CABONICO AND LIVISA.—From Tanamo the coast trends west 10 miles, to the entrance of the Harbors of Cabonico and Livisa; a reef extends also, 2 miles from this piece of coast. These two harbors have one common entrance, which divides within, into two branches; one to the eastward, leading to Cabonico, and the other to the westward, leading to Livisa. To enter these harbors, you must go in by the opening in the reef, and then steer for the windward point until it bears S.  $\frac{1}{2}$  E., and being then near it, keep mid-channel, avoiding a reef which runs out from the windward shore, and which lies out about a cable's length from the interior point. You may approach within a third of a cable of the leeward shore; once abreast of the interior points, steer for the channel of the harbor you wish to take, without any other care than to keep mid-channel.

NIPE.—From these ports the coast continues foul, having a reef about W. N. W., 5 miles to the Harbor of Nipe. This bay, for its magnitude and depth, is very extensive, and has a spacious entrance. The harbor is always accessible, for with either the breeze or the norths, you will run in with a free wind; coming out is quite the reverse, for this requires the land breezes, which, as we have said before, is often very rare in the season of the norths.

To distinguish this part of the coast, the mountains of Cristal may serve as marks; these are a continuation of the Cordillera, (or range,) which comes from Baracoa, and extends to the south from Port Livisa, at about 13 miles inland. The Pan of Sama, to the west, is also another excellent mark of recognizance: its figure being such that it cannot be mistaken, because the summit of it forms a table. It rises on the land to the north of Nipe and Banes, and is almost N. and S., true, with the Harbor of Sama; and as the mountains of Cristal terminate to the east, and the Pan of Sama, which begins to rise gradually, almost from Point Mulas, form an opening or break in the chain of hills or mountains, it is almost impossible for any one to mistake the place. The Pan of Sama may be seen 20 miles off.

BANES.—From the Harbor of Nipe the coast trends N. W. 11 miles, to the Port of Banes: it is all clean, and may be run along at half a mile's distance. The Harbor of Banes has its entrance in the middle of a bay formed by the coast, and which has  $2\frac{1}{2}$  miles of opening, whence it narrows into the entrance of the port, which is only a cable and a half in width, so that it resembles a funnel. The shores of both, the bay and channel, are uncommonly clear and deep to, and you have to fear nothing but what is seen. Only thus could this port be entered with facility, as its entrance is so tortuous, and with such elbows and turnings, that you must alter your course, almost in an instant, from S. to N. It is excellent as a place of shelter, for any class of vessels. It is extremely difficult, however, to get out of; because its mouth stands open to the trade wind, and it is necessary to avail yourself of the land breeze to get out clear, at any rate as far as the middle of the bay, that you may have room to tack and clear yourself from the rest of it, as well as of the coast, which there trends about N. by E. 10 miles, to Point Mulas, and which is foul, with a reef that stretches a mile from it.

**POINT MULAS.**—To enable any one to recognize Point Mulas, which, on account of its being very foul, and lying further to the northward than any of the anterior coast, may be very suspicious, the marks already given may suffice; these being the mountains of Cristal and Pan of Sama.

About 5 miles N. W. from Point Mulas is Point Lucretia, which is clear and high; the coast thence continues to the west, with some inclination to the south; for 13 miles, to the Port of Sama, forming a bay named Rio Seco, (Dry River.) Al this coast is very clear and scarped, excepting the bay, which has a beach.

**THE PORT OF SAMA** is fit for vessels only which do not draw more than 12 feet of water; and as the shores both of its entrance and the interior are very clean, the inspection of the plan will afford all the necessary instruction for taking it. You may know this part of the coast and harbor, by the Pan of Sama, and a hill or mountain near its western part, which is pretty long, and lies N. W. and S. E., and the top of it seems to be plain and equal, and at its west end are scarped rocks which seem white, and where much honey is made. From this slope a sandy beach, named Gaurdalaboea, continues to the west: to the south of it may be seen a detached hill, in the form of a sugar-loaf, and to the S. W. a small mountain covered with trees, the top of which forms a table, and which is named Mesata de Naranjo, (Little Orange Table.) Between the hill and the mountain is Port Naranjo, which is 5 miles distant from Sama.

**PORT NARANJO** is a good harbor for vessels of every class. Its windward point may easily be known by being high and scarped, while the rest is of beach. To take the harbor you must sail without the reef, until the windward point bears S.  $\frac{1}{2}$  E. when you may sail towards it, taking care to give it a cable's length berth, to keep clear of a shoal which surrounds it, and stretches out about two thirds of a cable from it. It is also necessary to be cautious of another shoal which stretches out from the leeward coast, and which sallies out to the north of the exterior sloping point, about one cable and one third. What ought to be done is, to run in mid-channel until you are past the two points of the entrance; and so soon as you are well past that to windward, you may luff up, and anchor in a bight formed by the east coast, at about two thirds of a cable from it, and in 10 fathoms water, opposite the spot where the mangroves come down so as to be bathed with the water.

This harbor has the peculiar advantage that a vessel may sail either in or out with the breeze.

From Port Naranjo the coast, which is a foul beach, trends W.  $2\frac{1}{2}$  miles to Point Presquera Nuevo, which is sloping and clean; thence it descends W. S. W. 3 miles to Port Vita, and is very clean. This little port is very good for vessels which do not draw more than 18 feet, and the inspection of the chart of it will be a sufficient guide. Three miles to the west of Vita is another small harbor, named Bariay, at the mouth of which there is shelter from the breezes, but only in the interior from the norths. Very small vessels only can get up there. The coast between Vita and Bariay is very clean. A mile to leeward of Bariay there is another port named Jururu, the entrance to which is very difficult, being very narrow; and although vessels drawing 20 feet may enter it, only small vessels ought to do so.

**GIBARA OR XIBERA.**—Five miles west from Jururu is the harbor of Gibara. Its entrance is 5 cables in breadth, and completely open to the north. The coast between it and Jururu is very clean. To find the port, three hills or mounts, which are to be seen to the south of it, and which, at a great distance, appear to be islands, are excellent marks. The first and most easterly of these is named Silla of Gibara (Saddle of Gibara:); the middle one resembles the shape of a sugar boiler; and to the west of the third are some hills of a regular height.

From Port Gibara the coast, which is clean and sloping, trends to the north, 2 miles to Point Brava, from which follows N. W. 10 miles, of the same kind of coast, to Punta Mangle (Mangrove Point;) and from it continues 6 miles in the same direction, but it is a sandy beach and clean. From this point it trends west, but is foul, with a reef of six miles to Puerto del Padre. All this land is low, and on the coast may be seen some small palm trees, called Miraguanas. At the west side of Port Padre there are two little mounds, very close together.

**PUERTO DEL PADRE.**—The harbor of Padre is excellent, and fit for any class and number of vessels. Its entrance is long, and only two cables in width; its shores are very clean and have deep water. To enter this harbor it is necessary to navigate outside the reefs, until the east point, named Jarro, bears S. by E.  $\frac{1}{2}$  E., when you may place the prow to the outer leeward point of the entrance channel; and it is necessary not to confound this point with another, which is to the N. E. upon the same coast, and which, for distinction, is named Guinchos. The last has an islet of the same name very close to it, and it may assist much in finding the mouth of this harbor. Running

for the before mentioned point to leeward, and then close past the S. E. part of Guinchos, no more remains than to steer for the channel, without its being necessary to be aware of any more than what is visible.

From PORT PADRE the coast follows to the west, 5 miles, to Point Piedras or Rock Point. Here is the entrance of the great bay of Malagucta, which is no more than a lagoon, formed in the interior, in consequence of the land being low and wet. The coast then trends N. N. W., 5 miles, to the Point of Covarrubias, from which it trends W. N. W., 10 miles, to the harbor of Manati. All this coast is foul, with a reef which stretches out from it about two miles.

PUERTO DE MANATI.—The harbor of Manati may be known by a mount, which may be discovered inland from it, shaped like a sugar loaf. It is called the Manueco, and may be seen at the distance of 15 or 20 miles. Close to the west of this may be seen another hill not quite so high as it, which is called Fardo, or the Table of Manati, which when seen in one, or shut in with the Manueco, looks like one hill, and presents to the view the appearance of the saddle of Gibara, which appearance has deceived many, and is dangerous to navigation.

This harbor of Manati may be considered as a lagoon, formed in low wet land, with a long, narrow and crooked channel in it, and in which there is depth of water for small vessels only; as this channel, throughout its extent, is bordered with shoals of 6 and 8 feet of water, it is running much risk to enter it with middling sized vessels, and much more so with ships of war.

Three miles N. N. W. from Point Manati, is Point Brava, which is foul, with a reef. The coast thence, which is also foul, with a reef, trends about west, for five miles, to the port of Nuevas Grandes, (Great News.) To enter this port, which is fit only for vessels of 12 feet draught, it is necessary to go in at a break in the reef, and the reef lies out 6 cables or two thirds of a mile from the coast, and follow in afterwards all that distance by a channel which the reef forms, and which in some places is only half a cable's length in breadth. This channel is very crooked, and therefore any one who is not well acquainted runs much risk. So soon as you are abreast of the points of the harbor, you may run along the coast at the distance of one quarter of a cable, without any fear.

NUEVITAS DEL PRINCIPE.—From Nuevas Grandes the coast trends about N. W., 11 miles, to the harbor of Nuevitas. It is all foul, with a reef, and may, as well as the harbor, be recognized by three mounts, of short extent, which rise within the harbor. There are also three islets in the harbor, named the Ballanates. These seem high to the east, and diminish towards the west. Nuevitas Harbor is a large bay, with many shoals, but fit for any number and class of vessels. To enter it is necessary to avoid its windward or east point, to which you ought not to approach nearer than a cable's length, but approaching, if you choose, within half a cable's length of the leeward point; but the best way is to keep in the middle of the channel, which is very long and crooked.

From mid-length of the channel, going in, the coasts send out shoals, to keep clear of which requires good practice; which practice is equally necessary in the interior of the bay.

From Nuevitas the coast trends about N. N. W. to the point of Maternillos, and is very clean. From Point Maternillos it trends about W. N. W., and is bordered with a reef which stretches out a mile and a half. All the coast from Maternillos rises a little; and nearly at the end of it, and about 14 miles from Maternillos, there is a little mount, called that of Juan Danne, which forms a kind of table. At this point commences a great white shoal or bank, which extends far to the west, and upon which are many keys and reefs. Here we cease from describing the coast, as being of no use to navigation, and begin to describe the edge of the white ground or shoal, with islets and keys upon it.

About W. N. W. from the point of Juan Danne, but almost joined to it, there is a little islet, and in the same direction, and at the distance of 6 miles, is the Island Guajaba. This island may be known by four little mounts, which lie almost in a line, east and west. The first three may readily be seen, but it is not so with the fourth, which being of less elevation than the third, remains hidden by it, but as you advance to the westward it opens out, and the whole four may be perceived. At about 4 or 5 leagues beyond these hillocks appear, as it were, many islets, caused by the lower lands of the coast being invisible above the horizon.

KEY ROMANO, &c.—To the west from Guajaba, at the distance of 8 miles lies Key Romano, an island stretching N. W. and S. E., in which direction it is 16 leagues in extent. This land properly consists of two islands, separated by a channel, half a mile wide. The eastern isle has some heights, which, in the middle of it, form a kind of saddle. The western isle is of low, wet, mangrove land. Key Romano lies considerably within the White Grounds, and two small keys, called Key Verde and Key Con-

sites, lie nearly N.  $\frac{1}{2}$  W. from its easternmost height; the first at the distance of 7, and the second at 12 miles. Key Verde lies N. W.  $\frac{1}{2}$  W. from the west part of Guajaba, and Key Confites, N. W. by N. Between these two keys is an anchorage, which may be taken in case of necessity.

The Key Verde or Green Key lies  $4\frac{1}{2}$  miles S. by E. from Key Confites, and a reef extends from it northward, to the distance of a mile and a half. From Key Confites a reef likewise extends to the southward, one mile, and there is a clear passage of more than two miles within these reefs.

In order, therefore, to gain this anchorage, when coming from the eastward, you must stand in for the passage formed by these reefs, keeping a little nearer to Confites than to Key Verde; and when the middle of Confites bears due N. W. by N., and the middle of Key Verde S. by W. you will be on or nearly on the edge of the bank. Then lay the ship's head W. N. W. and stand on in this direction, until the southernmost part of Key Confites bears north, when you will stand N. N. W., or a little more to the northward. Having at length brought the south end of Confites N. N. E. half a mile distant, you may let go the anchor, in  $3\frac{1}{2}$  or 4 fathoms, on sandy ground.

In getting under way from this anchorage, should the wind not allow you to stand to the S. E. you must bear away to the N. W. by N., until you have cleared a reef of rocks extending three quarters of a mile to the N. W. from Confites Key; after which you may stand to the north, in order the sooner to gain the main channel.

West from Key Verde there is a round key, named Palomas, (Pigeon's,) with various other small ones in its neighborhood. To the northward is the island named Key de Cruz, (Key of the Cross,) which is about 13 miles in extent, N. by W. and S. by E. To the N. E. of this isle, and at the distance of 3 miles, there is on the very edge of the grounds, a shoal named Tributario de Minerva, which lies N.  $41^{\circ}$  W. from Key Confites, at 12 miles distance.

The edge of the grounds, which is reef, stretches out a mile and a half from Juan Danue,  $2\frac{1}{2}$  miles from Guajaba, and from the E. N. E. to N. E. from the high part of Key Romano, forms an opening, by which, according to report, a vessel may enter, and anchor in 6 fathoms, upon sand, but good holding ground; but as we cannot guarantee this, any one who makes the attempt ought to exert great caution.

From this opening the reef rises again, but makes the opening already described between the Key Verde and Key Confites; and thence the edge of the ground continues, sometimes foul, and at others without reef, to the Tributario Shoal. This shoal breaks with a fresh breeze, and shows above the surface at low water. Six miles west by north from it is Key Baril, (Barrel Key,) and further to the west is Great Paredon Key. The edge of the grounds, which is sometimes foul and sometimes clean, lies out two miles from Key Baril, and one and a half mile from the north part of the Great Paredon. The latter key affords good anchorage for either the time of breezes or land-winds. To ascertain and take it, remember that at a cable's length to the north of its north point, there is a small round key, which you ought to leave on the larboard hand when going in, and passing within from half a cable to a cable's length from it. You anchor soon as you are sheltered from the land of the Great Paredon, in the depth of water that suits the vessel's draught. On entering you will leave to starboard another key, rather larger than the one you leave to larboard: it is called the Middle Paredon, and lies about  $2\frac{1}{2}$  miles from the first.

From the Middle Paredon to the west, there is another large key, called Coco, from the middle of which, to the west end, there is anchorage on its north side.

To the west of Coco follow the groups of trees called St. Philip's Guilermos, and Santa Maria's. To the west of these, and at the distance of 16 leagues from Coco Key, lies that called Key Frances, which may be known from its having three round mounts, two of them very close together, and the third separate. These are named Tetos de Vinda, (Widow's Paps.) Westward from this key is another portion of keys, one of which cannot be distinguished from another without difficulty, as they are so much alike.

The edge of the grounds from Key Frances, and even something before that, is clean, and the lead will there warn you before you are in any danger upon it. Nevertheless, there is considerable risk from the Baxo Nicolaq or Nicholas Shoal, which is a spot of sand, lying at a considerable distance to the northward of the other keys, and is 46 fathoms long, and 5 fathoms wide. It is surrounded by a reef to the N. E. N. and N. W. to the distance of a cable and a half. Two miles to the west from it, another shoal breaks, which is named the Alcatrazes, and, as these shoals present great dangers to the navigator, it is necessary to give some marks to recognize them by, and which will indicate the position of a vessel in respect to the shoals.

Among other mountains which are on the land of Cuba, and about S. S. E. and S. from these shoals, the Sierra Morena (Black Mountain) is the best known. It is long, and lies

$\frac{1}{2}$  N. where y

N. W. and S. E. The S. E. head of it is moderately high, and upon its extremities are various points or peaks (*pichachos*.) Of these peaks the two which are on the N. W. extremity of the Sierra (mountain) are high, and lie N. and S., true, with Nicolao Shoal. A little more to the west of the Sierra Morena rises another mountain, with three heights on it, of which the middle one is the highest: it lies S. by W., true, from the Nicolao Shoal. These heights are named the Tetas de la Bella, (Belle's Paps;) and being N. and S. true with the middle one of them, you will be also N. and S. with the Bay of Cadiz Key, and past both the Nicolao and Alacatraces Shoals.

To the west of the Tetas de la Bella, two mountains are seen. The first is of regular extent; the second or westernmost very long, and at the end of it are two hills, named Sierra de Limones, (Lime Mountain,) which runs S. by W., true, with the western extremity of the Bay of Cadiz Key. Farther to the west lies out another mountain, of proportioned extent, named Santa Clara; and something to the west of it may be seen the Paps of Camaricoa, of which there are four, though in some positions there do not appear to be so many. The middle one is the largest, and lies S. W. with the westernmost part of Key Cruz del Padre, (Key of the Father's Cross.) These mountains are the highest which are on the north coast of Cuba; but it is to be remarked that those which are to the east and west of them are very equal to those of the west; indeed, are little less elevated than these mountains themselves. Such are the lands that are seen in the interior of the island, from the proximities of the Nicolao Shoal.

The White Ground still trends to the west. There are many keys upon the edge or border of it, and the edge is dangerous, having some reefs on it. The ground and keys terminate at Point Jacos. The keys named Mono, Piedras, and Monillo, are the westernmost on the reef. These afford good anchorage where shelter from the swell of the norths may be found.

**THE YCACOS KEYS.**—The north-eastward of Port Yacos, at the distance of about a mile from the edge of the bank, lie the three islets called by the Spaniards Cayo Mono.

**PIEDRAS AND MONILLO.**—These keys afford convenient anchorage to vessels which cannot advantageously use the Harbor of Matanzas. The southernmost and smallest is the Monillo, which lies at the distance of three miles from Point Yacos. From Monillo to the Cayo de Piedras, (Rocky Key,) the distance is only half a mile, and from the latter to Mono Key it is two miles. At a mile and a quarter N. E. by N. from Mono, there is a dangerous reef.

The anchorage, in regular soundings of 5 to 7 fathoms, bottom of sand, is to the southward of Mono, and on the east and south of Piedras, where ships may lie defended from any sea, coming from the northward. The ground is sandy and clean, with from 5 to 6 fathoms, and vessels here may at all times get under sail. To take the anchorage so soon as you discover the keys, stand for the middle of either passage, and let go the anchor at pleasure. It is only necessary that, in approaching from the N. E. you must take care to avoid the reef above mentioned, lying to the north-eastward of Mono.

**MATANZAS.**—From Point Yacos the coast trends to the S. W. and W. S. W. fourteen miles, to the Point of Maya, which is the eastern point of the great Bay of Matanzas. You may run along this coast at the distance of a league. The Pan of Matanzas, which distinguishes the bay, appears from this direction like an insulated mountain, having a round surface, and without peaks, water-courses, precipices, or other inequalities, excepting a small fissure near the S. E. part of the summit, which can hardly be noticed at a distance, being of so little depth. When bearing from S. S. W. to south, it appears like one round hill; but on any other bearing, another appears on each side of it, adjoining, and not so high. The land to the eastward is even, though not very low; but it begins to rise at Matanzas with a gradual slope, and to the west the coast may be seen at the distance of eight leagues, but it is alike even or level, without any remarkable height, other than the Pan, which appears over it.

The Harbor of Matanzas, which is at the bottom of the bay, is well sheltered from the norths, but it has several reefs. The Derrotero says it is difficult to get out of this place; for, as there is not room to beat out, it is necessary to get clear of it with the land-breeze, which, during the season of the norths, occurs but seldom. The harbor is of easy entrance, but it is necessary to avoid some shoals which lie almost in the very anchorage. To accomplish this, it is advisable to keep along the leeward coast, at the distance of two or three cables' length, passing Point Maya at the distance of a mile and a half, while it bears to the southward. With the vessel's head nearly south, you pass the western shore at the distance above mentioned; and so soon as you see the Castle of St. Severino, bearing W.  $\frac{1}{2}$  S. steer in that direction, until the houses, which will be seen in the S. W. corner of the bay, bear S. 35° W. when you must steer towards them, and anchor so soon as the Castle of St. Severino bears between N. W.  $\frac{1}{2}$  W. and N. W.  $\frac{1}{4}$  N. where you will have 5 or 6 fathoms of water, on loose clay or ooze.

To get out of this harbor, it is best to clear yourself by towing, or by the aid of the land breeze, if you have any, at a time when you consider the weather as settled, and there is no appearance of norths coming on. If agreeable, you may cross over, and come to an anchor on the bank or shoal point of Maya, which will be a proper situation to make sail from, when convenient.

*Remarks on the Harbor of Matanzas, by Mr. Bellamy:—*"This harbor is easy of access, and capable of holding a great number of shipping of different sizes, completely sheltered from all winds, except those from the N. E. quarter, which send in a heavy sea. The anchorage is partly protected on the N. E. by two shoals, named Baxo Nuevo, or New Shoal, and La Laja. On the shallowest part of the New Shoal, which is also the northernmost, is a buoy, with a pole and white flag, in 2 fathoms water; and on the southernmost, (La Laja,) is a pole with a white flag in 2 feet; the principal entrance is between the two flags, and the channel is about 2 cables' length wide. These flags are very small, and at times cannot be seen at more than half a mile distant; and as they are badly fixed, very often break adrift. Therefore a stranger ought to pay strict attention to the leading mark, and keep a good look-out for the shallow water."

"The leading mark, is the south side or notch in the Pan, on with a large white house, standing on a hill at the back of the town, and is the westernmost house visible, bearing W. S. W.  $\frac{1}{2}$  W. by compass. This mark will carry a vessel in mid-channel between the shoals; and when the Castle of St. Severino bears from N. W.  $\frac{1}{2}$  W. to N. W.  $\frac{1}{2}$  N. you may, if in a large ship, anchor in from 5 to 10 fathoms, and at the distance of a mile from the town. Small vessels may anchor farther up, within one third of a mile from the town, according to their draught of water."

"There are also two other good channels into Matanzas: one between the New Shoal and the Castle of St. Severino, having 8 or 9 fathoms in it; and the other to the southward of the South Bank; but the middle channel is that preferred."

"The Spanish plan in the *Portulano de la America Setentrional*, published at Madrid, in 1809, is very incorrect, with respect to both distance and soundings, and should not be relied on. The tides rise and fall at times between 2 and 3 feet; but they are influenced by the winds, and very irregular. It is not so difficult to get out of this place as has been described. During the 19 days that we lay here, the sea and land breezes were regular; and in the event of their not being so, vessels may beat out at almost any time, if acquainted with the place."

The *Derrotero* continues: From the Harbor of Matanzas, the coast rounds to the N. W., to the Punta de Guanpos, which is the most projecting point to the northward, and is distant from the mouth of the harbor or bay, about 4 miles. From Point Guanpos the coast runs almost (West) W.  $\frac{1}{2}$  N. a distance of 40 miles, to the Morro of the Havana: it is all clean and bold to, and may be run along at the distance of a league, or less, if required; inasmuch as there is no other risk than a rocky shoal with little water on it, which stretches off from the coast, between the Rincon or Corner, and the Punta de Tarara or Cobre. Along all this coast are soundings on sand, which extend more or less from shore, and of which the edges are steep and clear, so that you suddenly pass from 100 fathoms to 20. With the lead going, there is no risk running along, because the soundings will warn you of the limits into which you stand without danger; and in good weather you may pass the night by dropping a kedge upon these soundings, which manœuvre may sometimes be convenient, either to avoid passing your port, if the wind blows fresh at night, or that you may not lose ground, if the land breeze is light or calm, as the current constantly runs eastward, at the mean rate of one mile per hour. The hills or mountains of Jaruco, which rise nearly in the middle of this coast, is a point which serves to recognize it by, and ascertain your situation.

HAVANA.—This, as noticed, is, in point of importance, the principal harbor of Cuba, and has been described as one of the best in the world, being deep enough for vessels of the largest class, sufficiently capacious to receive a thousand ships of war; and so safe that vessels ride securely without cable or anchor. The entrance is by a channel half a mile long, so narrow that only a single vessel can enter at once, and is fortified through the whole distance with platforms, works, and artillery. The mouth of this channel is secured by two strong castles, as exhibited in the figure beneath. That on the eastern side, called Morro Castle, is built in the form of a triangle, fortified with bastions, and mounted with forty pieces of cannon, almost level with the water. On the opposite side of the channel is another strong fort, called the Punta Castle, connected with the Castle town, on the north. The city is situated on the western side of the harbor, and is surrounded by ramparts, bastions, and ditches.

You enter which is a lig showing a re is so narrow, fort overtops rive at a seco (before ment opposite the

*The Morro Castle, Lighthouse, and Entrance of Havana.*

You enter under under the Morro Castle, situated on a high rock, on the south end of which is a lighthouse, containing reflecting lamps, which make a brilliant appearance, showing a revolving light which may be seen twenty-five miles, past which the channel is so narrow, that you may nearly touch the side with a boat-hook. The top of the fort overtops the mast of the stoutest ship. After entering through this pass, you arrive at a second, only one hundred yards wide, on one side of which is the Punta Fort, (before mentioned,) and on the other, Castle Blanca, a prodigious strong fort, directly opposite the city; having passed these works you enter a harbor almost unrivalled.

In passing the first castle, (Morro,) you must not come to anchor, as a reef lies off the starboard hand as you enter, which is dangerous.

It is stated that the entrance to the harbor of Havana is rapidly filling up. The channel by which three-deckers formerly entered will now barely permit forty-four gun ships to pass.

The harbor of Havana may be distinguished, at a distance, by the Paps of Managua, which, as already stated, lie on the meridian of the entrance; while the land, both to the eastward and westward, is low and equal, with the exception only of the Morro, or little hill, surmounted by the fortifications and lighthouse. At 6 leagues to the eastward, the Hills of Jaruco or Iron Hills, may be seen. These are of moderate height, and detached. The tables of Mariel are about 6 leagues to the westward; and in advancing not only these, but the Hill of Cavanias, may at times be seen. [The form of the harbor can be best understood by reference to the particular plan of it, from the survey of Don Jose Del Rio, by whom the position of the Morro Castle has been determined and delineated on a chart, published by E. & G. W. BLUNT.] The entrance lies nearly S. E. and N. W., and it is, therefore, very difficult to enter when the breeze is not to the northward of E. N. E. The breeze enters at about 10h. A. M., and blows till sunset; and, therefore, it is only between these hours that you can sail into the port. It is very difficult, if not impossible, to sail in when the breeze is from J. N. E. to S. E., which it often is in the rainy season, and sometimes even in the dry season. Under such circumstances, the only resource is to anchor in the Morro Shoal, or Bank, and entering by towing or warping, when the breeze takes off, which, as already stated, is at night. As, on entering, these difficulties are to be encountered, so, on going out, you will not be quite free; for when the breeze comes to the N. E., which it often does in the dry season, or that of the norths, it is not only inconvenient, from the wind's being scant, but also because a swell sets into the mouth of the harbor, which renders this operation much exposed to danger. Generally speaking it is best to enter about mid-day, and to go out at the dawn of day. Should the wind be scant for getting in, it is advisable to anchor outside the Morro, and tow or warp in at night.\*

The Morro Bank affords anchorage safe enough in the time of the ordinary winds and land breezes, but is much exposed in the season of the norths, and in the hurricane months. It is, therefore, advisable to anchor so as to have the mouth of the harbor open, and to be extremely vigilant, lest you should be surprised. To direct yourself into the harbor, the eye may suffice, for in the channel there is no other danger than the shallows, which stretch out from each side. That on the Morro side does not extend one third of a cable from the shore. To avoid the leeward shoal, it is requisite not to go farther from the eastern shore than a cable's length; working your vessel so as to run along half a cable's length from the coast on the N. E. side, the mid-channel being at about

\* In approaching the Havana from the eastward, care must be taken to avoid a shoal spot, more than a quarter of a mile from shore, and on which the ship *Mariner*, of Port Glasgow, grounded in 1815. The vessel drew about 17 feet of water; and from the shoal, the Morro Castle bore about S. S. W., distant one mile. This notice is given from the information of Mr. Cooper, who was mate of the ship *Jane* of Glasgow, then in company with the *Mariner*.

three quarters of a cable's length. When once abreast of the middle of Castle Blanca on the N. E., which will be when you are abreast of the N. E. front or side of the city, you may keep away, and anchor opposite to the eastern part of the city, at what distance you choose. The largest ships may approach near enough to lay a plank on shore.

At a short distance without the Morro Castle, to the S. W., is a very small shoal, with 5 fathoms over it. This bank is to be feared only when there is much swell on; and at other times the largest ships may pass over it without touching. Even when the water begins to shoalen, you need not be afraid of it, as at half a cable's length from the Morro, you will be perfectly clear of it. Finally, if you wish to pass in without any risk, send a boat to place herself on the Capstan Shoal,\* which will serve you for a mark; then steer so as to pass outside of her, and you will be free from all danger.

A respectable English navigator, in giving directions for the Havana, has said, "On going in, with the wind from the eastward, keep as close to the Morro as possible. So soon as you are within it, you may meet with flaws and variable winds; and should you be obliged to let go an anchor, great care should be taken to shorten sail and veer cable quickly, as the ground at the entrance of the harbor is not very good for holding. All ships lying in the channel of the lagoon, moor head and stern. There are two wrecks lying rather more than 2 cables' length within the entrance of the harbor, and denoted by buoys with small flags; the channel lies between them."

Ships of war and large merchant vessels, generally warp up the harbor, and anchor off the sheers or arsenal, where there is sufficient room for a great number of ships to moor, in from 7 to 5 fathoms.

From the Morro, or Castle of Havana, to Punta de Yacacos, (or Yacos,) the distance is twenty leagues, and the course nearly E.  $\frac{1}{2}$  N. From this point may be seen the *Loaf* or *Pan* of Matanzas, to the W. S. W. This hill, which is the northernmost that you will descry to the eastward of the Havana, lies over the bay of Matanzas, and constitutes the grand point of departure for ships bound hence to the northward, through the Strait of Florida.

*Pan of Matanzas to the E. S. E.*

## ISLAND OF CUBA.

We now commence with the south coast of Cuba from Cape Maize, proceeding regularly westward to Cape Antonio, including the Isle of Pines, &c. From Cape Antonio we continue to describe the coast eastward along the north side to Havana.

The greater portion of the coasts of Cuba, are extremely foul. Those most clear are the southern coasts, from Cape Maize to Cape Cruz, the N. E. coast from Cape Maize to Punta [Point] Maternillo, and the N. W. coast, from the Port of Mariel to Matanzas. On the other parts are many shallows, keys, and reefs, so thickly planted and so numerous, that in many places they form barriers, which prevent access to the coast of the island.

The land to the south-westward of Cape Maize, at about half a mile from it, begins to be high and clean, and it trends about S. W.  $\frac{1}{2}$  W.,  $6\frac{1}{2}$  miles, forming a small bay, with a sandy beach, named *Cala de Ovarado*. From this *Cala* or cove, the shore trends about S. S. W. 4 miles, to Punta Negra, or Point Negra, whence it winds more to the W. S. W. about 4 miles more, to Punta Caleta; 28 miles W.  $\frac{1}{2}$  S. from which, lies Point Savana-la-Mar, and 4 miles to the westward from the latter, is the Port of Baitiqueri.

The 'Derrotero' says that, "From Cape Maize to Point Negra, the shore ought not to be approached nearer than two leagues; for, as there is no inducement to approach it, surely it would be foolish to run in upon a coast which lies completely open to the breezes, and along which there is no anchorage, although it is clear, and has no unseen dan-

ger. From Point Negra to Baitiqueri, there is no risk in running along shore, at the distance of a mile, and along this part, and to the leeward of the various points thereon you may anchor in the depth of water which suits you, from 35 to 7 fathoms; but the best bottom is in 16 fathoms, where you will be at a good distance off shore. In this place, several rivers discharge, from which you may provide yourself with excellent water, and plenty of firewood may be procured."

The Cape Bueno, or Ocoa Point of the English charts, lies to the eastward of the Punta de la Caleta, of the Spanish; and it has been said by a British navigator, "Within this cape is the Bay of Ocoa, in which there is anchorage. The marks for anchoring are, the easternmost point bearing E. S. E. about one mile and a half, when the Table Land of St. Nicholas' Mole will be in a line with the point. You may anchor in any water, the depths being from 35 to 7 fathoms, but 16 and 18 are the best; and plenty of fish may be caught with hook and line. Two fresh water rivulets run into this bay, the one named Rio du Miel, or Honey River, lying 2 or 3 miles to the westward of the anchorage; the other, which lies nearer, is to the eastward, and at the bottom of the easternmost gully, but it is generally dry, from the unfrequency of rain."

The Harbor of Baitiqueri, already mentioned, is very small, and has a very narrow entrance; it has only from 15 to 20 feet of water, and therefore, is fit for small vessels only; it is well sheltered from all winds, and the rivulet of the same name, which runs into the interior of the harbor, affords an opportunity of watering. There is rather more than a cable's length between the two other points of the entrance; but a rocky reef, with from 10 to 17 feet on the edge of it, runs out from the windward point; and there is, also, a reef running out about a quarter of a cable from the leeward point. Between these two reefs lies the entrance channel, which is only 50 yards wide, and continues thus narrow for about a cable's length, after which it widens as you approach the two interior points; and the depth of the water admits of approaching the shore.

From Baitiqueri the coast trends about W. S. W., true, for 5 miles, to Point Tortuguilla, from which it follows W., true, 3 miles, to the river Yateras; S. W. 4 miles is Point Mal-Ano; and at 3 miles west from the latter, lies Puerto Escondido, (Hidden Port.) All the coast between Baitiqueri and Port Escondido is clean, and may be safely sailed along at the distance of a mile.

Port Escondido forms an anchorage sheltered from all winds; in the interior of it are various bays, fit for all classes of vessels, but its entrance is very narrow, for between the outer points there is only one cable's length; and as each of them sends out a reef, of which the windward one lies out a third of a cable, the channel is only 90 yards wide; it, however, luckily has no windings, and the whole length of the strait is not more than a cable and a half; and as to enter it, you must steer N. 43° W.; it may always be done with a free wind, even if the breeze is at N. E. The most prudent mode of entering this harbor, is to order a boat to be placed on the outer point of the windward reef, which is nearly in mid-length of the channel, and which will serve as a mark to sail in by. You have then only to bring the vessel's head into the direction above given, and run on in that direction, passing close to the boat, until you have passed the inner point to leeward, where you may anchor in 5 or 6½ fathoms, clay ground.

As there is no town on this harbor, nor any proper leading marks for running in, it is proper to allow the vessel sufficient room to alter her course from windward to N. 43° W., the course for entering the harbor. We therefore recommend, although the windward coast of the entrance may be passed at half a cable's length, that it should not be passed at less than 3 or 4; because thus, although in luffing to, the vessel may pass the demarkation given, (N. 43° W.,) yet there will be room to rectify this, by luffing to windward before you are between the points, so as to gain the proper bearing, which is absolutely necessary, as the channel cannot otherwise be passed without danger. Any one wishing to run further up the harbor, instead of bringing to in the anchorage we have mentioned, may easily do so by the eye, by towing, or even under sail; but for this it is necessary to consult a plan of the harbor.

Puerto Escondido\* having no commerce, it is seldom that any vessel is bound into it; and if, in any storm or hurricane, one is obliged to seek anchorage, we would rather advise every exertion to be made in order to reach the next harbor to the west, named Güntanamoo, because, if it be difficult to enter Port Escondido in good weather, it must be much more so in storms and obscure weather; and it will be by no means strange if, without a pilot, or even with one, a vessel might be driven on one of the reefs of the entrance; or, what is still worse, might get on the rocks at some point of the coast, which might be mistaken for the entrance of this harbor.

\* Puerto Escondido, or Hidden Port, is well termed so, as I have been within less than a mile of the entrance of it, and could not make it out distinctly.—A. L.

GUANTANAMO, or CUMBERLAND HARBOR, a very extensive and excellent harbor, lies more than 24 leagues to the westward of Cape Maize, and 4 leagues from Puerto Esc.uido. The coast, in the latter distance, forms some very small sandy coves, and it is very clean. The entrance of Guantnamo, between the two outer points, is more than a mile broad. The Derrotero says—"The east point may be approached without fear, as there is no danger but what is visible. The coast trends nearly north, about a mile and a quarter, whence it changes to the N. E. to form the harbor. On the windward side of the entrance, and at about three quarters of a mile within the outer point, a rocky shoal stretches from shore, upon the edge of which are from 4 to 5 fathoms of water; this shoal is rather more than a cable's length broad, and may be easily avoided by attending to the subsequent directions. On the western side there is also a reef of rocks, but it is narrower than that on the east. To enter this harbor, it is necessary only to place your vessel so as to pass its windward point at the distance of one or two cable's length, and thence luff up to N. W. by N., on which course you must continue until the north point of the River Guantnamo, or Augusta River, bears west; you may then change your course to N. by W., until you have the interior point of the windward shore bearing east, when you will be clear of the reef, which stretches from it. You may next haul by the wind, and anchor where it may suit you best; or, if you wish to run into the interior of the harbor, and the breeze will not allow you to lay through, you may beat in with the assistance of the lead only."

The following remarks on the Harbor of Guantnamo, were made by an officer on the Jamaica station, in 1809:

"The appearance of a remarkable spot of land, on the side of a hill, at a distance in-shore, determines the situation of Cumberland Harbor, which, if you fall in to the westward, exactly resembles a kite, and is totally open when it bears N. E.  $\frac{1}{2}$  E.; but if you are far to the southward, it will either be partly or entirely hid, unless you are far enough to the westward to bring it over the hills on that side of it."

The following directions for sailing in, have been given by Mr. J. Town, from observations made by him in 1817:

"On coming in, you will observe, in the middle of the bay, a remarkable light yellow (or brown and white) cliff; bring this cliff to bear about N. by W. or N. by W.  $\frac{1}{2}$  W., and run in with that bearing until you open, on the eastern side, a small sandy point, with two huts on it. This point, called Fisherman's Point, cannot be mistaken, as there is no other sandy point on the east side of the harbor. After you have opened Fisherman's Point, with the bearing above described, you may steer N. N. E., and when Fisherman's Point bears E. by S., haul up N. E. or N. E. by E., and anchor in 6 or 7 fathoms, muddy bottom. The best marks for anchoring are, Fisherman's Point S. by E. or S. S. E., the west head of the harbor S. W.  $\frac{1}{2}$  W., and the light yellow cliff W.  $\frac{1}{2}$  S., in 7 fathoms.

"On coming in from the eastward, you may keep in as near to the east head of the entrance as you please, there being 10 fathoms close to it; after passing, run to the westward, and bring the aforementioned bearings on, which will clear the reef that lies off the point a little to the S. W. of Fisherman's Point. The marks for the south end of this reef, which has heretofore been described as a single rock, are, the two huts on Fisherman's Point on with each other, bearing N. E. by E., and the point within the East Head S. by E., West Head S. W. by W.  $\frac{1}{2}$  W., entrance of Augusta River W.  $\frac{1}{2}$  S., the yellow cliff N. W. by N. The marks for the north end of the reef are, the N. E. hut about its breadth open to the northward of the S. W. hut, bearing N. E. by E.  $\frac{3}{4}$  E., the point within the East Head S.  $\frac{1}{2}$  E., the entrance of Augusta River W. S. W. The reef lies N. by W. and S. by E. about  $1\frac{1}{2}$  cable's length, and 20 fathoms in breadth. It has 17 feet water on its shoalest part,  $3\frac{1}{2}$  fathoms within it, and 5 fathoms close to the outer edge, which is about  $2\frac{1}{2}$  cable's length from the shore.

On coming in from westward, you may approach the point to a cable's length, as it is steep to; but, from the appearance of the point at a distance, a stranger would suppose there was a reef extending from it; at least, when you are within a quarter of a mile. After you are within this point, haul more to the eastward, as there is a flat that extends from the entrance of Augusta River, in a straight direction for the yellow cliff; this flat extends nearly one third of the distance across the harbor towards Fisherman's Point; but the soundings to and along it are very regular.

"If the wind is off the land, and you have to work in, your lead will be the best pilot when standing to the westward; but in standing to the eastward, be careful, and do not approach the land nearer than three cable's length, as the reef already described is steep to.

"In running in, with the marks described, you will be within the points before you get soundings; after which the soundings are very regular, from 18 to 6 fathoms.

Augusta River is narrow at the entrance, and has only 12 or 14 feet water at about one quarter of a mile up. You may go up the river by keeping the starboard shore on board, or go into a large lagoon on the larboard side.

From St. anchorages on this coas 11 miles dis leagues off.

Forty mile the Peak of this part of t Jago, and y or even less seems more tance from t leagues to th and reefs wit the edge of t Twelve-leag N. W. direct

When the entrance of the harbor bears nearly north, 5 or 6 miles distant, the land to the westward of the harbor and the Morro Castle of St. Jago de Cuba will be in a line, bearing W.  $\frac{1}{2}$  N., and the outermost land to the eastward E. N. E.

From Guantánamo to Point Berracos, the coast trends nearly true west, 26 miles; it is generally clean, and you may run along it at a mile from the shore. Point Berracos may be known by a morro or hill which rises on it. From this point the coast bends to the north-westward, and forms the Bay of Cabo Baxa, (Low Cape,) whence it trends west to the River Iuragua. The space between Cape Baxa and Iuragua is named los Altares, or the Altars, because the coast forms three beachy bays, separated from each other by high scarped mounts. The River Iuragua is 10 miles distant from Point Berracos.

From the River Iuragua the coast continues nearly west, 12 miles, to the entrance of the Port of St. Jago de Cuba; it is all clean, and may be run along at the distance of a mile. The Rivers De Sardinero and De Aquadores desembogue upon it; and near this last may be seen some small houses, inhabited by water-carriers.

The HARBOR of ST. JAGO DE CUBA is very good; but the entrance being narrow and crooked, is difficult to take. On the east point stands the Morro Castle, and a little farther in Estrella (Star) Castle, which is separated from the Morro by a bay, at the end of which is another small fort or battery. A rocky shoal runs out from the windward coast, which extends out about  $2\frac{1}{2}$  cables' length from the Morro Point; and, on the leeward side, another shoal runs out, about a cable's length south of the point. The channel lies between these two shoals. At its entrance is a cable's length in width, and farther in, is reduced by about a third of a cable; so that, when abreast of the bay, which is between the Morro and Estrella Castles, which is the narrowest part, it is only two thirds of a cable in width; and from this it continues, with the same width, until you pass Cape Smith, when the harbor begins to open.

To take this port you ought to sail half a league or two miles off the shore, until the Estrella Castle bears N. E., when, placing the vessel's prow in that direction, and steering the same course, you will enter the channel formed by the reefs; but, so soon as you are abreast of the Morro Point, within a quarter of a cable's length of which you may pass, you may begin to keep away; so that, when up with the battery, which is at the bottom of the bay, between the Morro and Estrella Castles, the vessel's head shall be N.  $\frac{1}{2}$  W., which course it is necessary to follow until you are past Cape Smith, when you may anchor.

The necessity you are under (from the crookedness of the entrance) of keeping away four points, viz. from N. E. to N., renders it almost needful that a large vessel should have sufficient space to make the turn in. To this end we advise that, so soon as you are abreast of the Morro Point, you ought to begin to keep away; for without this, you may very easily get ashore at the Estrella Castle. It must here be remarked, that it would be improper to keep the vessel's prow away to the north at once, though it may sometimes be done under favorable circumstances; for, by doing this, you incur a risk of getting ashore on the corner of the leeward reef.

The distance between the Morro Point and abreast of the battery, at the bottom of the bay, on the east, is one cable's length; with the knowledge of this, the Pilot will know to regulate the steerage, and trim the sails, &c., as may be necessary to gain his purpose, and according to the facility with which the vessel can be worked.

At the bottom of this harbor, on the N. E., is the city of St. Jago, or of Cuba, which is the most ancient city in the island.

From St. Jago de Cuba, the coast continues to the west, forming various bays, with anchorages of little importance, the knowledge of which is alone useful to coasters. Upon this coast are the high Copper Mountains, (Sierras del Cobre,) which are about 11 miles distant from St. Jago. In clear weather these mountains have been seen 33 leagues off.

Forty miles W. by S. from St. Jago de Cuba rises another very high mountain, named the Peak of Tarquino, which is an excellent landmark. Cape Cruz is the last place on this part of the island, where the coast is clean. It lies more than 30 leagues from St. Jago, and you may run along the whole intermediate coast at the distance of a league, or even less; but, as there is no motive to induce one to approximate it so much, it seems more advisable for those bound to the westward to run along at 2 or 3 leagues distance from the shore. At Cape de Cruz commences a White Bank, which extends 60 leagues to the north-westward, and terminates at Trinidad. Upon this bank are keys and reefs without number, which form channels of more or less width. Of the keys on the edge of the bank, the principal are those called the Cayos de las Doce Leguas, or the Twelve-league Keys, the whole range of which extend not less than 20 leagues in a W. N. W. direction.

To coast along the Doce Leguas Keys, and being 3 miles to the southward of Cape de Cruz, steer W. N. W.  $\frac{3}{4}$  W., with which course you will run along the edge of the bank; and, having run  $12\frac{1}{2}$  miles in this direction, alter your course to N. W.  $\frac{1}{4}$  N., with which you will enter upon the bank in 40 fathoms, on sand and rocks; keep this course for 23 miles, when, with the edge in sight, you will leave it in nearly 50 fathoms. Continuing the same course 17 miles more, you will again find 40 fathoms, or less, and soon afterwards will see Livisa Key to the N. N. E., and ahead will be seen the eastern head of the Doce Leguas Keys.

Having recognized these two points, you must run along on the bank, but without getting along into less than 4 fathoms, until you find yourself 3 miles to the south of the eastern head, and in 7 fathoms water, over a bottom of sand; you must then run W. by N. With this course you will shortly run off the bank, and may coast along the Doce Leguas Keys, at the distance of a league, without any fear; and having run  $21\frac{1}{2}$  miles, steer W. N. W.  $18\frac{1}{2}$  miles, and you will then have the Boca de Caballones (or mouth of the Caballones Channel) open; and it may be easily known, as it is broader than any other to the eastward, and because the S. and E. point of its entrance is very low, and the edges at the water of Soboruco Rock.

Having ascertained your situation from seeing this Boca or Channel, you may continue coasting along the keys, at the distance of three miles, continuing on the preceding course; and having run 21 miles, you will see to the northward a great opening formed by the keys, which is the Boca Grande; passing by it, pursue the same course, keeping the Cinco Balas, or Five Balls' Keys, in sight, at the distance of 2 leagues, and noting that a reef extends 3 miles to the S. W. of Key Breton. The latter is the westernmost of the Doce Leguas Keys, nearly in a line between Key Breton and Puerto Casilda. On the main of Cuba, is the Placer de la Paz, a sand-bank, having on its eastern part good anchorage, and no where less than 14 fathoms, on sand and shells.

**ADMONITIONS.**—If night comes on, when you are in the vicinity of Cape de Cruz, or to the south of it, as assumed in the preceding directions, you must steer W.  $\frac{1}{2}$  S. for 14 miles, and thence N. W.  $\frac{3}{4}$  W. to keep completely free of the Doce Leguas Keys, continue this course till daylight, changing it afterwards so as to make and recognize these keys, and thus include yourself in the route already recommended.

Should night overtake you in the traverse between Cape de Cruz and the Eastern Head, when it might suit you to anchor on the bank, you may do so on any part of it, observing only that the edges of the banks are rocky, and that to get clean ground, you ought to run in upon it into 20, or even 10 fathoms, on sand.

If night falls when you are coasting along the Doce Leguas Keys, as already directed, steer true West until you consider yourself from 3 to  $3\frac{1}{2}$  leagues from them, and even then continue the same course, considering that hereabout the current sets N. E. and S. W. and, if the tide happens to set in, it is very possible to get aground on the reef; hence no precaution ought to be omitted which similar cases require.

If when in sight of the Canal de Caballones, you wish to anchor in its mouth, from a case of emergency, you can do so without getting into less than 3 fathoms, on sand; and, in case of being unable to continue your course to the south of the keys, you can shape your course so as to descrie the land of Cuba, passing between the Bergantin and Manuel Gomez Keys, in 12 fathoms, on clay; following afterwards to the north, to make the Anna Maria Keys, and giving a berth to the shoal of Yagua, which you leave to larboard, and to some heads which are to the east of it, and which should be left to starboard. Having seen the last keys, and placed yourself about a league from them, you must steer for the coast; or act as directed in the instructions for this interior navigation.

**MANZANILLO.**—The reef, which extends two miles off Cape Cruz, can be passed within fifty yards, in 3 fathoms water. This reef is very steep. As soon as you have passed the reef, haul in for the land; you will then have  $2\frac{1}{2}$  fathoms water within one half a mile of the beach. The first point from the cape is called Point Calrado; this cape lies N. E. 6 miles from Cape Cruz. The anchorage is good from the cape to Manzanillo in the sloop channel. In passing Point Calrado, you will have 3 fathoms; as soon as you have passed the point, you will have from 8 to 10. This point should be passed within one half a mile. Three fourths of a mile from Point Calrado, in a N. W. direction, lies a shoal; it extends about 3 miles in the same direction. Six miles from Point Calrado, in a N. E. by E. direction, is Point Balona; this point has a shoal extending off from it, in a N. W. direction,  $1\frac{1}{2}$  mile. Three miles N. W. from Point Balona, lies what the Pilots call the Balona Shoal; the shoal extends N. W.  $2\frac{1}{2}$  miles. Three miles from Point Balona, in a N. E. direction, lies a small key, called by the Pilots, Mona Key; this key lies close to the main land, and cannot be seen as a key in passing along in the channel. The shoal water extends off this key about a mile. Two miles distant, in a N. W. direction, is what the Pilots call the Mona Shoal; between

there are 6 fathoms. Back of the Mona Key is Lime River, being the first fresh water about the cape. N. by E. 7 miles, as estimated by the pilots, lie two small keys, called by the pilots Swago. N. 4 miles from Swago lie a group of keys, tending E. by N. and W. by S. 4 miles, called Sloop Channel Keys. There are two shoals lying W. by N. of the Swago Keys. From Sloop Channel Keys the passage is clear to Manzanilla.

N. W. by W. 7 miles from Point Balona, commences the Great Bank, which extends 75 miles. Between this and the reef before mentioned, lies the main channel to Manzanilla.

A pilot can most always be found at Cape Cruz. There are but four pilots at Manzanilla, and in some cases a vessel might be detained for want of one.

The City of TRINIDAD, is situated in lat.  $21^{\circ} 42' N.$ , long.  $80^{\circ} 4' W.$  It lies on high ground, about three miles from the sea: the River Guanabo, or of Trinidad, passes rather more than half a mile to the northward of it, and falls into the sea at a little to the south of it. Trinidad communicates with the sea by this river, from the mouth of which it is three short miles distant; by Puerto Casilda, from which it is distant two miles and a half; and by Puerto Masio, the distance from which is  $4\frac{1}{2}$  miles. The mouth of the River Guanabo is to the north of the point of Maria Aguilar, at which the white grounds extending from Cape de Cruz terminate. The harbors of Casilda and Masio are to the eastward of this point, and to arrive at them a vessel must enter upon the white grounds.

