in which they are situated. All other circumstances being favourable, good clay soils are particularly adapted for the production of wheat and beans, and may be continued under these crops alternately, as long as the land can be kept free from weeds by drilling the bean crops. This is the most profitable course of cropping that can be followed, providing a sufficiency of manure be procured, and the drilled beans be alternately horse and hand hoed. The nature of the soil or other circumstances may render a crop of clover or rye-grass necessary occasionally for one year, and this can be succeeded by oats. This course may continue for six or eight years, or even longer, and will run thus:—1. Fallow; 2. Wheat; 3. Clover and rye-grass; 4. Oats; 5. Drilled beans; 6. Wheat. In this rotation, to procure full fertility and luxuriant crops, the soil ought to be recruited with manure every third or fourth year, the dung being first applied in the fallow year, and next to the bean crop. Whenever the soil gets foul with root weeds, which it will sooner or later do, another naked summer fallow must in most cases be resorted to, in order to extirpate the weeds; and this begins a new rotation.

Where circumstances are not favourable to the above rotation, the following may be advantageously substituted. It contains a variety of the crops usually cultivated, and by dividing the labour more equally throughout the year, may be carried on with a smaller number of horses, and consequently at less expense; 1. Fallow; 2. Wheat; 3. Drilled beans; 4. Barley; 5. Clover and rye-grass; 6. Oats; 7. Drilled beans; 8. Wheat; after which a new fallow begins a new rotation. In this rotation it is absolutely necessary that the land should have dung twice or thrice if possible, to ensure abundant crops throughout the course; and the proper periods of its application are—on the fallow before the first crop of wheat, on the clover stubble in the fifth year, and to the drilled beans the seventh year.

A favourite rotation on the strong lands of Essex is—1. Summer fallow, limed; 2. Barley; 3. Clover, first fed and afterwards kept for seed; 4. Wheat; 5. Beans, dunged; 6. Wheat; 7, Oats. It is a rule in Essex never to put in wheat in a fallow. Although two successive crops of white corn are justly objected to, on the best principles of cultivation, yet upon land of this nature both wheat and oats are frequently taken either before or after each other, without doing material injury to the soil. On the strong soils in the neighbourhood of Edinburgh, clover is found not to succeed when sown along with wheat, on which account barley is taken after wheat, and the grass sown along with it succeeds well. In the colder parts of Scotland, beans will not ripen in some seasons, and in these districts the clay soils are uniformly thin and sterile. On such soils and situations, the following rotation may be found to answer:—1. Fallow, with dung; 2. Barley, beans, or oats; 3. Clover, cut in the first year, and depastured for two or three years; 4. Oats; and a new rotation begins. By this method, the rotation is kept up for six or seven years, a period quite long enough, as the pasture on these cold and meagre soils, after the second or third year, will be found of little value; and after this, the soil will rather fall back than improve in fertility. But, as already mentioned, from the practice of furrow-draining, to which, even in exposed situations, these soils are subjected, a fallow crop of turnips is now superseding the naked summer fallow, which is of great advantage, as dairy farming is the principal object in these secluded districts.

In the south of England, the farmers consider that a clover ley is the best preparation for a crop of wheat; while in the north of England, and in Scotland, clover is more commonly sown with wheat or barley, and followed by oats, both because the oats are almost invariably found to produce a large return after clover, and from the wheat being better placed in the succession immediately after the fallow.

Rotation on Loams.—Every soil intermediate between absolute clay and sharp sand, has received the name of *loam*. Clayey loam, and loamy soils, in the rotation of crops, may be ranked as clay soils, and cropped exactly in the manner already explained, even though they should approach to the nature of light lands, from which they only differ in degrees of quality. Rich loam is the most profitable and the most agreeable to cultivate of any description of soil, as it almost uniformly produces abundant crops of all kinds, and affords excellent pasture. The mode of its management depends upon the nature of the subsoil. If this be retentive, and not furrow-drained, the soil will require to be subjected to a naked summer fallow every six or eight years, to free it from root weeds; and in this case, the steps of the rotation will be similar to those already described as suitable for the best clay soils. When completely furrow-drained, or if the soil lies on a porous bottom, a fallow crop of drilled turnips or potatoes will be found an effectual cleaning, and from the great value of these roots, they are in every way preferable to naked fallow. The rotation may then be as follows:—1. Turnip fallow; 2. Wheat, on such parts of the land as are freed from the turnips in time for that crop, and barley or oats on the rest; 3. Clover and rye-grass; 4. Oats after grass; 5. Drilled beans; 6. Barley; 7. Clover and rye-grass; 8. Oats; and this to be succeeded by turnips, or other green crop, to begin a new rotation. Some stop at the sixth crop, and make it wheat instead of barley, and then commence with turnips. To keep up the fertility of the soil, manure should be applied with the beans.

Rotation on Light Lands.—Light lands include all soils called sandy loam and loamy sand, which are merely gradations of the same. The general principles of management for this description of soil are precisely the same as those already described, and every rotation should be established on a well-wrought and well-dunged turnip fallow. The course of crops best suited for these light soils is—1. Turnips in drills; 2. Wheat or barley; 3. Clover and rye-grass; 4. Oats; and round again to a new rotation. On good turnip soils this rotation may be repeated indefinitely, provided the turnip crop be eaten on the ground, that the grass crop be pastured, or that the manure derived from the hay be returned to the ground. It will be necessary, however, to introduce occasionally the alternate system of pasturage, for without this, even with the most liberal treatment, it will scarcely be possible to keep up the fertility of the soil.

On good turnip soils, when what is produced on the farm is the only manure used, the following rotation may be found advisable:—1. Turnips; 2. Wheat or barley; 3. Clover and rye-grass; 4, 5, and, if necessary, 6. Pasture; 7. Oats; and round again. When manure is within reach, alternate white and green crops may be followed for a number of years, in this rotation:—1. Potatoes or turnips; 2. Wheat; 3. Drilled beans or peas; 4. Wheat or barley; 5. Potatoes or turnips; 6. Wheat or barley; 7. Clover and rye-grass; 8. Oats. The advantage of this course is, that it secures a good crop of clover, and it is practised near Edinburgh for this purpose; but wheat occurs too often in the rotation.

In the vicinity of London, Edinburgh, and Glasgow, the rotations are frequently—1. Potatoes; 2. Wheat; 3. Clover and rye-grass. By some, the clover is followed by oats, and the rotation again begins; others end the rotation with clover. Even with the manure which these short rotations secure to the soil, occasional pasturage must be had recourse to, if the soil is in any way exhausted.

Rotation on Sandy Soils.—Sandy soils are such as approach to the nature of sharp sand, having so little clay in their composition that they possess no adhesive quality, either in a wet or dry state. These soils require the most liberal cultivation, to produce either grain or green crops; for in the event of dry weather, they become so parched as to be unfit for the growth of almost any species of plant. The application of clay, marl, peat, earth, and manure, will be found materially to improve the texture of such soils, and their constitution will be ultimately changed to a sandy loam. When well manured, sandy soils produce good crops of potatoes or turnips: if possible, the latter should be consumed on the ground by sheep or cattle. It is difficult to make these soils too rich, and, from their nature, all the manure given them is soon consumed. Wheat, beans, or peas, do not succeed; barley, oats, and rye, are the only grain crops which yield a profitable return on these soils; and pasturage for a term of years is absolutely necessary. The following six years' rotation has been recommended for these soils:—1. Turnips, with dung, which are to be consumed on the ground by sheep; 2. Barley or oats; 3, 4, 5. Grass, pastured by sheep; 6. Rye or oats. The rotations on peat or moorish soils will be treated of in the section Improvement of Pasturage and Grass Lands by Topdressing, Tillage and Irrigation, on which account little may be said of them here.

In land situated in exposed and remote districts, the only grains which are cultivated are early varieties of oats, bear or bigg, and potatoes, as a change of seed for the more genial and fertile grounds. The following course of crops, proportioning the quantity sown to the manure supplied to the turnips and potatoes, may be followed in such situations:—1. Oats from old ley; 2. Turnips and potatoes, 3. Oats, barley, or bigg, sown with clover or grass seeds; 4. Hay; and then restored to pasture.

Rotations according to the state of Culture.—Having treated of rotations of crop under a variety of circumstances, we shall now consider the culture which arable lands may require; and this may be—1. The restoration of land to fertility which has become exhausted by over-cropping; 2. The management of land which has become very rich from being long in pasture; 3. The method of laying land for pasture which has been long under tillage; 4. The improvement of pasture-land by a short course of tillage.

To restore over-cropped land to fertility, the most liberal course of culture is necessary, and a tenant should therefore receive every indulgence from the proprietor. Where lime has been previously applied to the soil, it will not alone restore the ground to fertility. A summer fallowing with dung, or a fallow crop of turnips, and laying the land gradually down to pasture, are the true methods by which it may be brought back to fertility. If the turnips are consumed on the ground by sheep, bone-dust may be advantageously used, especially if the soil is light and friable. If composed of thin clay, and manure not easily obtained, a series of years will be necessary to restore the land, as the pasturage will be thin and unproductive. On light soils, pasturage will be found the most suitable for their improvement.

With regard to land which has become rich from long tillage, little need be said, the method of management being simple and well known. Over-cropping must be avoided, and care taken to keep up rather than diminish its fertility.

Summary of Rotations.—The rotations, as it will be perceived, vary considerably, according to the nature and wants of the soil, yet all possess a general resemblance, and embrace alternations of green with grain crops. It is necessary, however, to mention, that the land in time is apt to be injured by an unvarying routine, and seems to require changes in the character of those green crops which are usually reckoned to be so beneficial. In other words, there is a necessity for a change of rotations. This is done by either changing the green crops in the rotation, or alternating one rotation with another. The latter plan, which is called shifting from one course to another, is adopted by many of our best agriculturists.

Choice of Seed.—In choosing seeds, there are three rules that should be attended to:—1. That the variety to be sown is suited to the soil and climate; 2. The propriety of changing the seed; 3. That the seed has the appearance of being sound. Every species of grain has varieties which differ from each other considerably. In many districts the seed long used is still commonly sown, either from ignorance of better varieties, or fear that a change will not be attended with good consequences.

All seed should be allowed to arrive at full maturity before being sown, for the nourishment which the seed must yield to the plant in the first stage of growth can never be so great when this is not the case. The best cultivators choose the finest qualities of each species for seed; sowing them on the land best adapted for their growth. Some varieties are remarkably attached to particular soils, and certain degrees of fertility and moisture seem to suit them best. Others require a greater degree and duration of heat, and frequently take four or five weeks longer to ripen. Early sowing of these sorts ought to be resorted to.

Too sudden a change in climate and situation is hurtful; hence, Yorkshire seed has been found to answer better in Scotland than that brought from Essex. Many varieties may be introduced gradually, which would not answer if the habit of the variety were not a little consulted. The particular varieties of grain will be described under their respective heads, and the soils to which they are best suited.

Sowing.—The oldest established mode of sowing is by *broadcast*, or scattering the grain from the hand over the land which has been prepared for it. But this plan is not so economical, or otherwise so valuable as sowing in drills by machines. In Scotland, the usual method of sowing broadcast consists in the sower walking along the ridges, and at very regular intervals, so as to keep time with his steps, throwing a handful of grain before him by a wide sweep of the arm. He carries the grain in a sheet, which is slung round his neck and is open to the hand in front. A servant attends, to afford fresh supplies at the end of the ridges.

Culture of Wheat.—Wheat is the most important of all the grains, and its varieties are numerous. Among those now in cultivation, the following may be enumerated:—The bearded, the Dunglass, the golden ear, the velvet ear, the egg-shell, the hedge-wheat, the Essex dun, the Kentish yellow, the white and red Essex, the Mungoswell's, the Burwell red, the Hunter's, and the Georgian. A general division of wheats is made into white and red, with several shades between, and summer and winter. Winter wheat may be brought into the nature of summer, by altering the time of sowing. If winter wheat be sown at the period for putting summer wheat into the ground, in the course of two seasons the winter will become of a similar habit as the summer, and the same process will bring a summer wheat to be a winter one.

In general, the fine white wheats are preferred to the brown and red; but the latter is most profitable for wet adhesive soils and unfavourable climates, on account of its hardiness and ripening early. A red wheat, of great productiveness, has been recently introduced into Scotland from Mark Lane.

The variety of wheat most profitable to be produced must depend upon the nature of the soil, as land which has produced an indifferent crop of one may yield an abundant crop of another kind; and land is frequently found to yield better crops if the varieties be alternately changed. It has been observed, that a mixture of grain produces the heaviest crops, and that mixed flour makes the best bread.

The richer description of clays and strong loams are the best adapted for the production of wheat; but if properly cultivated and well manured, any variety of these two soils will produce excellent crops of this grain. Good wheat land ought always to possess a large quantity of clay and little sand; for although light soils may be made to produce good crops, yet the strong clay lands in general yield the heaviest grain. Sandy soils, being deficient in firmness, do not afford sufficient support to the roots of plants such as wheat, which do not sink far into the soil. There are light soils, however, made from decomposed granite, felspar, or clay-stone, compounded with vegetable matter, which produce excellent wheat.

"The season for sowing wheat is necessarily regulated by the state of the land, as well as of the season; on which account it is not always in the farmer's power to choose the moment he would prefer. After fallow, as the season allows, it may be sown from the end of August till the middle of November. On wet clays, it is proper to sow as early as possible, as such soils, when thoroughly drenched with moisture in autumn, are seldom in a proper state for harrowing till the succeeding spring. In the opinion of many experienced husbandmen, the best season for sowing wheat, whether on fallow, rag-fallow, or ploughed clover stubble, is from the beginning of September to the 20th of October; but this must depend upon the state of the soil and weather. In East Lothian, on dry gravelly loams, in good condition, after a clover crop, and well prepared, wheat has been known to succeed best when sown in November. After drilled beans, whenever the season will admit of ploughing and harrowing, wheat may be sown from the middle or end of September to the middle of November; after this season, the sowing of wheat ought not to be hazarded till the spring quarter returns.

"After turnips, when the crop is consumed or led off, and the ground can be properly ploughed, wheat may be sown any time betwixt the 1st of February and the middle of March; and it is customary to plough and sow the land in successive portions as fast as the turnips are consumed. It is only on turnip soil of a good quality, verging towards loam, and in high condition, that winter wheat, sown in spring, can be cultivated with success. When circumstances are favourable, however, it will generally happen that such lands, when wheat is not too often repeated, will nearly produce as many bushels of wheat as of barley. The wheat crops therefore, on an average of seasons, will exceed the value of the barley crop considerably; hence its culture is an object which ought not to be neglected."—(*General Report of Scotland.*)

Wheat is liable to certain fungous diseases, as, for example, smut, mildew or rust, &c. With a view of reserving the grain from these most injurious disorders, it is customary to prepare the seed by steeping or pickling it in a kind of saline brine, or diluted urine. Steeping or pickling is performed after the seed has been washed, by allowing it to lie for a time among stale urine, diluted with water, or salt brine, of sufficient strength to float an egg. The seed is put into tubs, containing as much liquid as will cover the grain a few inches, and allow it to be well stirred, so as to bring all the light grains to the surface, which are skimmed off as long as they continue to rise. Another way is to put the seed into baskets, which are immersed in the water, are easily taken out, and can be conveniently placed over an empty tub to drain. The seed is left for three or four hours in the chamber lye, or full six hours in the pickle, after which the liquor is drawn off, and the wheat spread thinly on the floor of the granary, where it is well sprinkled over with quick-lime slacked in the liquid. About half a peck of lime is sufficient for a bushel of wheat, and it should be well stirred, so that every grain may get a portion. If the seed is to be drilled, it should be passed through a coarse sieve after being limed, which will facilitate its progress through the machine. The grain will thus be quickly dried: and it should not lie more than six hours in the heap, then be spread out, and used the following day.

Some caution should be used in having the lime properly slaked, for if this is not done, too great a heat may be raised, which will destroy the vegetative principle. Doubts have been expressed of the efficacy of lime, and a solution of copperas is used on the Continent instead. Dry powdered lime would certainly have no effect, but when newly slaked it is very efficacious, as has been proved from experiment. It was found that a steep of lime-water alone, in which wheat was immersed for four-and-twenty hours, proved a powerful preventative of disease, while the good effects of unmixed brine were very inconsiderable.

Of the two kinds of steeps mentioned, urine is thought the most efficient, and it should be used neither too fresh nor too stale, as in the first state it is ineffectual, and in the second injurious. The seed should be sown as soon as dry; for if allowed to lie in sacks or heaps beyond a day or two, the lime may be very hurtful. Another steep, which is recommended by Sir John Sinclair, and is much used in Flanders, France, and Switzerland, is a weak solution of the sulphate of copper, or blue vitriol. The modes of using it are as follow:—

Into eight quarts of boiling water put one pound of blue vitriol, and while quite hot, three bushels of wheat are wetted with five quarts of the liquid; in three hours the remaining three quarts are added, and the wheat is suffered to remain three hours longer in the solution. The whole should be stirred three or four times during the six hours, and the light grains skimmed off. After the wheat is drained, slaked lime is thrown on it to facilitate the drying. Another way of using it is to dissolve five pounds of the sulphate of copper in hot water, and add as much cold water to this as will cover three bushels of wheat. The wheat is allowed to remain five or six hours, or even longer, in the liquid. After two or three bags, of three bushels each, have passed through the liquid, one pound more of the sulphate for each bag should be added; and after twelve bags or so have passed through, new liquid will be required.

To this we may add, that sowing the land with salt is considered an excellent means of preventing liability to any of these fungous disorders.

Rye.—Rye is usually sown on light soils, and does not require so much care as wheat; it suffers less by being sown on the stubble of another corn crop, or upon its own, and it is not unusual to grow it on the same land two years in succession. This grain is frequently sown to be cut for soiling instead of winter tares, and in England it is frequently used for early sheep-feeding, cut green, without obtaining a grain crop from it. It is extremely useful to breeding flocks, as it comes forward earlier than tares, and affords good food when other sustenance is scarce. Sometimes it is sown on the margins of fields of other grains, to protect them from poultry, which do not use it as food, and will seldom go amongst it.

Barley.—Barley is a much hardier grain than either wheat or rye. There are six varieties of this grain, distinguished by the number of rows in the ear, four of which are cultivated in Britain. The kinds which have been recently introduced into Scotland are the Chevalier, Annat, and other sorts; but the two-rowed and four-rowed, called bere or bigg, have been most extensively cultivated. In its culture, barley requires a clean, rich, mellow loam, moderately retentive, and on clays, tempered with sandy mould, or containing a certain portion of chalk and sand, it is found to succeed well. On poor wet soils it is never successful; and every kind of land on which it is cultivated should be well wrought and thoroughly pulverized. If the preceding crop has been wheat, the land should undergo three ploughings before barley is put into the soil. Barley usually follows turnips in the rotation, but it is found to grow very well after potatoes. It is thought best to have the turnips eaten on the ground when this can be accomplished; and if the preceding crop has been potatoes, the land should be well ridged up, in order to have it as dry as possible. The application of lime and earth, earth and dung, or urine, is thought of great advantage to the barley crop, and even to plough in the turnip leaves is beneficial. If the plough is not sufficient to pulverize the land properly, the harrow and roller ought to be used to accomplish this. In most cases more than one ploughing is given, but after a winter furrow the grubber may be used instead. When turnips have been consumed on the ground, it is much trodden down, and will require two ploughings; if this is not given, the soil should be well harrowed and rolled. If grass is sown along with barley, the land should be harrowed after the roller has passed over it, which covers the grass seeds. Barley should be sown as soon after ploughing as possible, when the land is fresh and moist, in order to obtain equal and speedy vegetation. The best season for sowing barley is from the beginning of April to the middle of May; but it has been sown a month after this with success. The bere or bigg sort is sometimes sown in October, and called winter barley.

In Scotland, clover and rye-grass are sown immediately after barley, and the seeds are covered by the last harrowing; a light grass harrow being sometimes used for the purpose. Rolling is practised by some immediately after, while others prefer allowing the plants to come above ground; the small clods in this case act as a shelter to the plants, which is of great service in frosty weather.

Oats.—The oat is suited to climates which are too cold for wheat or other grain crops, and therefore thrives in high regions better than in low-lying countries. When land is broken up, either from a state of nature or from pasture, oats form the first crop, as they may be repeated for a series of years without injuring the soil. They are also the best crop to follow clover, and are sometimes sown with clover and grass seeds. They often follow potatoes and green crops, and in either of these cases, the land should be well ridged up in the winter. When the seed is sown, the land should be completely harrowed, and then rolled across the ridges. A mixture of oats is generally sown along with tares, to prevent them from falling and rotting on the ground. In this state they are cut green, and form an excellent food for cattle and horses. A change of seed from hot to cold, and cold to hot, is always to be recommended; and the quantity of seed must depend on the nature of the soil and the variety to be sown. On poor soils, from the plants not spreading, oats should be sown thick. The Hopetoun, and many other varieties, do not tiller out, and therefore require more seed to be sown. The quantity of seed necessary, varies from four to seven bushels per English acre, and broadcast sowing is generally practised.

The usual time of sowing is from the beginning of March to the end of April: early sowing is to be preferred, as the grain is of better quality; but late sowing produces the greatest bulk of straw. Sowing in autumn has been practised with success in some parts of Ireland, the seed being put in early in October; but this is only done on dry sandy loams. This period of sowing is not likely ever to become common in Scotland, from the coldness of the climate. Scotland and Ireland seem better adapted for growing oats than England, and in the former countries greater attention is paid to their cultivation than in the latter, where the poorest soil and the worst tillage are thought sufficient for them. The produce differs materially according to the soil, climate, and the fitness of the particular variety for the land. The maximum quantity, soil and climate being favourable, may be estimated at seventy bushels, and the minimum twenty bushels per acre; the average being about four quarters. Oat straw is preferred to any other as fodder for cattle, as it is considered more nutritive.

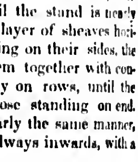
REAPING AND HARVESTING.

The ripeness of grain is shown by the straw assuming a golden colour from the bottom of the stem nearly to the ear, or when the ear begins to drop gently, the corn may be cut. Although the straw may be green from the ear for some distance down the stem, yet if it be quite yellow at the bottom, and for some distance upwards, the grain requires no further nourishment from the earth, and if properly harvested will not shrink. These indications of ripeness may suffice for wheat, barley, and oats. It was formerly the practice to cut grain with a saw-edged sickle; but this has given place to a larger instrument, with a smooth edge like a scythe. The reapers are usually divided into bands of six or seven, with a binder to each band. When the ridges are less than eighteen feet broad, three reapers are usually placed upon each ridge, the middle reaper making the bands with which the sheaves are bound up. When four reapers are placed upon one ridge, as is usually the case when the ridge is eighteen feet broad, two bands are laid upon one ridge; and we are enabled in this way to manage twelve reapers, placed on three ridges, stooking the corn all in one row upon the middle ridge. When the crop is very strong, however, it is often found necessary that each binder should stook by himself.

In harvesting oats and barley, each shock or stook is formed of ten sheaves placed in two rows, the head of each sheaf leaning upon the opposite one, and a sheaf on the top at each end. They stand usually due north and south, so that each side may receive equal benefit from the sun. The straw of wheat being longer than that of oats and barley, the stooks of the former are made larger, having six sheaves in each row, and one on the top at each end. When the crop is thin, half stooks are frequently set up; and to forward the drying process, the end sheaves are now generally omitted when the weather is good; but this should never be done where the climate is uncertain, as it exposes the corn to rain.

Oats and barley are now frequently cut with a scythe, which is either plain, or furnished with a bow or cradle, in order to lay the grain evenly in one direction. Wheat is almost universally cut with the sickle; and if the weather keep good after this operation is performed, it will be ready for stacking in the course of five or six days. Barley is frequently cut with the scythe in England, but the sickle is generally used in Scotland. Barley and oats require to lie ten or twelve days, as they are more or less mixed with clover, before being ready for stacking. The clover ought to be completely withered before the corn is stacked; and, indeed, it requires the greatest caution on the part of the farmer, in ascertaining whether his crops are in a proper state for being carried to the stack-yard. The best way for judging of this, is to take out a handful from the centre of the middle sheaf on the lea side of the stook, repeating this on several parts of the field; and if the knots or joints of this are dry and shrivelled, the crop may be led home in safety. All corn crops should be cut as near the ground as possible, for by this a great addition is made to the straw, and consequently to the future manure.

Stacking.—When the crop is thoroughly dry, it is led home to the stack-yard on open spar-built carts, and built into stacks so constructed as to afford complete shelter from the weather. The stool or bottom upon which the stack stands was formerly made of loose straw or brushwood; but in the best managed farms, it is now the practice to construct the stacks on stands made of stone or brick, or upon pillars made of stone or cast-iron, sparred across with wood or iron. These stands are formed so as to prevent the access of vermin, which is calculated to effect a saving of two bolls in thirty; and many have funnels from the top to the bottom of stacks, to admit a free current of air. In Scotland, the stacks being mostly round, a sheaf is first placed on its butt-end, in the centre of the bottom or stand; around



this others are placed, also upright, but with a slight inclination of the head inwards, until the stand is nearly filled. The stacker then places a layer of sheaves horizontally on the outside of these, lying on their sides, the ear-ends inwards, and, pressing them together with considerable force, he continues to lay on rows, until the outside sheaves are as high as those standing on end. The whole stack is filled up in nearly the same manner, the ear-ends of the sheaves being always inwards, with a regular inclination downwards and outwards to their butts, and the centre of the rick being higher and not so compressed as the outside. Proper attention to the sloping of the sheaves is necessary from the foundation of the stack, but particularly so at the intake of the inner layers, that part being always left more open. When this is done, the stacker sets up an outside circular row of sheaves, having their butt-ends projecting a few inches beyond the body of the rick, after which the outside layers come gradually inwards, until the roof is drawn to a narrow circle, when two or three sheaves placed upright completely fill up the stack. The topmost sheaves are then firmly bound with a few turns from the middle of the straw rope, the two ends of which are fastened on opposite sides of the stack. When carefully built and thatched, a stack will completely keep out rain, and be quite secure from high winds. Materials for thatching, and straw ropes, should always be made before harvest, so that no delay may arise from this, in the event of wet weather. The thatcher stands upon a ladder, placed on the sloping roof of the stack, and lays on the straw in handfuls from a quantity placed within his reach. One end of the straw he thrusts into the butt of a sheaf, and the other end hangs over the stack. He thus progresses up to the top, making each handful overlap the other; and on the top of the stack a thick covering of short straw is placed, over which a straw rope is carried perpendicularly, dividing the roof into equal sections. He then covers the topping of short straw with long thatch coming to a point, and ties the upper end of this with a straw rope into a peak, the form of the top resembling in appearance an umbrella. With the aid of two assistants on the ground, the thatcher now places a number of tough oat-straw ropes over the covering, to secure it firmly. These ropes are made to cross each other at angles, and are fastened either to the butts of the sheaves, or to a rope firmly bound round the body of the stack.

Stacks are sometimes constructed in England on a timber platform raised upon stones, and over the stack the framework of a perfect barn is placed, which can be either tiled or thatched. This is said to afford greater security to the crop, and to be less expensive than annually thatching. The price of erection is said to be comparatively trifling, when the convenience of such buildings is considered; and they have been known, when well put up, to last for thirty years.

Thrashing is either performed with the flail or the thrashing-mill. The use of the latter we by all means recommend in preference, on arable farms of above one hundred acres in extent. The machine may be driven by water, horse, or steam power, according to circumstances. Several improvements have been made on thrashing-mills since their first invention: the unthrashed corn is now made to pass through two revolving rollers, while it is acted on by beaters placed lengthwise upon a larger cylinder or drum, which moves at the speed of 2500 feet in a minute. The great essential in thrashing is to have regularity of motion, and the grain to be equally fed into the rollers. One man should be employed to feed in the corn; one man, or two boys, to carry the sheaves, and a woman to untie and place them on a table near the feeder. Other persons are employed in raking and carrying the thrashed straw to the straw-house, where it is built. When the machine is driven by steam or water, it is generally the case that one or two winnowing-machines, according to the power employed, are attached to the thrashing-mill, and thus the expense of preparing the grain for market is considerably lessened. A powerful machine will thrash from two to three hundred bushels in nine hours, and, allowing for wages and wearing of machinery, the expense of preparing grain for the market by the use of water or steam, is under one penny per bushel.

Winnowing or dressing.—Winnowing is a process performed by the aid of wind, by which the chaff of corn is separated from the grain. Winnowing-machines, or fanners, as stated before, are sometimes attached to thrashing mills, and they are a necessary appendage to every farm, either in conjunction with the thrashing-mill, or separately. Some farmers winnow their grain by hand-fanners, which are thought to be steadier in their motion than when driven by machinery, and consequently the grain is more thoroughly cleansed. After thrashing, the grain is regularly dressed in the clean corn room, by means of fanners, riddles, and sieves; and this final dressing is regulated according to the state in which the grain comes from the thrashing-mill. By the process of winnowing, chaff, bits of straw, the seeds of weeds, and other refuse, are separated from the grain; and it is a wise precaution to boil the latter before putting them on the dunghill, which will effectually destroy their vegetative powers. The different qualities of grain are also separated from each other, by which it is rendered more valuable than when the good and bad are mixed together. The thorough cleaning and dressing of grain are of great importance to the farmer, and he will find it added to his profit in the end to have this effectually done.

If wheat has been injured by wet, it is thought advisable to kiln-dry it moderately, and allow it to lie for some time before being ground. When grain is infected with smut, it should undergo three washings before going to the mill, which will be found an effectual way of cleaning it. Mere ventilation has been recommended for this purpose, but washing is as simple, and a far more certain operation.

Barley undergoes a process called hummelling, by which the awns are broken off from the grain. The machine is composed of a vertical spindle enclosed in a cylinder, and furnished with arms which act upon the grain. It is sometimes attached to the thrashing-mill, and sometimes driven by a separate power. The grain is put in at the top of the cylinder, and as it passes through, the awns are broken off by being struck by the arms attached to the spindle. A more simple process is, after the barley is thrashed, to take off the head of the drum and put on another cover of tin, perforated with small holes about three sixteenths of an inch wide. The barley is passed through the rollers, and by this the awns are rubbed off. Another method is to lay the barley on the barn floor, and beat it with a square instrument consisting of parallel bars of iron fixed on a frame, with a handle attached, which is worked in the same way as a pavier's rammer.

After being dressed and made ready for market, grain should be kept very dry, in a granary free from damp, and which is impervious to the incursions of vermin. It is, however, the best plan not to thrash grain till it be required for market, because it loses in weight, or shrivels in bulk, by keeping. It also loses in weight, though to a much less extent, by being kept long in ear in stacks; and therefore the sooner grain is thrashed and carried to market, the greater will be the return, supposing there be no rise in price.

GREEN CROPS.

No farming can be said to be perfect unless it involves a due alternation of *green* with *grain* crops. The more foul the land is with weeds, green crops of the drill kind are the more necessary, because, in the course of cultivating green crops, we have an opportunity of hoeing and trenching the land, not only once, but repeatedly, and of thus exhausting the seeds of weeds lodged in the soil. By administering manure, and this mode of cleansing, the necessity for *fallowing* is in a great measure obviated. But green crops also fulfil the important purpose of feeding live-stock and producing manure. The constant exhaustion of the soil, be it even very fertile, demands a periodical nourishment, and this is best done by means of live animals. It is customary on the well-organized farms of Norfolk, East-Lothian, &c., to manufacture manure on a large scale by means of *soiling;* that is, feeding cattle in houses or an open yard with turnips, the cattle at the same time treading on the waste straw of the farm, and thus using up a material which would be otherwise lost. Sheep are also turned into pens on turnip-fields, to eat up the turnips from the drills, and the droppings greatly enrich the spot. It is customary in Scotland for low-country farmers to buy cattle lean at the end of autumn, and sell them fatted to a certain extent in spring; and all this trouble is taken only for the sake of their manure. We shall now mention what constitutes the principal green crops.

Beans require the same sort of soil as wheat, namely, heavy clays, and should be sown in drills. Some suppose that beans exhaust the soil; but this is scarcely probable, from wheat always yielding a good crop after them. In preparing the ground for beans, it ought to be ploughed after harvest, or early in winter, that the soil may be mellowed with the winter frosts. The furrow should be deep, but, before sowing, the land should be drained of its superabundant moisture. Sow as soon as winter is over, or never later than the end of March in Scotland Four bushels of seed to the acre are sufficient; but it is common, for the sake of improving the fodder, to mix peas with the beans, to the extent of one bushel of peas to six of beans. Beans require frequent weeding with the horse-hoe. The crop, if late, should be carried to another field to dry, and thus leave the land for operations necessary for the wheat crop.

Peas grow best when mixed with beans, as they by that means gain a support for their slender trailing stalks. They, however, grow on a poorer soil than beans, such as a sandy loam, and neither too moist nor too dry. They are improved by lime and marl manures. Drilling, as in the case of beans, is greatly preferable to broadcast; and from four to five bushels of seed per acre is reckoned a proper allowance. The early kind of peas may be sown at any time till the end of May, but the late must be sown in February or March.

Tares are a valuable crop, both for soiling and feeding cattle. Tares are of two sorts, winter and summer. The seed of the summer tares should be put into the ground at intervals, from the end of March till the end of May, so as to furnish successive cuttings. The winter tare requires to be sown in September or October; and in early spring it is a very valuable food for cattle and sheep.

Clover and Rye-grass.—These are the most valuable artificial grasses that can be grown by the farmer. They should never be sown except when the land is in the best condition; if possible, with the crop immediately following a summer fallow, or after turnips or potatoes. Thus, in all well-manured and well-dressed land, clover and rye-grass are mixed with the crop of grain, being either sown at the same time or at a suitable period after. When the grain crop is cut in harvest, the tops of the young clover are perhaps cut at the same time, but this is of little consequence; the great bulk of the grass crop comes into maturity among the remaining stubble, and is then either scythed for hay or for feeding animals in a green state. When sown on land on which grain has been sown, it is customary to roll the ground, to assist in covering the light seeds. Great care requires to be employed in choosing proper kinds of clover and grass seeds, as there are many worthless sorts.

Many farmers [illegible] purpose to prolong the rotations, and prevent the too frequent repetitions of the clover crop, substitute a crop of peas or tares after the barley, sowing the clover after the wheat or barley in the next rotation, which makes the time between the two clover crops to be seven instead of four years. The crop of peas they consider as by no means remunerative, yet from the additional crop of clover reaped in the second rotation, they find themselves compensated for the deficiency in the peas. Surface applications are now administered on an extensive scale in improved districts, for the sole purpose of procuring an abundant crop of clover and rye-grass. Soot is one of the ingredients which is applied to the greatest extent, and it has uniformly the effect of strengthening and forwarding the crop. Liquid manures are also extensively used, and the urine of the cows is collected with great care, for the purpose of being applied to the soil. Liquid manures are much more lasting in their effects, and seem better adapted for clover than soot. Saltpetre is likewise much used, and forms an excellent top-dressing for seedling-grasses. It is by such means as these that the agriculturists of the Netherlands have been able to keep up the fertility of their lands, in the cultivation of clover, through time immemorial; and those, therefore, who neglect such measures, have themselves to blame when their clover crops fail. The whole of the agriculture of the Netherlands rests upon the cultivation of clover, which not unfrequently yields a heavy crop the first year, two and even three abundant crops the second, and, if allowed to stand another year, will yield a good crop, and afterwards be excellent pasture for cattle, till ploughed up to receive wheat seed.

Turnips yield a most profitable crop for the maintenance of live-stock; and they are also useful as a green crop, by permitting an effectual cleansing of the land from weeds. The leaves being large and spreading, they afford a shade which retains the moisture, and tends to decompose any vegetable matter in the ground. Turnips are divided into various classes, in each of which there are several varieties. The more common classes are the round or globe-shaped, the depressed or Norfolk, and the fusiform or oblong, the latter being better known by the name of Swedish. They are also sometimes known by their colour, as the white, the yellow, (including the Swedish,) and the purple-topped. The white, with the purple-topped, is early, particularly suited to those light soils where sheep are fed, and requires less manure. It must be consumed, however, as soon as possible, or is apt to run to seed or to be injured by frost. Upon the whole, the Swedish or yellow turnip is now preferred to most others, and yields the heaviest crop. It requires to be sown early, or from the beginning of April to the end of May; the seed should be given liberally, or at the rate of about three pounds per acre. In all cases, the sowing ought to be in drills, to permit an effective hoeing when the crop is getting up. After being sown on a well-ploughed field, the roller must be employed to press all smooth on the ridges. The plants will in general make their appearance about ten days or a fortnight after they are sown, according to the quality of the soil and the state of the weather. When the leaves are about two inches high, a horse-hoeing is given between the ridgelets, to cut up the weeds close to the plants. The hand-hoe is then introduced, to thin the crop, leaving plants standing at intervals of from eight to ten inches apart, the Swedish kind being somewhat [illegible] This distance is thought quite sufficient [illegible] neither too large nor too small in size. The [illegible] turnip, when allowed too great a distance, is apt to become very large, and its nutritive juices are found to be quite lost. The Swedish and other hard turnips should be allowed sufficient room to become as large as possible, for their nature is such that there is no fear of their ever being over bulky. The hand-hoeing and thinning are generally performed by women and boys, and three expert hoers will go over an acre a-day. A few days after the hoeing, a small swing-plough is used to make small ridgelets between the rows; and when weeds are still in abundance, it will be necesmay again to horse or hand-hoe the ground, which levels the intermediate ridgelet. After all weeds are thoroughly destroyed, and the thinning is accomplished, the earth is sometimes gathered up about the plants by means of a small plough with two mould-boards. This operation, however, is objected to, on the plea that the earth prevents the bulbs from growing, and also when the produce is to be consumed on the ground, the sheep may be injured by falling into the hollows between the rows. On wet soils, the earthing up is very beneficial, as it allows the free discharge of superabundant moisture; and when the weather is frosty, the earth is an excellent protection to the plants. Turnips may either be consumed on the fields where they grow, on grass fields, in fold-yards, or in feeding-houses; and in the vicinity of large towns they are sold to cowfeeders. A cheap and expeditious mode of lifting turnips has been practised in Ireland. The tops are first shaved off with a scythe, and given to young cattle, and the bulbs are ploughed out of the soil, which being afterwards harrowed, they are left entirely free of the ground. The turnips are then gathered into carts, commencing at the top of the field and going regularly down, so that none may be bruised; and it is calculated that six labourers will lift an acre of turnips by this method in a day. *Mangel wurzel* is introduced with advantage as a variety in green husbandry, and, as a food for cattle, supersedes turnips.

Potatoes.—Crops of this valuable plant usually enter into a course of husbandry, particularly in the neighbourhood of populous towns, where a ready market can be obtained. The usual period of planting in the British islands is the end of April or beginning of May, for the late and more common sorts. The early kinds, which are not kept for permanent stock, are planted in March. The potato harvest is in October or beginning of November. It has been customary to plant by sets or cut pieces of the potato, each having an eye or point of germination; but the numerous failures of the crops have introduced the practice of setting the whole tuber, which is preferable. In the large farms of Scotland, they are set in drill furrows (previously well manured), at a distance of eighteen inches apart, and six inches of earth is turned over upon them by the horse-hoe. When the plants appear above the surface, they are repeatedly earthed as may be required; this, with the weeding of them, is done by hand-hoeing. Potatoes are very susceptible of diseases, which cause failures of crop; but there is reason to believe that this arises from some kind of mismanagement, as, for example, producing again and again without change of seed, lifting of seed after frost, rot from wet seasons, heating of heaps after lifting, &c. Recommending all who feel interested in potato husbandry to consult the treatise of Mr. Jackson, formerly alluded to, for information, we need here only say, that the preventives of disease, likely to be most successful are frequent changes of seed, bringing seed from quite a different soil, not too frequent cropping from the same land, spreading out to dry after lifting, and careful protection from frost during winter. They are best preserved in pits, a layer of potatoes and earth alternately to a height of four feet, and finally covered with earth on the top and sides. This is considered the condition most natural to the potato, and is found to succeed well.

Hay-making.—When the grass has arrived at or near its full growth, but before the seed is perfected, it should be cut down by the scythe for hay. A short time after being mown, it should be turned over in full swathes, without being scattered. If not in a fit state to be cocked the first day after cutting, it should be put into small hand-cocks, as soon as its state of dryness will allow; from these it should be gathered into larger ones, and when its condition permits, put into tramp ricks. The gathering of the hay is generally performed by women and boys, some carrying and others raking up what may remain. Let it be remembered that the less the hay is exposed to the sun, the better is its flavour and strength. In wet seasons, the utmost care will be required not to stack the hay while moist; for then, like moist sheaves of grain, it will heat, and either burst into a flame, or be seriously damaged in quality. The criterion for good hay is, that it should be greenish in colour, be perfectly dry, and possess a sweet odour. In this state it will be eaten with avidity by horses

---

Within the limits assigned to us, it is impossible to impart directions for every step in husbandry; and we shall consider our task accomplished if we have impressed certain leading principles of agriculture on the minds of those hitherto ignorant of them. Not to be misunderstood, we shall specify, in conclusion, what we consider important truths in connection with this subject:—1. Land, to be well cultivated, must either be the property of the farmer, or be let on a moderately long lease. 2. The husbandry must be *convertible*, that is, on a precise system of rotation of grain and green crops. 3. Cattle must be kept, to produce a due share of manure for the fields. 4. If the land be moist, or liable to heavy rains, it must be effectually drained. (See next article.) 5. Deep ploughing, and thorough pulverizing of the soil are essential. 6. The fields must be properly fenced and of easy access. And, lastly, no land will be profitable as a speculation, unless closely superintended by a farmer whose mind is alive to all its varied wants, and neither rash in running into experiments, nor prejudiced against well-authenticated improvements.