Directions for sailing from Cape de Cruz to the neighborhood of these ports have already been given. We have only to repeat that it is always advisable to keep a good look out, and the lead going, especially by night. Having recognized Key Grande, continue the N. W. course until Key Breton bears N. E. bringing it the distance of 9 miles. From this spot a N. N. W.  $\frac{1}{2}$  W. course, 38 miles, will bring you to another, from which the Pan de Azucar, or Sugar-loaf Hill, will appear on with the most easterly of the hills of Bonao, which are some high ridges immediately to the westward of it. In this navigation the keys called the Zarza and Machos will be seen from without; and when the leading mark above given is on, you will still be in sight of the Machos, and of another very small key, named Puga; the latter is rendered remarkable by the breaking of the sea upon it, and it will bear about N.  $\frac{1}{2}$  W. a mile distant. From the same spot the Key Blanco will be seen, bearing about N. N. W.  $\frac{1}{2}$  W. This key is remarkable, both as the westernmost key on the bank, and because its shore is bordered with white rocks.

The place where you ought to enter upon the White Ground is between the Keys Puga and Blanco, to do which you must steer so as to pass about half a mile, or rather less, from the reef of Puga, which reef always shows; and in the passage you will always have 6 fathoms of water. Having passed Puga, you must steer N.  $\frac{1}{2}$  W. in order to anchor in 4 fathoms, sand and weed, with the south part of Key Blanco W.  $\frac{1}{2}$  S. that is, if the approach of night or waiting for a pilot, render it necessary.

On the route between Key Grande and Key Blanco, no one need be at any loss, who has the particular chart of the navigation between the Rio Guanabo and the Boca Grande. By it may be seen that any one who wishes to enter upon the bank by the Boca Grande may always do so, provided his vessel does not draw more than 14 feet of water; and it may even sometimes be convenient to run in here to anchor, under the shelter of Key Grande or those of Cinco Balas, in case of bad weather coming on, which will frequently happen, and which is much to be feared in August, September, and October; or, if he does not choose to anchor in the shelter of those keys, he may run in until he recognizes the key called Rabi-horcaulo, which he will leave on the larboard hand, and will afterwards see Cayo Bargayo; having passed to the eastward of the latter, he may run N. N. W. without fear, being guided in running by the vessel's draught of water; and, entering by the Machos Channel, he may run for Masio or Puerto Casilda, as he sees proper.

The key called Blanco de Zarza lies N. by W. 8 miles from the Cayo Zarza de fuera, and half a league to the southward of Punta del Caney. Between this key and the coast there is anchorage, as there also is in various other places hereabout, which will be found more or less commodious, according to the winds and draught of the vessel. The keys, in general, are but little above the surface of the water, and their low shores have no extent of beach; but rocky banks stretch out to a short distance from their points; excepting, however, those which form the Machos Channel, which within the strait are very clean.

*The Coast from the River Jatibonico, westward to Port Casilda, Trinidad, &c.*

The coast between Point Jatibonico, and Point Passabanao, in a distance of two leagues, forms a bay with  $2\frac{1}{2}$  and 3 fathoms. The shore is drowned and covered with mangroves. At Point Jatibonico the river of the same name enters the sea. To water in it, you must ascend the river for a league. Many cedar and Mahogany trees are brought down this river, and many vessels take in cargoes here. Three miles to the west of Passabanao is the Estero de las Caovas (Mahogany Creek,) in which small craft

not drawing above 6 feet, may find shelter from the south-east winds. After Estera de las Coavas, at three miles follows Point Manati, on which there are some wells of tolerable sweet water. Point Manati, with Point Tolete, which lies two leagues to the west of it, form a small bay, in the middle of which is the mouth of the Estero Nuevo (New Creek). Point Tolete and Point Zarza,  $4\frac{1}{2}$  miles distant, form another bay, in which the Estero de San Marcos, with very little water at its entrance. On the eastern part of Point Zarza, the river disemboques itself. By this river there is much traffic carried on with the town of Sancti Espiritu, which is 13 leagues inland. West of Zarza Point is the creek of the same name, with 7 feet water, where small vessels may find shelter from the south-easters, as they may also to the westward of Point Zarza, under the lee of a reef, which runs out from the W. S. W. of it for nearly a mile, and which forms a bay with a clayey bottom of 3 and  $3\frac{1}{2}$  fathoms.

A league to the west of Point Zarza is Point Caney, between is a small bay, with 3 and 5 fathoms, clay and grass bottom. On the west of Point Caney is the Estero (Creek) the same name, with 7 feet of water. To the south of this point is Cayo Blanco de Zarza, (the White Key of Zarza;) and between the reef which runs out from it, and the point, there is a good channel, navigable for any vessel, which, as before said, may find good shelter to the west of the key. Beyond Point Caney, on the west, is the Desembarcadero de Mangle (Mangrove Mouth.) Two leagues west of Point Caney is Point Ciego; between is a bay with from 3 to 5 fathoms: in the middle of it is the River Tallabacoa, which has very little water in the dry season; and that of a brook, at a very short distance to the westward of Point Ciego, is always preferable. After Point Ciego comes that of Yguanojo, at which is the river of the same name, the water of which is excellent, but to procure it, it is necessary to ascend the river for a league. One league and a half west from Point Yguanojo is that of Agabama, to the eastward of which run out the Caycos de Tierra (Keys of the Land,) which, with Point Yguanojo, form a bay called St. Pedros, having from  $3\frac{1}{2}$  to 6 fathoms, on clay.

The Caycos de Tierra, with Point Agabama, form another small bay, having 7, 5, and 4, fathoms, on clay and sand. At Point Agabama is the river of the same name.

The shores from Agabama to Point Casilda are drowned, and covered with mangroves (literally watery mangrove land:) and, from Casilda to Point Guanrabo, they are of sand and scarped rock. Relative to the interior of the land, we shall only notice that the Potrerillo, which is the highest point of the mountains above Trinidad, may be seen in clear days at 21 leagues off, and the Sugar-loaf (Pan de Azucar) and it are excellent marks for accurately ascertaining your position.

From Boca Grande, the reef forbids entering on the bank as far as the Outer Zarza, between which and the Outer Macos there is a spacious entrance, with depth for any vessels. Nevertheless, if when in sight of Key Breton, and to leeward of Boca Grande, you wish to anchor upon the bank, in order to regulate the time for making Puga and Cayo Blanco, or for any other course, it may be done by steering towards Key Breton, until the N. W. part of that key bears E.  $\frac{1}{2}$  N. but in running thus, sound frequently, until you have from 4 to 3 fathoms, on sand, when you may anchor. If the wind will not allow you to steer in for the anchorage directly east, and you are obliged to beat to windward, observe not to prolong the tacks to the northward longer than until the N. W. part of the key bears E. S. E., or the south tack farther than until the same point of the key bears N. E. by E. Between these bearings you may work, tack and tack, till you reach the anchorage, in which there is a shelter from the winds from N. by E. to S. W., caused by the cordon of reefs and keys which lie in these directions. All these reefs show above water, and the outer part of them lies nearly 3 miles S. W. from the west part of Key Breton.

Any large vessel seeking shelter from the weather or any other cause upon the bank, may enter between the outer Zarza and outer Machos, and may run over the whole of the interior of the bank, there being sufficient depth for vessels of any class, and for this the chart is the best guide.

**TIDES.**—We shall now terminate this part of the subject by remarking that the tides produce streams more or less rapid, and in various directions, according to the channels which the reefs form: but they are of very little importance, because the greatest rise of water, which is at the time of the new moon, is not more than a foot and a half, except with S. E. winds, when it sometimes rises 3 feet.

**MASIO, PORT CASILDA, AND TRINIDAD.**—To enter Port Masio, being within the bank, steer N.  $\frac{1}{2}$  W. until the south part of Key Blanco bears W.  $\frac{1}{2}$  S., in which situation you will find 4 fathoms, on clay and weeds, or grass (yerba.) From thence run N. 50° W., with which course you will run along the middle of the channel of Masio, which is formed by a shoal extending N. W. by W. from Key Blanco, and a shoal, with some heads nearly even with the water, on the land side; and you must continue thus till you have Point Jobabo N.  $\frac{1}{2}$  W. sandy beach. You must then luff up with the prow to the west point of the harbor; and steering N. N. W., take care to keep a very little away until you are past the Guard-house Point, that you may keep clear of the reef which runs out from it. Being past this, keep the prow, as above directed, to the west point, until near the entrance, when you may run up the middle of it by the eye, because the edges of the shoals show distinctly, and the eye and lead are the best guides. Having run up the middle of the entrance, luff up N. by E. until, having passed the points, and being in 4 or 3 $\frac{1}{2}$  fathoms, you may anchor where it suits you, being cautious solely of a clay bank which runs out from the landing place on the west shore, and the extremity of which is in one with the west point of the port, at south.

Passing in for Masio you leave the Bay of Caballonas to the starboard; and if you wish to anchor in it, for shelter from the N. and S. E. winds, you may do so by keeping in the middle between the two points which form it, and directing yourself mid-strait, and with the prow N. E. by E., anchor when you are in 3 $\frac{1}{2}$  fathoms, clay or ooze.

To enter Port Casilda, observe the same route as that given for Port Masio, until the south part of Key Guayo is on with the south part of the main land of Casilda, in which direction is the mouth or opening of Jobabo, by which you ought to enter, and keeping away in this position to run in the middle of it, the eye and lead will facilitate the entrance, which is 110 yards wide, with 4 fathoms of water. Being at the west of this opening, at a cable's distance, steer W. S. W., sailing in 6, 7, and 8 fathoms, clay, until you bring Point Casilda on with the north point of Cayo Ratones, at which moment place the prow to the westernmost part of the city of Trinidad, avoiding the reef, which runs out S. S. W. from Cayo Guayo, and which will be passed so soon as you bring the south part of this key on with the south part of Tabaco. Afterwards steer towards the easternmost part of the city, until you bring the south part of Key Ratones on with the westernmost part of the high hills of the Rio Honda, when you will steer towards these objects until you pass the shoal Eumedio; and following the same mark, with the precaution of keeping a little to starboard, you will pass clear of Point Casilda, which is rather foul; and passing on for the interior, go to the south of Key Ratones, giving a berth to the point of it; having passed which you may steer N. W.  $\frac{3}{4}$  W., and shortly afterwards anchor in 3 or 3 $\frac{1}{2}$  fathoms, on clay.

You may anchor in any part of these channels, if circumstances require it, upon a clayey bottom. You may also take Port Casilda, entering from the channel of Agabania, by the north of Key Guayo, or from the west of Key Blanco, and by the breaks or mouths in this part of the reef, as Boca Grande, the Negrilla and Mulatas; but the entrances are dangerous, and there are no proper leading marks.

To enter the mouth of Guaranabo or Trinidad River, steer outside the bank, and run in without fear, even within a musket shot of the shore, which in this place is very clean; and running on at the same distance, you will see the bay of the entrance, formed by the point of Ciriales to the south, and the point of the River Canas to the north; and when you have it well open, direct yourself (with little sail set) so as to pass nearer Point Canas than Point Ciriales, for it is much cleaner. Sound frequently, however, and, if in a large vessel, anchor immediately upon getting bottom, because the anchorage is of very small extent. If the vessel is small, you may run in, steering towards the south shore of the bay, keeping the prow between two sandy beaches, which are the only ones on it; and when in 6 or 8 fathoms, sandy bottom, you may anchor.

Having now described this navigation, it is necessary only to add, that Masio is preferable to Casilda, not only on account of its deeper water, and that you can sail out of it with the trade wind, but that it is more easy to take, and does not require a pilot; while, on the contrary, Port Casilda cannot be entered without one. Its anchorage is not more than four cables' length in extent. It is very difficult to get out of it with the trade wind; and finally, to obtain water it is necessary to send boats to the River Guaranabo. Port Masio is therefore the only one which vessels intending to load or discharge, or remain any time at Trinidad, ought to take.

From the River Guaranabo the coast westward is very clean, and you may run along it at the distance of a league. For eight long miles it trends W.  $\frac{3}{4}$  N. as far as the west point of the River Honda; from this it continues N. W. by W.  $\frac{3}{4}$  W. 9 miles, to the Point of San Juan, which is well marked, as the coast afterwards trends N. by W.  $\frac{1}{4}$  W. for a long mile to the River Guaguinico.

Between the river Guaranabo and the point of San Juan, the rivers Guanayara, Caba-gan, Honda, Yaguanabo, and St. Juan, run into the sea. In all these, coasting vessels which do not draw more than 6 feet, sometimes anchor. To get fresh water in any of them, it is necessary to proceed a league up from their mouths.

Along this part of the coast the water is deep, and the bottom clean, excepting a little reef, which stretches out between the Rivers Haguano and San Juan, and which does not extend from the coast so much as half a mile. The shore is scarped, and of a boru-

co rock. The land is mountainous or hilly, for a little to the west of San Juan's Point, and at it commences the mountains of San Juan, or of Trinidad.

From the river Guaginicó the coast trends 14 miles N. W. by W. to the Colorados Point, which is the east point of Port Xagua, and is so clean that it may be run along at less than half a cable's length. The land is level, without mountains, and in it the rivers Gavilan, Gavilancito, and Arimao, are met with; but they are of little importance.

The Port or Harbor of Xagua or Jagua, is very spacious, secure at all times, and has deep water, but its entrance is very narrow and crooked. The east point, named Colorados, and the west, Sabanilla or de la Vigia, are the exterior points of this port, and the distance between them is a large mile. The windward shore, from Point Colorados, trends N. W.  $\frac{1}{2}$  N. 2 miles, to Point Pasa Caballos, whence it sweeps to the N. by E. about two thirds of a mile, to Point Milpa, which is the interior eastern point of the strait. The leeward shore of the entrance follows nearly the same direction as the windward, and narrows the channel so much, that opposite Point Pasa Caballos it is only a cable and a third in width, and thus it continues to Point Milpa.

To enter Port Xagua, pass Point Colorados at the fourth of a cable's length; but shun the exterior coast to windward, as a reef stretches from it, and it cannot be approached nearer than a mile, you run on, inward, preserving the same distance of a quarter of a cable, until you arrive at Point Pasa Caballos, when you must luff, for the purpose of keeping in mid-channel, or rather nearer to the leeward side; and so soon as abreast of the interior points, place the vessel's head towards the S. E. point of Cayo de Carenas, and proceed thus, in order to avoid a shoal which lies to the northward of Point Milpa, and of which you will be clear when the northern point of the Key Alcatraz bears east. When once the interior points are passed, you may anchor where you please, a chart of the harbor being a sufficient guide.

The coast west of Xagua or Jagua, is all of soboruco rock, and without any bank or shoal, for nearly  $21\frac{1}{2}$  miles, to the point of Caleta Buena (Good Cove;) it thence trends W. N. W.  $\frac{1}{2}$  W.  $6\frac{1}{2}$  miles to the east point of Cochinos or Swine's Bay.

COCHINOS BAY is formed by the point above mentioned, and another point which lies W. by N. from it. The last is named Punta del Padre (Father's Point.) The bay extends 13 miles to the N. N. W. The edge of its eastern coast is of soboruco rock, without a bank, until at about a mile from the shore, when bottom is found in 15 fathoms, on sand and rock, diminishing the depth rapidly towards the coast. The western coast is a sandy beach, and sends out a bank to a short distance, but all of it is a rocky bottom. In the northern part of the bay is a landing place, which leads to the stock farms, (Haciendas de Ganado,) but it is little frequented, on account of its having so little bank, and the little that is having generally a bottom of sharp rocks.

Point Padre is very low, with a sandy beach. S. E. from it, at the distance of  $6\frac{1}{2}$  miles, lies Piedras Key, which is low, and of small extent. A little to the east of the point the bank which borders the west coast of the bay continues towards the south, and along the edge of it is a reef, which almost joins the north part of Piedras Key. The eastern side of this reef is very steep to, and has some openings, of 3 and 4 fathoms, which allow a passage on to the bank. The most frequented one is that formed by the southern extremity of the reef and Piedras Key, both because the key serves as a mark for it, and because it has a greater depth of water than any of the others. The break which terminates this reef ends to the westward at the Lavandera (Washerwoman) Rocks, which lie about 4 leagues W.  $\frac{1}{2}$  N. from Piedras Key.

From Padre Point to that of Don Christoval, all the coast is broken with lagoons, forming many keys, with groups of Mangroves, having their roots growing in the water, or so close to it that the water washes in among them, and having no navigable channels. In this large space is comprehended Cayo Blanco, the south side of which is a sandy beach; and there is fresh water, in holes, at its eastern part. On that side, at the distance of a mile and a half from the shore, is the Lavandera Reef, which extends two miles east and west. The west point of it lies west  $15\frac{1}{2}$  miles from Point Padre, and with another key, which lies to the N. W., forms the Boqueron (Little Mouth) of Calvario, which has little depth.

The Boqueron of Calvario, with the southern extremity of Diego Perez Key, which lies 6 miles distant from it S. W. by W., forms the bay of Cazonas, which extends inland N. W. by W. for about 7 miles. At the bottom of this is Masio Key. There are various small channels at the bottom of the bay, formed by Masio Key, which are connected with lagoons, lying along its sides and at the north end of it. To the south of this key is a bank of 3 or 4 fathoms, sand and rock; but it is of no use, there being no communication thence to the main land of Cuba. At the distance of more than a mile and a half to the east from the south point of Diego Perez Key, a reef begins which, stretching out with a turn to the S. E., unites with the eastern part of the Jardinillos, and is steep to. Between the same point of Diego Perez and the commencement of the

reef, there short distance other channels for it, and

To the south of the Key, there being no more than a mile from the beginning of the Jardinellos, the commencement of the

reef, there is a passage on to the western bank, which begins with 7 fathoms, but in a short distance has only 14 feet. Four miles to the S. E. of the same point there is another channel, with first 3 fathoms, and very soon after only 2. There is no good mark for it, and the former is most frequented.

S. W. by W. a mile and nine tenths from the Point of Diego Perez, lies the southernmost part of Palanca Key, after which follow in order to the N. W. by W., true, the chain of keys named Sal and Fabrica, and which, connecting with the main land of Cuba, at Don Christoval's Point, form innumerable passages, but with very little water. The southernmost keys of this chain, named Bointo, Cacao, and Palanca, are the marks for vessels sailing along the bank, which has no more, in many places, than 11 feet of water, and its bottom, of fine white sand, is studded with heads of rocks, with only 6 feet over them, but their color indicates where they are. This passage is bounded by the keys above mentioned, another key, Rabihorcado, to the south, and the edge of the Jardines Bank.

From Palanca Key, which lies 12 $\frac{1}{2}$  miles W. N. W., true, from Flamenco Key, the western Fabrica Keys take a turn to N. E. by N., true, towards the main land, and they form a passage or channel with another chain of keys, to the west of them, called Don Christoval's.

Don Christoval's Point lies N. N. W. 2 miles from Palanca Key; and from it the coast, which is low and swampy, trends W. N. W. for 18 $\frac{1}{10}$  miles, to a little key which lies at the entrance of a small bay called Matahambre. The interior of the country along this part of the coast, is firm land, and is called the Savannas of Juan Luis. To the south of it extends a chain of keys, which are also called Juan Luis' Keys. There is a passage between them and the coast, as there is also between the east part of them and the west part of Don Christoval's; only, however, in any of the channels, for vessels which do not draw more than 10 feet.

N. W. at the distance of 3 $\frac{1}{2}$  miles from the little key which lies in the mouth of Matahambre, the Great Mangrove Point and the swampy land ceases. From this point the coast trends to the N. N. E. and N. E. for a short distance; and then to the east, to form the Ensenada or Bay of Broa, which extends inland, in that direction, about 7 leagues. On the north it is bounded by the Point of Mayabeque, which lies N. by W. 15 $\frac{1}{2}$  miles distant from the Punta Gorda. The shores of this bay are all of mangrove and swampy land; and on its north side are the branches of the Cienega or Shallow Lake, which the natives of the country have distinguished by the names of the rivers Guines, Guanamon, Mora, Nueva, and Belen, as far as Mayabeque Point. In this bay, as well as in the whole space of sea comprehended between the coast of Batavano and the keys in front of it, as far as the Cayamas Channel, the depth is from 3 to 4 fathoms, on clay.

To the N. W. and about a mile distant from the Point of Mayabeque, is the river of that name, in which, vessels trading to Batavano, can easily provide themselves with water. From this river the coast trends W.  $\frac{1}{4}$  S., to the anchorage of Batavano, which is eight and a half miles distant from it.

From this place the coast trends to the west thirteen miles, to Point Cayamas; but, in the intermediate space, lies the Point of Cagio, and the river of the same name, in which the Batavano vessels sometimes also procure water.

The River Cagio, formed by the branches of the Cienega, runs into the anchorage of that name, in which, at a moderate distance from the coast, from 2 $\frac{1}{2}$  to 3 fathoms water is found, sheltered from all winds by the chain of keys which lies in front of it. The light of the Cienega, comprehended between its mouth and the main land, is more extensive than that of Batavano or Mayabeque, and the lands around it are well cultivated.

Cayamas Point, and the chain of keys to the south of it, form the channel of the same name, which has 7 feet of water; this chain of keys extends with a bend to the S. E. by S. about eleven miles, when it forms the channel of La Hacha, which divides it from another chain of keys, which extends from this place as far as Cruz Key, lying 13 miles S. by E.  $\frac{1}{4}$  E. from Batavano. The Canal de la Hacha has 11 feet of water, and is much frequented by vessels trading to Batavano, when they either enter or sail out to the westward of the Isle of Pines and Cayos de San Felipe. (St. Philip's Keys.)

At a short distance to the westward of Cruz Key lies another, called Redondo, under which the vessels belonging to Batavano, secure themselves in the season when the fresh (or stormy) south-east winds blow; that is, in the months from July till October, (hurricane months,) which are much to be feared on all this coast.

To the southward of Cruz Key, at the distance of two leagues, lies Monte Rey Key; and between is a channel, with 2 $\frac{1}{2}$  fathoms, clay. This channel is the largest of those leading to Batavano, although care must be taken to keep clear of a spit, which runs out about 7 miles to the S. W. of the Key; and to the heads, which are to the south of those keys, forming the north side of the channel.

From Cayamas Point the coast of Cuba trends W. by N.  $\frac{3}{4}$  N., forming a regular bay, called Ensenada de Majana, and which terminates to the south, at Point Salinas, which lies  $10\frac{3}{4}$  miles to the W. S. W. from the former. In the intermediate space, and near Cayamas Point, is the mouth of the River Guanima, at which the Cienega ends.

S. W.  $\frac{1}{4}$  W.  $12\frac{3}{4}$  miles from Salinas Point, a little point stretches outward. At a short distance to the north of it is the Creek of Savanna la Mar, which is much frequented by trading vessels. From the same point the coast continues forming a bay with Mediacasa Point, which lies  $15\frac{3}{4}$  miles to the S. W. of the former.

Between this coast and the Bank, or Middle Ground, on which stand the keys to the northward of the Isle of Pines, the depth of water is from 3 to 4 fathoms, on a bottom of clay, except a spit with one and a half and two fathoms, which stretches out from the southernmost key about two leagues, to the S. W.  $\frac{1}{4}$  W. of the Guanima Keys. The extremity of the spit lies S.  $\frac{3}{4}$  E.,  $5\frac{1}{2}$  miles from Salinas Point.

The Guanima Keys are included in the group which, to the westward, form the Channel of La Hacha, and are situated to the southward of the River of Guanima and of Point Cayamas.

S.  $\frac{3}{4}$  E. 12 miles from Mediacasa Point, lies Dios Key, between which and that point is the passage for vessels trading from this quarter to Batavano. Dios Key is low, and of small extent; it is detached, and the bank on which it stands turns to the eastward, and unites with that which surrounds the keys to the north and east of the Isle of Pines. It also forms a channel with the Indian Keys, and those of St. Philip, with from 3 to 4 fathoms depth of water.

From Mediacasa Point the coast trends W. by S., true, for about two leagues, after which, following S. and S. W., it terminates at Fiska Point, forming the bay of Ayanguas: this point lies S. W.  $\frac{1}{4}$  S., distant  $10\frac{1}{2}$  miles from the former.

About S.  $\frac{3}{4}$  E.,  $10\frac{1}{2}$  miles from Fiska Point, lies the easternmost of the Keys of San Felipe, from which this chain of keys continues in a westerly direction as far as the meridian of Guama Point; between these keys and the Indian Keys, there is a passage, with two fathoms of water; and the depth in the space of sea comprehended between the coast and the north part of them is generally from 4 to 5 fathoms, on clay and weeds.

From Guama Point the coast follows to the west, for about  $2\frac{1}{2}$  leagues, to the Point and Creek of Guano, where the Bay of Cortez begins. From this place the coast runs W. by N., true, for about two leagues, to the bottom of the said bay; and the inconsiderable rivers of San Juan, Martinez, and Galafre, disembogue in it.

About W. S. W. true, at the distance of three leagues from the Point of Guano, disembogues the River Cuyajuatete, to the S. E. of which, at the distance of about a mile, begin three little keys, which, extending themselves in the turn more to the east, for about a league, form, with the main land of Cuba, the Lagoon of Cortez, which has about 3 fathoms of water; but the little passes formed by the keys have not more than 7 feet. Some huts have been established on them by persons who fish for Hawksbill Turtle, or the turtle which produces the tortoise-shell.

The southern extremity of this lagoon, which is on a parallel with the Keys of San Felipe, and about 5 leagues distant from them, is the termination of the Bay of Cortez, in which there are 3 and 4 fathoms water, on a grassy bottom. About two miles to the east of the south end of said lagoon, begins the deep water; the edge is very steep; it begins with 7 and 8 fathoms on a rocky bottom, and continues on so as to join the coast close to the northward of Point Piedras.

Point Piedras lies about S. by W. from the Lagoon of Cortez, 7 miles distant; the coast, which is low, but of firm land and rocky, with spaces of sandy beach at the shore, running nearly in the same direction.

From Point Piedras the coast, which has no bank, runs nearly S. W. by S. to the Point Llana, distant about 5 miles. This point is low, and has no other marks to distinguish it than the different directions of the coast, and some huts near it, and to the west of it there is a small sandy beach. To the S. E. a reef, which is very steep to, extends out about two cables' length.

From Llana Point the coast trends W. S. W.  $\frac{1}{4}$  W., and more southerly to Point or Cape Leones, and then again follows the first of these directions as far as Cape Corrientes. All this piece of coast is of high soboruco rock, and without danger at a stone's throw distance.

CAPE CORRIENTES ends in a low point, with a sandy beach; and to the S. W. of it a short bank stretches off, on the edge of which are 15 fathoms; and close to the shore there are some rocks on which the sea breaks.

From the Cape the coast trends, without any bank, N.  $3^{\circ}$  E., true, for about a league, to Cape Cayman or the Point of Maria Gorda, and from it to the bottom of the bay, N.  $40^{\circ}$  E. The place called Maria Gorda is remarkable, being of soboruco rock, scarped, and higher than any other part of the bay; from it the bank again begins to run off with

bad holding ground, the bottom being rocky; although farther to the north, and from the inflection which the coast makes, the bottom is sand; and very near the beach an anchor may be let go in 5 fathoms, with the precaution of having a cable on shore, as the edge of the bank is very steep. This is the only anchorage in this bay, and affords shelter for the strong trade-winds, and S. E. winds: none of the rest of the bay has any bank. The water met with in the lagoons of Maria Gorda, is brackish; but the fresh may be perceived rising in bubbles in the middle of the salt, and near the bottom of the bay, and about 6 yards distant from the water's edge. With industry, and in case of necessity, it may be obtained in a drinkable state.

From the bottom of Corrientes Bay the coast trends west, true, to the Balcones, which is a short piece of coast, of high sobornco rock. From this place it continues W. S. W. to Holandes or Olandes Point. This point, which bears nearly west,  $5\frac{1}{2}$  leagues, from Cape Corrientes, terminates to the westward of the bay of that name. Near and to the east of it begins a reef, which extends in that direction about half a mile, but offers no danger, as it lies very close along the coast, and is very steep to. Point Holandes has an agreeable appearance, having a resemblance to the curtains of a wall, and extending with this figure about two miles, beyond which it descends in a kind of falls or steps, and the shore continues woody after passing it.

From Point Holandes, or Olandes, the coast trends nearly west to the point of Cayuelos, which is the southernmost point of the front of Cape San Antonio, or Cape Antonio. The westernmost point of the cape is called Pocillos, or Little Wells Point: and from this the coast trends N.  $9^{\circ}$  E., true, three tenths of a mile, or thereabout, to Sorda or Deaf Point, whence the coast inclines more to the north-eastward.

To the eastward of, and near Cayuelos Point, extends the bank, which thence surrounds the cape half a mile from shore, and continues on to the northward, where it forms the Colorados Bank. Its depth begins with from 20 to 25 fathoms, on a rocky bottom, and diminishes regularly towards the coast, with some spots which have a sandy bottom.

The front of Cape Antonio is of low land, very rocky, and its shore appears with mixed streaks of sobornco rock and sandy beach. In its wells, called those of Cueva de la Sorda, (Deaf Woman's Cave,) and the Pocillos, (Little Wells,) water is abundant and of good quality.

Cape Antonio, (A,) bearing N. W.  $\frac{1}{4}$  N., true, distant 5 miles.

Cape Corrientes looks very much like Cape Antonio; and in order to ascertain it, observe it is rather level land, of moderate height; but being near it or off it, in clear weather, some hills in Cuba, named the Sierras del Rosario, which stand toward the north coast, may be seen, bearing nearly true north. They are the only hills that can be seen from a similar situation, and present two summits only to the view.

Cape Corrientes (A) bearing N.  $35^{\circ}$  E., true, distant 4 miles.

#### *The Isle of Pines, Jardines, and Jardinillos.*

The form of the bank and reef which surround the isles or keys called the Jardines, &c., can be best understood by reference to the chart. Towards the N. E. on this bank is Diego Perez Key, already noticed, and the edge of the bank thence extends to the S. E., forming a bight at the Megano or Sand Islet of Biscayno, whence it extends to the easternmost key of the Jardines. From the north end of the latter, a reef stretches out to the eastward, about a mile, and the bank extends in the same direction about 3 leagues, and nearly 2 north and south, with a depth of 15 fathoms at the edges, and 7 or 8 on the whole of it, excepting the proximity of the key, where 4 fathoms are found, on sand and rocks. This key, as well as all those which follow to the westward, under the name of Jardinillos, which extend as far as Key Largo, are regularly high, and scarped at the shores.

To the S. W. about 2 leagues from the easternmost key, follows the edge of the shoal water, with a westerly direction thence, west for four leagues. It is studded or streaked with reefs, as far as a key which lies a league to the west of Trabuco. For

about  $5\frac{1}{2}$  miles the same edge forms a bend, as it approximates the east end of Key Largo.

Largo Key, which extends W. S. W. and E. N. E.  $13\frac{1}{2}$  miles, is the easternmost of the Jardines, under which name are comprehended all those which follow it to the west, as far as the Isle of Pines. The south side of Key Largo is a sandy beach, bordered with a reef, which runs out about a mile from the east end, and afterwards approaches nearer, so as almost to join the west end of the key, whence the same reef continues, without any break, W. by S. and W. by N., true, to the Rosario Channel, which is 5 leagues distant from Key Largo. On the very reef, and near the west point of Largo Key, there are two rocky keys, named the Ballenates, distant a league from each other, and they are of moderate height. In all the space comprehended between the Eastern Head of the Jardinillos and the Rosario Channel, the bank which extends along to the south side of the keys, does not extend farther out than one or two miles. Its edge begins with 15 and 18 fathoms of water, on a rocky bottom, and the depth diminishes rapidly to the very reef itself.

Rosario Key, the west end of which bears north, true, from the channel to which it gives name, forms a channel of 3 and 4 fathoms of water, with another key to the westward of it, named Cantiles; but its outlet on to the interior bank, to the westward of the Passage Keys, has not more than 10 feet of water. The opening or channel through the reef, is a third of a mile in width, with a depth of 3 fathoms in the middle. It is steep at the sides, and at half a mile from its north part there is a rock, which shows above water. Vessels smuggling into Cuba generally enter and sail out by this passage.

From the Rosario Channel the reef trends S. W.  $\frac{1}{2}$  W. 10 miles; then W. N. W.  $\frac{3}{4}$  W. 19 miles, to join the east point of the Isle of Pines. In this space are included the keys named Abalo, the Aguardientes, Campos, Matias, and many others which have no names. The outer edge of the bank is parallel to the reef, and generally extends out about 2 miles, excepting opposite Abalo Key, where it runs out almost 3 miles, at about 7 miles to the south of the key. The least water on all this bank is 5 fathoms, on a rocky bottom, with some scattered spots of sand.

The ISLE OF PINES, when first seen, appears mountainous or hilly, of a moderate height, and the tops of its mountains very sharp. From its east point the south coast trends S. W.  $\frac{1}{4}$  S. for  $5\frac{1}{2}$  miles, with sandy beach, as far as a point, which may be easily known, being of high soboruco rock, and having a detached rock (farallon) very near it. From this point the coast continues, without any bank along it, for seven miles, to another little point, which, with the former point, are the boundaries of the piece of coast denominated Playa Larga (or Long Beach.)

From the western point of Playa Larga, the coast continues W. and W.  $5^{\circ}$  N., true, for 8 leagues, to Cocodrillo, (or Crocodile Point,) which is the S. W. point of the island; and from the latter to the cove of the same name is  $3\frac{1}{2}$  miles N. W. by W. In this cove fishing vessels sometimes take shelter. The coast continues N. W. for  $8\frac{1}{2}$  miles, to Point Pedernales. All the ground between this and the west of Playa Larga is low and rocky, with shores of soboruco rock, and may be coasted along at less than half a mile. From Pedernales Point the coast bends (forming a bay) N. W. by N.  $2\frac{1}{2}$  miles, to Key Frances, which is the westernmost point of the island. Near the point are found the anchorage and watering place of Puerto Frances. This little roadstead, the bank of which extends about half a mile, with a depth of 5 fathoms, on sand, (and the shore is also a sandy beach,) is much frequented by vessels coming for timber, and affords shelter from winds of the N. E. and S. E. quarters.

Sierras de la Canada.

La Daguilla.

Caballos.

Isle of Pines, when the Mount La Daguilla bore N.  $53^{\circ}$  W., true, 25 miles.

Key Frances is separated from the coast by a small channel, and forms the west point of the deep Bay of Sigüanea. From that point the coast trends to the S. E. for five leagues, all watery or swampy, and broken into keys; thence it turns to the N. E. up to the Lagoon of Sigüanea, which lies at the foot of the hills of the same name, and has from 4 to 6 fathoms of water, but its entrance has not more than 9 feet; from it branches off a strip of water, which, in nearly an E. and W. direction, divides the island into two parts. At the foot of the hills of Sigüanea there are two filters of excellent water, which, at a short distance from the beach, rises out of the land.

From the Lagoon of Sigüanea, the coast trends N. W. by W.  $\frac{3}{4}$  W. for 10 miles, to a

little point which forms, to the west, the mouth of the Rio de los Indios, (Indian River,) whence the coast continues N. W. 7  $\frac{1}{2}$  miles to Buena Vista Point, which is the northernmost point of the Bay of Sigüanea, and is 10  $\frac{3}{4}$  miles N. N. E. from Key Frances. Sigüanea Bay extends 17  $\frac{1}{2}$  miles N. W. and S. E., and has from 2  $\frac{1}{2}$  to 4  $\frac{1}{2}$  fathoms water, on a grassy bottom; but the passage between Key Frances and the southernmost of the Indian Keys, has not above 3  $\frac{1}{2}$  fathoms, on sandy and grassy bottom.

The Indian Keys, separated by small channels, extend themselves to the N. W. by W. from the southernmost of them, which is 8 miles distant from the northernmost. The southern extremity lies N.  $\frac{1}{2}$  W. from the point of Key Frances, 9  $\frac{1}{2}$  miles distant, and 4  $\frac{1}{4}$  miles, W.  $\frac{3}{4}$  S. from Buenavista Point; in the channel between them and the latter, there are from 4 to 5 fathoms water, on clayey and grassy bottom.

From the Point of Buenavista the coast inclines to the eastward as far as the Cove of Barcos, and the point of that name, which terminates it to the north, and lies 4 leagues N. E. by E. from the former. From the last point the coast trends N. N. E.  $\frac{1}{2}$  E. to a short distance, and afterwards E. N. E. true, to the northernmost part of the island, which lies 3  $\frac{3}{4}$  miles distant from Barcos Point. From the northernmost point the coast continues E.  $\frac{1}{2}$  N. 5  $\frac{1}{2}$  miles to a little point which lies to the N. E. of, and close to Nuevas River; thence it follows E. by S. true, about 5 miles, to the high hill, called Ojos del Agua. This hill or mountain is one of the highest in the island, scarped or precipitous on the north side; and close to are 3 fathoms water. Nearly in the middle, between this point and the former, is the mouth of the River of Casas, which rises at the foot of the hills of the same name, and which, together with Nuevas River, are the most frequented in the Isle of Pines by those carrying on traffic with Cuba.

In the same direction, from the mountain of Ojos de Agua, at the distance of 5 miles, is the hill of Vivigagua, also precipitous and of moderate height: from this hill the coast runs S. E. by E. 4  $\frac{1}{2}$  miles, to Salinas Point, and thence continues S. E. by E. 7  $\frac{3}{4}$  miles to another point, to the north of the River Guayabo, and between the two disembogues the River of Santa Fe, which has excellent water. From the first a spit runs out, which, separating about 2 miles from the coast, joins it again at the river.

From the last point the coast winds to the southward as far as the eastern mouth of the Cienega. This part is named San Juan; and in the space is comprehended Mulatas Point and the River Guayabo, which disembogues close to the north of it. From the eastern mouth of the Cienega, (which divides the island in two,) the coast trends S. E. to Piedra Point, which lies N. by W. true, from the east point of the Isle of Pines, distant two miles.

From the Bay of Sigüanea to Nuevas River, the shore is all watery and covered with mangroves; and from this river to that of Santa Fe, it is firm land, continuing generally so, though with some watery places, as far as the east head of the island.

From the Bay of Sigüanea, as far as the River Guayabo, the coast may be run along, at two miles distance, in 3 and 3  $\frac{1}{2}$  fathoms water, on a clayey and grassy bottom; but a passage farther to the eastward is prevented by the shallow bank which surrounds the Jardine Keys, and is here connected with the Isle of Pines.

**INDIAN KEYS, &c.**—From Key Frances the edge of the deep water follows nearly N. W. 11  $\frac{1}{2}$  miles, as far as the parallel of the southernmost Indian Keys, and at 7 miles to the west of it; and continuing from thence to the northward and N. W., so as to approximate the most northerly of the Indian Keys, it then extends so as to pass about a league to the southward of the easternmost of the keys of St. Felipe, running parallel to those keys, as far as the middle of the chain; whence it nears them to within a mile, and continues along them at that distance, as far as the westernmost key, on the parallel of which it runs off to join the main land of Cuba, near Point Piedras. Generally, from Frances Key to the parallel of the southernmost Indian Key, from 13 to 25 fathoms are found at the edge of the bank; from the last named key to the meridian of the easternmost of the St. Felipe Keys, from 30 to 50 fathoms; to the southward of these keys, as far as the westernmost, 9 to 10 fathoms; and between it and the main land of Cuba, about 26 fathoms, except in the proximity of the latter, where it shoals to 7 or 8 fathoms. The bottom of the whole is rocky; and very soon after entering on the bank, the depth diminishes to 5, 4, and 3 fathoms, on sand. All these keys have sandy beaches towards the south.

This Great Bank, which we have now described from east to west, is studded with keys, which, with the coast, and among themselves, form the outer channels of Diego Perez, of the Rosario, of Sigüanea, and of Cortez; which afford a passage to Batavano, by the inner narrows of Don Christoval, Las Gordas, Monte Rey, and of La Hacha, all with a depth of 11 feet, except Monte Rey or Redondo Key Passage, which has 2  $\frac{1}{2}$  fathoms, on clay.

*Remarks on Cape Antonio, the S. W. of Cuba, and the Isle of Pines, by Captain Livingston.*

At about two cables' length to the northward of the pitch of the Cape, you may, when the weather is moderate, land with your boats, picking out, by the eye, the best place among the rocks. At about 50 yards within the first trees or bushes, you will perceive a space of about two acres in extent, clear of wood. On the opposite side of that opening, where the wood again commences, and at about 10 or 15 yards into the wood, you will meet with very sharp coral rocks, among which are two wells, in cavities of the rocks, of about 7 feet deep. The water of the northernmost well is excellent, that of the southernmost not so good but yet very palatable. There is a good rolling way from them to the beach, but boating large casks off is attended with difficulty, from sharp rocks which lie under water. We filled five or six puncheons at these wells on the 12th of August, 1817, and were not delayed altogether more than three hours.

There are plenty of excellent gray land crabs at Cape Antonio, which are quite safe to eat, there being no manchineal trees hereabout: also plenty of pigeons, and other birds, some of which are likewise excellent.

There is a fisherman's hut and a turtle crawl on the southernmost part of the cape, at which you may, in the fishing season, generally find a person to point out the wells; but what I have said will enable any person, who looks carefully, to find them, though a person may be within 8 or 10 yards of them and not perceive them, without a good look out. Men sent for water should always have their shoes on, to protect their feet from the sharp rocks. There is abundance of sponge to be found at the cape, although it is by no means, of first rate quality. The fisherman's hut is one of the best marks for Cape Antonio, when coming from the eastward. Off the cape about two miles out, the current often sets very strong to the S. E. When the current sets thus, it is advisable for handy working vessels to keep pretty close in shore, by doing which, they will avoid the strength of the current: this, however, is to be understood as applying only to vessels coming from the eastward.

Cape Corrientes and Point Piedras, were formerly exhibited on the charts considerably to the southward of their real positions; but having lost my memorandums of their positions by my own observations, I can only say that I think Point Piedras is placed nearly eight minutes south of the truth, and Cape Corrientes between 5 and 6 minutes. The coast between partakes of the same error, but Cape Antonio is very correct.\*

**ISLE OF PINES.**—The most dangerous error in the charts and tables, of the positions of places on the south side of Cuba, is that of the latitude of the Isle of Pines, which is uniformly stated as lying in  $21^{\circ} 22' N.$ , whereas the S. E. point lies, by a very excellent observation, taken on the 9th of August, 1817, in  $21^{\circ} 31' 37'' N.$  my observation and my mate's also, agreeing exactly in making our own latitude  $21^{\circ} 29' 37''$ , and both of us agreeing in opinion that the land was fully two minutes due north from us.

This error of latitude, and the prevalent, though most erroneous, idea that the current sets always from the eastward towards the Channel of Yucatan, has, I have reason to believe, deceived many; as, after sighting the Caymans and shaping their course for Cape Antonio, (more generally for Cape Corrientes,) the easterly current, which often runs very strong, causes them to make the Isle of Pines; and, finding the latitude quite different from that assigned to it, are completely at a loss to know what land they have made, or fall into the more fatal error of supposing it Cape Antonio; and, hauling round the S. W. point of the Isle of Pines, get embayed among the Cayos de los Indios; and, perhaps, are finally lost in the bay, as was the case with a very fine ship a few years since.

\* Captain James Wallace Monteath has made some observations on the Capes Antonio and Corrientes, which corroborate those of Captain Livingston. Captain Monteath says, "In April, 1820, I measured the distance between the two capes by chronometer. The distance gained was only 28 minutes of longitude. The latitude of Cape Corrientes given in the tables,  $21^{\circ} 41' 30'' N.$ , is incorrect, as I observed in  $21^{\circ} 43' N.$  when upwards of three miles south of the cape: it should be, at least,  $21^{\circ} 46' 30''$ . On the 12th of December, 1820, by nine observations, lunar and chronometric, the longitude of Cape Corrientes, as computed by Captain Monteath, appeared to be  $84^{\circ} 29' 20''$ ; it had previously been placed in  $84^{\circ} 23' 30''$ , being  $5' 50''$  more to the east. By similar observations made on the next day, the mean longitude of Cape Antonio was  $84^{\circ} 59' 8''$ . We had previously given it as  $84^{\circ} 54' 30''$ , from the Spanish observers. Here, it will be observed, the difference is only  $1' 38''$ ; and if from  $84^{\circ} 57' 3''$  we subtract  $28'$ , as above, the longitude of Cape Corrientes, will be  $84^{\circ} 19' 30''$ , which admirably verifies the preceding result of Captain Monteath, 12th December, 1820.

These remarks are more particularly to be regarded, because they show the inaccuracy of a Spanish chart of the south side of Cuba, published at Madrid, in 1821, which might otherwise be considered as the standard authority for this coast.

I have twice made the Isle of Pines when I considered myself to the westward of it; once when I expected to have made Cape Corrientes, and again, when, had it not been for a lunar observation, I should, from the courses steered, have thought us abreast of Cape Antonio. On the latter occasion my mate and myself calculated the probable effect of the current, from the courses steered, distance run by log, latitudes observed, and time elapsed, after we passed the Grand Cayman, taking also the landfall made into account. My mate, an intelligent young man, made the current set S. 67° E. at the rate of 63 knots per day. The result of my own calculation, perhaps not so carefully worked as his, gave E. S. E. and two and a half knots per hour, which nearly corresponds with Mr. O'Harra's.

I had, some time since, the misfortune to be upset in a small schooner, belonging to Kingston, Jamaica, about two leagues from the south coast of the Isle of Pines; two ladies, (passengers,) and one man were drowned; and the remainder of us, with difficulty, made the land, (owing to the current's carrying us off shore and to the eastward,) after about 13 hours of unceasing exertion. As many vessels have been cast away on this island within the last four years, and many more probably may be, while the charts continue so inaccurate, I subjoin the following remarks, the results of my own painful experience.

The Isle of Pines is very thinly inhabited, but I found it very difficult to obtain any exact account of the actual population. Most of the inhabitants reside in the north part of the island; indeed, so far as I could learn, there are only three houses on the south side, in an extent of twenty-one leagues. One of these is situated near Calabash Bay, at the east end of the island, and the other two nearly 2 leagues from Puerto Frances, or Siguanea Bay. There is also a fisherman's hut on Key Frances, sometimes called Bush Key; but it is inhabited only about five months in the year, viz. from March to August, being the season for catching the hawk's-bill turtle, from which the tortoise shell is got.

The houses are very hard to find, being all concealed among the trees, at a considerable distance from the shore; and it is perfectly in vain for a stranger to attempt finding them, as the paths which lead to them are no better than cattle tracks; and there are so many of the latter, intersecting the woods in every direction, that, unless a person is acquainted with the place, he must run much risk of losing himself in the woods, and of being starved to death; but he may possibly fall in with some of the inhabitants or their dogs: the latter are very sagacious, and I have known one of them to save two men's lives, by conducting them to his master's house.

Water is to be found in some places, but in very few quite fresh. There is none quite close to the west end, except at Puerto Frances, where about 15 yards to the westward of the most westerly cliffs in the island, a small path leads into the woods, by following which a well of excellent water may be found, at about half a mile's distance from the beach;\* it is in a hollow place, about 8 or 10 feet below the surrounding ground, and, unless when the sun is almost vertical, is little affected by its beams; and is, consequently, in general extremely cool and refreshing. Casks cannot be rolled from the well, but all the water must be carried by men in small casks, buckets, or demi-johns. There is not sufficient water to supply a vessel of any size; but it may afford seasonable relief in case of necessity, and I dare say supply two puncheons in 6 or 8 hours.

There is a kind of small beans, which grow upon a species of vine along the ground, and are inclosed in a rough pod; they are sweet to the taste, but extremely poisonous, and are therefore to be avoided.† To persons who may unfortunately be in the same predicament as I was, that is, destitute of food or the means of procuring it, it may be interesting to know that the thatch-tree, a species of palmetto, grows on the south coast of the Isle of Pines, in the most arid places, and is sometimes, as far as I can judge, 60 feet high. This tree when young, affords a wholesome and not unpalatable food. Cut or break over a thatch tree, of 7 or 8 feet in height, and tearing down the leaves in the neck, or more properly speaking, at the junction of the leaves to the trunk, you will find a part of the inside, about as thick as a man's wrist, very white, and of considerable length, and which tastes like something between a Swedish turnip and the common cabbage. I did not know this when I remained five days without any thing to eat, excepting some raw shell fish; and for four days out of the five, we were constantly passing thatch bushes.

During the nine days I remained on the south side of the Isle of Pines, the current constantly set strongly to the eastward. The whole coast from the east end of the island

\* A fallen tree lies across the path half way to the well, and may probably remain there for many years.

† These beans grow on open spots near the shore.

to the S. W. point, is bold, close to; but off the S. W. point, and between that and Puerto Frances, dangerous reefs extend out to sea, to a considerable distance.

I regretted much that the loss of my instruments did not permit me to renew my observations for latitude on shore: but the day before the vessel upset I had a good observation, corroborative of that of the 9th August, 1817. I am, therefore, certain that the latitude is incorrect in all charts I have seen.

The Rio de Sante Fe is on the north side of the island; on the south side there are no rivers, unless it may be possible some small ones may empty themselves into some of the *esteros*, or salt lagoons. We waded across all those that we met with, excepting one, near their junction with the sea. There are one or two other rivers on the north side, but that of Sante Fe is the only one that has two fathoms of water at its entrance; though some have much more than that depth inside, but with bars at their entrances.

There is some mahogany and plenty of lignum-vitæ in the island; also, I believe, very fine lancewood.

In Puerto Frances, or Signanea Bay, I am of opinion that, with good ground-tackle, a vessel may ride out almost any gale: so far, however, as I could judge from its appearance from the shore; and shelter may be found under the lee of the reefs. A Spanish fisherman informed me that it was a much better place than it was generally thought to be, and had clean ground, bottom of fine white sand all over, within the reefs, with from 3 to 3½ and 4 fathoms.

On approaching the Isle of Pines from the southward, the first objects you will discover are three very remarkable peaked hills or mountains, on what are called the Sieras de St. Pedro. The land appears extremely arid and barren. The greater part of it on the south side is covered with wood, among which, however, many cattle and pigs find pasturage.

Between the Isle of Pines and Bataviano, there is a great number of keys with shoal water between them. Among the roots of the mangrove-trees on them, are many and excellent cray-fish.

The Spanish master of a schooner told me that he had entered among the Jardines, and went quite through, carrying not less than 7 fathoms; and I am disposed to believe him; only I consider its entrance must be much narrower than what we found the deep water between the Bataviano and the Isle of Pine's Keys; as, from the deck of a schooner of about forty tons, we could not, when in mid-channel, see both at the same time.

In the neighborhood of it are immense quantities of the Palmetto Real, or cabbage tree.

JARDINES.—In all the Jardines excellent fresh water may be found, by digging a few inches deep in the sand, at a very short distance from the sea, according to my information, "not more than half a yard:" while in the Cayos de San Felipe, to the westward of the Isle of Pines, no fresh water can be procured. On the Jardines are also plenty of thatch-trees. Some of the Spanish fisherman have remained six or seven days at a time on one of the Jardines, living upon the heart of the thatch-tree, and upon the water got by digging, as before described.

*The North West Coast of Cuba, from Cape Antonio to Point Ycacos and Matanzas.*

Having already given the description of Cape Antonio, &c. from the Derrotero and the notes of Captain Livingston, we shall here only notice that the cape has since been described as a low sandy point, with a flag-staff upon it, and several huts. From Cape Antonio the coast sweeps to the N. E. and thence to the E. and E. N. E. in a broken and variegated form, which can be best understood by reference to the chart. Without this coast, to the W., W. N. W. and N. is the extensive bank and reef called those of the Colorados, after described, which are naturally divided, and ought, therefore, to be distinguished by different names, that is to say, the Antonio Bank and Colorados.

Following the Colorados, to the East, are the Banks and Reefs of Isabella, which terminate at the entrance of the harbor called Bahía Honda, in longitude 83° 7'. A too near approach here is very dangerous, as the reefs are generally very steep, and the current from the gulf sets along them mostly from the N. W. to W. and S. W. whence, it sweeps along the edge of the bank, near the shore, around Cape Antonio, and thence eastward towards Cape Corrientes, &c.