IMPROVEMENT OF WASTE LANDS—SPADE HUSBANDRY.

According to the best authorities on the subject, it appears that the British islands contain upwards of thirty millions of acres of waste lands. Much of this large division of our territory is situated at an altitude which places it beyond the possibility of improvement; but at least one half is believed to be improvable, and capable of being rendered suitable, if not for tillage and grain crops, at least for the feeding of cattle. The question as to the propriety of improving the really improvable waste lands of the country, is, in any individual case, to be satisfactorily answered by ascertaining at what expense, in relation to the probable profit, the process may be performed. A barren rocky desert may be rendered productive by covering it with soil and manures brought from a distance of miles, aided by years of skilful tillage; but will the cost of these operations be fairly returned by the profits of the produce? Gold itself may be purchased too highly, and so may agricultural improvements. We do not throw out this idea for the purpose of discouraging, but of cautioning proprietors and farmers of lands. In all projected improvements, they will require to ascertain, in the first place, what will be the probable return, within a moderate length of time, for their outlay—always keeping in view the prospective prices of rural produce during the period. Such, at least, is the principle of calculation which ought naturally to guide all proprietors of extensive tracts of waste ground, the outlay on which is to be strictly pecuniary. With reference to those who propose to improve wastes chiefly by an expenditure of time and personal labour, the calculation will take a similar turn; and the question will be, whether that time and labour could not have been employed more profitably in another line of pursuit. Leaving this, however, for further discussion in the sequel, we proceed to point out, *first*, to those whose situation in life and inclinations lead them that way, the means to be adopted, according to the best principles of science and lights of experience, for reclaiming large or small portions of waste lands, and the results which may be expected to reward their enterprise; and, *second*, the best plans which may be followed for improving patches of ground by spade-husbandry, and establishing thereupon small cottage farms, suitable for the support of a comparatively humble class of families. In the treatment of these certainly not unimportant subjects, we shall of course refer chiefly to the condition of waste lands in the United Kingdom; but the improvement of wastes in the colonies or in foreign countries will also be understood to be included, and in each case we will endeavour to adhere closely to practical details.

IMPROVEMENT OF MOSS LANDS.

The greater portion of what are usually called waste lands, are stretches of peat-bog or moss, covered by a thin benty grass and tufts of heath. This remarkable species of land is found to a very great extent in Ireland and Scotland, often in the midst of beautiful and productive tracts of country, but generally in high-lying districts, which are somewhat defective in point of climate.

Peat-mosses are supposed to be occasioned by the destruction of ancient forests, either by the hatchet or from natural decay. The trees found at the outskirts of these mosses appear to have been cut down, while those in the interior appear to have decayed by the gradual process of time. It is believed that the trees thus left upon the ground would soon become covered with moss, lichens, &c.; and the free drainage of the land being obstructed, aquatic plants, such as reeds, rushes, horsetail, and marsh trefoil, springing up and decaying, would leave a strata of soft vegetable matter, which every succeeding year would increase. These plants grow in greater or less abundance, according to the quantity of moisture on the ground; and this may account for mosses being deeper in some parts than in others. The hollows would naturally retain moisture in larger quantities than the level ground, and here the aquatic plants would be most prolific, and the hollow gradually become filled up. The peat, which has been in this manner formed, is therefore a compound vegetable substance, which, although it has undergone a change, has not been entirely decomposed; probably the cellular tissue, or transparent vegetable matter has decayed, while the woody fibre still remains. Water is indispensable in the formation of moss; and according as the ground is very wet, or only so to a certain extent, different plants will be produced. On ground completely saturated with water, various species of moss grow, to the almost total exclusion of other plants; but if the land should in any way become drier, reeds, rushes, marsh trefoil, horsetail, and other plants, spring up in the place of the moss. The quality of the moss may be judged of from the plants which grow upon it; all the moss tribe, the horsetail and the marsh trefoil, are fibrous, and difficult to decompose, while reeds, rushes, and sedge, are comparatively easy of decomposition. Peat-moss possesses an astringent quality, which has the power of preserving bodies immersed in it, and even keeps itself from entirely decaying. This power is supposed to arise from the carbonic and gallic acids which issue from decayed wood; and vegetable gums and resins will also have the same effect. The tannin principle exists, as is well known, in the oak; and the pine contains much both of resinous and astringent matter. Many mosses are formed upon decayed trees, and the wood most commonly found is either pine, birch, hazel, or oak; and in these cases the presence of the tannin principle is easily accounted for. It is also highly probable that the plants themselves, by the action of natural agents, may have acquired an antiseptic or antiputrefying quality. It is certain that acids of considerable strength exist in some mosses; and it is mentioned by Lord Meadowbank, that in preparing peat-moss for manure, he used lime to destroy a vitriolic salt of iron, which he says abounds in peat-mosses. In some cases, lakes and pools of water have been filled up by the accumulation of moss; and it has been observed that fermentation occurs where this has taken place. Gaseous matter is evolved, and the neighbourhood of such a moss is generally unhealthy; but true peat soils are always salubrious.

The reasonable question has sometimes occurred to inquiring minds—whence the substance of peat-mosses? for stagnant water alone could not have produced many feet deep of solid matter. This question is answered by chemistry. The vegetation which springs up in the form of aquatic plants, absorbs carbonic acid gas from the atmosphere, and a carbonaceous deposit is made in the form of vegetable fibre, or dead vegetables in the form of mould. Mr. Johnston, in his Lectures on Agricultural Chemistry, makes the following observations on this subject:—

"When lands are impoverished, you lay them down to grass, and the longer they lie undisturbed, the richer in vegetable matter does the soil become. When broken up, you find a black fertile mould where little trace of organic matter had previously existed. The same observation applies to lands long under wood. The vegetable matter increases, the soil improves, and when cleared and ploughed, it yields abundant crops of corn. Do grasses and trees derive their carbon from the soil? Then how, by their growth, do they increase the quantity of carbonaceous matter which the soil contains? It is obvious that, taken as a whole, they must draw from the air not only as much as is contained in their own substance, but an excess also, which they impart to the soil.

"But on this point the rapid growth of peat may be considered absolutely conclusive. A tree falls across a little running stream, dams up the water, and produces a marshy spot. Rushes and reeds spring up, mosses take root and grow. Year after year new shoots are sent forth, and the old plants die. Vegetable matter accumulates; a bog, and finally a thick bed of peat is formed. Nor does this peat form and accumulate at the expense of one species or genus of plants only. Latitude and local situation are the circumstances which chiefly affect this accumulation of vegetable matter on the soil. In our own country, the lowest layers of peat are formed of aquatic plants, the next of mosses, and the highest of heath. 'In Terra del Fuego (says Darwin), nearly every patch of level ground is covered by two species of plants, which, by their joint decay, compose a thick bed of elastic peat. In the Falkland Islands, almost every kind of plant, even the coarse grass which covers the whole surface of the islands, becomes converted into this substance.'

"Whence have all these plants derived their carbon? The quantity originally contained in the soil is, after a lapse of years, increased ten thousand fold. Has the dead matter the power of reproducing itself? You will answer at once, that all these plants must have grown at the expense of the air—must have lived on the carbon it was capable of affording them, and as they died must have left this carbon in a state unfit to nourish the succeeding races." In other words, the substance of peat-mosses is a deposit from the atmosphere, which is evidently a universal source of subsistence to vegetable life.

Though thus composed of a deposit of dead vegetable matter, which is a basis of fertility to new vegetation, peat-mosses are not in a condition to be actively useful till freed of superabundant moisture, and compounded with siliceous (sandy) materials. Where the subsoil, however, is composed of gravel or sand, it is necessary that the peat and these bodies should be mixed together, so as to form a soil The first of these methods was planned by the late Lord Kames, and performed with distinguished success on his estate of Blair-Drummond, in the county of Perth. The first process performed by Lord Kames, was to construct a ditch through the centre of the moss, through which a stream from the river Teith was directed. Branch ditches were cut in all directions from the main one, the water from which poured itself into the river Forth. The whole estate was divided into portions, and let to small occupiers of land, who received the most favourable terms from the proprietor, as an inducement to carry out his views. The peat earth was cut into small pieces, and cast into the running waters, by which they were carried into the Forth, and thence to the sea. After the moss was cleared away, the trees of the ancient forest appeared, and presented new difficulties to the workmen, which were only overcome with great labour and expense. The roots of these trees were firmly fixed in the earth. and the tanning process which they had undergone in the moss seemed to have added greater strength to their root-branches. They were completely eradicated, however; and in the year 1782, no fewer than 336 acres of ground were reclaimed and brought into cultivation. His son, who inherited his father's spirit of enterprise, pursued the same plan; and in ten years more, the population on the estate had increased to 764 persons, who cultivated 444 acres of land. In 1805, by survey, 577 acres were cleared; and in 1814, between 800 and 900 acres were under cultivation. Lately (1842), the whole has been cleared. Thus, an extensive tract of country, which at one time was entirely useless, has been brought, by labour and perseverance, to bear rich crops; and the land is now worth from £3 to £5 per acre of annual rent. In this case, the subsoil was good earth, and the operation necessary was the removal of the peat-moss, so that the subsoil might be made the surface soil.

Where the subsoil is gravel or sand, a very different operation must be performed; and this, perhaps, is the most common species of moss ground. Of whatever nature moss ground be, it is evident, that, so long as the stagnant water remains, no useful crop can be cultivated; and to remove the superabundant moisture, by means of draining, must be the first operation of the improver. In some cases, where the moss is not too wet, a road may be run through the land, which will greatly facilitate the after-operations. Should such a road be cut, and a deep ditch on each side of it formed, the next operation is to open drains leading to some main channel, by which the water can be carried away. The moss land should be sounded in different places, to ascertain where the greatest depth lies, and when this is found, the main drain should be drawn as nearly in that tract as possible. Where there are beds of great depth, it does not appear expedient that the drain should be cut to the bottom at first; and, indeed, a difference of opinion exists as to whether moss land should be thoroughly drained at first, so as to render it perfectly dry. Mr. Boroughs, the author of a treatise on waste land, is of opinion that the surface water only should be drained off at first; while Mr. Blackadder of Stirling asserts that there is no danger of over-drying moss by draining. This may depend upon whether or not the moss be in a decomposed state. When moss is rendered too dry, it becomes a fibrous inert matter; and, as is the case with all other lands, it will be easier to work afterwards when moderately moist. With regard to the size and form of drains, it was formerly the practice to make these wide and deep, and at about fifty yards apart. The lateral pressure of the water upon the sides of these drains, however, pressed them so much together, that in the course of years they were scarcely traceable. The depth of the main drain will depend in some measure upon the depth of the moss; and if the average depth of this be twelve feet, the drain may be seven or eight feet deep, and about the same width at the top. The sides should be made sloping, so that the bottom of the drain will not be above two or three feet wide; and this difference between the top and bottom will gradually diminish in consequence of the lateral pressure. It may in some cases be necessary to perforate the main drain with holes, if any water appear to be coming up from below. The next operation is to form smaller drains leading into the main channel. Experience has shown that the most effectual way of draining deep moss is to insert drains at small distances from each other, and as deep as the nature of the moss will allow. They may be either of tile or stone, and guarded from choking by overlaying turf. Moss ground drained in this effectual way, will be, first, surrounded with the main drain which carries the water entirely away from the field; second, cut into divisions with open drains, at from forty to sixty yards apart, leading into the main drain; third, these divisions will be again divided into smaller portions by the covered drains at five yards' distance from each other.

In this manner the moss will be effectually relieved from its superabundant moisture, and the next operation is to level the land with the spade. In cases of dry moss, of course the draining is needless, and may be omitted. The land being either naturally or rendered artificially dry, should never be ploughed with a peculiar kind of plough made of wood, and covered with sheet-iron, which can be freely used if the ground is free from rushes, heath, &c. If these plants be growing in profusion, however, it is thought better to burn them down to the surface before ploughing. After the ground is ploughed, some prefer rolling and others burning, as the next operation. If a roller is used it should be made of iron, with plates of thin iron six inches deep, five inches from each other, and placed at right angles to the cylinder. Repeated rollings from this will cut the sod fine enough to allow the mixing of it with sand or gravel. Instead of rolling, it has been found advantageous to burn the soil turned up, as a more effectual way of decomposing the roots of such plants as the cotton-grass, mat-grass, marsh trefoil, &c. If the land is burned, it should be ploughed immediately after, preparatory to being mixed with other substances. The next step in the process is to cart sand or small gravel to the field, and spread it over the whole to the depth of three inches. Now plough all down, as the first regular dressing and culture. Thus prepared, the land is ready for cropping, and it is generally allowed that the best plan is to sow with grass seeds; the kinds recommended for this purpose are the timothy grass, cocksfoot-grass, and ribwort. Wheat, however, has been taken from newly reclaimed moss land; and potatoes, if the moss is in the neighbourhood of cultivated ground, will be found a very valuable crop to be disposed of for seed. Italian rye-grass has been highly recommended for bog land, and also rape, to be followed by oats or barley.

One of the most remarkable experiments ever made in reclaiming peat land, was performed some years ago in the neighbourhood of Edinburgh, and is mentioned at length in Jackson's Agriculture. It was as follows:—"On the high and bleak grounds which lie on the boundaries of Mid-Lothian and Tweeddale, at the distance of twelve or thirteen miles south from Edinburgh, there existed, from time immemorial, an extensive tract of moss, which was dug for its fuel, and exhibited the appearance of precipices of peat rising from sour pools of water, the whole broken and disorderly, and of little or no value whatever for pasture. A portion of this dismal-looking land, which lies about eight hundred feet above the level of the sea, being purchased by Mr. John Carstairs, a gentleman in Edinburgh, he commenced operations for reclaiming it. The purchase was made twenty-five years ago, at which time there was neither tree, house, nor road, upon the whole moor; and a more hopeless attempt than that of bringing such a tract of utterly waste land into cultivation, cannot well be conceived.

"The first effort of Mr. Carstairs was to gain access to the ground, by forming a road to it from the great road between Edinburgh and Dumfries. He extended the road at a great expense through the centre of the moss, and built a handsome suit of farm offices at the western extremity. The moss was then subdivided into fields of various sizes, by running stripes of plantation in squares, protected by ditches and turf dykes; and the fortunate formation of a new line of road between Edinburgh and Peebles, going through a corner of his property, gave energy to his exertions. Well-formed metal roads, made at his own expense, now intersect and cross each other all over the property, affording easy access to every part of it.

"The extent of the land to be improved was from 500 to 600 acres; and this he partitioned into fields, protected by plantations and turf walls, as we have just described. The land was also effectually furrow-drained, and levelled on the surface by manual operations. The remainder of the process of reclamation consisted in the application of lime and sandy materials, and tillage. Year after year the land gradually assumed a better appearance, and yielded a better crop. At first, the oats which grew upon it were scanty in the extreme, but now the land is in heart, and yields good crops, and also excellent pasturage.

"To quote the words of Mr. Carstairs himself upon the state of this moss when he got possession of it—It was mostly composed of white foggy stuff, standing from two to twelve inches deep of water, and not worth sixpence an acre of rent, as it would carry neither man nor beast. In 1834, he commenced cutting sheep drains twelve inches wide and twelve inches deep across the whole moss, dividing it into regular riggs of from twelve to fourteen feet broad each, which has had the desired effect of drying the moss completely, the hollows being filled up with the sods taken from the drains. This drainage cost him £43, 11s. In the summer of 1836 and 1837, a great extent of it was top-dressed with earth and lime; and now it bears the horses and carts over its surface freely, although the moss is from ten to forty feet in depth.

"The application of gravel and sand effects perhaps more improvement, in consolidating and decomposing the moss, than either lime or dung. This is shown to be the case from the circumstance, that moss land, when overflowed, is rendered fertile by the deposit of earthy matter from the water. In imitation of this operation, Mr. Carstairs is in the habit, at every breaking up of the reclaimed moss land from pasturage, of giving a liberal application of clay, gravel, or sand. This he effects in an easy manner, by means of a portable railroad. The application of the gravel, and the committing of the land to pasturage, or irrigated meadow, for a given number of years, have the effect of consolidating it so much, as in most cases to render it capable of being ploughed by horses; but when rather soft, pattens are put upon their feet to prevent them from sinking.

"By the means detailed, some very large fields of the moss ground have been so reduced in depth as to allow the subsoil, formed from the application of clay, gravel, &c., to be brought up by the plough and incorporated with the moss. Complete furrow-drainage keeps the soil and subsoil always dry; and now this ground presents fields of as fine and as fertile vegetable loam as can be seen in the whole county, which nothing but their great elevation prevents from being equally valuable. The chick, the sorrel, the nettle, and other weeds, which usually infest moss land when first brought into cultivation, have entirely disappeared—a sure indication that a complete melioration of the land has been effected.

"When the depth of the moss is considerable, the under stratum, from being more decomposed and consolidated, is uniformly of a much better quality for agricultural purposes than that on or immediately below the surface. To get rid of this inferior soil, Mr. Carstairs has frequently resorted to burning; and even in this operation, the effects of lime and other earthy applications, some years previously put on, is singularly valuable. They not only make the moss burn more freely, and at a more uniform degree of depth, but the ashes are rendered highly valuable as a manure to the succeeding crops, by being mixed with the lime. Thus, by frequent applications of any earth or lime, but particularly clay, and occasional burning, the worthless moss soil becomes progressively reduced in depth, and fertilized."

The expense of draining and preparing moss land depends on many local circumstances. The usual cost is from £12 to £15 per acre; but much has been done at £7 or £8 per acre. The expense, in either case, is far the most part repaid in a very few years; and then good land, which may be let for £2 or £3 an acre per annum, may be said to have been absolutely conquered from the wilderness, and added to the productive soil of the country.

DRAINING.

In some countries the ground is naturally so dry, and the climate possesses so little moisture, that instead of drainage, the land may require to be irrigated profusely with water at certain seasons of the year. The lands, generally speaking, of England, Scotland, and Ireland, are of a very different character. There are few parts of the country where drainage, from superabundant moisture, is not requisite; and, therefore, the operation of draining should be thoroughly comprehended by every practical agriculturist.

The necessity for draining arises either from the water rising to the surface from springs beneath, or from the subsoil being of a retentive quality, by which water lying upon the surface, or absorbed in the upper stratum, cannot escape. According as either of these causes predominate, or are associated with each other, so must the process of drainage be regulated and conducted. All soils, those of a very sandy or gravelly nature, in some situations excepted, are more or less liable to over-wetness, either from their own nature or the nature of the subsoil on which they rest. Clay, whether on the surface or beneath, is, from its adhesive nature, very retentive of moisture. A mixture of clay, sand, and sometimes iron, is also found very impervious; and even loams, although they absorb water freely, generally retain too much. Rich black loams usually lie on a clay subsoil, of different colours and textures, according to which the land will be in various degrees wet. The wetness in these loams is not so apparent as on other soils, but it is in every case as injurious, and as great a necessity exists for its removal. Land subject to springs is usually very varied in its surface, and may require a number of drains before water is effectually removed.

Draining is the operation of drawing off the water from the over-moist land, and of reducing the soil to that proper degree of dryness which renders it available for productive tillage. Many moist lands, though undrained, will produce crops of grain, and the crops will be the heavier the dryer and finer the season; but, taking these lands on a common average of seasons, it will be found that they often greatly fail in yielding even moderate crops, and that, at the very best, their crops are inferior in bulk and weight to those of grounds which have been subjected to a thorough process of drainage, and the kind of tillage consequent upon such an improvement. The outward mark of all undrained arable land is, that little or no grain grows in the furrows. The crop is seen to run along the centre of the ridges, dwarfing gradually off to the sides, where it disappears, thus leaving a large portion of every field with no crop at all. Wherever land is observed in this condition—and apparently the greater part of that in England is so—there is a want of drainage. The practice of making narrow heaped-up ridges, and deep furrows at their sides, is a proof of the land being badly drained. With a right method of drainage beneath, no portion of the surface is lost for cropping; the crop is at liberty to grow all over the field, and the furrow is only a slight indentation, to mark off the divisions for the reapers in harvest.

Drains are of several kinds, according to the nature and situation of the land. Some drains are conduits built with stone, others are conduits filled entirely with loose stones, between which the water percolates and escapes, and others are constructed with tiles of a particular form. Of whatever description, main and tributary drains are required. We shall describe a main and an inferior drain, in the language of one of the most experienced writers on the subject, Mr. Smith of Deanston:—

"The main drain should be directed along the bottom of the chief hollow or valley of the grounds, where the whole or greater portion of the drains can be led into it. If any lesser hollows occur in the field, they must also have their proportional mains or leaders. The bottom of the main drain should be at least 3 feet, and, if possible, 3½ or 4 feet under the surface where it passes along; and it should have throughout as uniform a fall as the nature of the ground will admit.

"It should be flagged in the bottom, or, where flag-stones are expensive, built as an inverted arch, to prevent the possibility of washing away under the side building. The dimensions necessary will depend on the fall or declivity, and the area of the land from which it has to receive water. With a fall in no place less than one foot in 100 yards, a drain 10 inches wide and 18 inches deep will void the rain water from 100 acres. It is of great importance to make the open area of such drains narrow and high, as smaller bottoms and covers will suit, and be less liable to give way; and the current of water being more confined, mud and sand will be less apt to settle in the bottom. Let the sides be smoothly and securely built with flat stones, either with or without mortar; and let strong flat covers be placed over, or, where such are not to be found, rough simple arches may be built with thin stones and mortar, for the bottom and cover, packing the haunches of the arch well up to the sides of the cut. Where lesser hollows occur crossing the fields, it is necessary to cut submains along their bottoms, about 3 or 3½ feet deep, and having openings of suitable dimensions formed by inverted stone couples, or with drain tiles, or, where a very large flow of water has to be provided for, with an inverted tile, and a covering tile placed above the bottom one, or with larger tiles made on purpose.

"There should be a cross submain at the bottom of every field or stretch of drains, to receive the water from all the parallel drains; and such drain should always be cut six inches deeper than the drains running into it, that the water may have a free drop, which will prevent the lodgment of mud or sand at their junctions or mouths. Open cuts or ditches, either as mains or submains, should never, except from necessity, be adopted, being apt to get filled with mud and grass, by which water is thrown back into the drains, which often chokes them; besides, the loss of land, annoyance in ploughing, constant expense of cleaning, and the unsightly appearance of the thing, are serious objections.

"Having thus provided a main drain, with submains flowing into it, matters are prepared for setting off and executing the parallel frequent drains in the body of the field. The drains can be executed at any season, when the weather will permit; but the spring and summer are most suitable for the work. It is best to execute the drains when the field is in grass, as it can then be done in all weathers in a more cleanly manner.

"In laying off the drains, the first object for consideration is the nature of the subsoil. If it consist of a stiff strong till, or a dead sandy clay, then the distance from drain to drain should not exceed from 10 to 15 feet; if a lighter and more porous subsoil, a distance of from 18 to 24 feet will be close enough; and in very open subsoils, 40 feet distance may be sufficient. When the ridges of the field have been formerly much raised, it suits very well to run a drain up every furrow, which saves some depth of cutting. The furrow being thereafter made over the drains, the hollow is filled up, and the general surface ultimately becomes level. When the field is again ridged, the drains may be kept in the crowns or middle of the ridges; but if it is intended to work the field, so as to alternate the crowns and furrows, then the ridges should be of a breadth equal to *double* the distance from drain to drain; and by setting off the furrows in the middle between two drains, the crowns will be in a similar position; so that, when the furrows take the place of the crowns, they will still be in the middle betwixt two drains, which will prevent the risk of surface water getting access to the drain from the water furrows by any direct opening."

Small tributary drains, made with broken stones, and covered with turf, to prevent the earth from filling them up (called *rumble drains* in Scotland), are in most places falling into disuse, and are superseded by drains made with tiles. The tile drains are peculiarly available over the greater part of England, where there is a scarcity of stone; and both there and elsewhere they will soon constitute the only kind of field drainage in use. The tiles for these drains, which are made at most brickfields, are simple in construction. There is a flat tile for the bottom, and a semicircular tile to place upon it, with the concavity undermost. In hard-bottomed land, the sole tile is sometimes disused. The tiles measure from 12 to 14 inches in length; and being placed neatly in a row, close to each other, a channel of 4 inches wide and 6 inches deep is formed; the water is admitted by the seams or interstices, so as readily to flow away. A little straw, stubble, or loose furze, is placed immediately over the upper tile, by which the chance of stoppage by the intrusion of earth is removed. The depth at which the tile drain is laid is 24 or 36 inches, as above, which, being covered with 10 or 12 inches of gravel or stones, allows a sufficient depth of soil above for the operations of subsoil-ploughing. When the depth of the drain is three feet, and the soil a retentive clay, it is frequently filled up for about a foot with stones above the tile, and turf laid above the stones, the rest being made up with surface earth. Figure 1 represents a section of a tile-drain of the proper construction. It will be observed that the bent tile laid on a flat sole, is advantageously placed for carrying off all the water that may trickle through the earth and stones above, and cannot be easily choked up with soil.

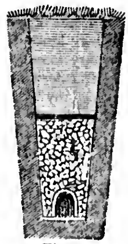


Fig. 1.

In cutting drains, three kinds of spades will be required—a common working spade, one a little narrower, and the third the breadth of the bottom of the drain. The cuttings should be done smoothly and neatly, preserving a descent throughout; and the tiles should not be laid till the cuttings have been carefully inspected. The terminations of the tile-drains may be led into subterranean mains, or into the shelving banks of open rivulets or sunk ditches; but in the latter case, their mouths will probably require to be protected from the intrusion of vermin, or from external injury. In planning the lines of drains, the straightest side of the field should be selected, the first being laid off as parallel as possible, and the others formed at the distances thought necessary.

In some places, from the extreme levelness of the land, or from obstructions in the subsoil, it will be found difficult to carry off moisture by drainage in the regular manner, and the leading of converging drains to a pit in a low part of the field, will be the only course open for adoption.

The drainage of sheep pastures is often not less necessary than land for tillage: it improves the grass, and, by drying the surface, renders the ground more salubrious—dry pasturage being indispensable for sheep. The mode of draining adopted for hilly sheep-walks is very simple. On the sides of hills, open drains a foot in depth, and from eighteen inches to two feet broad at the top, are cut, with a gentle slope towards a rivulet into which they are to discharge themselves. They are made to slope in different directions, and thus form so many furrows, which draw off the trickling moisture of land springs, and the superabundant rain which falls. In the south of Scotland, the sheep-walks have been prodigiously improved by these simple and unexpensive drains.

SUBSOIL-PLOUGHING.

It has been seen, in treating of mosses, that ground chiefly composed of inert vegetable matter, or peat, may be greatly improved by supplying a due proportion of sand or gravelly material, carted from a distance or raised from the subsoil. The same thing may be said of all lands which have been deteriorated by repeated cropping. A time comes when the silica and other earthy bases are found to have been abstracted in the crops, and fresh materials must be added.

The process of earthy restoration may be accomplished by scattering new materials upon the fields; and this might be easily accomplished in many parts of the country, so far as silica or fine sand is concerned; but the readiest and cheapest process in most situations will consist in trenching the subsoil, and gradually assimilating it to the mould above. The subsoil, or that portion of the under stratum which lies out of reach of the ordinary plough, may already be so good as to be available for bringing towards the surface, and in such cases it admits of easy and profitable management; but in most instances in our country, the subsoil is hard and stony, and will require to be trenched, and lie for a time in its underground position, before it is ready for mixing with the upper mould.

The most efficient instrument for trenching the subsoil on a large scale, is the subsoil-plough, invented by Mr Smith of Deanston, whose account of it we shall take the liberty to introduce.

"In the design, two essential points were kept in view:—1. The construction of an instrument that would effectually open up the subsoil without throwing any of it to the surface, or mixing it with the active or surface soil; 2. To have an implement of the easiest possible draught for the horses, while it was of sufficient strength and weight to penetrate the firmest ground, and resist the shocks on the largest stones. The extreme length of the plough is about 15 feet. From the socket at the point of the beam to the first stile or upright, 6 feet; from thence to the back of second stile, 19 inches; from thence to the outer end of holding handles, 7 feet; from the sole to the bottom of beam at stiles, 19 inches; length of head or sole-bar, 30 inches; from heal of sole to point of sock, 46 inches; broadest part of sock, 8 inches.

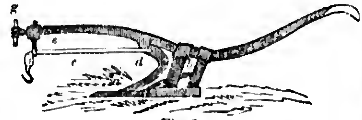

Fig. 2.

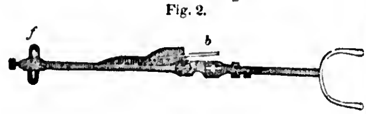

Fig. 3.

The coulter is curved, and in order to prevent its point being driven from its place by stones, it is inserted to the depth of an inch in a socket (*a*). The lateral dimensions of the sole-piece are 2 inches square. This is covered on the bottom and land side with a cast-iron sole-piece, to prevent wear. The sock goes on the head in the usual way, and from its feather rises the spur-piece (*b*), for the purpose of breaking the subsoil furrow. When the subsoil consists of very firm clay, or other hard and compact earth, the feather and spur-piece may be dispensed with, and a plain wedge or spear-pointed sock, such as those of the old Scotch plough, may be used. The draft-bar (*c*), of 1¼ inch round iron, is attached to the beam at the strong eye (*d*), and passing through an eye in the upright needle (*e*), is adjustable to any height or lateral direction, being movable in the socket (*f*), at the point of the beam, and can be made fast at any point by a pinching-screw wrought by the lever (*g*.) By the proper setting of the draught-rod, the direction of the power of the horses is so regulated as to render the guiding of the plough easy at any depth or width of furrow. The beam is about 5 inches deep at the middle, and 1¼ inch in thickness—towards the draught end it tapers to 3 inches deep, and 1 inch thick—at the holding end, where the handles branch off, it is 2 inches by 1. The whole weighs 440 lbs. imperial. This appears an enormous weight, and most people are alarmed at the strength and weight of the implement; but after repeated trials with lighter ploughs, those of the dimensions and weight now described have been found to be at once the most efficient, the most easy of draught, and the easiest for the ploughman to manage."

When a field is to be trenched, a common plough, drawn by two horses, goes before, throwing out a large open furrow of the active soil. The subsoil-plough follows in the wake of the common plough, slits up thoroughly and breaks the bottom, and the next furrow of active soil is thrown over it. This large subsoil-plough is a kind of *horse-pick*, breaking up without raising the under-stratum to the surface. The atmospheric air being by this means freely admitted to the subsoil, the most sterile and obdurate till becomes gradually meliorated, and the common plough may ever after be wrought to a depth of from ten to twelve inches without obstruction. For this heavy ploughing most likely three horses yoked abreast will be required. The charge for subsoil-ploughing may be estimated at twenty-four to twenty shillings per statute acre, being one-fifth of what a similar depth with the spade would cost, and, upon the whole, be as effectually done. The expense of subsoil-ploughing is no doubt considerable, but its advantages are incalculable. "All who have ever studied or experienced the most common gardening, must be aware of the important advantages of deep working; and when it can be attained in the broad field of farming at so small a cost, they may easily believe that the whole will be more than doubly repaid in every succeeding crop, and abundantly even in pasture. When land has been thoroughly drained, deeply wrought, and well manured, the most unpromising sterile soil becomes a deep rich loam, rivalling in fertility the best natural land of the country, and from being fitted for raising only scanty crops of common oats, will bear good crops of from 32 to 48 bushels of wheat, 30 to 40 bushels of beans, 40 to 66 bushels of barley, and from 48 to 70 bushels of early oats per statute acre, besides potatoes, turnips, mangel wurzel, and carrots, as green crops, and which all good agriculturists know are the abundant producers of the best manure."

LIMING.

Lime is the most important earthy substance which is usually applied to land. It is found in the form of rocky material, in which condition it is in combination with carbonic acid gas. On being burnt, this gas is expelled, and it assumes the form of a whitish brittle mass, easily reducible to powder. On being exposed to the atmosphere in its soft powdery condition, it has a strong tendency to imbibe moisture from the air, and soon becomes as heavy as it was previous to burning. It also recombines with itself carbonic acid from the air.

The use of this artificially prepared earth in agriculture is well known; but certain peculiarities in its action have never been satisfactorily ascertained. It possesses the power of decomposing animal and vegetable matter, and enters as an element into the fabric of plants; in certain cases it only alters the constitution of the soil, and in some instances its application would be positively injurious. Speaking of this remarkable fossil, Sir Humphry Davy observes—"When lime, whether freshly burned or slaked, is mixed with any moist fibrous vegetable matter, there is a strong action between the lime and the vegetable matter, and they form a kind of compost together, of which a part is usually soluble in water. By this kind of operation, lime renders matter which was before comparatively inert, nutritive; and as charcoal and oxygen abound in all vegetable matters, it becomes at the same time converted into a carbonate of lime. Mild lime, powdered limestone, marls, or chalks, have no action of this kind upon vegetable matter; by their action they prevent the too rapid decomposition of substances already dissolved, but they have no tendency to form soluble matters. It is obvious, from these circumstances, that the operation of quick-lime, and marl or chalk, depends upon principles altogether different. Quick-lime, on being applied to land, tends to bring any hard vegetable matter that it contains into a state of more rapid decomposition and solution, so as to render it a proper food for plants. Chalk and marl, or carbonate of lime, will only improve the texture of the soil, or its relation to absorption; it acts merely as one of its earthy ingredients. Quick-lime, when it becomes mild, operates in the same manner as chalk; but in the act of becoming mild, it prepares soluble out of insoluble matter. The solution of the question, whether quick-lime ought to be applied to a soil, depends upon the quantity of inert vegetable matters that it contains. The solution of the question, whether marl, mild lime, or powdered limestone, ought to be applied, depends upon the quantity of calcareous matter already in the soil. All soils are improved by mild lime, and ultimately by quick-lime, which do not effervesce with acids, and sands more than clays."

Let us now proceed to the practical application of this valuable fossil manure, commencing with its use in the reclaiming of waste lands. If moorish or waste soil is much infested with the tenacious roots of rushes, heaths, and other weeds which resist the mechanical action of the harrow, and yield slowly to putrefaction, the best mode is to till the ground, and allow it to lie in this state for twelve or eighteen months, or even two years, before applying the lime. It is then generally applied in autumn, and tilled in as soon as possible; but if not immediately tilled in, the soil with the lime on it should be harrowed, so that its decomposing effects may act as powerfully as possible upon the vegetable matter. After these operations, the land is sown two successive years with oats, without any fallowing; and along with the second crop of oats some persons sow it out in grass seeds for pasture. Others, after the first or second crop of oats, give the land a summer fallow for one season, or a green crop with manure. On the following season another crop of oats is taken, along with which grass seeds are sown, and in this state it is committed to pasture. In some cases, after tillage, the soil is allowed to lie for one, two, or more years, according to its nature, after which it is reduced to a complete state of pulverization by a well-wrought naked summer fallow On the spring following it is limed, and the lime is well harrowed in along with grass seeds alone, and in the following season the land is committed to pasture. This, however, is a very expensive mode, and cannot be recommended to tenants whose lease is of a moderate length. It is decidedly the most enriching mode of laying down waste land with lime only for pasturage, as the energy which the lime communicated to the soil is not exhausted by grain crops.

It will now be observed that lime is a most important engine of improvement for waste lands; for it decomposes and brings into active use the inert vegetable matter, and also serves as an elementary earth for the growth of plants. For peat lands, after being drained, and generally all rough lands reclaimed from a state of nature, lime is invaluable, and equally so for either tillage or pasture. In connection with turnip husbandry, it has been the grand reclaimer in many parts of Scotland, and will effect similar ends in any district of country not possessing a sharp and active soil; in such places it is not required, and its application may do harm. Laid on merely as a top dressing—that is, thinly powdered over the land—lime is found to have very extraordinary effects. Mr. Aiton, in his treatise on moss, observes—"If lime or other calcareous substances are laid on the sward, though the land be neither laboured nor any seed sown, such are the effects of hot lime, that the moss plants will instantly disappear, and a rich and beautiful sward of clover, daisies, and the richest poa or meadow grasses, will rise spontaneously."

From the result of experiments in many different situations, it seems satisfactorily proved, that the proprietors of waste lands within reach of lime have themselves to blame for the grounds continuing in sterility. Their complete melioration, however, is not to be expected at once; but upon proper arrangements being entered into between the landlords and the tenants, a great proportion of the pastoral grounds, lying in a state of waste, might by these means be progressively improved.

It seems to be a general wish of farmers to use lime rather in tillage than by top-dressing, which is much to be regretted, as the lime, when used in tillage, conjoined with over-cropping, eventually exhausts the soil; whereas, by applying it in top-dressing, it will prove highly beneficial. Therefore, in a climate rising six hundred feet above the level of the sea, top-dressing is the most effectual way in which lime can be applied for improving barren pasture-grounds. The land is never in this way exhausted by any species of cropping; it is put in a state of being benefited by the dung of the animals grazing upon it; and by due attention being paid to keeping the land free from wetness, by draining, it will be progressively fertilized. In the application of lime, it is a rule which should invariably be attended to, always to give abundance, and in a newly slaked condition, in order that it may have its full effect. If slaked a considerable length of time before it is applied, it does not act so powerfully either in reducing the natural herbage or neutralizing the acids, as when applied in a hot powdery state. There are very thin moorish soils, however, where lime by itself will not improve the herbage, these requiring a nourishing before a stimulating manure; and on such lands, a dressing of good earth will be found to have the same effects as lime has on a strong soil. Top-dressing with clay or sand may also be performed with advantage in mossy moorish tracts, where lime cannot easily be obtained. These earthy materials have a wonderful effect in improving the pasturage; they entirely destroy the growth of most plants; and if applied to the depth of an inch or so, will generate a sweet herbage, rendering the ground capable of being benefited by the droppings of the animals it supports.

IRRIGATION.

While some lands can be reclaimed only by draining, others, which are naturally dry, may be rendered equally serviceable by irrigation, or artificial watering. Lands in the dry climate of Australia seem to be in this condition; instead of depriving them of water, they require all that can be conveniently led towards them. Much of the land in the inner parts of North America is likewise so dry, that drainage is altogether undesirable, and irrigation is in many cases a means of fertilization. It may happen that lands naturally marshy are as much the better for irrigation as dry deserts; but in all such cases the lands must in the first place be drained. This leads to an explanation of the principle of irrigation.

When water lies in or upon the land, it stagnates and produces a marsh, which is alike insalubrious and unproductive. The extensive Pontine marshes in the neighbourhood of Rome present a remarkable example of both these conditions. In order that water may not be injurious, it must be kept flowing, always running amongst and from the blades of herbage. Regarding the theory of irrigation, Sir Humphry Davy says—"Water is absolutely essential to vegetation; and, when land has been covered with water in the winter or in the beginning of spring, the moisture, which has penetrated deep into the soil and even the subsoil, becomes a sort of nourishment to the roots of plants in the summer, and prevents those bad effects which often happen in lands in their natural state, from a long continuance of dry weather. When the water used in irrigation has flowed over a calcareous country, it is generally found impregnated with carbonate of lime, and in this state it tends, in many instances, to ameliorate the soil. Common river water, also, generally, contains a certain portion of organizable matter, which is much greater after rains than at other times, and which exists in the largest quantity when the stream rises in a cultivated country. Even in cases where the water used for flooding is pure, and free from animal and vegetable substances, it acts by causing the more equable diffusion of nutritive matter existing in the land; and in very cold seasons, it preserves the tender roots and leaves of the grass from being injured by frost.

"In general, those waters which breed the best fish are the best fitted for watering meadows, but most of the benefits of irrigation may be derived from any kind of water. It is, however, a general principle, that waters containing ferruginous impregnations, though possessed of fertilizing effects when applied to a calcareous soil, are injurious to soils that do not effervesce with acids; and that calcareous waters, which are known by the earthy deposit they afford when boiled, are of most use on siliceous soils, or other soils containing no remarkable quantity of carbonate of lime." Whatever be the actual properties communicated by the water, it is certain that the general effect of meadow irrigation is greatly to increase the quantity of herbage, and render it more sweet and nourishing for cattle than if grown on dry grounds.

In order to irrigate a field, there must be a difference of levels, the water being made to run in a main channel along the highest side, and thence sending small rills all over the lower parts of the ground. The principle of adjustment is by sluices. When the slope is considerable, the water requires to be sent diagonally across the field, and being catched in mains at intervals, is again distributed, if need be, in new directions. This is called catch-work irrigation. The following observations on the subject occur in Stephens' Practical Irrigator and Drainer: —"In the formation of an irrigated meadow, there are two rules of the greatest weight: one is, that no part of the works be made on the dead level; and the other, that every drop of water be kept in constant motion; but to give exact directions for the formation, is beyond the ingenuity of man; for no two pieces of land are precisely alike, which renders it impossible for the irrigator to follow the same plan in one field that he has done in another. Each meadow, therefore, requires a different design, the construction to be varied according to the nature of the ground and the quality and quantity of water. Inclined plains are absolutely necessary for the purpose of irrigation; and the benefit of irrigation depends so much upon the good management and patient perseverance of those who have the superintendence of it, that I do not wonder it has so often proved unsuccessful. However simple the construction of a water meadow may appear to be on a superficial view, those who enter minutely into the detail will find it much more difficult than is commonly imagined. It is not an easy task to give an irregular surface the equal slope requisite for the overflowing of water. It is very necessary for the irrigator to have just ideas of levels; a knowledge of superficial forms will not be sufficient. Few people unacquainted with the art of rrigation and the regularity of form which the adjustment of water requires, have any idea of the expense of modelling the surface of a field. Where land is very uneven, it is sometimes advisable to break it up with the plough, and take a crop of oats before the formation; by which means the land can be properly cleaned and pulverized before levelling it into form with the levelling plough and spade the following year—an operation which may be executed at half the expense of doing the whole with the spade and wheel-barrow. But there is one advantage by doing the whole work with spade and barrow, especially where the turf is strong, which is, that the water can be applied as soon as the beds are formed; but by breaking up, and taking a crop of oats, it will require two or three years after the grass seeds are sown before the water can be used, which some proprietors think too long to wait, therefore will rather be at an additional expense to have the turf lifted and laid down again; by so doing, the whole operations may be performed in one season. The grass seeds generally used for laying down land for water meadow are, vernal grass, crested dogstail, soft meadow grass, rough-stalked meadow grass, foxtail, fiorin grass (*agrostis stolonifera*), which last is one of the prevailing grasses in all good meadows; and the best way of planting it is to cut the whole into short pieces, the same way as cutting straw into chaff, and sow it with other sides. It is not always that those grasses give a good crop the first year; therefore, to obviate this evil, some perennial ryegrass seed should be sown along with the others, to produce a crop of hay before the watering commence."

It must be understood that the irrigation of any meadow is not to be incessant. There are times when the water must be altogether turned off, and the ground left to dry; it is at these times that the herbage is to be cut and removed. In large meadows, it is customary to turn off the water from different parts at different times, by which a constant succession of crops is obtained. Speaking on this part of the management, Mr. Stephens observes:—"One of the greatest defects in the management of irrigated meadows in this country, is the not paying proper attention to freeing the ground from subterraneous and stagnant water; for experience shows that, wherever there is too much moisture beneath the surface, or if the water lodges too long upon it, the crop will always be coarse and scanty. Another great error generally committed is, allowing the water to run too long at a time, without properly drying the ground. I know some instances in this neighbourhood where the ground is not attempted to be dried from the time the water is put on the meadows, in the autumn, till eight or ten days before the cutting of the hay; the consequence is, that the grass is of the coarsest quality, and the ground has become so very boggy, that the whole crop of grass is obliged to be carried by people to some other place to be made into hay. Another inconvenience arises from bad management, which, I am sorry to say, is too prevalent in this country; that is, permitting the grass to stand too long before cutting; the consequence is, coarse hay, badly made, and in many instances half rotten before being put into the stalk; and, moreover, owing to the lateness of the season, the aftermath is entirely lost; so that the proprietor has not received half the value of his meadow which he ought to have received, if the hay had been made in the proper season.

"The first operation of the irrigator is to adjust the water in the conductor, or, if the meadow is in more parts than one, the water in each conductor must be first regulated; then he commences anew by regulating the stops in the first feeder; but should there not be sufficient water in the feeder, a little more must be led in, by making the aperture wider or deeper, till the water flows regularly over the sides from one end to the other; from the first, he proceeds to the second feeder, and so on, until the water in all the feeders is adjusted. Let the beds of a water-meadow be ever so well formed, yet, by some places sinking more than others, or by the ice raising the surface of the ground, although the water along the banks of the feeders have been ever so nicely adjusted, it often happens that there may be some places between the feeders and drains with too little water, when it will be advisable for the manager to make a third round, redressing inequalities of the surface, so as to give every spot an inch deep of water. Every part of the works being regulated, the water should be allowed to run through the whole of October, November, December, and January, from fifteen to twenty days at a time, without intermission. At the expiration of these periods, the ground should be made completely dry for five or six days, to give it air; for there are few species of grasses, which form the most nutritious part of the herbage of water meadows, that will long exist under an entire immersion of water. Moreover, if the frost should be severe, and the water begin to freeze, the watering must be discontinued, otherwise the whole surface will become one sheet of ice; and wherever the ice takes hold of the ground, it will undoubtedly draw it into heaps, which is very injurious to the plants. The object of this early preparation of the meadows is to take advantage of the autumnal floods, which bring along with them a variety of putrescent matter, which is found very enriching to land." At the most convenient period of the year, the various channels will require to be cleaned out, and the works repaired.

PROTECTING RIVER BANKS.

Much valuable land on the banks of rivers and rivulets is often laid waste by the encroachments of floods. A few words on this important subject seem to be necessary. It may be laid down as a principle in natural science, that water is irresistible, and therefore it must not be resisted—it must be humoured. All windings in streams are causes by resistance. The water, in rushing onward, dashes against a projecting stone or hard part on one of its banks; this sends it in an opposite direction, and it strikes against whatever obstacle is presented. This process of interruption soon causes a mouldering of the banks in opposite directions, so that at length the water runs in a zig-zag or serpentine course. All this might have been avoided by allowing the water a perfectly free course.

The damage done to lands by flooding, has led to numerous experiments for keeping the water in its channel, but seldom with any degree of success; because the attempts have been to hem in the current by sheer force. In all cases in which it is desirable to keep out tides or high floods from lands, the only secure method consists in giving the banks such a slope that they will present no resistance whatever, but allow the water to rise and subside with equal ease and tranquillity. As a general truth, the greater the slope the better; and it should never be less than a foot and a half for every foot in the height. Employ no stones or stakes, or any thing else, for the current to catch upon; but cover the slopes with smooth turf, at a season which will allow of its growth before the floods set it. If any patches get broke, let them be annually mended. To keep out high floods, the banks must be made correspondingly high. Artificial embankments, in a flat country, should assume the form of a long mound, sloping on both sides.

Notwithstanding the obvious utility of this simple and unexpensive mode of protecting river banks, instances of damage are constantly occurring from projects of an opposite kind. Mr. Stephens mentions the following as one of many within his knowledge:—"An embankment was thrown round the small island Mugdrum, in the river Tay, to protect the land from being overflowed by the tide; but it was made so steep, that the first spring tides levelled the greater part of it to the ground. A second attempt was made, with the additional expense of a stone wall facing the water, which shared the same fate with the former bank. Since these failures, a third embankment has been erected with nothing but the natural soil of the land, and the whole covered with thin turf. The length of the present slope next the sea is five times the perpendicular height of the bank, and the inner slope three times; the water, meeting no resistance, rolls down the long slope without doing any injury." We refer to Mr. Stephens' useful treatise for further information on this subject, as well as on irrigation and draining.

In connection with the protection of river banks, we may say a few words on the method of gaining land from rivers and tidal estuaries. This may be done if the river appears to struggle over an unnecessarily wide space, and brings down quantities of mud so as to produce impediments to navigation. The process usually followed with most advantage, is to run out at intervals short rows of stakes, matted with twigs, calculated to catch the confluent particles of mud, but to allow the water to pass through. A sediment is thus gradually formed between the rows; in time it rises above the water, and ultimately forms a green productive surface. When the water is affected by the tides, a row of loose stones laid between high and low water-mark will similarly catch mud and sand, and while forming new land, will, by narrowing the channel, give greater impetus to the stream, and help to deepen its bed. When done on a great scale, the bed of the river is scooped by mechanism, and the rubbish brought up may afterwards assist in elevating the newly formed banks. In point of justice to all parties, any of these processes of river-bank improvement should be done on both sides of the river at the same time; for if effected only on one side, the water may be driven to the opposite shore, to the serious damage of the land in that quarter.

SPADE HUSBANDRY.

The reclaiming and culture of small pieces of land by means of the spade and other instruments of manual labour, is usually spoken of under the name of spade husbandry; but is also sometimes called cottage-farming, or field gardening—the operations of the culturist bearing an intimate resemblance to those applied in ordinary kinds of gardening. The apparatus supposed to be employed by the cottage farmer is simple and unexpensive. It consists of two or three spades of different sizes, a pickaxe, three-pronged digging-fork, hoes, rake, light harrow which he can draw, scythe, reaping-hooks, hay-forks, flail, wheelbarrow, &c., according to means. It is of great importance for the cottage farmer to be able to sharpen or mend his tools, and for this purpose he should have a grinding-stone and small forge, also some carpenter's tools. No horse or paid servant is kept. All the work is done by the manual labour of the farmer and his family. The only live stock is a cow or cows, pigs, and poultry. The homestead consists of a cottage with several apartments—a cow-house, pig-stye, and barn. The size of the farm is supposed to vary from four to six or eight acres, and to be laid out in six or eight distinct fields, properly fenced.

Trenching.

The basis of cottage farming is deep trenching with the spade; but before regular trenching can commence, the land if in a rough state, must be cleared and drained. We have already shown how these preliminary operations are performed on a large scale, and they may very easily be modified for manual labour. Suppose the patch of land is part of a moss, dig open drains round it to draw off the water; scarify the surface with the spade, and burn the heaps of turf; scatter the ashes on the land along with any sandy material or lime which can be procured, and then delve all from one end to the other. This process will cause a large portion of the mossy fibre to decay, and the exposure to the atmosphere and draining will be found to meliorate the soil. In twelve months, the face of the land will be more like *earth* and less like peat than it was at the time of delving.

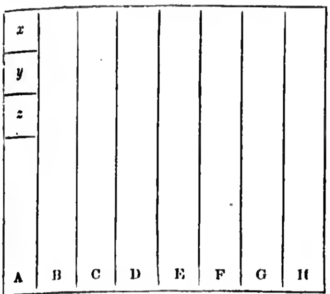
If the land be choked with stones or roots, all these encumbrances should be removed to the depth to which you design your trenching should go; and the sooner you get rid of them the better. The whole ground should be free of every thing which can present the slightest impediment to the spade. Stones of even an ounce in weight should be removed. Where subdraining is required, the stones may be employed to lay in the drains. With respect to the first crops taken from the delved field, it will depend on the natural fertility of the ground and other circumstances. If the land be comparatively dry and fertile, as, for instance, the forest land of North America, a good meliorating and opening crop is potatoes; but in the case of poorer soils, manuring will be required, and the first crop may be grass. If the land can be conveniently partitioned into separate fields, a different crop may be taken from each, thus commencing a regular rotation. In proportion as the upper layer of earth is meliorated and exhausted, it will be necessary to go the deeper down. On large farms, certain fields are occasionally left fallow, that is, doing nothing, unless it be gathering what strength can be procured from the atmosphere. In cottage farming, this wasteful practice must be unknown. Instead of trying to recruit the land by giving it a rest, you must recruit it by turning up the layer of mould immediately below that which has been affording nourishment to your crops. This stratum, which we shall call layer No. 2, extends from 9 to 18 inches below the surface, supposing you to have been employing a nine or ten-inch spade. It is, generally speaking, neither soil nor subsoil, but partakes of the qualities of both; and after two or three years' cropping, will be found to have imbibed a share of the manure delved in for the crops. The art, then, consists of raising up this layer No. 2, and turning down No. 1 in its stead. By doing so, perhaps manuring may be omitted for a year, and, at any rate, a light manuring will suffice.

In some districts the depth of available soil may not be so much as 18 inches, the layer beneath being rock or chalk, in which case the stirring of the soil cannot be carried deeper, unless at an immense cost of labour; but in the greater number of instances, the soil rests on a till or clayey-hardish substance, usually called subsoil; and this which we may call layer No. 3, must be stirred and gradually brought up in aid of the upper soils. As mentioned under the head *Subsoil Ploughing*, the proper method of nourishment consists of first stirring or breaking up the hard subsoil. Get down to it, and go over it with a pickaxe. Next year it may be incorporated with layer No. 2, and in two or three years the whole three layers may be indiscriminately mingled or made to change places. Such is the principle of trenching, by which three layers of soil are alternately, or at proper intervals compelled to do duty; and thus a farm of six acres, by being, as it were, three story deep, is practically as extensive as one of eighteen acres but one story deep. When we add, that while the plough leaves lumps of earth unbroken, and comparatively useless to the crop, the spade dashes and pulverizes the whole soil, bringing all into effective play on the roots, the value of spade over plough husbandry will be at once apparent. Another important advantage of deep trenching with the spade, is the turning down and destroying the larvæ of insects and seeds of weeds which may be about the surface; and it will be found that the first crops of trenched ground are always remarkably free of these nuisances.

The process of trenching to effect these important advantages is no doubt very toilsome; this, indeed, is a fact not to be concealed; but, without almost constant [illegible], and labour in which a pleasure is taken, cottage farming will generally come to nought; and he who is disinclined to undergo the trouble, should not commence the undertaking. To render the work as easy as possible, it should be methodic, and bit by bit, and always the more the ground is tilled, the less difficult will the trenching be.

Trenching, either for gardening or farming, is usually performed as follows:—Mark off the field in strips of two feet in width, as in the annexed diagram. Commence at x and y at top of the field, and take from each

Top of the Field.



Bottom of the Field.

the top layer, which wheel across to a and b beyond the top of the strip H. Then dig out the lower layer or subsoil from x, and wheel it away to a separate heap near where you have laid the top earth. The patch x being now empty, fill it two-thirds, first with layer No. 2, and next with layer No. 3 of y, and cover it with layer No. 1, or top earth of z. Thus go on wheeling and shifting till you come to the bottom of A. You now turn and trench upwards the strip B in the same manner; trench down C and up D, and so on till you have in every patch laid a layer No. 2 undermost, and a layer No. 3 above it. The overplus, wheeled aside, will fill up the strip H. You may vary the process in many different ways; and, if you think proper, place layer No. 2 uppermost, and layer No. 1 in the centre; but all this must be left to your own ingenuity, and your ideas of what will be best on the occasion. As a further means of melioration, some trenchers stir the bottom of each strip when it is exposed with a pickaxe, which is a good plan; for the more the subsoil is loosened and prepared for being brought into activity, the more fertile will the fields be.

General Management.

Whether the land of a cottage-farmer be part of a reclaimed bog or waste, or a section of fertile soil, or whether it be his own property, or rented, he must necessarily exert unremitting industry not only in digging and trenching his small fields, but in all the ordinary routine of manuring, cropping, and in attending to the other affairs of his establishment. To procure manure in sufficient abundance, he must keep one or two cows and a pig, and into a pit adjoining the cow-house, all the solid refuse, including all that may be collected from the family, must be removed. The urine from the cow-house should be collected in another pit, or a barrel sunk in the ground, protected from the air. This will be found a most valuable liquid for throwing over the land, to excite a young growing crop. While on the subject of manures, it cannot be out of place to mention that most surprising results have been effected in agriculture and market-gardening, by the use of night-soil. In some foreign countries, where this is well understood, the night-soil is carefully saved, and to destroy its offensive effluvia, is mixed with gypsum or earth, for a few shovelsful of earth thrown over it at once removes all offensiveness in this respect, besides bein, [illegible]erwise useful. So little thought and trouble are us[illegible] taken in Britain to preserve this material for manure, that for the use of enterprising agriculturists, quantities are now imported from France in a dried and prepared condition.

There are other means of increasing the quantity of manure. From every piece of ground a quantity of rubbish may be collected, as withered leaves, stalks, clippings of branches, roots, &c. Improvident persons burn much of this refuse, but we strongly advise the cottager or gardener never to burn any thing, except it be stumps of trees, or pieces of branches as fuel. Collect all the inferior stuff into a heap, to which scrape or carry all the mire that can be gathered from the pathways, and the whole will make a compost dung-hill; a pailful of cow urine thrown occasionally over the heap will be a valuable addition, and so likewise will be a shovelful of night-soil. A little lime will hasten the rotting of any compost. If properly managed, in twelve months all will be rotted, and then begin taking from one end for manure. To the other extremity you may keep adding new matter that is collected. The treatment of the ordinary dung-pits is to be on the same plan. Do not remove the manure till it has lain a sufficient length of time to decompose, but keep taking from one that is ready, while another is collecting.

If a rivulet can be made to run upon a meadow, as previously described under the head *Irrigation*, the cottager will add prodigiously to his stock of grain, fodder, and hay. From a single acre, well irrigated, as much as 200 stones of sweet, nourishing hay may be gathered every year, besides a quantity of green stuff. The proper saving of this meadow hay requires considerable tact; if any way spoiled, the cattle will probably not touch it.

In the scheme of working a cottage farm, it should be an object to make the very most of every day out of doors, when the season and weather permit, and to occupy the dead of winter and days of bad weather at work in the barn or house. The Swiss small farmers do much by working at some handicraft employment, particularly weaving and making toys, during those seasons when prevented from labouring out of doors; and in many instances they keep one member of the family at the loom. In short, none must be idle; the grown-up children, when not at school, being made useful as far as their capacities will admit of.

It is calculated that an active spadesman would find little difficulty in bringing half an acre annually into an improved state; for as 80 rods make the half acre, and there being 313 working days in the year, to accomplish this it would require little more than a quarter of a rod to be trenched daily, whereas a moderate day's work, even where the soil is stony and difficult to trench, would considerably exceed a rod. But where there is a boy or two to assist, an acre might with perfect ease be brought into an improved state yearly.

Whether it would be preferable to devote a cottage farm to a mixture of green and grain crops, as in ordinary husbandry, or make it chiefly a dairy farm, in which the raising of green crops for fodder is the principal if not the only object, must depend on local circumstances. If near a city, where fresh dairy produce could be profit ably disposed of, dairy farming might be most suitable, although the large rents usually exacted near populous towns would prove an obstacle. Several experiments have been made in order to ascertain the quantity of produce in roots, artificial grasses, &c., that an acre of ground, under this sort of culture, could be made to yield; and the result has been that even less than 80 rods, or half an acre, will produce food sufficient to maintain a cow. This calculation is founded upon the well-known fact, that 100 lbs. weight of green food, a considerable portion of it roots, is a sufficient daily allowance for an ordinary cow. But cows kept upon such produce must not be allowed to pasture on those portions of the ground that are devoted to grass crops, such as clover, lucern, tares, &c.; but for the better health of the animals they should have an open space to move about in adjoining the shed or out-building, where they find shelter from the storm and cold; for in soiling cattle during the hottest part of summer, an open shed, with a rack for their food, is to be preferred to shutting them up in close stables. Mr. Allen, in his *Colonies at Home*, very properly remarks—"Whenever it is possible to make a rod of ground produce 500 lbs. of the artificial grasses, in the several cuttings during the season, I greatly prefer it to any thing else, for cows thrive best upon grass and hay." He afterwards observes, in reference to this sort of food—"As it sometimes suffers much in dry seasons, we must not depend entirely upon it; but I have proved that it is possible to keep a cow all the year round upon the produce of half an acre of land if it be carefully cultivated." He then proceeds to give a list of the produce he raised, which consists of lucern, cabbage, tares, mangel-wurzel, potatoes, turnips, parsnips, and carrots; and as a portion of hay is indispensable along with some of the root-crops during the winter season, he did not attempt to grow it, but sold a portion of his potatoes, and laid out the sum he received for them in hay. We need only add, that whatever number of cows be kept, they must be fed entirely within doors, and only suffered to go out in any small enclosure for the sake of air and exercise.

Plan of a Three-Acre Farm.

With the view of keeping up in the country a certain number of peasant families who should be able to assist farmers at particular seasons, the late Sir John Sinclair planned a system of cottage farms of three acres each; these were individually to be cultivated entirely by manual labour, and by the cottager and his family. From the account of the method of managing these cottage farms, which he has given in the second volume of the *Farmer's Magazine*, we select the following particulars:—

"*Course of Crops.*—The three acres proposed to be cultivated should be divided into four portions, each consisting of three roods, under the following system of management:—

	Roods.
Under potatoes, two roods; under turnips, one,	3
Under winter tares, two roods; spring tares, one,	3
Under barley, wheat, or oats,	3
Under clover, with a mixture of rye-grass,	3
Total,	12

"Other articles besides these might be mentioned; but it seems to me of peculiar importance to restrict the attention of the cottager to as few objects of cultivation as possible. It is proposed that the produce of the two roods of potatoes shall go to the maintenance of the cottager and his family, and that the rood of turnips should be given to the cow in winter and during the spring, in addition to its other fare.

"The second portion, sown with tares (the two roods of potatoes of the former year to be successively sown with winter tares, and the turnip rood with spring tares), might partly be cut green, for feeding the cow in summer and autumn; but if the season wi permit, the whole ought to be made into hay for the winter and spring food, and three roods of clover cut green for summer food.

"The third portion may be sown either with barley, wheat, or oats, according to the soil or climate, and the general custom of the country. The straw of any of these crops would be of essential service for littering the cow, but would be still more useful, if cut into chaff, for feeding it.

"The fourth portion, appropriated to clover and rye-grass, to be cut green, which, with the assistance of the orchard, will produce, on three roods of land, as much food as will maintain a cow and her calf for five months, namely, from the end of May or beginning of June, when it may be first cut, to the 1st of November, besides some assistance to the pigs. It is supposed that an acre of clover and rye-grass, cut green, will produce 20,000 pounds' weight of food for cattle. Three roods, therefore, ought to yield 15,000 pounds' weight. A large cow requires 110 pounds' weight of green food per day; a middling cow, such as a cottager is likely to purchase, not above 90 pounds; consequently, in five months, allowing 1320 pounds' weight for the calf and the pigs, there will remain 13,680 pounds for the cow. Were there, however, even a small deficiency, it would be more than compensated by the rood of land proposed to be kept in perpetual pasture as an orchard.

"*Mode in which the family may be maintained.*—It is calculated that three roods and eight perches of potatoes will maintain a family of six persons for about nine months in the year, but according to the preceding plan, it is proposed to have but two roods under that article; for however valuable potatoes are justly accounted, yet some change of food would be acceptable; and the cottager will be enabled, from the produce of the cow, and by the income derived from his own labour, and from that of his family, to purchase other wholesome articles of provision.

"*Manner in which the Stock may be kept.*—It appears, from the preceding system of cropping, that ten roods of land, or two acres and a half, are appropriated to the raising of food for the cow in summer and winter, besides the pasture of the orchard; and unless the season should be extremely unfavourable, the produce will be found not only adequate to that purpose, but also to maintain the calf for some time, till it can be sold to advantage. It is indeed extremely material, under the proposed system, to make as much profit of the calves as possible, as the money thus raised will be a resource, enabling the cottager to replace his cow when a new one must be purchased.

"For the winter provision of the cow, which is the most material, because the summer food can be more easily procured, there is the produce,

"1. Of about three roods of tares made into hay.

"2. Of three roods of straw, deducting what may be necessary for litter; and if dry earth be put into the cow's hovel, and removed from time to time to the dunghill, little or no litter will be necessary.

"3. Of one rood of turnips.

"The whole will be sufficient for seven months in the year, namely, from the 1st November to the 1st June; and during the remaining five months, the pasture of the orchard, some of the winter tares, and the produce of three roods of clover and dry-grass, will not only suffice, but will furnish a surplus for the calf, if it is kept for any length of time, and some clover for the pigs. The inferior barley, potatoes, &c., will of course be given to the pigs and poultry.

"*Value of the Produce.*—The land thus managed will certainly produce, by means of the extra industry of the family, and at a small expense, a most important addition to the income which the cottager may derive from his ordinary labour. For instance—

	Per Annum.		
1. The orchard, after the trees become fruitful, will probably yield	L.1	10	0
2. Three roods of turnips and potatoes,	4	0	0
3. Eighteen bushels of barley, at 4s.,	3	12	0
4. The cow and calf,	7	0	0
5. Hogs,	3	0	0
6. Poultry and eggs,	2	0	0
Total,	L.21	2	0

"Where wheat can be raised instead of barley, the profit would be still more considerable. Opinions will differ much regarding the value put on each article; but that is of little consequence, as the total cannot be accounted too high.

"*Time required for Cultivating the Land.*—The quantity of land intended to be cultivated will not materially interfere with the usual labour of the cottager. It will only require to be dug once, and is then fit to be cropped. It is proposed that only nine roods shall be annually cultivated (the remaining three roods being under clover and rye-grass), and nine roods may be dug in the space of about 558 hours, or at the rate of 62 hours per rood. This may be done at by-hours (more especially when the family of the cottager shall be somewhat advanced, and consequently more able to furnish assistance; but supposing that the digging, manuring, harvesting, &c., will require twenty entire days per annum, in addition to the by-hours, and allowing sixty days for Sundays and holidays, there will remain 285 days for the ordinary hand-labour of the cottager, which, at 1s. 6d. per day, would amount to £21, 7s. 6d.; the earnings of the wife and children may, at an average, be worth at least £4 per annum more. This is certainly a low calculation, considering how much may be got during the hay and corn harvests. But even at that moderate estimate, the total income of the family will be as follows:—

1. Produce of the farm,	L.21	2	0
2. Labour of the cottager,	21	7	0
3. Earnings of the family,	4	0	0
Total,	L.46	9	6

"*Rent and Balance of Income.*—The rents of cottages and of land vary so much in different parts of the kingdom, that it is difficult to ascertain an average. But if the cottage shall be stated at £3 per annum, the land at 25s. per acre, and the orchard at 10s., the whole will not exceed £7, 15s. The cottager will also be liable to the payment of some taxes, say to the amount of £1, 5s. more. Hence the total deductions would be about £9, leaving a balance in favour of the cottager of £37, 9s. 6d. Considering the cheap rate at which he is furnished with a quantity of potatoes, equal to several months' consumption, and with milk for his children, surely with that balance he can find no difficulty not only in maintaining himself and family in a style of comfort, but also in placing out his children properly, and laying up a small annual surplus, that will render any parish assistance, either in sickness or old age, unnecessary.

"*Advantages.*—The land possessed by the cottager would be completely cultivated, and rendered as productive as possible. The dung produced by the cow, pigs, &c., would be amply sufficient for the three roods under turnips and potatoes, which would afterwards produce—1. Tares; 2. Barley; and 3. Clover; with a mixture of rye-grass in regular succession, without any additional manure. The barley should yield at least 18 bushels, besides 3 bushels for seed; and if wheat is cultivated, in the same proportion. The milk, deducting what may be necessary for the calf and the cottager's family, might be sold in its original state, if there shall be a market for it; or converted into butter, for the purpose of supplying the neighbouring towns or villages. Such cottagers, also, might certainly send to market both eggs and poultry.

"It is hardly possible to suggest a measure more likely to promote the benefit of a numerous and valuable body of people. The system of keeping cows by cottagers, which has been found so advantageous in the grazing districts, may thus be extended over the whole kingdom; and indeed, if the above plan is found to answer, in place of four or five acres employed in feeding a single cow, it would be much better, even in the grazing counties, to restrict the land to a smaller quantity under a tillage mode of management.

"It is of infinite consequence to establish the practicability of this system, as the means of removing a most unfortunate obstacle to the improvement of the country. It is well known to be the only popular objection to the enclosure of our wastes and commons, that, while unenclosed, a number of cottagers are enabled to keep cows by the means of their common rights, and that their cows disappear when the commons are enclosed. But if so small a portion of land as 3¼ acres, when improved and properly cultivated, can enable a cottager to keep a cow to more advantage than with a right of common, which can hardly be doubted, as he is enabled to provide winter as well as summer food, there is an end to that obstacle to improvement. Indeed, if sufficient attention be paid to the principles above detailed, the situation of the cottager, instead of being deteriorated, would be materially bettered by the enclosure; and his rising family would be early accustomed to habits of industry, instead of idleness and vice.

"I shall conclude with asking, if any one can figure to himself a more delightful spectacle than to see an industrious cottager, his busy wife and healthy family, living in a comfortable house, rented by himself, cultivating his little territory with his own hands, and enjoying the profits arising from his own labour and industry? Or whether it is possible for a generous landholder to employ his property with more satisfaction, or in a manner more likely to promote not only his own but the public interest, than by endeavouring to increase the number of such cottagers, and encouraging, by every means in his power, the exertions of so meritorious and so important a class of the community."

To the article comprehending the above account, there is added an appendix containing a letter from Sir Henry Vavasour, describing the field-gardening on his estate We extract from it the following passages:—

"I have for some years encouraged my cottagers in Yorkshire in this mode of managing their small garths or gardens, which are in general from one to three acres. I have now an opportunity of stating the husbandry of a poor industrious cottager's garth. As the man can neither read nor write, these particulars have been transmitted to me from his own mouth; and as I saw his land almost every day during the last harvest, I can vouch that this account is not far from the truth.

Produce.	Value.			A.	R.	P.
240 Bushels of potatoes,	L.24	0	0	0	2	0
60 Ditto of carrots,	6	0	0	0	1	0

"His stock was two cows and two pigs; one of his cows had a summer's gait for twenty weeks with his landlord. The land was partly ploughed and partly dug with the spade, cultivated (the ploughing excepted) by the man,

* These and the preceding calculations refer to prices a number of years ago.—ED.

his wife, and a girl about twelve years of age, in their *spare* hours from their daily *hired* work, seldom a whole day off, except in harvest: made the rent in butter, besides a little used in the family. The man relates that he thinks he clears, one year with another, from the three acres, about £30. The daily wages his family earns nearly keep them. It is very evident that this man clears, from his three acres, more than a farmer can possibly lay by from more than eighty acres of land in the common husbandry of the country—paying for horses, servants, &c.; and it must be obvious to every one how great the advantages must be to society in cultivating land in this manner. It would have taken more than half the quantity of his three acres in pasture for one cow at grass during half the year; whereas (except the summer's gait for one of his cows, as mentioned before) his stock of two cows and two pigs is kept and carried on the whole year. The family lives well; and a handsome sum has been yearly saved, to place out two sons, and supply them with clothes, washing, &c."

How to Keep a Cow and Pig upon an Acre of Land

A society was formed in London in 1833, called the Labourers' Friend Society, for the purpose of procuring allotments of small portions of land to the labouring poor, and whose operations, we believe, have been on the whole beneficial. The land, however, is let only from year to year, which, as a general principle, is pernicious; for no land will ever be properly cultivated when the holder of it is liable to be dispossessed at the end of every year. In cottage as well as large farming, the husbandman must be insured a continuance in his possession for at least ten or twelve years. Perhaps the above-mentioned society insures a renewal of the annual lease, provided a certain fixed rent is paid, which would be reasonable and beneficial to all parties.

The Labourers' Friend Society has published a cheap magazine of popular information on rural subjects, and from one of the numbers we extract the following advices, headed—How to Keep a Cow and Pig upon an Acre of Land.

"1. Never let the cow out of the cow-house. 2. Carry her food and water to her. 3. Do not keep one foot of land in pasture. 4. Dig your land instead of ploughing it. 5. Never throw away any thing that can be turned into manure. 6. Keep your land well weeded, and collect a large dunghill.

"A small cow, which is best for a cottager, will eat from seventy to eighty pounds of good moist food, of the following kinds, in a day:—Lucern or clover, and the leaves of yellow beet or mangel wurzel, from the beginning of spring to the end of autumn; and the roots of yellow beet or mangel wurzel, Swedish turnips, potatoes, and straw, from the end of autumn till the beginning of spring. If the cow is curried once a day, it will increase the quantity of milk.

"To procure the above-mentioned crops, you must have plenty of manure, which you will obtain by careful management. Rushes, potato-stalks, and weeds before they seed, should be industriously collected for the cow's litter.

"*Lucern* requires a good and deep soil. The ground for it should be well dug, two spits deep, and the manure deposited at one spit deep. It must be sown very early in the spring, in drills nine inches apart. The quantity of seed is one ounce and a quarter to the perch. It must be kept carefully free from weeds, and watered with the liquid manure from time to time; ashes also are a good manure for it. It sometimes admits of four cuttings in the summer, and, with attention to the foregoing rules, will continue productive for ten or twelve years. It will not do well upon shallow or boggy land, in which case red clover will be the substitute.

"*Swedish Turnips.*—Prepare the land as if for drilling potatoes; open the drills about twenty inches distant, the deeper the better; fill them with manure, cover them with four or five inches of earth, make the top smooth and level, then with a dibble make holes two inches in depth, and about twelve inches apart, and drop a seed into every hole. Keep them free from weeds. Three-quarters of a pound of seed will sow twenty perches. The time for sowing is May.

"*Mangel Wurzel*, or *Yellow Beet.*—The ground to be prepared in the same way as for Swedish turnips; from the 20th to the end of April is the best time for sowing; half a pound of seed will sow twenty perches. In August and September pull the leaves for the cow; these will last till you take up and store the roots, which should be done before the frost sets in.

"*Red Clover* (to be used only where lucern will not suit the soil) will afford a large quantity of green food as well as hay from ten square perches. It will last from two to three years on the same ground; one ounce and a quarter of seed is sufficient for a perch. The ground should be well and deeply dug, and made as fine as possible. The time of sowing is from February till April. The seed put in immediately after you have sown your oats half an inch deep in clayey soils, and one inch on loose soils; a coat of manure should be put on in spring and autumn. It may be cut two or three times in the season, and should not be given to the cow till it has been cut some hours, or she would be in danger of bursting.

"Some dry food should be given with the roots. The daily supply for a cow for the winter (about 180 days) may be as follows:—30 lbs. of mangel wurzel, or yellow beet—30 lbs. of Swedish turnips—14 lbs. of straw." The writer adds, with respect to the rotation of crops—"That, supposing the land of the peasant to consist of four roods, in the first year he devotes a rood for oats, a second rood to potatoes, a third to lucern, and a fourth to beet and Swedish turnips; in the second year he puts potatoes on the first rood, beet and turnips on the second, lucern on the third, and oats on the fourth; in the third year he puts beet and turnips on the first, oats on the second, lucern on the third, and potatoes on the fourth. By this means he effects a proper rotation of cropping, advantageous in keeping his land in heart. It will be easy for him to devote spare borders to the raising of onions and seeds."

Spade Husbandry in Belgium.

As a picture of rural affairs under a well-conducted system of spade husbandry, we present the following from the report of Mr. George Nichols respecting Belgium, laid before Parliament:—

"The extensive manufactures which at no very remote period flourished in Belgium, appear to have congregated a numerous population of artisans in and around the great towns. As the scene of manufacturing industry changed, this population was deprived of its means of handicraft employment, and was compelled to resort to the cultivation of the soil for subsistence. This seems to have been the chief, though possibly not the sole, origin of the system of the small farms which still prevails, and which are cultivated by the holder and his family, generally without other assistance. The farms in Belgium very rarely exceed one hundred acres. The number containing fifty acres is not great. Those of thirty and twenty acres are more numerous; but the number of holdings of from five to ten and twenty acres is very considerable, especially those of smaller extent, and to these I chiefly confined my inquiries.

The small farms of from five to ten acres, which abound in many parts of Belgium, closely resemble the small holdings in Ireland; but the small Irish cultivator exists in a state of miserable privation of the common comforts and conveniences of a civilized life, while the

Belgian peasant-farmer enjoys a large portion of those comforts. The houses of the small cultivators in Belgium are generally substantially built, and in good repair; they have commonly a sleeping-room in the attic, and closets for beds connected with the lower apartment, which is convenient in size; a small cellarage for the dairy, and store for the grain, as well as an oven, and an out-house for the potatoes, with a roomy cattle-stall, piggery, and poultry-loft. The house generally contains decent furniture; the bedding sufficient in quantity; and although the scrupulous cleanliness of the Dutch may not be everywhere observable, an air of comfort and propriety pervades the whole establishment. In the cow-house the cattle are supplied with straw for bedding; the dung and moisture are carefully collected in the tank; the ditches had been scoured to collect materials for manure; the dry leaves, potato-tops, &c., had been collected in a moist ditch to undergo the process of fermentation, and heaps of compost were in course of preparation. The premises were kept in a neat and compact order, and a scrupulous attention to a most rigid economy was everywhere apparent. The family were decently clad, none of them were ragged or slovenly, even when their dress consisted of the coarsest material. The men universally wear the blouse, and wooden shoes are in common use by both sexes. The diet consists, to a large extent, of rye bread and milk; the dinner being usually composed of a mess of potatoes and onions, with the occasional addition of some pounded ham or slices of bacon. The quantity of brown wheaten bread consumed did not appear to be considerable. I need not point out the striking contrast of the mode of living here described with the state of the same class of persons in Ireland; and it appears important to investigate the causes of this difference.

In the greater part of the flat country of Belgium the soil is light and sandy, and easily worked; but its productive powers are certainly inferior to the general soil of Ireland, and the climate does not appear to be superior. To the soil and climate, therefore, the Belgian does not owe his superiority in comfort and position over the Irish cultivator. The difference is rather to be found in the system of cultivation pursued by the small farmers of Belgium, and in the habits of economy and forethought of the people. The cultivation of the small farms in Belgium differs from the Irish—1st, In the quantity of stall-fed stock which is kept, and by which a supply of manure is regularly secured; 2d, In the strict attention paid to the collecting of manure, which is most skilfully managed; 3d, By the adoption of a system of rotation of five, six, or seven successive crops, even on the smallest farms, which is in striking contrast with the plan of cropping and fallowing the land prevalent in Ireland.

In the farms of six acres, we found no plough, horse, or cart; the only agricultural implement, besides the spade, fork, and wheelbarrow, which we observed, was a light wooden harrow, which might be dragged by the hand. The farmer had no assistance besides that of his wife and children, excepting sometimes in harvest, when we found he occasionally obtained the assistance of a neighbour, or hired a labourer at a franc per day. The whole of the land is dug with the spade, and trenched very deep, but as the soil is light, the labour of digging is not great. The stock on the small farms which we examined, consisted of a couple of cows, a calf or two, one or two pigs, sometimes a goat or two, and some poultry. The cows are altogether stall-fed on straw, turnips, clover, rye, vetches, carrots, potatoes, and a kind of soup made by boiling up potatoes, peas, beans, bran, cut hay, &c., into one mess, and which, being given warm, is said to be very wholesome, and to promote the secretion of milk. In some districts the grains of the breweries and distilleries are used for the cattle; and the failure of the Belgian distilleries has been reckoned a calamity to the agriculture of the country, on account of the loss of the supply of manure which was produced by the cattle fed in the stalls of these establishments.

The success of the Belgian farmer depends mainly upon the number of cattle which he can maintain by the produce of his land, the general lightness of the soil rendering the constant application of manure absolutely necessary to the production of the crop. The attention of the cultivator is always, therefore, especially directed to obtain a supply of manure. Some small farmers, with this view, agree with a sheep-dealer to find stall-room and straw for his sheep, to attend to them, and to furnish fodder at the market price, on condition of retaining the dung. The small farmer collects in his stable, in a fosse lined with bricks, the dung and moisture of his cattle. He buys sufficient lime to mingle with the scourings of his ditches, and with the decayed leaves, potato-tops, &c., which he is careful to collect, in order to enrich his compost, which is dug over two or three times in the course of the winter. No portion of the farm is allowed to lie fallow, but is divided into six or seven small plots, on each of which a system of rotation is adopted; and thus, with the aid of manure, the powers of the soil are maintained unexhausted, in a state of constant activity. The order of succession in the crops is various; but we observed on the six-acre farms which we visited, plots appropriated to potatoes, wheat, barley, clover (which had been sown with the preceding year's barley), flax, carrots, turnips, or parsnips, vetches, and rye, for immediate use as green food for cattle. The flax grown is heckled and spun by the farmer's wife, chiefly during the winter; and we were told that three weeks' labour at the loom towards the spring enabled them to weave into cloth all the thread thus prepared. The weavers are generally a distinct class from the small farmers, though the labourers chiefly supported by the loom commonly occupied about an acre of land, sometimes more, their labour upon the land alternating with their work at the loom. In some districts, we were informed, every gradation in the extent of occupancy, from a quarter or half an acre to the six-acre farm, is to be found; and in such cases more work is done in the loom by the smaller occupiers.

The labour of the field, the management of the cattle, the preparation of manure, the regulating the rotation of crops, and the necessity of carrying a certain portion of the produce to market, call for the constant exercise of industry, skill, and foresight, among the Belgian peasant-farmers; and to these qualities they add a rigid economy, habitual sobriety, and a contented spirit, which finds its chief gratification beneath the domestic roof, from which the father of the family rarely wanders in search of excitement abroad. It was most gratifying to observe the comfort displayed in the whole economy of the households of these small cultivators, and the respectability in which they lived. As far as I could learn, there was no tendency to the subdivision of the small holdings. I heard of none under five acres held by the class of peasant-farmers; and six, seven, or eight acres, is the most common size. The provident habits of these small farmers enables them to maintain a high standard of comfort, and is necessarily opposed to such subdivision. Their marriages are not contracted so early as in Ireland, and the consequent struggle for subsistence among their offspring does not exist. The proprietors of the soil retain the free and unrestricted disposal of their property, whether divided into smaller or larger holdings. The common rent of land is about 20s. an acre, and the usual rate of wages for a day labourer is a franc (or 10d.) a day.