The Derrotero says that, "between the bank (that of San Antonio) and the reefs and keys of the Colorados, there is an interior passage, for vessels of 11 or 12 feet draught, but much experience is required for taking it and all vessels are recommended to pass outside, keeping well away from the edge of the reef, which is very steep to; and near it a vessel may be entangled by eddies proceeding from the general current of the strait."\*

\* Mr. Finlaison says, when you are abreast of Cape Antonio, you will perceive the discolored water on the bank, and should take care not to approach too near, particularly in light winds, the edge being steep to, with generally a current setting over it.

ceive the discolored  
y in light winds, the

Mr. Gaüld says it is high water at Cape Antonio, on full and change days, about 9h. 33m., and that the vertical rise is 18 inches. The flood sets to the southward,\* and the ebb northward. The velocity is about three quarters of a mile in an hour.

From Cape Antonio, the bank, which appears of a whitish color, with only 10 or 12 feet water on it, trends north by compass, about 8 miles, whence the edge turns gradually round to N. E. by N. and north-eastward to lat. 22° 8', with very uneven soundings, from 6 to 3 fathoms, rocks and sand. To the eastward and southward, the soundings decrease from 6 fathoms, very gradually to the shore, all fine sandy ground. The late Mr. Owen, of Jamaica, said the edge of the bank is clean all along, and steep to, and that he had run along it, at a very short distance, in a line of battle ship, guided by the eye, and himself keeping at the mast-head.

In proceeding from Cape Antonio to the northward, it is requisite to be aware of a shoal, seen in 1797, and which is represented at 14 miles N. N. W.  $\frac{1}{2}$  W. from the cape.† In the day time you may safely take the passage between this shoal and the edge of the bank; but in the night, or in thick weather, it is better to make sure of passing outside of it. It is also proper not to forget the bank of Sancho Pardo, which lies about 6 leagues to the W. by N. from Cape Antonio, a near approach to which is unnecessary.

If, when at Cape Antonio, the wind comes to the north, it will be best to maintain yourself to leeward of the cape, either on short boards, or by coming to anchor; because, with such a wind, in place of advancing on your passage, you would probably be caught in a gale or storm.

The Colorados Reefs and Keys are very extensive. The S. W. extremity lies in about 22° 19' N. and 84° 45' W. The whole are, in general, steep to. Of the principal rocks or keys, the westernmost or Black Key shows itself above water like the hull of a ship, and may be seen 4 miles off; the other two, Colorados or Red Keys, are not seen unless the weather be quite calm; they have not above two feet of water on them; and to the westward no ground is to be found at a short distance, or less than a mile. The channel between is half a mile wide. Between the Black and Red Keys is a depth of 4 fathoms, but very foul ground. Capt. Street, in his account of these rocks, gives the following detail: "We took our departure from 4 or 5 leagues, abreast of Cape Antonio, and made our way good N. E. by N. 15 leagues, and then fell upon the Colorados in 3 feet water. They were about me dry in several places, without any distinction of swells and breakers; we saw flocks of pelicans sitting upon the reddish white sand. In this place we could see no dry land from the top-mast head, though very clear weather, but we saw to the east of us three hummocks on Cuba; the innermost, or biggest, bearing E. by N. so near us, that we could see other hummocks within and without these three, and low land; trending away from the innermost hummocks to the southward, and likewise the hummocks almost join with the low land between them. All this we could see on deck, or but two or three rattlings up; but the three aforesaid hummocks we raised upon deck, when we were about 8 or 10 leagues off our aforesaid station of 5 leagues to the westward of Cape Antonio."

The high lands of Cuba are in many places particularly marked. The principal lands, thus remarkable, in regular succession from West to East, have been enumerated as follow: the High Lands of Buenavista, the Coxcomb,‡ the Saddle Hill, Dolphin Hill, Tables of Mariel, Maiden's Paps, to the southward of the Havana, Iron Hills to the eastward of the Havana, and the Pan, or Loaf, or Hill of Matanzas, to the S. W. of the Port of that name. The appearances of all these may be seen on the new chart of the Gulf and Windward Passages, as well as on the old chart by Mr. Romans. Those noticed in the Derrotero, are the Hills of Rosario,§ the Gap of Yoldal—we presume the notch in the Coxcomb; the Pan of Cavanias, or Dolphin Hill; the Tables of Mariel; the Tetras de Managua, or Maiden's Paps; the Sierra de Jaruco, or western part of the Iron Hills, and the Pan of Matanzas. These, it is added, are all points from which a ship's situation may be ascertained in clear weather; but it frequently happens, in hazy weather, that they cannot be seen from sea at 5 leagues off.

\* The flood therefore bends with a southerly current; and thus it appears to continue eastward, within the Isle of Pines, &c.

† The British ships *Clara* and *St. Vincent* sounded on this shoal, and found 5 fathoms, sandy bottom; they were two hours in passing over it, but do not mention the rate of going. Cape Antonio bearing S. S. E. 15 miles distant.

It seems that Mr. Bishop was once near this bank. He says that, having worked from Cape Antonio, to the N. N. W. about 5 leagues, he had soundings in 15 fathoms. He then went up to the mast-head, being the main-top-gallant mast of the *Sphinx*, a 29 gun-ship, and from thence saw the tops of three small hills to the eastward, with Cape Antonio bearing S. S. E. distant 5 leagues.

‡ Mr. Finlaison says, "With the Coxcomb Mountain bearing S.  $\frac{1}{2}$  E. you will be in lon. 84° W." § Probably the high lands of Buenavista; for the charts of this part are yet inaccurate and contradictory.

**BAHIA HONDA, &c.**—The harbor called Bahia Honda, or Deep Bay, is situated at the eastern end of that range of islands and reefs distinguished by the name of Isabella. Its entrance, according to the Spanish officers, is in latitude  $22^{\circ} 59'$ , long.  $83^{\circ} 71'$ . When you are before that entrance, it bears nearly south, but you cannot get in till the sea-breeze comes on, at about ten in the morning.

Bahia Honda is a spacious and well sheltered harbor, but the points which form its entrance, as well as the interior points, are bordered with a reef and edge of shallow water. The outer point, on the east or windward side, is named El Morillo, (Little Morro,) from its presenting a rising ground. From this a shoal extends two thirds of a mile to the N. W. having, however, at its extremity, a depth of 5 fathoms. The outer point on the west, is Punta Pescadores, (Fisherman's Point,) from which a reef extends to the N. N. E. about one third of a mile. The distance between the two points, which are nearly east and west, true, from each other, is about two thirds of a mile; but the channel formed by the edges of the shoals is only a cable and a half in width.\*

At a third of a mile with in the exterior points are two others, Punta del Cayman on the west, and Punta del Real on the east; and between these the breadth of the channel does not exceed two cables' length. From Point Real the edge of the bank extends at the distance of two thirds of a cable; but from Point Cayman not more than half a cable's length. At half a mile further in, the harbor opens, and you arrive off Punta del Carenero, which is on the eastern side. At a third of a mile to the southward of Point Carenero is an island, Key Largo, or Long Key,† the west point of which (Punta di Difuntos) lies a little more to the west than Point Carenero, and it may therefore be seen from the sea.

*To enter this port,* it is requisite to keep at some distance from the coast, and outside the edges of the reefs, till you are N.  $\frac{3}{4}$  W. from the mouth, when you may run for it. When near it, or at about the distance of a mile, you may perceive Point Difuntos; and placing your vessel most carefully to S.  $\frac{3}{4}$  E. you may steer in that direction; as with that course, keeping Point Difuntos open, in the mid-channel, you will run in with sufficient water, 12 to 6 fathoms. When abreast of Point Carenero, you will see to the W. S. W. a long point on the west side of the harbor, named Punta de Mangles, or Mangrove Point.‡ With this in sight you may now steer to the S. W., and when you have arrived on a line between it and Point Difuntos, you may anchor in 7 fathoms, upon clay; or, if more convenient, you may hull up to the south-eastward of Point Difuntos, and drop your anchor in 6 fathoms, same ground. There is also anchorage to the northward of Key Largo, between it and Punta del Carenero, in 6 or 7 fathoms, which may be found, after sailing in by the lead, along the reef on the eastern side.

The **BAHIA BANK** lies rather more than 5 leagues to the N. W. by N. from the mouth of Bahia Honda. It extends nearly east and west a league in length, and is about half a league broad. On this bank you may come to an anchor, taking care that you do not go too near the rock that lies in the middle of it. There is no water on the rock, and when the breeze blows strong the sea breaks over it; but on the bank are 6, 5, and 4 fathoms of water.

**PUERTO DE CABANAS, OR PORTO DE CAVANAS.**—This harbor lies rather more than four leagues to the eastward of Bahia Honda. It has an extensive reef on each side of its entrance; yet it is a fine bay to sail into, having 5 and 6 fathoms at the entrance, deepening to 8 and 10 within, with room enough for several hundred sail of ships. The Derrotero says, you may run along the coast between Bahia Honda and this place, at the distance of two miles. Port Cavanias is a good anchorage, sheltered from all winds, and fit for any class of vessels. It may be known by a round hill, which forms a gap or break, and upon the summit of which there is a grove of trees, and by another hill, named the Pan of Cavanias (Dolphin Hill.) The latter descends gradually towards the east, until it ends in low level land, which continues for a long league, until it meets the table land of Mariel. In addition to these marks, you may see upon the coast two rows of hillocks, which resemble shepherds' huts, and from which the place has derived its name. These hillocks lie to the eastward of Bahia Honda, and the Pan of Cavanias appears as if in the middle of them.

*To enter this harbor,* you ought to open the mouth well out, until you are on its meridian, and that of the east part of an island (Isla Larga) which is within the harbor on its west. Steer in S.  $\frac{3}{4}$  E. until past the reef of Punta Longa, on the east side, when you

\* In a late description of Bahia Honda, by a British officer, it is said that it may be known by a remarkable tower and a small hut on the eastern side of the entrance, and a large plantation on a round hill just on the back of it, and two small huts about  $\frac{1}{2}$  mile to the westward of the west point of the entrance.

may luff up, and anchor in from 7 to 9 fathoms. Be cautious, in advancing, not to touch on the reefs on either side; that to windward extends out more than half a mile, and that to leeward about two cables' length. At the extremity of Punta Longa the reef extends out only two-thirds of a cable; but the channel here is only two cables in breadth. Another reef extends to the same distance, northward, from the eastern point of Larga Island.

PUERTO DEL MARIEL, OR PORT MARIEL, which is  $4\frac{1}{2}$  leagues to the eastward of Port Cavanas, is large, well sheltered, and fit for any class of vessels. You may know when you are to the north of it by the Tables of Mariel, which are moderately high, and form very broad table lands or hills. On approaching these you will perceive various white patches. The coast hence trends to the eastward, towards the Havana, and is very low. In proceeding towards the latter, you may descry the Paps of Managua, commonly called the Maiden's Paps, which are two round hillocks, lying on the meridian of the port. To the westward of Mariel the coast is likewise low, for a long league, until it rises and forms the hill of Cavanas. Farther to the west may be distinguished other high lands in the vicinity of Bahia Honda, and which seem to rise from, or to be surrounded by, the water.

To enter Port Mariel, you have only to steer towards the western extremity of the Tables; and having recognized it, may run in, along the windward shore, at the distance of a cable's length. This will lead clear of the reef, which borders the coast, and on which the sea breaks. Having the mouth of the harbor well open, place your vessel's head towards a small rocky key, which lies off the leeward point; and so soon as you are within two thirds of a cable from it, steer S. <sup>a</sup> E., or what amounts to the same, steer in that direction, when the leeward point of the interior part of the entrance has the same bearing. Continue this course until you pass the round tower, which you will see on the windward side. You may then luff to port, (larboard,) so as to maintain yourself at a cable's length from the eastern shore, and you may anchor upon it, where you please, in 8 or 10 fathoms water. If more agreeable, you may run into the interior of the harbor, for which a reference to the plan of the harbor will be a sufficient guide. We only add, that, as the narrowest part of the entrance is only 50 yards wide, it is requisite to be very cautious on entering with a large vessel.

It sometimes happens that strangers mistake the land to the westward, and about Bahia Honda, for the table land of Mariel; but it is to be observed that the latter is not so high, and is more regular than any land near, or to the westward of Bahia Honda.

## HAYTI OR SAINT DOMINGO.

This island, once more called Hayti, its original name, was discovered by Colombo, (Colon or Columbus,) in 1492. By Colombo it was called Hispaniola; but giving the name of St. Domingo to a city which he founded in 1494, the whole island, in process of time, came to be so called. At length the island was divided into two parts, under the respective governments of Spain and France, when the name of Hispaniola was limited to the eastern or Spanish portion; and finally, the whole is now independent, under the title of the Republic of Hayti.\*

To the natives the climate, though hot, is healthy; yet it is exceedingly pernicious to Europeans, and the shore of Hayti has been the grave of thousands, who have been the victims of its heat and moisture. Many of the inhabitants are, nevertheless, said to live to a great age. The thermometer in the plains rises as high as 99°, but the country is continually refreshed by breezes and rains, and its salubrity is increased by the beautiful variety of its surface, exhibiting hills and valleys, woods and rivulets. Its highest elevations are about 6000 feet above the level of the sea, and its hills are covered with forests of mahogany, Brazil-wood, palms, elms, oak, pine, walnut, gayac, maple, iron-wood, cedar, ebony, &c. The island is said to have its mines of gold, silver, copper, quick-silver, iron, lead, precious stones, and chrystal.

The rivers are numerous, but none are navigable, even by boats, in the dry season: in the rains, they often rise 25 feet perpendicular, and sometimes spread destruction over the plains.

The principal towns are, the city of Cape Haytien, formerly Cape François, in the N. W., the city of St. Domingo, in the S. E., Port au Prince, Leogane, and the Mole of St. Nicholas, in the west.

\* The whole was united under one government, General Boyer, President, in 1822.

We commence the description of the shores of Hayti with the Mona Passage and eastern coast, and thence proceed in succession with the southern, northern, and western coasts, as this seems to be for the mariner the most convenient mode of arrangement.

*The Mona Passage and Eastern Coast of Hayti, from Cape Raphael to the Island Saona.*

The channel called the Mona Passage, between Porto Rico and Hayti, is 26 leagues in breadth, and generally clear and safe, with the exception of shoals in the vicinity of the coasts of the two islands. On the N. E. side, the land of Porto Rico is low, to the westward of the harbor of Arrecibo, until it reaches Punta de Pena Agujereada, (or Point of the Holed Rock,) where a kind of cliffy high land begins, which trends S. W. rather more than a mile, to Point Bruguén, the north-westernmost point of Porto Rico. The coast again declines in height, and forms a convex bow to Punta de Penas Blancas, (Whitestone Point,) the north point of Aguadilla Bay.

**DESECHO OR ZACHEO.**—This little island, nearly covered with trees, stands like a beacon in the ocean, at the distance of  $11\frac{1}{2}$  miles W.  $\frac{1}{4}$  N. from Point St. Francisco, or Porto Rico. It appears like a green mountain, 800 or 1000 yards broad at the base, and is so high as to be seen at 12 leagues off. The coast is generally clean, and there is no danger but what may be seen.

**MONA PASSAGE.**—We found the winds generally light in this passage, and but little current. The island of Zacheo, bearing W. by N.  $\frac{1}{2}$  N. 11 miles from Aguadilla Bay, may be seen on a clear day from any part of it. It is high, and very bold. We frequently approached it very close, without observing any danger, or getting soundings near it. Off the north and south ends there are a few rocks, but close to the shore it is covered with small brushwood, and the landing place is on the south side.

**MONA AND MONITO.**—These isles lie nearly in the middle of the Mona Passage, towards the south.

**MONA ISLAND.**—This island is nearly level, and of a moderate height. We could not see it farther than 18 miles on a clear day. Its north-east, south-east, and south-west sides, are bounded by a reef a quarter of a mile off shore. At the distance of two miles, we ran along these sides, but saw no other danger than a reef which extends one mile and a half off the south point.

The S. W. point (to the northward of which is the anchorage) is sand, long and low, with brushwood and small trees on it. There is a reef off this point, about a quarter of a mile in length, to the westward.

We anchored here in his Majesty's ship *Arachne*, with the sandy point bearing S. by W. one mile and a half; island of Monito, N.  $\frac{1}{4}$  E.; N. W. Point of Mona, (high and bluff,) N. E.  $\frac{1}{4}$  N.

We came to our anchorage from the northward, passing Monito to the westward within 6 miles, but had no soundings; neither could we see broken water, or any danger between it and Mona. This island is the resort of innumerable quantities of boobies; its sides are very white, and are inaccessible. Our anchorage was off the sandy bay formed by the S. W. point, (bearings as above mentioned,) sandy bottom; this, the N. W. side, is also bounded by a reef, about three cables' length from shore; the passage through it is nearly in the centre of the bay, but it is narrow, and a boat must pick her way through. The soundings are very regular; we found 4 fathoms close to the reef; and there would be no danger in anchoring within a quarter of a mile of it, bearing in mind it is open to all westerly, and from south to south-east winds.

We landed on the sandy beach, and found the west end of the island, which is low, covered with small trees, brushwood, and, at a few cleared spots, with grass; in the latter of which were small pools of fresh water, apparently dug, but of a bad quality; around these we found the print of the hoofs of cattle and horses, or mules, very recently made, as was evident by the sun not having hardened the soil. These pools of fresh water were on the south-east side of the sandy point, about one mile and a half from the landing. We did not find any signs of habitation or inhabitants; and, excepting the before mentioned fresh-water pools, we saw no possibility of obtaining water. A small quantity of fire wood might be obtained, but with labor. The remarks on this island in the Columbian Navigator are imperfect; they give the anchorage in the following bearings: Monica Island, N. by W.; S. W. point of Mona, S. E.; but it is not possible to bring these bearings on.

Near the west point, however, some vessels anchor, in order to procure grass, when engaged in carrying cattle. The island may be seen at the distance of 6 leagues.

Monito is an islet, the greatest extent of which scarcely reaches to two thirds of a cable's length: it is much lower than Mona, and in shape resembles a shoemaker's last; on its surface no bush is seen, and it is the perpetual resort of immense numbers of booby birds. The pilots of these coasts state that there is a clean and deep passage between it and Mona.

**EASTERN COAST OF HAYTI OR OF ST. DOMINGO.**—The eastern shore is generally low, but the land may be descried at the distance of 10 leagues. Cape Enganno, the easternmost point, lies in lat.  $18^{\circ} 34\frac{1}{2}'$ , and long.  $68^{\circ} 20\frac{1}{2}'$ . From this point the land of Porto Rico may, in clear weather, be seen.

From Cupe Enganno to Cape Raphael, the bearing and distance are N. W. by W. 14 leagues; at about 3 leagues to the south-eastward of the latter the land rises, and so continues to the cape.

Cape Raphael is of moderate height, and appears at a distance like an island. It is distinguished by a conical peak island, which resembles a sugar loaf, and is commonly called the Round Hill. The shore eastward is not only low but foul, and ought not to be approached nearer than a league. At rather more than half way from Cape Raphael towards Cape Enganno, is Point Macao, on the S. W. of which is a little town of the same name.

Cape Enganno is low by the sea, and a shoal extends from it nearly 3 miles to the N. E. This shoal, having little water on it, must have a good berth. Cape Enganno, bearing W. by S. 6 leagues, makes with two heads like a wedge.

From Cape Enganno the coast trends to the S. W. and south to Point Espada, which is low and bordered by a white shoal and reef. From this point to the S. W. the coast forms a bay called Higüey, and a smaller one, Calamité; both are very foul, with reefs. To the southward of the latter is the island Soan, having a channel of considerable breadth between it and the land of Hayti; but it is so obstructed as to be impassable to any but small craft.

*To the Southern Coast of Hayti, from Soan to Cape Tiburon.*

**THE ISLE OF SOAN**, which lies off the S. E. coast of Hayti, is about 13 miles in length from east to west. It is covered with trees, and is surrounded by a white shoal to the distance of nearly two miles. The position of the eastern point of this isle, according to the Spanish observers, is lat.  $18^{\circ} 12'$ , and long.  $68^{\circ} 31\frac{1}{2}'$ . At the western end are several islets on the bank.

From the S. W. extremity of Soan to Point Cauceado, on the eastern side of the bay of St. Domingo, the bearing and distance are W.  $\frac{1}{2}$  N.  $16\frac{1}{2}$  leagues. The coast between is in general tolerably clean; for there is only one place, the Playa de Andres, (Andrew's Beach,) which has a reef, and this stretches out to sea about a league; but at four leagues from Soan, is the little island of Santa Catalina, (St. Catharine,) the eastern part of which is narrow, and the western foul.

On the west of Cape Cauceado is an anchorage, named La Caleta, which affords shelter from the breeze. The coast hence sweeps to the westward, to form the Great bay of St. Domingo, at the bottom of which the river Ozama disembogues. On the western bank of this river stands the city of St. Domingo. Along all the front of the bay is a sand bank, the Estudios, having 5, 6, and 8 fathoms of water, and extending about half a mile out to sea. On this bank vessels anchor, but with some risk, especially in the season of the souths, which raise a heavy swell, and there is no shelter from these winds; added to which the coast is wild and rocky, without any beach, and the sea breaks on it with violence. The safe anchorage is within the river, but it has a bar of rock which prevents vessels drawing more than 13 feet from taking it; and even these are in danger of striking during the souths.

*To anchor on the Estudios Bank*, it is necessary to coast the windward land from Cape Cauceado, at the distance of from three cables' length to half a mile. It is very clean and deep, and only on the eastern point of the river is there a shoal of little water: this stretches out about two cables' length, and to keep clear of it you must not haul to the northward, in any degree, until the west point of the river bears north.

The city of St. Domingo, which is the metropolis of the eastern division of Hayti, is situated, according to the late observations, in latitude  $18^{\circ} 28'$ , and long.  $69^{\circ} 50'$ . It stands on the right or western bank of the river Ozama, the entrance to which may be known by a great fort on that side. To the westward of this fort is a large savanna, which forms an amphitheatre, and makes a beautiful prospect. The harbor is very commodious, and ships may lie close to the shore to take in their lading, by planks, from the wharves.

The city is built on a rocky point. The streets are at right angles, N. and S. and E. and W., and have footways of brick. The greatest part of the town is built of marble found in the neighborhood, and in the style of the ancient houses of France and Italy. The more modern houses are of clay, which acquires the hardness of stone, or of wood thatched with the leaves of the palm-tree. The cathedral is spacious and magnificent. The population is computed at more than 20,000. The fortifications have been judiciously constructed, and the town is surrounded by a thick wall.

To sail into the harbor, run in directly towards the church with a flat steeple, and to within a mile of it. Here you will have 15 fathoms of water, nearly opposite the eastern point, and a little within, off a small fort on the larboard. Run in directly: you cannot do amiss.\* Towards the sea there is no danger.

In navigating off this coast, allowance must always be made for the currents, which set most frequently to the eastward; and there is very commonly an draught into the Bay of Nave, to the west, which must of course, in some degree, affect the navigation towards that of St. Domingo.

*Remarks and Directions for St. Domingo, by Capt. Mackellar.*

"The anchorage is about three quarters of a mile from the shore, and is open to all winds from S. S. E.  $\frac{1}{2}$  E. to S. W. by W. and, when the sea-breeze is at all to the southward, there is of course a very heavy swell. The bottom is of black sand and mud, apparently a good holding ground. Ships intending to anchor here, and being round Point Nisao, with the tower in sight, ought to keep well to the eastward; and when the tower bears N. N. W. they may steer for it, keeping it in that bearing, until within a mile and a half of it; then bring the west point of the entrance of the river, on which stands a signal-tower, to bear N.  $\frac{1}{2}$  E. and in a line with some houses on the east side of the river; these houses stand within the river's mouth on a small sandy beach; and, by keeping them in one with the west point of the river bearing N.  $\frac{1}{2}$  E. will carry you into the best anchorage.

"On coming within a mile of the town, you will get soundings of 40 or 50 fathoms; the next east 15; then 10, and from that it shoals gradually to the shore. The bank being very steep, I should recommend to ships having the wind free, to shorten sail in good time, and run in with their sails chued up, by doing this you will get your soundings true: and so soon as in 8 or 9 fathoms, let go your anchor, not waiting to round to, as there is but little room.

"The east point of the entrance of the river is a flat rocky point, and stretches considerably out farther than the west point. The east point will be the nearest land to you when you anchor, bearing about N. E. The whole of the town is on the west side of the river, and has been well fortified, but the fortifications at present are out of repair.—The river forms an excellent harbor inside; but has a bar of solid rock at its entrance, with never more than 13 $\frac{1}{2}$  feet water on it. The pilots here affirm that the anchorage outside is perfectly safe; in my opinion it may be well enough to stop a day or two in that season of the year when the weather is settled; but not, on any account, should a ship anchor here during the hurricane months.

"I had no opportunity of determining the situation of this place while lying here. I got the latitude at anchor by two stars, one on the north, and the other on the south: they gave the anchorage 18° 27', and the town was nearly a mile north of us. I should say the latitude of the town was about 18° 28', but not to be depended upon.

Point Nisao is the western point of the Bay of St. Domingo; and to clear it in going out from that anchorage, you must steer S. by W. or S. S. W. and having run 14 miles on either of these courses, you will be to the southward of it.

From Nisao Point the coast trends about S. W. and W. S. W. and is so clear that you may run along it at less than two miles. It then sweeps to the westward towards Nave Bay, in which there are various harbors and anchorages.

Salinas Point, on the east side of Nave Bay, is in latitude 18° 12', long. 70° 36'. From this point the coast extends to the N. E. a mile and a half, to Caldera Point, where a large bight begins to form. Here is an inlet of two miles to the east, in which every class of vessels may anchor in the greatest security, sheltered from both wind and sea. The mouth of this harbor (that is, the space which intervenes between Caldera Point and the nearest land) is half a mile wide, but the good and deep channel is reduced to a cable's length; for a rocky shoal, at the edge of which there are 4 $\frac{1}{2}$  fathoms water, stretches out about three cables' length from the coast; and another of the same kind, and with the same depth of water at its edge, runs out to half a cable from Caldera Point. The depth of water in this channel is from 7 to 8 fathoms, on oozy sand. Although this harbor is large, the ledge of rocks which borders the coast rounds the whole interior of it, and reduces it much; it is also further reduced by various rocky shoals in the very anchorage, but they have between them good and deep channels. As these shoals obstruct it so much, it is extremely difficult, even with a good knowledge of it, to enter it under sail, and totally impossible if you are not acquainted with it. In addition to this, on account of the narrowness of the channel, you cannot work in, and therefore no one should enter into this bight

\* It has been said, that since this description was written, the depth of the harbor has been reduced by an accumulation of sand: caution in entering is therefore necessary.

otherwise the Point, and at cables' length small point, sends out a cable's length. If the wind on both boards once anchored examine and farther in, you

From Caldera Ocoa; when is sheltered from are apt to draw are in the bottom cable ashore, also a cable to and W. N. W. until the breeze Point well proved very heavy.

harbor has been re-

otherwise than by warping or towing; having previously anchored to the north of Caldera Point, and at about a cables' length from it. In order to this, you must keep within 2 cables' length from Salinas Point, and preserve the same distance until you are past a small point, which the coast forms between Salinas and Caldera Point, which is foul, and sends out a rocky shoal, on which there is not more than 2 or 3 fathoms water. Having passed that point, which is called Rancheras Point, you may run within less than one cable's length of the coast, if you choose to make Caldera Point, and anchor in its vicinity. If the wind is not favorable for obtaining this situation, you may tack in, but take care on both boards, to tack in 8 or 10 fathoms, that you may keep clear of the ledges. If once anchored outside, you must get a warp carried out by your boats (which must also examine and ascertain the proper channel) and having warped two or three cables' length farther in, you will be in a very secure and well sheltered anchorage.

From Caldera Point, the coast trends towards the N. W. to the Point and River of Ocoa; whence it returns towards the N. E. and forms a very extensive roadstead, which is sheltered from the breezes; but the bank, which is of sand, is so steep, that the anchors are apt to drag, and the cables sometime fail, being damaged by the loose stones which are in the bottom. From these reasons vessels anchor very near the land, and send a cable ashore, which they make fast to some of the palm trees that are on the bank, having also a cable laid out for the changes of wind which take place in the night from the W. and W. N. W. and which render it necessary for those, who take this anchorage, to wait until the breeze comes in, which happens at 10 A. M. With the breeze you leave Ocoa Point well prepared to receive the gusts of wind which come off the coast, for they are very heavy.

From Ocoa Roadstead the coast follows to the north for 4 miles, and then to west eight more, where it begins to take to the south, to form the west coast or shore of the great bay.

Near the turn where the coast begins to descend to the south, there is a harbor named Escondido or Hidden Harbor, which lies nearly N. W. from Salinas Point. The mouth of this is more than half a mile in width, and to enter it you must keep near its south point, which is clean; and the water is so deep that at half a cable from it there are 5½ and 6 fathoms. A reef stretches out a cable's length from the north point. Half a mile within the harbor, and in the direction of the middle of its mouth, there is a rocky shoal, which is two cables in extent from N. to S. and one from E. to W. and upon which a vessel must run, if keeping in the middle of the harbor, and steering N. W. To avoid it, you must keep within two cables' length of the south shore, and anchor about half a mile within the harbor, but not farther in with large vessels, for the depth diminishes so that at two cables farther in there are only 15 feet of water. You can also anchor to the north of the shoal, in 5 fathoms, taking care not to run farther in than 3 or 4 cables' length from the mouth. In fine weather this harbor is excellent for vessels which do not draw more than 15 feet, which may enter, and be sheltered from all winds. Frigates and ships of the line remain always exposed to some swell from the S. E., and had better be, in this case, near the south than the north part of it.

BEATA POINT, OR LITTLE CAPE MONGON, is the southernmost point of Hayti. Its bearing and distance from Punta de Salinas are about S. W. ½ W. sixteen leagues. Of the coast between we have no particular description. Eight miles to the north-eastward of Beata Point, is Cape Mongon, and between these points appears the high mountainous land of Baurneo.

ISLE OF BEATA.—This island lies to the south of Beata Point, and is 1½ league in length from north to south, and about two miles broad from east to west. It is low and covered with bushes. There is a breaker off the N. by E. side of it, stretching towards Cape Mongon, at the extremity of which is a white shoal, that very much narrows the passage between Beata and the shore. In the passage are but 3 fathoms of water. There is anchorage to the westward of Beata between it and the shore, in 7, 8, and 10 fathoms, sandy and weedy bottom, with the N. W. end bearing about N. by E. or N. N. E. one mile, and the S. W. end S. by W. four miles.

East of the isle the water is deep, and there is no ground at a short distance from it with 50 fathoms of line. There is, nevertheless, a shoal stretching from the S. W. point, to which a small berth should be given, as there are no more than 4 fathoms of water west, three cables' length from the point. When the latter bears E. S. E. you may haul up from the N. W. end. In the anchorage there is good fishing.

The Frayles or Friars, a number of steep rocks above water, lie west 3 leagues from Beata. The sea breaks over part of them, and they are so bold to that vessels may sail within a quarter of a mile round; but it will be prudent not to approach within a mile.

Near all the isles off the main coast, the bottom may generally be seen; but near the shore of Hayti the water is very deep. The coast hereabouts is a flat of white and hard rocks, about 40 feet high, in which appear large holes and breakings, with some prickly shrubs.

ALTAVELA, or the Little Mount, a high rocky islet, lies at the distance of five leagues south from Beata Point, in latitude,  $17^{\circ} 28'$  and longitude about  $71^{\circ} 23'$ . The islet is peaked, but its summit has a rotundity resembling the upper part of a bell. It is generally seen before any other land in the vicinity, particularly from the southward, and appears like a dome emerging above a mist or fog. Being very bold, it may be approached with safety.

At the distance of two and a half leagues N. N. E. from Altavela, lies the south end of Beata Island. Between is a good and very deep channel. There cannot, however, be any motive for preferring a passage between these island to passing southward of Altavela; and therefore, vessels bound to the westward from Ocoa Bay, may steer S. S. W. twenty-two and a half leagues, and a west course will then lead well to the southward of Altavela; a more southerly course is, however, to be preferred, in order to avoid danger should the wind become scant, with a westerly or W. by N. current, which has often been found to prevail here with considerable strength.

POINT AGUJAS, or the False Cape, bears from Beata Point W. N. W.  $\frac{1}{2}$  W. six leagues, and from the Frayles N. W. by N. three leagues. Cape Lopez bears north, true, five miles from Point Agujas. The coast between forms a bay, affording good anchorage. From Cape Lopez, Cape Roxo bears N. by W. two and a half leagues, and between is the Ensenada sin Fondo, or Bottomless Bay; from this bay the coast trends to the N. W. and at five leagues from Cape Roxo, is the mouth of the Rio de Pedernales, or Petre's Cove which constituted the old limit between Hispaniola and Hayti. At this place is a good anchorage, which it is easy to take, a bank here extending along shore, and there is no risk in nearing the coast.

From Cape Lopez, the promontory called Morne Rouge, or Red Hill, bears N. W. twelve leagues. A league and a half to the eastward of Morne Rouge, is the village of Sale Trou, or Foul Hole, where there is a good anchorage for vessels drawing less than 16 feet: larger ships may anchor there, but they must lie farther out when the ground is not so good.

From Morne Rouge the coast trenches in a little to the northward, then out again E. S. E. to the Anses a Pitres, or Pitre Cove. All the coast is clear and may be approached with great safety, as noticed above.

There is good anchorage at the Anses a Pitres, and of very easy access. At two miles from the shore the water is very deep. All the coast hereabout appears white, being chalky. You may anchor either before the plain of Anses a Pitres, or southward of a small cape before the mouth of a river, which is considerable enough to be easily distinguished. The water is smooth, and you will be well sheltered in 6 or 8 fathoms, good ground, or in 4 fathoms and better ground nearer shore.

From Morne Rouge the coast round to Cape Jaquemel or Jacmel, which bears from the former W. S. W.  $\frac{1}{3}$  W., twenty-nine miles. From Cape Jaquemel, Cape Marechal bears N. by E.  $\frac{1}{2}$  E. distant rather less than two miles.

In approaching Morne Rouge from Cape Jaquemel, it may be known by its white hummocks. The coast in the space between forms several little creeks, wherein small vessels may anchor; but in none of them will they be sheltered.

JACQUEMEL OR JACMEL.—Between Cape Jaquemel and Cape Marechal, lies the Bay of Jaquemel, in the upper part of which there is anchorage for shipping of every class. The town of Jacmel stands at the head of the bay, to the east of the River Guache, which has several mouths in the beach. This bay, which is two miles in depth, was surveyed by Captain Mackellar and the officers of the British ship *Pique*, in 1817; and from this survey it appears that in the middle of it no bottom could be found at 70 and 80 fathoms; but the bank around the coast, which is about three cables' in breadth, has from 20 to 3 fathoms, shoaling to the land. On this bank, upon the N. E. side of the bay, is a dangerous reef, nearly half a mile long, the outer edge of which is three cables' length from the shore. To the westward of this reef, and opposite the town, is the anchorage, having from 5 and 7 to 3, and in one spot  $2\frac{1}{2}$  fathoms. You may sail in with a remarkable white cliff, the last cliff on the western side, bearing from W.  $\frac{1}{2}$  N. to N. W.  $\frac{1}{4}$  N. until the wharf, near the middle of the town, comes on with the eastern side of an old battery, bearing N. by E.  $\frac{1}{2}$  E., and with this mark on you luff up to the anchorage, which, at half a mile to the southward of the town, has the depths above mentioned.

Jacquemel Harbor may be distinguished at a distance, by the sudden cut off or drop of a hill, seen over another long hill at the upper part of the harbor. Running in towards that drop will lead directly to the entrance.

BAYENETTE.—From Cape Jaquemel Cape Bayenette lies nearly W.  $\frac{1}{4}$  S., distant 5 leagues. The latter may be known by the white hummocks and cliffs on its extremity. This cape forms the south side of a bay of the same name, which is open to the S. E. Its name Bayenette, signifies Clear Bay, and is supposed to have been given

from its great depth of water, and being entirely clear of shoals. This bay is unsheltered, but there is anchorage on the north side near the shore.

**LA VACHE.**—From Cape Bayenette to the east point of La Vache, the bearing and distance are W. S. W.  $\frac{1}{2}$  W., thirteen and a half leagues. The isle is three leagues long and about one broad; it is hilly, and at the distance of six or seven leagues, appears like an assemblage of small islands. The south side is bold, and along the north reef extends to the distance of a cable's length. From off the east point is a white shoal, connected with a reef, extending from an islet to the N. W., called La Folle, or the Fool's Rock.

From the Fool's Rock to the N. W. end of La Vache, there is a range of islets and shoals, among which are some narrow passages. On the north side of La Vache is a bay, called the Baie de Feret, where there is good anchorage, but it is accessible only to those who are well acquainted. The northernmost of the islets above mentioned, is Grosse Caye, called also Caye de l'Eau or Water Key, which is readily known by a great tuft of large trees. It is bold to, and at some distance from its north side there is good anchorage, in from 15 to 30 fathoms.

The western end of La Vache forms the east side of the entrance of the great bay, called Bay of the Cayes; and from its S. W. point, called Point Diamant, Point Abacou bears nearly W. by S. five miles. In mid-channel between, there is a depth of 25 fathoms, thence decreasing towards the island. From the S. W. point of the isle a white rocky spit extends to the south, having from 7 to 5 fathoms over it, at about two miles from shore.

*Remarks on the Anchorages within La Vache, by Captain Mackellar, 1817,*

"The N. W. point of La Vache is in latitude 18° 5' 12" N., longitude by chronometer, &c. 73° 43' 15" W. Variation, 6° 20' E. Ships coming from the westward, and intending to anchor here, ought to round Abacou Point, at a good mile off, as a reef stretches to the S. E. to nearly that distance from it. Having rounded this reef, there is nothing in the way, and you may steer for the N. W. point of La Vache. At half way between it and Abacou Point there are soundings in 15 fathoms, and the bottom thence shoalens gradually to the island. The best anchorage here is with the N. W. part of the island bearing E. N. E. in 5 fathoms; you will then be about three quarters of a mile from the shore, on a white sandy bottom. The soundings all over this part are so very regular, that you can hardly err in anchoring any where, so long as you keep the N. W. point of the island bearing to the northward of east. From the N. W. point to the S. W. point of the island the soundings are not so regular, and strangers ought not to come nearer than in 7 fathoms, especially near the S. W. point, for a reef stretches from it to the southward not less than two miles, having very foul ground with irregular soundings, to upwards of a mile or more. Therefore, ships, coming from the eastward and intending to anchor, ought to keep Abacou Point bearing west until the west point of La Vache bears north. They may then haul in to the northward, and steer for the anchorage.

"About a mile to the eastward of the town of Aux Cayes, which stands to the north, there are three small white cliffs close to the sea side; and the mark I have generally run in and out by, is the easternmost cliff bearing north, and in a line with a small round hill on the highest land behind it; and anchoring with this mark nearly on the N. W. point of La Vache, bearing E. N. E. or N. E. by E.

"The whole of this large bay to the westward of La Vache is clear, and the soundings very regular while you keep the west end of the island bearing to the northward of east. To the northward of this I had no opportunity of sounding, although I am well aware that between La Vache and Aux Cayes, the bay is covered with large reefs, and several are above water."

**THE CAYES, ST. LOUIS, &c.**—Point Abacou is composed of two points or reefs, which stretch three quarters of a mile to seaward; but you may pass without fear, at the distance of half a league, and will find no ground with a line of 40 fathoms. The town of the Cayes bears from Abacou Point, nearly north four leagues. In sailing towards this place, and approaching Point Diamant, before noticed, you will not find the white ground for more than a quarter of a league from it; and the ground is good in 6 or 7 fathoms. With Point Diamant bearing east there are soundings all across. There is good anchorage to the west of Diamant Point, and farther to the northward opposite a sandy cove, in from 6 to 7 fathoms, bottom of mud and sand.

To go into Aux Cayes you range along the N. W. point of La Vache, in 6 fathoms water; and you steer nearly N. by E. to make on your starboard hand, the white hummocks of Cayavillon. You will then leave on the larboard hand a large reef, surrounded with a white shoal, which takes up almost all the middle of the bay. When you have

brought the town to bear N. W.  $\frac{1}{4}$  W., you must haul up two points to windward of the town, standing towards the Company's Islet, where you may anchor if you do not mean to go into the road: if you do you shorten sail a mile from the shore, and wait for a pilot. The channel is two thirds of a cable in breadth. Ships drawing more than 13 feet water cannot go in; those of 15 and 17 feet water always anchor at Chateaudin, half a league to the westward, and which is separated by shoals from the port.

To anchor in the road of Chateaudin, (coming from the mooring of La Vache,) W. or W. N. W. off Diamant Point, in 8 or 11 fathoms, you must steer directly for Torbec, which is a small town very easily distinguished in the cod of the bay: this track will be about N. W. When you are within about two miles of the shore, you will discover a little white flag, which is on a shoal; you double it to the westward at about half a cable's length, leaving it on the starboard hand; when you have brought it to bear south, you steer along the coast for the road of Chateaudin, and anchor in 6 or 7 fathoms, mud. In all this passage, if you keep the proper channel, you cannot have less than from 7 to 9 fathoms, and often 12 and 16, muddy ground.

In advancing towards the Tapion of Cavaillon, you must not approach too near its S. E. side, as a shoal of only 6 feet water, called Le Mouton, or the Sheep, lies S. E. from the eastern point, at the distance of about half a mile. There is a depth of 8 fathoms between it and the coast.

CAVAILLON BAY is spacious, although its anchorage is of small extent. The coast on the western side is very steep, and the bottom full of rocks; but there is anchoring ground on the eastern side, opposite a coast covered with mangroves, which may be approached without fear, the bottom being clean, with 5 fathoms close to the shore. This bay affords shelter from the sea breezes by the eastern point of an island, which leaves a passage into the Baie des Flamands, next described.

Baie des Flamand's, or Flamingo Bay lies a quarter of a league from Cavaillon Bay, and extends upwards towards the N. E. Its entrance and shores are clear and bold, and it is the place where ships lie up in the hurricane months. There is a good careening place, and anchorage in every part.

BAIE DU MESLE.—From Flamingo Bay the coast extends E. by N. two miles to the Grand Baie du Mesle, all over which the anchorage is good; but as the entrance is broad and open to the southward, there is no shelter from southerly winds. The coast hence, continues its direction to Point Pascal, half way towards which is the Petite Baie du Mesle, in which a vessel may anchor, but it will not be sheltered even from the sea-breeze.

Off the Great Bay du Mesle is a shoal, lying like a bar across the bay, and extending opposite the point, which is to the westward of the Little Bay du Mesle. This bank has not, in some places, more than from 15 to 18 feet water; it is very narrow, and leaves a passage of three quarters of a mile only between it and the coast. To the southward it extends about half a league from shore.

To go into the Great Bay, with a ship drawing more than 15 feet, you must keep close to the shore on the western side, steering by Pointe Paulin, which forms that side of the entrance.

BAY OF ST. LOUIS.—The great entrance of the Bay of St. Louis lies between Point Pascal, which is steep and wide, and a little isle called Orange Key; the bearing and distance from one to the other being E.  $\frac{1}{2}$  N. rather more than half a league. This isle may be seen from the entrance of the Cayes, thirteen miles distant, whence it appears nearly in a line with the southern extremities of the intermediate coast.

About two thirds of a mile N. E. by N. from Pascal Point is the Vigie or Old Look-out Point; between is a cove, called the Bai du Paradis. When off the Vigie Point you will have the whole of the Bay of St. Louis in sight. The bay is shut in on the eastern side by Cape Bonite, which bears from the Vigie Point, N. E.  $\frac{1}{2}$  E., distant one mile and three quarters.

In proceeding to the anchorage of the Bay of St. Louis, run along past Point Pascal and Point Vigie, and thence along the western coast of the bay, in 8 or 10 fathoms water. The anchorage is west of the Old Fort,\* about a quarter of a mile from the western shore, and so situated that the town may be seen from it, between the Old Fort and shore, in the bottom of the bay.

In the anchorage before the town, called the Little Anchorage, the greatest depth is 5 fathoms.

S. S. E. three quarters of a mile from the Old Fort, and west of Cape Bonite, at nearly the same distance, is a shoal called Le Mouton, (The Sheep.) There is a good

\* The Old Fort is on an island of rocks towards the middle of the bay, half a mile to the southward of the town. In the passage between it and the shore, there is a depth of six fathoms.

passage between it and the shore, as well as between it and the Old Fort; but the depth of water is less on the eastern than on the western side of the bay.

Between Orange Key and the shore, in a N. E. direction, there are two islets and some shoal ground; the first of which, next to Orange Key, is called Rat's Key. You may pass into the bay of St. Louis through a small passage immediately on the north side of this Key.

**AQUIN BAY.**—One mile and a half E. by N. from Orange Key, is Moustique Key, a little island clear of shoals, unless very close in shore. You may pass without or within it at the distance of one eighth of a league, in 10 fathoms. Cape St. George is north of Moustique Key, and N. W. of a key called Caye a Ramiers, (or Pigeon's Key,) which bears E. by N. two miles from Moustique Key, and is known by a white hummock rather steep, and seen at some distance. There is a deep passage between it and Moustique Bay, by which ships pass into the great Bay of Aquin.

South of Caye a Ramiers is a shoal extending half a league, which has, on its middle part, only 3 fathoms. East of the same key is a small isle, called L'Anguille, or the Eel, and to the N. E. is another, called Le Ragale; the three form an equi-lateral triangle, having each side half a league in length.

E. N. E. three quarters of a league from Caye a Ramiers, lies the west end of the Great Key of Aquin, which is two miles in length, and distinguished by two very remarkable white hummocks. It extends E. and E. by N. true, and its south side is bold to; but the white shoals of L'Anguille extend to its western point, so as to prevent a passage between it and Caye a Ramiers, for ships that draw more than 12 or 14 feet.

East of Aquin Key, at the distance of a short quarter of a league, is a white insulated rock, called Le Diamant, or the Diamond; to the eastward of this, at the distance of two cables' length, is the point of Morne Rouge, or Red Hill. Thus the eastern end of Aquin, the Diamond Rock, and the point of Morne Rouge, form the two passages into the bay. All the islands and shores are bold. In the Morne Rouge Passage are 5 and 6 fathoms water, and in that between Aquin Key and the Diamond, 6, 7, and 8. The bay is extensive and trenches considerably inland, but the water is shallow, and there are only 3 fathoms at a distance from shore.

The point of Morne Rouge may be readily known at a distance, by three very high white hummocks, called the Tapions of Aquin, which together form a great cape, under which is an anchorage in 10 and 12 fathoms, at a distance from land. This bottom continues as far as the Petite Baie des Flamands, or Little Flamingo Bay, which is W. N. W. a league and a quarter from the Tapions of Aquin.

To enter the passage into Aquin Bay, between Caye a Ramiers and Moustique Key, before mentioned, steer N. N. E. so as to get into the mid-channel between the shore and the island: Having doubled Key a Ramiers, you will see La Ragale, which is a very low isle of sand; leave this on the starboard side, keeping in mid-channel between it and the shore; then haul up for Aquin Key as much as the wind will permit, and anchor to the northward of it in 6 or 7 fathoms, or farther in at pleasure.

**GENERAL REMARKS.**—Observe that from Point Pascal all the capes are broken and steep, and from the S. and S. E.; and as, on all this coast the land is white, many white hummocks will be seen. Aquin has two above mentioned; but the easternmost and highest are those of Morne Rouge, and, with attention, it will be impossible to mistake them. From the point of Morne Rouge, or the hummocks of Aquin, the true direction of the coast, after having trenced in to form the Petite Baie des Flamands, is east, southerly 10 leagues to Cape Baint. The whole of this coast is free from danger and bold to, but has no bay or anchorage, or shelter from the common breeze. Two leagues and a half westward of Baint the coast is iron bound, and the water near it of great depth.

**POINT ABACOU TO CAPE TIBURON.**—From Point Abacou to Point a Gravois, the bearing and distance are west, southerly 2½ leagues. The latter is low, not easily distinguishable, and has frequently been mistaken for the land of Port Salut, a small cove lying a league farther to the N. N. W.

From Point Gravois N. W. by N. 4 leagues, there is a bight of half a league, in which anchorage may be found. This bight lies about two miles to the southward of Les Coteaux. From this spot to a large hummock called Les Chardoniers, which is very remarkable at a distance, the bearing and distance are nearly W. N. W. 10 miles.

From Les Chardoniers to the Fond des Anglois, or English Bottom, the coast extends W. by N. 4 miles, and a bay thence rounds to within a league and a half of Pointe de Vieux Boucan or Boucan Point. All this part is safe, but it has no anchorage. A ship may indeed anchor very near the land, but it is every where exposed to the sea-breeze.

From Boucan Point to Point Burgos, which is a low point, the coast trends westward 4 miles. Between these places, off a point called Aigrettes Point, there are some white shoals, rocks and breakers; but their extent is not more than half a league.

*The Northern Coast of Hayti, or St. Domingo, between Cape Raphael and St. Nicholas' Mole.*

[Variation generally about 5° E.]

CAPE RAPHAEL is of moderate height, and lies in or about lat. 19° 2' and long. 68° 52'. It has already been described. From this cape to Cape Samana, the bearing and distance are N. W.  $\frac{1}{2}$  W., nearly 7 leagues. Between the two is Samana Bay, about 10 leagues deep, so that you can scarcely see the land at the bottom of it; but what appears to the eye is very high double land.

CAPE SAMANA is a broken rugged point of land, which appears, from a great distance, like a ship with her topsails down, and seems not to join the main, but on a nearer approach, this shape changes. The cape makes with two points, both alike, bluff and steep, about the height of Beachy Head, in the English Channel, but not so white. They are 4 or 5 miles asunder, with a small bay and harbor between them. At 2 or 3 miles to the westward of the westernmost point, there is very high land, which falls down to the water side, and is twice as high as Cape Samana.

SAMANA BAY.—There is good anchorage in Banistre or Levantados Road, on the south side of the peninsula of Samana. In advancing for this place, observe that when Cape Samana bears N. W. by W. about a league, it appears like two points, the westernmost of which, as you come farther in, you should bring open with a white spot of sandy ground, which may at first be mistaken for one of the sand keys, although it is connected with the main shore. In order to ascertain the true point, observe that in coming about it it will appear as if a small rock were lying off it, which, on a nearer approach, will be found to join to the land. The soundings are uncertain. Having well shot into the bay, you may have 10 fathoms, and then no ground in 20.

Or, being off Cape Samana, and intending for this port, sail S. S. W. 3 or 4 miles along shore, (you may go within a mile, for it is bold to.) to Point Velandras or Blue Point, which has two or three black rocks lying near it. When at the length of this point steer thence west about half a mile, and you will leave three keys, which are high and woody, a mile from you on your larboard side. With the westernmost of the three keys bearing S. S. W. you may anchor in 15 fathoms, half a mile from shore, and have good water. Then Levantados or Banistre Key will bear W. by N. 1 mile off.

There is good easy riding in this harbor, in from 7 to 3 fathoms. You may also find good fresh water in many places, with plenty of fish and fowl. Here is commonly a fresh breeze from the eastward all day, and open to the north.

The preceding paragraphs are from the French of the Count Chastenot de Puységur, &c. The following from the Spanish Derrotero.