A small occupier, whose farm we examined near Ghent, paid 225 francs per annum for about two bonniers, or six acres, of land, with a comfortable house, stabling, and other offices attached, all very good of their kind; this makes the rent (reckoning the franc at 10d.) equal to £9, 7s. 6d. sterling per annum; and if we allow £3, 7s. 6d. for the rent of the house, stabling, and other offices, there will be £6, or £1 per acre for the land, which accords with the information we obtained at Antwerp, Brussels, and other places, as to the rent of land in the flat country, the soil of which is generally of the same quality throughout. This farmer had a wife and five children, and appeared to live in much comfort. He owed little or nothing, he said; but he had no capital beyond that employed on his farm. We questioned him respecting his resources in case of sickness. He replied, that if he were ill, and if his illness were severe and of long duration, it would press heavily upon him, because it would interrupt the whole farm-work; and in order to provide for his family and to pay the doctor, he feared he should be obliged to sell part of his stock. If his wife and family were long ill, and he retained his strength, the doctor would give him credit, and he should be able to pay him by degrees in the course of a year or two. The thought of applying for assistance in any quarter appeared never to have entered his mind. We suggested that the Bureau de Bienfaisance, or charitable individuals, might afford him aid in such a difficulty; but, with evident marks of surprise at the suggestion, he replied cheerfully that he must take care of himself. If a sick club or benefit society were established among these people, so as to enable them by mutual assurance to provide for the casualty of sickness, the chief source of suffering to their families would be obviated, and there would be little left to wish for or amend in their social condition."

Comparative Value of Spade Husbandry.

It is, we believe, an indisputable fact, that a garden produces heavier crops, space for space, than a field under culture with the plough. "In regard to the difference of produce, an experiment was tried in the neighbourhood of Hamilton, expressly to ascertain that point. A field was taken, which had been cropped with beans the preceding year, and the previous year with oats. Two ridges were dug, and two ploughed alternately, and the whole was sown on the same day. A part both of the ploughed and dug was drilled with the garden-hoe. The whole was reaped the same day, and being thrashed out, the result was, that the dug land sown broadcast, was to the ploughed sown broadcast as fifty-five bushels to forty-two; while the dug and drilled was as twenty and a quarter bushels to twelve and a quarter upon the ploughed and drilled. The additional grain produced was not the only beneficial result gained by digging; for in this instance there was also a great deal of straw, and the land was much more free of weeds, and more easily cultivated next year."—*Sir John Sinclair's Code of Agriculture.*

Some soils, however, are unsuitable for spade husbandry; as, for instance, heavy wet lands liable to inundation; stony, gravelly, or shallow soils, more especially if incumbent on chalk. Manual labour is also inapplicable where the climate is precarious, and it is necessary to be expeditious in tilling the land, and in sowing and harrowing for a crop. On these accounts spade husbandry cannot be universally resorted to with advantage either to the culturist or the community. With respect to its economy, where it is available, there are two questions.

First, Whether the cottage farmer with his six acres can raise as much produce, and at as cheap a rate, as the capitalist can from any given six acres on his farm? If he cannot raise so much at so cheap a price, and cannot pay the same proportion of rent, cottage farming is decidedly injurious to the community; but if he can compete on all these points, there can be no solid objection against the practice. From the foregoing evidence of Sir John Sinclair, and from what is known respecting spade husbandry in Belgium and some other continental states, it is placed beyond a doubt that more produce is raised for human subsistence—space, soil, and climate being equal—by small farmers using only manual labour, than by large farmers with horses and ploughs; and it is certain that the produce is always more accessible to the public than that of large farmers, who, by means of their capital, which is very frequently not their own, but borrowed from banks, can hold themselves indifferent respecting sales, till, by a fortunate contingency, the prices rise and become highly remunerative.

Second, How far is spade husbandry available in the shape of paid labour to the capitalist farmer? We are unable to answer this question from our own experience, and therefore refer to a paper written by a competent authority on the subject. This is an essay by Mr. Archibald Scott of Southfield, near Haddington, who obtained a prize of £100, which the Rev. C. Gardiner, a clergyman of the church of England, had proposed to grant for the best plan of giving employment to the poor.

"I am quite convinced," proceeds Mr. Scott, "there is but one way of employing the surplus population of England and Ireland, and that is by a judicious introduction of spade husbandry.

"To show that I am not a mere theorist, but a practical man, I may mention that I rent a farm from the Earl of Wemyss in East Lothian, consisting of 530 Scottish acres; that I have cultivated land to a considerable extent with the spade for the last three years, and that the result has exceeded my most sanguine expectations. In 1831, I determined to ascertain the difference of the expense and produce between trenching land with the spade and summer fallowing with the plough in the usual way: I therefore trenched thirteen acres of my summer fallow-break in the months of June and July. I found the soil about fourteen inches deep, and I turned it completely over, thereby putting up a clean and fresh soil in the room of the foul and exhausted mould, which I was careful to put at the bottom of the trench: this operation I found cost about £4, 10s. per Scottish acre, paying my labourers with 1s. 6d. per day. The rest of the field, which consisted of nine acres, I wrought with the plough in the usual way, giving it six furrows, with the suitable harrowing. I manured the field in August; the trenched got eight cart-loads per acre, the ploughed land 16; the field was sown in the middle of September. The whole turned out a bulky crop as to straw, particularly the trenched portion, which was very much lodged. On threshing them out, I found them to stand as under:—

By trenched wheat per acre, 52 bushels at 6s. 9d.		£17 11 0
To two years' rent at £2, 10s. per acre	£5 0 0	
Expense of trenching - - -	4 10 0	
Seed, three bushels at 6s. 9d. - -	1 0 3	
Eight cart-loads of manure at 4s. - -	1 12 0	
Expense of cutting, threshing, and marketing - - - -	1 10 0	
Profit - - - - -	3 18 9	
		£17 11 0
By ploughed wheat per acre, 42 bushels at 6s. 9d.		£14 3 6
To two years' rent, at £2, 10s. per acre	£5 0 0	
Six furrows and harrowing at 10s. -	3 0 0	
Seed, three bushels at 6s. 9d. - -	1 0 3	
Sixteen cart-loads of manure, at 4s. -	3 4 0	
Expense of cutting, threshing, and marketing - - - -	1 10 0	
Profit - - - - -	0 9 3	
		£14 3 6

"I now saw, that though it might be difficult to trench over my fallow-break during the summer months, it was by no means making the most of the system, as the operation was not only more expensive, owing to the land being hard and dry during the summer, but that it was a useless waste of time to take a whole year to perform an operation that could be as well done in a few weeks, provided labourers could be had; and as in all agricultural operations losing time is losing money, as the rent must be paid whether the land is carrying a crop or not, so that in taking one year to fallow the land, and another to grow the crop, two years' rent must be charged against the crop, or at least there must be a rent charged against the rotation of crops for the year the land was fallow. As I felt satisfied that, by trenching with the spade, the land would derive all the advantages of a summer fallowing, and avoid all the disadvantages attending it, I determined on trenching thirty-four acres of my fallow-break immediately on the crop being removed from the ground, and had it sown with wheat by the middle of November, 1832. I may here remark, that I did not apply any manure, as I thought the former crop was injured by being too bulky. As it is now threshed out and disposed of, the crop per acre stands as follows:—

By average of 44 bushels per acre at 7s. - -		£15 8 0
To rent of land per acre - -	£2 10 0	
Expense of trenching - - -	4 0 0	
Seed - - - - -	1 1 0	
Cutting, threshing, and marketing -	1 10 0	
Profit - - -	6 7 0	
		£15 8 0

"The advantages of trenching over summer fallow are, in my opinion, very decided, as it is not only cheaper, but, as far as I can yet judge, much more effectual. I am so satisfied of this, not only from the experiments above noticed, but from the apparent condition of the land after it has carried the crop, that I have this autumn cultivated about a hundred acres with the spade, and the crops at present are very promising. When I first commenced, I was laughed at by my neighbours, but now when they see me persevering in what they considered a very chimerical project, they are suspending their judgment, and several of them have made considerable experiments this year. I should think there are at least 250 acres under crop cultivated in this way this season in East Lothian; in 1831, the year I commenced, there was not a single acre. I have therefore the satisfaction of knowing that I have been the means of causing £1000 to be spent this year among the labouring classes in my immediate neighbourhood; and I feel confident, that should the season turn out favourable for the wheat crop, and fair prices obtained, their employers will be handsomely remunerated for their outlay. I do not say that this system will succeed in every description of soil, as it must necessarily be of some depth to admit of the operation; but there are few districts where such soil will not be found in sufficient abundance to give ample employment to the surplus population of the neighbourhood.

"Now, this is going on in a county where agricultural labourers *are better employed* than almost any other in Great Britain. The system was not introduced, nor is it persevered in, for the purpose of giving employment to the poor, but entirely for the benefit of the employer. The East Lothian Agricultural Society are now offering premiums for the most satisfactory reports on the subject. I last year received a medal from the Highland Society of Scotland for introducing the system; and, what I value still more, I received a piece of plate from the labourers I employed, as a token of their gratitude. The system, I admit, is only in its infancy, but I have this year put it completely to the test; and should it succeed as well as it has done hitherto, it must take root and spread over the kingdom; and the landed interest in those districts of England where the poor-laws are so oppressive, and still more, the Irish proprietors, will do well to investigate the system, and have it introduced with the least possible delay, that what is now a burden on their estates may become a source of wealth, and what is now a curse may become a blessing.

"This system, if it succeed to my expectation, possesses all the requisites you require; it furnishes employment for the surplus population by substituting manual labour for that of horses—and certainly, if there is a lack of food for both, it is desirable that the one should give place to the other. It will make bread plenty, as the naked summer fallows of Great Britain will be covered with grain instead of lying waste for a season; it will render corn-laws unnecessary, as we will be then independent of foreign supplies; farmers will be enriched who are enterprising and industrious, and they only deserve to be so; it will raise rents by increasing the capabilities of the soil, enabling the farmer to cultivate wheat to double the present extent; it will raise up a home market for our manufactures, as the paupers, who are at present starving, or living a burden on the parish, will find employment, and thereby be enabled to procure the necessaries and comforts of life; it will check the poor-laws, as there will then be none but the aged and the helpless dependent on parochial aid."

Stronger testimony in favour of spade husbandry could not well be adduced, but we doubt its being generally practised with success in the ordinary routine of agriculture. It seems to be best suited for mere cottage farming, in which the labour is of little exchangeable value. Referring to this point, the Rev. Mr. Hickey (Martin Doyle), in his *Cyclopædia of Practical Husbandry*, observes—"On even an extensive scale of farming, we recommend spade husbandry in *potato or cabbage culture*, but not for general crops. However gratifying to the benevolence of an individual farmer it may be to employ a vast number of men to dig his land in preference to the usual course of plough and horse-labour, he must consider that there is a limit beyond which he cannot multiply his labourers without occasional inconvenience and perplexity to himself, and without *unceasing superintendence*. Should any of the numerous causes which may occasion a change of occupiers on a given farm, or a change of *system* occur, what is to become of the numerous families collected by an individual who has largely introduced the practice of manual labour, and confined his operations to that system alone? What is to become of an excessive population of agricultural labourers, if their services be no longer required by the successor of the spade husbandry farmer? If any one replies, 'Oh, let the system be generally introduced, and there can be no danger of their want of employment somewhere,' the answer is plain. 'If you substitute the spade for the plough to such an extent, you raise the price of labourers beyond what you can afford to pay, and you diminish the chances of success in your general farm operations, by giving up too much time to one department of labour. Time is money to a farmer; let him lose a week in a critical season, and the delay may be highly injurious to him in many respects. Promptitude and despatch are essential to his completion of farm labours at the proper times: without the aid which improved machinery affords him, it would be utterly impossible for him to get through his work in due course. Let him abandon the more rapidly working plough, and take the tedious spade, and he will soon heartily regret his exchange. After what we have premised on this subject, it is almost superfluous to repeat, that if these latter remarks possess any accuracy at all, they are merely true in their application to *large* farmers, and not intended by any means to affect the subject as it is connected with the cottier or small farmer, who has rarely any capital but his labour, and needs no other if he be suffered to use it freely and fairly.' What is the limit, then, to the capital of his labour? What sized farm should he have that will make it the most productive? Why, the exact amount, and no more, to which he can apply all his capital? Has he a family? he may then have more capital of labour to bestow by their assistance; consequently a larger allotment will be needed to employ all the capital of more extended labour. If he be single, then less, of course, will suffice."

The only point that remains to be settled is one connected with political economy. It is alleged by the leading political economists of England, that cottage farming (see article *Cottage System* in the *Encyclopædia Britannica*), while calculated to promote the growth of a population of paupers, is only distracting manual labour from its proper field of employment. But this allegation proceeds on an unproved assumption. If it could be shown that every able-bodied man could make five shillings a-day by working as a weaver, at a factory, or any other branch of labour, the assertion would in part be correct; but such is not the case. There are countries in which remunerative employment cannot be permanently had, and in such situations—to which society in England seems advancing—the choice is in a great measure between spade husbandry and starvation, not between spade husbandry and well-paid employment. Besides, the political economist entirely overlooks the fact, that the cottage-farmer derives immense advantages from the labour of his wife and children, not one of whom, most likely, would be able to earn a penny at any kind of labour in towns. It is by calling up these engines to assist him that he can outdo the large farmer with all his capital and machinery—a fact distinctly proved, at least as respects the keeping of cows and selling their produce; no joint-stock company of cow keepers being able to compete with the miscellaneous and unmarketable labour of an humble dairyman and his family. As to the allegation that cottage-farming would cause a deterioration in society, it is also founded on narrow views. In some parts of the canton of Vaud and elsewhere in Switzerland, where the farms are all small, and mostly wrought by their proprietors, there is no pauperism worthy of the name, no overplus population; and who would compare the orderliness of manners, the sobriety and thriftiness of the people, and the small amount of crime in that country, with the vice, intemperance, and poverty, for which England and Scotland, with all their large and splendid farms, are now becoming unhappily distinguished? It might be difficult to prove that large farms have been in any material degree the cause of the social evils now exciting so much attention; but it is clear that they have not prevented those evils. Without going so far as to say that cottage-farming would furnish a universal remedy, we think that, independently of its use in increasing the productive surface of the country, it would at least afford some relief, and add to that section of the population which is still in a healthful moral condition.

THE KITCHEN GARDEN.

There are various kinds of gardens—the Italian gardens, with their splendid terraces, vases, and statues; the old French gardens of Le Notre, of which we have a specimen at Versailles, with their long straight walks, clipt hedges, formal parterres, and fountains; English gardens, with their elegant blending of natural with artificial beauty; and so on. But it is none of these princely kinds of gardens which will engage our attention in the present and succeeding sheets. We propose to treat of the three departments which belong to the greater number of gardens of the middle and humbler classes; those, in short, which, designed on a moderate scale, are intended to afford the three staples of garden culture—vegetables for the kitchen, flowers to charm the eye, and the more easily attainable kinds of fruit. These various articles are for the greater part the production of one garden, a section or scattered part being set aside for each; but, for the sake of clearness, we shall confine ourselves in the present sheet chiefly to the economy and products of the kitchen garden.

LAYING OUT OF GARDENS.

A garden of the ordinary mixed description usually extends from the eighth of an acre to a whole acre; but the more common size in country places is about half an acre. Whatever be the dimensions, the garden ought to be enclosed with a wall from ten to twelve feet high, and, if possible, be surrounded by a strip of cultured land, which should be fenced with a hedge and shrubbery, so as to remove the appearance of stiffness from the walled enclosure, and serve for other useful purposes. Besides a wicket or small door for ordinary entrance and exit, there should be a gate that will admit a cart, to take away produce or bring in manure. A much more important circumstance than size or an external appearance is exposure. In a flat country, the garden must of course be level; but if there be a choice as to situation, select by all means a spot which lies with an easy slope—an angle, for instance, of fifteen degrees—towards the sun at his meridian. In the British islands, this will be facing the south. The next best exposure is towards the south-west, and the next is the west. Avoid a northern or eastern exposure. An exposure towards the morning and mid-day sun, even though at a very small inclination, is as good as being many degrees farther south: hoar-frost on the grass and plants will be melted within an hour after sunrise; whereas, if the garden lie in the smallest degree away from the sun, the hoar-frost will remain unchanged perhaps the whole day. Allow no house, wall, or trees, to interrupt the fair action of the morning sun on your garden; for the sun is the main agent in bringing all things to perfection, and if you be deprived of it, your operations will be blighted and retarded in every possible way. So important are the sun's rays, that, if your garden be small, rather have no wall on the south and west sides, but only a low fence, than submit to their exclusion. Some gardens are so disposed that they receive the sun in abundance in summer, but only partially the rest of the year. These gardens are imperfect. The garden should be visited all over by the sun daily, except, perhaps, in the heart of winter, when his rays are of comparatively little use. The exposure should also allow a free admission and currency of air; for this reason a garden is best away from a wood, and is most advantageously placed in an open sloping lawn, overlooked by, or near, the house of the proprietor.

The shape of a garden is of little consequence. It may be square, oblong, semi-circular, or irregular, according to taste or local circumstances. In the greater number of instances, an oblong, as represented in the adjoining figure, will be found most convenient. It is surrounded by a wall, in which is an entrance marked *e*. Within the wall is a border of several feet wide, and dotted round with flowers or flowering shrubs.

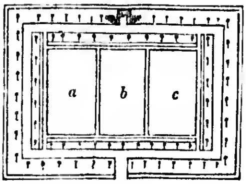

Fig. 1.

Next is a gravel walk; and within is another border containing fruit, bushes, or perhaps fruit trees on espaliers, and in the centre is the body of the garden laid out in three plots, marked *a*, *b*, and *c*. Between the plots and around them are paths of twelve or fourteen inches in width, not for ordinary walking, but for admission to the various plots or sections into which the ground may be divided. These paths are only flattened by the feet and by the spade, and are to be delved up annually in the course of digging.

At the opposite side of the garden from the door there may be supposed to be an arbour or summer-house, overhung with trailing plants and honeysuckle, and fitted up according to taste.

The regular walks in all moderately sized gardens should be not wider than three feet; any thing wider is a mere loss of ground. Much care is required to keep walks in order, for they are very liable to show crops of weeds and grass; but the best remedy is to bottom the walks well with broken cinders from a coal fire; this effectually prevents worms coming up, and also stops the growth of weeds. Over a smooth bed of cinders, put a layer of small gravel that will bind, or, failing this, a layer of brayed yellow ashes from a furnace, if they can be procured. Smooth all with the rake, and flatten with a roller. Many small flowering plants, such as daisies and thrift, are used for edgings to walks; but if not constantly attended to, they straggle over the borders. The most effectual and also the prettiest edging is dwarf box. It is easily set in an even row, grows regularly, requires little trouble in trimming—for it should not be always close shaved—and, summer and winter, is ever fresh and green.

No precise directions can be given respecting garden tools and apparatus; the following are the articles required in moderately sized gardens of a mixed kind:—Spades of three sizes, a trowel for lifting flowers, Dutch and common hoes, a broad iron rake, a rake with short teeth for the walks, a small rake for flower borders, a strong clasp-knife for pruning, a pair of strong pruning shears, an axe, a hand-saw, a hammer and nails (those made of zinc are best), a wheelbarrow, a wooden scuttle for carrying a little earth or manure, a roller, a pair of large compasses, a dibble and line, a watering-pot, and a ladder. Flower pots of different sizes, conical earthenware blanching pots, bell-hand glasses, and glazed frames of different sizes. These frames are among the most serviceable parts of a garden apparatus, and may be had either in one piece or with a movable top, as in fig. 2. A neat small kind, framed in zinc, useful for protecting early seedlings or flowers, may be had in London for 1s. 6d. each. Other utensils employed by gardeners, such as forcing pumps to wash wall trees, fumigating bellows, &c., need not be particularized.

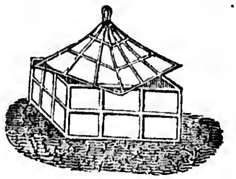

Fig. 2.

A person possessing only a small garden will shortly discover by experience what are the articles required in his operations. For gardens in which cucumbers and melons are to be grown, glazed frames and brick-built pits will be necessary. It is a great advantage for every garden to have a command of good fresh water for the purpose of irrigation, and also a small pond in which aquatic plants can be grown. If water is procured from a pump-well, it should be allowed to stand in the open air in a trough for at least a day, before being poured on the plants.

A garden is in all cases laid out according to the taste or fancy of the proprietor; but there are certain general rules which all follow. The wall is reserved for fruit trees. As fruit trees require much air and sun, the borders must not be clogged up with bushes, peas, or any other tall vegetables. The borders should contain only small articles which are delved up yearly; because the soil at the roots of the trees requires occasional renewal and loosening, and these operations cannot be done if the ground is encumbered with permanent plants. If a row of gooseberry or other small fruit bushes be placed on the borders, they should be near the outside, and not less than ten feet apart.

The body of the garden within the walks is laid out in larger or smaller plots, according to taste. These plots are generally oblong, and are subdivided into sections, rows, or beds for the different kinds of kitchen vegetables. In the corner of one plot are the cucumber and melon pits, partially secluded by bushes. In different corners are plots, and round the edgings are the flower parterres, disposed to meet the eye, and to be easily accessible from the walks. In some gardens, much of the ground is overshadowed by fruit trees. This is seriously detrimental to the growth of the plants beneath, exhausts the soil, and prevents the proper flowering and fructification of every vegetable within reach. Permit no tree to overshadow your ground; the only allowable places for trees are the walls and narrow espaliers running up one side of the central plots. When a garden possesses the addition of an outside strip, enclosed by a hedge, the exterior sides of the walls may be lined with fruit trees, and the ground laid out for potatoes and other common classes of vegetables; it will also afford the most proper site for compost dung-heaps and forcing pits.

SOIL—DIGGING—COMPOST.

The soil of a garden should be deep, rich, and easily penetrable. Whatever it may have been originally, the soil admits of vast improvement, and no trouble can be considered too great to bring it into a good condition. If shallow, trench it according to the plan mentioned in the previous sheet on Spade Husbandry, so as to loosen the subsoil, and gradually bring it into operation above. In many instances the soil is too stiff or clayey. Such a soil may not be unfit for plough husbandry, but is out of place in a garden. The method of loosening and meliorating a clayey soil is to give it a large volume of sand and vegetable manure, which may be delved in at the winter digging, and, at the spring digging, the new and old materials will be well mixed. In general, far too little attention is paid to giving sand as a restorative; such is absolutely necessary in all soils but those of a very sandy nature, because every crop actually carries away a certain proportion of the silica lodged in the soil. If the soil be already too sandy, it may be assisted by clay, mud from ditches, &c. Whatever be the nature of the soil, it should be thoroughly pulverized. Lumps thrown up by digging at the commencement of winter are meliorated by the frost, and have imbibed nutritious gases from the atmosphere. In spring all should be well delved, dashing every spadeful as it is turned down, and leaving no hard part impervious to the tender roots of the vegetables. A garden should not contain a single stone the size of a boy's marble. Every particle of soil should be capable of doing duty in feeding the plants. It will save much future trouble in lifting stones by the hand, if you would begin by putting every spadeful of mould through a sieve. Persons owning small gardens ought to pay particular attention to this. A working man having only a small patch for his amusement at leisure hours and holidays, could not do any thing more serviceable than to trench his ground bit by bit, and riddle every part of it as he proceeds.

No garden can be conducted with the least advantage without giving it a regular manuring. If you hunger a garden, it will hunger you in return. In connection with every rightly-managed garden, there must either be a compost heap, in which dung is preparing for use, or there must be some means of readily purchasing old manure when it is required. The manures employed are the same as in agriculture (see article on that subject), but being required for a more delicate purpose, they must in general be well rotted and ready to unite with the soil. A compost dung-heap is prepared by putting alternate layers of stable dung, or night soil, &c., with earth, weeds, and general offal of vegetation—turning the whole occasionally till the mass appears to be ready for use. A small quantity of this stuff will often be required to place at the roots of plants.

The practice of professional gardeners as respects composts, may be learned from the following brief notice in the "Encyclopædia of Gardening:"—"Composts for particular plants may be reduced to light sandy loam from old pastures; strong loam, approaching nearly to brick earth, from the same source; peat earth, from the surface of heaths or commons; bog earth, from bogs or morasses; vegetable earth, from decayed leaves, stalks, cow-dung, &c.; sand, either sea-sand, drift-sand, or powdered stone, so as to be free as possible from iron; lime rubbish; and lastly, common garden earth. There are no known plants that will not grow or thrive in one or other of these earths, alone, or mixed with some other earth, or with rotten dung, or leaves. Nursery-men, whose practice may be considered a safe criterion to judge from, have seldom more than three sorts of earth: loam, approaching to the qualities of brick earth; peat or bog earth, from heaths or morasses; and the common soil of their nursery. With these, and the addition of a little sand for striking plants, some sifted lime rubbish for succulents, and some well-rotted cow-dung for bulbs and some sort of trees, they contrive to grow thousands of different species in as great perfection (taking the difference between plants in pots and plants in the free soil and air) as in their native countries; and many, as the pine, vine, camellia, rose, &c., in a superior manner." The same author afterwards observes: "Peat earth, or heath earth, being generally procured in the state of turfs full of the roots and tops of heath, requires two or three years to rot; but after it has lain one year, it may be sifted, and what passes through a small sieve will be found fit for use. Some nursery-men use both these loams and peats as soon as procured, and find them answer perfectly for most plants; but for delicate flowers, and especially bulbs, and all florists' flowers, and for all composts into the composition of which manures enter, not less than one year ought to be allowed for decomposition, and what is technically called sweetening. The French gardeners allow for their rich orange-tree composts from three to six years."

Near large towns, where there is a constant demand for kitchen vegetables, market gardens are established for producing the required articles in variety and abundance. The finest market gardens in the world are near London, where the soil is deep, and any quantity of manure, in the form of night soil, from the metropolis, is easily obtainable. The plan on which these gardens are conducted might serve as a model for all kitchen gardeners in this country. It is thus briefly described in the article *Gardening* in the "Penny Cyclopædia:"—"The gardeners' year properly begins in autumn, when the land is dug, or rather trenched, and well manured. Various vegetables, which will be required in winter, are now sown, and especially those which are to produce plants to be set out in spring; spinach, onions, radishes, and winter salads are sown, and, when the weather is severe, are protected by a slight covering of straw or mats. In February, the cauliflowers, which have been raised in frames or under hand-glasses, are planted out. The cabbage plants are pricked out. The radishes, onions, and salads, go to market as soon as they are of sufficient size, and sugar-loaf cabbages succeed them. As the cauliflowers are taken off, they are succeeded by endive and celery, and the same is the case with the cabbages. Thus there is a constant succession of vegetables, without one moment's respite to the ground, which, in consequence of continual stirring and manuring, maintains its productive power. Deep trenching in some degree prevents that peculiar deterioration of the soil which would be the consequence of the frequent repetition of similar plants. This effect is most perceptible when the plants perfect their seed, which is seldom or never allowed to take place in market-gardens; but great attention is paid to the species of plants which succeed each other on the same spot. The principle which experience and theory unite in establishing, is that of avoiding the too frequent recurrence of plants which belong to the same natural families. The greater variety cultivated in gardens, in comparison with the common produce on a farm, enables this principle to be fully acted upon. Those gardeners who overlook this, and repeatedly sow or plant the same kind of vegetables in the same spots, are soon aware of their error by the diminution of the produce, both in quantity and quality, and by various diseases which attack the plants, however abundant may be the food supplied to them, or careful the tillage.

The principle on which the gardens are cultivated, is that of forcing vegetation by means of an abundant supply of dung, constant tillage, and occasional watering. The whole surface is converted into a species of hotbed; and crop succeeds crop with a rapidity which is truly astonishing. Those vegetables which arrive at a marketable state in the least time are always the most profitable, and those also for which there is a constant demand at all times of the year. With an abundant supply of manure, the market-gardeners have no fear of exhausting the soil; and dissimilar vegetables may grow together on the same ground.

The value of the produce in one year from an acre of garden-ground in the most favourable situation, as stated by Mr. Middleton, from the account which he received from a market-gardener, is almost incredible. It is as follows:—Radishes, £10; cauliflower, £60; cabbages, £30; celery (first crop), £50; (second crop), £40; endive, £30: making a total of £220 for the gross produce of an acre in twelve months. The expenses of cultivation are very great. In inferior situations, the produce is much less, but the expenses are also somewhat less.

When it is considered that there are nearly 2000 acres thus cultivated, the gross amount of produce must be very great."

The domestic gardener will now perceive, that, independently of a good soil, he must give his ground plenty of rich manure, and by so doing he need scarcely ever have any part of his surface unoccupied. To attain and keep up fertility is the grand principle of his operations; the delving may be awkward, the lines of beds uneven, the raking may not be neat, but all is of no importance in comparison with keeping the ground in good heart. He will likewise maintain a regular connective rotation, leaving no cropping to caprice at the time, or to a system of unintelligent routine.

GARDEN OPERATIONS—CULTIVATION.

Digging or *delving* with the spade is the principal means of garden culture. The spade usually employed is 10 inches deep in the blade or spit; but as delving is not direct downwards, but sloped, the depth to which the spade goes in digging is seldom more than nine inches, and often not more than eight inches. In commencing to dig a piece of ground, take out a spadeful all along one side, and carry it to the opposite side where you are to leave off. Now begin at one end of the trench just opened; thrust the spade with the foot into the ground, taking about five inches in breadth, lift it up, and turn it over into the open trench, the top undermost, and the fresh earth above. Do the same with the second spadeful, and so on with all the others to the end of the line. Take care to dig always a uniform depth and uniform breadth, so as to keep the line even, and the trench or furrow one width. If there be any weeds or loose offal on the surface, put them in the trench and cover them in. Break or pulverize the mould as you proceed, and keep the fresh surface level. When you have delved row after row to the last, the earth laid aside will fill in the concluding trench. Ordinary digging is performed best in dry weather; but digging to throw up lumps for winter melioration should, if possible, be performed when the soil is moist. In this kind of digging, do not touch the lumps with the spade after throwing them up.

Raking is usually performed after delving. Hold the handle of the rake at an angle of 45 degrees, and draw it lightly over the surface of the newly dug ground. The object is not to draw earth along, but to even or comb down the irregular surface, and bring away any loose refuse or stones. Like digging, it should be performed in dry weather.

Marking with the Line.—When there is any difficulty in delving in a straight line by the eye, mark off the ground with a cord, drawn from a reel stuck in the earth at one end to a dibble or pin at the other. This reel cord will be indispensable in marking off the edges of parterres, plots, &c. In such cases, having fixed the line, go along it with the spade, taking out a very small quantity of earth immediately beneath the cord. Then do the same with the opposite side and ends of the plot, and so its dimensions will be fairly marked. The gardener measures and marks off all his figures in the ground with his line and spade. With the lines he can draw a circle round a central pin, or make an oval from a union of two circles, or from semicircles, spirals, triangular spaces, or polygons. When he wishes to make a small path between rectangular plots, he sets his line accordingly, and walking along it, with a foot on each side, he tramples down the earth from one end to the other, and then he can even it and beat it down with his spade.

Hoeing.—With a common hoe, the earth is cut and drawn towards the operator. The object of hoeing is to draw the earth up the stalks of plants growing in a row, or to destroy weeds. In hoeing weeds, cut off the weed beneath the surface, and do not cover the stalk. If convenient, rake away all the loose stalks, and place them on the dung-heap. Weeds, such as dandelion and groundsill, which become winged when ripe, should be hoed and removed before seeding. As many such weeds which infest gardens are blown into them from adjacent road sides, it would not be misspent time to clear the neighbourhood of them periodically.

Animal annoyances.—All gardens are less or more exposed to the destructive inroads of wild animals. Hares and rabbits gnaw the bark off the stems or lower branches of trees, and also the buds in season. To prevent the encroachments of these quadrupeds, the garden ought to be properly fenced; but if they get in notwithstanding, the trees may be saved by smearing the lower parts with a mixture of cow-dung, soot, and water, reduced to the consistency of thin paint; a smearing of tar or grease will also answer the purpose. Moles, rats, and mice, may be caught in their appropriate traps; moles, also, may be got rid of by placing slices of leek, garlick, or onion, in a green state, within their holes, as they have a great antipathy to the odour of these vegetables.

Birds are sometimes an annoyance, particularly when new-sown peas or seeds may be easily scratched up. But though in some instances injurious, it is believed that, on the whole, their visits are beneficial; for they pick up large quantities of slugs, insects, larvæ, or caterpillars of different kinds. Wall-fruit may be preserved by nets, or by the more simple method of fixing horizontal lines of black worsted in front of the trees; the repeated ineffectual attempts to alight on the lines is said to scare the animals and cause them to desist. Lines of worsted threads, in which feathers are fastened, are employed in many cases to protect beds of seeds from birds; this preventative can be easily tried.

Insects are the grand pest of gardeners; their appearance is so mysterious, and their devastations so varied, that all schemes to extirpate them are often ineffectual. They are most destructive in their first condition of larvæ or caterpillars. In this state they should be removed by the hand from kitchen vegetables. To destroy the smaller kinds of larvæ, fumigation of tobacco smoke, by means of a fumigating bellows, is employed with advantage; and the plants are cleansed with a syringe and water. For the cleansing of fruit-trees from insects, we refer to our article on Fruit Gardening.

Slugs are another chief annoyance, especially in low-lying situations. A little salt destroys them, but, as in the case of caterpillars, the best plan is to clear them out at their first appearance by the hand or a pair of pincers. Worms in the ground are not considered injurious; in a properly trenched garden, however, they exist only in small numbers. Salt kills them.

Sowing.—The greater number of garden vegetables are reared from seeds, which are sown at certain seasons in the ground. Some seeds, such as peas, are sown in drills, the hand deliberately dropping them in a straight shallow trench. Other seeds, such as seeds of onions, leeks, cress, &c., are sown broadcast, which is a thin and equable scattering over a bed prepared for the purpose. Most seeds, peas included, require to be pressed down by treading or gentle rolling, and then covered up by the hoe or rake. All seeds should be sown and covered up in dry weather.

Planting.—Many vegetables require to be removed while young from the bed in which they were grown from seeds, and planted out in rows. A straight row is made with the line, which is gently treaded on each side. Commence now at one end of the trodden line, and in the central or untrod part pierce the earth with the dibble. Into the hole so made insert the root of the plant, and pierce the earth at its side, so as to press the mould round the root, leaving no vacant space below.

Watering.—In dry seasons, artificial irrigation is of great use for giving due liquid aliment to plants, and is indispensable to plants newly transplanted, in order to consolidate the roots. Watering, for whatever purpose, is most advantageously performed in the morning or evening. If done during the time the sun is shining, take care not to water the leaves of any plant, for the heat will raise the temperature of the liquid, and the leaves will be scalded. If the day be cloudy and cool, watering the tops of plants can do no harm. The watering, in any case, should resemble as nearly as possible a soft shower, and be performed with a rose watering-pot. The greater number of flowers are injured by watering, if the water touches them.

GARDEN VEGETABLES.

The vegetables usually grown in kitchen gardens are of various tribes or classes, which, for convenience, we shall arrange in certain intelligible groups, as follows:—1. The brassica, or cabbage kind of vegetables; 2. The pea and bean kind; 3. The root kinds, or those grown only for the sake of their roots; 4. The onion and leek kinds; 5. The salad kind; 6. The various kinds of sweet herbs; and, 7. miscellaneous kinds, including several of a delicate nature. This arrangement of groups, it will be understood, has no reference to botanical order, and has only been adopted in preference to the confusion of kinds in alphabetic lists.

The Brassica, or Cabbage Tribe.

This includes some of the most hardy, easiest cultivated, and useful of kitchen vegetables. The following are those which we would recommend to be cultivated: broccoli, Brussels sprouts, common cabbage, red cabbage, cauliflower, savoy cabbage, and Scotch kale.

Broccoli.—This is one of the best kinds of greens, and is valuable from coming at a season when not liable to be affected by caterpillars. There are various kinds of broccoli, but all may be arranged under two heads—those for spring use, and those for use from September to Christmas; the latter are termed "Cape" or autumn broccolies. The best varieties for spring use are Bowles's new sulphur, Moody's dwarf, Granger's cauliflower, and Portsmouth cream-colour.

One ounce of seed of broccoli is calculated to sow a bed four feet wide by ten long, broadcast on a prepared bed, but if sown in drills, rather less seed will be sufficient. Each kind should have a place allotted to itself. The soil should be a fresh sandy loam, not manured, and the season for sowing will be comprised between April and July. The Cape plants are finally set out in beds made rather rich with manure, at any time when they have leaves six or eight inches long; two feet distances, plant from plant, will be sufficient. Each plant is to be firmly secured in the soil; and if the weather be dry, every hole should be filled with water. This species will come in season in August, and continue to produce a supply throughout the autumn; in mild seasons, some heads may be cut even at the turn of the year.

The spring hardy varieties are treated by most persons in the same way as the Cape; that is, the plants, when they are six or eight inches high, are transplanted as they become ready, between the first week of July and that of September, into beds of richly manured loam, and set two feet apart, the largest sorts, as the Portsmouth, at thirty inches, and they are kept perfectly free from weeds. If the seasons be favourable, a successional supply of broccoli is thus obtained from the first week of March to the end of May. It is also customary to lay plants down in September, with the heads turned from the sun, applying earth on the south side over the stems, to protect them from snow and frost. We prefer to plant in six-inch deep trenches, properly manured, removing the plants to them when not less than a foot high, filling each hole with water, and repeating the watering for two or more successive evenings. This treatment, even in the driest seasons, will secure the plants; and as the winter approaches, by drawing the earth from the ridges on each side, and thus filling up the trenches, the stems will be protected, and the ground levelled and rendered light. We have practised this method during seven or eight winters, and have lost no opportunity to recommend it to others. Broccoli plants do better in trenches than any other members of this extensive family.

To save seed, it is only necessary to watch the progress of some very fine plant left late in the spring, to cut out all the weakly and crowding parts of the heads when expanded, and to secure the seed before it be quite ripe, or rather before the seed-vessels shed the seed. But as all these plants pass by crossing into other varieties, it is generally not desirable to attempt seed-growing.

Brussels Sprouts produce tall stems, three or four feet high, which support a head somewhat resembling an open savoy, of little value. This being cut off, the lateral buds down the stem protrude a succession of little green heads, like small savoys, delicate in flavour, very much admired, and yet but seldom seen, inasmuch as the true vegetable is not easily obtained. Our best authority is still that of Professor Van Mons of Brussels. We copy the following from the last edition of the *Domestic Gardener's Manual*, wherein the Brussels practice is noticed, and a few experimental remarks appended.

"The plants are raised from seed sown in March or April, of which an ounce may be requisite for a seed-bed of four feet by ten. Van Mons says (*Hort. Trans.* vol. iii.), 'The seed is sown in spring under a frame, to bring the plants forward; they are then transplanted into an open border with a good aspect. By thus beginning early, and sowing successively till late in the season, we contrive to supply ourselves in Belgium with this delicious vegetable fully ten months in the year; that is, from the end of July to the end of May. The plants need not be placed at more than eighteen inches each way, as the head does not spread wide, and the side leaves drop off.' With us (in England) the Brussels sprout is so hardy that it will stand twenty degrees of frost; and its head about Christmas is a tender and delicate species of greens. Being then cut, the plant will remain nearly torpid till the advancing sun causes it to start into new vegetation; then the spaces between the rows should have a little leaf-soil or good manure lightly forked in; and the young heads, all of which were quiescent, but visible in the winter, will speedily advance from the axils of the leaves, and yield a supply for many weeks, if they be properly pulled or cut in succession."

We cannot add much to the above, but may observe that, if any one can procure true seed, it will be advisable to try to ripen some, and to abandon seed-growing of every other kind of the brassica during that season, for fear of crossing it; also to try Van Mons' repeated sowings, for in truth a more delicate family vegetable cannot be cultivated.

Cabbage.—The cultivated varieties of the common or white hearting cabbage are very numerous; and as all can intermingle, so no one who aims at raising seed can be confident of what he shall produce. The best varieties in ordinary use are—1. Small and large York; 2. London variety of York; 3. Sugar-loaf; 4. Knight's Downton; 5. Battersea; 6. Vanack. The cabbage is a biennial plant; it runs a two years' course, bears seed, and dies. Therefore, to obtain hearted cabbages throughout the year, two or more sowings must be made; one in the spring, the other in summer. Spring-sowing can be effected at once, or it may be divided into two or three operations; because, from the third week of March to the first week of May, the seed can be successfully sown for the supply of summer and winter. Yet by attentive management, one sowing may be made to produce all that a large family can require; we restrict our directions to that simple operation.

Prepare a bed of good sound loam in an open exposure, and let it be very slightly manured, for cabbage seedlings benefit much by strong contrasts, and ought not to be made to run up while tender. Dig the ground for four rows, nine inches asunder, and from fifteen to twenty feet long. Break the earth finely, and leave it to settle for three or four days; then place boards to tread on, while a first drill, one inch deep, is struck by the line; make the bottom of this and every other drill even and a little solid, either by pressing a long pole into it, or by patting it with the back of a wooden-headed rake. Sow the seeds rather thickly, because it is better to thin out an abundance of plants than to lose the major part of a few by insects. When sown, cover the drill with fine earth, proceed to make and sow other drills, till the bed be finished, and then either tread the surface over with the feet placed nearly close together, or pat the surface with the spade, and then finish it off smooth with the back of a rake. Always avoid to tread ground into holes, and therefore recede from the work backward; prefer to use the feet in light sandy soil, but rarely with stiff and binding ground. In a very dry season, seeds will not easily vegetate; therefore, in such cases, strike the drills, and water effectually along them for three successive evenings, covering the plot with mats throughout the day. In the third evening make the drills even, sow, cover with earth, sprinkle again, and lay on the mats by day, till the plants be visible, then dust them once with the finest road sand while the dew is on, and in the evening with air-slaked lime.

These directions need not be repeated. We never saw a set of cabbage, turnip, or celery plants, so dusted with road sand that was much infested with the turnip beetle; and as to slugs, lime, or lime with coal-soot, will prevent their ravages or destroy the vermin.

When the plants begin to produce their true leaves, thin them out, first to an inch asunder, and again to two inches; they will thus gain strength rapidly; and when they have three or four good leaves four inches long, they will be fit to go out, some into nursery beds, and others to the plots where they are to remain. Those set in the former, six inches asunder, will require stocky roots, and be prepared for successional beds. The size of the plants will indicate the season during any of the summer months. Those planted permanently will require the ground to be made rich with manure, and the transition from poor to rich earth will make them grow rapidly. The smaller Yorks, &c., should stand twelve or fifteen inches apart, the large varieties twenty to thirty inches. Set each plant as deep as the base of the lower leaves, and observe the directions given under Broccoli, p. 356. These seed and nursery beds will supply the table from May to November, and in fine seasons even later.

Cabbage Coleworts—a favourite vegetable in London, known by the name of *spring greens*—are raised by sowing the seed of the hardier middle-sized cabbages from the end of June to the middle of July, to be transplanted in August and September in rows twelve or fifteen inches asunder, the plants nine inches from one another; they form pretty little heads—not properly cabbages—at a period when the old stock is exhausted, and the spring cabbage is not come in. They fail in very severe winters.

The main summer crops are raised from seeds sown between the 25th of July and the 10th of August; the last week in the former month comprises the most favourable period. The directions previously given will apply in every respect to the treatment of the plants; we need only remark, that it is advisable to plant the young cabbages first in nursery beds of simple loam, wherein they will be more secure during the frosts than they would be in rich beds; but being transferred to the latter at the end of February or early in March, they will make rapid progress, and, according to the season, produce hearted cabbages in April, May, and June. All the departments must be kept clean, and free from litter or weeds. Seed can easily be raised, but the result is always doubtful.

Red Cabbage is only used for pickling; it is raised by a two years' course—that is, by sowing in August, and transplanting as directed above; but this variety requires a little more space. The heads form in the ensuing summer, and are in fine condition in October. If sown in spring, little-hearted cabbages can be obtained, which may supply a loss, or serve as a substitute for the others.

Cauliflower.—This plant, which is grown only for its rich white head, requires in the open air a warm and moist climate, or it must be grown under glass. In Holland, it grows to great perfection, and, like many of our garden vegetables, is most likely imported from that country. One of the chief difficulties attending its open-air culture is its destruction by caterpillars, and therefore great care is in many respects necessary to bring crops forward. Under glass, the plants are rendered very expensive.

Spring sowing, for a first crop, may be made in March, over a temperate hot-bed. The seedlings are to be pricked out when the leaves are an inch broad; and from this nursery bed they are moved to the garden bed in May, to stand more than two feet asunder, the ground being made extremely rich. The plants, after they begin to grow, are occasionally watered with liquid manure collected from the drainage of dunghills. A second spring-sowing is made in the open border in May, to obtain plants from September to November, by a similar mode of treatment. The last sowing occurs in the middle of August. The plants, when about four or five weeks old, are to be thinned out to two or three inches apart, the best to go into nursery beds of rich earth, three or four inches asunder. Here they must grow till November, when the strongest are to be set out in rows, to be preserved under bell or hand-glasses. Dig a bed of rich ground in an open situation, and make it still richer with manure; set three or four plants together, five inches apart, in patches, each patch a yard asunder; give water, and cover close with a hand-glass till the plants begin to grow; then tilt the glasses on the sunny side with a brick; and thus continue to give air on mild days during the winter, and on some occasions take the glasses quite off, but replace them and cover close every night.

In the spring thin the plants to two under each glass, making good any deficiencies with some of the best plants thus taken up, and plant the surplus in a warm spot of ground two feet apart. Keep the glasses on the other plants, raising them more and more, occasionally exposing them to mild rains till about the beginning of May (unless in the event of intense frost, such as we have experienced within a few years), when the glasses may be finally removed. Cauliflowers will thus be produced in succession from the end of May throughout June.

Other plants should, in November, be placed in frames four inches apart, in a bed of rich dry loam, over a very slight hot-bed: give water, close the lights, and be guided as respects the admission of air by the directions for the hand-glass division. The lights should be covered with mats and boards during severe frosty nights. In February, March, and April, the plants are removed in succession to beds richly prepared; and the cauliflowers will come into perfection during July and August. It is customary to form the earth immediately around the stems into the shape of basins, to contain water or the liquid manure: it is a useful practice, and this, with hoeings between the rows, will comprise the general treatment.

The Savoy, or Savoy Cabbage, is very hardy, and the most useful of winter cabbages. Its culture is very easy, and admits of four sowings. There are two approved varieties, the *hardy small green*, and the large *yellow;* the former is generally preferred. Begin to sow in February, sow a second time in March; a third, and this is for the main crop, in April, about the middle of each month. Let the situation be open, the soil a good natural loam, if possible, and laid out in a bed three or four feet wide, digged and made fine. Scatter the seeds evenly, and rake them. Repeat, for the fourth time, in August. The plants of this last sowing will attain a large size by the following August and September, if planted out in April. As the plants of all the sowings, after thinning, become four or five inches high, they are transplanted between crops standing widely apart, as in the single-row system of asparagus, or as succession on potato-land. Moist weather should be chosen, and the savoys should stand two feet apart. Keep the ground clean, stir it occasionally, and draw a little toward the stems on each side, always, however, leaving a sort of furrow three or four inches wide, to receive the rain, and convey it to the roots. Seed can be sown in the second year, but it may be rendered spurious.

Scotch Kale and German Kale are the hardiest among our winter greens. They are raised by sowing the seeds either in beds or single drills late in February or early in March; to be first thinned out to three inches apart, and finally transplanted to beds or rows, wherein the plants are to stand thirty inches asunder. The plants may go out in succession, from June to the middle of July. The heads are cut first, and subsequently side-shoots arise, which produce excellent winter greens, till early cabbages come in. The plant runs up to flower and seed during the succeeding summer.

Instead of growing kale, cabbage, or any other of these plants from seed, it will save much trouble to purchase young plants by the hundred from a nursery of such vegetables.

The Pea and Bean (or Leguminous) Kinds.

The Pea.—There are various sorts of this nutritious little vegetable, but it is only those of a fine kind which are cultivated in gardens, and called *garden-peas*, that we require to notice. When fresh, they are a bright green, and when dry for seed, most are a buff yellow. Peas are a summer delicacy, and the chief art is to produce them in the open air, by the middle of May, and to keep up a succession of crops till other vegetables supersede them. Skilful gardeners do not consider it a difficult process to effect an early crop, as the plant is very hardy, and sustains violent transitions without much danger. Peas, therefore, may be accelerated in frames and vineries during February, and being transplanted into rows fronting a south and east wall, will continue to advance progressively though the weather be cold. They can also be sown (provided there be no frost) in the open ground at any time. The chief varieties for the earliest and latest crop are the *early Warwick*, *bishop's dwarf*, *Charlton*, *frame*, and some other peculiar to localities. The varieties for the main summer crops are the *blue Prussian*, the *imperial*, *Knight's dwarf* and *tall marrowfats*, and the *cimetar*.

The soil most affected by this vegetable is a free, light, but rich loam, abounding with vegetable matter, but not manured with recent dung. The situation for crops from June to August should be exposed and open. The times of sowing are very various. Some obtain an excellent yield from seed sown early in November in long drills; and if the winter be open, success is nearly certain. At whatever season persons commence, a better general rule cannot be adopted than to sow for a successional crop as soon as the peas of the preceding sowing are fairly above the surface. The plants, when three inches high, should have earth drawn against their stems on both sides, after which the soil may be superficially opened by passing the hoe lightly through it, and thin brunchy sticks, of a height suitable to the habit of the variety, ought to be thrust into the ground, converging a little, so as to meet at top, and interlace each other. Shallow soils over chalk are soon over-cropped by peas, and refuse to bring a healthy plant; and in all kinds of ground, the frequent repetition of pea-sowing is to be deprecated. The land also must be purified by a rotation of cabbage and potatoes.

Sticks for peas are indispensable in keeping them from trailing on the ground; and therefore every person who wishes to grow this vegetable in his garden, should take care to preserve the sticks from one season to another, as long as they are serviceable. Any kind of branchy twigs will answer the purpose. When all the pods are taken, remove the haum or pea-stalks to the compost dung-heap.

Dwarf-Beans are planted in rows, and the seeds are generally sown at different periods between the 1st of May and the middle of July. The situation should be open, not crowded by other vegetable crops, or under trees—the soil a free-working loam, moderately manured. The drills should not be nearer to each other than thirty inches, and not more than two inches deep. In these the beans are to be dropped at regular distances, not exceeding three or four inches. Make the ground firm at bottom, but let the covering earth be light, and only slightly raked, not trodden or made hard. The one leading principle of successful growth is to bring the plants up as soon as possible, and this is effected by selecting warm weather, and opening the drill early in the day, that its base and the loose soil about it may be rendered hot by exposure to the hottest sun for two or three hours. A cold, wet, cloddy condition of the land causes decay.

The Kidney Bean comprises two species of plants, which, though of one family, are of very different habits. Both, however, are natives of the east, and are very impatient of cold; hence the necessity of deferring the sowings till the weather be nearly settled in the spring, and the ground warmed to the depth of several inches. The two species are, first, the dwarf with its numerous varieties, all bearing the title of *French Beans;* and second, the climber, commonly termed *Scarlet beans*, or runners, although there are varieties with white and variegated blossoms: one of the latter, *the painted lady*, is very prolific. There are few of the many varieties of the dwarf which can surpass the buff or dun-coloured bean—it is free of growth, and fertile, either when forced in pots, or planted in the open ground. The black speckled dwarf is also an excellent bearer; the white-seeded is the true *haricot* of the French; in Kent it is called *caravansera*.

Runner-Beans are planted with similar precautions, or, if sown early in pots and boxes, will transplant very well. When the plants attain the height of three or four inches, they should have a little earth drawn about the stem, and be sticked; that is, somewhat tall branchy sticks should be placed on each side, converging towards each other at the top; these props ought to be eight feet high, and when the plants reach their summits, they should be nipped off and kept stopped, to cause them to produce fruit-bearing laterals. "Gather beans and have beans," that is, never leave any pods to ripen; if redundant, let them be given away, or go to the pig-stye, for a maturing pod arrests the fertility of the plant by tasking all its powers. Keep all the crops clean, and the surface of the ground about them rather open.

The Garden Bean is known to every one, and it has been in use from time immemorial, as appears by the allusion made to it by ancient classical authors. Though a native of the east, it is in all its cultivated varieties very hardy; these varieties are numerous: some of the more approved are, the early *mazagan* for the first crops, which may be sown from October to February; early *long-pod*; an excellent fertile bean for general use, not highly flavoured; *broad Windsor*, the best of all beans for flavour, but not a prolific bearer, a hybrid between the two last, combining the fertility of the one with much of the high flavour of the other.

Beans prefer a sound and rather firm loam, retentive of moisture. They suffer much in a very dry season and soil, particularly if attacked by the black blight (*aphis*), which covers the tops, preys upon the fluids of the plant, and as we have seen in the summer of 1840, almost entirely destroys whole fields in a very short time. *Topping*, when the insects are first seen, appears to be the only remedy. The seeds should always be sown in rows, and one pint is considered enough for eighty feet. The beans ought to be sown in one long row, three inches deep and four inches apart, returning the soil and treading along the course of the row; after which the rake should be employed to level the surface. Beans transplant extremely well, and therefore may be sown thickly in autumn, covering the plants with hoops and mats, or with a garden frame and lights.

When the plants rise in the rows, or begin to grow after being transplanted, loosen the earth by pushing the Dutch hoe along the surface, and draw three inches of it to each side of the stems; or rather shovel up two or three inches of the earth, and lay it flat a foot wide on each side of the row of beans, shelving rather towards the stems than from them, for then the rains would find their way directly to the roots. The seasons of sowing are autumn for the mazagan, January and February for long-pods, and from March to June for the Windsor. Sow succession crops one after the other, according to the demand, as soon as the plants of the preceding sowing shall be quite above ground. To cross the variety, sow Windsor and long-pods alternately in the row, and save the beans, introducing in future sowings an occasional Windsor bean, till the desired rich flavour be obtained.

As the beans ripen and turn black, draw them up, and place them to dry in an airy situation, guarding the pods from mice, which sometimes take every bean, and thus, as we have found, deprive the gardener of a choice variety, which he had been at considerable pains to procure.

Esculent or Root Vegetables.

The vegetables grown for the sake of their roots are of two kinds—1. Those in which the roots are round or lumpy, including the Jerusalem artichoke, the potato, and the turnip; and 2. Those which are tap or taper rooted, including the carrot, the beet-root, the radish, and the horse-radish. Strictly speaking, the tubers of potatoes, &c., are not *roots*, but merely parts of the vegetable below the ground, the real roots being small fibres which shoot out from the tubers, and bring nourishment to the plant. All require depth of soil to penetrate, and also looseness and breadth of soil to allow of expansion.

Jerusalem Artichoke.—This is a root which may be said to combine, in point of flavour, the turnip with the potato. Its name is an absurdity, for the plant has no resemblance to an artichoke; and the word *Jerusalem* is a corruption of the Italian name *Girassol*. The plant is a native of Brazil, and botanically belongs to the same family as the sunflower, but it rarely produces flowers in the British islands. The tubers, which alone are eaten, are produced abundantly under the surface close to the base of the main stem. The plant is set like the potato, by either whole roots or cuts with one or more eyes to each. The pieces or cuts should be prepared at the time of planting, and set by depositing in shallow trenches two feet apart, and one foot asunder in the row; and being covered with earth, nothing more will be required but to keep the ground clean by the hoe. The season for planting is in the first dry weather of March; and half a peck of tubers, according to Abercrombie, will plant a row 120 feet long. A good mellow loam is the proper soil, and the spot for planting should be apart from the vegetable garden, otherwise this prolific plant may intrude and become a complete nuisance. Being set in March, the plant is perfected about October or November; the crop is ready for use when the stems are quite dry. Dig only when wanted, if that be convenient; but if there be a danger of frost, as will most likely be the case, lift the crop, and store away for winter use in moist sand or any kind of light soil through which the frost cannot penetrate.

Potato.—Like the Jerusalem artichoke and some other plants, the potato is a naturalized exotic in English gardens from the wilds of America, and has been greatly improved by culture within the last hundred years. There are now many varieties, individually distinguished by colour and flavour; and as some are better than others, it is very important that proper sorts should alone be cultivated. There are two distinct kinds—*early* and *late*. Early potatoes are a premature and transient kind; they soon come to perfection, and cannot be stored for future use. On this account no cottager should have any thing to do with early potatoes, which are never grown but as a luxury, and after all they are in general poor waxy stuff. The true potato is the late kind, which will store for winter and spring use. Of this there are hundreds of sorts, every district apparently having one which is best adapted to its soil and climate. The sorts to be preferred are those possessing the quality of mealiness, and which will not degenerate or fail in cropping. The kinds we recommend, as far as they may be found suitable as to climate, &c., are kidney-shaped, or long and flattish; red roughs, a round reddish-coloured potato; and those white kinds which are smooth skinned. Of early potatoes, the ash-leaved kidney is among the best for open-garden culture.

The potato may be cultivated either from seed procured from the apple on the stalk, or from the tuber itself. If from the seed, the first crops of tubers are only a little larger than peas, and several seasons are required to bring the plant to an edible size. The common method of cultivation is by pieces or cuts, each having at least one well-defined eye; cuts with two eyes are generally preferred. These are set in trenches, the ground being in good heart with previous manuring, or good old manure placed along with the sets. The season for planting is late in April. Dig and plant sets, fresh cut as the work proceeds, placing the sets from nine to twelve inches apart, and the rows being about twenty inches asunder. Heap six inches of soil loosely over the sets, and when the shoots have risen sufficiently above ground, keep earthing them up with a hoe. When the stalks begin to decay in October, the crop is ready for lifting. (For further information on potato culture, see Agriculture.)

The Turnip.—Of this useful vegetable there are many varieties, but three only are grown in gardens: these are the *early Dutch*, which is white; the *yellow Dutch*; and the *Swede*, also a yellow kind. The white is the most delicate while young, but the yellow Swede is preferable as a keeping or late turnip. The yellow Dutch has also an excellent flavour. Turnips are cultivated from seeds in drills one foot apart, and thinned when they come into leaf, to afford room for their expansion. For the two Dutch varieties, the best soil is sandy, enriched with bone-dust or good old stable dung. One ounce of seed will go over a great space—Aber crumble says as much as 200 square feet of surface. Small sowings should be made in succession from March till July, and then the main crop for winter should be sown. To avert the encroachments of the turnip beetle, scatter road-dust over the leaves before the dew is off them in the morning. This, when timely applied, will never be found to fail. Swede turnips should be sown in April and May. Deeply hoe the ridges after thinning, and keep the surface clear of weeds.

THE CARROT.—The favourite varieties are the *early horn*, the *Altringham*, and the *long orange* or *Surrey*. All require a deep light soil. The early horn is sown in February for the spring crop, and in July for a late crop; the two other kinds are sown in March, April, and May. All are sown broadcast in beds. The seed may be saved by planting a few of the best carrots to stand the winter; seed will not retain its growing principle above a year. Carrots may be stored like potatoes in winter.

THE PARSNIP is a taper-rooted vegetable resembling the carrot in shape, and in England is a favourite vegetable with salt fish. The seed is sown in drills a foot asunder. The period of sowing is comprised between the last week of February and the first week of May. On thinning out, let the remaining plants be nine inches apart in the row.

THE RADISH.—There are two distinct kinds of radish, which comprise all the numerous varieties which are occasionally cultivated. According to Lindley's catalogue, these are—

The *taper-rooted spring radish*, of which the varieties are—1. the long white; 2. purple or salad radish; 3. salmon or rose-coloured, 4. scarlet; 5. white Russian radish.

The *round turnip-rooted spring radish.*—6. Crimson turnip-rooted; 7. yearly white; 8. purple turnip; 9. white turnip; 10. yellow turnip.

Winter radish.—11. Black Spanish; 12. brown oblong; 13. large purple; 14. round brown; 15. white Spanish, a large bulb, which in good soil grows to the size of a small stubble turnip.

Numbers 2 and 3 are the best of the spindle-rooted radishes; numbers 6 and 7 of the early turnip-rooted. The winter black radishes are rarely seen in gardens; but the large white (15) is very mild, if the soil and season be favourable, and its texture is tender.

Sown in February and March, the spring radishes come into use in April and May; if required earlier, they must be protected by frames or mats. The market-gardeners obtain them early by gentle forcing, covering the beds every severe night. The sowings of all the early varieties may be repeated monthly till August. The winter radishes are sown in July and August, and come into use from September till the spring. A rich and light soil suits the radish, with occasional copious supplies of water; and rapidity of growth is required, otherwise the roots will not be tender, nor will the flavour be mild.

HORSE-RADISH is a vegetable which in certain soils is of extremely difficult culture, in others of uncontrollably luxuriant growth: it is a most pernicious weed where it intrudes, because of the multitude of vital germs with which its root-stock abounds, and by which it is rendered a sort of vegetable polypus, every inch of it being capable of developing a growing bud.

Such being the difficulty of artificial propagation, it may be questioned whether much trouble is not expended uselessly to effect that which nature produces by the most simple means. However, horse-radish can be procured by trenching two feet deep a plot of free loam, removing all stones as the work proceeds. One trench being well cleared, a layer of manure two inches thick should be laid at the bottom (for none must be mixed with the soil), and upon that three inches of the fine loam. Some fine straight roots being in readiness, they are to be cut into two-inch lengths and piece after piece pressed into the soil eight inches asunder, in a row, to the whole length of the trench, and exactly in the middle. The soil is then to be dug out another two feet space, turning it into the open trench, clearing away the stones and other rough substances. Thus alternately trenching and planting, a bed will be formed of any extent that may be required. The work should be performed either in October and November, or in February; and the dryest weather of the season should be selected.

Abercrombie, one of the best practical writers on gardening, made the following judicious remarks, which will, if duly considered, throw light upon those habits of the plant which have led to the deep method of culture just described. "The root," he says, "being durable, forms itself into a thick knotty stool at a certain depth, sending up several erect, straight, root-shoots, in length proportionate to the depth of the stool or main root, which, if planted fifteen or eighteen inches below the surface, the shoots or sticks of horse-radish will rise to that length. They will rise in May, increasing all summer till October, when in rich ground they will be sometimes large enough to dig up for use, being an inch thick, if not, they must have another year's growth, taking them up clean to the bottom by cutting them off close to the old stool, which remaining, sends up a fresh supply annually."

These habits indicate two important facts. First, that the crown or stool must enjoy all the benefit of the manure, to enable it to send up a straight stem, and to nourish that stem by its own power; therefore no manure must be placed in the upper soil, since it might excite lateral growth. Second, it points out the method of taking up the roots, which should always be that of trenching, beginning at one end of the bed and clearing away the soil to the full depth of the original trench Thus a row can be taken without disturbing the crowns, by cutting off the sticks or upright shoots close to the head of each stool or stock, and what is surplus of each digging can be preserved in sand till more be required.

BEET-ROOT or RED BEET.—This is one of the most valuable of the spindle-rooted vegetables; it has heretofore been wasted by most persons, who, overlooking the really useful purposes to which a root so salubrious can be applied, have considered it as little more than a garnish to salads. Beet-roots should be boiled or baked till they become perfectly tender, when they may be eaten warm as a dinner vegetable. When cold, they should be cut into slices, and covered with vinegar. The plant is a biennial, that is, it grows, and perfects its roots in one season; in the following spring it sends up its flower-stalk, ripens its seeds, and dies. Seed, therefore, can thus be procured; but it is better to purchase or exchange than to grow it. Of the two varieties of red beet, the smaller deep-purple variety is greatly preferable to the larger, which approaches to and is little better than mangel-wurzel. We select two varieties. 1. The short-rooted deep purple beet, for its root. 2. The *beta cycla*, or silver beet, the leaves of which only are used in lieu of spinach.

To grow the red beet well, the ground ought to be light and pulverizable, otherwise the spindle-root will be diverted if it meet with obstacles, and become forked and distorted. Trench the plot to the depth of eighteen inches, removing large stones, roots, and hard clods of earth; lay a stratum of manure at the bottom of the trench, in order to attract the root downward; then return the fine earth. Let the work be completed before frost set in, and mark out the beds according to the number of rows required. At the middle or latter end of March, the seeds are to be sown. These are contained in a curious seed-vessel of rude shape, and cannot conveniently be separated from it. In sowing, stretch the line, and draw an even drill about an inch or an inch and a half deep, and drop the seed-vessels at even distances, two or three inches asunder; for although these spaces as much too small for final growth, it is in all cases wise to be liberal of seed, because insects and other enemies destroy many plants, and thus a season may be lost. Cover with light fine earth, and either tread or beat the covering earth with the spade till it lie firm on the seeds. If the plants rise equally, thin them gradually, till they stand from nine to twelve inches apart every way, or even eighteen inches for the large rooted variety. Beet will transplant, but the operation dwarfs the plants; and at best it is attended with some risk. Keep the rows or beds entirely free from weeds by hand-weeding or flat-hoeing. Some roots will be ready in September, and thence throughout winter. In using them, or prior to storing up during winter, cut off the straggling leaves, being careful not to wound the roots; they keep well in dry and well-washed sand, but become tainted if wet straw or decomposable vegetable substances are present.

To collect seed, either reserve two or three of the best roots in the spot where they grow, or transplant them in autumn to a convenient situation. The flower-stems will be produced in the following spring, and should be secured by stakes till the seeds ripen. Then cut down the stalks, and dry them on a cloth under an airy shed; separate the seed-vessels, and preserve them in paper bags in a dry and cool situation; the seeds will retain vegetative power for several years.

Remark applicable to Beet, Carrot, and *Parsnip.*—In stiff clayey or cloddy land these spindle-root vegetables succeed very indifferently, carrot especially; therefore, to avoid repetition, it is thought right to observe that at the time of sowing (the land having been previously trenched, and left exposed to frost in ridges), the soil is to be levelled, and holes made along the course of a garden line with a strong pointed crowbar about four inches asunder and twelve inches deep. Fill them with very light sandy earth sifted, and make a little cavity in the centres, into which drop four or five seeds; cover them with the same light earth, and beat the surface level with the flat of the spade; the roots so treated will tap downward, and be preserved as in a sort of sheath by the binding earth around them. Thus carrots, which always fail in certain soils, as we have often observed, may be produced of handsome figure and good quality, and beet-root may be grown without a fork in it—a circumstance of considerable importance with a root which is so liable to be injured by the loss of its purple juice whenever it is wounded by the knife.

The Alliaceous or Onion Kinds of Vegetables.

This savoury class of kitchen vegetables comprises the onion, leek, garlick, and shallot, the two former being by far the most important. All are natives of eastern countries, but they grow to great perfection, as respects pungency of flavour, in the British islands.

The Onion.—For a crop of onions the soil should be rich, light, and deep, and well exposed to the sun. Before sowing, work and enrich the bed to the depth of eighteen inches, and then beat it flat and firm with a spade. Sow the seeds at any time of March, thus—scratch drills by the line just so deep as to be clearly discernible, and sprinkle the seeds along them about three or four in an inch. Sift fine sandy earth over the seeds, and pat the surface even. As the onions advance, thin them out according to the variety, allowing alternately an intervening space fully equal to the breadth of the onion between bulb and bulb. In September twist the necks, take up the crop when the leaves become yellow, and expose the onions to sun and air under a shed till they be externally quite dry. Many sow onions broadcast in beds, in which case they likewise require thinning.

A summer supply of onions, at a time when the previous stock is exhausted, and the growing autumn crop has not come into season, must be desirable, and it is easily obtained. Prepare the ground early in February; select a number of those small bulbs that are always found in every bed of the larger kinds, which are not above an inch broad. The bed being ready about the end of the first week, mark out squares on the surface by means of cross-strings, but do not move the ground. At each intersection of the lines, press in an onion, the root downward, to one-third of its depth, so that the bulb remain firm and erect. Thus, when completed, the bed will exhibit the onions in squares five or six inches asunder. The onion forms its bulb in the first year of its growth, and the flower and seed in the second year. These small onions will therefore naturally attempt to produce a flower head, which, as soon as it is fairly visible, is to be pinched off. Another attempt will be made, and that also must be frustrated. The natural course of the vital-fructifying sap being thus interrupted, will be diverted to the bulb, and gradually, almost imperceptibly, two, three, or four onions of medium size will be produced and grow freely. These are to be taken, as soon as they are ripe (which, if the summer be fine and sunny, with occasional showers, will be in July,) and dried in the air as before directed.

The Leek is another of the garlic family, and if properly treated in a favourable soil and situation, grows to a very large size. It is a plant which is much improved by proper transplantation, but yet can be grown very well in its seed-bed; the London leek is the best. Sow the seeds in a shallow drill at the close of February or early in March, and cover them with half an inch of fine soil; as the plants grow, keep the surface clear of weeds by hand-picking and passing the Dutch hoe lightly on each side of the leeks. Presuming that they are thinned out at first to stand three inches asunder, half of the plants will remain, and the other half will be removed to another situation. Thus the plants in the seed-bed will stand six inches asunder, and will be greatly assisted if the ground be opened on each side of them at the distance of nine inches, and manured spit deep. A crop of fine middle-sized leeks will be obtained in the succeeding autumn.

To transplant leeks, prepare a bed at the end of June to contain either two or four rows nine inches asunder, and manure the soil richly to the depth of a foot or fifteen inches. Let the bed settle during a week or more, and in July make holes along the intended lines six inches deep and as far apart. Collect a number of the strongest leeks, trim off the straggling roots, and all the suckers or offsets. Drop a small handful of powdery manure or reduced year-old cow-dung into each hole, place in it a leek, and holding it by one hand, fill the hole with water. The object is to fix the leek as in a case, to which it can adapt itself, and will fully occupy, becoming, under propitious circumstances, a plant of large size and of most excellent quality.

Garlic, one of the most pungent species of *allium*, is increased by dividing the bulbs into cloves or small bulbs, and planting them in good sandy loam, at any period between the middle of February and the end of April. Draw drills two inches deep and ten inches apart, then press the root-end of each clove firmly into the earth, till it stand erect; let the distance between each be six inches, and fill up the drills with fine sand. Keep the ground free from weeds, and when the leaves turn yellow, take up the bulbs with a trowel or hand-fork, and keep them in a dry room. *Rocambole*, a mild species of garlic, may be cultivated in the same manner.

The Shallot is a native of Palestine; its culture is precisely the same as that of garlic, therefore both may be grown to great advantage by adopting the plan suggested by the late Mr. Knight, described in vol. ii. of the *Transactions of the London Horticultural Society.* Let a rich soil be placed beneath the roots, and raise the mould on each side to support them till they become firmly rooted. This is then removed by a hoe, and by pouring water from the rose of a watering-pot, till the bulbs stand wholly out of the ground. Thus they become mere surface bulbs, supported entirely by the fibrous roots, which pass deeply beneath into the rich soil. The growth of these plants, Mr. Knight adds, so closely resembled that of the onion, as not readily to be distinguished from it till the irregularity of form become conspicuous. "The form of the bulbs, however, remained permanently different from all I had ever seen of the same species, being much more broad and less long; and the crop was so much better in quality, as well as more abundant, that I can confidently recommend the mode of culture to every gardener."

Chives, one of the smallest of the garlic tribe, is a hardy and useful vegetable, far superior to young immature onions. The plant grows in tufts somewhat like small rushes in appearance, but of a colour resembling the yellow green of young onions or scallions; it never bulbs. A crop is readily increased by dividing the roots in April or early in May.

SALADS.

Salads are those watery plants whose long fresh leaves are eaten at table raw, or only dressed with zests and condiments without the preparation of cooking. The principal vegetable of this kind is

The Lettuce, of which there are several varieties, but all may be classed under two heads—the upright or cos lettuce, and the open or cabbage lettuce. Of the upright, the green and white cos, and of the open, the inner cabbage and grand admirable, are the best. In spring culture, sow every month in very shallow drills of fresh-digged ground, in good heart, made extremely rich with rotten manure. Strike the drills a foot asunder, and as the plants rise, thin them to stand in regular order, first to two inches, then, for table use as small salad, to six inches, and for the larger sorts, finally to one foot. Never transplant during spring and summer, as the plants, by removal, sustain a check which urges them to fly up to seed. Spring and summer lettuces are sown from February to July. In September, two small sowings should be made of the hardy sorts, to come in use during the late winter and spring; but it would be safer to make use of a large three-light frame. Some lettuces heart freely; those which do not should be assisted by passing a flat string of matting round them from the middle upwards. This bandage must not remain many days, otherwise the lettuce will run to seed, and become bitter.

In autumn culture, sow in August, in drills pretty close together, for the express purpose of transplantation in September or October; they will not then run up. When the plants are three inches high, thin out half of them, and transplant some into warm quarters, and others under a frame; protect by coverings of hoop and mats those in the open ground; and if they bear the winter, thin the plants early in the spring to six inches apart. The plants in the frame will rarely fail if the earth be free from slugs.

To save seed, transplant some of the finest lettuces when about half grown; they will produce a flower stalk, and when the down of the seeds becomes visible, cut off the upper portion of the stalk, and dry it in a warm and airy room: thus save all the seed as it ripens in succession for it is very valuable.

Endive is a salad of a pleasant bitter taste, and some authorities say it has been imported from China. There are three principal sorts in ordinary cultivation, the *green-curled*, *white-curled*, and *Batavian*, with undivided flat leaves. The seeds are sown at different periods between the beginning of June and the second week of August, as required for the autumnal, winter, and spring crops. When the plants are three or four inches high, they may be removed to beds of moderately enriched loam, to stand a foot apart. But transplantation is not essential, for very fine plants are produced in the seed beds. When they are nearly full grown, they must be prepared for the table by blanching, as otherwise they would be too bitter for use.

Blanching may be effected by several methods; the most simple is that of passing a string of soft bass matting round the centre of each plant, so as to exclude the light from the heart; but as hard frost is very injurious, some plants ought to be removed to a bed of dryish earth or sand under an airy shed; or a garden frame partially covered might be placed over a certain number of those already tied up. A good kind of pot for blanching is one of French invention, made of earthenware, and perforated with holes; a representation of it is given in fig. 3. Many persons blanch only by throwing straw loosely over the plants, but this makes a litter not very pleasing in a garden. The curved endives would blanch in a short time without tying within a darkened frame or pot, and be thus less liable to decay; for it is known that the plants suffer from being tied. The Batavian endive, however, requires a bandage at all times, otherwise its harsh green leaves will be useless, and the central heart, which alone is eatable, will never be rendered tender and white. Some persons blanch in a simple way by laying a tile over the open heart of the plant.

Fig. 3.

Corn-salad—Lamb's Lettuce, a native of Britain, formerly used much more than it now is, and cultivated in gardens as an agreeable but rather insipid salad. A quarter of an ounce of seed was estimated by Abercrombie as sufficient to sow a bed 4 feet by 5 broadcast. The first sowing is effected in August, the second in September, for winter use. Thin out the plants when an inch high, to stand at three times that distance asunder. For summer salading sow once a month, beginning in March. Cut the plants for use as soon as they are large enough; this the taste will determine; but they should be taken very young, otherwise they become rank in hot weather.

Cress, or Garden Cress.—In alluding to the culture of this common salad, we will include *mustard*, because they naturally are companions, and are always mentioned together, though they are of two very different families. In cultivating mustard and cress, it is essential only to remark, that the latter should be sown three or four days in advance of the former, because cress is more tardy than mustard. Both are very accommodating herbs, inasmuch as they will grow upon wetted flannel in a saucer placed in any apartment as well as on the floor of a green-house. On ship-board, thus, under cover, they can be obtained throughout the winter; and in the gardens, from March to November, by successional sowings made once every fortnight. Sow either broadcast over the surface of a fresh digged bed, raking, and patting in the seeds by the flat of the spade, or in shallow drills half an inch deep, covering the seeds with a little fine soil. Sow thickly, and if the young plants rise, as they are apt to do, with a covering or cake of earth over them, remove it by means of a light heath-wisk. Salad should be taken before the true rough leaves be fully developed.

Water-Cress, a valuable antiscorbutic, and wholesome as a fresh alterative to the inhabitants of cities, is grown to most advantage by the edge of running streams. If a small rivulet can be introduced into the garden, nothing can be more easy than to plant the roots in spring, and when they have once seeded, there will be speedily a mass of water-cress, which it requires only trouble to pull. The moisture is required principally in summer. The soils best calculated to bring the plants forward are loams inclining to gravel. The London markets are now supplied with immense quantities as "fine spring water-cresses," from the moist lands of Essex and neighbouring counties.

Celery is a native of Britain, found in ditches and marshes near the sea. The odour of the wild plant is very rank and disagreeable, and its juice is acrid and dangerous. By cultivation, this dangerous weed has been brought to the condition of that highly esteemed vegetable which is called sweet celery. Of this there are three varieties: 1. The common upright hollow white celery; 2. The purple-stalked; 3. The giant white and red. Of the last (for which Manchester is particularly celebrated) there is a new sub-variety, extremely tender and delicate in flavour, the plants growing in favourable soils, and, under skilful management, to an enormous size, but in ordinary cases not larger than the common white, yet always possessing a superiority in texture and flavour. Half an ounce of seed is deemed sufficient to sow a bed 4½ feet wide, and 10 feet long, comprising, therefore, 45 square feet of surface; and it may be sown in a frame, with gentle heat, at the end of February, for the first crop, and thence to the end of May, on a warm sheltered border for succession. All the seedling plants should be pricked out into intermediate beds of soft rich earth (the first sowings over a gentle hot-bed), to bring plants in June and July.

The roots of celery become bushy, and its leaf-stalk firm and stout; it likes moisture, and the soil to be rich with decomposed vegetable matter. Self-sown seed, that which falls from a seeding plant, if it light on rich earth, as that of a newly-dressed asparagus bed, in October, will bring noble plants in the spring, fit to go at once into trenches. Such plants may be thus shortly described: they are about six or eight inches long, with numerous stout leaves, and a massive collection of short fibrous roots. If these be produced by autumn-sown seed, nothing more is required; but the spring sowings will always furnish weak and lax plants, that, when grown three inches high, must be removed to a nursery bed over manure to strengthen and become stocky. Few persons can obtain these plants till June, unless grown constantly under glass.

To trench for celery, prepare the trenches by previously manuring the whole plot in the method recommended for asparagus, and after the ground has settled, dig a trench or two for the first plants at a moderate spade's depth, depositing the earth on a ridge to the right and left of the trench. Clear the bottom, lay on it three inches of leafy manure, and re-dig the ground to incorporate it with the manure. Then [illegible] a number of the strongest and most regular plants, trim off loose straggling fibres and all the side suckers, but do not touch a true leaf: set the plants four or five inches, and the large sorts six inches asunder, and fill the holes with water; shade during sunshine for three days, and give water every evening, unless there be copious showers. The size of the plants will indicate the season of transplanting.

As to future attention, water the plants frequently in the evenings till they begin to grow; and when they become three inches higher, stretch a line along each edge of the trench, and cut down by the spade as much soil as will suffice to earth the stems to that height; break it fine, and grasping each plant firmly in the left hand, insinuate the soft soil around it; then place a little finely-reduced manure along the channel of the trench on each side, remote from the stems; this will nourish the fibres, without coming into contact with the leaves; water poured once or twice along the course of this manure will promote its action. Repeat the earthings as often as the plants advance three inches, and manure the extreme edges where the spade has made a groove, till at length the trenches become level with the surface of the ground. Then dig out soil, and add it, sloping ridgewise till the plants are "landed" up fifteen, eighteen, or more inches above the surface level. Celery may be preserved from frost by two or more sloping boards placed as a pent-house about the leaves

SWEET HERBS.

These we shall class under two heads—namely, those that are purely fragrant, and those which are used for culinary purposes.

Rosemary and Lavender.—These are hardy under-shrubs, natives of the south of Europe. They yield powerful essential oils, when distilled with water, that of lavender being employed, as are also the dried flowers, in the preparation of the spirit usually but erroneously called *lavender water*. Bees are extremely partial to the flowers of rosemary.

Both these shrubs are propagated with great facility by slips of the young side shoots, trimmed of the strip of ragged bark, and merely dibbled into the soil. They will grow almost anywhere, and in any aspect, but the flowers possess the highest degree of fragrance when the plants grow in a dry, sandy, or gravelly earth. Spring or September is most favourable to the propagation by slips.

Thyme and Lemon Thyme are used in seasonings; the latter is one of the most fragrant herbs of the garden; both are raised from seeds sown early in spring, or by opening the earth around the stems, spreading the reclining shoots like layers upon it, and spreading some fresh sandy mould over them. Roots are soon formed, and thus a supply of young plants is obtained. It appears essential to renew thyme, and to place it (lemon thyme particularly) in a new soil, otherwise the plant dwindles and perishes.

Sage, red and green, is propagated in the same way as lavender.

Marjoram.—There are three sorts of this herb—*pot marjoram*, *sweet* or *knotted marjoram*, and *winter marjoram*, all hardy or sub-hardy perennial and biennial small shrubs, natives of the south of Europe, which grow readily in a dry light soil, but require change of situation. The first and third sorts may be propagated by division, in the manner of thyme, but the sweet marjoram should be raised from seeds sown in April every year, the plants to be thinned out to the distance of six inches.

Savory.—Winter and summer savory; the former is propagated either by slips and cuttings, by separating the lower shoots, or rooted offsets, in spring; the latter is an annual, sown in April, and becoming fit for gathering in the summer and autumn.