SAMANA BAY.—From Cape Raphael the coast trends nearly West, and forms a gulf, shut in to the N. W. by the peninsula of Samana. The east point of this peninsula, named Cape Samana, lies 7 leagues N. W. by W.  $\frac{1}{2}$  W. from Cape Raphael. This bay, which is more than 11 leagues in extent, from east to west, and 4 from north to south, is obstructed and almost shut up by a great reef, which extends from the south coast, and so far to the north, that a channel of only 3 miles in width remains between it and the peninsula of Samana. The northern extremity of this reef is marked by some keys or islets, the largest of which, called Cayo Levantados, must be left on the larboard hand on going into the bay. Within there are several anchorages, but little frequented, as there is scarcely any commerce here. The first anchorage is on the coast of the peninsula, and near the entrance of the bay; it is named the Carenero Chico, (or Little Carenage;) to enter and anchor here, it is necessary to approach within half a mile of Point Velandras, which is the S. E. point of the peninsula, and to keep along the edge of the coast at this distance, until sheltered by Vinas Point, when you may anchor in 6 fathoms, taking care to keep half a mile from a key, named the Key of the Carenero Chico, which is at the west part of the road, and has, to the south of it, either four or five small islets. Behind this key, and between it and the coast, is the proper anchorage; but it is much narrowed by shoals, and must be entered by warping. Point Vinas is easily known, as it bears true north from the west part of Levantados Key. In the entrance there is nothing to be feared, because there is no danger but what may be well seen; and only inward from Point Vinas there is a shoal, having on it two feet of water; to keep clear of this shoal, bear in mind that it bears east, a long mile from Vinas Point. By following the coast, as we have directed, at the distance of half a mile, you will go safe from it; but, for greater certainty, keep something to starboard, when you will sound in 5 fathoms water; for in the channel, between it and the coast, there are 6  $\frac{1}{2}$  and 7 fathoms.

A league and a half to the west of the Carenero Chico, is the Puerto de Santa Barbara, or of Samana: the anchorage here is very narrow at the entrance, which is formed by a great reef, that runs out to the east from Point Escondido, the S. W. Point of the har-

bor; and on the pezon; the south coast the Point Escondido, the first is cape point of its Bay there is but has 7 fathoms principal harbor a is found to the north coast, a nearer to, north mid-strait; and northern reefs, or, of a cable. le Santa Barbara  
ch is formed by a  
Point of the har-

bor; and on this reef, rise several keys or islets, of which the outermost is named 'Tropazon'; the second is the Greater Carenero; and the third, Cayo Escondido, is very near the Point Escondido, on the west. There is not only this reef at the entrance, for the north coast sends off two, which stretch far to the south, and form two bays: of these the first is called Aguada, or Watering Bay, and it has Point Gomero for the N. E. point of its entrance. The second roadstead lies between the two reefs. In Aguada Bay there is good anchorage, in 6 fathoms, clay; the second anchorage is very narrow, but has 7 fathoms water. To the west of these two reefs and roadsteads, lies the principal harbor and anchorage of Samana, with a depth of 5 and 6 fathoms, on clay, which is found to the south of the town. To enter this harbor it is necessary to run along the north coast, at half a cable's distance, and steer to the west, taking care neither to get nearer to, nor farther from Point Gomero, than half a cable; for you will thus run in mid-strait; and by keeping farther off, you would incur the risk of getting on the southern reefs, or, by coming nearer, get on those of Point Gomera, which lie out one-third of a cable. So soon as past Point Gomero, you may see a little riyulet in Aguada Bay; and then you ought to place the prow direct for the western extremity of Carenero Key, until Point Escondido, or its key, bears W. ½ S. when you may run about W. by N. towards the bottom of the harbor, and perfectly free from the northern reefs, and may anchor to the south of the town, in 5 or 6 fathoms water, upon clay. If you wish to anchor in Aguada Bay, you must run in, huffing up to the northward so soon as past Point Gomero, in order to anchor in the middle of it, and about S. ½ E. from the riyulet of Aguada.

From this anchorage the coast of the peninsula continues bold, and with roadsteads, in which there is nothing to fear, except the south winds, which in their season are often violent. Two leagues to the west of Samana lies Point Espanola, with an islet; and thence, in the interior of the bay, there is no establishment whatever. A large clay bank, in the interior of the bay, runs out more than two leagues.

From Espanola Point, in which you will be well to the west of the reef at the entrance of the bay, you should steer to the south for the Bay of Perlas or of St. Lorenzo, in which there is no necessity to run far in; and it may suffice to anchor at its entrance, and about south of Arenas Point, which is the north point of this bay; for although farther in there is sufficient depth, yet there are sand banks, on which you might easily get aground. To find this bay, it is better to make the land to the east than to the west; for the south coast of Samana, from Perlas Bay to the west, is very wild and unsafe, on account of the many islets along it. Steering from said Point Espanola to the S. ½ E. you will fall to the east of the bay, and make a little town named Savanna de la Mar, which affords anchorage for very small vessels; and thus, so soon as you discover Arenas Point, when crossing over, steer towards it, and you may approach within a cable's length of it.

The entrance of Samana Bay is effected with the regular breezes; but you can get out with the land breezes only, which blow by night.

Cape Samana is of considerable height, and steep down to the water's edge; on nearing it, you may also discover Cape Cabron, which is N. W. from it, nearly 3 leagues: this is even more high and scarped, or steeper, than the former, and the coast between is green, and covered with large trees: on it there are some islets, and as it is foul, it should not be approached nearer than one league. From Cape Cabron the coast takes to the west, and forms a great bay called Escocesa Bay; the coasts of this bay are low, and very foul; from which reason, and as there is neither town nor establishment in it, to induce vessels to visit it, they ought to proceed direct from Cape Cabron to Cape Viejo Francois, or Old Cape Francois, which lies 15 leagues from it, W. N. W. ¼ W. Old Cape Francois may be seen, in clear weather, at the distance of ten leagues. It is known by a mountain inland, which may be seen at the distance of 15 leagues.

#### *Directions for those Sailing in from the Eastward.*

Ships coming from the eastward towards the N. E. coast of Hayti, should, previous to their making the island, run down between the latitudes of 19° 20' and 19° 50', taking particular care not to pass either to the northward or southward of these latitudes. In this track they will make the land, either by Cape Cabron, or Old Cape Francois, and they will pass clear of the Silver Key Bank on the one side, and the current commonly setting towards Samana Bay on the other.

**BAJO NAVIDAD.**—The north point of this bank lies in long. 68° 46' W. and lat. 20° 12' N. and extends in a southerly direction about 25 miles; it is 12 miles wide in the centre, and has on it from 14 to 26 fathoms water, and is perfectly free of danger. Vessels bound to the north side of St. Domingo, can have an excellent opportunity of correcting their longitude by running for this Bank, which is laid down from the recent surveys of Capt. R. Owen, R. N. and published by E. & G. W. Blunt, 1833.

In passing to the northward of Porto Rico, a look out should be kept for a rock or shoal, (if not more than one,) which certainly exists there, although its exact situation is not yet known. This danger has been noticed, where it is stated that an American schooner struck upon it in 1817, in latitude about  $20^{\circ}$  north; and we have since met with another notice which states that, "At fifty miles north from Porto Rico, Captain Baxter, in the brig Robert, struck on a rock, and remained several hours."

**OLD CAPE FRANCOIS.**—The point of the Old Cape is rather low, and stretches out in the form of the snout of a porpoise; at 5 or 6 leagues distance to the N. N. W. of Cape Cabron, in a clear day, the Old Cape is seen making like an island, whose ends slope gradually into the sea. When you have made Cape Cabron, being 4 or 5 leagues to the north-westward of it, you must sail 13 or 14 leagues N. W.  $\frac{1}{2}$  W. and you will pass 5 leagues to the northward of the Old Cape; then steer W. by N., when, having run 15 leagues, you will see Point Casrouge at about 3 leagues distance from you; continue on for 5 leagues, when Ysabella or Isabella Point will bear S. W.  $\frac{1}{4}$  W., distant 4 leagues; having advanced thus far, you have nothing to fear, and if necessary, you may keep within half a league of the shore, the coast being very clear.

At about 4 leagues off to the northward of Old Cape Francois, its point appears like a porpoise snout, projecting to the eastward; and 3 leagues farther west is a point named Cabo de la Roca, or Rocky Cape, very much resembling it, and projecting to the westward. The coast between lies W.  $\frac{1}{2}$  N. and E.  $\frac{1}{2}$  S.; it is low, rather steep to the sea side, and covered with trees remarkably green.

Towards the point of the Old Cape, a mountain is perceived inland, which, in clear weather, can be seen 15 leagues off, and is a good mark to point it out.

There is some foul ground laying off the pitch of the Cape, and a harbor a little to the westward of it for small vessels. When sailing from Cape Samana to Old Cape Francois, which is about 6 or 7 hours sail, you see a point of land on the east side of the Cape, which often times at first sight, you suppose to be the Cape, but coming nearer you will see your mistake. And when you are due north of Old Cape Francois, you will perceive to the eastward of the Cape a very steep point, which seems to be divided from the main, and running off the land rises higher and higher in such a manner that the highest part of it lies open to the sea, so high that you cannot see the land within.

When from Old Cape Francois you sail for Monte Christi, observe to steer a more northerly course in hauling off, giving a good distance between you and the shore, because the currents always set upon it; and unless you do this you will run the hazard of being ashore.

From Cape de la Roca, the land trenches in to the distance of 2 leagues, and forms a bay pretty deep, which is sheltered by reefs. This coast trends to the W. N. W. and, rising in height to the northward, comes to Punta Macuris or Point Mascary, which bears W.  $\frac{1}{2}$  N. from Cape de la Roca. This point is high, and its shore bold; it serves as a mark for the small harbor of St. Jago, which is 3 leagues distant from, and to the eastward of Puerta de Plata.

**PUERTO DE PLATA,** or Port Plata, lies 17 leagues from the point of the Old Cape, and bears from it west. It is known by a mountain at some distance inland, which appears insulated like the Grange, although not in so precise a manner. The anchorage is good, and the entrance nearly covered with mangrove islets, which you range along, leaving them on your larboard hand; when you are within these islets, you anchor in 17 to 20 fathoms, good bottom. Observe, when sailing in, to keep close to that point of land on your larboard side, which you will see to be broken and rugged. When coming about the said point, luff up round and run up as far as you can, with your sails almost shivering in the wind; thus you will gain the best place in the road.

On approaching the coast you will desery to the westward, a great cape, very high and steep; the extremity of this is Punta del Algarroba, or Point Casrouge, which is readily known by its magnitude.

The bight from Port Platato Point Casrouge is bordered with reefs close to the shore, and does not admit of any anchorage.

Old Cape Francois and the Great Point of Algarroba, or Casrouge, bear from each other W.  $\frac{1}{2}$  N. and E.  $\frac{1}{2}$  S.  $19\frac{1}{2}$  leagues. When at the distance of about 3 leagues to the northward of Casrouge, you will see a low point projecting out to the westward, which is remarkable by its having the appearance of being detached from the coast like an island; it is Ysabella or Isabella Point, the northernmost point of Hayti.

**YSABELLA, OR ISABELLA POINT,** according to the late observations, lies in latitude  $19^{\circ} 59'$ , longitude  $71^{\circ} 10' 30''$ , and at the distance of 4 $\frac{1}{2}$  leagues W. N. W.  $\frac{1}{2}$  W. from Algarroba or Casrouge Point. To the eastward of it lies the deep bight, called Puerto Caballo, Port Cavallo. In the bight between these, is an anchorage for vessels drawing 12 or 13 feet water, and sheltered by the reefs: the entrance is readily known by running to it along the reefs.

observations, lies in agues W. N. W. e deep bight, called anchorage for vessels ce is readily known

On the western side of Isabella Point is a more extensive anchorage, and more easy to gain than that of the east, but the ground in many places is foul: there is a depth of from 5 to 7 fathoms water.

From Isabella Point to the Grange the bearing and distance are W. S. W.  $\frac{2}{3}$  W. 10 leagues. The coast between is bordered with reefs, among which the entrances are narrow and dangerous.

West of Isabella Point is Punta Rucia, or Rocky Point, to the westward of which is an anchorage for large vessels, which being very bad, ought to be used only in case of necessity.

To gain this anchorage you must haul very close to Rocky Point, and anchor so soon as you are in 12 fathoms, white bottom.

This anchorage, which is sheltered by the reefs that stretch N. N. W. from Punta Rucia, lies about four leagues from Isabella Point.

THE GRANGE.—The Grange Point is known by the mountain of that name, and is seen at a great distance before you perceive the sea coast. This mountain, which is insulated and stands upon a low peninsula, has very much the appearance of the roof of a barn, from which it takes its name Grange. The northwest part of it is bold, and you may approach it within a quarter of a league, or even less. Close to the west part of the Grange Point is a rocky islet, named the Frayle, or Friar; and from its S. W. part, at three cables' length, is another somewhat larger, and named Cabras, or Goat's Islet. These are the islets of Monte Christi.

HAUT-FOND.—Two leagues to the N. N. E. of the Grange Point lies a white shoal of not more than two cables' length each way, called the Haut-Fond; there is a small spot on the shoal, with only 25 feet of water, on which the Ville de Paris struck in 1781. Close to it is a depth of 6 fathoms, then 10 and 15, and suddenly no ground. The white ground has generally scattered rocks, so that it cannot be ascertained whether there may not be some spots on it, even with less than 25 feet. When you are on this shoal, the Grange bears S. by W.  $\frac{1}{2}$  W. you will then have the islets of Monte Christi open of each other, the westernmost of them bearing S. S. W.  $\frac{1}{2}$  W.

MONTÉ CHRISTI REEF.—About 3 leagues to the westward of Haut-Fond, lies another reef, on which the British ship Torbay struck and lost her rudder, in 1783. It extends nearly N. E. and S. W., is about three quarters of a mile in length and half a mile broad. On the shoalest part the points of rocks stand up like sharp spires. On other parts were seen white patches of sand. The shoalest water, 3 fathoms; thence 3 to 4, 5, 6, and 7 fathoms. It is steep to, and has from 15 to 17 fathoms close to it, and 20 to 25 all around. The bottom is soft in 20 fathoms; and in some places you will have coarse sand. The water, when smooth, is very clear, so that you may see the pinacles of the rocks as you pass over them in a boat. From the shoal, in 3 fathoms, the eastern end of a grove of trees, open to the south-westward of Monte Christi, (and between it and the key,) bore S. E. and the Mount of Cape Francois, (now Cape Haytien,) S. W. by W. The variation at the same time was  $6^{\circ} 20'$  E.

With Isabella Point bearing S. W., distant four leagues, the course and distance to pass without the shoals called the Haut-Fond and Monte Christi Reef, will be a few degrees to the northward of west, seventeen leagues; and then the latter will bear about S. E. But, should you be up with Isabella Point, and prefer the mid-channel between these shoals and the coast, a W. by S. course sixteen leagues, will clear the shoals and bring you in sight of the high land of Cape Haytien, (formerly Cape Francois,) at the distance of about five leagues.

In sailing between Old Cape Francois and the Grange, be careful to keep sufficiently to the northward in hauling off, that you may not be driven ashore by the current, which always sets upon the coast.

There is anchorage under the Grange to the west: to take it you must range along the Frayle, or islet of Monte Christi, and let go your anchor so soon as you have 6 fathoms; but under the south side of Cabras, the westernmost islet, you may anchor farther in, with 4 fathoms. From the Grange you may see the mountains above Cape Haytien.

In approaching this anchorage you must be cautious of a shoal, which lies W. by S. from Cabras Isle, at the distance of a long mile: to keep clear of it on entering and leaving the anchorage, take care not to bring Cabras Isle to bear any thing to the northward of E.  $\frac{1}{2}$  N., but on the contrary, keep it rather to the southward of that bearing.

The Shoal or Bank of Monte Christi extends fourteen miles to the west, and to the south as far as Manzanilla or Manchioneal Point, and it thence continues to border the coast at the distance of half a mile, more or less, according to its sinuosities. On this bank rise the islets named the Seven Brothers, which are low, and covered with mangroves. The islet named Monte Grande is the most remarkable of all of them: it is the second from the eastward, and has high trees upon it. This bank, as well as many

others in these seas, has a very white bottom, and is very dangerous, because the bottom is very irregular in its depth, with stones and rocks; you may have eight, and immediately after three fathoms. You should therefore avoid sailing on this or similar banks, unless they have been well examined and sounded.

**MANZANILLA BAY, &c.**—To the east of Manzanilla Point there is an excellent anchorage in Manzanilla Bay; from this bay the coast trends in to the S. E. and then turns to the west, in which direction it continues to a distance of 8 leagues, when it ascends to the north, and terminates with Point Picolet. The Grange Point with Point Picolet, form a great bay, in which, besides Manzanilla Bay, there are two harbors; the first of these, named Bayaha or Port Dauphin, is to the S. W. of Manzanilla Point, and about two leagues from it; and the second, at the western extremity of the bay, is known as Guarico, or the City of Cape Haytien, or City of the Cape.

The coast from Bayaha to the west, is bounded by a white bank and reef, on the edge of which there are from 50 to 80 fathoms: between the reef and the coast is a channel, with two or three fathoms of water, to which there are various passes in the reef, known to the coasters and pilots only.

The navigation from Grange Point to Manzanilla Point, should be made on the white bank of the Seven Brothers; it is, therefore, very necessary to know the channel; and, though you may proceed on the outside of the islets and the bank, extending to the westward, it follows that, in doing this, vessels must get much to leeward, and are then obliged to beat up to the anchorage. The delay in following this route is not so great when bound to Bayaha, or Port Dauphin; but the channel for crossing the bank, which we are about to describe, being very safe, it does not seem requisite that any one should go round about, but that all should proceed as follows:

Having passed near the Grange Point, steer W.  $\frac{1}{2}$  S. without going to the southward of that bearing until you are to the north, or on the meridian of Yuna Point;\* the vessel, having arrived at this situation, should now steer towards Yuna Point, until the islet named Monte Chico, which is the easternmost of the Seven Brothers, bears west; whence you must steer S. W., leaving to starboard the islet or key Tororu, which is the southernmost of the Seven Brothers; and when you mark it at about N. by E., you must steer S.  $\frac{1}{4}$  E. until you have Manzanilla Point E.  $\frac{1}{2}$  N., when you must haul to the wind on the larboard tack to take the anchorage, if you can; and if not, you must prolong the stretch to the southward as far as necessary, to enable you to get into the bay upon the other tack, in the understanding that you may run along the whole of the south shore at half a mile, or even less. In running by the way we have pointed out, you will find upon the bank 7 to 8 fathoms of water, on sandy clay, and you may anchor on any part of it commodiously, especially to the S. W. of the eastern keys, Monte Chico, and Tororu; and it may even be convenient to anchor in case of night coming on, by which the inconveniences arising from darkness may be avoided.

The edge of this bank is so steep that, from 12 to 20 fathoms, you rapidly pass into 100 fathoms, and of the same nature is Manzanilla Bay; for, from 7 fathoms you pass to 100 in the short distance of 5 cables' length; from which reason an anchor should never be let go until the depth has been previously ascertained by the lead, keeping in mind that the best anchorage is in from 6 to 10 fathoms, on a stiff clay bottom, which the anchors catch well, and at less than half a mile from the shore.

In the River Tapion, (E. S. E. of Manzanilla Bay,) and also in that of Axabon, to the S. E. water may be conveniently got, and you may cut wood on any part of the coast that is desert and uncultivated. In this bay there are always fresh land breezes, which facilitate much the communication between Bayaha and Monte Christi; for those to whom the breeze is contrary, navigate at night by aid of the land breeze. In Manzanilla Bay no hurricanes are felt, which is an advantage of great consideration.

**THE HARBOR OF BAYAHA OR PORT DAUPHIN** is one of the finest ports in Hayti; for to its great extent it adds shelter equal to a dock, with an excellent clay bottom, and the depth does not exceed 12 fathoms, nor is it less than 5 fathoms, which are found at half a cable from the shore; but notwithstanding these singular qualities, if the difficulty of entering and getting out of it, in consequence of the narrowness and foulness of the channel or mouth, is considered, it will be seen that it would not answer for any vessel on actual service to enter and be shut up in a harbor from which she could not sail, unless at night, with the land-breeze, and thus exposing herself not only to the danger of getting aground on the shoals of the entrance, but also, in case of the land-breeze failing, she may both lose the time for getting out and the object for doing so. The interior of this harbor needs no description, more than the chart, by which it may be seen that its entrance is only a cable and two thirds in width; and this narrow breadth continues inwards, to the distance of a short mile. are in this passage render the entry still more difficult. The risk of this consists in a shallow ridge which borders both sides of the channel, and which, at the points, stretches out more than half a cable, and reduces the channel to one cable's length in width. Again, this channel being serpentine, it is necessary that a vessel, in running in, should take the turns with much dexterity and promptitude, in order to avoid getting aground. It is therefore necessary to enter this harbor when the breeze is to the northward of E. N. E., for if more scant, an attempt to take the entrance will be impracticable. Keeping well in the middle of the channel, you pass close to the White Shoal, which runs out from the windward point of it; and when abreast of it you must luff up so as to place the prow towards the second point on the windward side, so as to free yourself from the ledge which lies off the second point to leeward; and so soon as you have this abeam, on the larboard side, you must luff up for the last point to windward, till you have passed the third leeward point, when you may run in and anchor between Port Dauphin and the little isle called Tonantes Island, without approaching near the N. E. part of the latter, because a shallow bank stretches off it. From what has been said, it may be seen that the harbor requires no other direction than that of an eye accustomed to run in mid-channel through a devious passage; and he who knows how to do this, need never get ashore here; for his eyes will direct him when to luff and when to bear away, without particular leading marks. From the mouth to the third leeward point you cannot anchor, from want of space to turn the vessel, and because the bottom is of sharp rocks. The tide, at full and change of the moon, flows here at 7h. A. M., and spring tides rise  $5\frac{1}{2}$  feet, but neaps only  $3\frac{1}{2}$  feet.

THE HARBOR OF GUARICO, OR CAPE HAYTIEN, is no more than a bay, formed by the coast, and shut to the east and north by a group of reefs which rise upon the White Bank, extending outward, at this place, more than a league. Those bound to this port ought to run from the Grange Point towards Picolet Point, outside the Seven Brothers, and to place themselves so that they may run down towards Point Picolet, with the vessel's head to the S. or S. S. W. In this direction they may approach without fear, within the distance of a musket shot, and may wait for a pilot, as convenient; but if obliged to take the anchorage without one, they must steer from Point Picolet S. E. and S. E. by E., leaving a white flag (if there) on the larboard hand, and which, placed upon the northern extremity of a reef, serves for a beacon, taking care to carry plenty of sail to clear a red flag, which they will see a little afterwards, and which must be left half a cable's length to the starboard; and so soon as they have this flag on their beam, they may steer for the city, and anchor in from 7 to 9 fathoms.

Those who go out from Manzanilla or Bayaha (Port Dauphin) to the cape, ought to steer to the northward until Picolet Point bears to the southward of the true west, and then direct their course to the west, as convenient; for they will be clear of the white bank off Point Picolet; but if bound to the east, they must run to the northward until the Grange Point bears to the southward of the true east, in order to clear the Seven Brothers' Bank.

The Count Chastenet de Puysegur, in his directions for the coast of Hayti, gives the following for Cape Haytien, &c. These were written in 1787, but they include some descriptions not given in the Derrotero, and we therefore insert them here, with a trifling correction.

"Ships bound from the eastward to Cape François always make the Grange; for the coast in the environs of the cape offers nothing remarkable, unless they be near enough to distinguish the hummock of Picolet, and the rock of that name, lying to the north, and very near the hummock. Having brought Monte Christi to the south, distant about a league and a half, the proper course, in order to fall a little to the northward of Picolet Point, is between the W. S. W. and S. W. by W., distant 9 leagues.

"The mark is surer, when you approach the cape from the Grange, in steering W. S. W. and S. W. by W., for in this last position, the hummock of Picolet must appear to project in the sea more than the rest of the coast. The best mark that can be given is, that the hummocks which are to the west of the road of the cape, are the highest of all this part; besides, you can distinguish in them large white spots. With some attention you will discover Point Picolet, which is lower than the said hummocks, and seems to lose itself among them. This point terminates the road of the cape on the west side; in coming near, you descry Fort Picolet itself, built upon the point, at whose end lies the rock of the same name, which is not discernible at a greater distance than a league.

"So soon as you have descried Fort Picolet, you steer directly against it, because you must sail very near that fort to enter the road, whose opening is bordered with dangers or keys, which you leave on the larboard in coming in. We would advise no stranger to attempt the channel without a pilot, for whom he must wait in the offing.

"At half past ten the wind comes to the E. S. E. but it must blow from the N. E. to carry you into the harbor, for you are obliged to steer S. E. and even E. S. E. The breeze is very regular. The land-wind blows in the evening, and often during the night; but about 10 or 11 in the morning, after an interval or calm, it turns to the E. N. E. or N. E. So that at 12 o'clock ships are able to enter the harbor.

"The city of Cape Haytien is under Picolet Mount. There is no danger in running in for Picolet Point, if you keep it bearing from S. S. W. to S. S. E. Should you not have time to wait for a pilot, you must range along Picolet Point, having it about S. or S. S. W. at the distance of a short musket shot.

"To sail into the harbor, bring Point Picolet to bear S. by W.  $\frac{1}{2}$  W. and steer S.  $\frac{3}{4}$  W. A remarkable mountain, called the Bishop's Cap, will then be seen directly ahead; bring this mountain, which appears in three points, in a line with a remarkable hummock, by the water side, in the harbor, which will bear S. by W. Steering in this direction will lead to the westward of the outer reef, named *Le Coque Veille*. The water generally breaks on this reef, which has (or had) a buoy, or white flag upon it. Continue in the same direction, leaving the buoy at the distance of about 15 fathoms on the larboard side, until a small rock, standing detached a little from Picolet Point, appears just open of that point. Now haul to the S. E. or S. E. by S., keeping the rock just open, and you will pass between the *Coque Veille* and *Le Grand Mouton Bank*, a bank having a buoy or flag on its eastern edge, which is  $\frac{1}{2}$  ft on the starboard side. The *Petit Mouton*, a danger that always breaks, and a short named *Trompeuse*, with a buoy or white flag on it, are to be left on the larboard side. You must, therefore, have sufficient sail out to weather round the *Grand Mouton Bank*, giving the buoy or flag upon it a berth of half or two thirds of a cable's length; and having passed it, steer for the town, and you may anchor where you please, in 8 or 9 fathoms, good ground.

"A ship cannot enter the harbor unless the wind be at N. E., as she is obliged to steer S. E. by S., and even S. S. E. The breezes are very regular; they come from the land in the evening, and very often during night; but at about ten or eleven in the morning, after an interval of calm, they chop about E. N. E. or N. E. Strong norths have a great swell into the bay."

"The town is on the western side, about 2 miles from Point Picolet, in lat.  $19^{\circ} 46' 20''$ , long.  $72^{\circ} 14'$ .

**PORT FRANCOIS.**—From Point Picolet the coast trends west to Honorat Point, which is the north point of Port Francois, whence a reef stretches out, a cable's length to the N. W. At its extremity are 3 fathoms of water. The anchorage off Port Francois is in a small bay, and about two cables in extent. Between the points of the bay there is good shelter from the breezes. To enter, you must run along the edge of the reef of Honorat, which is on the north side; and after having gone about two cables to the S. S. E. you may anchor in 8 or 10 fathoms, on clayey sand, about S. W. by W. from the fort.

**BAY OF ACUL.**—From the south point of Port Francois, a reef extends as far as the entrance of the Bay of Acul, without leaving any practicable pass. The Bay of Acul is extensive. It has three entrances, but the western is the best, the eastern being narrow and devious. The first entrance is between Rat Islet and Sandy Islet, situated on the reefs extending from Port Francois, and which shut in the entrance to the N. and N. E. That to the N. W. is shut in by other reefs and shoals, which, though among themselves they have only difficult and narrow passages, form an excellent channel with the west coast of the bay. The three channels into the harbor are called the East, the Middle, and the West or Limbe Channels. To enter any one of these channels, it is necessary to approach on the outside of the White Bank, extending along shore between Port Francois and the Bay of Acul until Rat Islet bears S. by W.  $\frac{1}{2}$  W., and so soon as you are a league from the Sandy Islet, you will plainly see *Trois Maries' Point*, which is the eastern point of the bay; and approaching nearer, you will also see a low point on the western side, in the interior of the bay, named *Point Belie*, which is known by a clump of trees that is upon it. Having recognized these points bring them in a line, and steer in with this mark, keeping by small variations of course, the depth of 10 fathoms. Thus you will run in mid-channel, which is not more than a cable's length wide, and the bottom of clay. On both sides of it there are white banks, with 4 fathoms of water on their edges. It is necessary to notice that you must have recognized the two points which serve for the leading mark at two miles from *Trois Maries' Point*: for from that distance it is necessary to come in by the mark described. In thick or hazy weather, when these objects cannot be seen at the proper distance, you must not attempt to enter by this channel. At about four cables' length within, the channel begins to widen, so that when Rat's Islet, which you leave to the starboard, bears N. W., you may anchor in from 14 to 18 fathoms. All the reefs which lie within Rat Island are visible.

To enter S. by E.  $\frac{1}{2}$  in 9 fathoms of a league to approach or S. E. by Islet, and you may a danger in but if you In case there will be free are sheltered

ANSE A of Margot, w very useful two miles we you must keep you have p moment you This happen bay, there is depth, and is

FOND L Fond la Grande named Palm west, and almost of necessity,

To enter by the Middle Channel, you must run outside the bank until Rat Islet bears S. by E.  $\frac{1}{2}$  E., and placing the prow in that direction, steering that course, and keeping in 9 fathoms of water, you will pass very near to some reefs which are about one quarter of a league to the northward of Rat Islet. These are easily seen, and it is necessary to approach them within a cable's length, on the larboard hand, and to luff up to S. E. or S. E. by E. to pass along the north side of that which stretches to the east from Rat Islet, and which must be left to starboard. Having once got to the S. E. of Rat Islet, you may anchor, as above stated. All the reefs show clearly, and therefore there is no danger in taking this channel when the winds allow you to shape the proper courses; but if you cannot do this, you ought not to take it, as there is not room for working in. In case the wind becomes scant in the channel, you must anchor in a moment, and you will be free from danger; for the holding ground is very good, being hard clay, and you are sheltered from the swell of the sea.

The West or Limbe Channel is the best and widest, for you may work in it, if requisite. To enter by this channel, run outside the banks or shoals, until Point Icaque, on the west side, bears south. This point lies between Limbe and Grand Boucand Points. That of Limbe is the north-westernmost, and has an islet at its base.

Point Icaque is easily known by the scarped or bluff rocks which form it; and from its being the only one of any elevation lying to the south of Limbe. So soon as Point Icaque bears south, steer towards it, and as you get near it you will see, to larboard, the breaking of a reef of considerable extent, named Coqueville, on the edge of which there are 5 fathoms of water; having recognized this reef, taking care to pass in mid-channel between it and Point Icaque, in 10 or 15 fathoms of water, and with nearly a S. E. course, with which you must run in, amending successively a little to the east, to pass about 3 or 4 cables' length from Grand Boucand Point. You may then anchor to the west of Trois Maries' Point. If obliged to tack, you must prolong the tacks until very near the reefs, on the supposition that their breakers afford the best marks for avoiding them; and that, at the very edge of them, there are 5 and 6 fathoms of water. You may also prolong the tacks to a cable from the coast, without any risk; for though Boucand Point is foul, the reefs show above water, and have 8 and 10 fathoms up and down at their edge. The anchorage, or place which we have assigned for anchoring, between Rat Islet, Trois Maries' Point, and Boucand Point, is not properly that which is called the Bay of Acul; but as there is good shelter in it, those who have no occasion to make a long delay, or to discharge, may avoid entering the bay.

To enter the Bay of Acul, you must not approach Trois Maries' Point nearer than three cables' length, for it is foul and shallow; and so soon as you are past it, steer towards the point of Morne Rouge, (Red Hill,) on the east, which you must pass at about half a cable's length, in order to give a berth to a shoal which lies off Belie Point, opposite. Having passed Morne Rouge Point, you will see a fine cove, on the same side, called the Lombard Cove, in which you may anchor in 7 fathoms water, at about a cable's length from the shore. From this cove southward, into the interior of the bay, there are many shoals; and no one should pass the cove who has not a practical knowledge of them. In the route above described, you will always find from 10 to 15 fathoms of water, on clay.

Between Trois Maries' Point and that of Morne Rouge, in a line with them, and about half a mile from the first, there is a shoal of small extent, which you will shun by taking care to pass at not less than three cables' length from Trois Maries' Point, and not to place the ship's head towards Morne Rouge Point until you are at half the distance between the two points. The anchorage of the Lombard Cove is a natural rock. In Acul Bay it is difficult to get water; the best is on the eastern side of the cove, between Trois Maries' and Morne Rouge Points.

ANSE A CHOUCOU, OR CHOUCOU BAY.—To Point Limbe follows that of Margot, which has a round islet, lying rather farther out than that of Limbe. It is very useful to make this islet, in order to direct yourself to Chouchou Bay, which lies two miles west from it. In this bay there is a good depth of 6 or 7 fathoms; to enter it you must keep towards the east point, which has 6 fathoms close to it; and so soon as you have passed it, and the vessel begins to lose headway, you may anchor; for the moment you enter under the point the breeze calms, and the little you have comes ahead. This happens even when the wind is very fresh without the bay. To the west of this bay, there is a small one, called La Rivière Salée, or Salt River Cove, which has little depth, and is fit for small craft only.

FOND LA GRANGE.—Four miles westward from the Bay of Chouchou is that of Fond la Grange, or the Grange Bottom, 600 fathoms broad, and the west point of which, named Palmiste, is distinguished by a chain of reefs extending nearly a league to the west, and almost to Point d'Icaque. Fond la Grange is a good roadstead, and in case of necessity, a ship of the line may ride in it; for throughout it there are not less than 6

fathoms water, and at less than a cable's length from the shore. To enter in it, you must pass near the east point, and anchor in about the middle of the bay, on clayey sand. At a short league westward from Palmiste Point lies that of league. The coast between is foul, with sunken reefs, which advance half a league out to sea.

**PORT PAIX.**—Eight miles from Point d'league is that of the Carenage, which is the northernmost headland of this part of the coast, and which, from a distance, may be mistaken for Point d'league. The coast between is very clear. From this point the coast trends S. W. by S. to form the cove of Point Paix. To enter here you must avoid the east shore, because from a point which lies a little to the N. E. of the town, a reef stretches out about a cable's length, and immediately without it there is a depth of 13 fathoms, with oozy sand. To avoid this reef, keep in the middle of the entrance, which has only three cables' length in breadth, and anchor to the N. W. from the town, in 12 or 13 fathoms, on clayey sand, about a cable and a half from the shore.

**CHANNEL OF TORTUE.**—Nearly north from Point d'league is the east point of Tortue or Tortugas Island, which extends nearly east and west, and, in that direction is about 6 leagues in extent, but only 1 from N. to S. All its north side is iron bound, and steep to, and the south side is for the most part bounded by a white shoal and reefs. The only good anchorage in Tortue is that of Basseterre, on its south side, at a league and a half from the east point. It is formed by the shore and the reefs which run out from it, and no vessel drawing more than 14 or 15 feet can enter it. The passage is narrow, but easy to fetch. You must keep the weather reefs on board, leaving them on the starboard hand, and steer N. N. W. and N. to double the reefs you leave on the larboard hand. Do not be afraid of coming near the land, and anchor in good ground so soon as you have brought the lee reef to bear S. W. Large ships may come to anchor outside the reef, upon white ground, a mile to leeward of Basseterre.

To the eastward of Basseterre, towards Portugal or the east point, there are several bays or coves, in which boats or schooners may anchor, but nothing of a larger size.

The channel which the Isle Tortue forms with Hayti, is 6 miles wide, and fit for every class of vessels, which may commodiously beat in it, and often with great advantages for getting to windward, when the currents in it run to the eastward, which they do for the greater part of the year; for rarely, and only during souths, do they change their direction to west. In the latter case, it is necessary to advance northward, and get 6 or 7 leagues from the Tortue, to beat to windward. When beating in the Tortue Channel, you ought to stand on within less than a mile of the coast on every tack; for towards the coasts the current is stronger, and the wind more favorable, than in mid-channel. As there are several bays on each side, the setting of the current is neither uniform nor in the same direction. You will sometimes see it run in numerous directions; and sometimes, in the middle of the channel, it will run contrary to the current in shore.

**PORT PAIX TO ST. NICOLAS' MOLE.**—Four leagues from Port Paix lies Port Moustique. The coast between is clear, and bluff or scarped. Port Moustique has scarcely an opening of 4 cables' length: its bottom is unequal, and impeded with rocks, which render it necessary to examine it with the lead before you let go an anchor; for between the two outer points you cannot find bottom with 40 fathoms of line.

At a league and a half from Port Moustique is Port a l'Ecu, and the coast between the two is rocky, steep to, and bluff. This cove is better than Port Moustique, but not so easy for large ships, as its entrance is narrow, in consequence of a reef which stretches off about two cables' length from its eastern point, and upon which there is not more than 3 fathoms water. To take this anchorage, it is necessary to keep near to the reefs off the east point, and haul by the wind, ranging along the reef, to anchor in 8 or 10 fathoms in the centre of the cove, on clay, and about N. N. E. from a house which is at the bottom of the bay.

Six miles from Port a l'Ecu is the anchorage of Jean Rabel, which is good, safe, and easy to take. On approaching this place you ought, without any fear, to approximate the reef on the east side, which has 10 fathoms close to its edge. The anchorage for large ships is about two cables' length from the eastern breakers, in 12 or 15 fathoms; and care must be taken not to shut in the two points which are on the east coast, for though it is possible to run farther in, yet it is not advisable; for the depth suddenly diminishes, and the bottom is not very clean.

Should you be to the north-west of Jean Rabel, at a short league's distance from the land, and have half the island of Tortue open with the point, you will find 60 fathoms of water, oozy ground, and a little farther out 80 fathoms.

From Jean Rabel the coast forms a great bight to the southward, as far as the peninsula, called Presqu' Isle, or the Mole, the western point of which, called the Mole Point, lies 13 miles W. S. W. from it. All the shore between is rocky, and does not offer any shelter. At all times the currents here are very perceptible near the shore, and generally set on it. At two leagues in the offing they are less so, and run to the north-east. Near the peninsula they are much stronger, and commonly set towards the north.

**ST. NICOLAS' MOLE, BAY OR HARBOR.**--This harbor is large and spacious at its entrance, but narrows towards the town, which you will desery as soon as you have doubled the cape. You may stand very close to either shore, but it is advisable to allow on the south side more room for veering than on the north side, as there is no anchoring ground, which you have on the north side, though very near the shore. The anchorage is before the town, and under the barracks, in 15 or 18 fathoms, sandy bottom. In going in, you must be prepared against the pulls or squalls, which come down from the land with such violence as to endanger the masts.

Within the bay or harbor you will be sheltered from every wind. There is a fine river to water at, and places where a ship may be careened with her side to the shore. When it blows hard it is difficult to get to the anchorage; and if you are not quick in letting go, the anchor may fall from 6 to 30 and 35 fathoms.

The Derrotero says that the north coast from Cape St. Nicolas, sends out a white bank, which stretches about one third of a cable from the shore, and on which there are 3 and 4 fathoms water. The south shore has also its white bank, which extends out about a cable's length from an interior point S. W. of the town, upon which there is a battery. From this point the white bank extends directly to the Fort Point, the N. E. end of the town; and, therefore, when to the northward of that point, you must not prolong the tack to the south farther than to bring the north part of the town to bear east. You should also be aware, that on the south coast, and a little to the west of the above mentioned point, no bottom has been found; therefore you ought to look out and tack in time. On the northern tack there is not so much danger; for it is possible to let go an anchor, although it must be done very near to the shore. In the anchorage, which is well sheltered from all winds, vessels pass the dangerous season of the hurricanes.

In going out you will see, to the southward, the point of the cape which forms its entrance; and farther to the southward you will then desery the Point du Cap a Foux, or of Fool's Cape. The latter lies  $5\frac{1}{2}$  miles to the southward of St. Nicolas Point; and the coast thence extends  $2\frac{1}{2}$  leagues more, nearly in the same direction, to the Point a la Perle, or Pearl Point.

The sea-breeze at the Mole is from N. E. by N. It comes on at 8 in the morning, and blows very strong till 10 or 11 at night. The land-breeze comes on moderately at S. E. It continues till 6 in the morning, then dies away, and it is calm till 8. If bound to the northward, ships generally weigh at 8 or 10 at night, when the sea-breeze begins to slacken enough to run them out.

*Directions for Ships bound to Cape Haytien, &c., from the Westward.*

In advancing from the westward towards Cape Haytien, give the N. E. part of Tortue Island a good berth; and after you get to windward of the east end of the island, you will desery the cape.

The land to the west of Port Paix shuts, to the northward, a low point, and rises gradually towards the south to a high mountain, with a sugar-loaf top, and then it declines on the same side to a large valley, whence it rises quickly to a prodigious high mountain, smooth at the top, and the highest land in this part of Hayti. The high land after this, to the southward, is of sugar-loaf form, with a little one to the south of it, which are both 10 or 12 miles in the country. The next high land, or point, which is seen by the water side, is Cape Haytien. The land, at first, makes like a saddle; but on nearer approach, a low point will appear, which shuts from the eastward the eastern part of the saddle-land. This is Point Picolet, or the Cape Land, the extremity of the cape already described.

**MANZANILLA BAY.**--Ships from the westward may with safety proceed to Manzanilla Bay. It is quite clear, and you may approach within one third of a mile in every part of it.

The Seven Brothers, which have been described, are mostly barren, with reefs about them. There is some wood upon them, and plenty of fish all round. You need not approach the western part of them nearer than two leagues, until you see the bay. On advancing into this, there will be found 10 fathoms water, at about three quarters of a mile from shore.

The River Massacre, formerly a boundary of the Spanish and Haytien territories, falls into the bay, to the eastward of Port Dauphin; but it will be very difficult, if not impossible, to water there, as you must go up the river nearly two leagues to obtain it.

To anchor properly, so as to have the best shelter, run along the inside of Manzanilla Point, and drop it in 6 fathoms, muddy bottom. All the anchoring places are within the Spanish line, where the land is low, marshy, and covered with mangroves. The bay is as easy to go in as to get out, having regular land and sea-breezes, and being quite se-

cure from any swell. A ship, having lost her anchors, may run in upon the muddy shore. The landing is very easy. Here is game and fish; and bullocks, cows, and hogs, may be purchased.

The ROAD OF MONTE CHRISTI is more open than Manzanilla Bay, although in it there is good anchorage, well sheltered from the N. E., E., and S. E., which are the strong breezes; and during the norths you may anchor in 5 or 4 fathoms, under Cabra, the islet of Monte Christi. The same resources may be found here as in Manzanilla Bay.

"The anchorage at the Grange," says an able navigator, "is less spacious than that under Point Ysabella, but it is more sheltered from the norths by the islet. Ten ships of war might easily be anchored, in from 5 to 7 fathoms, within pistol shot of this islet, which makes half a league distance from the islet to the reef that is as far from the shore. We had four strong breezes, which might be called gales of wind, yet we rode with only half a cable, and had not occasion to freshen hawse.

"The islet Cabras, or Cabra, is nearly half a circle of 200 fathoms diameter, and has a hillock about the height and length of 30 feet, with a cut in the middle, of near 10 fathoms; and this is what breaks off the sea and winds. The French had made there a very good salt-work, which the Spaniards have let go to ruin. It differs from those at Turk's Islands, produces better salt, and is more convenient, as you may introduce the salt water as you want it, in the several pans.

"The landing is easy every where. Very good hay is made on the island: it is a kind of dog's grass, which they pull up by the roots. That which grows by the river's side is coarser. The river (St. Jago) is one league from the island to the S. W. of the town, and marked by a tuft of trees. The water is very good, and easily got. The boat may go in at high water, and at about half a cable's length within, you will find it fresh, the current being so strong that the salt water cannot get in. You have commonly a quarter-wind to fetch it in, and bring it back. Here is very good fishing, and you may haul the seine, as well as near the shore. On the larboard side of the town, about a league from the shore, it is good shooting. You will find plenty of wood-pigeons and India fowls."

*The Western Coasts of Hayti or St. Domingo, between St. Nicolas' Mole and Cape Tiburon.*

In proceeding from St. Nicolas' Mole, as already observed, you will descry to the southward the Point du Cap au Foux, or of Fool's Cape, which lies  $5\frac{1}{2}$  miles to the southward of St. Nicolas' Point; and the coast thence trends  $2\frac{1}{2}$  leagues more, nearly in the same direction, to the Point de la Perle, or Pearl Point.

This part of the coast is steep, without any shelter; but here it is generally a calm. The currents in-shore set to the northward, and two leagues in the offing, to the W. and W. S. W.

PLATTE-FORME OR PLATFORM, &c.—From Point de la Perle the coast rounds to the south-eastward and east, to the point of the Platform, which is at the distance of 3 leagues from the former. This point is easily distinguished, as well by its flat form as by its being the southernmost of this part of the island. The anchorage is before a small sandy cove, at the bottom of which some houses are seen. You anchor near the shore in 8 or 10 fathoms, weedy bottom. At this place water may be obtained after rains, but there is none to be had at other times.

To anchor under the Platform, bring its southernmost point E. by S., the westernmost point in sight W. N. W., the watering place N. N. E. Then come to in about 9 fathoms. In deeper water the ground is foul; and the nearer the shore the clearer the bottom. The bank is very steep for two cables' length. Without, 10 fathoms soundings will not be found. The bay is very convenient for cruising ships to heel and boot-top in, &c.

From the Platform Point to Point a Pierre, on the north side of the entrance of the Port of Gonaives, the bearing and distance are E.  $18^{\circ}$  S., 10 leagues. The point is high and steep, and all the coast between is safe, and may be ranged very near. There is anchorage, even for large ships, at Henne Bay and at Port Piment, but it ought to be used only in case of necessity. In the winter months there are tornadoes or gales of wind almost every night, coming from the S. E., some of which are violent; and unless you have business on this part of the coast, it is best to stand off two or three leagues, so that you may, with any wind, keep to the westward.

GONAIVES.—The bay of Gonaives or Gonaivees, as the French pronounce it, is very large and fine, the anchorage excellent, and the entrance very easy. You range along the shore, at half a league or two miles distance, steering nearly east, and let go your anchor in from 10 to 6 fathoms, ooze. You will find from the entrance under Go-

Gonaives Point, which is low, and one mile east of Point Pierre, 15 and 12 fathoms: the water decreases as you get into the bay. When you are a good half league from the land, and two miles from the Debercadaire, (or landing place,) you will have 6 fathoms. After you have doubled the point, leaving it on your larboard hand, you will see Fort Castries on a point of land, which you must not approach too near, as there is a key that lies about a mile south of the point.

Observe that from the south point of the entrance, a reef extends to the N. E. to the distance of a quarter of a mile. It is nearly steep to from 6 fathoms.

Captain Mackellar says that the harbor of Gonaives is an excellent one, and capable of containing any number of ships of the largest size, completely shut from all winds; it is of very easy access, and generally clear, excepting a small reef that extends about 2 cables' length from Fort Castries, on the north side. The latitude of the town is  $19^{\circ} 26' 41''$ , and its longitude  $72^{\circ} 41' 7''$  W. Var.  $5^{\circ} 50''$  E. 1817.

Ships intending to anchor at Gonaives, and having advanced to Point Pevis, on the north side of the entrance, will gain soundings in 15 or 16 fathoms, and have the town in sight, bearing about E. by N. they may proceed for the town on that bearing, keeping in mid-channel, or any way near it; then soundings will be very regular. When well up the harbor, you will see Fort Castries, which stands on the north side, on the top of a small hill, about a mile without the town. When this fort bears N. by E.  $\frac{1}{2}$  E. you will have 7 fathoms in mid-channel, fine soft mud. When it bears N. by W.  $\frac{1}{2}$  W. in  $5\frac{1}{2}$  or 6 fathoms, this seems to be the best anchorage, and as close in as a ship of war ought to go. I have been so far up the harbor as to have Fort Castries bearing N. W. in 4 fathoms; but the best anchorage is with it bearing N. by W.  $\frac{1}{2}$  W. and the middle of the town E.  $\frac{1}{4}$  N. nearly in mid-channel.

The soundings all over the harbor are so very regular, that it is not necessary to have marks for running in and out by; but in the event of having to beat with the sea breeze, you must not stand too near Fort Castries, as there is a small reef extending from it to the southward: the mark for keeping clear of this reef, is a large tree behind the town on with the northernmost houses, bearing E. by N.; but this reef stretches to so short a distance that a ship will scarcely stand so near the shore as to touch it. In standing to the south side of the harbor, give the shore a good berth until without the inner point, and after that you may stand from shore to shore, by your lead, with safety.

ST. MARK, OR ST. MARK.—From Point St. Pierre, without the entrance of the Bay of Gonaives, the distance to Cape St. Mark, in a direction nearly south, is nearly seven leagues. A league and a half to the northward of St. Mark's Bay is a low point, which appears at a distance like an island, and forms a cape that is called La Point du Morne au Diable, or the Devil's Bluff Point: it points out the mouth of the River Artibonite, which falls into the sea two miles northward of the point. There is an anchorage the whole length of this coast for small vessels only.

Cape St. Mark is high, and of a round form; you will descry at a great distance the hillock which forms it, and stands only one mile from the sea side.

The opening of the Bay of St. Mark, lies to the north of the cape; it extends one league within the land, and the water in it has a great depth. Ships anchor in the bottom of the bay under the town, in 15 or 18 fathoms of water; small vessels may come into less water, but they will be very near the shore. In the south side of the bay is a piece of foul ground, extending two miles from a bluff point to the S. E., and on which a reef stretches out about two cables' length from the coast.

*The following Description of the Navigation between the Platform and St. Mark, is given by Capt. Hester, an eminent English navigator.*

About 9 leagues eastward of the Platform is the fine bay and harbor of Gonaives. All along this coast you are sure, about 10 o'clock in the forenoon, to have the sea breeze, which lasts till night, and then you have the wind off shore; therefore you may stay till that time, before which there is little or no wind at all. If you intend to go into Gonaives, you must keep a good distance off the south point, which is flat for a considerable distance. When you are about the point open with the bay, you will descry a small island, which you must leave on your larboard side and run in with your lead in 10 or 12 fathoms of water. You may also run along close by the island if you choose, in 4 or 5 fathoms.

About two leagues to the southward of Gonaives is Artibonite Point, and two leagues farther south, Artibonite River. In sailing from Gonaives to the latter place, it is good to keep your lead; for, as you come near the river, you will find the water shoalen to about 4 fathoms, and after that deepening again to 7 or 8 fathoms.

"This place is very remarkable, the land being high and uneven and a bold clear shore all along to the northward, from the Platform to Gonaives. When you have run 8 or 9

leagues E. S. E. ! E. you will then see the land ahead, or eastward, very low by the water side and prodigious mountains over it ; this low land reaches from Gonaives to the southward of Artibonite River, about a mile ; and its south end, somewhat higher than the rest, appears like a table land, overgrown with weeds and green trees ; this is the Devil's Bluff : round its south end is the Bay of St. Mark, the other point of which you can see to the S. W. of the Devil's Bluff. To anchor off the river bring the south end of the low land to bear south three miles distant, and as you run in, you will see five or six small houses by the water side ; bring them to bear E. S. E. two miles ; then the river will bear S. E. On the starboard side, or the south side of the entrance of the river, there is likewise a small hole where you may see. Be sure to keep these bearings, and you will be upon a fine level bank, where you may anchor in what water you please, from 20 to 6 fathoms. But if you go within 2 miles of the shore you will drop off that bank from 6 fathoms to 20, the next east ; then 50 or 60, and then 90 or 100 fathoms, within less than half a mile of the shore, and from that to 5 at once. When you are at anchor at Artibonite, you may see the Platform, bearing W. N. W. about 10 leagues.