Mint.—Garden and spearmint, and peppermint, are not properly sweet herbs; the latter, indeed, is only used medicinally, the essential oil possessing extremely pungent qualities, which render it one of the best diffusible stimulants we possess. Spear, or garden mint, is used in the kitchen for a variety of purposes familiarly known. All the species, including *pennyroyal*, another medicinal mint, are cultivated by division of the roots in spring. Mint delights in moisture; and when growing in a soil which it affects, extends with great rapidity. Care, however, is required to give it a new situation when the plant becomes weak, and its leaves appear of a pale and yellowish hue.

To dry and preserve these herbs, select the shoots just as the flowers [illegible] and show colour, but before they expand; suspend them in an airy situation, under cover, not exposed to the sun.

MISCELLANEOUS VEGETABLES.

Artichoke.—This vegetable is esteemed by many, yet is found in few gardens; it is a native of the south of Europe, and was brought to England nearly three hundred years ago. Two varieties of it are cultivated in the best gardens—the conical oval-headed, and the round-headed, with dark purplish heads, the scales turned in at top. The plant has fibrous, rather fleshy roots, large deeply-cut leaves, whitish with down, and it produces an upright stem, bearing at the summit an oval or roundish flower-head, not unlike a thistle. Artichokes can be raised from seed, but much more speedily by offset-suckers, which are produced freely by the parent plant. Select a spot of open ground; any soil will do, but a free light loam is to be preferred. Dig out a trench two feet wide, and of the same depth, if the good soil extend so low; if not (and this remark will apply to every future allusion to trenching), remove all the good soil, whatever its depth, to a space beyond the boundary of the farthest intended trench, and dig and turn the inferior bottom soil, incorporating with it three or four inches of good half-decayed stable manure. Then mark out another two-foot trench, and throw into the first eight or nine inches of the surface-soil of the second trench; add another similar layer of dung, and work it and the earth thoroughly together. Again, throw in the remainder of the good soil of trench 2, and add a third layer of manure, which mix also with the soil. Thus trench 1 will be completed, and by repeating the work till the earth dug out of 1 be deposited in the last intended trench, all will be manured and laboured alike; and a piece of rich ground will be prepared that may be expected to keep in heart during many years. These directions will apply to all enriched trenching, therefore we shall not repeat them. The work ought to be performed before the frosts of winter set in; and if the land be constitutionally heavy, it will be prudent to set it up in ridges.

Suckers are generally ready at some period of April; and gardeners are willing enough to part with them. Having procured the desired number, level the ground, dig a portion of it again, and reduce the surface to the finest condition possible; then, after trimming off decayed leaves and damaged roots, plant the suckers in a row, two feet asunder. It is usual to form a complete bed of three or more ranks, the rows to be five feet apart —and we have prepared ground, as above, for such a bed—but, in truth, artichokes and all other permanent vegetables ought to be set in single rows ten feet apart, because the ground between the rows can be cropped with other annual vegetables, which will benefit the artichoke, not only by the rich manure applied at the first, and other successional croppings, but by abstracting from the soil whatever it may exude from their roots of an excrementitious nature, and which, of necessity, must be injurious to the individual itself, though nutritious as manure to a vegetable of a different habit and character. The garden, in all its crops, permanent or temporary, ought to be made a laboratory of corrective rotations, wherein one crop shall attract and consume that which another deposits. A dozen good artichokes will be sufficient for a moderate family; but as some suckers may fail, it will be prudent to set the plants one foot asunder, securing the roots firmly in the soil, and giving a copious watering at the time of planting; the supernumeraries can be removed when all are safe.

The subsequent culture is as follows:—Hoe occasionally to destroy weeds, and keep the surface open. A crop cannot be anticipated during the first year; and if little heads be pushed up, it will be wise to remove them as soon as seen. When the plants become torpid and yellow in autumn, a few of the outside leaves are to be scaled off by the hand; the ground should then be marked by the line on each side at eighteen inches distance from the plants; and being cut straight by driving the spade to its full depth along the line, the earth is to be dug up, broken fine, and laid on the surface of the eighteen inches left on each side of the plants, bringing it carefully against them, so as not to fall into their hearts, but yet to protect them effectually near the tops of the leaves; the operation is called *landing up*. This done, fill the trenches with littery straw, dung, or fern; and in the event of hard frost, bring more litter close to the plants and lay it over the *landing* earth, for artichokes are rather tender, and may be destroyed during severe winters. This practice is to be observed every year, with the additional precaution to cut the flower-stems close down.

Spring-dressing consists in removing suckers after levelling the earth, and digging in a little of the short manure that is left on the ground after clearing away the straw, &c., and making the soil neat. One or two of the strongest suckers may be left on the stock.

Asparagus.—This is justly esteemed one of the choicest vegetables of the garden, and indeed it possesses every quality to recommend it—flavour for the palate, hardihood of constitution, facility of culture, and it brings profit to the grower. It is a native of the British isles, but in its wild state bears little resemblance to the plant in a state of cultivation. Perfectly hardy, so much so as to resist a frost below zero, as was that of January, 1838, it nevertheless benefits by protection and generous tillage: this it will now be our object to prove, while explaining the method by which it is cultivated. In forming new plantations, it is customary to purchase two years' old plants, because they are safely removed at that age, and will come into bearing in two years more; April is the best season for planting; but having ourselves produced beds from *seeds*, we prefer that method of propagation. Let the ground be prepared before frost sets in by deep trenching and rich manuring; but by all means adopt the practice recommended by Grayson, who produced what he styled *giant asparagus* about the year 1830. We give his own concise directions in the following quotation:—"If your ground be stiff and unpleasant to work, get some milder earth to mix with it, and a very large cart-load of rotten dung to about every ten square feet; trench it two spit deep, and loosen the bottom; let the dung and earth be well mixed together. When your land is fit for planting, draw your drills six inches deep and sixteen inches from the first row to the second; that will form a bed; and ten inches between each plant in the row. Do not raise your beds till they have been planted one year; then put on about four inches of mould out of the alleys, and cut till the 10th of May. If you keep them well manured, they will last twenty years; but *never cut later than the 4th of June*. Let them be eight feet in the clear from bed to bed, so that you may crop between, and lose no land."

Here we find the sum of all that constitutes asparagus planting; but, after all, persons must be content with such plants as the constitution of their ground will produce; for this very sort, which in the rich water-deposited grounds (alluvial) about the Thames, produced shoots an inch in diameter, would and did dwindle in the loams of ordinary gardens to less than half that size. Nevertheless, if the beds be narrow, thoroughly manured at first, remote from each other; if, also, about February of the first year after planting, a trench eighteen inches deep, and a foot wide, be formed on each side of the narrow bed, and twelve inches distant from the plants, and be half filled with the best rotten dung, incorporated with an equal quantity of the earth dug out, a most excellent asparagus will be obtained, speedily, and the quality will not deteriorate. This enrichment may be occasionally renewed, but these auxiliary trenches are to be made at an increased distance each time, so as to avoid cutting and mutilating the roots, which extend very rapidly. As this vegetable will no doubt be sold by the cottager, too much pains cannot be bestowed in order to obtain an early supply of the very finest quality.

The seed of asparagus may be purchased, but it is yielded abundantly by every good bed, and should be gathered before it falls off, and kept in the berry till spring

We will presume the object to be double—first to raise bearing beds, and second, to raise a stock of young plants for forcing. In the former case, the ground is to be in readiness for narrow beds, eight feet asunder; in the latter, wide beds, like those directed for artichokes, should be made. Towards the latter end of March, rub out the seed, and place the line along the course of the bed; strike two drills with the hoe at the distances directed by Grayson, two inches deep: or in the broad beds, make similar drills nine inches asunder; and in both scatter the seeds pretty thickly, we will say half an inch apart; cover with fine earth, and pat it to an even surface with the spade. Watch the coming up of the plants, and be prepared to dust them with air-slacked lime, if slugs threaten them. When they shall have fairly formed rows of young seedlings six inches high, thin out the *narrow beds* first to four inches apart, and again to nine inches. The *seed rows* for forcing, thin first to three, and afterwards to five inches, and then leave both to grow, observing to use the Dutch or thrust hoe repeatedly, to keep down weeds.

In future treatment, suffer the stems to become yellow, then cut them down at two inches above the soil; clear the surface with hoe and rake, and lay on the beds eight inches of decayed leaves. Such manure is the nearest approach to that substance which it is now fashionable to call *humus;* this word is the Latin for *the ground,* and the meaning of it, if it have any, is this: all good ground contains substances which the living principle of the plant converts to sap; *earths pure* cannot be so converted, but *manure,* or decayed vegetable and animal remains, when mixed up with earth, can. After a time, ground so prepared contains what is called *humus,* and leaves or dung from an old dunghill is in a condition to be soon converted to food; therefore we say it approaches pretty nearly to the state of humus. This surface-manuring, which will generally take place about the end of October, will tend greatly to protect the young plants, and impart a stimulating principle to the ground; so that in early spring the plants will be strongly excited, and rise through the remaining manure in perfect safety. The trench manuring also, before alluded to, will come in aid of the top-dressing. We have cut excellent "grass" within three full years of the sowing, and our two large beds now existing, were prepared from seed sown in 1831. These annual enrichments, be it observed, might be persisted in with every bed that is used for cutting; but for the beds devoted to raising plants for forcing, it will suffice to make the ground thoroughly rich at the time of trenching; because the plants, when three or four years old, will be removed to the forcing department; yet a coating of half-decayed leaves or manure, after the stalks are cleared off, will not be lost, as the stronger the plants, the more remunerative will be the produce.

When once asparagus is in full bearing, if the cuttings be judiciously made, that is, by taking only the strong shoots, always leaving one or two of medium strength to each crown, and duly applying manure, a bed may keep in high condition for twenty years. But it must not be forgotten that, if every shoot be taken off a crown, to the end of a long season, that root will be destroyed. To prevent the crowns from being too deeply buried, in consequence of the autumnal dressings, it is customary to fork the beds late in March, digging them carefully, or rather loosening the surface with a fork of three prongs, and raking the rough earth into the alleys; this operation also gives freedom to the plant by opening the top soil.

With respect to forcing, it is very easy, with narrow distant beds, to bring the plants somewhat more forward in the spring, by digging trenches eighteen inches wide or wider, and above a foot deep, and filling them with warm stable dung, blended with a third part of forest-tree leaves, raising the dung to six inches above the surface level The gentle warmth communicated will stimulate vegetation, and it would be assisted by covering the beds with hoops and mats, or with boards set up ridgeways, in the event of sharp frosty nights. Successional forcing beds are prepared as soon as the cutting of the earlier begins to decline, or even when it is at its height.

The Cucumber.—This juicy vegetable is tender, and requires a fine climate and extremely rich soil. It is usually grown over a heap of old horse-dung, on a spot of ground open to the south, and large enough to permit a two or three-light frame to rest upon it. Dig out the soil a foot in depth, and lay it on one side or around the trench. If this soil be a light friable loam, incorporate it, a month before it is to be used, with one third part of leaf or vegetable earth and old decayed dung, and again dig this mixed earth two or three times. But if the soil produced from four or five year-old couch grass roots, harrowed from a field of sound loam, can be procured, it is the best aliment for the cucumber. The soil should be ready in April, and the work of planting begun in the first week of May, by filling the excavation with stable manure to the height of six inches above the surface-level of the unmoved earth, and placing on it the frame and lights. In a week the manure will have settled, and is then to be covered with a six-inch layer of the couch mould or other soil, and a hill of dryish earth raised a few inches higher under each light, in which eight or ten seeds of any approved variety may be sown. If preferred, the seeds may be prepared by previous sowing in pots in a slight hot-bed, and the plants so raised can be transferred to the hills. But as the plan now recommended is not one of forcing, it is safer to begin on the spot, by sowing seed, and covering the bed with the lights, and those with mats or boards every night. As the plants rise, observe them carefully, and pick out the central buds when the true leaves have become strong. Persons differ much in opinion at this stage concerning the practice of stopping the shoots. M. Phael, gardener to Lord Liverpool, at Addiscombe, Surrey, pointed out the true theory and results of stopping, as may be perceived by the following abbreviated extract from his work on the cucumber. He first directs to stop (nip back) the young seedlings at their second joint, then—"When the plants shoot forth after a second stopping above the second joint of the latterals, produced by the first, they seldom miss to show fruit at every joint and also a tendril, and between this tendril and the showing fruit, there may be clearly seen the rudiments of another shoot. This shoot is then in embryo but if developed it becomes a fruitful lateral. And when the leading shoot has extended itself fairly past the showing fruit, then with the finger and thumb pinch it and the tendril off just before the showing fruit, being careful that, in pinching off the tendril and the shoot, the showing fruit be not injured. This stopping of the leading shoot stops the juices of the plant, and enables the next shoot—the rudiment above mentioned—to push vigorously, and the fruit thereby also receives benefit."

The remarks will avail equally with the melon-plant as with the cucumber; and when the few remarks which follow on forcing shall be considered, nothing farther need be said of the cultivation of melons.

Whether cucumber and melon plants have been raised separately in pots, or from seed sown in the frame, they ought to be progressing early in June, and should be stopped occasionally, till fruit begin to show itself. The soil must never be *wet* but always retained in a free and rather moist condition, water being kept in the frame for the express purpose. No water ought to be poured against the stems—it should be applied to the soil round the slope of the hills only. Air ought to be admitted in all warm days, by tilting the back of the lights till three o'clock, but after that hour the frame should be kept closed. When fruit is visible, stopping, according to M. Phael's direction, should be persevered in, and its fertilising effects will soon be apparent. Cover with mats, and boards over them, at sunset. Every decayed leaf and weak shoot should be removed as soon as perceived.

In order to raise and fruit cucumbers or melons before midsummer, *forcing* must be employed. The hot beds of the best regulated gardens are conducted without masses of manure under the roots; heat is excited by an atmosphere of warm air; thus injury from internal rank vapour is avoided, and manure is economized. By this method cucumbers and melons can be produced during the spring and summer months with certainty and precision. In the cultivation of both these plants, equability of heat is important; and nothing would be more likely to secure this, and also to ward off sudden accession of cold, than to case the frame with an inner lining of thin boards, leaving a space of an inch or two between them, to be filled with some imperfectly conducting substance, such as powdered charcoal or very dry deal saw-dust, taking care to secure it from the ingress of water. The expense would be trifling, and the security afforded very great.

Celeriac, or turnip-rooted celery, is raised and nursed the same as celery; but in planting out, the ground is dug and enriched, not trenched, and the plants are set by the dibble or garden trowel along the course of shallow drills drawn by the hoe, six inches apart, watering them freely. As the growth advances, bring earth to the plants, by which the knobby roots will be bleached, and made delicate and tender. When these are the size of small turnips, they are fit for the table. Celeriac is never eaten raw; it is boiled, and served up with melted butter. The seeds of both the species ripen freely in the summer of the second year, and many fine plants are obtained from self-sown seeds, which may serve as excellent substitutes should the spring-sowings fail.

Mushrooms.—We have great hesitation in saying any thing of the artificial growth of this species of vegetable, both on account of the difficulty which unprofessional gardeners labour under respecting the right sorts, and the complex methods which require to be employed for bringing forward crops. The greater number of mushrooms brought to market are of natural growth on old rich pastures; and it would appear that, without providing a similar kind of soil full of decaying matter, the plants cannot be raised. The method of procedure is very peculiar. The mushrooms are not sown in the form of seeds, for they have no observable seeds, but by spawn, or portions of their substance, mingled in the prepared soil. Mr. Rogers, in his work, *The Vegetable Cultivator*, to which we would refer for much useful information on kitchen gardening, describes the process of mushroom culture which he says is that approved of by the Horticultural Society. We extract a few passages for the sake of general information.

"In June or July take any quantity of fresh horse-droppings (the more dry and high fed the better), mixed with short litter, one third of cow's dung, and a good portion of mould of a loamy nature; cement them well together, and mash the whole into a thin compost, and spread it on the floor of an open shed, to remain till it becomes firm enough to be formed into flat square bricks; which done, set them on an edge, and frequently turn them till half dry; then with a dibble make two or three holes in each brick, and insert in each hole a piece of good old spawn, about the size of a common walnut. The bricks should then be left till they are dry. This being completed, level the surface of a piece of ground, under cover, three feet wide, and of sufficient length to receive the bricks, on which lay a bottom of dry horse-dung, six inches thick; then form a pile, by placing the bricks in rows one upon another, with the spawn side uppermost, till the pile is three feet high; next cover it with a small portion of warm horse-dung, sufficient in quantity to diffuse a gentle glow of heat through the whole. When the spawn has spread itself through every part of the bricks, the process is ended, and the brick may then be laid up in a dry place for use.

Mushroom spawn made according to this direction, will preserve its vegetative power many years, if well dried before it is laid up; but if moist, it will grow and exhaust itself. The next subject to be treated of is the preparation of the dung for the bed; and for this purpose none answers so well as that of the horse, when taken fresh from the stable; the more droppings in it the better.

About Michaelmas is the general season for making mushroom beds (though this may be done all the year round). A quantity of the dung mentioned should be collected, and thrown together in a heap, to ferment and acquire heat; and as this heat generally proves too violent at first, it should, previously to making the bed, be reduced to a proper temperature by frequently turning it in the course of a fortnight or three weeks; which time it will most likely require for all the parts to get into an even state of fermentation. During the above time, should it be showery weather, the heat will require some sort of temporary protection, by covering it with litter or such like, as too much wet would soon deaden its fermenting quality. The like caution should be attended to in making the bed, and after finishing it. As soon as it is observed that the fiery heat and rank steam of the dung are gone off, a dry and sheltered spot of ground should be chosen on which to make the bed. The place being determined on, a space should be marked out five feet broad, and the length (running north and south) should be according to the quantity of mushrooms likely to be required. If for a moderate family, a bed twelve or fourteen feet long will be found (if it takes well) to produce a good supply of mushrooms for some months, provided proper attention be paid to the covering.

On the space marked for making the bed a trench should be thrown out, about six inches deep; the mould may be laid regularly at the side, and if good, it will do for earthing the bed hereafter; otherwise, if brought from a distance, that of a more loamy than a sandy nature will be best. Either in the trench, or if upon the surface, there should be laid about four inches of good dung, not too short, for forming the bottom of the bed; then lay on the prepared dung a few inches thick regularly over the surface, beating it as regularly down with the fork; continue thus, gradually drawing in the sides to the height of five feet, until it narrows to the top like the ridge of a house. In that state it may remain for ten days or a fortnight, during which time the heat should be examined towards the middle of the bed, by thrusting some small sharp sticks down in three or four places; and when found of a gentle heat (not hot), the bed may be spawned; for which purpose the spawn bricks should be broken regularly into pieces about an inch and a half or two inches square, beginning within six inches of the bottom of the bed, and in lines about eight inches apart; the same distance will also do for the pieces of spawn, which, in a dung ridge, are best put in by one hand, raising the dung up a few inches, whilst with the other the spawn can be laid in and covered at the same time. After spawning the bed, if it is found to be in that regular state of heat before mentioned, it may be earthed. After the surface is levelled with the back of the spade, there should be laid on two inches of mould—that out of the trench, if dry and good, will do; otherwise, if to be brought, and a choice made, that of a kindly loam is to be preferred. After having been laid on, it is to be beaten closely together, and when the whole is finished, the bed must be covered about a foot thick with good oat-straw, over which should be laid mats, for the double purpose of keeping the bed dry and of securing the covering from being blown off. In the course of two or three days the bed should be examined, and if it is considered that the heat is likely to increase, the covering must be diminished for a few days, which is better than taking it entirely off

In about a month or five weeks (but frequently within the former time, if the bed is in a high state of cultivation) mushrooms will most likely make their appearance, and in the course of eight-and-forty hours afterwards they will have grown to a sufficient size for use; in which case the author recommends that, instead of cutting them off close to the ground, they be drawn out with a gentle twist, filling up the cavity with a little fine mould, gently pressed in level with the bed."

As mushrooms may be said to cost no more than a little trouble, manure, and space for growth, at what an inconsiderable cost might not this excellent vegetable be abundantly procured! No product of the garden has hitherto been less attended to, and few afford so high a relish, either in their substantial form or as ketchup.

Nasturtium, or Indian cress, is a native of South America, but is not tender: it is used occasionally (that is, the green seed-vessels are) as a pickle. These, when they ripen, separate, and drop on the ground, where they remain torpid till the spring. Thus the plant sows itself, and so do most of the garden ornamental varieties. It therefore requires no minute directions; and any one who once possesses a plant, can multiply it by sowing seed in any way or place which may suit his taste.

Parsley.—Several species and varieties of parsley are in cultivation; these are the plain and curled-leaved, and the common and the broad-leaved, or Hamburg parsley. Preference ought to be given to the curled-leaved parsley. This vegetable is one of the most easily cultivated, and it will long keep the ground with little trouble. It is sown in drills in any spare patches of border, and arrives at maturity the next season. When it has attained this state, sprigs may be taken from it when required. When it becomes rank, it may be rooted out, and fresh parsley sown.

Rhubarb.—This is a large vegetable, grown for the sake of its firm leaf stalks. The leaves are very broad and spreading, to catch moisture, and shelter the ground around the main [illegible] from the exhausting heat of the sun. When on[illegible]d, it requires no trouble, but keeps growing [illegible] plant runs up to seed. To give additional size to the stems, cut off the seed stalk. Suckers taken from known and approved plants succeed well, but the plant can easily be raised from seed. Each plant requires considerable space. In taking away the stalks for use, do not cut them, but wrench them from the main stock, so as to take them out by the socket. The earliest sorts in repute are *Buck's scarlet*, and the *new Tobolsk*, or yellow stalked. *Radford's scarlet Goliath* is later, but remains in season till August; it surpasses for delicacy, fullness of flavour, and extreme productiveness, all its competitors. Rhubarb may be forced by very simple means. A common method is to cover the plant in the early part of the year with a box, to which air is admitted, and covered with a little stable-manure. This blanches, as well as brings forward the stalks; but that is an advantage, as it renders the vegetable more tender and delicate in flavour. Some bring forward the plants in pots in darkened forcing-houses, and, for this purpose, plants two years old are most suitable. Watering copiously is necessary in the early stages of growth, whether in the open air or under boxes. As rhubarb forms a valuable vegetable for tarts in spring, before gooseberries are ready, it would not be misspent time or trouble for a cottager to attempt forcing by the simple means above recommended.

Sea-Kale.—This is a perennial vegetable, deriving its name from being found growing in a wild state on the sandy downs which border the southern coasts of England. The method of garden culture is as follows:—Beds or spaces for single rows should be trenched and prepared as for asparagus; and at any dry period of March, when the surface earth will work freely, one or more drills should be drawn by the line, two inches deep, and the seeds scattered along the drill; or, the line being strained tight, five or six seeds should be inserted in rings two inches deep, made at the distance of two feet apart. The seeds are then covered with earth, and when the plants become strong, they are to be thinned of supernumeraries, leaving one or two of the strongest remaining eighteen inches or two feet asunder every way. If the plants be weak, it will be prudent to retain double the number. During the first season, nothing more will be required than to keep the bed or row free of weeds. In the following spring, if the plants stand nearer to each other than eighteen inches, the surplus number should be carefully raised, and transferred to another prepared space, planting the crowns of the roots two inches below the surface. Eighteen inches to two feet, according to the strength of the plants, may be the regular distances at which they are to remain. The first bed, if pots be placed over the crowns, will yield a moderate supply of blanched kale during April or May of the second spring.

Sea-kale may be forced at various periods, commencing with November, by inverting large pots over the plants, and covering those with warm dung, or dung and leaves, to excite and maintain a heat in the pot and soil of about 55 degrees. Sea-kale, like other plants, subjected to heat, can be, as it were, educated and made to conform to induced habits. Thus, at first, it seems to remain long torpid, even though the heat be considerable; but after a second season, provided the gardener be himself regular, the plants will yield to the stimulant almost to a day, though it be comparatively mild; hence sea-kale is at command from December to March by heat, and then the succession can be maintained during April and part of May by the cold beds or rows. As soon as the kale is cut from one or more roots, a sharp spade should be thrust through it, so as to cut the plant level with the surface.

Spinach is an annual, of which there are many varieties. The following are the principal kinds:—1. The round-leaved, smooth-seeded, which is sown chiefly for spring and summer crops. 2. The triangular-leaved, prickly-seeded, or winter spinach—it is sown in August, stands the winter, and continues in full bearing during spring and till midsummer. 3. The New Zealand spinach, a plant very different from the true spinach, and now neglected. 4. The white beet spinach, cultivated only for the leaves. The round-leaved should be sown about the end of January, and again in February and March, for successive spring and summer crops. The triangular-leaved is to be sown at the end of July or first week of August, and the leaves come into use at the beginning of winter; the plants require thinning and hoeing. The outer leaves only are to be taken during winter and spring, the inner leaves forming in their turn an ample succession. The seed or flower stalks will become apparent in the early part of the summer, and some of the best plants, male and female (for spinach produces both separately), should be left to perfect the seeds.

Vegetable Marrow is a species of gourd (*cucurbita*) cultivated extensively of late years. It was brought originally from Persia, and was particularly noticed by Mr. Sabine, in the *Horticultural Transactions*, vol. ii., where he described the best culinary variety as bearing a "fruit of uniform pale-yellow or light-sulphur colour, when full grown, about nine inches in length, four inches in diameter, of an elliptic shape, the surface being rendered slightly uneven by irregular longitudinal ribs, the terminations of which uniting, form a projecting apex at the end of the fruit, which is very unusual in this tribe." There are other varieties which produce fruit that weighs twenty or thirty pounds, oblong in figure, and quite green during growth; this is coarse in flavour, and in no respect equal to the small cream-coloured variety.

Sow in pots of any light soil early in April, treating the plants exactly as cucumbers under glass. About the middle of May, transfer them to a bed of rich earth over a trench filled with warm stable dung. Protect the plants by a hand-glass or frame, which, if the shoots are to run on the ground, should be raised by four or more bricks, giving air freely. When danger of frost ceases, remove the light or frame.

We have seen the best plants nailed and secured to a wall, as trees usually are. They bear profusely in summer and autumn, and are not subject to be injured by damp. The seeds are sown on the spot at the end of May, and one strong plant remains, being stopped once or twice at the tips of the advancing shoots, of which six are enough for each plant. It would be wise to place a large spare light or two sloping in front till midsummer, and again early in September. Glass diminishes the direct solar power to the extent of from 8 to 12 degrees, but it wards off the primary attack of frost, which is fatal at once to these plants. If it be desirable to save seed, preserve the fruit first formed on a plant reserved for the purpose.

HORTICULTURAL MONTHLY CALENDAR.

Having in almost every instance mentioned the seasons for sowing, planting, transplanting, and otherwise attending to the culture of vegetables in the kitchen-garden, it would only be waste of room to repeat directions, as is usually done, in connection with the different months. It is hoped, therefore, that the following general references to the months will be sufficient:—

January.—Trench and delve up all open grounds, if the weather permit; and in warm exposures, sow articles that are to be brought forward early. *February.*—Continue turning up the ground designed for early crops; sowing may go on a little more briskly. *March.*—This is a particularly busy month, being, from its open and drying character, favourable for all works of preparation. Peas, beans, asparagus, onions, carrots, &c., are sown; and various articles are transplanted from frames. *April.*—A continuance of preparing, sowing, and planting; hoeing, thinning, and clearing out of weeds, require also to be attended to.

May.—The main crops are now to be sown, early peas earthed up and staked, and young plants transplanted. The garden is now supposed to have assumed its perfect summer garb, with all things advancing in their early and mid-stages of growth. *June.*—Sow kidney beans, runners, &c.; water growing plants, if required; hoe potatoes, cabbages, and peas; and thin out beds. *July.*—Sow broccoli for the last time; also turnips, lettuces, &c.; and prepare all the unoccupied plots of ground for autumn and winter crops.

August.—Commence now to sow for the crops of next year, such as onions, early cabbages, and parsley; also winter spinach. Earth celery: hoe and thin turnips; cut down stems of gathered artichokes, and generally clear out all stumps and stalks of used plants, for their continuance exhausts the ground to no proper purpose. *September.*—The kitchen gardener has now got his principal labours in cropping over, and his chief work is continuing to sow for winter and spring successions; he also digs potatoes that seem ready, and takes care to cut down and clear off weeds.

October.—The garden having been prepared for spring vegetables, sow what was left over last month, including celery, asparagus, also early peas and beans. The cabbages and savoys require to be earthed up as high as the leaves. Remove carrots and other roots, which store away for winter use. *November.*—If temperate and open, a little sowing may be continued in sheltered borders; but frost usually sets in early in the month, and puts a stop to cropping operations. *December.*—During the latter end of November, and the open period of this month, the chief operations are digging, manuring, or trenching vacant ground, and attending to the preparation of composts. In frost, the labour exerted on the plants need only be protective; and the gardener usually occupies much of this period in pruning his trees, and attending to the more delicate plants in frames and sheltered borders.

We have now presented a sketch of the principal vegetables grown in the kitchen gardens of England, with the modes of general treatment, and the seasons suitable for their culture. It may be necessary to add the observation, that kitchen gardening, except among skilled professional men, is still in a backward condition in all parts of the British islands; and that, except in and about London, the people generally either do not know what fine vegetables are, or very seldom see them. Much has been done by horticultural societies to promote a better knowledge on the subject, and taste is evidently improving as respects all the products of the garden; nevertheless, the bulk of the people are still far behind their continental neighbours both in the cultivation and preparation of culinary vegetables. In order to produce a sensible improvement in kitchen gardening, we should require to impart a knowledge of what vegetables can be made to perform by proper cookery—what relish can be given to a plain diet, at scarcely a farthing of more expense, merely by adding a few sprigs or slices of some highly flavoured plants. In the article COOKERY, we have attempted to throw out a few useful hints on the best means of preparing vegetables, and would here add the recommendation to all persons in an humble condition of life, that, if circumstances at all permit, they should endeavour to rent and cultivate a small garden, for the purpose of rearing at leisure hours a supply of kitchen vegetables, as well as a choice of flowers, and at least small fruit. The directions afforded in the preceding pages (and in the two sheets which follow) have been drawn up in a great measure for the use of this class of people, and those in a somewhat higher sphere; and though these directions may not apply in any individual instance, they will, it is hoped, lead the mind to the true principles on which garden-culture is to be conducted; and by thought, diligence, and experience, each person will in a short time attain that amount of skill which will bring his operations to a successful issue.

THE FLOWER GARDEN.

Flowers are the ornament of vegetable existence, and have in all ages been cultivated by persons of leisure and taste, for the pleasure which they yield to the eye and the fancy. While generally healthful and exhilarating from being pursued in the open air, flower-culture is justly reckoned to be a pure and harmless recreation, which, by leading to the tranquil contemplation of natural beauty, and diverting the mind from gross worldly occupations, has a positively moral and therefore highly beneficial tendency. It has also the advantage of being alike open to the pursuit of high and low, the peasant and the peer, the over-toiled man of business and the industrious artisan. It may be followed with equal enjoyment by individuals of both sexes, and, as is well known, on every imaginable scale, from that of a single flower-pot or ornamental border, to the princely greenhouse and exquisitely varied parterre.

The natural grace, simplicity, and attractive colouring of flowers, have afforded endless themes to moralists and poets, and volumes have been penned to show how many associations of feeling, simple and sublime, these beauteous objects are calculated to excite. As our desire is to improve the feelings as well as to instruct the understanding, we hope to escape blame for pausing an instant over this agreeable view of the value of flower-culture, and would refer, for one of the most glowing eulogies on the subject, to the elegant work of Miss Sarah Stickney—the *Poetry of Life*. According to the well-expressed sentiments of this lady, few natural objects are more poetical, or more calculated to refine the taste than flowers. "From the majestic sun-flower, towering above her sisters of the garden, and faithfully turning to welcome the god of day, to the little humble and well-known weed that is said to close its crimson eye before impending showers, there is scarcely one flower which may not from its loveliness, its perfume, its natural situation, or its classical association, be considered highly poetical.

"As the welcome messenger of spring, the snowdrop claims our first regard, and countless are the lays in which the praises of this little modest flower are sung. The contrast it presents of green and white (ever the most pleasing of contrasts to the human eye), may be one reason why mankind agree in their admiration of its simple beauties; but a far more powerful reason is the delightful association by which it is connected with the idea of returning spring. Perhaps we have thought long of the melting of the snow that impeded our noonday walk. But it vanishes at last; and there, beneath its white coverlid, lies the delicate snowdrop, so pure and pale, so true an emblem of hope, and trust, and confidence, that it might teach a lesson to the desponding, and show the useless and inactive how valuable are the stirrings of that energy that can work out its purpose in secret and under oppression, and be ready in the fulness of time to make that purpose manifest and complete. The snowdrop teaches also another lesson. It marks out the progress of time. We cannot behold it without feeling that another spring has come, and immediately our thoughts recur to the events which have occurred since last its fairy bells were expanded.

"It is of little consequence what flower comes next under consideration. A few specimens will serve the purpose of proving that these lovely productions of nature are, in their general associations, highly poetical. The primrose is one upon which we dwell with pleasure proportioned to our taste for rural scenery, and the estimate we have previously formed of the advantages of a peaceful and secluded life. In connection with this flower, imagination pictures a thatched cottage standing on the slope of the hill, and a little woody dell, whose green banks are spangled all over with yellow stars, while a troop of rosy children are gamboling on the same bank, gathering the flowers, as we used to gather them our selves, before the toils and struggles of mortal conflict had worn us down to what we are now, and thus presenting to the mind the combined ideas of natural enjoyment, innocence, and rural peace—the more vivid, because we can remember the time when something like this was mingled with the cup of which we drank—the more touching, because we doubt whether, if such pure drops were still there, they would not to our taste have lost their sweetness.

"The violet, while it pleases by its modest, retiring beauty, possesses the additional charm of the most exquisite of all perfumes, which, inhaled with the pure and invigorating breezes of spring, always brings back in remembrance a lively conception of that delightful season. Thus, in the language of poetry, 'the violet-scented gale' is synonymous with those accumulated and sweetly-blended gratifications which we derive from odours, flowers, and balmy breezes; and, above all, from the contemplation of renovated nature, once more bursting forth into beauty and perfection.

The jasmine, also, with its dark-green leaves and little silver stars, saluting us with its delicious scent through the open casement, and impregnating the whole atmosphere of the garden with its sweetness, has been sung and celebrated by so many poets, that our associations are with their numbers rather than with any intrinsic quality in the flower itself. Indeed, whatever may have first established the rank of flowers in the poetical world, they have become to us like notes of music, passed on from lyre to lyre; and whenever a chord is thrilled with the harmony of song, these lovely images present themselves, neither impaired in their beauty nor exhausted of their sweetness, for having been the medium of poetic feeling ever since the world began.

"It is impossible to expend a moment's thought upon the lily, without recurring to that memorable passage in the sacred volume—'Consider the lilies of the field how they grow. They toil not, neither do they spin; and yet I say unto you, that Solomon in all his glory was not arrayed like one of these.' From the little common flower called heart's ease, we turn to that well-known passage of Shakspeare, where the fairy king so beautifully describes the 'little western flower.' And the forget-me-not has a thousand associations tender and touching, but, unfortunately, like many other sweet things, rude hands have almost robbed it of its charm. Who can behold the pale narcissus, standing by the silent brook, its stately form reflected in the glassy mirror, without losing himself in that most fanciful of all poetical conceptions, in which the graceful youth is described as gazing upon his own beauty, until he becomes lost in admiration, and finally enamoured of himself; while hopeless Echo sighs herself away into a sound, for the love which, having centred in such an object, was neither to be bought by her caresses nor won by her despair?

"Through gardens, fields, forests, and even over rugged mountains, we might wander on in this fanciful quest after remote ideas of pleasurable sensation connected with present beauty and enjoyment; nor would our search be fruitless, so long as the bosom of the earth afforded a receptacle for the germinating seed—so long as the gentle gales of summer continued to waft them from the parent stem, or so long as the welcome sun looked forth upon the ever-blooming garden of nature.

"One instance more, and we have done. The 'lady rose,' as poets have designated this queen of beauty, claims the latest though not the least consideration in speaking of the poetry of flowers. In the poetic world, the first honours have been awarded to the rose, for what reason it is not easy to define, unless from its exquisite combination of perfume, form, and colour, which has entitled this sovereign of flowers in one country to be mated with the nightingale; in another, to be chosen, with the distinction of red and white, as the badge of two honourable and royal houses. It would be difficult to trace the supremacy of the rose to its origin; but mankind have so generally agreed in paying homage to her charms, that our associations in the present day are chiefly with the poetic strains in which they are celebrated. After all the pains that have been taken to procure, transplant, and propagate the rose, there is one kind perpetually blooming around us through the summer months, without the aid or interference of man, which seems to defy his art to introduce a rival to its own unparalleled beauty—the common wild rose. Blooming in the sterile waste, this lovely flower is seen unfolding its fair leaves where there is no beauty to reflect its own, and thus calling back the heart of the weary traveller to thoughts of peace and joy—reminding him that the wilderness of human life, though rugged and barren to the discontented beholder, has also its sweet flowers, not the less welcome for being unlooked for, nor the less lovely for being cherished by a hand unseen."

To these elegantly expressed sentiments, nothing need be added by the writer of these pages.

LAYING OUT OF FLOWER GARDENS.

Flowers are cultivated in the borders and parterres of gardens of a mixed kind along with kitchen vegetables and fruits; and this may be said to be the general plan in those grounds of limited space belonging to persons of moderate means, and limited in the extent of their possessions. Many, however, cultivate flowers in gardens exclusively appropriated to them, and also in the isolated clumps which decorate ornamental lawns. In whichever way, the method of culture is clearly the same; and therefore it is unnecessary for us to enter into particulars with reference to all the sizes and kinds of gardens in which flowers may be grown.

The directions given in the previous sheet on the laying out, shelter, and exposure of kitchen gardens, apply also to flower gardens. The soil should be rich, dry, soft, and partially improved with decomposed peat and leaf mould; the exposure should be towards the sun; a free air should be allowed to play over the ground; and means should be at hand for procuring a plentiful supply of pure soft water for irrigation. Every flower garden, also, should possess a small store of fine washed sand as a restorative, and for scattering beneath the finer kinds of flowers when in bloom, as a protection from creeping vermin. Besides the utensils usually employed, the flower gardener should have a pair of small scissors to clip off decayed leaves, and some stripes of mat for tying up certain drooping plants.

The greatest difference of taste prevails on the subject of disposing the various parts of a flower-pot or garden. Straight-lined borders, ovals, circles, and fancy figures, have each their admirers; and we should advise every one to adopt that form which will be most effective in striking the eye. If the garden is seen from a parlour window, as is often the case, the plan most agreeable is to lay out the foreground as a patch of well-shaven green, which is fresh both winter and summer; on its further side there may be a semicircular border; then a walk; and next parterres of such form and size as will suit the extent of the ground. If the ground contain kitchen vegetables, they should be out of sight of the windows of the dwelling-house, or at least not brought ostentatiously forward. "It is more difficult," says the author of the *Florist's Manual*, "than may at first appear, to plan, even upon a small scale, such a piece of ground nor, perhaps, would any but an experienced and scientific eye be aware of the difficulties to be encountered in the disposal of a few shaped borders interspersed with turf. The nicety consists in arranging the different parts so as to form a connected glow of colour; to effect which, it will be necessary to place the borders in such a manner that, when viewed from the windows of the house, or from the principal entrance into the garden, one border shall not intercept the beauties of another—nor, in avoiding that error, produce one still greater, that of vacancies betwixt the borders, forming small avenues, by which the whole is separated into broken parts, and the general effect lost. Another point to be attended to is the just proportion of green turf, which, without nice observation, will be too much or too little for the colour with which it is blended; and, lastly, the breadth of the flower-borders should not be greater than what will place the roots within the reach of the gardener's arm without the necessity of treading upon the soil, the mark of footsteps being a deformity wherever it appears among flowers."

Whether all the flowers of a class—such, for instance, as violets, hyacinths, &c.—should be cultivated together, or interspersed and mingled with others, is another matter for taste to decide. The preferable plan seems to be to form a choice variety in borders and other spots, but also to cultivate a quantity of certain sorts in compartments by themselves. Neill judiciously observes, on the choice of flowers for borders—"The plants are arranged in mingled flower-borders, partly according to their size and partly according to their colour. The tallest are planted in the back part, those of middling size occupy the centre, and those of humble growth are placed in front. The beauty of a flower border, when in bloom, depends very much on the tasteful disposition of the plants in regard to colour. By intermingling plants which grow in succession, the beauty of the border may be prolonged for some weeks. In a botanic garden, the same plant cannot be repeated in the same border; but in the common flower garden, a plant, if deemed ornamental, may be often repeated with the best effect; nothing can be finer, for example, than to see many plants of double scarlet lychnis, double sweet-william, or double purple jacobea."