"Artibonite River is not a place of great note, because it ebbs almost dry at low water ; neither is there any town in this place, but only some plantations five or six miles up the river ; there you can have good water but no wood. The sea wind comes on at noon at N. W. till 10 at night, and the land wind at E. by S. till 8 in the morning."

From St. Mark's Point the coast of Hayti trends nearly S. E. true, six and a half leagues to La Souffriere, or Vazes Point, and thence E. S. E. five leagues, to Port au Prince. The coast is generally clean and bold, and you may run along it at the distance of a mile, in 10, 15, and 20 fathoms of water. In proceeding thus, you will first perceive the Magazine of Montrou, and afterwards the villages of Arcachais or Arcachave, and Boucassin ; and finally the city of Port au Prince. Off the coast, at about half way between St. Mark's Point and Port au Prince, are three small islets, called the Arcadins, which are situate at nearly a league from the shore, and separated by channels about half a mile in breadth. Near these islets, on every side, the depths are 5 and 6 fathoms.

To the E. by S. of Boucassin, and very near the coast, is Mouton or Sheep Key. A passage ought never to be attempted within this key ; near it, on the outside, the coast is clear and water deep. About two leagues to the southward of this island is the roadstead of Foso ; this to the N. E. and Lamentin Point to the S. W. form the entrance of the Bay of Port au Prince. To the westward of this roadstead is an extensive bank, with a cluster of islets, of which the easternmost is distant about two miles from Foso Roadstead, and the southernmost three miles from Lamentin Point. There are, besides, two other islets, which lie almost in the direction of the two points of the bay, and which are four miles from Foso Road, and two from Lamentin Point.

**PORT AU PRINCE.** \*—The shore at the bottom of Port au Prince Bay is very foul, and has a large group of islets. These form the inner anchorage ; and to gain this, the aid of a pilot is indispensable ; but the Grand Road is without the reefs, and may be entered without a pilot.

Those bound to Port au Prince from the N. W., after having made St. Mark's Point, may shape their course, either to pass between the Arcadins and the coast, or between them and the island Gonave : the first appears to be the best route, for thus the foul grounds on the S. E. side of Gonave must be avoided : it is also to be observed that the wind in the channel is generally from the N. E. ; the nearer, therefore, you pass to the main land, the more free will you run to the eastward. Again, almost every afternoon, in the rainy season, there are tornadoes in the channel, which compel vessels to lie to, and to keep on boards or tacks, that they may not fall upon the reefs of Gonave. If you can foresee the gale, it will be best to gain an anchorage near Arcachais Point, and there ride it out. † When past the Arcadins, your course will be about S. E. by S. to get near Lamentin Point. If caught by night to the eastward of this point, here you may anchor. From the point to the anchorage of Port au Prince, the distance is four miles ; and to make it you must steer towards the city, and anchor about half a mile outside the islets, in 10 or 15 fathoms.

The channel between the Arcadins and coast is two miles wide, and in the middle of it you will never have more than 28, nor less than 10 fathoms. The water decreases towards the Arcadins to 6 or 8 fathoms corally ground ; at the same distance from the opposite shore is the like depth with muddy bottom.

From Pearl Point to the entrance of St. Mark's Channel, mid-way between Cape St.

\* See Plan by Com. R. Owen, published by E. & G. W. Blunt, 1833.

† Or, you may anchor to the northward of Leogane, on the south side of the channel, upon the ground extending from Gonave Island, as shown in the chart.

between Cape St.

channel, upon the

Mark, and the Island of Gonave, the course and distance are S. E.  $\frac{1}{2}$  E. sixteen leagues. This will bring you to the westward of Cape St. Mark, for which you may steer; or, you may continue the same course six leagues farther, which will lead clear of the Arcadins.

Should it be night when you enter the channel of St. Mark, you should steer S. S. E.  $\frac{1}{2}$  E. in order to clear the Arcadins and the eastern end of Gonave Island. Having run about four leagues on this track, the course will be about S. E. by E. five leagues, to make Point Lamentin, which is on the south side, to the westward of Port au Prince. You may range along this coast without fear, only avoiding the shoals of the sandy key, which lie at a short league northward of the point. Should you pass this point in the night, you would do right, after you have run a mile or a mile and a half, to anchor; you will find 12 or 18 fathoms water, the ground good and the water always smooth.

You may be forced to turned in this channel, but you must not go so near to the Gonave as to the St. Domingo side; the latter being safe, may be approached any where within half a league.

The Arcadins, as before noticed, are not to be feared; a shoal stretches out from them a mile, or half a league at most, with 5 or 6 fathoms on it; on the edge of the west and south-west sides you will have from 12 to 15 fathoms, corally ground; but there is good ground to be found in 8, 12, and 13 fathoms, coarse sand and shells.

**GONAVE ISLAND.**—The greatest length of Gonave Island is 10 leagues E. S. E. and W. N. W., its breadth, which is very regular, is nearly two and half leagues.

This island was surveyed in 1787, by M. de Lieude de Sepinanville, who has given the following description of its coasts, and the adjacent dangers.

The most dangerous reefs are those which lie to the S. E. of Petite or Little Gonave, which is situate near the S. E. point of the great island. These seem to be joined with the land of the Little Gonave, and stretch more than a league into the offing, lying at about 800 toises, or nearly a common English mile from the shore. A vessel may pass, in an urgent case, between them and the Little Gonave, but the attempt would be imprudent, especially if the wind be not well set in, as the currents are very strong and irregular. I have observed, however, that in this part, they run more generally to the N. N. E. and between the two Gonaves.

Small vessels, drawing 8 or 9 feet of water, may find a good anchorage to the west of the Little Gonave, which may be best entered from the southward.

The N. E. point of Gonave, called Galet Point, is low, and bordered with a reef, which stretches along the east coast, towards the south, and extends 1100 toises (1170 English fathoms) opposite the place called Trou a l'Eau, or Water Hole: within is a white ground, where there are from 4 to 6 fathoms of water.

To sail near this reef, which every vessel can do that draws 9 or 10 feet, you must, in coming from the east, take a channel which is opposite to a fisherman's hut. There are several other channels, which are easily known by the non-appearance of white ground. About 88 fathoms within the reef, you may range along the coast as far as Anse a Galet, or Galet Cove, in case the wind should fail. There is anchorage every where; but the places to be preferred are Piron Cove, Consantin's Hole, and especially Galet Cove, which are very convenient; the hold is good, and the reefs shelter you from the swell of the sea.

The several anchorages on the north coast, for boats or schooners, are, L'Islet a Mare, Grand Lagoon, and Bahama Channel, where you are equally sheltered; the remainder of the coast is likewise bordered with reefs, but they are very near the shore, and you find there no anchorage.

The western part is an iron-bound coast, along which you may range pretty near; but it is not so from the S. W. point of Point-a-Retoures, where you may find a number of small detached reefs, almost even with the water. Several small vessels may anchor in that part, on the spot named Les Baleines, or the Whales, but not without a pilot well acquainted.

The only place where two or three large ships, such as frigates, can anchor, is La Baie du Parc, or Park Bay, which lies to the N. W. of Point Fantansque, the south point of the island; but coming into it is dangerous, on account of several detached reefs, which are never seen.

**ROCHELOIS.**—The reef called Rochelois had been fatal to many ships, and was still much feared by navigators, its true situation having never been well ascertained: it lies in the channel which separates the south coast of the Gonave from that of Hayti. M. Le Compte de la Luzerne ordered me to survey, and determine the position of that reef. I went and anchored within a cable's length of the rocks, which are above water: I landed on these rocks, where I took four observations of latitude, as well as the bearing of all the objects in sight; and, having measured the whole extent of the shoal, I found its breadth to be 2000 toises, (2130 fathoms) in a direction N. and S. nearly, and its length 3155 toises (3360 fathoms) from E. to W.

The rocks, called Pirogues, which are towards the middle of this reef, were already known; I found their extent to be 125 toises (133 fathoms); they are quite uncovered at low tide, but three heads only are perceived at high water. M. Le Compte de Chasteney Puysegur, who had no occasion to explore the extent of this reef, says, in his account of the navigation along the coast of St. Domingo, that the rocks, which show themselves at low water, are the only things to be feared on the Rochelois; but I have found two other shoals of very small extent, which are very dangerous, since they have only two fathoms water. They lie to the N. W. of the rocks in the middle, one at 800 toises distance, and the other at 300. There may be some other dangers on the Rochelois, but I could not make myself sure of it, having been only four days on that expedition. Prudence requires, that with a large ship, you should avoid it entirely: there is more room for tacking to the north of that reef than to the southward of it: you are only to keep at the distance of one mile, at least, from Gonave, if you pass by the north; whereas, in passing by the south, you may range along the Haytien coast, which is clear and safe.

The latitude of the middle of the Rochelois, deduced from the four observations, is  $18^{\circ} 37' 20''$  N.

**PORT AU PRINCE, to the WESTWARD.**—On leaving Port au Prince, when bound to the Petite Goave, you may range along the south coast, at the distance of one or two miles, all the shores being bold and safe, as far as Point Leogane.

From Point Lamentin to Leogane Point, there is no anchorage; but you will find a good bottom for anchoring between the latter point and the anchorage off the town of Leogane.

From Leogane, the coast trends to the south, and forms the bay of Grand Goave and Petite Goave, which are separated by a point and a hill, named the Tapion or Hummock of Goave. You enter into Petite Goave Bay, by leaving on the larboard hand an islet which is very near the coast, and which lies to the north of the town; to the westward of this islet you may anchor in 9, 12, and 15 fathoms. Petite Goave is 10 leagues from Port au Prince, but, as you are forced to double Point Leogane, the run is longer.

**MIRAGOANE.**—From the Hummock of Petite Goave to the Tapion du Trou Chouehou, or Hummock of Miragoane, the coast runs west eight miles, then W.  $\frac{1}{2}$  S. six and a half miles, to the careening island or Miragoane Bay.

To anchor at Miragoane, you come within a mile of the careening island, when you perceive a small town at the foot of a mountain, and some mangrove islands to the westward. You keep the mid-channel, between the first islet and the shore, where the village is situated, and come to an anchor within, in from 18 to 8 fathoms, sandy bottom. This anchorage ought not to be taken without a pilot; the channel is not more than a cable's length in width, and you must anchor so soon as you are within.

From Miragoane Careening Island, the coast bends in, and forms the bay of that name. It is shut in on the north by Frigate Island, a small islet, from which a white shoal extends half a league to the eastward, and nearly north to the anchorage at Miragoane, which obliges you, in coming in or going out, to keep the island shore very close aboard. From this place the coast trends west, to the village of Rochelois, which is situated at the foot of a large hummock.

From Miragoane the coast to the westward is clear and deep; and beyond Rochelois are seen the towns of L'Anse-a-Veau and Petit Trou. From the last, the coast forms a large bay, Baradares.

**BARADAIRES BAY.**—From the village of Rochelois to the entrance of the Bay of Baradares, the coast runs W. 5 leagues. Baradares Bay is formed on the S. E. by Roitelets Point, and on the N. W. by the Bec du Marsouin, or the Porpoise Snout; these points bear from each other nearly N. W. and S. E. four miles. Near the east coast of the bay there is an island, with several islets, which send out a reef and shallow that almost join the western coast, leaving a pass or channel, of only five or six cables' length in breadth. To proceed into the bay, you keep along the peninsula of the Bec, and come into from 8 to 10 fathoms. There is a good depth of water in the middle of the bay, which is of great extent; but there are several weedy shoals, which prevent your going in without a pilot, well acquainted.

**THE CAYMITES, &c.**—The northern extremity of the Bec de Marsouin, and the north part of Grand Caymite Island, bear nearly W. N. W. and E. S. E. four leagues.

The coast west of the peninsula of the Bec bends in to the southward, and forms a bight; thence, rounding out a little, it trends W. by N. as far as Point Jeremie. This bight and Great Caymite Island form a large bay, called Caymite Bay, where there is very good anchorage for all sorts of vessels. You may come to it without a pilot, and anchor under the island in what depth you choose. You may also proceed to Flamand's Bay, near the peninsula, ranging along the peninsula side, and anchor opposite a sandy beach, in what depth you please.

The Bay of Caymites presents several very fine anchorages, very easy to come at with the assistance of the lead alone; but there is not a good passage between the Grand Caymite and the shore; and you will not find more than 13 feet water upon the white shoals of the Little Caymite, or of Foucaud Islet; and then there are several coral rocks, which rise within two or three feet of the surface of the water, so that no vessel, but very small ones, ever attempt it without a pilot. These white shoals extend three leagues W. S. W. from the Grand Caymite.

**JEREMIE.**—From the north part of the Grand Caymite to the Point Riviere Salee, or Cape Rosa, which is one and a half league W. N. W. of Point Jeremie, is nine and a half leagues; this Salt River Point is the northernmost point westward from Port au Prince. Under Point Jeremie, is the village of that name, whose anchorage is very small, and not proper for large ships; schooners and small vessels may anchor within the reef, but no ships which draw upwards of twelve or fourteen feet should ever anchor here, except in case of necessity, there being no shelter for them; in short, it is a bad anchorage which must be avoided during the norths.

From Cape Rosa, or Salt River Point, to Cape Dame Marie, or Donna Maria, the coast trends W. S. W. thirteen miles.

All this shore is safe and bold, within a quarter of a league; it does not present any shelter, although in case of necessity, you might anchor in the Anse a Claire, or Clair Bay, which is  $1\frac{1}{2}$  league from Salt River. This bay, or rather cove, is so very small, that two ships, 100 feet long, would be embarrassed by each other: it can only serve as a shelter to very small vessels, and is easily discovered by keeping along shore.

**CAPE DAME MARIE, or DONNA MARIA.**—So soon as you descry Cape Dame Marie, by the False Cape of that name, and are half a league distant from it, you will strike soundings of from 15 to 18 fathoms, and may range along this cape, at the distance of a quarter of a league, in from 8 to 12 fathoms, weedy bottom.

*To anchor in the Bay of Dame Marie*, you must keep the shore on board, steering about S. E., the wind being generally adverse; and with your lead, you come to an anchor W. N. W. of a large white tapion or hummock, on which stands a battery, and within a musket shot of which you will find 5 fathoms. There is anchoring bottom all over this bay; a mile from the shore you will have from 4 to 6 fathoms, and at 2 miles from 5 to 10. You will be sheltered from the winds between the north and south, passing by the east; notwithstanding which, ships that lie in 8 or 10 fathoms will feel the swell, if there is a fresh breeze without. In entering, keep about half a mile off, but not less, in order to keep clear of a reef which extends to the length of a cable and a half to the west from the cape. Preserve this distance from the coast, until past the False Cape, to the southward of Cape Dame Marie, and which is also foul. When once past False Cape, you may haul to the wind, which is generally scant in the bay, to get the vessel's head to S. E., with which course, and keeping the lead going, you may gain the anchorage as above.

From Cape Dame Marie, the coast runs S. by W. 5 leagues to Point des Irois, and forms, at that distance, several bays and coves, where vessels may anchor. In general, a frigate may run in along this coast, with her lead, and anchor in any part, there being no shoals, or any danger under water, the ground gradually increasing towards the shore.

To the S. by W. of Cape Dame Marie,  $2\frac{1}{2}$  leagues distant, and about half a league off Point Ministre, or Minister Point, are some rocks, called Les Baleines, or the Whales. These rocks are above water, and surrounded with a white shoal which does not extend more than half a cable's length from them, and on which are four fathoms. A ship can sail between it and the shore. In the mid-channel she will have 6 fathoms, and may go as close as she pleases to take them on the off side. The sea always breaks on this shoal.

One league to the S. S. E. from the Whales, lies Pierre Joseph's Islet, where a convoy may anchor. The anchorage is very good and easy, and large ships anchor to the S. W. of the islet.

All along this western coast you have ground at two leagues from the shore, the depth gradually increasing as you leave the land; so that, in general, you will find four and five fathoms, at one mile distance; 10 or 12 at two miles, and regularly from 15 to 17, at 3 miles. When you get into 30 fathoms you will lose soundings suddenly.

**POINT DES IROIS, OR IRISH POINT**, as the English sailors call it, is the westernmost point of Hayti. It is not very high, though remarkable from a small hummock on its extremity, which appears detached from the coast, and makes like an island. This point forms the north part of the Bay des Irois, or Irish Bay. You may range very close to the land on the north side of the bay, there being from 9 to 18 fathoms, touching the shore.

The anchorage is to the N. W. of a black rock, which is seen a little way to the southward of the town. It is in from 9 to 10 fathoms, shelly ground. You may anchor like-

wise to the southward of the rocky islet, N. N. W. of a small hummock, towards the middle of the bay. The depth is here from 8 to 9 fathoms, sand and muddy ground.

The bay is exposed to southerly winds. There is always a great sea within, and the Debercadair, or landing place, is of course a bad one. It is situated in the eddy of the currents, which set to the northward, on the west side, and to the S. E. on the east coast. Besides, the sea in the offing is alternately agitated with violence by the N. E. and east breezes, which prevail on the west coast, and by the S. E. winds that blow from the south coast. Trois Bay is terminated to the south by Cape Carcasse, which, with Cap a Foux, or Fool's Cape, forms a large roundish point, whose end is at Cape Tiburon.

CAPE TIBURON.—These three capes, seen at a distance, form but one, which is called Cape Tiburon, and is very easily known by its form and height. It is a large mountain, very lofty, whose top is rounded like the back of a dosser, or French band-basket, and comes gradually down towards the sea.

Cape Tiburon, properly speaking, is 5 miles S. 25° E. of Irish Point, and forms the entrance of Tiburon Bay, which is to the eastward of it. Its situation is, lat. 18° 19' 25", long. 74° 27' 32". You will get no ground at 50 fathoms, two cables' length from the coast, between Cape Carcasse, and very near Cape Tiburon; but off the latter, at that distance, you will have from 24 to 30 fathoms, and a little further out, quickly less soundings.

On the North Shore of Tiburon Bay, the water is deep to within 2 or 3 cables' length of the rocks, and within half a cable's length you have 6 and 7 fathoms, stiff clayish ground. On the east and S. E. shores, you have 4 and 4½ fathoms, fine muddy ground within a cable's length, all round. The edge of soundings runs as the bay forms, half a mile from its head. You may anchor any where in the bay; but bring Point Burgos the south point, (which is foul,) S. by E. and the pitch of Cape Tiburon W. N. W. in 4 or 5 fathoms. From that to 8 or 9 is very good ground. Wooding and watering in plenty. You may either land your casks, and roll them over a narrow neck of land into the river, or fill them in your boats with buckets.

#### *Directions for making the Island Hayti, and its different Ports.*

[From the Derrotero de las Antillas, &c.]

If a vessel is bound to a port on the north coast, she may, as we have already shown at once get into the latitude of Cape Cabron, without making any of the Carribbe or Virgin Islands. By this she will go clear of the dangerous isle of Anegada, and be sure of not getting to leeward of her port of destination. Having made Cape Cabron, no more is to be attended to than to follow the coast, at a proper distance from the projecting points, and without getting into the bays it forms, until approaching your destined port, when you may keep so near to the coast, to windward of it, as to make sure not to pass it. If bound to a port on the south coast it is proper to make the island of St. Bartholomew, passing its south side, and run down by the south of Porto Rico, to make the island of Saona, if you are bound to the harbor of St. Domingo, or to Ocoa Bay; but if not, you may proceed at once to make Beata and Altovela, passing to the south of them, and so directing yourself as to approach the coast to windward of your port of destination, in sufficient time to be certain of not overrunning it. Those bound direct for harbors on the west end of the island, ought to make the north side in the rainy season or season of the souths, and the south side in the dry season, or that of the norths: thus they free themselves from the dangers and anxieties which the souths cause, in the first instance, and which the norths cause in the second; for it is well known to every seaman, that not only is an off-shore wind not dangerous, but that it allows of continuing your voyage; for, though it may blow very hard, it can raise no sea, and you can regulate the sail according to circumstances.

In navigating from leeward to windward, this island affords the very great advantage of land-breezes. It is well known that the nearer you are to the land, the fresher these winds are, and therefore the farther you can run with them: thus, in this case, it answers to keep as near along shore as you can, which is sufficiently easy, and keeping in mind the particular description of it, you need not fear.

If it be a matter of indifference to you, whether you beat up the north or south side, you ought to choose the first in the season of the souths, and the second in the season of the norths; and this is the more requisite, as when you are running from windward to leeward, you have not the same necessity to keep near land, as when bound from leeward to windward; and it is very certain that, in the latter case, if either a north or a south catch you, when very close on their respective coasts, fatal consequences may ensue; but if it be not a matter of indifference to you, which side you work to windward on, or that you must of necessity take one in preference to the other, notwithstanding

the obstacles, the risk, at greatest, is not such as ought to thwart a navigator from this track, who knows that in proportion to the difficulty, must be his vigilance and activity.

Relative to the currents which may be found along the shores of Hayti, we may add that their effects may be looked upon as inconsiderable. Some, however, affirm and suppose, that there are currents of a mile an hour setting to the westward; but, for ourselves, we can only say that we have no foundation for such an assertion, but rather have grounds for thinking them of little importance.

#### *The Windward Channel between Hayti and Jamaica.*

By the Windward Channel is meant that channel which lies between Hayti on the one side, and Cuba and Jamaica on the other. The coasts which form it on the east and north have already been described, and the coasts of Jamaica are described hereafter. The breadth of the channel between Cape Tiburon, in Hayti, and Morant Point, the eastern end of Jamaica, is 31 leagues, in a W. S. W. direction; and to the northward of this line is the little isle called Navaza, and a dangerous shoal bank called that of the Formigas; to the southward is a bank of soundings, but clear of dangers, and the Morant Keys, with their surrounding bank. These we shall describe in order.

NAVAZA is about 2 miles in length, E. S. E. and W. N. W., and about 1½ mile broad at its widest part. It was surveyed in 1803 by Mr. Francis Owen, Master, R. N., who says, "This island is a flat level rock, apparently of volcanic origin, is above 300 feet in height, and covered with small shrubs. It may be seen on a clear day from the deck of a line-of-battle ship about 7 leagues. Every part thereof shows a rocky perpendicular cliff, except a small space on the northern side, which is but little above the surface of the sea. From the western extremity of the island, a coral reef stretches to the westward about 100 fathoms, on which are only 27 feet with 15 fathoms all round it. In every other part there are 12 fathoms water close to the shore. On the western and southern sides, soundings from 16 to 40 fathoms, sand, extend to the distance of three fourths of a mile, on which you may anchor and lie smooth in a strong sea-breeze. On the north side the bottom is rocky, and the bank does not extend beyond half a mile. In crossing this island, on its eastern side, at the distance of about one third of a mile, you will have 34, 25, and 18 fathoms; and at half a mile 38, and soon after, no ground, with 75 fathoms. At the distance of 1½ mile from the east end, no bottom will be found with 230 fathoms. The N. W. end bearing N. or N. by E., and the S. E. point E. S. E. or a little more southerly, you may anchor in 16 fathoms, fine sand, about half a mile from the shore. There are great quantities of sea fowls on the island; and round the rocks, cod, and red snappers in abundance. Between Navaza and Cape Tiburon there is a small bank of fine white sand, with plenty of fish thereon. The depth is from 14 to 16 fathoms, with the following bearings:—Navaza W. ½ S.; Cape Tiburon E. S. E. ½ E.; and Cape Dame Marie N. E. ½ E., by compass.

From Navaza to Cape Dame Marie, the bearing and distance are N. E. by E. ¾ E. 14 leagues.

From Cape Tiburon to Morant Point, which is the east end of Jamaica, the bearing and distance are W. S. W. ½ W. 34½ leagues; and from Navaza to the same point, S. W. by W. ¾ W. 23 leagues.

THE FORMIGAS, OR ANTS, are some dangerous coral spots upon a sand bank, nearly 9 miles in length, extending in a N. E. and S. W. direction, about 10 leagues to the westward from Navaza. Its eastern part bears N. E. by N. 40 miles from Morant Point, Jamaica; and from the body of the shoal the N. E. end of Jamaica bears S. W. by W. 38 miles. The eastern part is the shoalest, not having, in some places, more than 13 or 14 feet of water. The edge here is nearly steep to, and there is generally a great swell upon it. In standing over the bank, when the depth increases to 7 or 7½ fathoms, there will be a sudden increase to 13 and 15 fathoms, and thence no bottom at 20. On the eastern edge the bottom is dark, and not easily seen in hazy weather; but to the westward the water is discolored, and appears lighter.

The centre of the bank is in about 18° 30' N. and 75° 40' W. The fall of the high land over Plainant Garden River, which is the easternmost high land on Jamaica, bearing S. W. by S. leads directly on the bank.

THE MORANT KEYS.—These keys, which lie at the distance of 32 miles S. S. E. from the east end of Jamaica, consist of four low islets or keys, situate in form of a crescent, and are surrounded by a dangerous reef. They are distinguished by N. E. Key, Sand Key, Savanna, or Bird Key, and S. W. Key. You may approach within 2½ miles of any of them. The reef on the eastern side is a most dangerous ledge of coral. The keys lie between lat. 17° 24' and 17° 28', long. 75° 55'. To the N. W. of them is good anchoring ground, in 5 or 6 fathoms, white sand and shells. To anchor, give the N. E. Key a berth of 1½ or 2 miles; and when the S. W. Key bears S. by E. steer

directly for it, and you will pass close to westward of the rocky spit, that extends to the westward from the N. E. Key, and has but little more than 3 fathoms over it. When the N. E. Key bears E. by N. or E. N. E. you may haul more to the eastward, and anchor with the S. W. Key bearing S. or S. by W. and Savanna Key, the next to it, S. E., in from 5 to 6 fathoms, sandy bottom. As there are some spots of coral, it is requisite to ascertain that the bottom be clear.

These keys are only 7 or 9 feet above the water. The body of them lies from Port Morant, Jamaica, S. S. E.  $\frac{1}{2}$  E., about 11 leagues. With the keys bearing S. W. nearly 4 miles, there are about 18 fathoms water, stony ground, mixed with fine red speckled gravel. With them S. W. by S. about 4 miles, there are 16 fathoms; and when S. S. W.  $\frac{1}{2}$  W. 6 miles, there are 23 fathoms, with ground as above.

In order to ascertain when you are to the eastward of the keys, observe that Morant Point, or the east end of Jamaica, and the north-east end of the same, bear from each other N. W.  $\frac{1}{2}$  N. and S. E.  $\frac{1}{2}$  S. so that when the north-east end, which is high and bluff, is to be seen on that bearing, or to the westward of it, you will be to the eastward of the keys.

Also, when coming in from the southward for Jamaica, by keeping Yallah's Hill, hereafter noticed, to the northward of N. W.  $\frac{1}{2}$  N. you will pass clear of the keys to the westward.

Be very cautious on approaching the keys in the night, lest you be driven on them by the current.

In turning between the Morant Keys and the east end of Jamaica, there is a good 8 leagues of turning ground; and as it seldom happens that the land is not descried before night, its bearings may direct in turning or sailing.

Capt. Mackeller tells us that the cocoanut-trees formerly on Morant Keys have been cut down since 1816, and there is not a shrub of any kind to be seen, except a few small cocoanut-bushes on the N. E. Key. Very great care should be taken in approaching the N. E. Key, on either side, as it is foul to a great distance off; and vessels intending to anchor at the keys, ought not to come on the white water at all, that is, to the westward of the N. E. Key, until they are far enough to the southward to have the south part of the N. E. Key bearing E. by N.; they may then haul up to the eastward for Savanna or Bird Key; and when it bears S. E. and the S. W. Key S. or S.  $\frac{1}{2}$  W., anchor in 5 or 6 fathoms. If it is necessary to work up to this anchorage, with the wind east, you may stand to the S. W. Key, by your lead, not going nearer than 5 or 6 fathoms; but the reef off the N. E. Key is steep to, and you will have 5 fathoms at one east, and the next 3, or perhaps less; therefore, in working up, keep the point of the N. E. Key always to the northward of E. by N. after you are in the white water.

*Directions for the Windward Passages, which is the principal channel to the north-eastward of Jamaica, including those for sailing to and from Jamaica, and thence to New Providence, Havana, Europe, &c.*

Ships from Europe, when bound to Jamaica, generally take the broad and safe channel between the islands and Guadaloupe, but they may pass with equal safety between St. Bartholomews and Saba, or St. Eustatias, and thence make the parallel of  $17^{\circ} 20'$  to the southward of Hayti, or on the meridian of  $70^{\circ}$  W. When thus far advanced, they may continue W.  $\frac{1}{2}$  S. until they make Alto-Vela or the Little Mount, which lies off the southern point of Hayti, as already described. They will thus avoid the dangers in the vicinity of Neiva Bay, towards which there is frequently an indraught, as before noticed.

Should you happen to miss Alto-Vela, you may probably make the land of Jacquemel, or Jacmel, before described; or if not, with the next great promontory, of which Point Abacou and Point a Gravois are the extremities. Jacquemel may, as already shown, be distinguished from sea by the sudden cut-off or drop of a hill, seen over another long hill at the upper part of the harbor. This mark leads directly to the harbor's mouth.

The Isle a Vache lies to the eastward of Point Abacou, and forms the channel to Aux Cayes, &c. From Alto-Vela to the east end of the Isle a Vache, the bearing and distance are W. by N.  $42\frac{1}{2}$  leagues. From the east end of the Isle a Vache to Point Abacou, W. by S. 14 miles; thence to Point a Gravois, W.  $\frac{1}{2}$  S.  $2\frac{1}{2}$  leagues.

When off at sea, abreast of the Isle a Vache, the middle of a saddle mountain over Port St. Louis, bears nearly N. by E., and then the eastern end of a Vache is between it and the ship. The island is low, though hilly, and lies so under the land of the main, that it is not distinguishable from it at any considerable distance. At 6 leagues off, it appears, as already said, like an assemblage of small islands. The water towards it shoalens gradually.

The saddle mountains over St. Louis, which are called the Grand Anse Mountains, are the second high range from the west end of Hayti. The westernmost, which is the

highest, is

highest, may be seen in clear weather 30 or 40 leagues off, on both sides of the island. Observe, however, that after noon the exhalation of vapor is sometimes so great as to render them invisible. Be cautious, at such times, of making the land, lest you run on the dangers of the Isle a Vache.

From Point a Gravois to Cape Tiburon, the bearing and distance are N. W. by W.  $\frac{1}{2}$  W. 13 leagues. The land about Cape Tiburon is so high as often to be seen at more than 20 leagues off.

Morant Point, the easternmost extremity of Jamaica, already noticed, bears from Point a Gravois W.  $\frac{3}{4}$  S. 42 leagues; and from Cape Tiburon, W. S. W. 31 leagues.

In running for Jamaica, from the west end of Hayti, or the Isle of Alto-Vela, be cautious of running too far north, lest you should get on Morant Point, this point being, as already shown, extremely low. In thick hazy weather it may possibly be approached so near as to make it difficult to weather; the wind setting right on, and the current always going to leeward. By keeping the proper parallel, ( $17^{\circ} 45'$ ) you will run down without danger, and make Yallah's Point, off which you are sure to meet with pilots, who will conduct you to Port Royal Harbor, if required.

#### *Sailing Directions for the Coast and Harbors of Jamaica.*

**MORANT POINT TO KINGSTON.**—The southernmost high land of Jamaica, to the eastward of Port Royal, is Yallah's Hill, which is very remarkable. The middle of this hill is 20 miles to the eastward of Port Royal Point. When the fall of this hill bears W.  $\frac{1}{2}$  N. steering W. by S. will carry a vessel a league or more to the southward of the east end of the island, which is very low. The latitude at noon will be a guide; for when Yallah's Hill bears W.  $\frac{1}{2}$  N. 11 or 12 leagues distant, the ship will be in lat.  $17^{\circ} 50'$  or  $17^{\circ} 51'$ .

Should you make the southernmost high land, bearing W. S. W. 9 or 10 leagues distant, when bound to the south side of the island, you must haul up S. W. to clear the east end, which will not be in sight at a greater distance than 4 leagues; and observe, also, that a current frequently sets to the northward around this end of the island.

From off Morant Point, or the east end of Jamaica, when bound to Port Royal, ships should keep at a distance of 4 miles from shore, until past Morant Bay, as the coast from the east end to the southward of Rocky Point is lined with a reef that stretches nearly 2 miles outward, and over a part of which the sea generally breaks.

To the westward from Rocky Point, the coast continues rocky to about one mile from the shore, as far as Morant Bay; it is then clear to the white cliffs called the White Horses, off which there are some rocks, at about half a mile from shore.

From the White Horses to Yallah's Point, the distance is one league. In running down, when the former bear north, and Yallah's Point west, you will have soundings, and frequently see the bottom in  $7\frac{1}{2}$ , 8, 9, and 10 fathoms; and on approaching Yallah's Point, the water will be found to deepen until you lose soundings.

From Yallah's Point to Cow Bay Point there is no danger; the latter is bold to, as well as all the coast to the westward, as far as Plum Point. The course and distance between the two points are W. by N. eight miles; but should you be three or four miles from Cow Bay Point, you must steer more to the northward.

Plum Point is the southeast point of the Palisades; you may run in boldly for it, and approach its extremity within half a cable's length, having nothing to fear until abreast of it, or between it and the Middle Ground, in the entrance of the eastern channel to Port Royal.

When you have brought Rock Fort N. by E. you will come on a cross ledge without the entrance of the channel, and must then bring the leading mark on, which is the north part of the Apostles' Battery and the magazine of Fort Charles in a line. This mark is to be kept on until you are abreast of Lime Key. When thus far advanced, steer a little to the southward towards Rackham Key, giving Lime Key a good berth, until Port Royal Point comes open between Gun Key and Rackham Key. Now steer in mid-channel between these keys, and immediately after passing them, proceed directly towards Port Royal Point, till you bring the fall of Yallah's Hill on the centre of Gun Key, which will bring you between the Knoll and Port Royal Point; you may approach the point within half a cable's length, and, by sailing close to it, you will also pass between it and the Harbor Knoll, which lies to the westward about the length of a cable and a half, with 19 feet on it.

Having passed the point steer to the northward till the Admiral's Penn comes to the north of Gallows Point. This mark leads you clear of Old Port Royal, where you may anchor abreast of the Dock Yard, or even before you come to it. With a land or north wind, the Channel between Gun Key and Port Royal is to be preferred; then the 'Twelve Apostles' Battery on the south angle of Fort Charles leads you clear of Gun Key reef.

Strangers, in case of necessity, may pilot their ships down to the anchorage in the channel, even when the marks are not to be seen, as nothing is to be feared on the side of the Palisadoes, which is low and bushy. They must only keep within half or three quarters of a mile of Plum Point, and steer down by the Palisadoes, till they bring Lime Key to bear S. S. E. or S. E. by S. then they anchor in 15, 16, or 17 fathoms, near the middle of the channel.

**SHOALS IN THE EASTERN CHANNEL OF PORT ROYAL.**—The most remarkable shoal in the Eastern Channel is the Middle Ground, or Eastern Middle Ground, which lies one and a quarter mile S. S. W. from Plum Point; it consists of two patches, rocky bottom; the east patch having twelve feet, and the west patch, (about 70 fathoms to the W. N. W. of the other,) having 9 feet; they are divided by a narrow swash, 10 fathoms deep, and both break with strong sea breezes.

A Beacon, with a small triangle about 50 feet above the level of the sea, has been erected on the Palisadoes, between Great and Little Plum Points. When bearing N. by W. by compass, or in one with Kingston Church, it will lead clear to the eastward of the East Middle Ground.

You may sail within the Middle Ground, or without it to the southward, as necessity requires: but to the northward is the best and safest channel. The soundings in that channel are uneven, from 7 to 19 or 20 fathoms; but, when you are past the Middle Ground, they are regular from 19 to 13 fathoms between Rackham and Gun Keys.

The first key you meet with, in steering from the Middle Ground towards Port Royal, is Lime Key, from the north end of which a reef stretches about a cable's length; your eye is the best mark for it, as it is generally seen: to the westward of the key lies another shoal, with 8 or 10 feet upon it.

The knoll off Port Royal Point is the third shoal; it is a small hard coral bank to the southward of the point, with only 16 feet water upon it. If your ship draw 12 or 13 feet water, you must be careful to keep clear of it.

To go within the knoll, the leading mark is to bring the highest bush on Gun Key, (which is near the middle of it,) in one with Yallah's Point; you have then 10 fathoms water; and the channel is 70 fathoms wide. The mark to strike the knoll is the south point of Gun Key on the high hill of Yallah's, or a ship's length open of Yallah's Point: the breast mark is the church on the seventh or eighth embrasure of the Fort, Sandy Key just open with Lime Key, and you will have 16 or 17 feet of water.

To go between the knoll and the Western Middle Ground, which lies about 300 fathoms to the south-westward of it, the leading mark is True Land's Hummock, within Yallah's, on the southernmost part of Gun Key, or Yallah's Point, well open to the northward of the north point of Rackham's Key. This channel, which is the widest, and has 12 fathoms of water, is mostly used when taken with the land wind.

The anchorage is good all over Port Royal Harbor: but the best anchoring for ships that are bound to sea, is in 9 fathoms, with a notch on the east side of a high mountain, called the Leading Notch, a little open to the eastward of Fort Augusta, and Rackham Key in one with Port Royal Point.

**SOUTH CHANNEL OF PORT ROYAL.**—To go to sea from Port Royal, you make use of the South or the New Channel; the small craft generally go through the East Channel, but it is to be avoided by large vessels, unless they are prime sailers, and have a strong land breeze or north, with an appearance of its lasting long enough to carry them through.

When bound through the South Channel you should get under weigh with the land wind, so soon in the morning as you can see the marks, observing that the current then sets most commonly to the westward. The general leading mark is the Leading Notch in one with the magazine of Fort Augusta, which is the easternmost building of the fort. This mark leads ships of 16 or 17 feet water clear through; but, in a line of battle ship, the notch should be kept very little to the eastward of the magazine, until Hellshire Hummock comes open with Fort Small.

To keep well to the westward of the Middle Ground, be careful not to bring the church steeple upon the corner of the wall with embrasures, until Yallah's Hill is brought in one with Lime Key. In case you should not see Yallah's Hill Point, look out for a hummock on Hellshire, and when it is open of Salt Pan Hill, you will be to the southward of the Middle Ground.

This Middle Ground is a large coral bank which often breaks, with only three feet on it in the middle; the north and west sides are almost steep. On its N. W. edge lies a buoy, whose marks are, Port Royal Tower on the fourth embrasure of Fort Charles, counting from the westward, and Hellshire Hummock on the flag-staff of Fort Small.

When you have opened Hellshire Hummock with Fort Small, you steer out with the Leading Notch a little to the eastward of the magazine, which carries you between the Drunken Man's Key, the Turtle Heads, and the South Knoll; or, to avoid these heads,

you are to haul up so as to bring the church steeple to the easternmost part of the fort, and continue to keep that mark until the South Key is brought on with Yallah's Point. Then you may haul to the westward if the wind will permit. But if you should not keep up the leading mark, and the church steeple should come near the corner of the fort, you must then come to, or tack and stand in. The mark, when ashore on the Turtle Heads, is the church steeple upon the magazine of the fort, and Spanish Town land just open.

When Maiden Key is open a ship's length to the southward of Drunken Man's Key, you will be to the southward of the South Knolls, and should bring the Leading Notch in a line with the magazine, which will bring you close to the westward of the Little Portuguese, in 8 or 9 fathoms: when Yallah's Hill comes to the southward of South Key, you are then clear of the Portuguese, and may haul to the S. E. giving South Key a berth of about a mile.

Drunken Man's Key is a narrow ledge of rocks just above water, covered with some loose sand that gives it the appearance of a sand bank. To the southward of it about half a mile, there is a shoal which breaks with strong sea breezes; and between it and Drunken Man's Key is a channel having 6 or 7 fathoms of water.

The Turtle Heads are three dangerous spots, with 10 or 11 feet of water on their shoalest part, and deep water close to them. The South Knolls to the S. E. of these heads, are two small patches, about 70 fathoms asunder, with 23 feet water on them. And to the S. by W. of these lies One-Bush Reef, which always breaks, and is almost steep to. The Three-Fathom Bank is a large coral shoal, with 19 or 20 feet of water, which breaks with strong sea breezes. A small patch, about a quarter of a mile to the S. S. E. of it, has 20 feet of water; it is called the Warrior's Bank, from the British ship Warrior having lost her rudder there in 1782.

The Little Portuguese is the southernmost shoal on the eastern side of the south channel. It has from 22 to 29 feet water over it, and in general, a great swell.

When Portland makes as an island, open about three quarters of a point, or a point, with Hellshire, you will be to the southward of the Three-Fathom Bank and Warrior.

It frequently happens that the land breeze fails before a ship can get clear of the channel; and there is sometimes a long interval of calm between the land and sea breezes. Should this occur it would be requisite to anchor so soon as the breeze fails, or there will be danger of being set, by the swell, on the Three-Fathom Bank or One-Bush Reef. By inattention to this precaution, there have been instances of ships slipping or cutting their cables, when the sea breeze has come on, and running into Port Royal to save the ship.

The best anchorage is within the length of the Little Portuguese, with the leading notch a little open to the eastward of the magazine of Fort Augusta. Then, if the wind changes southerly, a ship may easily return to Port Royal, or with the common sea breeze, may proceed to sea.

When clear of the channel, if bound to leeward, you may steer S. by W., or not farther to westward than half a point more westerly, in order to avoid some shoal spots that lie to the south-eastward of Wreck Reef.

Wreck Reef always breaks. This danger lies about a mile, or little more, to the S. E. from Hellshire Point, and is about a mile in length from N. E. to S. W. There is a channel for small craft between it and Hellshire Point. About a mile to the S. W. of the reef, there is a shoal spot of 3½ fathoms with 7 fathoms around it.

*To sail through with the sea breeze.*—Ships of war, or those that sail well, may safely proceed to sea from Port Royal, if they can lay S. by E. or a little to the eastward of it, if the foregoing precautions be strictly attended to. When through the channel, soundings will be found of 10 and 11 fathoms, if steering S. by W. until Portland bears W. N. W.

The shoals in general, when the sea breeze prevails, may be distinctly seen from the mast-head. They appear of a brownish color, being covered with large branches of coral. The greatest part of them are very steep, having a depth of several fathoms close to them. The bottom of the channels between is mostly soft mud or clay.

SHIPS BOUND to WINDWARD from Port Royal, if they can weather the Middle Ground by the time the sea-breeze comes on, may pass through the Eastern or Windward Channel, and thus they may gain 6 or 7 miles more to windward than by going through the South Channel. Small sloop-rigged vessels generally pass this way; but to others it is hazardous; because if the land-breeze fails, with an interval of calm, a swell may come on ahead, and be extremely dangerous.

NEW CHANNEL of Port Royal.—The New Channel lies to the eastward of the South Channel, and almost parallel to it; it is certainly preferable, on many accounts, to the South Channel; it has smooth water till you come to South Key, with good anchoring ground, easy riding, and a facility of going to sea to the southward with the sea-breeze, as far as S. E. & C.

The leading mark to enter this channel is, a remarkable flat hummock on the mountain to the N. N. W. of Port Royal. When the middle of this hummock is in a direct line with the white house standing to the N. W. of Fort Augusta, it leads to the westward of the harbor and Point Knolls, as well as between the east edge of the Western Middle Ground, and the west end of Rackham's Key Shoal. Steer with these marks on till a remarkable round hillock, to the westward of Stony Hill Barracks, comes open to the eastward of Gun Key.

After you have opened this hummock, you steer away to the southward, keeping it open till a saddle in the mountains to the N. W. comes in a line with Fort Small. Then you bring the same hummock on the centre or west edge of Gun Key, which marks carry you to the westward of the shoals on the east side of the channel, and about a quarter of a mile to the eastward of the Great Portuguese. So soon as Portland appears like an island, you may haul to the eastward, being clear of the reef and shoals of South Key.

The shoals in this channel are, 1. The Western Middle Ground, (on the east side of which there is a buoy,) and the small shoals to the southward of this ground.

2. The Great Bay Shoal, which has 16 feet least water, and a floating beacon in 16 feet.

3. The Four Fathom Knoll, a very small spot, with no less than 24 feet water on it, and deep water all round. Ships of 20 feet draught may sail over it, as the water is smooth.

Between Great Bay Shoal and South Key Breakers there are two shoals; the northernmost, at about half a mile S. by W. from the former, is steep, and a small part of it appears just above the surface of the water. This shoal always shows itself by the rippling on it. About half way between this and the breakers lies the second shoal, having only 16 feet of water.

The South Key Breakers have a buoy upon them. The marks for the west edge of this reef are the leading notch open a little to the eastward of the capstan-house, and a saddle mountain to the N. W. and Fort Small in one.

Half a mile to the southward of these breakers is the Eighteen Feet Reef, remarkable by the great swell upon it. To the westward of that reef, lies the Great Portuguese, which is the southernmost shoal on the west side of the channel.\*

**OLD HARBOR, LONG'S WHARF, &c.**—Mr. Leard's directions for these harbors are as follow: Being clear of the South or New Channels, steer to the southward, or S. by W. and give Wreck Reef a berth of two miles; and then edge away, and bring the fall of Braziletto Hill to bear W.  $\frac{3}{4}$  N. or W. by N. and steer for it: this will lead you to the southward of the foul ground off the Pelican Keys,† and as you approach them, you will see Pigeon Island, which is low and bushy, in a direction of the fall of Braziletto Hill; keep it so, and pass the Pelican Keys in  $7\frac{1}{2}$ , 7, and  $6\frac{1}{2}$  fathoms; and, as you steer down with those marks on, you will see a remarkable hummock on the mountain to the northward, called Cudjoe Hill, (it is like a jockey's cap.) When this hummock comes on the west extremity of the slant fall of Goat Island, and will bear N.  $\frac{1}{2}$  W. then haul to the N. W. by N. for Old Harbor. This last mark leads you clear to westward of Dry Shoal, part of which is even with the surface of the water, and you will see it. You will have from  $6\frac{1}{2}$  to 6, or  $5\frac{1}{2}$  fathoms; and, after you have passed Dry Shoal, continue steering N. W. by N. and you will deepen your water to 8 fathoms.

And as you approach Careening Key, will shoalen it to seven and six fathoms. You must give Careening Key a berth of nearly half a mile to avoid a reef that runs from it to the southeast; and steer direct for the wharfs at Old Harbor, and anchor in  $4\frac{1}{2}$  or 4 fathoms, keeping clear of the reef on the south side of the harbor, which generally shows itself.

**Long's Wharf and Salt River.**—If you are bound to Long's Wharf, in sailing to the northward of Pigeon Island, there is a small white shoal of only 18 feet on it; it shoalens

\* The preceding description of, and directions for, the South Channels, may be considered as more for the use of the pilot, than of the general navigator. Captain Livingston has said, "I think the Derrotero is right in omitting directions for any of the channels at Port Royal, Jamaica, excepting the eastern one, as directions for the Southern Channels are absolutely useless: because no one who is unacquainted ought to be fool hardy enough to attempt carrying any vessel in or out, except by the Eastern Channel, even with the most correct instructions and most accurate chart."

† The most frequented and best channel for entering into this great bay is between Pelican and Bare Bush Keys; and to take it, those who come from Cow Point must steer W. S. W.  $\frac{1}{4}$  W. 9 leagues, and until the slope of the Braziletto Mountain bears W. by N. With this mark and bearing you proceed to Pigeon Island, &c. The Braziletto Mountain cannot be mistaken; it being the northernmost of the two, which are seen to the west, and the southern is of a round shape. The opening which these mountains form is the point to be used as the leading mark, bearing W. by N. as above.—Derrotero, §5.

gradually on the east end, and bears north from Pigeon Island, distance one mile. The south edge of Round Hill, just open with Braziletto Hill, leads on it. You may sail between this shoal and Pigeon Island, in 8, 7, 6, or 5 fathoms; but to the northward is the straightest course. After passing Pigeon Island, steer to the northwest, and bring the top house about one-third from the north side of the large opening or gap in the mountains; this mark leads between the reefs to the anchorage at Long's Wharf, in 4 or  $3\frac{1}{2}$  fathoms.

*Salt River Anchorage.*—If you are bound to Salt River, after passing Pigeon Island, keep the south part of Braziletto Hill open a little on your larboard bow, which will lead you close to Salt Island; you may go either to the northward or southward of Salt Island, but the north passage is the best. You may pass within a cable and a half's distance of Salt Island, on the north and west part: on the south part is a reef which shows itself, and is steep close to it. There is a reef extending along on the east side of Long Island, which you see; and also a reef extending from the Salt River shore to the eastward, which sometimes breaks. Therefore steer round the north end of Salt Island, at about two or two and a half cables' distance from it; and then steer towards the entrance of Salt River, until you bring the south edge of Pigeon Island almost in a line with the south edge of Salt Island: keep them in that direction, and when you are in  $4\frac{1}{2}$ , 4, or  $3\frac{1}{2}$  fathoms, anchor according to the size of your ship. If you are in a low vessel, it will be necessary to go a little up the shrouds, to see Pigeon Island over Salt Island. The south end of Pigeon Island, a little open to the southward of Salt Island, leads on the edge of the Salt River Reef. There is good anchorage under the west part of Salt Island, in five fathoms and a half, good holding ground.

*Peake Bay.*—To sail into this bay, give the reef that runs off Rocky Point a berth of a cable's length or more, and steer towards the north part of the sandy beach, and anchor in  $4\frac{1}{2}$ , 4, or  $3\frac{1}{2}$  fathoms, good holding ground. The reef off Rocky Point, and the reef on the south side of the bay, are nearly even with the surface of the water, so that you generally see them. There is a great sea in this bay, with strong sea-breezes.

*West Harbor.*—The entrance into this harbor is between two coral reefs, that are nearly even with the surface of the water; and the heads of coral frequently show above water. The channel between the reefs is above half a mile wide, with 6 and  $6\frac{1}{2}$  fathoms in it. There is very good anchorage, with smooth water, just to the westward of the north reef, in  $5\frac{1}{2}$ , 5, or 4 fathoms, good holding ground. The land to the westward does not show any mark that I could find to guide you into this anchorage, but it is not difficult. As you go to the westward in the west harbor, the water shoalens to 8 or 9 feet. It is also shoal on the south side towards the mangroves, and smooth water.

*Going to Sea from Old Harbor, Long's Wharf, &c.*—Ships generally get under way with the land wind, so as to get clear of the reefs near the anchorage, before the sea-breeze comes on. Being clear of the reefs, you may turn out with the sea-breeze, and may go on either side of Pigeon Island. The channel between Pigeon Island and the reef of the Half Moon Keys is two miles wide, with deep water; but the smoothest water is to the northward of Pigeon Island. You may stand towards Goat Island and Cabarita Point by your lead; the soundings are gradual, and tack when you come to 5 or  $4\frac{1}{2}$  fathoms. If the sea-breeze should be very strong, you may anchor under Dry Shoal, and wait for the land wind. But, with moderate sea breezes, any ship may turn out between the keys and reefs. Being as far to the eastward as Dry Shoal, and in standing to the southward, your leading mark for the channel between Bare Bush Key and Morris' Shoal, is Cudjoe Hill, on the slant fall of Goat Island, the same as for Dry Shoal; keep it so until the Half Moon Keys come in one; then you are to the eastward of Morris' Shoal, and may edge away a little, keeping the Cudjoe Hill about a large sail's breadth on the lower part from the slant of Goat Island, which mark will lead you along the white water on Bare Bush side to sea. But if, in standing to the southward from Dry Shoal, you find that you cannot weather Morris' Shoal,\* which you will know by the fall of Cudjoe Hill not being within a sail's breadth of the fall of Goat Island; in this case you must tack to the northward, when Bare Bush Key bears E. S. E. or when a saddle hill to the northwest of Pigeon Island is just coming on the north end of Pigeon

\* It is said, that about thirty years ago, ships sailed over this shoal; if so, it must have grown fast, for there is not at present, more than 9 or 10 feet on the north edge of it, and a great swell in general. Marks for the east end of it: Cudjoe Hill, about half way from the fall of Goat Island, upon the low and bushy land towards the rising to the westward (this rising is commonly called Little Goat Island;) and the Half Moon Keys about four degrees open, and north part of Bare Bush Key bearing E.  $\frac{1}{4}$  S. Marks for the west end are, Cudjoe Hill, on the afore-mentioned rising of Little Goat Island, and Bare Bush Key bearing E.  $\frac{1}{4}$  S. It is in length little more than a quarter of a mile, and in breadth about one-sixth of a mile, and shoalens too sudden for your lead to be a guide in standing towards it.

Island. And, in standing to the northward, tack when the fall of Braziletto Hill comes on the centre, or near the north end of Pigeon Island: you may approach the white water on the side of Bare Bush to 5 fathoms. There is a good channel between Morris' Shoal and Half Moon Keys, but it is dangerous to approach the latter on the southeast side, for you will have from 6 or 7 fathoms to 12 feet in one or two casts of the lead. To the E. S. E. and S. E. of Bare Bush Key, distance about one mile, are some spots of coral, with from  $3\frac{1}{2}$  to 5 fathoms on them, and 7 fathoms close to them. And to the southward and S. S. E. of the Portland Keys, distant about two miles, are some spots of  $3\frac{1}{2}$  and 4 fathoms on them. After you have passed those keys in sailing to the westward, come no nearer Portland than two or two and a half miles, or 7 or 8 fathoms; for the reef off Rocky Point, which is the west part of Portland, extends nearly two miles from the point to the southward.

**PORT ROYAL TO PORTLAND.**—In proceeding towards Portland, observe that Wreck Reef, which is a large shoal composed of dry rocks and breakers, lies about half way between Port Royal and Old Harbor, at the distance of more than a mile from the shore. This danger, which appears in the day, consists of two parts, having between them a channel of 4 fathoms water. Ships passing in the night should approach no nearer than in 12 fathoms, or come to an anchorage until morning. Within the reef there is good shelving, and tolerable anchorage in 4 and 5 fathoms, bottom of sand, with shells and mud. Here vessels occasionally ride during the prevalence of a breeze, &c.

From Port Royal to Portland, the distance, on a circuitous course, is 9 leagues. In this track, when clear of the South Channel, give Wreck Reef a berth of 2 miles.

There are soundings outward as far as with the easternmost land of Hellshire, bearing N. by E. and Rocky Point, or the southernmost land of Portland, N. W.  $\frac{1}{2}$  N. With these bearing, soundings have been found of from 17 to 23 fathoms, and the next east no ground at 80 fathoms, although not a ship's length from the former.

*The Pedro Keys: from the Remarks of H. M. S. Winchester, Captain, the Hon. W. Wilesley, R. N.*

**THE PORTLAND ROCK** is elevated from 15 to 20 feet above the level of the sea. The Winchester rounded it on the south side, and brought it to bear east, carrying from 10 to 14 fathoms water, on a sandy bottom, with pieces of coral. In this bearing a vessel might anchor with safety in moderate weather.

We made the latitude, .....  $17^{\circ} 7' 23''$  N.  
 ————— longitude .....  $77^{\circ} 25' 20''$  W.

which is only  $20''$  different from De Mayne's meridian distance reduced; he having considered Port Royal in  $76^{\circ} 52' 38''$  W., whilst we used  $76^{\circ} 49' 00''$  W.

We stood from the Portland Rock to the S. W., carrying from 12 to 15 fathoms, and having these soundings farther to the southward than laid down by the chart. We saw the Eastern Breakers, so called by De Mayne: they appeared to have an extent of about two cables' length, with two small rocks above water, and were breaking in all quarters.

Near these the watershoaled to 8 fathoms and a half; and when they (the rocks) bore N. N. E., distant 4 miles, we only had  $7\frac{1}{2}$  fathoms, the Pedro Keys just then coming in sight. Steering W. by S., we soon after had no bottom, having got into the indent, as shown in De Mayne's chart, so that the shoalest water we had must have been very near the edge of the bank.

We did not go nearer than a mile and a half to the eastward of the Pedro Keys, and had no soundings with the hand-lead; but the chronometers gave the centre of the middle key  $77^{\circ} 47' 13''$  W., or  $58' 13''$  west of Port Royal.

**THE SOUTH-WEST BREAKERS.**—They are dangerous, and require a strict lookout. The sea breaks over two small rocks, not more than three feet above the level of the sea, constantly, but so irregularly, that from the deck of a vessel, and in a moderate breeze, a high breaker might not be distinguishable oftener than once in 5 minutes, and the ordinary ones would be taken for waves. In the Winchester, with a good mast-head lookout, we passed within three miles of these, without their being discovered.

On the west side they are bold to. Having stood to the northward on the bank, passing them at the above named distance, we carried 12, 11, and 10 fathoms for six miles. When the breaker bore S. S. W. about that distance, we tacked, and stood for it; and when about three miles distant, the soundings become irregular, varying from 11 to  $8\frac{1}{2}$  fathoms.

We were at noon as near to it as one mile, bearing east, and we had not less than nine fathoms.

The whole breaking part does not extend more than 1 or  $1\frac{1}{2}$  cable's length; but it is to be supposed there is foul ground to the eastward of it for a mile or so. The ocean color of

The Pedro Shoals (Bivora Bank of the Spaniards) have been regularly surveyed, and the representation of them in the charts is to be relied on. Of the Cascabel, or Rattlesnake, which is supposed to distinguish the N. W. end of the Pedro Bank, it does not exist, as there has been an accurate survey of the bank, and it was not to be found.

CARLISLE OR WITHEY-WOOD BAY, to the west of Portland, is an open bay, winds from W. to S. E. Its S. E. extremity is the rocky point of Portland, from which a spit, of 12 feet of water, extends about three quarters of a mile to the S. W. Westward of Rocky Point is a bank, called Robertson's Shoal, on some part of which there are only 6 feet at low water. The outer edge of this shoal is one mile and a half west from Rocky Point. The form of the shoal is nearly oval, from E. to W. Its breadth, N. and S. is three quarters of a mile.

To sail into the bay, bring a remarkable round hill to bear nearly north, and steer for it, until Rocky Point comes almost on with the east point of Portland. Hence, rounding Robertson's Shoal, you may come to an anchor in from 5 to 4 fathoms. With the hill above mentioned N. by E., there is a spot of  $3\frac{1}{2}$  fathoms, at about  $2\frac{1}{2}$  miles from the beach. With the fort N. E. or N. N. E. is the best place to anchor in for loading, because your boats can sail both ashore and aboard with the sea-winds. No tides here, but a strong westerly current generally runs in the offing. Var.  $6^{\circ} 50'$  E.

Along the coast to the westward, to the distance of nearly twenty miles from Carlisle Bay, at a mile or a mile and a half from shore, there is a regular depth of 4 and  $4\frac{1}{2}$  fathoms.

ALLIGATOR POND KEY.—Alligator Pond Key is a key just above the surface of the water, with a reef all round it. Its distance from the shore is about four miles, and vessels may approach it by the lead, or on seeing the breakers. There is good anchorage for small vessels along shore, between it and the main, in 3 and 4 fathoms.

BRUNE BANK, a small bank, having on it little more than 4 fathoms, with 12 or 13 close to it, lies six miles S. E. by compass, from Alligator Pond Key. The shoal is about a mile and three quarters in extent, from east to west, and one mile and a half in breadth: it has from 4 to 6 fathoms water on it, and the outer edge is about 8 miles from the shore.

PEDRO BAY, &c.—In Pedro Bay, to the westward of Pedro Bluff, there is good anchorage for any vessels, but it is open to southerly winds. The lead is here the best guide for anchoring. The coast thence to the westward, nearly to Parratee Point, is bold to. Off Parratee Point is a small reef; and to the N. W. of this point is Black River, which is formed by extensive reefs. To clear these reefs, keep Pedro Bluff open with Parratee Point.

The entrance of Black River is between two reefs, and has not more than 18 feet water. To sail into the river, when advancing from the eastward, keep Pedro Bluff open of Parratee Point, till you bring the church on with a gap in the highland, or to bear N. E.; then steer directly in for the church, which will carry you into the best of the channel. It is full of heads of coral rocks.

PORT ROYAL TO BLACK RIVER; by Mr. Town, 1817.—On leaving the South Channel of Port Royal, when bound to the westward, you may clear Wreck Reef by keeping the Magazine of Fort Johnson open of St. George's Rocks, until Portland bears west; thence you may alter your course along the land, as there are no dangers to be apprehended, until you approach Alligator Key, about 4 miles S. E.  $\frac{1}{2}$  E. from which is the Brune Reef, already described.

Pedro Bluff is very remarkable, and may be known from any other land on the coast. At 4 or 5 miles to the eastward of the bluff, there is a remarkable white spot in the cliff, called the White Horses, which, when you first make it from the eastward, appears like a schooner under sail, close to the land.

From Parratee Point to Luana Point, the bearing and distance are N. W. by W.  $\frac{1}{4}$  W. 9 miles. The coast between forms the bay of Black River, which is obstructed by a number of reefs, all of which lie within the line of the two exterior points, and a course N. W. by W.  $\frac{1}{2}$  W. will therefore lead clear of them. The bay does not appear to have been regularly surveyed. The main channel, which is between two reefs, has only 18 feet of water.

If going to Black River, or its bay, when advancing towards Parratee Point, take care not to approach the point nearer than one mile, as there is a reef extending off to

the S. W. nearly a mile. Your leading marks into this bay, to the anchorage where merchant ships load, will be the church just open to the eastward of a large cotton-tree: run in with this mark, until you are within half a mile of the town, and anchor in about 18 feet. Large ships, that cannot approach so near the town, should anchor under the eastern shore, in 8 or 9 fathoms. Your best mark for anchoring is, Pedro Bluff shut in about a cable's length of Parratee Point, in  $9\frac{1}{2}$  fathoms, with the town bearing about N. E. by E.  $\frac{1}{2}$  E. There is a very dangerous reef lying on the western side of this bay, with only 4 feet of water on the shoalest part. There is also a coral bank, nearly in the middle of the bay, with only  $2\frac{1}{2}$  fathoms over the shoalest part.

From Luana Point, the coast continues clear for a league and a half to the N. W., but it thence becomes foul, and so continues to Bluefield's Bay, &c. The direct course and distance, clear of danger, from Luana Point to South Negril, the S. W. end of Jamaica, are W. N. W.  $\frac{1}{4}$  W. nearly 10 leagues.

\*BLUEFIELD'S BAY.—This part of the coast is environed by reefs, and the anchorage here for large ships is without a rocky ledge, which stretches from Crab Pond Point to the west of Bluefields, and joins the reef of Savanna la Mar. Vessels coming from the eastward, to anchor in the bay, must keep down by the outside of the reef, or keep the land to the eastward open of the point, until the leading-mark is brought on, which is the overseer's house, a little open to the eastward of the tavern, bearing N. E. by E.  $\frac{1}{2}$  E. For anchoring, bring the overseer's house and tavern in a line, N. E. by E.  $\frac{1}{2}$  E. and the easternmost point E. S. E. Ships drawing 16 or 17 feet of water, may sail over the rocky ledge, in  $3\frac{3}{4}$  or 4 fathoms, with the overseer's house and tavern as above, until over the ledge, which may be known by finding a sandy bottom, and a depth of  $5\frac{1}{2}$  or 6 fathoms. The watering place is to the northward of the Bluff Point, on the lee side of the bay. Water may also be obtained at a stream off Bluefield's River, near the tavern.

In steering in, keep the lead going, and be ready to anchor, as the water shoalens rather suddenly.

SAVANNA LA MAR.—The coast from Bluefields to Savanna la Mar is rocky, in some places, to the distance of two miles from the shore. The entrance to Savanna la Mar is very narrow, and lies between a small reef called the Middle Ground, (on which there is a depth of only 4 feet,) and another reef having 7 or 8 feet over it. In the channel there is a depth of 19 or 20 feet. The leading mark in, is a large gap on the highland, called the Dolphin Head, in a line with a remarkable large tree on the lowland, to the eastward of the town, and bearing N.  $\frac{3}{4}$  W. This mark leads close to the Middle Ground, which will be seen. After passing the latter, haul to the eastward, and anchor in 17, 16, or 15 feet of water. This channel should never be attempted without a pilot.

A mile and a half to the westward of the former channel, is the Great Channel of Savanna la Mar, which is a mile in breadth, and has a depth of 24 to 19 and 13 feet towards the shore. To sail through, in mid-channel, it is only requisite to bring the fort on, bearing N. N. E.

On the southern extremity of the bank extending from shore, between Savanna la Mar and John's Point, the British ship *Monarch* struck, in 1782, upon a bottom of coral. This extremity lies with John's Point bearing N. W. by W.  $\frac{1}{2}$  W. and will be avoided by keeping one half of the high land of South Negril open to the southward of John's Point.

In traversing hereabout, it is necessary to be very particular in the use of the lead: for the bank, which extends along the front of Bluefields, and thence to opposite Savanna la Mar, &c. is rocky, and has, on its edge, from 20 to 24 feet of water; and on it, as on the White Banks, there are many shoals with little water on them, some of which uncover, and many have breakers. Without the edge of the reef, and very near to it, are 5 fathoms of water, which augments to 13 fathoms at three quarters of a mile from the edge of the bank; the depth, therefore, is the best guide, for, when you get from 8 to 10 fathoms, you will be from one third to half a mile from the edge of the reef; and when you get 13 fathoms you will be three quarters of a mile from it: and, pursuing your route, you should not keep in the depth of 8 to 10 fathoms, but in that of 13 to 15; for only in the vicinity of the anchorage they are for taking, should vessels get into the first of these depths. The anchorage of Savanna la Mar is of the same nature as that of Bluefields: large ships must anchor outside of the reef, and, in such a situation, they will not be sheltered from the sea, from east round to S. by W. It seems probable that such will very seldom come to this place, because they here run much risk of losing the anchors; as, the instant there is the least appearance of the wind freshening,

\* South  $\frac{1}{4}$  leagues from Bluefields, lies a rocky bank, discovered in 1821, with from 13 to 20 fathoms on it.

they must make sail. Such vessels as do not draw more than 12 or 13 feet of water may anchor upon the bank, and behind, (or in the lee of the reef,) in 15 or 16 feet of water with the town bearing N. N. W.  $\frac{1}{2}$  W. nearly three quarters of a mile distant. You may cross over the edge of the bank so soon as the wharves at Savanna la Mar bear N. W. by W. which will be three quarters of a mile to windward of the Eastern Channel, (that is, if the vessel is on the edge of the reef, or near it,) and sending a boat to be placed to the westward of the Middle Ground; it will serve for a guide and buoy; and then you have only to shave close to the boat, as the mean to keep clear of the reef to leeward. The boat may proceed with the leading mark as above, or may steer northerly until she comes to the edge of the reef, which runs along to the east of the anchorage; and, keeping along the southern edge of this reef, she must thence steer N. W.  $\frac{1}{2}$  N. so soon as the wharf of Savanna la Mar bears on that rhumb; with this course she will pass over the rock.

**WESTERN END OF JAMAICA.**—From St. John's Point to South Negril, the coast is bold to, or high and steep. The indent between South and North Negril, is called Negril, or Long Bay, and affords tolerable anchorage. Close to the south side of North Negril, is Negril Harbor, a small harbor with good anchoring ground for small vessels; and, to the north are Orange Bay and Half-moon Bay, places fit for Drogers, &c. Six miles to the N. E. from North Negril is Green Island Harbor, and about  $2\frac{1}{2}$  miles from the latter, is Davis Cove. These are places seldom resorted to, but by those who go thither on purpose to load, and have pilots.\*

Between Negril and North Pedro the coast is bold, excepting at Green Island, which is low, and environed by a reef, nearly even with the water. From Pedro Point to the harbor of Lucea, vessels may stand within a mile of the shore.

Mr. Town says, a ship being off the west end of Jamaica, and bound to any port on the north side, should endeavor to round the points called South and North Negril, as close as she can; for the current, in general, sets to the N. E. If proceeding for the Harbor of Lucea, you may know its entrance by a remarkable notch in the mountain, called the Dolphin Head. At a little to the westward of the harbor there is, also, a remarkable white spot in the land, which may be seen eight or ten miles off.

**HARBOR OF LUCEA.**—This harbor is one of the best on the north side of the island. It is safe, there being little danger in sailing in or out. The N. E. point is called Lucea Point, and on the western point stands the fort. Vessels, having opened the harbor, stand directly in, only giving the Fort Point, on the western side, a berth, as a reef stretches from it, on the extremity of which there is generally a buoy. To sail in, bring the remarkable mountain, called the Dolphin Head, open to the westward of Barbara Hill, which has a house on the top of it, and is on the east side of the harbor, bearing nearly S. by E. Continue on in this direction, until the fort bears west, when you will be within the Fort Reef. Hence proceed towards the town on the west, and anchor in 5 or 6 fathoms, muddy bottom, with the fort bearing from N. by W. to N. N. W. and Lucea Point, at the eastern side of the entrance, from N. N. E. to N. N. E.  $\frac{1}{2}$  E.

Those approaching this place from the eastward, must observe to keep at least three miles from shore, until past Buckner's Reef, which lies off Mosquito Cove, and sometimes breaks. It is also to be observed that, around Lucea Point, and to the north-eastward, there is a rocky flat, extending out to a considerable distance.

Within the point the reef extends to a cable's length from shore. It is nearly steep to, and the heads of coral sometimes appear above water.

For passing clear of the edge of the eastern bank, the mark is Malcolm House, which stands on a small hill or rising at the east end of Lucea Town, brought on the east end of the fort, and kept so until you bring the Dolphin Head, as already mentioned, to the westward of Barbara Hill. This mark leads through 8, 7, and 6 fathoms, then deepening to 13, and shoaling again into the harbor.

**MOSQUITO COVE,** an excellent harbor, lies three and a half miles to the eastward of the harbor of Lucea. Here a hundred sail of merchant ships may lie securely from all winds. The channel, at the entrance, is little more than a cable's length in breadth, but widens inward to where the harbor has from 7 to  $4\frac{1}{2}$  fathoms. The bottom, in general, is muddy. To sail in you may pass to the eastward of Buckner's Reef, or over its eastern end, in  $5\frac{1}{2}$  or 6 fathoms. The course into Mosquito Cove is nearly S. E. by S., but it should not be attempted by a stranger without great caution, as the entrance is much contracted by a reef from the eastern side.

**MONTEGO BAY.**—The northern point of Montego Bay lies in latitude  $18^{\circ} 32\frac{1}{2}'$ . This is a good bay with the wind from N. N. E. to the eastward and southward; but it

\*A rock, with 24 feet water on it, was seen some years since by one of the ships in a convoy lying to, about, as well as I can recollect, 40 miles west of Negril Point, Jamaica: and I am pretty certain it was in lat.  $18^{\circ} 24'$ . It was noticed in public orders at Port Royal.

is open to the north and west; and the northerly wind, in December and January, has frequently driven vessels on shore.

To sail in from the eastward, give the point, on coming down, a berth of two miles, in order to avoid a reef which extends from it, and which may be distinctly seen from the bows, when in 4 or 5 fathoms. When you open the town you may approach the reef, which is pretty steep, into 10, 9, or 8 fathoms, and will see the bottom. You now haul round towards the town, but must not venture to anchor until you have well shut in Sandy Point, (without the bay on the north,) with Old Fort Point. For, with Sandy Point in sight, there are from 35 to 30 fathoms, and the bank is so steep that the anchor will not hold. If a ship drives off she will, with a sea breeze, be in danger of grounding on the lee reefs. The mark for the best anchorage is the barracks upon the hill in a line, or nearly so, with Redwick's Stone Wharf, on the N. E. side of the bay. The ground here is good in 11, 10, and 9 fathoms. On entering from the westward with a fair wind, the church bearing east leads directly to the anchorage.

The following description and directions, are those of Mr. Town:—Montego Bay affords good anchorage for 20 or 30 vessels, except during the prevalence of strong north winds, which generally commence in the beginning of November, and end in the latter end of February. With the general trade wind, which is from the N. E. to the E. N. E., ships will ride here with perfect safety. There is a small harbor, or cove, in the N. E. part of the bay, which will hold from 10 to 12 vessels. This is the only safe place for ships during the strong north winds.

On coming into this bay with the sea breeze, which is from N. E. to E. N. E., you should endeavor to get well to the eastward before you attempt to run in.

The leading mark for clearing the Old Fort Reef, which extends from the anchorage in the bay to the northward of the northernmost point, is the Buge Road end on, bearing south, or south a little westerly. Proceed with this mark until Montego Church comes open of Old Fort Point; then haul in for the S. E. part of the town, and when Sandy Point is shut in with Old Fort Point, you may anchor in from 17 to 10 fathoms, fine sand and mud. The reef off and to the northward of Old Fort Point, lies nearly one mile and a quarter from the shore; advance, therefore, no nearer to the point northward of Old Fort Point, than two miles.

About 5 miles to the westward of Montego Bay, is a small creek, a bay without, which is called Great Roads. In this bay merchant vessels lay to load; there being a shoal extending nearly the whole of the way across, which affords good shelter for ships lying here during the north winds.

All ships lying either in Montego Bay or at Great Roads, pay harbor dues, at the rate of one shilling per ton, register tonnage; and in the event of any ship's going into the Inner Harbor, at Montego Bay, she is charged one half-penny per ton for every day that she may lie in this harbor, in addition to the fee that is paid for anchoring in the bay.

If bound from Montego Bay to the eastward, I would recommend leaving the bay in the evening, so soon as the land wind comes off, which will generally run you clear of the bay and in a good offing for the sea breeze. It is generally recommended to beat to windward close to the land, in order to have the advantage of the eastern currents; but I am of opinion that the only advantage you have by keeping in shore, is, that you meet the land wind, which sometimes will carry you well to the eastward during the night, for the current sets to the westward as often as to the eastward. If your destination be Falmouth Harbor, endeavor, if by night, to keep the shore close aboard, and the land wind will lead you to the eastward.

**PEAK OF TARQUINO.**—In working hence to windward, in clear weather, when Cuba is visible, a remarkable hill will be discerned. This is the Pico de Tarquino, the highest land on this side of Cuba, which bears from Montego Point N. E.  $\frac{3}{4}$  N., distant thirty-five leagues; from St. Anne's Bay, N. by E. twenty-eight and a half leagues; and from the east end of Jamaica, N. N. W. forty leagues, by which you may judge how far you are to windward on any other bearings. The Peak of Tarquino, &c. have already been described.

**FALMOUTH HARBOR, OR MARTHA BRAE.**—This harbor, which lies six leagues to the eastward of Montego Bay, is a bar-harbor. Its channel, or entrance, is very narrow, not more than 16 or 17 feet in depth, and too intricate to be attempted without a pilot. The town of Falmouth is situate on the western side of the harbor, throughout the greatest part of which, there is a regular depth of from 5 to 10 fathoms.

**MARABONA BAY.**—At about three leagues to the eastward of Falmouth, is Marabona Bay, which is very remarkable. It has a low pleasant plantation close to it; and on the hill over it, is a large house or castle, formerly the residence of Brian Edwards, Esq. historian of the West Indies. Within a league to the eastward of this, is the small harbor of Rio Bueno.

**RIO BUENO AND DRY HARBOR.**—Rio Bueno, which lies nearly four leagues to the eastward of Falmouth, is a bay exposed to all winds between N. and W. N. W. and has but indifferent anchorage, the bank being steep. It is seldom visited by other than merchant vessels, which go there to load. From the entrance to the place of anchorage the distance is about two miles. The harbor is formed by two reefs. A ship may lie with the point N. N. W.  $\frac{1}{2}$  W. in 9, 8, or 7 fathoms. Dry Harbor, which lies three miles more to the eastward, is, however, a good harbor for small vessels, although its channel be narrow and has a depth of only 16 feet.

**ST. ANNE'S BAY.**—The entrance of this bay lies in lat.  $18^{\circ} 31'$ , long.  $77^{\circ} 15'$ . It is narrow, and lies between two reefs, which have on their ridges 3 and  $3\frac{1}{2}$  fathoms, deepening abruptly in the channel to 10 and 11 fathoms. The entrance is less than half a cable's length in breadth, and lies with the barracks on the rise of the hill, bearing nearly S.  $\frac{1}{4}$  E., but it is not to be attempted without a pilot. With a northerly wind, a stream of considerable strength sets outwards through the channel: this is occasioned by the great quantity of water thrown over the reefs by the swell. In passing in, as the water is clear, vessels generally pass close to the western reef, on the starboard side.

Mr. Town says, St. Anne's Bay lies about twelve miles to the eastward of Dry Harbor. This bay may be known by its having a very regular row of cocoa-nut trees around it, close to the water's edge, and the town of St. Anne, which stands on the side of a hill on the S. E. side of the bay. The houses stand close to the water's edge on the western side, and the plantations are, in appearance, in a state of cultivation much superior to any westward of this place. The harbor of St. Anne is small, and is close to the town. You may anchor here in from 6 to 9 fathoms, good ground.

**OCHO RIOS**, which lies seven miles to the eastward of St. Anne's, is an anchorage open to the north and N. W. winds. To enter, you sail by a reef which spits off from the eastern side of the bay, hauling up and bringing the westernmost part of it N. N. W.  $\frac{1}{2}$  W. to N. W. in 7 fathoms. There is another reef to the southward, but as the water is very clear it will be seen. This is a small harbor, frequented by merchant vessels only, which go there to load.

**ORA CABECA**, 10 miles to the eastward of Ocho Rios, is another anchorage, exposed like the former, to N. and N. W. winds. To sail in here when advancing from the eastward, first make Galina Point; in order to which, when off at sea, bring the westernmost high land of the Blue Mountains S. S. E., which, thus kept on, will lead to the point. To anchor, give the small reef on the east side a berth, and when the westernmost bluff point bears west, or W. by N., anchor in  $5\frac{1}{2}$ , 6, or 7 fathoms.

Captain Livingston says, it is not generally known that in Allan's Hole, which is formed by reefs level with the water on the one side, and the eastern shore of the bay on the other side, vessels drawing from 10 to 12 feet, may lie as secure as in any harbor in Jamaica. When once inside the reefs the bottom is quite clear, and the reefs completely break the sea off. Vessels drawing not more than 12 feet of water may warp into this place. At the north end of the reef is an islet, with bushes on it, divided from the main land by a narrow and shallow channel. Allan's Hole has two entrances; one through the reef, which is extremely narrow, and one by the point of the reef: but neither ought to be attempted without a pilot.

**GALINA POINT** lies four miles to the eastward of Ora Cabece. This point is low, but the land to the southward of it is high; and in making it from the westward, are remarkable round hill that stands within the point, will, on its first appearance, form the point; but, on a nearer approach, the land slopes off to the northward to a low point.

**PORT MARIA.**—The entrance of this harbor lies in lat.  $18^{\circ} 27'$ , and long.  $76^{\circ} 53'$ . Its anchorage is open to N. N. E., N., and N. W. winds. In coming in, the high island, named Cabarita Island, must be seen, and its northern point should have a berth of two cables' length. You may haul into the bay, and anchor with the N. W. point of the island N. E. or N. E. by N. at the distance of about a cable or a cable and a half's length. Small vessels drawing 10 feet of water, may anchor between the island and the main. The bottom is foul in the outer part of the bay, and many ships have injured it by heaving over their ballast. There is not room for more than 10 or 12 vessels to lie here, as the foul ground extends nearly over the whole harbor.

From Port Maria the coast trends E. S. E. six miles, to Blowing Point; thence it continues S. S. E.  $\frac{1}{2}$  E. about five miles, to Anotta Bay.

**ANOTTA BAY**, which lies about 11 miles to the S. E. of Port Maria, has its anchorage open to N. and N. W. winds. To sail in, give the reef on the eastern side, which is called the Schoolmaster, a sufficient berth; then steer down until you bring the tavern, a building easily known, S. by W. or S. When advanced within the Schoolmaster, haul a little to the eastward, and have the anchor clear, the bank being steep and narrow. The first sounding will be 10 or 9 fathoms. Let go in 7 fathoms, which is about a quarter of a mile from shore, with good holding ground. Be cautious of an-

choring on the western edge of the bank, as it will not hold, and you may be in danger of getting on shore to the westward.\*

Of Anotta Bay, Captain Livingston says, "This is the wildest road I ever saw. No vessel ought to enter it, without being uncommonly well found in ground-tackle. They ought, by all means, to have chain cables. The following is from memory only:—The reef off Gibraltar Point, the Schoolmaster, is much more dangerous than is generally supposed. The late Mr. Angus McDonald, the harbor-master, informed me that it extends fully  $4\frac{1}{2}$  miles out; and some places have only from 6 to 9 feet of water, while there are gaps or gateways through them, with as many fathoms."

PORT ANTONIO, which lies about 8 miles from the N. E. end of Jamaica, was formerly a king's port, where there are still to be seen the remains of a careening wharf, &c. It is formed by nature into two harbors, divided by a peninsula, on which stands the town of Titchfield, to the N. and N. W. of which lies the island called Navy Island, extending E. and W., and about half a mile in length.

To sail into the eastern harbor, first bring the eastern part of the Blue Mountains to bear about S. S. W., and steer in that direction until you approach near Folly Point, the east point of the eastern harbor. Next bring the church (which is a large square building on the side of the hill in the S. W. part of the bay) on with the second wharf from the westward, bearing S. by W.  $\frac{1}{2}$  W., and you will thus pass safely into the harbor. But observe that on approaching the fort, (which stands on the western side, upon the point of Titchfield Peninsula,) to open the church to the eastward of the wharf. When the fort bears N. W. you may anchor in 8, 9, 10, or 11 fathoms, good holding ground. The bottom is, indeed, so stiff that it is rather difficult to get up the anchors.

The preceding directions must be particularly attended to, in order to avoid a reef, which stretches from the eastern end of Navy Island, as well as from the point of the peninsula. The eastern side of the harbor is shoal, and there is a reef nearly in the middle, having over it only 8 or 10 feet of water.

To sail into the western harbor, after having brought the church well open to the eastward of the fort, proceed, under easy sail, into the entrance of the channel between Navy Island and Titchfield, bringing a long building, which is a storehouse, standing on a hill to the westward, open of the south-western point of Navy Island. This mark is to be kept on until the church appears open to the westward of the Peninsula; then haul round to the S. W. and anchor in from 7 to 4 fathoms, where there is good ground.

A channel, called the Hog Channel, leads directly from sea into the western harbor, from the west end of a long reef that extends from Navy Island; but it is crooked and narrow, has only 13 or 14 feet of water on the western part of it, and is therefore used only by small vessels.

The tides here are not regular, being influenced by the winds. The variation in 1771 was  $7^{\circ}$   $15'$  E., and it is still nearly the same.

Of Port Antonio Mr. Town says, the western harbor is the best, the eastern being open to the north winds. When entering the port, with the sea-breeze, keep as nearly in mid-channel between Navy Island and the main as you can. Run in with the leading mark on, and anchor in about 6 or 7 fathoms. If in a small ship, anchor in 4 or 5 fathoms, as the ground without the latter depth is foul.

PORT MORANT.—This is a good harbor, but the reefs extend to the distance of half a mile from shore, on each side of the entrance, and the breadth of the channel between is only a cable's length and a half. As the direction of the entrance is N.  $\frac{1}{2}$  W., it can be attempted only with the sea-breeze, or between the hours of 10 and 2 in the day.

\* A brig of war was lost on the outer reef, a few years ago. I have often heard her name, during my residence at the bay, but it has escaped my memory. She was so far out that no one had any suspicion that she was in the least danger; and it was only in consequence of her loss that they discovered the reefs lay so far out. Mr. McDonald, harbor-master and senior pilot at the bay, surveyed the reefs; but he informed me his survey was forwarded to Port Royal, to be produced at the trial of the officers of the brig which was lost. What I have stated above was from his information.

The earthquake felt in Jamaica, in 1811, was particularly severe at Anotta Bay. Part of the bottom of the bay, about one quarter of a mile from the shore, sunk, and where vessels used to anchor, there is now no bottom to be found; or at least I have been assured none has been found, though I heard somebody at the bay say that it has been, at 170 fathoms. When this spot sunk a vessel was riding, with a kedge out in that direction to steady her. In an instant, as an eye witness assured me, she seemed as if going down stern foremost, and then suddenly rising again, swung round at once. This, it was soon discovered, was occasioned by her kedge being swallowed by the bottom of the bay when it sunk; and the sudden rise of the vessel again was caused by the hawser, bent to the kedge, giving way, or the timber to which it was attached yielding.

Anotta Bay is an extremely unhealthy place; so is Port Maria; but Ora Cabeza is a tolerably healthy situation.

"At the time the barometer a 70°, from which lently adjusted."

To sail in, a ship must lie N. or N. by E. until the leading mark is on. This mark is a remarkable house, which stands upon a hill, in a line with the east end of the easternmost red cliff bearing N.  $\frac{1}{2}$  W. With this mark you may sail into the bay with safety. Take care not to approach too near the reefs, but bring the marks exactly as described. You will thus have 9, 8, 7 $\frac{1}{2}$ , 7, 6 $\frac{1}{2}$ , 6, 5, and a quarter less 5 to 4 fathoms of water. There is anchorage in 6 $\frac{1}{2}$  and 7 fathoms, with the leading mark on, and Pero Battery, which is on the eastern side, bearing E. S. E.

The CAYMANS are three islands lying between the meridians of 79° 30', and 81° 35' W. and parallels of 19° 10', and 19° 45' N. The larger and westernmost is named the Grand Cayman, the second, the Little Cayman, and the easternmost the Cayman-brack.

The Grand Cayman was regularly surveyed by Mr. George Gauld, in the year 1773; but that gentleman ascertained neither its true latitude nor its longitude. Captain Livingston, however, by observations taken 5th August, 1817, proves the key near the S. W. point to lie in 19° 14' N. and the longitude of the east end has been determined by more than one observer; it is 81° 5' W. hence we gain that of the S. W. key, by survey, 81° 29'.

The GRAND CAYMAN is about eight leagues long, and two and a half broad. The S. E. end lies in latitude 19° 16' N. and the N. E. point in latitude 19° 22'. The eastern end is surrounded by a reef, extending a mile and a half from shore, which thence extends along the north and south coasts. Off the S. W. point there is, also, a key and reefs, to which a good berth must be given. The N. W. or west point is three leagues from the S. W. point, and between is the spot called the Hogsties, where there is a small village, off which you may anchor in from 12 to 7 fathoms, by bringing the southernmost house to bear E. by S. at half a mile from shore. The bottom is rocky, but you may see the ground, where you let go, as the water is very clear; it will, however, be proper to buoy up the cables, and steady the ship with a snail anchor.

Captain Dalzel, in some observations on passing the Grand Cayman, has said, "The island is low, covered with cocoa-nut and other trees, and of greater extent than people who never saw it generally imagine. The north side forms a bay, across the mouth of which runs a reef of sunken rocks, which may be readily seen in the day time, before you are near enough to run any kind of risk. It is totally impossible for any thing but small craft to anchor on this side, for there are no soundings close to the reef, and the deepest water over it is 6 feet, although there are 2 or 3 fathoms within it. The small vessels of the island go in here, as they do, likewise, on the south side, which is also foul, and not to be approached by strangers.

"The west end of Grand Cayman, which is best inhabited and mostly resorted to, is the only place where large vessels can come to; though even here, it is but indifferent anchorage; for, without the utmost care you are in danger of getting your cables cut by the rocks; or may, perhaps, let go your anchor in a place where it cannot be purchased. Our anchor got under the shelf of a rock, and we had two days' hard work to purchase it; nor could we have weighed it at all, if we had not borrowed a small anchor, (we rode by our only anchor) and backed with a swivel. This luckily hooked another shelf; we have upon the cable that was fast to it, and then with much difficulty purchased our own anchor from under the rock. We came to in 11 fathoms, but most of the inhabitants say that 8 fathoms is the anchorage.

"Your first soundings going in are about 17 fathoms, three-quarters of a mile off shore; after which you shallow your water 2 or 3 fathoms, every ship's length, till you get into 8 fathoms, where you may come to in one of the white holes. These holes are

\* Observations by Captain James Wallace Monteath:—"In latitude 19° 13' the N. E. point of Grand Cayman, bearing N. 20° W., S. W. point, S. 84° W. and Eastern Reef, north, true.

"Longitude of ship, in time, 81° 5' 15"; by lunars, 81° 2' 1"; mean longitude of the East Reef, 81° 3' 53". Longitude of the east end of the Cayman, by Captain Wilson, of Greenock, 81° 5'; by chronometer, 81° 3'; mean longitude, by Captain Wilson, as in Nautical Almanac, 81° 4'.

"After these observations were made, the ship ran on a W. course for 15 minutes, at the rate of four knots, 6 fathoms; which gives nearly one and a quarter mile departure; equal to 1° 20' difference of longitude; which, added, places the east end of the island in 81° 5' 13' W."

Captain Monteath repeated his observations in latitude 19° 13', when the easternmost point of Grand Cayman bore north; and here his lunars and chronometer exactly agreed. Again, in latitude 19° 15', with the east end of the island bearing W. by N. five miles, the results of four sets, lunar and chronometrie, gave a difference of only 2' 52". The longitude of the Caymans may, therefore, be considered as finally settled.

"At the time the positions of these points were ascertained, the atmosphere in general was clear; the barometer and thermometer stood, on an average, from 29.15 to 30 inches, and from 60° to 70°, from which maximum the corrections for refraction were made, the instruments being excellently adjusted."

patches of sand among the rocks, which you can easily see when looking over the side. Let a careful person look out forward, to pick a large hole, and be sure you let go your anchor well towards the weather side of it, that, when you veer away cable, it may not come upon the rocks. If it should come to blow, and you are in danger of dragging your anchor towards any of the shelves, you must heave it up again. You can plainly see your anchor as often as you please, and you can easily distinguish the rocky bottom from the white holes, by its blackness. Observing the above directions, you cannot get amiss; perhaps you will do best not to take a pilot, as they are not over careful.

"The west end forms a kind of double bay; the southernmost is the road. Give the middle point a good berth, as some rocks lie off it: you need not heave the lead until you see the bottom, for you will get no ground till then."

The Grand Cayman is inhabited by many persons, descended from the old buccanniers, exclusive of negroes. The climate and soil are singularly salubrious; the people are vigorous and commonly live to a great age. They raise various produce for their own use, and have some to spare. As navigators, their chief employment is to fish for turtle, and to pilot vessels to the adjacent parts.

Refreshments may be obtained here; as fowls, turtle, yams, plantains, cocoa-nuts, &c. but no beef nor mutton. Water is procured by filling a bucket about twenty yards from the beach, the well bearing N. N. E. or N. by E. from the anchoring place.

From the S. W. end of the Grand Cayman to Cape Corrientes, the true bearing and distance are N. 47° W. 74 leagues; and to Cape Antonio, N. 51° W. 84 leagues.

The CAYMAN BRACK is very level land, covered with small trees, and at a short distance presents a smooth, unbroken surface, very like Navaza, except towards the S. W. point, where there is a small bunch of trees a little higher than the rest, apparently logwood trees, as they are small leaved. The S. E. point appears very bluff, and the south side also very bold: we run down it at less than a mile distant, and saw no danger of any kind except the breakers on the shore. From off the S. W. point, which is low and sandy, a reef runs off an eighth of a mile, but you can easily see the breakers, and even the colored water, a mile and a half distant. We were not far enough to the eastward to ascertain whether any reef extended from the east end or not, but from the bold appearance of the S. E. point, I should think that if there are any reefs they do not extend to the southward of the east point. The east end of the Cayman Brack is the highest, and with a slight but even declination towards the west end. The Cayman Brack is considerably higher than the Little Cayman, and before leaving the Cayman Brack, you will rise the Little Cayman, of which you will not at first discern scarce any thing, except three large cocoa-nut trees on the east end, and which, at a distance, appear like two vessels at anchor. These cocoa-nut trees are the only ones I saw on this island. These islands are separated by a deep channel, and are resorted to by the turtles.

## THE ISLAND OF PORTO RICO.

This island is thirty leagues in length; and throughout this extent from east to west is a chain of mountains, with branches diverging to the north and south, and extending to the coasts. The whole are covered with wood, and in the intervals are fertile valleys and plains, watered by more than fifty rivulets, in the sands of which gold-dust has been found. The highest summits of the mountains are called the Peaks of Layoonita. They are often covered with snow, and may be seen from a great distance.

The capital, St. Juan, stands on the western part of an island on the north side, which forms a good harbor, defended by a citadel, called the Morro Castle, and other works. The town is populous and well built; the see of a bishop, and the residence of the governor.

The northern coast, which extends like the southern coast, nearly east and west, is but imperfectly known. It is rugged and uneven, having many rocks and islets, on which the sea breaks heavily. Fifty miles north from Porto Rico, Captain Baxter, in brig Robert, struck on a rock, and remained several hours. The town of St. Juan, which stands at the distance of 9 leagues from Cape St. Juan, is the N. E. point of Porto Rico.

There are no large bays either on the northern or southern coast, and a vessel may generally run along the former without any risk, at the distance of three miles, and along the south coast at five; only observing in the latter case, to give sufficient berth to the

small isle called Dead Chest, which lies about half way between the S. E. and S. W. points of Porto Rico.

The Harbor of St. Juan\* is very capacious, and the largest ships may lie there with the utmost safety, in 5, 6, and 7 fathoms. The entrance is along the island on which the town is erected, and between the Morro Point and three islets, called the Cabras or Goat Islands. South of the latter is a small islet, occupied by a little square fort or castle called the Canelo, which defends the western side of the harbor. The channel is generally buoyed.

The western and southern sides of the harbor are flat and shoal. The western side of the entrance is rocky, but in the channel the ground is generally of gravel and sand, with a depth of 5, 6, 7, and 8 fathoms. From the south side of the town, a low point of land extends to the southward, and is surrounded by a shoal. Ships generally ride to the eastward of this flat, and out of the wash of the sea, occasioned by the trade-wind, which commonly sets directly into the harbor.

If you make the harbor with the wind southerly, you must run into the channel with all the upper sails well set, in order to preserve your way, when you come under the lee of the Morro, and have a boat out for towing, or to carry out a warp, both of which are frequently necessary. It is high water in the harbor at 8h. 21m. on the full and change, and the greatest rise is about one foot and a half.

Off the eastern coast of Porto Rico, are numerous keys and rocks which cannot be approached by large vessels, and therefore serve as a rendezvous for smugglers, &c. Before these are the isles Culebra and Vieque, or Snake and Crab Islands. The passages among these isles and rocks are generally deep; but no one may venture in who is not intimately acquainted with the place.

#### *Passage between St. Thomas's Island and Culebra and Crab Islands.*

In this channel there are soundings, with 20 fathoms on the west side of it, and, approaching either the island of Culebra or Vieque, it is shoaler. We had 10 fathoms, with the following bearings:—East end of Crab Island, S. by W.  $\frac{1}{2}$  W.; east end of Culebrita, N. by W.  $\frac{3}{4}$  W.; and Sail Rock, E. by N.  $\frac{1}{4}$  N. The currents set through this channel strong to the westward, which would render it necessary, in case of being becalmed, to anchor before you are drifted on the western shore.

**VIEQUE, OR CRAB ISLAND.**—It is of moderate height, and well wooded. The S. W. end is hilly, and to the westward it is low and uneven. On the west end is a low and sandy point, and with it bearing N. by E., about one mile and a half, is the anchorage. In working in do not bring this point to the southward of east, as there are numerous shoals between it and the east side of Porto Rico. We found the soundings regular, and  $1\frac{1}{2}$  mile from shore you will have 6 fathoms. The shore should not be approached nearer, as the soundings there are irregular and the ground rocky. There are a few settlers, principally on the north end. There are two sandy bays on the west side: the northernmost is bold and the bottom of sand. You may approach it to within three fourths of a mile, with 4 fathoms. The southern one has a rocky bottom, soundings irregular.

**CARLIT, OR SERPENT'S ISLAND**, sometimes called the Great Passage Island, is more than six miles in length. It has numerous reefs and keys about it, which require a large berth when passing. Off its eastern side is Culebrita or Little Passage Island, from the south end of which a dangerous reef extends to the S. S. W. and S. W. three miles. To the west or the southern part of this reef is the harbor of Culebra, which is two miles in extent from the entrance. There are two channels into this harbor, which are divided by a bed of rocks, and bordered with reefs, but the interior is clear and secure. Great caution is required when entering; but a pilot lives in the port. Plenty of wood, water and fish, may be obtained. The neighboring keys are famous for the great number of tropical birds which breed here.

The course through the Virgin's Passage, on the east of Vieque and Carlit, is N. W. by N., or rather N. N. W., in case of a calm and lee current; the western side being foul, and without wind, it is dangerous. Continue on this course until Cape St. Juan, the N. E. point of Porto Rico, bears W. by S. or W. S. W., and you will be clear of all danger.

If you are bound down the south side of Porto Rico, observe you will see the S. E. point of that island when lying at anchor at Crab Island; it bears from thence, S. W. by W.  $\frac{1}{2}$  W., or W. S. W., about  $4\frac{1}{2}$  leagues, and is called Pasqua, or S. E. Cape. You may run down till you come abreast of that cape, within three or four miles of it, and then steer west, and by the time you have run three leagues down past the cape, and it bears

\* See plan published by E. & G. W. BLUNT, 1833.

N. E., you will see a large breach or shoal, two or three miles in length, which lies three or four miles from the coast. By keeping a mile or two without the breach, in running down, you will descrie a small building by the water side, which is a guard-house; and by running down as directed until the guard-house bears N. or a little to the weathermost of that bearing, you may haul in N. or N. by E. for it, and anchor in 4 fathoms, with the house bearing N. or N. by E. one mile distant, and the west end of the breach S. by E. This place is called \*Guayamo or Yamma Bay, and is much frequented, though there is no other shelter from the effects of sea-breezes than the reef. In going in, although you give the west end of the reef a good berth, you must keep the lead going; the soundings are irregular, from 5 to 7 or 8 fathoms, whence it shoalens gradually in shore. The land by the water side is low, but up in the country high and uneven, as before explained. In going out of Guayamo Bay, run S. S. W. or S. W.

From Guayamo Bay the next trading place is Salinas, a good place to lie in. The Caja de Muertos or Dead Chest, may be seen from, and is a guide to it. When at the distance of from two to three leagues from Guayamo Bay, you may steer W.  $\frac{1}{4}$  S., passing several keys to the northward, which lie near the shore; then, having run to a sufficient distance, haul in for the western end of the outermost of these keys, and about a mile or a mile and a half off that end is a reef, or sunken key, which cannot be seen, but the sea breaks over it; leave this to the westward, and run with the westernmost key on board, within a cable's length. This key is bold to, but shoaler to leeward towards the breach. The guard-house is three or four miles from this key, and may be seen before you get within. You may run in boldly for two miles towards the guard-house, and anchor within a mile of the same, in four or five fathoms, good ground, and moor to the north-west.

When at anchor at Salinas, with the guard-house bearing N.  $\frac{1}{2}$  E., there is a good watering place close to the water side, a kind of lagoon which will be about N. by W. from the ship, and half a mile to westward of the guard-house. The water appears white to nearly a league without the key. The soundings are from 12 to 7 fathoms, very gradual, and there is no danger.

Within the key above mentioned, there are several other keys a little to the eastward of it; and in running in you will see, at about three leagues to westward, two small keys at a little distance from each other, one appearing double, the other single; you leave them to windward.

In quitting Salinas, steer outward in the same way as you entered. When without the key steer S. S. W. until the Dead Chest bears west; you may then run down boldly, giving that isle the berth of a mile. There is a small key about a cable's length from the S. W. end of the Dead Chest, to which a berth of a mile and a half should be given. You may then haul in, and anchor under the lee of the isle, at pleasure, in from 7 to 12 fathoms. With the west point of the small key S. by E.  $\frac{1}{2}$  E., one mile and a half distant, and the north end of the Dead Chest, N. E.  $\frac{1}{2}$  E., there are 10 fathoms of water, at a mile from shore.

**CAXA DE MUERTOS, OR DEAD MAN'S CHEST.**—This island is on the south side of Porto Rico, and bears E.  $\frac{1}{2}$  S. 36 miles from Cape Roxo. When made it appears in form of a wedge. The north end is high, the centre low, and the south end has a sugar-loaf mountain, which at a distance appears a detached island. The anchorage is on the west side, off the low land, half a mile off shore, in 8 fathoms, in the following bearings:—South-east point of the small island, connected to Caxa by a reef above water, S. W.; the only sandy bay, S. by E.; the north-west point and northern peak in one, east. There is no danger on the west side of this island, and off the low land the soundings are regular; but to the northward of it the water is deeper, and you will have 17 fathoms close to the shore. Off the southward of the island there is a shoal, which breaks about half a mile off shore.

**PONCE.**—The town and harbor of Ponce lie about 4 leagues to the east of Guanico. To run for this port keep a mile off the small key off the S. W. end of the Dead Man's Chest, and run N. W.  $\frac{1}{2}$  N., or N. W. by N. The land is low near the water, covered with mangrove bushes and some coconut-trees; but the houses are also low, so that you will not see them until you open the harbor. In running over, you will see a low sandy island, which you leave on the larboard hand. If it blows fresh, the reef which you turn round on the starboard hand, will appear as though there were breakers across the mouth or the harbor, but as you approach you will find the breakers do not make off far from the bushes. You may pass them within two cables' length, and keep nearest the shore on the southern side of the harbor.

\* Guayamo may be known by a windmill on a hill one mile to the westward of the anchorage.

In proceeding low, the cape, at this cape, the edge no boat W. 8 or 9.

In proceeding on a west course towards Cape Roxo, that cape, when first seen, appears low, grey, and like two keys. A shoal, called the \*White Grounds, encompasses the cape, and extends to the S. W. At 2 or 3 leagues to the eastward and westward of this cape, there are 10, 12, and 15 fathoms. It is a coral bank, and close to the outer edge no bottom is to be found. The southern extremity bears from the cape S. W.  $\frac{1}{2}$  W. 8 or 9 miles.

The schooner Dick, Capt. Miles, of and for Baltimore, from La Guayra, with a cargo of coffee, struck on the Morillos Rocks, south side of Porto Rico, at midnight, on the 13th of June, and was totally lost.

Nearly half way between the Caxa de Muertos and Cape Roxo is the small but secure harbor of Guanico, which is described hereafter. Four leagues more to the east, is the village and road of Ponce.

To enter Mayaguez, (Porto Rico,) bring the island of Zacheo to bear W. N. W. and steer E. S. E. You may approach the island within 50 fathoms. There is a reef which begins about  $1\frac{1}{2}$  mile from Zacheo, and extends to Cape Roxo, forming a chain with only 10 feet water, and not to be attempted but by small vessels. In steering E. S. E. you will perceive a gully running from the mountain, made by frequent rains, without a tree or bush on it.

To anchor in Mayaguez Bay, bring the island of Zacheo to bear W. N. W., then steer E. S. E., which will bring you in sight of the town. Going in you will see a reef on your starboard hand; when abreast you will have soundings in 13, 12, and 10 fathoms; you may run into 7 fathoms and anchor: the extreme points of the bay will bear from S. by W. to N. W.; the east part of the reef about N. W.  $2\frac{1}{2}$  miles. There is a good river for watering.