The Dutch, who are among the best flower gardeners in the world, have lately begun to copy the English in ornamenting turf lawns with plots of various kinds of flowers; but in all their large and regular gardens, they still dispose each kind of flowers by themselves. "We ridicule this plan," says Hogg in his Treatise on Flowers, "because it exhibits too great a sameness and formality like a nosegay that is composed of one sort of flowers only, however sweet and beautiful they may be, they lose the power to please, because they want variety. It must undoubtedly be acknowledged, that a parterre, no matter in what form—whether circular or square, elliptical or oblong—where all the shrubs, plants, and flowers in it, like the flowers in a tastefully arranged bouquet, are variously disposed in neat and regulated order, is a delightful spectacle, and worthy of general imitation. Yet still, in some particular cases, I am disposed to copy the Dutchman; and I would have my bed of hyacinths distinct, my anemones, my ranunculuses, my pinks, my carnations distinct, and even my beds of hollyhocks, double blue violets, and dwarf larkspurs distinct, to say nothing of different sorts of roses. Independently of the less trouble you have in cultivating them when kept separate, you have beauty in masses, and you have likewise their fragrance and perfume so concentrated, that they are not lost in air, but powerfully inhaled when you approach them." Leaving this question to be settled according to taste and other circumstances, we have only to recommend that no flower or herb of any kind should be sown or planted in figures resembling familiar objects. Some persons, for example, will be seen sowing annuals or planting crocuses in the figure of a letter of the alphabet, a spoon, a ship, a house, &c.—a practice so essentially vulgar that it cannot be too loudly condemned.

An error not uncommon in deciding which flowers shall be planted, is to select numbers merely for their rarity or novelty, without reference to what will be their appearance when in bloom, and which generally leads to disappointment. Unless for botanical illustration, make a choice of flowers on two principles—those which will be beautiful when in bloom, although common, and those which will bloom at the particular seasons required, to ensure a succession of variegated beauty from spring to autumn. The true amateur gardener takes a pride in improving even the commonest flowers—urging them by careful culture to the highest state of perfection as to size and brilliancy of colouring of which they are susceptible in our climate.

GENERAL CHARACTER AND TREATMENT OF FLOWERS.

All flowering plants belong to the division *Phænogamia* in the vegetable kingdom; but it is only those in which the flower is conspicuous, beautiful, or odorous, that are the objects of garden culture. The part of the plant which constitutes the flower, bloom, or blossom, is the *corolla;* it consists of several divisions or leafy parts, called *petals.* The corolla encloses the *stamens* and *pistils,* or organs of reproduction (see VEGETABLE PHYSIOLOGY); and to bring these to perfection, so as to effect the development of the seeds, is the prime object of vegetable growth. When the seeds are perfected, or in the way of being so, the corolla languishes and dies. The design of the flower gardener is less to produce size and strength in his plants, than to cause them effectually to bloom; he wishes a fine corolla. It is proper, then, to mention, that whatever tends to give excessive vigour to the stems will prevent the formation of flower-buds and the same result will follow from stunting or starving the plant. To induce flowering, the plant must be fully exposed to sun and air; at a lower temperature than 50 degrees the blooms cannot be expected to open; but from that to 65 degrees, the sap will ascend, and the buds, if duly provided with moisture and fresh air, will be rapidly developed. When freely exposed to seasonal influences, flowering plants appear withered and nearly gone in winter; they begin to shoot up in spring; come to perfection in their bloom in summer; and languish and yield their seeds in autumn. But if treated properly in the artificial climate of a greenhouse, they will be found disregarding seasonal influences, and perhaps blooming in winter or spring.

It has been remarked, that when plants have been slightly checked by frost or dry cold air, they sooner come into bloom. "This," says Mr. Rennie, in his *Alphabet of Gardening,* "arises evidently from the pulp being concentrated instead of being expended in the production of new leaves and branches, while perhaps part of the effect may be owing to increased excitability. On this principle the early potato, which does not flower freely, may be made to do so by removing the tubers; and, on the other hand, the tubers are increased in the late sorts by picking off the flower. The greater the quantity, then, of good healthy pulp which can be prepared by the leaves, the more really vigorous and healthy will the plant become; and as flowering and fruiting exhaust a great quantity of this pulp, and, of course, tend to weaken the general system of the plant, it follows that the artificial prevention of flowering must preserve in the plant the digested pulp which would have gone to nourish the flower and the fruit. Thus, by pruning off the luxuriant shoots of melons, &c., the pulp induces the shoots to spring into flowers and fruit. Upon this principle is founded the practice of treating bulbs so as to cause them to bloom vigorously, by cutting off the flowering stem as soon as it appears, in some cases, and in others so as to have the blossoms evolved when placed in water, taking care to encourage the growth of the leaves by rich soil and free exposure to air and sunshine. In this way the greatest quantity of strong pulp is stored up in the bulbs, and luxuriant blossoms are produced the succeeding season. The practice, consequently, of some unskilful gardeners, of trimming off the leaves of snowdrops, crocuses, and tulips, after the blooming is over, for the purpose of rendering a border or a bed neat, is very bad; and it is not much better to tie up the leaves, as is also preposterously done, for in this way they cannot be duly exposed to the air and the light. The same principle will apply to all other flowering plants. When a flowering branch or stem has been produced, and has begun to show the flower buds, it must be considered that it can only blow finely in proportion to the quantity of healthy pulp, either previously in the branch, or from time to time prepared by the leaves of that branch. Consequently, if there are two or more flowers on the branch, each will require its due proportion of food; but if one or more of these be artificially removed, all the spare pulp will go to feed the one, two, or more blossoms which may remain. On this is founded the practice of thinning out the flower-buds from the bunches of auriculas, polyanthuses, chrysanthemums, and other plants, in order to increase the size and beauty of those which are left to expand. It is in consequence of the same principles that free exposure to air is indispensable for producing fine flowers, inasmuch as they depend for nourishment on the pulp, which without these cannot be formed. The vivid colours and pleasant odour of flowers depend on the same causes—for in the shade these are both feeble."

Flowering plants are usually divided into the following kinds:—*Annuals;* plants which require to be sown annually, as they live and bloom only one season. *Biennials;* which do not blossom till the second season after sowing, remain a certain time in perfection, and then die; they are produced by seed, but some of the finest double varieties are continued by cuttings. *Perennials* are plants which continue to grow and blossom annually *Indigenous plants;* those which are natives of this country, and may have been perfected by culture from a wild state. *Exotics;* plants of foreign origin, which have been introduced into this country. The greater number of our fine flowers and fruits are exotics. Many of these have been acclimated, or accustomed to our climate, and rendered hardy by a course of culture; but others require to exist in green-houses and hot-houses, or under glass frames, for at least a part of the year. It would appear that each region of the globe possesses plants as distinctive in their features as the different races of men. On this subject Mr. Loudon remarks—"The native countries of plants may often be discovered by their features, in the same manner as the national distinctions which are observable in the looks and colour of mankind, and which are effected chiefly by climate. Asiatic plants are remarkable for their superior beauty; African plants for their thick and succulent leaves, as in the case of the *Cacti*; and the American plants for the length and smoothness of their leaves, and for a singularity in the shape of the flower and fruit. The flowers of European plants are but rarely beautiful. Plants indigenous to polar and mountainous regions are generally low, with small compressed leaves, but with flowers large in proportion. Plants indigenous to New Holland (or Australia) are distinguishable for small and dry leaves, that have often a shrivelled appearance. In Arabia they are low and dwarfish; in the Archipelago they are generally shrubby, and furnished with prickles; while in the Canary Islands, many plants, which in other countries are merely herbs, assume the part of shrubs and trees."

The different kinds of flowering plants are either *herbaceous* (green herbs) or *shrubby*, the stems of the latter consisting of small woody fibres. A *deciduous* tree or shrub is one which casts its leaves every winter and is recovered in spring. An *evergreen* is a shrub which retains its leaves during winter, but casts them in spring as the new buds come out. A *fibrous-rooted* plant is one whose roots send out small fibres; polyanthuses are examples of this class. A *tuberous-rooted* plant is one whose root forms small tubers or lumps; dahlias, ranunculuses, and anemones are examples among flowers, and the potato among kitchen vegetables.

The prevailing colours of flowers are yellow, orange, white, pink, scarlet, red, blue, purple, and many are variegated or composed of different tints. Proper culture, with pure air and sunshine, increase the brilliancy of the tints, and give massiveness to the corollas. Plants of a kindred species may, likewise, be improved by hybridizing or crossing, the general principle of which is the artificial application of the pollen of one plant to another. By this means, some of the most beautiful flowers have been originated. Change of soil and climate, however, are the great means of improvement. As long as it is confined to its native habitation, the corolla of the plant and all its other appurtenances are meagre and generally unattractive; but when nourished in a cultivated soil, and all its wants supplied, the whole plant strengthens and expands, and the corolla flashes on the eye in all its brilliancy of colour. The changes effected on the daisy, the rose, and the violet, will here occur to remembrance as striking instances of metamorphoses by culture and change of habitation. Speaking of the laws by which a change of colour is produced, Dr. Lindley, in his *Introduction to Botany*, observes—"A blue flower will change to white or red, but not to bright yellow; a bright yellow flower will become white or red, but never blue. Thus the hyacinth, of which the primitive colour is blue, produces abundance of white and red varieties, but nothing that can be compared to bright yellow; the yellow hyacinths, as they are called, being a sort of pale yellow-ochre colour, verging to green. Again, the ranunculus, which is originally of an intense yellow, sports into scarlet, red, purple, and almost any colour but blue. White flowers, which have a tendency to produce red, will never sport to blue, although they will to yellow; the rose for example, and the chrysanthemums. It is probable that white flowers, with a tendency to produce blue, will not vary to yellow; but of this I have no instance at hand."

Improvement in the brilliancy or change of colour, is not effected without a certain loss in the odorous properties of the plant. It is remarked, that cultivation naturally renders the odour less intense, and sometimes altogether destroys it. Thus the pleasant odour of the wild violet is not to be found in the heart's-ease.

Propagation.

Flowering plants are propagated in various ways—by sowing seeds at the proper seasons, by dividing the roots, by suckers, layers, pipings, cuttings, and bud-grafting.

Dividing the Root.—This is one of the most simple methods of propagation. The root of the growing plant is partially uncovered, and one or more portions are removed; the root is then covered up, and the removed parts transplanted in soft earth prepared to receive them. Nine-tenths of herbaceous perennials are treated in this way.

Suckers.—These are young plants thrown up from the roots of the main plant, round which they cluster. They may be removed by taking up along with them a part of the root. They should be removed in spring, after the plant has begun growing, and immediately planted out. If any flower-buds be developed on them, take them off, so as to give strength to the plant.

Layers.—Some plants, as, for instance, strawberries send out layers or runners along the ground; these have joints, if we may call them such, at certain points; and where any joint strikes the earth, it takes root, and becomes the centre of a new plant. Thus a running plant will speedily cover, as with a network, a large space of ground. Nothing is more easy than to propagate by causing the layers of some plants to take root. In the case of the carnation and similar plants, fix a stem at one of its joints to the ground, with a hooked stick or peg, covering it slightly with mould, and giving it a little moisture. Roots will, in general, strike out in a few weeks; and at the end of the season the plant is ready for being cut from its parent, and transplanted. Where layering is tedious or difficult, propagation by division of the root or cuttings is preferable.

Pipings.—Propagation by piping is an expeditious mode of raising young plants. The following is the method prescribed in a small and useful work, entitled *Every Lady her own Flower Gardener*:—"Take off the upper and young part of each shoot, close below a joint, with a sharp knife, and cut each off at the third joint, or little knob; and then cut the top leaves down pretty short, and take off the lower and discoloured ones. When you have piped in this way as many as you require, let them stand a week in a tumbler of water, which greatly facilitates their doing well. Indeed, I never failed in any pipings, slips, or cuttings, which I allowed to soak and swell in water previous to planting. When you plant the pipings, let the ground be newly dug, and raked very fine; dibble no hole, but gently thrust each piping half way down into the soft earth round each, to fix it in the bed. Water them often, if the weather is dry, but moderately, just to keep them moist; and shade them from the hot sun in the day. If pipings are covered with a hand-glass, they root earlier by three weeks than those which are exposed. Laying, piping, and slipping, are done in June and July. The plants will be well rooted and fit to plant out in October." Slips are shoots wrenched off at a joint, instead of being cut, and are treated in the same manner as pipings.

Cuttings.—A cutting is a strong shoot of last year's growth, cut from the parent stem or branch, and set in the ground. The cutting should be about six inches long, and cut off slantingly and smoothly. The soil in which the cutting is inserted requires to be dry or not too moist. Roses and honeysuckles are among the class of plants propagated by cuttings. The operation should be performed in January or February, so that the cuttings may root and vegetate in the opening of spring; but several months are required to bring the cuttings to a state fit for transplanting. Some cuttings of flower-stalks may be set as late as May and June.

Budding.—This is the method of propagation chiefly used in connection with fruit-trees; but as it is likewise applicable to rose-bushes, it may here be described. Budding is a species of grafting, and consists in inserting the fresh-cut extremity of a small twig or bud beneath the bark of another plant. A leaf bud, easily known by its tapering point, should be alone selected, and not a bud on which a flower is developed. The leaf on the selected bud is to be taken off, for if it remained it would exhaust the sap, and the bud would in all likelihood wither and die. Along with the bud, a small slip of bark is to be taken; and if this bark separate freely, it is a test of there being pulp enough to form a union. The slip of bark is to be inserted beneath the bark of the other plant, in a slit made for the purpose, and the whole tied with a strip of mat to keep out the air.

The annexed cut represents the various parts in bud-

b a c

ding. *a* is the bud cut out, with a shield of bark attached to it; *b* the stem, with a slit in the bark to receive the shield attached to the bud; *c* the bud inserted and the leaf cut away.

Shrubby plants are also propagated by *in-arching*: but a notice of this, and also of ordinary *grafting*, will be more appropriately given in Information on Trees.

SELECT FLOWERS FOR THE GARDEN.

Flowering plants are now so numerous, both as respects species and varieties, that a bare list of them would more than fill the present sheet; all, therefore, that can reasonably be expected from us is a few hints as to those which are most approved, and cultivated chiefly in the open air. A person with little experience should stock his garden only by degrees—a small number of different sorts every year, according to fancy, and what he finds to be the capabilities of the soil and exposure. In commencing to make a choice for a moderately sized garden, or for still smaller plots of ground and borders, we should also recommend the plan of cultivating a mixed variety of different colours and different heights; those which are smallest being in front or nearest the eye, and the other rows rising in height and massiveness as they recede. With as few as four colours, four sizes, and six different periods of coming into bloom, a mingled border may be established with ninety-six sorts, which will present a pleasing assemblage to the eye.

Annuals.

Some annuals are called *hardy*, and others *half-hardy*. The hardy kinds will grow and blossom in open borders, without artificial heat or protection; those which are more tender will also grow in the open air, but are improved by being brought forward under hand-glasses. Of the delicate class of annuals which must be constantly kept under glass frames, it is not our purpose to speak. The greater number of annuals may be sown at the end of March or beginning of April. The soil should be fine, and have a warm exposure; and, on being sown, cover the seeds with only about a half an inch of mould; peas and lupines should be an inch below the surface. If the weather be dry, irrigate with pure soft water occasionally. Take care that the seed you sow is fresh and good; the way to test its quality is to throw it into a glass of water; if it be worthless, it will swim; if good it will sink to the bottom.

Among the vast number of annuals that offer themselves to the choice of the gardener, the following, each having varieties as to colour, may be mentioned as taking the lead in the *half hardy kinds*:—African marigold, French marigold, China aster, marvel of Peru, chrysanthemum, sweet sultan, Indian pink, love apple, gourds, bottle gourd, convolvulus, yellow balsam or touch-me-not, amaranthus, ten-week gilliflower, white ten-week stock, cannacorus, and Chinese hollyhock. *Hardy kinds*:—Adonis-flower, candytuft, larkspur, lupines, sunflower, lavatera, poppy, major convolvulus, nasturtium, Tangier pea, sweet pea, winged pea, Lobel's catchfly, dwarf lychnis, Venus's looking-glass, Virginian stock, heart's-ease, snapdragon, mignonette, xeranthemum, purple jacobæa, Clarkias.

If annuals are required on a more extended scale, the best plan is to leave the selection to a respectable nurseryman. Such a person will at least present a copious list to make your choice from, and mention the size or height to which the plants will respectively grow. Mr. Loudon in his *Encyclopædia of Gardening*, quotes a list by Mr. Swindon, a Brentford nurseryman, consisting of nearly ninety hardy annuals, distinguished in ranges according to heights. From this we make the following extract—for the sake of clearness, leaving out the Latin names:—

"*First range—from* 8 *to* 12 *or* 14 *inches high.*

Cape marigold: purple and white. Large caterpillar; yellow, and singular pod. Venus's looking-glass: light purple. Ram's Horns; yellow: the pod is its beauty. Round snails; yellow, and singular pod. Dwarf variegated lychnis; crimson and white. Heart's ease; purple and yellow. Half-moons, or moon-trefoil; white, and singular pod. Blue meadow lychnis; sky-blue. Dwarf Virgin's stock; purple. Small hedgehogs; yellow, and singular pod. Woodroof; light-blue. Red hawkweed; pale red. Large hedgehogs; yellow, and singular pod.

Second range—from 12 *to* 18 *or* 20 *inches high.*

Oak of Jerusalem; yellowish, with fragrant smell. Small white candytuft: clear white. Long-horned devil in a bush; yellow, and singular pod. Convolvulus minor; bright blue, with yellow eye. Large purple candytuft; light purple. White Lobel's catchfly; reddish white. Annual snapdragon; purple and yellow. Scarlet or wing peas; dark and light red. Large white candytuft; clear white. Stripped convolvulus minor; blue and white. Red Lobel's catchfly; bright red. Dwarf nasturtium: deep orange. Broad Spanish nigella, with brown seed; deep blue. Red flos Adonis; dark red.

Third range—from 20 *to* 24 *or* 28 *inches high.*

Spanish nigella, with black seed; light blue. Spanish hawkweed; pale yellow and purple eye. Blue Moldavian balm; deep blue, and fine scent. Annual rest-harrow; pale red. Double Roman nigella; white mixed with blue. Small running nasturtium; dark orange. Nettle marjoram; yellowish, no smell but to the over-curious. Rocket larkspur; pink and white. Sweet-scented lupines; bright yellow. White Moldavian balm; fair white, and fragrant smell. Dutch lupines; fine blue. Annual hare's-ear; pale yellow. Purple jacobæa; purplish-red and yellow eye. Dutch ranunculus marigold; sulphur-colour. Red-topped clary; pale red, and pink leaves.

Fourth range—from 2 *to* 2½ *or* 3 *feet high.*

Belvidere: yellowish—a handsome plant. Small variegated corn-poppy; various, red and white, &c. Double upright larkspur; blue, blush, &c. Cyanus minor; blue, crimson, &c. Thorn apple; white, and singular pod. Prince's feather; dark crimson. Crown-larkspur; pale pink, spotted, &c. Honey scabius; pale blue, and globular pod. Portugal lychnis; pale red. Small blue lupines; bright blue. Love lies a-bleeding; bright red. Ranunculus-marigold; deep orange. Honeywort; dark purple, and singular shape. Strawberry spinach; bright red fruit.

Fifth range—from 3 *to* 4 *feet high.*

Venetian small-flowered mallow; purplish-white. Double crimson jagged-leaf poppy; dark crimson. Tall narrow-leaf wall-flower; bright yellow. Arach; deep crimson. Double stripped carnation poppy; red and white. Blue sweet trefoil; lead-colour. Red lavatera; light changeable red. Branching larkspur; blue and white, &c. Tall white lupines; clear white. Double black carnation poppy; rose-colour. Small Peruvian nasturtium; dark orange. Lord Anson's peas, fine blue. White lavatera; snow white. Dwarf double and quilled yellow sunflower; deep yellow. Bladder ketmia; pale sulphur and purple eye, with singular pod.

Sixth range—from 5 to 7 or 10 feet high.

Tall double yellow sunflower, with black-seed; deep yellow. Painted lady sweet-scented peas; pale red and white. Arach; sulphur-coloured. Purple sweet-scented peas; dark and light purple. Tall Indian persicaria; bright crimson. Painted lady crown peas; black and white. Convolvulus major; fine purple. White crown peas; clear white. Large Indian nasturtium; dark and light orange. Tall double brimstone sunflower; sulphur-coloured. White sweet-scented peas; clear white. Plain Tangier peas; fine crimson. Tall oriental mallow; purple. Painted lady Tangier peas; pale red and white. Scarlet beans; fine scarlet. Curled leaf upright mallow; white tinged with purple."

Whether tender or hardy, all annuals should be carefully trimmed and kept from straggling. Some will require thinning. Preserve the strongest blossoms for seed; and remove withered blooms to add vigour to those which remain.

Biennials and Perennials.

The difference between biennials and perennials is in many instances very ill defined. A biennial is said to be a plant which, when sown, does not bloom till the following spring, and dies out in the course of autumn. This is true as respects some biennials, but it is equally certain that many will survive and bloom year after year, the same as perennials. For instance, carnations are called biennials, although it is notorious that these plants will grow and multiply by roots in the same spot, year after year, with only ordinary culture. Another circumstance requires notice. No treatise on gardening that we have seen sufficiently recognises the power which biennials and other plants possess of continuing themselves by dropping their own seeds on the spot where they grow; by which means, in point of fact, many biennials, and annuals also, possess much of the virtue of perennials. In all treatises, far too much stress is laid on the necessity of artificial propagation. In most instances, biennial and perennial flowering plants simply die off from the top to the bottom of the stems at the beginning of winter, and the roots remain dormant in the ground till revived by the warmth of the ensuing spring. Except, therefore, as respects thinning, and propagating by a division of roots, and transplanting occasionally for the sake of change of soil, the unprofessional gardener has little or nothing to do in the way of multiplying the number of his plants, or artifically keeping up the species during winter. Of course, we here refer to gardening operations in the British islands, where the winters are generally so temperate that every kind of root is safe in the ground, excepting those of a tuberous nature, such as potatoes, dahlias, ranunculuses, &c., which the frost would reach and destroy. The case is very different in the Netherlands, North and Central France, and several other continental countries, where bulbs would perish if left in the ground in winter, and where even hardy evergreens require protection. The laurel, for example, remains unscathed in the open air at Edinburgh during winter, while at Brussels, five degrees farther south, it must be sheltered.

Among biennial plants suitable for ordinary flower gardens, are included the following, each having several varieties:—Canterbury bells, carnations, French honeysuckle, globe thistle, hollyhocks, scabius, sweet-william, rose campion, wallflower, lavatera arborea, purple digitalis, and stock gilliflowers. Some of these are very beautiful flowers, and none more so than carnations.

Carnations.—The carnation is an elegantly formed flower, with a slender stem and blossom at top, each blossom consisting of a convolution of petals like the rose. As a number of stems grow up together, the show of brilliant heads is considerable. Of the carnation, Hogg observes—"Of all the flowers which adorn the garden, whether they charm the eye by their beauty, or regale the sense of smell by their fragrance, the carnation may be justly said to hold the first rank. The stateliness of its growth, the brilliancy and diversity of its colours, and the sweetness of its perfume, never fail to attract our regard and admiration. The tulip, though styled the queen of the garden, cannot boast of more admirers; they may, with propriety, be considered the two masterpieces of nature; and though rival beauties, may be said to share the sovereignty of the garden equally between them; yet it must be admitted that the carnation, independent of its fragrance, has this advantage over its rival, that it continues longer in bloom, and that, when planted in pots, it can be removed to decorate the green-house, the conservatory, or the drawing-room."

There are many varieties of the carnation, but all are arranged in three classes—flakes, bizarres, and piquettees. Flake-carnations possess but two colours, with large stripes through the petals. Bizarres are variegated in colour, with irregular stripes and spots. Piquettees have a white ground spotted with purple or some other colour, and are serrated on the edges; they are the most common. According to amateurs, the finest carnations should have a flower at least three inches in diameter, with the edges of the petals waving or smooth, not serrated. The petals must fill the calyx, but not to bursting; if a calyx burst, the flower has been imperfectly cultivated. "The calyx," says Hogg, "should be at least one inch in length, terminating with broad points sufficiently strong to hold the narrow bases of the petals in a close and circular body. Whatever colours the flowers may be possessed of, they should be perfectly distinct, and disposed in long regular stripes, broadest at the edge of the lamina, and gradually becoming narrower as they approach the claw of the petal. Each petal should have a due proportion of white, one half or nearly so, which should be perfectly clear, and free from spots. Bizarres, or such as contain two colours upon a white ground, are esteemed rather preferable to flakes, which have but one, especially when their colours are remarkably rich and very regularly distributed. Scarlet, purple, and pink, are the three colours most predominant in the carnation. When the pink flake is very high in colour, it is distinguished by the appellation of rose flake."

The following, which we copy from an agreeable horticultural treatise, "The Manse-Garden," are the plainest directions we have seen respecting the culture of carnations:—"The best soil for carnations is good loam, enriched with well-rotted stable-dung, and quickened with a little sand. The quantity of manure can only be determined by the previous strength of the ground; if made too rich, the flowers will lose their fine colours; if left too poor, they will want vigour. No recent manure should ever come near a fine plant. Let the ground be prepared before winter with dung, and a rough furrow laid up to the frost. In April give a fresh digging, and plant in rows three feet by two. This width is to make room for layers, without which a fine blow of carnations cannot be maintained above one year. As the plants shoot up, they must be tied to neat green rods; and in order to have a fine blow, superfluous flower-buds must be pinched off, leaving only three or four to each stem. The young shoots near the ground, which do not run to flower, are denominated grass; and from these the layers are selected. The operation is somewhat nice, but when rightly done, is always successful, and good flowers are thus preserved and multiplied from year to year. Towards the end of July, stir up the ground about the plants, and mix with the soil a little old well-wrought compost. Have at hand a sharp penknife, a trowel, and a number of small pegs with an angle at the head: pieces of fern will do, or wood of no more strength than to bear pushing into the ground. Scoop out the earth in the form of a basin around each plant; select the strongest grassy shoots for layers, and remove such as are in the way; crop the top leaves an inch from the heart, and pinch off all the rest, taking care not to peel the stem. Begin an incision on the under side of the shoot, a little below the second joint from the top, and cut upwards till the joint is slit in the middle. Set the pointed extremity made by the slit into the bottom of the excavation, and there fix it with the peg; place the head of the shoot erect, fill in the earth, and make it firm, and finish the work with a good watering. The young plants will be ready for removal by the end of autumn, when they may be set in flower-pots if the soil is too damp, and apt to cause rotting in winter; but if sufficiently dry, the layers may remain till spring, and it will be of use before winter to earth them up, sloping and beating the mould about them so as to throw off the rain. Although the propagation of this plant by pipings (as the grass shoots taken off and stuck in the ground are called) is by no means so sure as the above method, yet of a number some will take root; and as pipings are more easily procured than plants, the experiment may be made. If carried to some distance, steep the slips in water till they swell to their proper size; trim them as above directed, and set them firm into old elastic compost; water plentifully, and set over them a handglass, first throwing water on the glass, and then earth to darken it, and let it not be stirred for some days, it being found that a deficiency both of light and air promotes the striking of slips—probably on this principle, that the sick, having no appetite, must avoid the exertion which requires food as well as that which food requires." We may add, that carnations require room to expand and blow; and when fully grown, the stalks should be tied with a strip of bass to a small stake sunk into the ground at their side.

Hollyhocks.—The hollyhock is a splendid flowering plant, and exceeds all others in tallness. With good soil, shelter, and proper exposure, it will attain a height of twelve or fourteen feet, and generally reaches seven or eight. It is a substantial herbaceous plant, with a thick stem, along which, to the top, are the broad showy blossoms; and from this attractive appearance it is very suitable to ornament fronts of cottages, edgings to shrubberies, or the centre of clumps in lawns. The colours are very various, as pink, dark purple, yellow, &c., the double sorts being the richest and most esteemed. The seeds of hollyhocks are sown in May; and in September or October the young plants are transplanted into the ground where they are intended to blossom. Although classed as biennials, the plants will spring and bloom for a number of years.

Wallflower.—There are several sorts of this fragrant plant, those flowers which are dark and most massive being most highly esteemed. Every cottage-garden should have two or three wallflowers, as their perfume is very pleasing, and their culture no way troublesome. "To insure," says the author of the "Manse-Garden," "a succession of the best breed (and the method applies to the double flowering, which yields no seed, and cannot otherwise be preserved), about the beginning of July, pinch off a hundred slips or young shoots of five or six inches in length, taken only from the finest stocks; crop the leaves, and strip the rest of the stem bare; dibble the slips, so prepared, into a bed newly dug, and shaded by trees or a north wall. Sprinkle them with water, and shade any part to which the sun has access. Not one will go back, and in this way a bountiful profusion of one of the sweetest flowers, and the best of its kind, may be had from year to year."

From what are usually called biennials, we turn to the copious list of *perennials*, which may very properly be sectioned into those with bulbous roots, tuberous roots, and fibrous roots—the latter by far the most numerous, and including plants of a herbaceous and shrubby nature; to these may be added climbing and aquatic plants.

Bulbous-Rooted Flowers.—In this class are included the hyacinth, narcissus, iris, lily, tulip, snowdrop, and crocus, with their kindred varieties.

The *Hyacinth* has a tapering bulb, shoots up long green leaves, and in the centre is a stalk on which the bloom, in the form of bells, grows all round, causing it to droop or bend. There are several varieties, differing in colour, as blue, red, and white, but the blue is the most common. The hyacinth is a favourite of the Dutch, by whom it has, like the tulip, been brought to great perfection. The best kinds have double flowers with brilliant colours. A sandy soil and saline atmosphere, with a warm exposure, are favourable in developing these properties. In the British islands, they will endure the winter in the ground, and are among the earliest blossoming plants of spring. In Holland, the bulbs are lifted and carefully stored during winter.

Of the *Narcissus* there are many varieties, which include daffodils, white narcissus, jonquils, and polyanthus narcissi. The chief difference is in colour and size of petals. Most have a lightish-yellow flower, with a deeper yellow cup. A fine narcissus has tall and firm leaves, and from the centre springs the round tube-like stalk, on the top of which is the bright yellow bloom, with petals spreading out like rays from a star. Some send up two flower-stalks, and the criterion of excellence is massiveness and distinctness of colour in the corolla. Of the polyanthus species there are at least a hundred sorts, sulphur-coloured, single and double, white, &c. Like hyacinths, the bulbs remain in the ground during winter.

Of the *Iris* there are also various kinds, some low and others tall, but always beautiful from the delicacy of colour. The Persian iris is low, with delicate blue and violet blossoms. The Chalcedonian iris is more tall, distinguished by the great size and magnificence of its flower, which is a purple-blue striped with white. The English iris is of still greater height, and has flowers of double the size of the former. None requires much sun.

The *Lily* is a plant equally tall with the larger iris. There are many species, with different colours—white, orange, and carmine. The orange, speckled with dark dots, is the more common. This plant will grow and bloom with little sun, or under the shade of trees. The effect of the orange blossom is pleasing among green plants which require to be set off by a contrast.

The *Tulip* is the pride of the garden, or at least stands pre-eminent in general estimation. Like most other bulbs, it is a native of the Levant, and was brought to its perfection in Holland, where tulip-fancying was at one period a mania, and the bulb is still a large article of trade. The finest tulip-gardens are at Haarlem, which has a warm and saline climate, with a soil light and rich. Round the roots and over the beds sand is freely scattered, so that the tulips seem as if growing from a sandy beach. In planting in this country, follow the same practice. Before planting, take off the brown outer rind. Plant in October or early in November, so that the plant will blossom in April. In forming a bed of tulips, the bulbs should be set at a distance of seven inches apart, and in straight rows, taking care to mix the different colours. To raise from seed, or to improve the varieties by crossing, are works of time, and not to be thought of in ordinary circumstances. Bulbs can be obtained from nurserymen at a price ranging from five shillings a dozen to five guineas a bulb. Half-a-crown each is a common price for tolerable bulbs; but, of course, all depends on taste. The following is Hogg's criterion of a fine variegated late tulip:—"The stem should be strong, elastic, and erect, and about thirty inches above the surface of the bed. The flower should be large, and composed of six petals: these should proceed a little horizontally at first, and then turn upwards, forming almost a perfect cup, with a round bottom, rather widest at the top. The three exterior petals should be rather larger than the three interior ones, and broader at their base; all the petals should have perfectly entire edges, free from notch or serrature; the top of each should be broad and well rounded; the ground colour of the flower, at the bottom of the cup, should be clear white or yellow, and the various rich-coloured stripes, which are the principal ornament of a fine tulip, should be regular, bold, and distinct on the margin, and terminate in fine broken points, elegantly feathered or pencilled. The centre of each leaf, or petal, should contain one or more bold blotches or stripes, intermixed with small portions of the original or breeder colour, abruptly broken into many irregular obtuse points. Some florists are of the opinion that the central stripes or blotches do not contribute to the beauty and elegance of the tulip, unless confined to a narrow stripe exactly down the centre, and that they should be perfectly free from any remains of the original or breeder colour. It is certain that such appear very beautiful and delicate, especially when they have a regular narrow feathering at the edge; but the greatest connoisseurs in this flower unanimously agree that it denotes superior merit when the tulip abounds with rich colouring, distributed in a distinct and regular manner throughout the flower, except in the bottom of the cup, which, it cannot be disputed, should be a clear bright white or yellow, free from stain or tinge, in order to constitute a perfect flower."

In order to have tulips in any thing like perfection, they require a vast deal of care. As strong sunshine injures them, they must either be placed in some shady situation, or covered with a slight awning from the sun's rays. They must, also, on no account be allowed to go to seed, for in that case the bulb is exhausted and done. To prevent this catastrophe, they should be watched when they approach perfection, and the head and stalk cut off. A usual signal for cutting is when they cease closing at sunset, or when the edges of the petals exhibit the slightest appearance of withering. They should be cut rather too early than too late. After cutting, admit the sun to the stems; and when these wither, which may be in June or July, lift the bulbs and lay them aside in a dry, airy situation; there let them remain till the period for planting, which is the end of October or beginning of November. If the bulbs require to be sent to a distance, twist each separately into a piece of paper; in this state, and kept dry, they will remain dormant, yet fresh and ready for planting, for years.

The *Crocus* and the *Snowdrop* are two small bulbous plants, so well known for their hardy growth that little need be said of them. Crocuses are very various in colour—blue, yellow, white, and so forth; and the principal thing to attend to in planting is mixing these colours in a pleasing variety. When the bloom withers, remove it, but do not cut away the numerous small green leaves. Crocuses, like all other bulbous roots, require occasional transplanting: this may be done in October.

Tuberous-Rooted Flowers.—In this class the *Dahlia* (named from Dahl, a Swedish botanist), both from its beauty and size, deserves the first place. It is a native of the temperate plains of South America, and requires a dry and airy situation for its growth. The tubers at the root resemble long potatoes, and as they spread to some distance, the plant should have a free space of from two to three feet all round. The stems, at and near the top of which are the rose-like blossoms, rise to a height of four feet, and require to be supported by stakes. A new plant may be procured by separating a part of the root, to which a stem is attached. Frost at once blights the green stalks; and when these seem utterly withered and dried, carefully lift the tubers and place them in a dry situation for the winter. In May they must be sprung on old manure under a glass frame, and then planted out and occasionally watered. Dahlias are now found of almost every colour—the Acme, a white variety edged with crimson; Amanda, rosy lilac; Ariel, white and lilac; Augusta, purple; Countess of Liverpool, scarlet; Enchantress, creamy edged cherry; Lord Althorp, dark puce; Yellow Perfection; Peerless White; and so on.

Ranunculus.—This is a stock beauty in all gardens, and it has some hundreds of varieties. The tubers are small, and require to be treated like those of the dahlia. The blossom resembles a compact small rose, of a flattish form. The soil in which the plants are placed requires to be fine and in good heart. In planting ranunculuses and dahlias, the colours should be arranged so as to produce an agreeable variety.

The *Marvel of Peru* is a very fine tap-rooted plant, rising to a height of two or three feet, and bearing beautiful transient flowers, differing in colour, as pink, white, and yellow, according to varieties. There is a succession of blossoms daily, the old ones dropping off and a new set advancing. In its native climate, the blossoms do not open till after the heat of the day is over, about four o'clock; the plant is therefore viewed as a kind of time-measurer, and is called the *West India four o'clock.*

Fibrous-Rooted Flowers.—The genera, species, and varieties of flowering plants with fibrous roots include the greater part of vegetable productions. A few of those most prized are all we need notice. Take, first, the humble *Daisy*, which has been cultivated up from the wild *gowan* or daisy, the "wee modest crimson-tipped flower," and is now found in two principal varieties, the mottled crimson and white, and the pure crimson. This plant is the hardiest of the herbaceous tribe, keeps longest in bloom of any, and may be propagated to any extent by separation of roots.

Pinks are another universal favourite; they may be viewed as an inferior kind of carnation, and are divided by florists into the three classes—damask, cobs, and pheasant's eye. The criterion of a fine pink is clear white petals, laced with crimson purple, and finely serrated on the edges. The branches of stalks require tying to stakes; and they should be cultivated, so as, if possible, to avoid bursting the calyx.

The *Primrose* family includes several pretty flowering plants—all, as is believed, sprung and cultivated up from the wild primrose (*primula vulgaris*) and cowslip. There is no great beauty in the primrose as a garden plant, but it is useful as an early spring flower, and succeeds the crocus in giving colour to the borders. The highest cultivated of the race is the *Polyanthus*, which sends up stems loaded at top with a bunch of peduncles, brown, red, and yellow. The colour most admired is that shaded with a light and dark rich crimson, resembling velvet, relieved by a bright golden hue. The *Auricula* (*primula auricula*) is a larger plant, but varying in colour, and more delicate in many respects. It flourishes best in rich soil from old turf and rotted cow-dung. The chief colours are red, pink, crimson, white, blue, apple-green, and mulberry. On the petals there is a fine meal, which is injured and marked by drops of rain or artificial irrigation; and therefore flower-fanciers take care to shelter the plants with a glass frame, and allow no drops from the watering-pot to touch them. When treated with attention, a bed of auriculas may be rendered very beautiful to the eye.

The *Anemone*, when double, is a pretty flower, with a number of flattish petals forming a cup, in the centre of which is a great number of long small petals clustering over each other. The *Lobelia*, in its different varieties, is a fine tall showy flower; that which is most common is the cardinal flower, with splendid scarlet blossoms. The *Lychnis* is another pretty scarlet flower, but small in size. The *Sweet-William* is deserving a place in every garden; it may be had of various colours, and ing from deep crimson to light pink. The *Campanula*, or pyramidal bell-flower, in its different varieties, blue and white, is a graceful flower, with pendant bells, which should also be found in all tastefully laid out borders. It may be kept long in flower, by cutting off the blooms as soon as they begin to wither. The large herbaceous *Peony*, with its brilliant and deep crimson disk, is another choice flower; it requires little care beyond supporting with stakes.

The *Violet* family, which now embraces what are termed *heart's-ease* and *pansies*, is a cultivation from the original wild violet (*viola odorata* and *viola tricolor*). By the French, the cultivated violet or heart's-ease is called *pensée* (thought), and hence our name *pansy*. No flower in the garden has lately engaged so much attention as the heart's-ease; and by means of culture and hybridizing, it has attained a most extraordinary degree of perfection as respects size and richness of colour. As many may look to us for some distinct information on this beautiful flower, we cannot do better than offer the following intelligible directions on the subject from a work of merit, Harrison's *Floricultural Cabinet*:—"The most approved method of propagation is by taking off young slips in the autumn, which is the best time, as then the ground and weather are most suitable for the formation of young rootlets, on account of its dampness and dullness. About the first week in October a bed is prepared of light but rich soil, raised a little above the path, in order to drain off all superfluous moisture. The cuttings are then made ready, by stripping them of their under leaves, and cutting close below the bottom joint, from which the roots must spring; for if this is not done, the cutting will decay to that joint, which frequently destroys the whole. After the bed is prepared, the cuttings are arranged according to their varieties, each sort being marked by a tally stick, numbered or named according to the pleasure of the owner. The cuttings will be found to be well rooted in about six weeks, when they may be planted out for blooming in the spring, or potted to keep over winter in a frame.

"The soil in which the pansy is found to flourish best is a compost of cow-dung one-half, fresh loam one-quarter part, leaf mould one-eighth part, and coarse sand one-eighth; but peat soil should on no account be intermixed, as it burns up the pansy completely. These ingredients should be well mingled together, and purified from worms and slugs by having lime-water frequently thrown over the heap, and in a short time it will be fit for use. The situation best adapted for the heart's-ease is one which is sheltered from the mid-day sun, but which receives a little in the morning, as then it is not so powerful as to injure the colours.

"Transplanting may be performed at any season, but in doing so an error is prevalent. We see the plants taken up with a ball of earth around them, and planted again with it. Now, as every thing deteriorates the soil in which it grows, and as the pansy entirely pierces every particle of earth its roots can reach, therefore that which we take up with it must be entirely exhausted, and when planted again can receive very little food from its new situation, as its roots do not by nature straggle far from the stem. To prevent this starvation, it would be much better to wash away all the soil from the roots, and plant it again with its roots unconfined; then it would be able to seek food for itself abundantly, and thereby produce much larger flowers.