*Extract from the Journal of an experienced Navigator, along the south side of Porto Rico, and in the channel between Porto Rico and St. Domingo, &c.*

"May 19th, at 5 o'clock, P. M. we thought we descried to N. W. and N. W. by N. the little island of Boriquem, (Crab Island,) situated near the S. E. end of Porto Rico. At 11 we saw the land on the larboard hand: I supposed it to be the east point of Porto Rico, which bore from us N. W. and N. W. by N., distant about 3 leagues: I steered west to run along its south side.

"May 20th.—At half past 5, A. M. we saw Porto Rico, and the Dead Chest, which is a small island detached from the main one, and having the form of a coffin. It lies very near the middle of the south coast, and I have been assured that there is a passage for the largest ships between it and the main land.

"I ran along the land, with an offing of 3 or 4 leagues, to fetch Cape Roxo, the westernmost of the south coast of Porto Rico, and which forms, with the S. E. point of St. Domingo and Saona Island, a channel from 15 to 20 leagues broad.

"About 10 A. M. we saw the water discolored: we were upon a shoal called the White Grounds, which encompasses Cape Roxo, and extends 3 or 4 leagues to the S. W. and 2 or 3 leagues to the eastward and westward of this cape. You have there 10, 12, and 15 fathoms. The sand at the bottom is of such a shining white, that it pierces through the water. We caught plenty of fish with the line.

"At 11 we distinguished a cape, which lies a little to the eastward of Cape Roxo. It is terminated to the south by four little islands, which seem to be one league distant from it. To the east of this cape is a small bay, called in Van Keulen's chart by the name of Porto Guanico. The West India sloops can moor there: we saw two of these at anchor. This cape is low, and appeared at first as a detached land, but we soon discovered the low land by which it is connected with the main island. Cape Roxo, which you soon descried to the westward of this, and which is the westernmost point of the island, is still lower than the former. Between the two you distinguish a flat and very white sandy shore: it consists of the same sand that composes the White Grounds, through which you may sail, but you must not come nearer the coast than two leagues.

"In the western part of the channel, between Porto Rico and St. Domingo, and near mid-channel, are two small islands; the easternmost, which is likewise the southernmost, is called Mona: the second to the N. W. of the former, distance about  $2\frac{1}{2}$  leagues, is called Monica. You must pass, if possible, to the windward, that is to the eastward of those two islands, in order to double with more facility Cape Engaño, that forms the going out of the channel, to the west on the side of St. Domingo. When you have doubled Cape Roxo, you descried to the northward of Zacheo, a little island lying 8 or 9 leagues to the N. E. by N. of Mona. You leave Zacheo to windward, to pass between

\* The tracks and soundings on this shoal are those of the U. S. frigate Congress, Charles Morris command, and may be depended on.

of the anchorage.

it and the small island of Mona, very near mid-channel: there is no danger but what you can see. When the wind comes from the E. S. E. or only from the east, you are not obliged to tack, you cross the channel with a quarter wind. It is sufficient to steer N. W. by N. to fetch Cape Raphael, which is the N. E. point of St. Domingo, or even Cape Samana, that lies about 8 leagues to the N. W. of the former. Samana Island, whence this cape takes its name, extends from east to west, 12 leagues: it is so near St. Domingo that it appears to be joined with it.

"At noon Cape Roxo bore N. by W. distance  $3\frac{1}{2}$  leagues. It was not possible, on account of the cloudy weather, to take the meridian altitude of the sun. We steered N. W. by N. to enter the channel.

"At half an hour after 12, I could see Zacheo very plainly: I continued the same course to run along it, at one or two leagues distance. This island appears to be 800 or 1000 yards long; it is nothing more than a green mountain, on several parts of which you see some woods. I was too much to windward to see the islands of Mona and Monica from the deck, but they could be perceived from the mast head. The wind kept to the S. E. till 4 o'clock. It is very seldom that in sailing through the channel of Porto Rico, you go before the wind as I did."

*Description of Porto Rico, from the "Derrotero de las Antillas," &c.*

"This island is 31 leagues in length from east to west, and 11 leagues in breadth in the broadest part. The N. E. point of it is named Juan, (St. John's head,) where the range of mountains called Luquillos commences. The highest part of these, El Yunque, or the Anvil, may be seen at the distance of 68 miles. The range continues to the westward with many intervals or openings, until it ends at the hill named Silla de Caballo, (Horse's Saddle,) which is to the southward of Arrecibo.

The harbor of San Juan requires a pilot. The harbor of Arrecibo is about  $9\frac{1}{2}$  leagues more to the west; it has a small town on its western side, and a good river, but is little frequented, being open to the north winds. From Arrecibo the coast trends nearly true west to the N. W. end of the island. The land here is generally low until it reaches

Punta de Pena Agujereada, (or Point of the Holed Rock,) where a kind of clifly high land begins, which trends S. W. rather more than a mile to Point Bruguén, the north-westernmost point of Porto Rico. The coast again declines in height, and forms a convex bow to Punta de Penas Blancas, (Whitestone's Point,) the north point of Aguada Bay.

**AGUADILLA BAY.**\*—From the Point Penas Blancas, the little town of Aguada bears S. S. E. 2 miles. In the bay before the town, or rather village, is anchorage for the largest ships, with shelter from the sea breeze. This bay may be entered at any hour of the day, with facility and safety, but not at night, as the breeze then dies away and a calm ensues. There is excellent water to be obtained at a rivulet which passes through the middle of the village. The situation of the latter as given by the Spanish officers, is lat.  $18^{\circ} 25' 53''$ , long.  $67^{\circ} 0' 20''$ .

This bay is much frequented by vessels bound from Europe to Cuba, both on account of the facility with which they can procure refreshments, and because pilots for the Bahama or Old Channel may always be found here. If intending to anchor in Aguada Bay, after rounding Point Bruguén, keep about three cables' length from the shore, in order to give berth to a shoal which spits out from Punta de las Palmas; whence to that of Penas Blancas you may approach the coast nearer, as it is very clean; and at half a cable's length from the shore you may find four fathoms of water.

To anchor bring Point Aguada N. N. W. 2 or 3 miles, the church tower E. N. E., the island of Zacheo W. by S., when you will be in 10 fathoms water about three cables' length from the shore; there is a good river of fresh water; the sea in general smooth, with usual trade wind; but should the wind incline to the northward avoid anchoring, or weigh as soon as it sets in.

At S. W. by W.  $7\frac{1}{2}$  miles from the village of Aguada, is Point St. Francisco, with various rocks about it. All the coast between has a beach, with many shoals formed by the rivers that empty themselves into the sea. At two cables' length from the coast are 4 fathoms of water, with bottom of rocks and sand; but there is no anchorage. At S. W. by S. rather less than half a mile from Point St. Francisco is Point Guigero, the westernmost point of Porto Rico, otherwise called El Rincon. About it the ground is shoal with many rocks.

\* Called Aguada on some charts.

*Remarks on Aguadilla Bay, &c. by Capt. John Mackellar, R. N.*

"The town is in lat.  $18^{\circ} 24' 57''$ , and long.  $67^{\circ} 8' 15''$ . In proceeding for the anchorage from the northward, you may run round the N. W. point of the island, about S. W. or S. S. W. within a mile of the shore; your depth of water will be 20 or 25 fathoms. Point Bruquen, the N. W. point, is a high steep cliff; about a mile to the southward of it is Point Palmas, a low sandy point, covered with trees. The latter forms the north side of the bay, and in rounding you must give it a berth of a mile, as a reef stretches off at that distance. Having rounded this reef, with the bay fairly open, you will see the town, lying in the N. E. side of the bay, with straggling houses to the S. W. for two miles. The anchorage is before the town and near the shore. The whole of the bay is perfectly clear with the exception of the white reef, (Penas Blancas,) extending from Point Palmas; and you may stand to a quarter of a mile from shore any where, for the depth of water will not be less than 7 or 8 fathoms. The marks for anchoring are, a large house standing by itself, about a cable's length from the north end of the town. Between it and the town is a small battery of three guns. Bring this house to bear N. E.  $\frac{1}{2}$  N., the church steeple E.  $\frac{1}{2}$  S., and the north point of the bay N. by W. Here you will have 18 fathoms, and very good bottom, at about half a mile from shore. The anchorage is very good farther in shore, in from 10 to 15 fathoms. If you moor, lay your anchor in 10 fathoms, and enter one in from 15 to 18. There is also good anchorage in from 20 to 24 fathoms, but there you are more liable to drive off the bank. In shore the anchorage is so extensive, that you can hardly err in anchoring any way before the town. The winds are frequently variable, and render it difficult to get up to the anchorage. At times the sea breeze blows fresh over the land from the N. E.; then you may beat in with ease.

In the winter months, when the north wind blows strongly, there is a heavy swell into the bay, and great surf on the beach. Large ships ought not then to anchor farther in than from 23 to 25 fathoms; they will thus have room to get under weigh and work out, in event of its coming on to blow; and, as the west point of the bay bears from the anchorage S. W.  $\frac{1}{2}$  W. a ship will lay out with the wind at N. W., and may run through between Zacheo and the S. W. point of the island.

"Ships coming from the southward for Aguada, may also pass between Zacheo and the island, and when Zacheo bears W. by S. they will have the bay fairly open, and may work up as above; taking care to keep the west point of the island bearing to the southward of east; for off it there is foul ground all the way to the southward, as far as Cape Roxo, but all clear to the northward.

"From Point Guiguera, (says the Derrotero,) the coast trends S. E. by S. three and a half miles to Punta de la Cadena, having one small bay, named del Rincon, which, although well sheltered from the sea breeze, has a very unequal bottom, and is full of rocks. After Punta de la Cadena follows that of Algarroba, which lies S. E.  $\frac{1}{2}$  S. from the former. Between these points lies the Bay of Anasco, fit for vessels of any size, in which they will be completely sheltered from the Norths, or north winds. The coast is all beach, and the bank or shallow water which extends from it about half a mile, is probably formed by the river Anasco, which disembogues at this place.

"The Punta de Algarroba is the north point of the Bay of Mayaguez, and lies nearly N. by E. and S. by W. with the south point named Punta de Guanagivo: the distance between them being about four miles.

"The Anchorage of Mayaguez is well sheltered from the Norths and fit for brigs and ships, provided they are not very large; but a good knowledge of its entrance is necessary, in order to avoid a shoal, which stretches out about half a mile from Punta del Algarroba. It is necessary, also, to give a berth to the Punta or Little Point, for a reef stretches out about two cables' length from it.

"To the westward of Punta del Algarroba, and about a large mile from the coast, there is a rocky shoal named las Manchas, with 4 fathoms of water on it: but vessels may pass very well between it and the shore.

"A little without the line of the two points, and about half way between them, is a rocky shoal, stretching nearly N. and S. Its length is about half a mile, and its greatest breadth not much less; it is named Pazo de Rodriguez, (Rodrigo's Shoal.)

To anchor in the part of the bay which is best sheltered, having rounded the Little Point, (Puntilla,) place your vessel in such a situation that when the island Desecheo is directly astern, you will have the highway of the town of San German exactly ahead. St. German is upon a hill which is pretty high and pointed. The highway is of red earth, and winding like a snake, and there can be no danger of mistaking it, as there is no other. Run thus until being something to the southward of the Little Point, you may luff up and anchor within it, in either 3 or 4 fathoms, as you may think proper. The

river of Mayaguez runs into the sea at the bottom of this bay, and in it the schooner and sloops for the most part winter, as it is the best anchorage on the west coast of the island.\*

"South from Punta de Guanagivo, about  $5\frac{1}{2}$  miles, is Puerto Real de Cabo Roxo; its figure is almost circular, and the extent from west to east is about three quarters of a mile. At its entrance are 3 fathoms of water, and in its middle 16 feet. The entrance is by a very narrow channel, near the south point of the harbor, and from the north point a great reef stretches out, which, doubling Cayo Fandeco, ends at Puxta de Varas.

"S. S. W. from this port, at the distance of two miles, is the Punta de Guaniguilla, which is the north point of a bay named Del Boqueron; this is so full of reefs as not to allow anchorage. Punta de Melones, (Melon Point,) which is the south point of the bay, is distant from the first (Guaniguilla) about two and a half miles, or a little more; and nearly west from this point, at about six and a half miles distant, is the Baxo de Gallardo, (Gillard's Shoal,) of which we shall speak hereafter. Along the whole of the west coast the Monte (or Hill) de la Atalaya may be seen. It is the highest and most northerly peak of the two, which are seen on the highest part of the mountain range, and which stands S. E. by E., true, from the Punta de San Francisco, and which does not alter the appearance of its shape even when you are to the southward of the Isle Desecheo."

**SHOALS OFF THE WEST COAST.**—Besides the shoals on this coast already noticed, there are several others, which we shall now describe.

"1st. That denominated Baxo Negro, (Black Shoal,) which is a reef of very small extent, and upon which the sea always breaks. It is distant from the nearest coast about  $3\frac{1}{2}$  miles, and lies W. S. W.  $\frac{1}{2}$  W. from Punta Guanagivo, and S.  $\frac{3}{4}$  E. from Punta de Guiguera.

"2d. That called Media Luna, (Half Moon,) which is a reef of about two thirds of a mile in length, north and south, and about two and a half cables' length. The sea always breaks upon it; it is about five miles from the coast; half a mile from it, about E. N. E., there are three rocks which show above water, and on which the sea always breaks. The northern extremity of the reef is nearly S. W. by W. from Punta de Guanagivo, and south from Punta de Guiguera.

"3d. That named Las Coronas, (the Crowns,) which are shoals of sand, on which at times the sea breaks, and the extent of which, in all directions, is scarcely a mile. It is about three and a half miles distant from the coast, and bears nearly S. W. by S. from Punta de Guanajibo, and S.  $\frac{1}{2}$  E. from Punta de Guiguera.

"4th. A shoal which lies to the westward from Punta de Guaniguilla, at the distance of two miles. It may be about two cables' length in extent, and there are three fathoms of water upon it: the bottom is rocky. It bears S. by W.  $\frac{3}{4}$  W. from the Punta de Guanagivo, and S.  $\frac{3}{4}$  E. from Punta de Guiguera.

"5th. Baxo de Gallardo, which is almost due west from Punta de Melones, and six miles and a half distant from it. Its extent is about three cables' length, and the least depth of water on it is 3 fathoms, with rocky bottom. It lies with the Isle Desecheo bearing N. by W.  $\frac{3}{4}$  W., Monte de Atalaya S. by W.  $\frac{3}{4}$  W. and the southern extremity of the Morillos E. S. E."

**The South Coast, from West to East.**—From the Morillos, or Little Hills, in the S. W., to Cape Malapasqua, which is the S. E. extremity of the island, the coast is of double land, and is very foul, with reefs, islets and shoals, which stretch out from it. In the middle of it is the island Caja de Muertos, or Coffin Island, distant from the coast four miles, and foul on both its N. E. and on its S. W. sides.

**Guanico.**—On this coast the best anchorage is in the harbor of Guanico, five leagues to the eastward of the Morillos: it is fit for vessels of all classes, with from  $6\frac{1}{2}$  to 3 fathoms of water, which latter depth is found in its interior. The bottom is of sand and gravel. The mouth of the harbor is in the middle of a bay, formed by the point and cliff of Brea, (Pitch Point,) on the west, and that of Picua on the east. In the neighborhood of this last are two islets, and from them to Punta de la Meseta, which is the

\* The following is a former description of the Bight of Mayaguez: On the western side of Porto Rico is the Aguada Nueva, one of the finest roadsteads for shipping in the West Indies, being sheltered from the trade winds by the island. Here the galleons and flota generally anchored and obtained refreshments when they came from Spain. Ships may anchor in the road in from 23 to 3 fathoms, good ground. In 23 fathoms, soft oozy ground, the northernmost point bears N. N. W. 3 miles, the other point S. by E. about two leagues, and a small village among the trees is distant about one mile. In coming into this road from the northward, you may sail within a mile of the shore to the southward of the north point, there being 10, 12 and 15 fathoms of water; and, having passed that point, you will have 25 and 30 fathoms, soft oozy ground. Some part along the ground is flat and rocky, but you may sail all round within half a mile of the shore.

you ought to c

east point of the entrance of the harbor, there is a reef, which reaches out from the coast about a mile, and nearly forms a circle, uniting at one end with the islets, and at the other with Punta de la Meseta.

Between Punta de Brea and Punta de los Pescadores, (Fisherman's Point,) which last is the west point of the mouth of the port, the coast forms another bay, of which the mouth is shut by a reef that, running out from Punta de Pescadores, ends on the southside of the bay, about a mile within the point and cliff of Brea. It is necessary not only to give a berth to the reef which runs from Punta de Picua to Punta de la Meseta, but, also, to a rocky shoal, which stretches out a short half mile from it.

To enter this harbor you must steer on the outside of these banks or reefs. To do this, bring the Punta de la Meseta exactly in one with one of the Paps of Cerro Gordo, which are at some distance inland. If you run in with the point in one with the western Pap, you will shave the bank very close, but will have 10 fathoms of water: but, if you run in with Punta de la Meseta in one with the eastern Pap, you will pass without any risk whatever. You will have passed the shoal when the islets at Punta Picua bear E.  $\frac{1}{4}$  N. or perhaps a little sooner.

If you advance to the harbor by Punta de Brea or Pitch Point, you may pass this point or bluff at a cable's length, and thence steer to within the Punta de la Meseta, passing it, if necessary, at a quarter of a cable's length, and thence proceeding for the interior of the harbor, only observing that you may make holdier with the south than with the north side of the entrance. You may anchor where you please in 4 or 5 fathoms of water.

#### *Directions for making Porto Rico, &c.*

By those advancing from the eastward, and bound for Porto Rico, every precaution must be taken, so as to avoid the dangers of Anegada. This island, the last of the Virgins to the N. E., is so low, that it may be considered rather as a dangerous shoal, than as an island. If navigating with care, and with certainty of the situation of the vessel, nothing is easier than to cross the meridian of Anegada on a parallel above  $19^{\circ}$ , and so to run down afterwards on Porto Rico, as to make the land to windward of your destined port: thus you will not be obliged to beat up again for a distance overrun, at the expense of both time and labor. But as it may happen, among the multitude of those who navigate, that some one may be misled by an erroneous reckoning, and find himself in this predicament, we recommend it to such, in order that they may avoid the dangers of Anegada, and also avoid overrunning Porto Rico, that they, at all times, shape a course to make the islands of St. Bartholomew and St. Martins, (or the parallel of  $18^{\circ}$ ) because these islands are high and clean, and there is no danger of being wrecked on them, although sailing by night, or in thick weather, so that you have a league of horizon; for that distance here affords time, either to steer so as to take some of the channels, or in case you prefer it to haul by the wind, and wait for daylight, or for clear weather. Neither is there a risk of passing them without seeing them; and even if by a combination of circumstances, which will be very strange, this should happen, they could not fail, on the following day to see some of the Virgin Islands, by which the situation of the vessel might be rectified. In choosing either of the channels between St. Bartholomew and St. Martin's, or between the latter and Anguilla, we should prefer the latter, because it has no detached islets lying off from the principal lands: and, therefore, running through it, even at night, it is not so unsafe. Having run through any of these channels, the course must be made to the south of the Virgins, and thence to the N. W. so as to make the Cape of St. Juan of Porto Rico, and having recognized this, you have only to run afterwards as may best answer for your port of destination.

From the island of Porto Rico you may escape from the region of the general or trade winds, into that of the variables, merely by steering to the north; and, as this island is so far to windward, it is easy to gain all the easting that is necessary for going to the lesser Antilles or Caribbee Islands. You may gain thus to windward, and beating with the breeze without being under the necessity of running into high latitudes to catch the variables. On Porto Rico you cannot count on land breezes to facilitate the getting to windward, for on the next coast, the utmost is that the breeze calms at night, but no land breeze proceeds. Lastly, from this island you may, on one stretch, catch any point of the Colombian Main, from Laguayra to leeward.

#### *General Directions for the making of, and navigating among, the Caribbee Islands.*

[From the Derrotero de las Antillas.]

As to choosing the north or south part of any of these isles for making your land-fall, you ought to consider, firstly, which point is nearest to the port or road to which you

are destined; and, secondly, the season in which you go. In the dry season, it is to be remembered that the winds are generally from the north-eastward, and in the rainy season they are often from the south-eastward. Thus, in the dry season, it is best to make the north side, and the wet season, the south, but without losing sight of the first consideration.

There can be no mistake in recognising any of the Antillas; and, in making St. Bartholomew's and St. Martin's alone, can there be any doubt on seeing at once the eminences or heights of various islands. That this may not mislead any one, they must remember the following instructions.

When in the parallel of St. Bartholomew's, at less than four leagues off, if there be no fog or haze, the islands of St. Eustatius, Saba, St. Kitts, Nevis, and St. Martin's appear plainly.

The mountain of St. Eustatius forms a kind of table, with uniform declivities to the east and west. The top is level, and at the east part of this plain a peak rises which makes it very remarkable. To the west of the mountain seems to be a great strait, (in consequence of the lands near it being under the horizon, or seeming drowned,) and to the west of that there then appears, as it were, another long low island, the N. W. part of which is highest; but it is necessary not to be deceived, for all that is part of the land of St. Eustatius. From this station Saba appears to the N. W.; it is not so high as St. Eustatius, and apparently of less extent than the western part of St. Eustatius, which is seen insulated.

The N. W. part of St. Kitts is also seen, formed by great mountains, in appearance as elevated as St. Eustatius, with low land to the east: to the eastward of this low land Nevis will be seen, apparently higher than all the others.

The lands of St. Martin's are notably higher than those of St. Bartholomew's; and this island appears also when you are some leagues farther distant from it than from St. Bartholomew's.

When there are any clouds which hinder St. Martin's from being seen, there may be some hesitation in recognising St. Bartholomew's; and thus it is proper to notice that the latter, seen upon its own parallel, appears small, and with four peaks, trending north and south, and occupying almost its whole extent; and if you are not more than eight leagues from it, you will see, also, the appearance of an islet to the north, and another to the south, at a very short distance. As this island has neither trees, high mountains, nor thickets, it is not subject to fogs; and it may therefore be seen oftener than St. Martin's, St. Kitts, Nevis, St. Eustatius and Saba; it is therefore advisable to keep its appearance in mind.

At eight leagues to the east of St. Bartholomew's you may see Nevis very high; from it to the west the strait called the Narrows, and then the lands of St. Kitts, appearing to rise out of the water, and which continue increasing in height to the westward, so that the westernmost of two mountains, which are at the west part of it, is the highest. This mountain, which is higher than that called Mount Misery, has to the west of it a gentle declivity, terminating in low land; and it cannot be mistaken for any other. To the west of this you may also see the large strait towards St. Eustatius; but from this situation you will see only the high S. E. part of that island, or rather its mountain, in consequence of which it appears like a very small island, while its mountain seems to be lower than Mount Misery; but it is easily known from the table which its top forms, by the uniform declivities to the east and west, and by the peak on the S. E. part of it. Saba seems, from this situation, equal in size to the visible part of St. Eustatius; but it shows only an eminence without peaks, with uniform declivities, and almost round.

If a small islet appears to the west of, and very near to, St. Eustatius, that must not confuse you; for it is the N. W. extremity of that island; and on getting nearer, you will perceive the land which connects it with the S. E. part. Mount Misery, on St. Kitts, which has a very high and sharp peak on the eastern part of its summit, seems at a distance to be the summit of Mount Eustatius; but it cannot be mistaken for such, if you attend to its surface being more unequal than the table land at the top of St. Eustatius, and that there is another less elevated mountain to the east, and with gentle declivities, which show much land to the east and west of the high peak.

On no part of Mount Misery can any resemblance be traced to a man carrying another on his back, and which, according to a saying, was the reason why Columbo named this island St. Kitts.

When you are six leagues to the east of St. Bartholomew's, its N. W. extremity appears insulated, and has the appearance of a pretty large island, on the top of which there are four small steps, (like steps of stairs, Escalones,) with a considerable strait to the south, between it and the principal island. In the middle of this strait you may also see a smaller islet. This is really one of the islets which surround the island; but the first is only the N. W. point, to the north of which you will see also some islets: all these are much nearer St. Bartholomew's than St. Martin's.

Finally, to navigate from one of the Antillas to another of them, there is no more trouble than what a simple navigation requires; but it is something greater when you have to get from leeward to windward; yet this will be reduced to a trifling consideration, if the navigation is made by the straits which are to the north of Martinique, and in which the currents are weakest; but the same does not follow in the southerly straits, in which the waters set with more vivacity towards the west; and it would be impracticable by the straits of Tobago, Grenada, and St. Vincent, in which the waters run at the rate of not less than two miles an hour.

## WINDWARD AND LEEWARD ISLANDS.

Under the denomination of Windward Islands, we include the whole range from the Virgins to Trinidad; and under that of Leeward Islands, the range which exists between Trinidad and the Gulf of Maracaybo.

The Windward Islands appear at a distance as if united together; but there are many deep channels between them, through which those acquainted sail with safety.

The Passage Isles, which are dependencies of Porto Rico, and the Isle of St. Croix, or Santa Cruz, which lie to the southward, were originally included under the general name of the Virgin Islands.

The western division (Danish) includes the islands of St. Thomas and St. John, with the numerous islets, as those of St. James, Montalvan, or Little Saba, Savanna or Green Island, the Brass Isles, Hanseatic, and others. The eastern division (British) includes Tortola, Virgin Gorda, Anegada, Jost Van Dyke's Isles, the Thatch Isles, Normand's, Peter's, Salt, Cooper's, Ginger, Beef, Camanoa, Scrub, and Guana Isles, with a number of islets in their vicinity. The whole group, Anegada excepted, is high, craggy, and mostly bold to.

Tortola, a few miles to the N. E. of St. John, is the principal of the English Virgin Islands. It is near 5 leagues long, and 2 broad, but badly watered, and has the name of being unhealthy. The entrance is wide, with plenty of water.

The town is situated on the south side, at the bottom of a bay 2 miles deep, with a pretty good road at the entrance, with 12 fathoms water, good ground.

Virgin Gorda, that is, the Great Virgin, or Penniston, more commonly Spanishtown Island, lying to the eastward of Tortola, is formed of elevated land, and is watered even worse than Tortola. The island has two good harbors, the largest of which is that called East Bay, on the northern side, wherein you may anchor very safely in from 5 to 10 or 12 fathoms, to leeward of the island called the Prickly Pear; but the entrance is narrow, being obstructed by a reef on each side. The next harbor is that called the Great or West Bay, which is in some degree sheltered to the west by the islets called the Dogs. The roadstead here has very good holding ground, of sand and ooze, in 8 to 10 fathoms of water. In the smaller bay, called Thomas Bay, more to the S. W., vessels may anchor before the town, in 6 or 8 fathoms; but there is a reef in the middle of the bay, which stretches north and south; and there are likewise many rocks in the bottom, which chafe the cables.

The course from Saba to Virgin Gorda is N. W. by W. northerly, above 26 leagues. When Virgin Gorda bears from you N. W. by N. 7 leagues off, the Virgins appear like three islands, with a great many small ones about them; the middlemost is the longest, and when you come within 3 leagues, they seem as if they were joined together.

The best mark for Virgin Gorda is an insulated hill, of moderate height, standing near the middle of it, and which is easily known by its being alone. This hill, in clear weather, may be seen at the distance of 7 leagues.

Mr. Lockwood, who surveyed these isles, says that under the lee of Virgin Gorda, the ground is so clear, that 300 sail might anchor in the space between the Dogs and the Valley. The North Sound, he adds, is a perfectly secure port, and of great capacity. The entrance between the two reefs is not difficult to discover.

ANEGADA, OR ANAGADA, is the most northern of the Virgin Islands, and is unhappily celebrated for the number of wrecks, accompanied, in many instances, with a heavy loss of life, which it has occasioned.

Anegada is about the size of Virgin Gorda, but so low that its coasts are inundated at high tides, and it has not even the smallest hummock on its surface. You may discern over it two high hills on Virgin Gorda, which appear like a great hummock. There is good water on the low part, near the south point.

Within the last 20 years above 50 vessels, mostly American, have been lost on this dangerous island and the reefs surrounding it, which has been caused by the strong north-westerly current, which prevails there most of the time; its average set being about one knot per hour in that direction.

Those bound to St. Thomas, or any of the islands in that parallel, will find it necessary to take every opportunity of ascertaining their latitude at night, as, from the causes above stated, there will always be a great uncertainty in their position.

The whole of the windward side of Anegada is bordered with a dangerous reef, which thence continues under the name of the Horse-shoe, about 4 leagues to the S. E., and terminates at E. N. E., 7 miles from Point Pejaro, the east end of Virgin Gorda. There are swashes in the reef, but on many parts only 2 to 6 feet of water. On approaching the isle from the north-eastward, the hill on Virgin Gorda will appear over it like a great hummock, and by this mark the relative situation of a vessel may be known.

From the observation of R. H. Schomburgh, who has made a plan of this dangerous island, it appears that the greatest number of wrecks on Anegada occurs in the months from March to June, and that vessels of large burden strike usually on the reefs to the south-east, while smaller ones generally go on shore farther west, which he imputes to the wind which blows frequently from S. and S. E. from March to June, thereby increasing the north-westerly current, in consequence of which vessels bound during that time for these islands, are more subject to error than at any other period, and that light bodies being more influenced by the current than heavy ones, is the cause of the small vessels going on shore farther to the westward.

**FALLEN CITY, OR OLD JERUSALEM.**—A very remarkable cluster of broken rocks, to the southward of Virgin Gorda, bears this name. They appear to have been thus left by some great convulsion of nature. To the southward of these is a large bluff rock, called Round Rock, next to which follows Ginger Island. Between the two latter is the general entrance into Sir Francis Drake's Channel, which is called the King's Channel, it being the best passage inward for those bound to the Road of Tortola.

**TORTOLA.**—The following directions for sailing through the King's Channel to Tortola, have been communicated by Mr. Backhouse:

"To run through Sir Francis Drake's or the King's Channel, between the Round Rock and Ginger Island towards Tortola, so soon as you make the land of Virgin Gorda, steer for the S. W. end of it, W. N. W. northerly; and when you are within six or seven leagues of it, you will raise the high land of Tortola, and also the highest keys and islands to the eastward and southward of it; that is, beginning with the easternmost or Round Rock, Ginger Island, Cooper's Island, Salt Island, Dead Chest, Peter's Island, and Norman's Island.

Having these keys in sight, steer for the south end of Round Rock, which you cannot mistake, for within three or four leagues of Round Rock, you will raise the low keys called the Broken City, or Old Jerusalem, which keys extend from the S. W. end of Virgin Gorda, in a S. S. W. direction, to within two cables' length of the north side of Round Rock: these keys are the more remarkable, not having the least earth or verdure on them, but are merely heaps of large stones, resembling the ruins of a city or island.

When at the distance of two or three leagues to the eastward of these keys, having the Round Rock N. W. westerly, steer for the south side of the rock, keeping it on board as you run through; that is, keep about one third of the breadth of the channel from it towards Ginger Island; this caution is necessary in case of light winds, when strong leeward currents may hurry you close to Ginger Island. The course through is nearest N. W. by W. by compass. The Round Rock is a barren slate rock, and the eastern cliffs of Ginger Island are, also, full of slate. The channel is about half a mile over: you may pass safely within a cable's length of Round Rock, at which distance we sounded 14 and 15 fathoms, no ground.

Having passed Round Rock to the W. N. W. of you, on the island of Tortola, you will see a negro town, a white dwelling-house, and a fort. Keep to the westward of this mark, steering W. by N. and W. As you run down towards Tortola, the easternmost point of Tortola Road bears nearest west, by compass, from the Round Rock, and makes as shown in the plate. You may see with a glass, at the same time, the fort and flag-staff on the west point of the harbor, from which extends a dangerous reef: the eastern point is a craggy bluff, with a footpath or road winding around it. The first soundings in running down, (with the handline,) were found abreast of the east end of Ginger Island, 15, 13, and 12 fathoms. The course from W. to W. by S., which soundings continued nearly to the east point of the road.

"It is particularly to be observed, that there is a bay to the westward of Road Harbor, called Sea Cow, or Rogné's Bay, which, by strangers, may be mistaken for the road, as the points make alike. Therefore, when drawing near the eastern side of Road Harbor, if you have any doubt, look to the S. W. quarter, and you will see four remarkable per-

our remarkable per-

pendicular rocks, called the Indians, off the N. W. end of Normand's Island, and bearing S. W. by S. (See the plate.) At this time the easternmost point of Tortola Road will bear nearest to W. N. W.  $\frac{1}{2}$  W. With this bearing on we sounded, and had 8 fathoms, about half a mile from Tortola. Come no nearer. We found no ground, after 8 fathoms, on the next east with 14 fathoms of line; and, thinking it bold, we borrowed to the shore, having the point N. N. W., but again found that it had suddenly shoaled to 4 fathoms, then at 3 cables' length from the shore. Hauled off W. S. W. and deepened in two or three casts to 7 fathoms; and, at the fifth cast, no ground at 15 fathoms. Be cautious to keep at least half a mile from the point.

You now open the Road of Tortola, and keep your eye on the easternmost or weather shore of the bay. On the third bluff point in you will descry a battery, (Fort Shirley,) abreast of which ships of war anchor. Keep to the westward, until you open the next point to the northward of this, on which stands Fort George, or the citadel, with a flag-staff: bring this citadel, (see the plate,) north, westerly; then haul in and steer for it.

As you steer in for the citadel on the above bearing, keep in 10 fathoms of water; indeed the mark will lead you in 14, 12, and 10 fathoms. You anchor abreast the point of the first battery, with the battery bearing N. E., but the mark for letting go the anchor is the flag-staff of the battery on the west point of the bay, in one with the south end of the guard-house, which is close behind the battery: depth 10 fathoms and about one cable's length from the shore. The western battery will bear nearest S. W. by W. westerly. Moor with your stream to the N. N. E., because the ground is foul; and, should you part your bower, your stream will check you into the bay, and clear the reef off the western point of the road.

The merchant's anchorage is in from 10 to 13 fathoms, on the western side."

In proceeding outward, from Tortola, you sail outwards through the southern channel between the west end of Normand's Island and the east side of Flanagan, or between the latter and the east end of St. John's Island.\*

**CURRENT, &c.**—About Virgin Gorda, and the passage of the Virgin Islands, the current runs regularly, setting eastward during the moon's passage from the horizon to her zenith, and from her setting till she arrive at nadir, and to the westward while the moon passes from zenith to the horizon, and from nadir till her rising. The rate varies, according to the breadth of the channels, from two to five and a half knots, and the rise is from 20 to 40 inches.

**ISLAND OF ST. JOHN.**—This island is 2 leagues broad and 4 in length, has no heights or eminences of importance. The north and south coasts are cliffy, and the former rather foul; as is also the east coast. The island is said to be the best watered of any of the Virgin Islands, and its harbor, called Coral Bay, is reported to afford as good shelter as any harbor in the West Indies. An inlet on the west, having 4 fathoms within it, is a complete natural dock, where a frigate may careen or refit, lashed to the shore on each side.

The following description and marks on this place have been extracted from those of Captain Hester:

"The east point of the harbor is called Moor's or North Point. The walls of the fortress upon it, which are white, may be seen from the distance of seven or eight leagues. From a little without Moor's Point quite into the harbor, there are regular soundings, with from 10 to 5 fathoms of water.

"With the wind any degree to the northward of east, you may lie into the entrance of the harbor; but if it be to the southward of E. S. E. you must anchor without the point, and warp in. The governor's house and part of the town are not above half a mile within the point on the east side; but there is a large harbor, with lagoons, &c. above that: though English ships of war seldom go higher than the governor's house. You anchor within a quarter of a mile from the weather shore, in 5 fathoms of water, good ground, and run a stream anchor to the S. W. by reason of the land breeze, which is, at most times, betwixt the S. S. E., south, and S. S. W. You moor N. E. and S. W.

"Observe, in coming in, to leave one third of the channel to windward from Moor's Point, and two thirds to leeward towards the key called Duck Island, and you will not have less than 5 fathoms of water.

"There is a small bank, which does not show itself, and lies directly off from the gate, at a cable's length from the shore, with only 10 feet over it. The watering place is at the south side of the town, just without the south gate, but it is brackish."

\* Mr. Lockwood says, "In the passages, and also in Drake's Channel, the current, running quick over the foul ground, causes a ripple, which wears the appearance of danger. The anchorage at Tortola is not good; and, when the convoys rendezvoused in that neighborhood, experienced masters of merchantmen, usually anchored under Peter's or Normand's Islands, both of which have good bays."

If you are bound to Porto Rico from the eastward, night coming on, and you off the E. N. E. part of St. John's, you will take notice of the easternmost high land; it is inland a little from the east end of the island, which is low. You may run to the westward till you bring that high land to bear S. by E. and then bring to till morning. But take great care that this high land does not deceive you, for it lies a long way in the country, and it is all low land by the water side. In the morning make sail; you may see the walls and works all white about Moor's Point.

From the south point of St. John's island, called Ram's Head, to the entrance of St. Thomas' Harbor, the course is about W. five and a half leagues: from the north side of Santa Cruz, N. N. W.  $\frac{1}{2}$  N. ten leagues. The latitude of St. Thomas town is  $18^{\circ} 22'$  N.

**ISLAND OF ST. THOMAS.**—The eminences of this island are almost like those of St. John's, and descend gently towards the shore. The entrance into the harbor is very easy and commodious; the town has more commerce than any other of the Virgin Islands, and is always well supplied with every requisite, being a kind of warehouse or depot of rich merchandise; it has a regular careening place, and is defended by a fort and several batteries.

In running down from St. John's to St. Thomas' Harbor, you leave Bird Key to the southward of you, and you continue your W. N. W. course till you come down to Buck Keys; they are much lower and longer than Bird Key, before mentioned, and there is a small opening of no consequence, between them. You leave these keys to the southward of you\* about one mile, and then steer N. W. when you bring them S. E. and continue that N. W. course about two or three miles till you bring the harbor open; then haul in for the town N. by W. or N. N. W., giving the east shore all along a good berth, and run within half a mile of the fort, which is white, and plainly seen at the east of the town. You anchor in 5 fathoms water, fine clear ground; it is a fine harbor, where you are landlocked from all winds, but from the S. by W. to the S. E. by S., which part lies open to the sea; but the wind seldom blows in unless it is in the hurricane months. There is a rock above water in the harbor's mouth, (called Prince Rupert's Cliff,) which you leave to the eastward of you; you may make bold with the west side of it, but there is no passage within.

From St. Thomas' Harbor, if bound to Porto Rico, being in the offing, steer W. by N. till you come down the length of the west end of the island, which is about 3 leagues from the harbor. You will see a small island called Little Passage, about 4 or 5 miles to the westward of the west end of Little St. Thomas. Little St. Thomas is a small island, that almost joins with the west end of the Great Island; there is a small opening between them, but of no note. There is likewise a channel of small importance between Little Passage and Little St. Thomas; but there are two other islands before you come down to the west end of that island. The easternmost, just to the leeward of the harbor, is called Water Island, and almost joins with the main land; about two or three miles to leeward of that, is a rocky island, about half a mile round, which lies a mile from the shore, and is called Little Saba; it is foul all round, and must have a good berth. All the shore along these islands must be left on your starboard hand. In running down till you pass Little Passage, you have soundings all the way, but deep in some places.

W. S. W.  $\frac{1}{2}$  S. from the mouth of St. Thomas' Harbor, above 4 leagues, and S. W. by S. 7 miles from the west point of the island, lies a remarkable rock in the middle of the channel. It is round, rugged, and double pointed, as high as Beachy Head, and may be seen 5 or 6 leagues off, being all white; it appears at some distance like a sail, whence it has been called St. Thomas' Carvel or St. Thomas' Hoy. This rock is bold to all round, and appears at some distance like a sail, and may be seen 5 or 6 leagues off.

\*The channel between the main island and Buck Island, is but one and a half mile broad, and at the entrance, in the fair way, lies a rock, called Packet Rock, which is a hard whitish rocky shoal, the S. W. point of which is from the flag-staff on Mucklenfell's Battery, (the eastern battery at the entrance of the harbor,) S.  $57^{\circ}$  E. 2180 fathoms, and from the northern, or nearest point of Buck Island, N.  $40^{\circ}$  E. 1050 fathoms distance.

This sunken rock or shoal extends from its S. W. point in a depth from 6 feet water, E. N. E. upwards of 15 fathoms in length to  $5\frac{1}{2}$  feet—in the centre of the depth are 9 feet. From  $5\frac{1}{2}$  feet water it inclines a half point to the north, upwards of a quarter cable's length, with a depth of 12 and 9 feet water.

The whole shoal is consequently little above 40 fathoms in length, and has a direction of nearly E. N. E. and W. S. W. Its position being one third the distance from St. Thomas to Buck Island. The passage between this sunken rock and Buck Island is perfectly free, with good soundings from 10 to  $14\frac{1}{2}$  fathoms. The way to clear this shoal is to keep Buck Island close on board.

*Remarks on the Passages in general, from the "Derrotero de las Antillas."*

The straits between the Dogs' Isles and Virgin Gorda are all excellent, and are those by which the entrance into Drake's Channel is made from the northward. The channels to the southward are, that between Salt Island and the Dead Chest or Peter's Island; that between Peter's and Normand's Islands; and that between Normand's Isle and Flanagan Key. The pass between the Dead Chest and Salt Island, when used for going out of Drake's Channel, requires the breeze to be steady, that it pass not from E. S. E. toward S.; for otherwise you will be apt to get entangled with Peter's Island, as the water sets strongly towards the strait which it forms with the Dead Chest, and the swell also aids. (which is likewise heavy, when there is a fresh wind,) as it diminishes the vessel's way, and increases her lee-way.\*

Vessels which navigate by the south of the Virgins, commonly pass between Bird's Key or Frenchman's Cap and Buck Island; and all those who run for the southward of the Virgins for St. Juan's Head, in Porto Rico, pass through the channel between the Sail Rock and Savanna, or Green Island.

The sea along the whole of the west coast of Virgin Gorda, is tranquil during the time of the breezes, and you may anchor along the whole length of it, in the certainty of not having more than 16 fathoms, nor less than 8 fathoms at a mile from the shore, and the quality of the bottom is commonly sandy.

On the west coast of Norman's Island there is a harbor, Man of War Bay, which is much better sheltered and more secure than that of Virgin Gorda; for in it, and as far as Flanagan Islet, the sea, during the breezes, is as calm as a bath. Within this harbor they do not experience gusts of wind, and it also appears that the breeze in it is light, when it is fresh outside. As the interior of the harbor is to windward of its points, and it is not more than half a mile wide, large vessels cannot beat up into it; and, therefore, when these come from the north, it is necessary that they should shave the point, and luff up and anchor in about the middle of the harbor's mouth, warping or towing in afterwards, if they have to make a long stay; for if not, they will lie very well at the very mouth, if it be not in the hurricane season. On coming in from the south, they must prolong the tack to the north, in the certainty that they will find no unseen danger; and when far enough, they must heave about to manœuvre, on the south tack, as already directed. If the wind with which you run to take this harbor should be from the north, you may run farther in, and lie as if in a dock; but it is necessary to furl your sails smartly; for with norths there are flaws of wind which might cause you to drive, and there is no room for manœuvring. Keep in mind that about a league to the S. S. E. of the S. W. point of Normand's Islands, there is a rock of small extent, which has not more than nine feet water on it. On this rock the frigate Santa Monica struck, and subsequently foundered. The situation of this rock is not well ascertained; for, though the brigantines under the command of Don Cosme Churrua made every exertion to find it, they never could succeed.

ST. CROIX, OR SANTA CRUZ, is the southernmost of the Virgin Islands, and lies W. by N. from Sandy Point, in St. Kitts, 33 leagues. It is not very high though full of hummocks, two of which, on the eastern side, are higher than the rest. At the S. W. end of the island, there is a flat extending outwards to the distance of a mile; and the whole of the south side is bordered with reefs, which render an approach dangerous to a stranger. The island is scantily watered; and with wood which can be procured only at a high price.

There are two towns, one on the north and the other on the west side. The first and chief is Christiansted, the capital of the Danish West India Islands, lying on the south side of a harbor, protected to seaward by extensive reefs, and on the land by a fortress.

The chief town, called Christiansted, is situated at the bottom of a bay on the north coast, under the cannons of a fortress which defends the principal harbor. The other town, named Friderickstæd, lies on the west side, about half way up on the middle of a spacious bay, wherein ships may anchor at pleasure, in from 3 to 10 fathoms.

From the town of Christiansted to the S. W. point of St. John's Island, the course is N. by E. about 10 leagues. In the channel, about six miles S. by W. of this point, lies a remarkable round rock, called Bird Key, which is about one quarter as large as Redondo, near Montserrat.

The harbor of Christiansted is difficult of access, and shoal in several places. It is defended by the fort of Louisa Augusta, situated on a neck of land which trends from the eastward, and by that of Sophia Frederica, situate on Loot's Key, an islet north of

\*But, it is to be noted that, at about half a mile to the E. N. E. of the Dead Chest, is a rock, having over it only 12 feet, and on which the Blonde frigate, and several vessels have struck.

the town, under the guns of both of which, vessels must pass to the anchorage. This is one of the handsomest towns in the West Indies; its principal streets being wide, long, and straight, and intersect each other at right angles.

The greatest length of St. Croix from E. to W. is 20 miles. On advancing, its north side presents a chain of eminences, almost like those of the Virgin Islands. At about a league to the W. N. W. of the East Point, and half a league from the north coast, there is an island named Bokken, or Goat Island, which appears at a distance like a part of the coast. Between this island and St. Croix there is a passage, but it is bad and little frequented. The east point of Goat Island sends out a reef, a mile and a quarter to the E. S. E.; there are others stretching to the N. and N. W.

The west coast of St. Croix is clean; the south coast is very foul, and requires much practice, either to navigate near it, or enter into its bays, of which there are two, as shown on the chart.

To enter the port of Christianst d much practice is required, and therefore a pilot must be taken.

**ISLAND OF SOMBRERO.**—Between the Virgin Islands and that of Anguilla, lies a small rocky island, about two miles in length; it consists of a very flat eminence, without any hummock upon it, covered with birds from the southward. You cannot descry this island farther off than 5 or 6 leagues at most.

This wretched island is rugged, steep, and barren; a little camphor and grass are the only vegetable productions which appear on its surface; the little water that lodges in the cavities of rocks during rains, soon evaporates. You may anchor on the west side of it. The cliffs are steep to, and are from 40 to 15 feet high. In 1792 an American brig ran against it, and her crew crept from her yard arm to the cliff top. The brig disengaged herself, and drifted down to Virgin Gorda, where the hull and cargo became a prize to the wreckers.

The latitude of Sombrero is  $18^{\circ} 33'$  N. and its longitude is  $68^{\circ} 30'$  W. Two leagues off Sombrero, when it bears from E. N. E. to E. by S., is found from 35 to 22 fathoms, uneven ground and rocky bottom. It lies about 14 leagues E. by S. from the island of Anegada, and 12 leagues due east from the reef lying off the S. E. end of it. In going between the two you have 5, 6, 7, 8, and 10 fathoms of water. The course from Saba to Sombrero is N. W. by N.  $\frac{1}{2}$  N., distant 20 leagues.

The passage to leeward or windward of Sombrero, is very clear and safe: there is no swell. The winds are generally favorable for going out, and when once you are past Sombrero, all obstacles are at an end.

#### *Anguilla, and the Islets in its Vicinity.*

Anguilla lies E. by N.  $\frac{1}{2}$  N., and W. by S.  $\frac{1}{2}$  S. above two leagues to the north of St. Martin's; it is a low, flat and withered island, without any mountains, so that it cannot be seen farther off than 4 or 5 leagues. The anchoring ground is good on the south side, because the current there has no force, on account of a long ledge which stretches off S. E. from the east point. On the south part of the west point there lies, about one mile from the shore, a small island, not above 100 fathoms in length. To the N. W. by W. of the west point of Anguilla, distant about 4 leagues, lie several small islands, the principal of which are Dog and Prickly Pear Islands, between which is a good channel. The first is the easternmost; the second, which is the largest of all, lies farther than any of them to the west, save a little rock that is almost joined with it on the west side. It is about one mile in length, and has a few inhabitants. All these islands are very low, and cannot be seen farther off than 4 or 5 leagues.

#### *Bearings taken and Remarks made in sailing between the above mentioned Islands, by an experienced Navigator.*

"When we came to sail so far out, I found that the highest top of St. Eustatia came even with the top of Brimstone Hill, and that the two southernmost points of St. Kitts and St. Eustatia were in one, and bore N. W. by N. At the same time Fort Tison bore N. E. easterly, when Sandy Point, and Tumble-down-dick, or the northernmost part of St. Eustatia came in one, and bears W. N. W.

"The direct course from the west end of St. Kitts is N. N. W. to St. Martin's west end, and so through between the Dog and Prickly Pear. For when you are within half a mile of the west end of St. Martin's, the southernmost land of St. Bartholomew comes in one with the southernmost land in sight of St. Martin's, and they bear S. E. by E. and then Saba will bear S. by W. westerly. By the aforesaid bearings of St. Bartholomew and Saba, if you see either of them, you may by them know how to direct your course for the west part of St. Martin's.

"The west part of St. Martin's and the west end of Anguilla, bear N. N. W. north-erly. When the N. E. part of Anguilla, the north side of Prickly Pear, and the middle of Dog Island, bear all in one, it is east and west. Three miles north of Dog Island, I observed at noon, and found the latitude  $18^{\circ} 26'$  N., and the variation  $2^{\circ} 30'$  E. At the same time St. Martin's showed itself beyond Anguilla from E. S. E. to S. by W."

Dog Island N. N. E. distant one league.

The following particulars of Anguilla, &c. are from the *Derrotero de las Antillas, &c.* Anguilla is situated to the north of St. Martin's, and separated from it by a channel of which the least width is four miles. It is extremely low, and has neither the smallest hill nor prominence. Its soil is very sandy and sterile, and both fresh water and wood are very scarce. The town is on the east side, near the N. E. end. It is very small, and has no commerce. The bay is shut almost entirely with reefs, and is therefore of very little value. To the N. E. of the east end, there is an islet, Anguillita, which is still much lower. It is very clean on its south side, and has 12 fathoms water on the side of the channel which separates it from Anguilla, which channel is nearly half a mile in width. On passing here, when running from windward to leeward, Anguillita seems part of Anguilla, and the strait between them cannot be seen until you are to the westward of the meridian of the former. Off the east end of Anguillita are four rocks, on which the sea breaks with violence, but they do not lie further out than two cables' length, and at less than a mile there are 24 fathoms, on sand, gradually increasing to 30 fathoms at 4 miles.

The channel between St. Martin's and Anguilla is excellent, and fit for any class or number of vessels; for it has not less than 13 fathoms of water, and the depth is in general from 13 to 20 fathoms, of sand and gravel; and near both coasts it does not decrease to less than 7 fathoms. The only thing which is to be avoided is the Spanish Rock, lying within a mile from the N. E. end of St. Martin's, on the south side.

The British brig *Saltoon*, Capt. Melville, was wrecked off the island of Anguilla, on a rock called *Graffan*, about one mile from Scrub Island, east of Anguilla.

ST. MARTIN'S is divided from Anguilla by the channel above described. It is divided between the Dutch and the French, and contains a great number of hills, or rather huge rocks covered with heath, which may be seen above 10 leagues off. The shape is very irregular, and the western coast is comparatively low. Rains very seldom fall here, and as the soil of the plains and valleys is sandy, they are consequently unfruitful. The island, destitute of rivers, has fountains and cisterns, which afford good and drinkable water for the planters. The air is very healthy, the shore full of fish, the sea rarely disturbed, and the anchorage safe every where about the island, especially with a N. E. wind. Wood is scarce and dear.

The principal town, Philipsburg, lies on the S. W. side, in a harbor called Great Bay, which has 8, 9, and 10 fathoms, good sandy ground. Near it are three salt ponds, where a great quantity of salt is made. This is the chief place of the Dutch quarter, the French quarter being to the north.