"The following list contains some of the best varieties in cultivation:—Argo, Augusta, Anne Eliza, British Queen, Colonel Dundas, Captivation, Dandie Dinmont, Eclipse, Feronia, Haidee, Henrietta, Imogine, Jewess, Livia, Laura, Magnet, Miss Jane, Miss Towers, Paul Pry, Peter Dick, Platonia, Penelope, Queen of the Whites, Reliance superb, Triumph, Victoria superba, Wycomb Abbey, Westminister Abbey, Windsor Castle, White Perfection, Liberal, Acme of Perfection, Ringleader, Revenge, Victory Miss May, Glory of North Durham, Beauty of the Wear." To this we may add the Fair Maid of Perth, and Lord John Russell.

Shrubbery Garden Plants.—Among these the *Rose* unquestionably deserves the first place, having from time immemorial been a favourite in every garden. There are some hundreds of species and varieties of roses, among which are included China roses, hardy climbing roses, moss roses, select double Scotch roses, red and white roses. The China rose is delicate, with few petals in the flower, and yields a succession of blossoms monthly through a great part of the year; it is hardy, and is green and flourishing in winter. Among red roses the moss rose is the most beautiful, and next it may rank the cabbage rose; but both are excelled in fragrance by the leaves of the *Sweet Briar*, a rose shrub, which, for the sake of its delicious odour and hardy green leaves—a thing of moment in making up a bouquet—should have a place in every garden. All kinds of rose-bushes are exhaustive of the soil, and should be frequently manured, if not transplanted to fresh mould. In order to keep them in bloom, cut off all blossoms which seem about to wither. The branches require careful pruning. For adorning the walls of summer-houses, cottages, &c., the *Honeysuckle* excels, and should, both for its beauty and fragrance, by all means have a place in every garden, however humble. The honeysuckle is a *twining* plant, and has a tendency to climb in a spiral direction from right to left, which requires to be accommodated. The *Hop*, which is sometimes grown in gardens, and allowed to climb on tall poles, twines in an opposite direction, or left to right, or with the sun, and this peculiar tendency, also, must not be frustrated, but assisted by strings of bass. In point of massiveness of green surface, the honeysuckle is surpassed by the *Jasmine*, a tall running shrub, growing up in numerous branches, which, being well covered with small narrow leaves, is very suitable for leading up verandahs or concealing pieces of wall. It does not adhere, and requires nailing; when carefully treated, its massive green and elegantly drooping small branches have a pleasing effect. *Ivy*, the most pertinacious of climbing plants, will grow almost anywhere, and only requires pruning, to keep it within bounds, every winter or spring.

Among the various tall bushy shrubs most appropriate as an ornamental background in gardens, are the different species of Laurustinas, Azaleas, Rhododendrons, and Lilacs. The *Laurustina* yields a plenteous crop of small variegated blossoms. The *Arbutus* is likewise a beautiful shrub, but more suitable as an embellishment in lawns; it has small whitish bell-shaped flowers, and yields a strawberry-like fruit in warm exposures. Perhaps all out-of-door exotic shrubs should yield the palm of beauty to the *Ribes sanguineum*, a plant profusely adorned with small red blossoms which appear in spring. It resembles the currant, and matures its berries in our climate.

Evergreens.—This is a class of shrubby plants, more suitable for the ornamental front-plots of dwelling-houses, or for approaches and lawns, than for gardens; because, although the green of the leaves is pleasing in winter when other vegetation is dead, these plants are very exhaustive of the soil; often prevent the sun from getting to the borders; and keep the ground in a litter with fallen leaves at a time when trimness is expected. Many species of evergreens are now cultivated in gentlemen's grounds; but those which are most generally esteemed for ornamental plots or other limited situations, are the various tribes of laurels, alaternus, arborvitæ, holly, juniper, and box. With proper care, any of these may be lifted and transplanted into situations more agreeable to the eye, either at the beginning of September or May, when young shoots are preparing to burst forth. The plan is to dig all round them, at a distance equal to the compass of the branches, sinking the trench to a point beneath the sole of the plant; then lift them bodily with the whole mass or ball of earth round the roots. A pit must be prepared for the reception of the ball, and when placed in its new situation, fill in the rest of the pit with fine earth, laying the rootlets straight, and packing in all neatly to the surface. A copious stream of water must now be poured from a watering-pot upon the newly placed mould, round the stem; this carries the particles of earth to the rootlets, surrounding each with its proper nourishment and giving solidity to the plant. If likely to be exposed to winds, the plant should be supported in some manner.

Concluding remarks on the Garden.

The preceding are the principal flowering plants annual and perennial, herbaceous and shrubby, usually grown in open gardens in England and Scotland; and, if we have failed to do so, we wish now to impress on the minds of the unprofessional flower-culturist three main principles which should govern his labours. 1. Let him, by every reasonable attention to soil, culture, and other circumstances, endeavour to produce the finest corollas of which any given flower is susceptible: 2. Produce these flowers only in their proper season, and throw away as little time as possible in forcing blooms at unnatural periods: 3. To maintain a garden, as far as possible, in continual beauty, try to keep up *successional variety*, for in that is exhibited the experience and foresight of the gardener. The directions given in the foregoing pages, and in our floricultural calendar, it is hoped, will assist in leading to this arrangement, on which so much beauty depends; and, as a further aid, we offer the following hints furnished by a correspondent to the "Gardener's Chronicle:"—

Successional Variety.—"It is the desire of every one who possesses a garden to have as much variety of colour and succession of gayety throughout the season as the situation and means of the possessor can accomplish; yet, in viewing most gardens, even where expense is not an object, borders devoted to the cultivation of particular plants may frequently be observed to be only attractive when such plants are in blossom, and looking bare, if not unsightly, after the blossom is over.

"Supposing equal skill in the cultivation of plants in general to exist among gardeners, the great superiority in effect of one garden beyond another, consists in the distribution and arrangement of the plants themselves, so that a succession of blossom, and a due contrast of colour should, where practicable, keep every border furnished even to the end of autumn. In this respect most gardens are deficient. Succession is not attended to, except for the more limited space and favoured spots near the mansion, or in front of the conservatory. In most gardens it is considered sufficient to keep any border where plants have blossomed free from weeds and neatly raked. To the mind of the gardener this border tells its own history, of the beauty of which he had boasted but a few weeks since; but the visiter or casual observer, who walks through the garden, only seeking to please his eye with varied gayety, makes no allowance for the past, which he has not seen; and remarks, that though some parts are beautiful, a great portion of the ground has nothing worth looking at.

"By the following method, the comparative gayety of the scene may be kept up, and a relief to the eye, not without interest to the observer, preserved. Mix the seeds of the following annuals:—

Mignonette,	Heart's ease,
Carnation poppy,	Clarkia pulchella,
Papaver amœnum,	Do. white,
Dwarf Dutch poppy	Godetia of all sorts,
French poppy.	Antirrhinum majus,
Branching larkspur,	Do. sparlenum,
Eschscholtzia Californica,	Do. versicolor,
Do. Crocea,	Collinsia bicolor,
Campanula speculum,	Coreopsis tinctoria,
Candytuft, varieties,	Convolvulus minor,
Nasturtium,	Gilia tricolor, and other species.
Centaurea Cyanus, of various colours,	

"Then let this mixture of seed be very thinly scattered upon the borders early in the spring; it need not interfere with any ordinary work on the borders that may be required afterwards; and in places where the ground may be disturbed, many of the seeds will only appear at a subsequent period, and consequently flower later in the autumn.

"Most of these annuals will continue flowering until the frost kills them, and, if not removed too soon, will leave behind them sufficient seed for years to come. Every gardener has remarked the strength, the beauty, and the effect of single plants of self-sown annuals that spring up occasionally in a flower-border, and have escaped that destruction which the merciless hoe, in the hand of the undiscriminating labourer, inevitably entails upon them; yet if the intelligent labourer is properly instructed he will soon learn to confine his extermination to weeds, and his skilful eye will spare the annuals at proper intervals.

"One case yet remains of much consequence to present as well as to future effect, though generally but little attended to: this is the frequent examination of all annuals as they expand their first flowers, and the pulling them up, unless, in habit, form, and colour, they are fit to remain for stock. Crowded as annuals generally are in the patches sown in gardens, their true character and beauty are seldom seen; and if among the mass sown, some few blossoms appear more striking than the rest, and the seed of these is considered more worthy of preservation, it is generally too late to take away the worthless without destroying the plants most desired; and the seed so saved from the most select variety is but little better than that from the other plants.

"The system now recommended gives the advantage of separation and a power of selection, with the certainty that a selected plant will, by its position as a single plant, not only blossom in beauty and vigour, but afford that abundant harvest of good seed which will amply repay in future years the trifling care thus proposed to be bestowed upon it."

Garden-Walks.—In the previous article on Kitchen-Gardening, we have recommended walks to be three feet broad, laid with gravel bedded on hard cinders, and edged with dwarf-box. As an improvement, some place a bed of stones beneath the cinders, or at least the upper gravel, and on this point all must, less or more, be governed by circumstances. Where it can be afforded, asphalte pavement may be employed instead of all other materials. In the neighbourhood of London, where fine yellow Kensington gravel can be obtained at little cost, it is largely employed, and forms a beautiful walk, the yellow contrasting finely with the green of the plants. On the subject of garden-walks and borderings, the author of "The Manse Garden"* offers the following recommendations, in which we unite:—

"In making walks amongst shrubs and flowers, dryness and variety of edging are the chief things to be promoted—these not being here, as along a fruit-wall, for the sake of the trees, any scruple as to the burying of stones; and there ought to be none as to the trouble of a two-feet excavation; for every cart-load of earth so saved is worth money, and the convenience of depositing stones in place of the earth will save a great expense of carriage. Box, though tiresome, if there be no other, is by far the best edging for general use; but the planting of it is often bungled or done at a needless expense. Take up with a spade a portion of the edging that has grown too old, and part the roots: one yard of the old will serve for ten of the new—a supply that is not obtained from the nurseries without cost. In parting, tear all the old

* 'The Manse Garden,' by Nathaniel Patterson, D.D., minister of St. Andrew's church, Glasgow. Glasgow: Collins. London: Whittaker and Co. 1838. It affords us much pleasure to recommend this valuable and modest treatise to notice

bush down into the smallest shreds; throw away every one that is thicker than a crow-quill, and cut off all the roots beneath the uppermost tier of fibres; a single fibre is enough; with none the plant may do, but it is not necessary to try it. The plants so trimmed should be about four inches in length. Having filled the excavation with stones, all to four inches left for gravel on either side of the walk, dig the surface, set the line to a nicety, using many pins at every turn, to make the windings easy; bring the level exactly to the line, and beat all smooth and firm, so that the earth may stand cutting. With a trowel, cut by the line to the depth of three inches, pulling the earth towards the walk, and lay the green tops of the plants to the line, setting their heads above it, not more than one inch, and all touching one another. The roots will vary a little in depth, but let a few plants be held exact at the top with one hand, whilst the earth is applied to the unequal roots with the other. The reverse rule of evenness, providing for the roots and not the tops, is frequently adopted; hence the straggling appearance that ensues—some leaning out, and others in; some set like a tree, having a stem from which branches proceed, and others having branches sunk up to the middle. The effect is a strong feeling of indignation; and remarkable it is, that though correctness of lining be of small repute in matters of taste, yet, where a line ought to be and is designed, few things are harder to be endured than unmeaning deviations—as in the case of ill-set teeth, or the attempted dash of a clumsy handwriting. Box may be planted in September, October, or November; in February, March, or April. To wet clay, brought up by new trenching, coal-ashes may be added; and to avoid rotting by long moisture without growth, the plants may be set in May or June.

"For other edging, sea-pink is very good, but it soon gets deformed with blanks, unless taken up and replanted: whereas box, annually clipped in autumn, will serve for the half of a lifetime. London-pride admits of pairing, and will last for five years; coarse polyanthus or primrose does well beneath trees. Should the root of an old tree come in the way, it is easy to keep up the green line by planting periwinkle, which needs little soil, or ivy at some distance, and leading the runners past the tree, where they will take root all the way, and being clipped, make a handsome appearance. The propensity of ivy to run up the tree is easily counteracted; but should it be indulged, few things are more beautiful, and the tree is there rather for ornament than for the value of its timber. Double-daisy and cowslips may be used, and may be kept any length of time by occasional lifting and parting of the roots. Hepatica, blue and red mingled, make a beautiful edging, and will last an age: but the most brilliant of all is dwarf gentian; it lasts long, but must have half a foot in breadth, to secure plenty of its bright sky-blue flowers. The pansy or tricoloured violet is also fine, but must be replanted every year. For any place where the walk gets amongst high shrubs or trees, or where a sloping bank is of difficult keeping, there is nothing so fit for a low hedge as butcher's-broom; it suffers no injury by drop or shade, and grows immovably strong; and not agreeing with the shears, it is in such a place more suitable in the natural sluggishness of its growth."

The writer now proceeds to speak of the gravelling process:—"In the gravelling of walks, any rule for the avoiding of unnecessary expense, and the subsequent trouble of weeding, must be a desirable object. Let the top stratum of stones be such as are raked from the surface of the garden in dry weather, and made perfectly clean by sifting, which is by far the readiest way of getting quit of them in clearing the ground. By such method, the top stratum being of small stones, much less gravel, which perhaps must be brought from a considerable distance, will suffice. To have no unnecessary carriage, the gravel at the pit or river side must undergo one sifting with a search one inch between the wires, disposing of all large pebbles. Of stuff in this state walks are commonly made, and the result is evil continually. The small sand is a seedling bed for all manner of weeds, and the coarser part compacted with it renders hoeing almost impracticable; nor is the work well over till, in showery weather, there is need to begin it again. Thus the coarse and fine work to each other's hands, the one giving birth to weeds, and the other protecting them. Divide and govern; dissolve the compact, and the conquest is easy. Use a quarter-inch search for second sifting, and apply the coarse to one part of the walks, and the fine to another. The coarse, it is true, does not bind; but that is the beauty of it; it will not grow one weed for many years. No feet are idle on such a walk. Every one who comes into the garden does some good; the gravel is continually shuffled about, and an immense deal of work is saved to the hoe. For dryness it is admirable—a property which makes the roughness a pleasure, as every one feels in walking on the sea beach, though much rougher, and not more dry. And now for the small sort, which is almost pure sand, and in most cases will be three to one of the gravel; it binds and grows weeds, but the Dutch hoe pares it as easily as moss is scraped from a tree. For the wheels of a little coach, such walks have the smoothness of marble; and, as to the raking of leaves, on gravel the work is imperfect; on this as neat as the sweeping of a floor."

GREEN-HOUSE PLANTS.

These are of various kinds, both herbaceous and shrubby, and require to be distinguished from the preceding, only because they are exotics, too delicate for open-air exposures in all weathers, and require to be kept in a temperature above the freezing-point. This is done by placing them in a conservatory or green-house, which is a light fabric, covered with glazed frames, and, if necessary, heated a slight degree in winter by means of flues or pipes of hot water. The most approved situation of a green-house is against a wall with a southern exposure; and, if possible, placed in connection with a range of artificial vineries or hot-houses. In many instances, a conservatory is connected in a very agreeable way with the parlour of a dwelling-house, by which its beauties are enjoyed without the trouble of going out in bad weather or during the inclemency of winter. All the plants are in pots; and, whenever it can be done without risk of injury, the frames are opened and free exposure permitted. At the country-seats of various English noblemen, conservatories are formed on a magnificent scale, so as to allow the free growth of even tall trees, such as the palm and other large tropical plants.

The most beautiful green-house flowers usually cultivated are *Camellias*, *Geraniums*, *Fuchsias*, and those of the Cacteæ tribes, to which has lately been added the *Azalea Indica*. The *Camellia*, or *Camellia Joponica*, is a woody shrub, yielding splendid rose-like flowers, of colours varying from white to red. The *Geranium* is a well-known herbaceous exotic, with clustering bunches of flowers of different colours. The *Fuchsia*, introduced from Chili, is a handsome shrub, of different varieties, yielding exceedingly beautiful flowers, of a bright crimson hue; and the manner in which these flowers depend from the branches, like drops of ladies' ear-rings, has a singularly graceful effect. The *Cacti* are an interesting kind of exotics, distinguishable by their thick and substantial leaves or fronds, on which usually grow small and sharp prickles; the flowers are splendid. Besides these, we may enumerate, either for their great beauty of blossom or fragrant odours, the Nerium, Jasminum, Gardenia, Daphne, Heliotropium, Acacia, Mimosa, Eucalyptus, Diosma, Gnidia, Xeranthemum, Bignonia, Passiflora, Amaryllis, Gladiolus, and Calceolarius; the latter very beautiful and suitable for open air in summer.

An airy parlour or drawing-room, with windows facing the sun, may be considered a domestic green-house; and these apartments, as is well known, may be furnished with flowering plants, which will bloom and thrive if certain precautions be adopted. Flowers of nearly every kind may be thus treated, and made to form an elegant ornament, and means of delightful recreation, in a dwelling-house. According to their nature and size, they are planted in earthenware pots, or small wooden tubs or boxes, filled up with the appropriate mould, which requires occasional renewal, at least in part, with the removal at the same time of the outer rootlets. Bulbous plants will grow and blossom in glasses filled with water; but the plants are necessarily weakened by the process. The glasses should be dark coloured, for the roots of the plants are injured by light.

On the subject of the cultivation of flowers in windows, we find the following useful observations in an excellent periodical, the *Gardener's Chronicle*:—"The three principal things requiring consideration are *air*, *light*, and *moisture*. Plants kept in windows naturally extend their branches and leaves to the light, and they thereby become one-sided; and it is wrong to endeavour to make them otherwise by frequently turning them, as the plants will as constantly turn their growth to follow the light, which not only weakens them, but spoils their appearance. As for plants receiving no perpendicular light, it is more natural to spread them out, forming one good face or tier of healthy foliage to the window; for well-balanced heads under such circumstances are almost out of the question. Place them as near the glass as possible; of course, windows having a south aspect possess the greatest advantage.

"Judicious watering of plants in rooms is perhaps the most important feature in their management; and it is unfortunately in most cases ill understood, being too often given mechanically, as it were at stated times, whether required by the plants or not; and, by a too eager desire for their welfare, they are frequently surfeited to death with water, which is justly termed 'killing by kindness,' and is practised with success, especially by ladies, from a false apprehension of their wants. In summer this cannot be easily accomplished, unless the plants are allowed to stand in saucers constantly filled with water, which, by overloading them with juices, will soon engender sickly soft growths, unsuited for the production of flowers or healthy foliage. An exception to this rule is the growth of annuals in pots during summer: they, if well drained, may stand in feeders; but these, whenever used, should be half-filled with fine gravel or sand, which may be kept in a state of moisture. The best and only general rules that can be adopted are—in *winter*, keep plants not then growing fast rather dry; in *spring*, increase the quantity with their activity and the sun's power, keeping them in a medium state of moisture; in *summer*, water daily; and in *autumn*, decrease with the length of day and the returning torpidity of the plants, until the dry state of winter is again reached. All this resolves in the following:—Plants when growing fast may have free supplies of water, which must be lessened as their growths approach maturity, and cease, or nearly so, when that is attained, until the return of their growing season. As regards *air*, similar rules to those given for watering may be followed; and indeed they are analogous. In *winter*, when the plants are not growing, large supplies of air are not so important, enough being usually given by the room door. As *spring* advances increase the quantity, carefully guarding against the cold of mornings and evenings, or cutting winds; and if the plants are placed out in the middle of fine days, take care to bring them in before the chill of evening comes on. After the first or second week in May, they may be set outside for the summer; and towards the end of September, or as soon as heavy cold rains occur, they should be placed again in their quarters for the winter, setting them out of doors when fine, or supplying them with plenty of air by the window, until the cold weather and decrease of moisture at the roots bring them to a state of comparative rest. It should be remembered in spring and autumn that the plants must not go out to-day, because they were placed out yesterday, but the weather alone must determine: sudden changes must at all times be avoided. The leaves of plants act as lungs, by which they breathe; if they become dirty, their respiration is impeded; therefore an occasional careful sponging will be useful to them. In spring and summer allow them the full benefit of genial showers, which will do them more good than any artificial watering. Never use spring water if soft or rain water can be had; and always let it be about the same temperature as the air in which the plants are growing. It should hardly be necessary to mention the removal of decaying leaves and flowers; the last are exhausting as well as unsightly.

"One principal potting is usually required, and afterwards as often as the plants may fill their pots with roots, or seem to require it. The most important thing is good soil, which, if composed of three parts loam of a fibrous open texture, with a fourth dung, most plants will thrive in, using plenty of drainage to allow water to pass off readily. Never suffer the surface-soil in the pots to become hard or moss-grown, but let it be loosened occasionally with a piece of stick.

"Succulents are well suited for growing in rooms, as they are not so impatient of either air or water as most other plants; and the abundance of their beautiful flowers renders them objects of interest. Cactus speciosus, Jenkinsonii, flagelliformis and speciosissimus, Mesembryanthemums, and Flowering Aloes, deserve special notice.

"Green-fly is apt to infest the young shoots or undersides of the leaves; to destroy them, moisten the infected parts, and dust with Scotch snuff, or brush them off as soon as detected with a feather, or dip them in tobacco-water. Fumigation with tobacco will also destroy them."

To the foregoing is added the following list of flowers for pots, with the period of their blossoming:—

"*For Spring*.—Snowdrops, Russian violets, early tulips, crocus, narcissus, hyacinths, heart's-ease, mignonette, mimulus moschatus, ranunculus, anemone, myrtle.

"*For Summer*.—Pelargoniums, mignonette ten-week stocks, China roses, double wallflowers, pinks, carnations, cactus, aloes; annuals, as nemophila, schizanthus, collinsia, &c.; myrtle, heliotrope.

"*For Autumn*.—Pelargoniums, lobelias, campanulas, salvias, hydrangea, verbena, fuchsias, petunias, calceolarias, myrtles, heliotrope.

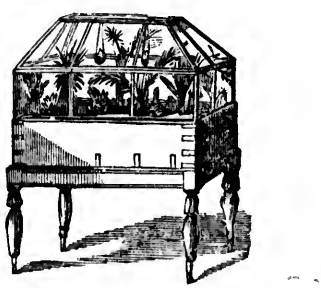
"*For Winter*.—Chrysanthemums, pelargoniums, heliotrope, myrtles, fuchsias, aloes, cactus.

"*Creepers suitable for training round the outside of windows*.—Rhodochiton volubile, maurandia Barclayana, lophospermum scandens, convolvulus major, tropæolum atrosanguineum."

DOMESTIC CONSERVATORIES

If the atmosphere of the apartment in which flowering plants are kept be liable to vitiation by the action of coal fires, by the breathing of the inmates, or other circumstances—in short, if the air is not preserved pure, it is clear that the plants will languish, and afford little pleasure to their amateur keepers. In order to remedy these and other disadvantages, a plan has lately been invented of keeping plants in a secluded box, formed chiefly of glazed frames, in which situation they grow flourish, and perform the remarkable function of preserving their own atmosphere in a state of purity. This being an exceedingly interesting department of floriculture, we beg to offer a full explanation of the subject from "Chambers's Edinburgh Journal," No. 422:—

"Any person, whether inhabiting the most humble or the most splendid dwelling, provided it be freely exposed to the sun's light, has it in his power to rear and cultivate a miscellaneous collection of plants, to enjoy the beauty of their appearance, and to watch their progress through all the stages of their growth, at an expense so insignificant as to be within the means of every man in very moderate circumstances. To do this he must provide an apparatus, consisting of a box, with a glass-case over it, of a size according to his desires and means, from the capacity of a small trunk to that of an ordinary closet. We shall suppose he wishes one of a small size, to stand at a window in an apartment of limited dimensions. Procure a strong wooden box, three feet in length, one and a half feet in breadth, and nine or ten inches deep; no top is wanted; it should be painted, or otherwise prepared to resist damp. Two small holes for corks are to be made in the bottom. The ledges should be covered with lead or zinc, and slope inwards. Over the box is placed a glass-case, resembling a garden forcing-frame in shape; it should measure eighteen inches high up to the sloping top, and then the top or roof should slope inwards on all sides, to meet in the centre. This case must be framed with lead or zinc, whichever be the metal employed for the ledges of the box. Difference of metal may cause a galvanic action injurious to the plants. When great elegance and durability are required, brass is used, and the box is made of mahogany. The case must be made to fit with nicety upon the ledges of the box, and in such a way that moisture will flow down the inside of the case into the box. The case should have a door on one side to open and shut at pleasure, but also to fit as nicely as possible; there must, in short, be no crevices to permit a free interchange of air betwixt the room and the interior of the case. The glass panes in the case should be fitted with care, and the putty well painted, to preserve it from the action of the moisture. The finer the glass is, the better will be the view of the plants. When we add, that the box, with its glass cover, are to be placed on a four-footed stand or low table, in front of a window which is exposed to the sun during several hours of the day, the entire fabric of the apparatus has been described. The apparatus, in a complete state, is represented in the annexed figure.



We now come to the preparation for the plants. Lay the bottom of the box with pieces of broken earthenware, to a depth of two inches, as an open subsoil. Next, lay a stratum of turfy loam an inch deep, and fill in the remainder of the space with good soil, mixed with a portion of peaty loam and sand. The artificial garden-plot is now ready to receive the plants. Set these in the usual manner, and then shower over them with a watering-pot from three to four gallons of water, till the soil be pretty well saturated, and the liquid runs off by the two openings in the bottom. When this is done, cork up the holes, place the case on the box, and the operation will be finished.

A question will here readily occur—What species of plants are best adapted for these domestic greenhouses? We are fortunately enabled to answer this inquiry by referring to a learned paper on the subject by Mr. Ellis, which was read to the Botanical Society of Edinburgh, January 13, 1839, and afterwards published in the "Gardener's Magazine," vol. xv., and also as a separate pamphlet. According to this gentleman, the plants most suitable are "those which partake largely of a cellular structure, and possess a succulent character, and especially those which have fleshy leaves; whilst, on the contrary, the continued humidity is unfavourable to the development of the flowers of most exogenous plants, except such as naturally grow in moist and shady situations. Plants, therefore, which have to grow and bloom in cavernous and moist situations, or at least in moist and warm climates, are best adapted for these cases. However, within this class of vegetables there are many beautiful and highly luxuriant plants, which it would afford no small pleasure to contemplate. The following is a list of plants from various countries, which were set in a box under Mr. Ellis's directions, and examined from nine to twelve months afterwards:—

Botanical Names.	*Country.*	*Remarks.*
Chamærops humilis	Italy, Sicily, Spain	Increased 1-4th its original size.
Gentiana verna	England	Flowered, but no difference in size.
Adiantum Capillus Veneris	England	Increased 1-8th.
Primula farinosa	Scotland	Flowered; atmosphere rather damp for it.
Scotica	Scotland	Flowered; atmosphere rather damp for it.
Verbascum Myconi	Scotland	Increased 1-8th.
Androsace villosa	Scotland	Flowered; not very healthy.
Chamærops *Palmetto*	Carolina	Increased 1-3d.
Dionæa Muscipula	Carolina	Made 1-8th.
Surracenia purpurea	Carolina	Increased four times its original size.
Epigæa repens	Carolina	Increased one-half.
Testudinaria elephantipes	Cape of Good Hope	Made a shoot ten inches long.
Aloe retusa	Cape of Good Hope	Made 1-3d. showing flower spikes.
Rhododendron chrysanthum	Siberia	Increased one-half.
Chamæcistus	Austria	Increased 1-3d.
Cycas revoluta	China	Increased 1-8th.
Nepenthes distillatoria	Ceylon	Increased 2-3ds.
Cypripedium venustum	Nepal	Increased 1-5th.
insigne	Nepal	Increased 1-4th.
Agave geminiflora	Mexico	Increased 1-3d.
*Goodyera discolor	Mexico	No perceptible difference.
*Echinocactus multipl.	Mexico	Increased one-half.
*peruviana	Mexico	Increased one-half.
myriacantha	Mexico	Increased one-half.
*formosa	Mexico	Increased 1-3d.
Ottoni	Mexico	Increased 1-4th.
candida	Mexico	Increased one-half.
Epiphyllum truncatum	Brazil	Increased 2-3ds.
Cereus flagelliformis	Peru	Increased one-half.
Lycopodium stoloniferum	Cuba	Very luxuriant.

Those marked thus * are growing in fancy pots, and suspended from the roof of the plant-case.

Plants, after the first preparation, require little or no care; the case need only be opened for the removal of dead leaves, or for a little trimming when required. Plants in open flower-pots are exposed to the vicissitudes of change of climate, and require constant watering; but the plants in these cases seem to be independent of any change of temperature in the air, and water themselves. The moisture rises by the sun's influence from the moistened earth, cherishes the leaves of the plants in its aërial condition, and during the cool of night falls to the earth again like rain or dew. In this manner there is a constant succession of rising and falling of moisture, in imitation of the great processes of nature daily going on in the fields around us. The plant-case is a little world in itself, in which vegetation is supported solely by the resources originally communicated to it.

Not the least remarkable point in the economy of the case, is the preservation of atmospheric purity. To all who reflect for the first time on this subject, it will seem incomprehensible how the plants can possibly thrive and blossom without the occasional interchange of fresh air with the atmosphere. This certainly does appear extraordinary, yet it is ascertained by experiment that no such reinvigoration is requisite; to account for the phenomenon, it will be necessary to remember that while plants inhale oxygen from the atmosphere, and expire carbonic acid, their leaves possess the remarkable property, in conjunction with the sun's light, of retransforming the carbonic acid into oxygen. At night, when the light of day has departed, the expired carbonic acid may be detected in the neighbourhood of plants, and hence one cause of injury to health by breathing night-air; but when the morning sun again bursts upon the scene, a great chemical process commences in the atmosphere—the carbonic acid is decomposed, oxygen is evolved, and all nature rejoices in a re-creation of its appropriate nourishment.

With reference to the closed conservatory, we now see that the deterioration of the atmosphere will be daily counteracted by an opposite process of purification: so that amidst the vicissitudes of perpetual change, the air is maintained in a state of nearly uniform composition and purity, and serves over and over again for all the purposes of vegetation. It may, however, be stated, to prevent misconception, that the more pure the air of the apartment, the plants will have the better chance of thriving, because there must necessarily be an interchange to some extent betwixt the air of the room and the case, in consequence of the daily expansion from heat and nightly condensation from cold. This interchange will be effected by the minute crevices in the apparatus, and therefore requires no special provision.

ROCK AND AQUATIC PLANTS.

If space and means permit, a flower garden may be much improved by introducing a piece of artificial rock-work, and a small pond; because, in connection with these, certain highly interesting plants may be reared or kept, which would not answer in a plain earthy soil or surface. In order to increase the effect, the pond should be at the base of the rock-work, and receive from it the trickling of water which has been conveyed to the summit in pipes. Let the rock-work possess a natural appearance, with rugged sides, and perhaps be ten or twelve feet high. Rocks of the same kind and colour should be placed together; if intermixed, they seldom wear a natural appearance. A dark cave, penetrating into the thickest part of the erection, is not very difficult to construct, and, when encircled with ivy, and inhabited by a pair of horned owls, which may be easily procured, it will form a most interesting object. Rock plants of every description should be profusely stuck around, and, in one short twelve-month, the whole scene will exhibit an impress of antiquity far beyond anticipation. The undertaking, when completed, will present a field of varied and interesting study, and more than compensate for all the attention and outlay bestowed upon it, the aquatic and rock plants, which formerly were "far to seek and ill to find; will thus be brought within the range of every-day observation; the wagtail, oxeye, and stonechatter, will be attracted to the spot, not, perhaps, because they are lovers of the picturesque, but because they find every thing here suited to their nature; and colonies of the wild bee will soon be seen and heard around the interstices of the rocks, and heavily laden with their winter store.

A weeping-willow adjoining and one or two mountain-ashes, will add materially to the beauty of the scene; and, if the spot be airy, there might with advantage be planted, on or about the top of the eminence, a variety of what is usually called the *Scottish thistle*. This tall elegant plant will not thrive in low or damp situations, and prefers a bracing to a warm atmosphere; hence, though a beautiful object in borders, it will be found difficult to bring to perfection in some situations. It may be remarked that there has been some uncertainty as to which is the true Scottish thistle, or that figured in the national emblazonment. Mr. Dovaston, in a communication to Leighton's *Flora of Shropshire*, states that, in a tour of Scotland, he asked many persons which was the Scottish thistle, and found many different opinions. A Hebridean gentleman pointed to the *Carduus eiophorus*, and Sir James Grant, at Inverness, indicated the *Carduus nutans*. For our own part, we do not believe that, when the emblem was adopted, any particular species of the plant was meant: the leading idea was the self-defending power of the thistle, as emblematical of the determination of Scotland, though poor, to submit to no injury or offence without retaliation.

Among the plants suitable for growing from the crevices of the rocks may be mentioned various heaths and mosses, the Valeriana diœcia montana, Trifolium alpestre, Thymus vulgaris, Epilobium alpinum, Campanula cervicaria, Alyssum calycinum, and Viola banatica. Many plants might be mentioned as suitable for the marshy borders of the pond, as the Acorus, Littorella, Lychnis flos-cuculi, Saxifraga irrigata, Epilobium angustifolium, Primula farinosa, and so forth. We should recommend the unprofessional gardener, in replenishing either a rock-work or pond with appropriate plants, to consult a nurseryman skilled in the subject; as soil, air, climate, moisture, and other circumstances, require careful consideration.

GARDEN PLOTS IN TOWNS.

The attempt to have a neat and flourishing garden or garden plot in populous towns, is very often defeated by the abundance of smoke and other impurities in the atmosphere; for, as repeatedly mentioned, pure air is essential to the proper growth of plants. It is found, however, from experience, that certain kinds of shrubs and flowering herbs are less delicate in this respect than others; and that, with a reasonable degree of care, open plots in towns may be made to yield a surface of vegetable bloom and beauty. On this branch of flower-culture, so important to many town residents, there appeared, some time ago, a well-written paper in that useful publication, "The Magazine of Domestic Economy," describing the experience of an amateur florist; we take the liberty of extracting from it the following passages:—

"When I first took possession of my garden [in town], I found it encumbered with old lilacs and laburnums, the common aster, and other ordinary plants. These I immediately removed; by my west wall I planted a Buddlea globosa, and a Virginia creeper; and by my south wall, which was partly covered by a vine, I planted the jasminum revolutum, the small white clematis, and the pyrus Japonica. The latter grew luxuriantly, and bore an abundance of flowers, which, glowing upon the light wall, enlivened my prospect in winter. I had a great deal of the south sun in my garden, but none of his morning beams reached it, and there was a corner which never had a gleam at all. In this spot I planted a quantity of roots of the lily of the valley, and they flowered well, although late. The laurustinus also grew well with me; and I should strongly recommend this pretty shrub, together with the laurel, instead of those deciduous shrubs which we see in town gardens. The latter become very shabby as they grow old; neither the lilac nor syringa flower well in confined situations; besides this, the untidy appearance of their falling leaves is a great annoyance. My jasmine grew quickly, and, with the clematis, soon covered as much wall as I could afford to them; the great inconvenience of the latter plant is, that it requires frequent attention as to nailing up, and this, where there is not a gardener always at hand, is troublesome; as, although the stem should be cut down within three feet of the ground every autumn, yet the young shoots soon grow beyond a woman's reach. However, it is worth while putting ourselves to a little trouble for the sake of the delicious scent of the flowers of this pretty trailing plant. As regards perennials, I dare say all who are fond of flowers have endeavoured to nurse the China rose, and induce it to flower in the town. I have grieved over many a healthy plant which refused to show a single bud, and watched the gradual wasting away of others, notwithstanding my unceasing care. The common Provence roses, both white and red, flower well in the town; but it is vain to attempt the China—it requires a very pure air, and I do not know any flower whose colour varies so much with the quality of the atmosphere. I am but slightly acquainted with the names given by botanists to the numerous varieties of roses; but I have tried many of them, and found the Tuscan, the rose de Meaux, the Tudor, the little early crimson, and one surpassing them all in beauty, the Bengal celestial (I believe), flower extremely well. With regard to spring flowers, the snowdrop I could not tolerate in the city—the smoke robbed it of all its beauty; the crocus, either the mice or the sparrows would not leave undisturbed; and, after replenishing the edge of my border several times, I gave up the matter. The hepatica and gentianella flowered well with me; anemones also I had of very good colours. Heart's-eases pined sway after the first year, but they were easily replaced, and they were too ornamental to be relinquished. Then followed the white lily, and a variety of irises, all of which increased fast, and flowered abundantly. The peony I could never persuade to flower; in the first place, it does not blossom well until it has been for years settled in a garden, and I believe its beauty even then is greatly dependent upon the purity of the air. My buddlea was every spring covered with its golden balls, and grew so quickly that I scarcely knew what to do with it. I am surprised this beautiful shrub is not more common; it is perfectly hardy, even as a standard; it will remove well, even when it has attained a considerable size; it is very easily raised by layers; and there is an air of grandeur about it, both as to leaves and flowers, that raises it above the common flowering shrubs of our gardens. But we go on in the old-fashioned manner of planting our gardens: the same varieties of deciduous shrubs are taken, without considering with how much advantage their places might be supplied by those more lately introduced. The magnolia, for instance, grows quickly, and flowers abundantly in the city upon a south wall; and the arbutus is not at all particular with respect to situation. The bignonia grandiflora also does not withhold its scarlet trumpet-like blossoms in the immediate vicinity of a steam-engine. To return to my garden, the glory of which in the autumn was the lobellia fulgens, I managed it thus: I sank in the ground, up to the rim, a large and deep seed-pan; this I filled to about three quarters of its depth with rich soil properly mixed, and planted my roots. As soon as the shoots appeared, I supplied them plentifully with water, and from time to time added more soil. The plants grew luxuriantly, furnishing tall and thick stems, with large and highly-coloured blossoms; indeed, the gardener who had assisted me said that he had never seen finer flowers. The sweet-scented marvel of Peru thrived well with me, and the tiger-flower also. Carnations and picotees I tried one year, but was so much disappointed in the result, that I gave them up, although very reluctantly as I believe carnations do not require a very pure air, and I have fancied since, that my failure with them arose from some other cause than the smoky atmosphere. Dahlias, also, although they flowered very well, I gave up. The amaryllis lutea flowered well with me, when once established, and the hemerocalias cerulea and flava did the same."

After condemning annuals in general, the same writer goes on to say—"I own I am willing to make some exceptions myself in favour of the coreopsis, and such brilliant flowers particularly; the French marigold, too, and the scarlet zinnia, I could scarcely give up. The lupinus mutabilis blossoms well in the town, but it is very liable to be destroyed by a caterpillar; the easiest method of preventing which is to strew a little soot around the plant. The grub, I suppose, will not rise through this: I found it more effectual than tobacco, which I also tried. The scarlet colutia is much eaten by an insect: I found the same method succeed in this case. I had forgotten to mention that all bulbs of the narcissus and jonquil tribe flowered well with me: the primrose and polyanthus gave miserable-looking blossoms. I planted the double pomegranate against my south wall, and it grew well: I left the house before the plant was old enough to flower. I should notice one great recommendation which American shrubs possess to those who are likely to change their residence—they may be removed without danger at almost any size. Mine were planted in a border of common earth, in a hole filled up with peat and loam fit for them; and when a rhododendron, four feet in height, was removed, it was found that the roots formed a complete ball, none of the fibres having penetrated beyond the soil which was proper for them. The common and Portugal laurel may be removed when very large: I have myself seen one of the latter, which three men and a boy could with difficulty lift, transplanted with success. Of course it was carefully tended as to water. The scarlet lychnis does not mind the corrupt air of the town; but it will not grow to so great a height in such a situation as it does in the country. There are many other plants which might be treasures in a town garden; experience, however, is the best teacher in this as well as in more important matters, and if a garden be stocked with the plants I have mentioned, experiments may be made as to others; should they all fail, the garden will still be gay."

To the foregoing we need only add, that much may be done to keep garden plots neat by frequent trimming and raking, and particularly by keeping the plots in grass close shaven. To be kept in the best trim, grass should be mown once a fortnight.

FLORICULTURAL MONTHLY CALENDAR.

January.—Little can be done in the flower-garden except the weather be open and dry; but advantage ought to be taken of favourable intervals to render the plots and borders neat; to protect by coarse screenings of leaf-mould fuchsias, China roses, and other choice shrubs; for though they may not perish by frost, the mulch tends to enrich the soil, when forked in.

Propagate, by division of roots, daisies and thrift: protect the beds of hyacinths, anemones, ranunculuses, and tulips, by a covering of coarse litter. Top-dress auriculas, using a compost of light loam and two year-old cow-dung, mixed with a twelfth each of sea or river sand, and rotten wood. Plant all the bulbous roots that are still out of the ground.

In heat, sow mignonette, annual stock, penstemon, [illegible] fusus, gentianoides, and other half-hardy annual and perennial plants, using the propagation-pot, by which means the entire number of seedlings (allowing for previous thinning out) can be transferred, with roots undisturbed, to the plots or borders. Commence sowing in the last week, for hot-house culture, seeds of Gloxinia and Gesneria these, if obtained from impregnated plants, may yield new and striking varieties. Sow also (broken up and mixed with sand) the berries of Psidium Cattleyianum; this plant is one of the choicest evergreens of the stove, or even green-house, for it is not tender.