The *Derrotero* says, St. Martin's has many heights and hollows, but no mountain of consequence. On the S. W. side in Philipsburg Bay, vessels anchor more commodiously than in any other in the island. The town, the capital of the Dutch part, extends in the direction of the shore. On the south side of this harbor stands an eight-gun fort, called St. Peter's, and on the N. W. point is Amsterdam Fort. These two forts defend the entrance. The harbor has from 3 to 4 fathoms of water, on fine sand, but on the line between the two exterior points, are from 6 to 9 fathoms, and vessels of a large draught go no farther inward than this line. About a mile to the S. W. of this bay is a rock named the Man of War, which has only 10 feet of water on it, and is about  $2\frac{1}{2}$  cables' length in circumference. The point of it on which there is the least water, may be found by bringing the S. E. point of Simson's Bay, which is to the N. W. of Philipsburg Bay, on with the high point of the westernmost mountain in St. Martin's; and on the opposite direction, by bringing the flag staff at the Governor's house, which is at the eastern end of the town, on with another large house which stands on the top of the hills to the north of the bay. The last house may be known by its standing to the east of a great tamarind tree, which is insulated and separated from the other trees. In addition to these marks it may be kept in mind that the shoal is exactly S.  $38^{\circ}$  W., true, from

the White Point, which is the western point of the bay, and S. 6° 30' E., true, from Fort Amsterdam. At a third of a cable's length around this rock, or shoal, 6, 7, and 8 fathoms, with rocky bottom, are found.

On the N. W. coast there is a bay named Marigot Bay, open to N. W. winds, and having a depth of from 4 to 7 fathoms, on sand; at the bottom of it stands the town of Marigot, which belongs to the French, and which is defended by a fort to the north of it.

To the east of the N. E. end of St. Martin's is an islet named Hat Island, which is very bare, and surrounded by reefs close round it. The channel between it and St. Martin's is a mile broad and passable. The shoal named the Spanish Rock lies nearly two miles to the W. N. W. of Hat Island. This is a very small rock, the least water on which is three feet. When passing to the north of Hat Island, and near to it, in order to steer to the N. W., be careful to give a sufficient berth to the rock. The strait between this island and St. Bartholomew's, is 10 miles wide. It is without shoals, sunken rocks, or any other invisible dangers; but those bound through it and not destined for any of these islands, ought to leave to the south all the islets to the N. W. of St. Bartholomew's, and to the north all those of St. Martin's. The navigable channel is thus reduced to a league and a half in width. The ordinary depth, until touching the islets, is from 13 to 20 fathoms, but almost always upon rocks, and you may safely run within half a mile of the islets. The navigation of this channel is excellent, not only for those going from windward to leeward, but also for those bound from leeward to windward; but attention must be paid to keep clear of the rock called the Man of War, before described.

**ST. BARTHOLOMEW'S.**—St. Bartholomew's S. W. end bears from Sandy Point in St. Christopher's, N.  $\frac{1}{2}$  E., distant 10 leagues. It lies E. and W. and is five or six leagues long. The middle part is very high land. Its shores are extremely dangerous, chiefly on the north part, where there are many rocks above and under water, and the approaching them requires an experienced pilot; but it enjoys the advantage of having a very good harbor, of an excellent hold, in which ships of any size are perfectly sheltered from all winds. The island of St. Bartholomew's appears at first almost round, and can be seen nine or ten leagues off. E.  $\frac{1}{2}$  N. fourteen leagues distant from the island, lies a large bed of rocks, about 20 yards square. On the west side of it is a swell. The rock is sharp pointed, and sometimes covered. When the sea falls, it is about four feet dry.

Vessels bound for this island from the eastward, should endeavor to run down the south side, and keep as near the shore as possible. There are several rocks on the south side, but all above water, and bold to, the largest of which is a long flat key called Turtleback. From Turtleback round Point Negro, the coast is clear and bold.

Vessels bound in for the harbor should keep about 200 fathoms from the shore, and when abreast of the first battery, lay off and on and wait for the pilot. A stranger should not enter the harbor without a pilot, as the channels are narrow, and the winds often baffling.

There are three channels by which vessels enter the harbor, according to the winds, viz: South, South-West, and North-West Channels.

The South Channel has a good depth, but it is dangerous for a stranger to attempt, as a rocky reef extends from the middle key, called the Saints, two thirds across the channel; but, should a vessel be compelled to run in without a pilot, keep the main shore close aboard and anchor when within the second battery, in 4 fathoms. With the wind at east, the South-West Channel is the best, and with a N. E. wind the North-West Channel is the best, as it is the broadest of the three.

The north side of the island is perfectly safe; there are several keys and small islands, but the channels between them are all bold and free from danger with the wind at N. E.

I would recommend to those bound in, to run down the north side of the island, double the west point, and stand in for the harbor. The Baleine, or Whale, is a rock 150 fathoms west from the key called the Islets, in front of the harbor, is even with the water, and has a point standing up like the fin of a whale. Vessels can pass all around, within 10 fathoms of the rock.

On the west side of the island is the town of Gustavia, pleasantly situated at the foot of a hill, forming three different sections, and in the centre is the careenage, with wharves all around. On the south-west side of the water are several ship wharves, with conveniences for careening, caulking and carpenter's work well executed, and at a moderate expense. The careenage can contain 60 sail, and the road from 3 to 400 shipping, good holding ground, from 1, 2, 3, 4, 5, and 6 fathoms, sandy bottom.

About the Island of St. Bartholomew the flood, at new and full moon, runs S. E. and it is then high water at 10h. and 30m. P. M. while the sun is farthest to the north of the equator, but comes about two hours sooner in the following months, till the sun gets farthest to the south, when it is high water at 10h. 30m. A. M. and it runs afterwards in

the same proportion back again. The winds, which are of long continuance, sometimes make a trifling difference. The horizon is also lowest at the time when the sun is farthest to the north of the line; and so to the contrary. The greatest difference in the ebbing and flowing is 3 inches; but, in general, only 10 inches.

**DANGEROUS ROCK.**—S. 51° E. 12 miles from the S. E. point of St. Bartholomew's lies a dangerous rock nearly even with the water's edge.

**SABA.**—The island called Saba belongs to the Dutch. It is very high, and its shores bluff and clean. On the S. W. part is a small town, built in a plain, but hid from the sea by very high hills, except to the southward. A very high mountain constitutes the centre of the island. The island appears like a steep rock, of a round form; it is about nine miles in circumference, accessible only on the south side, on which there is an intricate and artificial path leading to the summit, which admits only one man at a time.

It is said that the bottom may be seen all round. On the N. W. side there is a rock, called the Diamond, standing at about a musket shot from the shore, and which appears afar off like a sail. There is an extensive bank of soundings, extending seven leagues to the southward and S. S. W. of the island, as shown on the chart, having on it, within that distance, from 12 to 17 fathoms. Beyond these soundings, to the south, no bottom is to be found. At four miles to the southward of the island there is a shoal spot of 3 or 4 fathoms, on which the sea breaks, during gales of wind, but the exact spot has not been ascertained.

**THE ISLAND OF ST. EUSTATIUS** makes, at a distance, like a steep rock, rising out of the sea, and in a sugar-loaf form, ascending upwards in a round hill, but, on a nearer approach, its figure changes, and it appears longer. The rock is composed of two mountains, whose middle land is pretty even. The eastern mountain is much higher than that to the N. W.; it is hollow in the middle, the excavation being the crater of an exhausted volcano, which has probably constituted the island: the bottom is pretty nearly on a level with the town, and is frequented by sportsmen in pursuit of game.

The town stands on the south side, and is divided into two parts, called the Upper and Lower Towns. The latter is on the shore; it consists of shops and warehouses, and is inhabited in the day only, as the inhabitants pass their nights and holidays in the upper town, 50 or 60 feet above the level of the sea, to which they climb by means of steps cut in the rock. The lower town consists of a single street, and is very indifferently built.

The anchorage, which is off the town, is not of the best; there is a swell when the wind blows from the S. E. quarter, and landing is rendered very difficult by the great and continual breaking of the waves against the shore. If bound into the road, give the eastern point a small berth, and anchor in 12 fathoms, before the town. The ground is mostly coarse sand and coral, and merchantmen buoy up their cables. The anchoring marks are, the church bearing E. N. E. or N. E. by E., about three quarters of a mile from shore; and the west end of the bay, called Interloper's Cape, N. W. by N. Vessels may even anchor farther in the offing, in 14 or 15 fathoms, similar ground. The road is much frequented, and ships are often there, even in the hurricane months; but in this season, the wind must be attentively observed, as, on the smallest indication of a squall from the southward, they should immediately proceed to sea.

The Derrotero says, "This island shows itself from the S. W. The only hill which it has, is situated near the S. E. extremity, and extends to the west, descending tolerably gently, and comes down to the shore at the place where the town and anchorage is situated. The latter is so bad that, being open to S. and S. W. winds, (when the breeze even comes to the southward and eastward,) so much swell comes in as to incommode the vessels much, and prevent landing on the shore conveniently; the depth in this roadstead is from 7 to 12 fathoms, on sand, and vessels in it must remain at single anchor, ready to make sail the moment the wind comes on shore, which, however, does not frequently occur. The channel between it and St. Christopher's is excellent and without any danger whatever."

**NEVIS AND ST. KITTS** are high, and their eminences may be described at the distance of eighteen leagues; they are separated by the Narrows, a channel of half a league wide, but which, though there is depth enough in it for every class of vessels, ought not to be attempted by a stranger without a pilot, as it is obstructed by several shoals.

**NEVIS** is a small island, which may be readily known, being low on both sides, and very high in the middle. The top of the high land, which, to those athwart it, N. or S. makes like a saddle, reaches far above the clouds. The plantations are on the sides of it, near the bottom. On the western side are two brooks of fresh water, and three tolerable roadsteads, on the principal of which, near the S. W. end, is Charleston, the principal town of the island.

As the shores of the southern and western sides are very low, ships must not approach near to them in the night, as they are not to be distinguished from the high land behind

them. From the S. and S. W. points there are reefs stretching off to the distance of nearly half a mile, which, of course, must also be carefully avoided.\*

The Narrows, or straits, between St. Kitts and Nevis, is rather more than half a league broad, and lies N. E. and S. W. Nearly in mid-channel, at the eastern end, there is a remarkable high rock, called Booby Island; and nearly one mile and a half to the S. W. of this island, are two others, called the Cows. The channel, which has a depth of from 3 to 12 fathoms, is between these rocks and St. Kitts, for on the southern side there are several shoals.

An extensive shoal, from a mile to a mile and a half in breadth, and five miles long, from N. W. to S. E., lies without the eastern end of the Narrows. The passages in are, therefore, between its north end and St. Kitts, and between its south end and Nevis. The southern half of the shoal, which is the broadest, is rocky, and has not, in some parts, a greater depth than 10 feet. There is also a dangerous patch of 18 feet of water, near the north end.

In sailing up to the Narrows, between this bank and the Isle of Nevis, bring Booby Island W. N. W. and keep it so until the Cows bear S. W. by W. This leads clear of the reef, whence you may proceed as shown hereafter. In sailing in from the northward, before arriving at the Narrows, Booby Island will be seen nearly in mid-way of the channel. In sailing downwards, that isle is to be kept on the larboard side, keeping over towards the shore of St. Kitts. The south part of Nevis, kept open to the westward of Booby Island, will clear the reef. The Cows are also to be left on the larboard side, keeping over to the shore of St. Kitts in  $4\frac{1}{2}$ , 5, or 6 fathoms, good ground.

The Road of Nevis is on the west side of the island. In approaching it from the southward, give the Fort Point near Charleston, a berth of a mile, to avoid a shoal which lies to the southward of that point; then huff up and anchor in from 10 to 7 fathoms, good ground, with the fort bearing S. E., the S. E. part of St. Kitts N.  $\frac{1}{2}$  E., distance off shore about one mile.

In running from Nevis to Basseterre, you will cross a bank, on the shoalest part of which there are 4 fathoms, or quarter less 5. It is not quite a mile over, and its middle lies S. by W. westerly from the Nag's Head, or the south end of St. Kitts, two miles.

**ST. KITTS.**—The centre of this island is occupied by a great number of high and barren mountains, intersected by rocky precipices, and almost impassable, and among which there are several hot springs. Mount Misery, which is an exhausted volcano, whose head is hidden in the clouds, is the highest of all these mountains, its perpendicular height being 3711 feet.† The assemblage of hills makes the island appear, on an approach from the sea, like a huge mountain, covered with wood; but advancing nearer, the coast becomes less abrupt, and the ascent of the mountains, rising one above another, will be seen cultivated as high as possible. The S. E. side, on sailing along at two leagues distance, appears like several detached islands. The N. W. part is the highest, but declines gradually to the sea.

The principal town is that of Basseterre, on the south coast, situate at the mouth of a river, which opens into a bay called Basseterre Road. Sandy Point Town, towards the N. W. is also a town of consequence. There is no harbor whatever, and, on the contrary, a surf continually beats on the shore, which is sandy, and prevents any tree or wharf being erected upon it, and also makes landing always inconvenient, sometimes dangerous. Owing to this the inhabitants are under the necessity of landing and shipping heavy goods in the manner practised at Montserrat.

**SOUTHERN SIDE OF ST. KITTS.**—In sailing off the southern coast of St. Kitts, the following lands are to be particularly noticed, namely, the Nag's Head, or south end of St. Kitts, on which there is a high hummock; the high lands on each side of Frigate Bay, the bay at the northern end of the isthmus which connects the northern and southern parts of St. Kitts; Monkey Hill, a high mountain to the northward of the town of Basseterre; and Brimstone Hill, another high mountain, with a square fort on it, to the eastward of Sandy Point Town in the west.

In proceeding from the southern side of Nevis towards Basseterre, you may cross a bank lying off the Narrows, on which the least depth is about 4 fathoms. It is rather more than a mile in breadth, and its middle part lies nearly two miles S. S. W. westerly from the Nag's Head, above mentioned. Advancing towards Basseterre, and having passed

\* The Derrotero reports that there is a shoal off the windward coast of Nevis, the situation of which has not been made known; all that is known of it being, that an English sloop touched on it at two leagues from the shore. It is added that an English ship of the line also touched upon a rock, nearly two miles S. S. E. from Nevis. This may probably be the same.

† The bottom of the great crater of Mount Misery is a level of fifty acres, of which seven are covered with a lake, and the rest with grass and trees; amongst the latter is mountain-cabbage. Streams of hot water, impregnated with sulphur, still issue from the fissures.

the south end of Nevis, the course will be N. W. by N. When off Frigate Bay, run in until the Nag's Head appears to the southward of the mountain in Nevis, or until the hummock on the Nag's Head appears on with the southern part of the top of the same mountain; keep this mark on until a single tree on the green ridge behind the town of Basseterre comes on with the edge of Monkey Hill, or begins to shut in behind it; you may then anchor in 10 or 9 fathoms, mud or clay, with the fort on the east side of the town bearing north, about half a mile distant, and the west point of the bay W. by N. Vessels from the westward, when bound for the road, may run in with the single tree above mentioned just open to the eastward of Monkey Hill; and, when the points of high land on each side of Frigate Bay begin to shut in on each other, the water will be found to deepen from 7 to 10 fathoms, after having passed over a rocky ridge into clean ground.

The following remarks on sailing from Nevis to Basseterre, have been made by Mr. Backhouse. "In sailing past the island of Nevis for Basseterre Bay, give the S. W. point a berth of a mile and a half, and steer N. N. W. and N. W. by N. and there is no danger. You may anchor in 7, 8, or 9 fathoms of water, coarse sandy bottom, with Fashion Fort bearing N. E., the Half Moon Battery N. W. by W., and the town N. N. W. You cannot wood nor water here."

Old Road lies five and a half miles to the westward of Basseterre. In sailing close along shore to this place, the embrasures of the low battery on Stony Point, (the eastern point of the bay,) will first appear. The town on low ground will then come in sight, with its houses intermixed with trees. The anchoring place is nearly mid-way between Stony Point and the town. In sailing to this spot, run first so far to leeward as to fetch it upon a wind, or nearly so; and then stand in under easy sail, directly for the gully to the eastward of the town; and when the church of St. Thomas, standing nearly a mile to the westward, is brought on with the flag-staff on Brimstone Hill, you may anchor, at about a cable's length from the beach, in 9 or 10 fathoms, stony, but good ground. Fresh water here is obtained by the casks being landed and rolled about 100 yards, then filled at the running gullet, and floated off to the boat. There is a great surf on the rocky shore.

The remarks made by Mr. Backhouse on Old Road, are as follows:—"Give the eastern point a small berth, and anchor a little to the eastward of a red house, abreast of a large gully, in 10, 11, or 12 fathoms of water. If you go abreast of the town, you will soon be off the bank. The mark for anchoring is Old Road Fort by the Red House N. by W. half a mile, and the extreme points S. E. and W. N. W. You cannot wood here, but watering is extremely convenient."

Sandy Point Town lies a mile to the westward of Brimstone Hill. Off this town, and to the eastward of it, the bank is narrow, and the ground rocky; the anchoring place is consequently to the westward, at about a cable's length from shore, in from 9 to 13 fathoms, and the mark for anchoring is, the street extending from the landing place, through the middle of the town, end on. In running along shore to the anchorage, you must cautiously avoid a reef stretching half a mile from Charles Fort Point.

#### *Remarks made in Basseterre Road and Old Road.*

In Basseterre, which is a large open bay, the marks of the anchorage are as follows: The long point of Nevis S. S. E., Nag's Head S. E., Bluff Point W.  $\frac{1}{2}$  N., the town of Basseterre north, distance off shore half a mile, depth of water 7 fathoms; wood purchased, water better and easier got at Old Road, about one and a half league from hence, tides none.

In Old Road the following are the marks of the anchorage, viz: the Long Point of Nevis S. E. southerly; Stony Point E. S. E., the westernmost point of Old Road, N. W. by N., Stony Point S. E.  $\frac{1}{2}$  E. Depth of water where the anchor lay, 10 $\frac{1}{2}$  fathoms, one third of a cable out—wind off the land; 13 fathoms under the stern—west distance off shore two thirds of a mile. You land your casks, roll them about 100 yards, and fill them at a running gullet; then float them off to the boat. A great surf and a rocky shore.

BARBUDA.—The greatest extent of Barbuda, from S. E. to N. W. is 15 miles.—Its highest land cannot be discerned at more than six leagues off. The greater part of the coasts of this island are very foul and dangerous. In its proximities, it is not uncommon to sound with 50 or 60 fathoms at the prow, and have only 4 or 5 fathoms at the stern; the reef extends several miles to the S. E. from the island, and the rocky soundings continue to the south as far as mid-strait between it and Antigua, where 9 fathoms, on the same kind of bottom, have been found. To the N. and N. W. the reef extends outward to the distance of 5 miles, and here lie the wrecks of the British ship Woolwich, and of a brig, which was under the convoy of that ship.

There is anchorage in a well sheltered road on the western side, where ships may ride in 9, 12 or 14 fathoms of water; or within the reef in 3 $\frac{1}{2}$  fathoms, four miles above

Palmeto on the south-west Point. There is also anchorage off the S. W. coast in 5½ fathoms, sandy bottom, with Palmeto Point N. W. by W. three miles, and Cocoa Point, the south point of the island, E. by S. 4 miles distant.

ANTIGUA, has, in general, a rocky shore, and is surrounded by many dangerous reefs. The climate of this island is commonly hotter, less healthy, and the hurricanes more frequent than those of Barbadoes. There being no rivers, and but few springs, and those brackish, the inhabitants are obliged to preserve the rain water in cisterns. Excessive droughts frequently impede and destroy vegetation.

Antigua, however, derives considerable advantages from the circumstance of having several excellent harbors, particularly English Harbor on the south side, which is capable of receiving the largest ships of war in the navy; here also is a dock-yard, with stores and all materials and conveniences for repairing, heaving down and careening ships. To the westward of English Harbor is the harbor of Falmouth, and to windward is Willoughby Bay. At the eastern end of the island is Nonsuch Harbor; and, on the north side, is the town and harbor of Parkham, &c. The coasts are, in general, very foul, especially on the N. and N. E. whence many reefs extend out to the distance of more than a league.

The town of St. John on the N. W. side, is the capital. This town is situated on the harbor of the same name, in which there is a sufficient depth for merchant vessels, and perfect security in all winds. Ships from the eastward generally make for the S. E. coast of the island.

WILLOUGHBY BAY.—The first harbor on the S. E. side is that called Willoughby Bay, on the western side of which is a little island, called Sandy Island, environed to a short distance by sunken rocks. From the eastern side of the bay a long narrow reef extends more than two-thirds over the entrance, and to within a half a mile of Sandy Island. The passage in is therefore between the island and the reef; and even in mid-channel between, there is a shoal having only 9 feet over it, called the Weymouth, which lies only half a mile from Sandy Island, on which the Mail Packet Maria was lost, and 20 persons drowned, in March, 1826. Between Sandy Island and this shoal, there is a depth of 4 fathoms; between it and the west end of the reef there are 7 fathoms, and the channel is wider. At a mile within the entrance there is good anchorage, in 4 and 5 fathoms; in going up, it is recommended to borrow toward the larboard shore.

ENGLISH HARBOR.—This harbor is perfectly safe, and lies close under the west part of the easternmost high land, so as to afford a shelter in all winds; and ships of war commonly lie here during the hurricanes. In the bay without the harbor, ships may anchor in 5, 6, or 7 fathoms. They must warp in, and cannot lie excepting N. N. E. There are, generally, flutterings of wind from the high land.

In entering the harbor, give the Old Horse Shoe, or low battery point, on the starboard side, a good berth, and keep as nearly as possible in mid-channel, between that and the opposite point, on which stands Fort Barclay, until you get into the bay on the eastern side, called Freeman's Bay. In this bay there are moorings for shipping, and good anchorage hence up to the store-houses on the western side, in 3, 4, and 5 fathoms. The water is generally smooth. It is not, however, perfectly safe for a stranger to conduct a ship in, as the entrance is narrow and rather shoal. When you are off the harbor, a pilot, or the master attendant, will come on board.

Large ships lie at proper moorings, but small ones lie with one anchor to the E. S. E. and the other made astern, on shore. There are four moorings for ships in Freeman's Bay, just within the harbor's mouth, the best bow to the westward, and the moorings on shore to the eastward.

Wood and water are not to be obtained here. You may, however, obtain the latter at Falmouth, about a mile and a half to leeward. It is not very good, being soft, muddy and brackish.

FALMOUTH HARBOR.—To sail into this harbor, run close in towards the western point, called Proctor's Point, and you will pass clear of a ledge of sunken rocks called the Bishops, which lie toward the middle, just within the entrance, and terminate a shoal extending from the eastern point, on which there is a redoubt for the protection of the harbor; beyond these rocks there is good anchorage in from 3 to 6 fathoms water. There is a battery on an islet within for the defence of the town, on the western side of the harbor; beyond which there is a spring of fresh water.

Vessels bound to St. John's Harbor, from the south side of the island, on approaching westward, must give the coast a berth of 3 or 4 miles, until they come abreast of Johnson's Point, (the S. W. point of the island,) in order to avoid the dangerous reefs which lie about 2 miles from shore eastward and north-westward of that point. If bound to the north-westward from English Harbor, the course to abreast of Johnson's Point is first W. by S., or W. S. W., about 8 miles; then hauling towards the N. N. W., and keeping the lead going, still keeping at the above mentioned distance from the island,

NORTHER Antigua are en the land there i ber of small isl The whole are the latter, the n ledge stretches fathoms lies abo

steer for Sandy Island, the little island lying to the westward of St. John's Road, and about 7 miles N. by W. from Johnson's Point.

Or, in sailing from off English Harbor, to the westward, when to leeward of Falmouth Harbor, keep the small battery on the eastern side of the entrance of that harbor open with the western point of the same, until you are off Carlisle Bay, or Old Road. The bluff land of English Harbor being then kept open without that of Old Road, will lead clear of Johnson's Reef, in a depth of about 18 fathoms.

On the western side of Antigua, at about half way up, and nearly a league to the southward of Sandy Island, is a large harbor, called Five Islands Harbor, and so called from a cluster of five remarkable little islands, which lie nearly in a line, about half a mile east and west, off the point on its south side. About three quarters of a mile to the northward of the harbor, and close in-shore, is another conspicuous little island, called the Hawk's Bill. When you have approached so far to leeward with the mark above mentioned, namely, the bluff of English Harbor kept open without that of Old Road, as to have the Hawk's Bill open to the westward of the Five Islands, you will be clear of the reefs, and may tack up towards Sandy Island. In approaching this island, keep it on your starboard bow, in order to avoid several shoals extending to the distance of a mile from shore, to the N. W. of Five Islands Harbor.

Should the wind permit, you may run within Sandy Island; but it is better for strangers to go to leeward of it, at the distance of not less than two cables' length, so as to avoid a reef which stretches from its southern side to the S. W. Be careful not to stand above three miles to the northward of this island, lest you be caught by a lee current, or touch on the shoals which lie to the northward. By keeping in 15 fathoms, you may pass clear of the island in the night.

**ROAD OF ST. JOHN'S.**—This roadstead lies about  $1\frac{1}{2}$  mile east, a little northerly from Sandy Island. It lies in lat.  $17^{\circ} 10'$ , or very nearly so. The western point, on the south side, which forms the bay, is called the Ship's Stern, at about a mile north of which there is a dangerous ledge of rocks, with not more than 3 feet water over them, called the Warrington. Here are breakers in a wind.

The road lies to the southward of the Warrington Rocks, and has a depth of from 6 to 10 fathoms. The anchorage, which is 2 or 3 cables' length within the rocks, lies with the Ship's Stern S. W. by W.; Fort James on the north point of the entrance of the harbor E. S. E.; and the Warrington N. by W., or with the flag-staff of Fort James on with the north side of the island in the harbor, called Rat Island, where there are from 5 to 7 fathoms water, and good holding ground.

The middle of the Warrington Rocks lies with the northern part of the buildings on Fort James on with Rat Island above mentioned. Close to the westward of them, in the depth of 9 fathoms, the largest of the Five Islands appears open to the westward of the Hawk's Bill. The western part shoals about a cable's length from the breakers, but the eastern part is bold to.

Ships bound to the road stand on upon a wind for half a mile above Sandy Island; then tack, and run close in to the Ship's Stern; but be sure not to get farther to windward than to open the Hawk's Bill without the land, or to bring it in a line with the easternmost of the Five Islands. When thus far in, if standing to the northward towards the Warrington, you must tack so soon as the flag-staff of Fort James appears on with the middle of Rat Island.

To sail up within Sandy Island, bring the westernmost of the Five Islands N. by E.  $\frac{1}{2}$  E., and keep them open on the starboard bow, which will lead clear of danger.

At the distance of a mile from the westernmost of the Five Islands, you will be in the channel; keep Sandy Island, as before mentioned, on the starboard bow, until you open the Hawk's Bill, and then luff. The eastern side of Sandy Island is nearly bold to, and in the day, the shoalings may be seen. The Ship's Stern is bold to. After the Hawk's Bill bears E. by S. you may haul up as near to it as you choose, there being 11 fathoms of water close to it. In steering for the harbor, keep along the south shore, which is all clear.

There is a bar at the entrance of the harbor, which stretches from the north side S. W. to the land on the south side. The deepest water, 14 feet, is on the southernmost part of the bar. The depth on the northern part is about 12 feet.

**NORTHERN SIDE OF THE ISLAND.**—The northern and western coasts of Antigua are environed by numerous reefs, (as shown on the chart,) between which and the land there is a good channel for shipping. At the N. E. part there are also a number of small islands, of which two or three of the outermost are called the Bird Islands. The whole are encompassed by reefs, which render them inaccessible to shipping. Of the latter, the northernmost is a narrow ledge, part of which is sometimes dry. This ledge stretches N. E. about a mile from the northernmost Bird Island. A shoal of 3 fathoms lies about three quarters of a mile to the northward of the end of the ledge, be-

tween which and the Bird Islands Reef there is a clear channel of 8 and 6 fathoms. The white water from the shoal may frequently be seen at the distance of a mile and a half.

The HARBOR OF PARHAM lies at the distance of 2 miles westward of the Bird Islands Ledge. This harbor, though large, will admit small vessels only. The town is situated on the south side of the harbor.

A little island, called the Prickly Pear, lies off the west point of the entrance of Parham Harbor, and about 4 miles due west from the north end of the Bird Islands Ledge. In advancing towards this island, and thence to Boon's Point two miles to the westward of it, be sure not to get over to the northward, as the reefs on that side are extremely dangerous, and in some parts, not more than a mile from the coast.

From Boon's Point to go clear of the Warrington Rocks, on the northern side of St. John's Road, the course and distance are W. S. W., southerly, 4 miles.

The NORTHERN LEDGES off the north coast of Antigua, commence with the rock called Addison's Rock on the east, and terminate with the reef called the Diamond Reef on the west. Addison's Rock is a shoal, having on some parts only 4 feet of water, and lying nearly north of the fort on Baruaque Point, upon the western side of the entrance to Parham Harbor. It has a depth of about 3 fathoms around it. Within a short distance, N. by W. westerly, from Addison's Rock, there are two other shoals of about 3 fathoms; and half a mile thence, west, is a reef, sometimes above water, and called the Horse-shoe. This reef bears north, one mile and a quarter distant from the Prickly Pear, close to the westward of the Horse-shoe, and between it and the great cluster of reefs which stretch to the westward, there is a channel of 5 fathoms.

At a short distance to the westward of Beggar's Point (the point to the southward of the Prickly Pear) there is a wind-mill; and at the distance of one third of a mile to the S. W. there is another. These mills form the mark for sailing through the channel on the western side of the Horse-shoe; and steering S. by W. between them, will lead a vessel through.

A small shoal of only 5 feet of water, lies S. W. by W. at the distance of nearly a mile and a half from the Horse-shoe, and nearly at the same distance N. W. by W. from the Prickly Pear. There is also a shoal stretching half a mile from the western side of the Prickly Pear, which may be seen during the day.

Capt. Bradshaw has observed, that there are so many shoals and rocky spots without the great reefs above mentioned, that it is dangerous to come too near. That, in particular, called the Diamond, lies a mile to the west of the reef, and in the channel between you have 6 and 5½ fathoms. You will be in this channel whilst you keep the western side of the leeward Sister in a line with the flag-staff of James Fort. The Diamond is of a circular form, and one mile in extent: the depth of water over it is from 1 to 9 feet. To avoid it, when coming in from the N. W., bring the Ship's Stern to bear S. by E. before you haul up with the fort, and then look out for the Warrington Rocks. If the wind will serve, you may pass close to the westward of the westernmost Sister, and you will thus weather the Warrington, which bears north, above a mile from the Ship's Stern. The westernmost part shoalens from the breakers a full cable's length, but to the eastward it is bold to.

#### *Remarks on the Coast of Antigua.*

[From the Derrotero de las Antillas.]

On approaching Willoughby's Bay, upon the S. E. coast, great caution is required, in order to avoid its rocky shoals, and a pilot will be requisite for strangers who enter here.

From this bay the coast to the westward continues very clear, and in it you will soon find ENGLISH HARBOR, which is an excellent port, having a dock-yard and careening place for vessels of any size. The straight of this harbor is about a cable's length in width, and in the middle of it there are from 4 to 5 fathoms, and 3 fathoms at a quarter of a cable from the points. After English Harbor, that of FALMOUTH follows, and thence the coast begins to be foul, sending out to more than two cables' length from it, very dangerous rocky reefs. Thus it continues to CARLISLE BAY, or the Old Road. From Carlisle Bay to Johnson's Point, the south-west point of the island, the coast extends to the north, but has a rocky shoal, of the length of 2½ miles, which lies at a mile and a half from the coast. Between this shoal and the coast there is a passage fit for any vessel, but it ought not to be attempted without a pilot.

From Johnson's Point the coast continues to the north, to the FIVE ISLANDS, on the south side of the harbor of that name; and another shoal of rocks and sand extends between these points, which lies about a mile and a half from the coast. The depth between is very unequal, and the navigation therefore dangerous.

From the Five Isles the coast forms a great bay, named Five Islands Harbor, of which the north point is called Pelican Point. At about two miles to the N. N. E. of this point, is the point called the Ship's Stern, which is the S. W. point of St. John's Bay. Between the two points is a sand bank which extends out above a mile from the coast, and its edge is nearly on the meridian or south of Sandy Island, an islet two miles to the west of the Ship's Stern. A reef surrounds Sandy Island, and is three quarters of a mile in extent from N. E. to the S. W.

Two miles to the N. E. by N. of the Ship's Stern are two islets, named the Sisters, which are three quarters of a mile N. W. by W. from Corbizon's Point, on which there is a fort.

Between the two Sisters and Sandy Island, and just within this line of direction, is the rocky shoal called the Warrington, which has in its shoaler part not more than 3 feet of water.

The town of St. John, situated at the bottom of a bay of the same name, is the capital of the island, and centre of its commerce. We therefore give directions which may guide any one to the anchorage. The north coast of this island is very foul, as already noticed: it is therefore more advisable, on advancing, to make the island on the south side, and direct your course so as to pass about two miles to the south of its southernmost points, and continue steering true west, but nothing to the north, until the westernmost part of the Five Islands bears north, when you may luff up to N. N. W., with which course you will pass about a mile from the outermost part of the Irish Bank, a shoal of sand and rock, and you will follow it until the Five Islands bear east, when, if the wind allows, you will steer so as to pass about two cables' length from the S. E. side of Sandy Island, taking care not to pass to the eastward of N. E. by N., that you may keep clear of the sand bank, which extends from the coast between Pelican Point and the Ship's Stern, until Sandy Island bears north, when you may luff to the wind all you can; and, if you can, place the vessel's head towards the Ship's Stern Point, which is very clean, and follow on towards the road within, and anchor in 5 or 6 fathoms water, nearly south from the Warrington Shoal. If, when passing between Sandy Island and the coast, the wind will not permit your approach to the Ship's Stern Point, you may follow the tack until Fort Hamilton, which is the middle one of the three standing on the coast to the north of the town, bears east; then go about on the other tack, and continue beating, taking care not to prolong the north tack more than until Hamilton Fort bears east; or go about even rather sooner; but the south tack you may follow until you are within a cable's length of the shore of Ship's Stern Point, for it is very clean.

If, when to the west of the Five Islands, the wind will not permit you to pass to the S. E. of Sandy Island, you must steer to the north until the north point of Sandy Island bears east, southerly, and then you will haul by the wind, and prolong the stretch until you can weather Sandy Island on the other tack, and having weathered it, you will beat in as above stated, that is, on the north tack, until you are nearly west of Fort Hamilton, and on the south tack, to within a cable's length of the coast, near the Ship's Stern.

To proceed to the northward, from the road of St. John, it is necessary to give a berth to the rocky shoal called the Diamond, and others, which extend west almost to the meridian of the Warrington, and the northernmost part of which is nearly five miles distant from the Ship's Stern Point. To effect this, you must steer from the anchorage about N. W. by N., but nothing to the north of that, until Sandy Island bears from south towards east, and then you may steer north, which you will continue until the Sisters bear S. E. by S., when you may haul to the wind, and pursue your route, according to destination.

If, having made the north part of Antigua, you wish to anchor at St. John's, you ought to steer true west, passing outside of all the shoals; that is, avoiding the north coast by about four miles, until Sandy Island bears south, a little easterly, when you may steer towards it, until you are due west from the northernmost land of Antigua; thence steer for Ship's Stern Point, and so run, until, being something to the south of Fort Hamilton, you may haul by the wind, or shape the most convenient course to gain the anchorage.

The channel between Guadaloupe and Antigua, is most excellent, and does not offer the least danger.

The channel between Antigua and Barbuda, on the contrary, is, at times, dangerous, particularly between May and November, during which season, no one should pass through it, because there are many calms in it, alternating with very heavy squalls of wind; and as the depth of the channel is so unequal, and the bottom frequently rocky, an anchor cannot be let go when the calms come on, and the risk is incurred of being driven upon the rocks, either on one side or the other, by currents that may occasionally prevail here.

**MONTSERRAT AND REDONDO.**—There is no harbor in the island of Montserrat, and the greater part of the coast is so encompassed with rocks, as to render riding dangerous, in case of a hurricane or tornado. The principal roadstead is off the town, and there are two others shown in the chart, namely, Old Road and Ker's Bay; but in all these a surf beats continually on the shore. Large heavy goods are therefore landed and shipped by means of a boat, called a *Moses*, manned by expert rowers, who, when they see what is termed a *hull*, or abatement of the surge, push ashore, and lay the broadside of the *Moses* on the beach, so as to roll out or admit the hogsheads, &c. Cotton, rum, and other commodities, which will bear the water, are generally floated off or ashore.

It has been recommended to those who lie near this island, when the state of the atmosphere indicates an approaching tornado, to get under way for Antigua or St. Christopher's, according to the wind and other circumstances.

The Spanish description says, "Montserrat, which lies nearly S. S. E. and N. N. W. is a great rock formed by two mountains. The N. E. part is remarkably high, scarped or cliffy, and clean. The island has not the smallest bay, nor any breakers, except they break upon the very shore, which you may come so near as almost to touch it without the least risk. The N. W. point is also high and scarped, (or cliffy,) and bluff. The highest parts of the island may, in clear weather, be seen at the distance of fifteen leagues. The S. E. part is higher than the N. W., but it has a gentler declivity, and where it joins the sea, is rather low; the south part is also very clean; but when the breeze south-easts, the sea breaks upon it with much force. The road is an opening of some depth, which affords shelter only when the breeze is N. E. This renders it impossible for large vessels to anchor in it, and none frequent it but some small ones, to carry away the produce of the island, which they take to Antigua.

**REDONDO**, which lies three leagues to the N. W. from the north end of Montserrat, is a very high, round, barren, and uninhabited rock, having the appearance of a hay-cock, and which may be seen from the distance of 9 or 10 leagues. There is anchorage on the west side of it, in the depth of 11 fathoms. You may approach the isle on either side, it being steep to. On the S. E. side is a little islet, called the Pinnacle, which is nearly joined to the land.

**AVES, OR BIRD'S ISLAND.**—This little solitary isle, which takes its name from the multitude of sea fowl with which it is always covered, lies, according to the Spanish chart, in lat.  $15^{\circ} 50'$ , and long.  $63^{\circ} 43'$ . It is extremely low, and surrounded by a sandy beach. In the middle it is somewhat higher than at its extremities, and has some trees. There are reefs on its S. E. and N. W. sides, which extend out to a short distance, and on which the sea always breaks. The length is about three cables, from N. to S., and nearly the same from E. to W. The height is about 12 or 15 feet above the level of the sea. At the western part of it there is good shelter from the sea, where a vessel may anchor in 10 or 12 fathoms of water, on a sandy bottom. This island may be seen, in a clear day, at  $3\frac{1}{2}$  or 4 leagues off, but the flight of birds, at the setting of the sun, will always point out its situation.

Father Laval says, that there is anchorage on the S. W. side, at half a pistol-shot from shore, in  $3\frac{1}{2}$  fathoms, white sand. He adds, there is neither pond nor a spring of fresh water on the island: but, it is supposed, that by digging at the distance of 150 or 200 paces from the shore, water might be found.

On the west and N. W. sides, are two islets or barren rocks, white with the dung of birds, which resort there. These islands are connected to Aves by shoals and breakers, which may be seen.

Mr. James Finlaison (M. R. N.) describes the Isle of Aves, as follows:—"The Island of Aves lies in lat.  $15^{\circ} 40'$  N. long.  $63^{\circ} 33'$  W. variation  $4^{\circ} 20'$  E. it is a low small island, about three-quarters of a mile in length: you will not see it farther off than six or eight miles; broken water extends from both ends of the island, about half a mile from it.—Ships must be careful that they keep near the parallel, in the night-time, as it is impossible to see it, being so very low; there is a slight covering of grass on the top."

The position of Aves, as given in the French Tables, is  $15^{\circ} 30' 18''$  N. and  $63^{\circ} 38' 17''$  W. The mean of the three statements is  $15^{\circ} 40'$  N. and long.  $63^{\circ} 38'$  W. A positive determination seems to be still a *desideratum*.

**GUADALOUPE.**—The form of Guadeloupe is very irregular, as shown by the Chart, and the land is divided into two parts by an arm of the sea, called the *Riviere Salée*, or Salt River; a stream diminishing in width from 50 to 15 fathoms, and of which the soundings are in some places deep enough for a ship of five hundred tons, whilst, in others, there is scarcely water enough for a bark of fifty. The length of this strait is about two leagues, and no scene can be more pleasant than the passage; the water being clear and still, and the banks on each side lined with mangroves and palmettoes, which afford excellent refreshment, and shelter from the heat.

On this coast coise, and the s town, a little in

The western division of the Island, which is the most important, is divided into two parts, by a ridge of very high rugged mountains, extending north and south; so high indeed, that the continual cold suffers nothing to grow but fern, and some useless trees covered with moss. Towards the south point there appears, in the middle region of the air, a mountain called La Souffriere, or the Sulphur Hill, which is about 5,500 feet in height, above the level of the sea. This mountain exhales a thick black smoke, mixed with sparks, visible in the night. From the mountains flow many streams, that carry fruitfulness into the plains, and attemper the burning air of the climate.

The eastern division of the island, distinguished by the name of Grand Terre, has not been so much favored by nature as the western part; indeed it is less rough, and more level, but it wants springs and rivers; the soil more sandy is not so fertile, nor is its climate so healthy. Its principal town, Port au Petre, or St. Louis, is a place of considerable trade.

The chief town of Guadaloupe is that named Basseterre, situated on the west side near the south end of the island.

The English ship Temple, being at anchor at Basseterre Road, had the westernmost part of the Saintes, and some part of the western side of Dominica in one, bearing S. E. by S. : Montserrat, at the same time, bore N. W. northerly, and the westernmost part of Basseterre Bay N. W. by N., distant one mile.

The Flore, French frigate, being moored N. N. E. and S. S. W. in this road, in 1772, in 7 fathoms, sandy ground, and the small anchor in 37 fathoms, similar ground, had the following bearings by compass :—The fort to the S. W. of the town, S. E. by E. ; the church N. E. ; the N. W. end of the town N. by W. ; Point Irois N. N. W. ; and the southernmost point of Dominica S. E. by S.

Should you be bound from the road of Basseterre to Antigua, the best way is to weigh at night, and sail at such a distance from the shore as to keep the land wind, that it may carry you to the northern part of the island by morning, where you will have the sea-wind to carry you across. Should you act otherwise you may be caught by the baffling winds from under the high lands. Off the N. W. Point of Guadaloupe there is a small but remarkable high rock, called Tête a la Anglois, or Englishman's Head ; it appears grey, and particularly distinguishes this coast, and there is no passage within it.

#### *Remarks on Guadaloupe.*

[From the Derrotero de las Antillas, &c.]

This island, the mountains of which may be seen in clear weather at the distance of twenty leagues, is divided into two almost equal parts, by a channel navigable solely for boats and canoes. The eastern part is named GRAND TERRE, and the western part is subdivided into two, by the mountains; the east being named Cabes Terre, and the west Basseterre. The capital of this island is St. Louis or Point a Petre, on the western part of Grand Terre, and at the south entrance of the Riviere Salée, or channel, which separates it from Cabes Terre. The anchorage of Point Petre is sheltered, and vessels which have to remain at Guadaloupe winter in it. In the hurricane season it is necessary to have a pilot to take this anchorage. If bound to it, you proceed towards the town of St. Louis, taking care not to get to the west of it, but keeping to the southward and eastward, that is, you must make it to the N. W. of you.

On the S. W. point of Basseterre, stands the town of the same name, which is the most considerable in the island, and the centre of its commerce. This is the reason why it is generally resorted to. The anchorage here is a very inconvenient unsheltered roadstead, where there is a constant swell: its bottom, at the edge, is so steep, that at two cables' length from the shore, there are 80 and 100 fathoms. The ground is not good, and these circumstances make it necessary to keep close to the shore, and let go one anchor in 20 or 30 fathoms, on clay, and hang to it, without letting go another: that you may be ready to make sail the moment that winds from the S. E. quarter come on.

From the anchorage of Basseterre you may approach as near to the west coast as you choose, so far to the northward as the hill named Gros Morne, which is the N. W. extremity of this part of the island.

Every one bound to Guadaloupe ought to make the south part of it, for the principal commercial ports are on it. If bound to Point a Petre you ought to approach within two miles of the south coast or Grande Terre, and continue at that distance to the Point and Bay of Fergeant, on which is the town of St. Louis, whence you ought to take a pilot to carry you into Point a Petre.

On this coast there are two roadsteads, with towns at them, the first called St. Françoise, and the second St. Anne's. Between the last and Fort Louis there is another town, a little inland, named Le Gosier, which is nearly north from an island of the same

name. From this islet to the west, in about two miles of the coast, are 6 or 8 fathoms of water.

If bound to Fort Royal or Basseterre, direct your course so as to approach Cabez Terre about Point St. Sauveur; then follow the coast, at the distance of a mile or thereabouts, and pass about half a cable's length from Point du Vieux Fort, or Old Fort Point, which is the southernmost point of Petit Terre, and luff up immediately when round it, in order to keep at the same distance, of half a cable's length from the coast, until you are opposite the town, where you must anchor.

It ought to be observed, that when sailing either to the northward or southward, to leeward of Guadaloupe, you ought to keep within two miles of the shore, as by doing so, you may have the advantage of a light land-breeze, which will be almost always sufficient to pass it before day; but, getting farther off the coast, it is no uncommon thing to be four or five days absolutely becalmed. Any one who is not able to get near the land of Guadaloupe, that is, within the distance of two miles, must positively pass at 7 or 8 leagues from it to avoid the calms.

**POINT PETRE.**—Point Chatteaux, the easternmost land of Guadaloupe, is composed of irregularly shaped rocks, some of which appear ready to tumble over into the water. From this point you may keep down the south side of the island, within about two miles of the shore, until you pass an island called Le Grosier, which is the first island you come to, and between which and the main island there is no passage, and only a small opening. From this island to near the harbor, you may go along in the edge of the white water. When up with Isle Le Grosier, you will discover a building, on a hill near the water, which is called a fort, although it has not much the appearance of one. About a mile, or a mile and a half from the fort, is the entrance to the harbor of Point Petre. In sailing along here, you will, if not too far off shore, observe an island so low that the mangrove bushes appear to stand in the water, from which a reef extends off some distance to the westward. A little to the westward of the last is another island, larger and higher, with cocoanut-trees and some houses on it, where the pilots stop, from which a reef extends off in an easterly direction. Between those two reefs is the entrance to the harbor. A little inside the low island are several large square buoys, near which you pass, leaving them all on the starboard hand. There are several islands to the westward of those already mentioned, among and around which the ground is foul, so that vessels lying off and on should keep to windward.

While I was on shore my mate sounded in three fathoms, on a small piece of shoal ground, nearly S. by E. from the entrance to the harbor. Point Petre is one of the best in the West Indies, and pilots are readily obtained.

**THE SAINTES, MARIE-GALANTE, DESIRADE, &c.**—These islands are dependencies of Guadaloupe, from which island Marie-Galante, the principal, is 11 miles distant. The channels between them are generally clear and deep.

**THE SAINTES.**—The assemblage of little islands, called the Saintes, or All Saints, were so denominated from having been discovered by the Spaniards on All Saints' day. They are all bold to, and so happily arranged as to form as fine a road for shipping as any in the neighborhood.

The two largest islands are called Terre d'en Haut, or the Upper Land, and Terre d'en Bas, or the Lower Land. The first is the easternmost, and contains the town, or rather village, which is situated about half way down, on its western side. Between this town and a small island to the N. W. is the anchorage, which is nearly half a mile broad, and has a depth of 16 to 14, 10, and 6 fathoms. On the Terre d'en Bas is a neat wooden church, with two convenient creeks for anchorage and landing.

The islands have constantly a fresh breeze, let the wind blow from what quarter it may.

On the S. W. side of the upper island is a mountain, called Mont de Filles, the summit of which is 813 feet above the level of the sea, and which is therefore a proper station for a signal post. To the N. W. of this mountain, on the north coast of this island, is a remarkable promontory, called the Sugar Loaf, which serves as a guide to ships coming in from the northward; for bearing S. W. by S. it leads between a rock, called the Whale, and a bank lying more to the north-westward, at the entrance of the channel, within which ships may haul round to the road.

In passing out hence to the westward, keep over towards the south shore, in order to avoid a shoal which lies at the distance of a cable's length from the south point of the island to the north-westward.

It is said that there is a sunken rock lying a mile and a half to the northward of these islands, of which the particulars are unknown.

**MARIE-GALANTE.**—The land of Marie-Galante is of moderate height, and it rises gradually towards the north. On the south and eastern sides are several sunken rocks and dangerous reefs, some of which extend nearly a league to sea; but the western side

is a fair shore, with good anchorage in several places. The town, Basseterre, which is protected by a fort, stands on the S. W. point of the island.

Along the eastern shore are lofty perpendicular rocks, that shelter vast numbers of tropical birds. The western shore is flat, and the ground, in general, is proper for cultivation. It has several large caverns, where crabs are found with many little streams and ponds of fresh water.

**DESIRADE, OB DESEADA.\***—This is a small rocky island, destitute both of wood and fresh water, but whereon some cotton is cultivated. The island lies nearly E. N. E. and W. S. W., shaped like a galley, the eastern end making like the head or prow, and the western end like the tilt. But on advancing towards the north side, some white broken patches will appear, like heaps of sand with red streaks in them. On this side there are some rocks under water.

There is anchorage off the S. W. part, at a mile and a half from some houses standing near the shore. You may anchor in from 5 to 7 fathoms of water, taking care to look out for a clear spot, as the ground is rocky. When at anchor, Petite Terre will bear south, easterly, and Point Chateaux W. by S. The latter is the easternmost point of Guadaloupe, and may be known by a hummock on it. Between it and Desirade there are 22 and 23 fathoms of water.

**PETITE TERRE** is a small sandy island, divided into two parts by a shallow channel. It lies directly in the fair-way, or in a line between the eastern coast of Marie-Galante and the isle Desirade. Captain Bishop has said, "There is pretty good anchoring by Petite Terre, to the westward, at two miles from shore, in 7 fathoms of water."

**DOMINICA** has, properly speaking, no harbors, but there is good and safe anchorage along the western side, all of which is bold. Ships are, however, exposed to westerly winds as in the other islands; but those winds prevail only in the winter months.

The chief town is that called Roseau, or Charlotte Town, on the S. W. side of the island. In its road vessels may anchor in from 15 to 25 fathoms, good holding ground.†

Between 3 and 4 miles from the north end lies a noble bay, called Prince Rupert's Bay, from the famous Prince Rupert's anchoring there, which, besides its safety, its magnitude, the depth of water, and the goodness of the anchorage, has the advantage of three fresh rivulets running into it. Fleets destined to other parts of the West Indies commonly come to anchor in this bay, for the purpose of supplying themselves with wood and water, for which there are excellent conveniences.

Scot's Head, or Point Cachacrou, the south point of Dominica, is a high rock, having a flag-staff on it, which, from a distance, appears like an island.

The town of Roseau is about six miles to the northward of Scot's Head, and will be readily discerned when sailing along shore. Merchant ships generally anchor in the bay off the south end of the town, but ships of war in the smaller bay to the northward, called Woodbridge Bay, abreast of a gibbet erected near the beach, and appearing on with the middle of a large cane-field. To come to an anchor here, run in under easy sail, nearly opposite to the gibbet, and let go the moment you get proper soundings.

The course and distance from Roseau to Prince Rupert's Bay are nearly N. N. W. seventeen miles. The coast between is generally bold and steep.

**BARBADOES TO DOMINICA, &c.**—If you are bound to Dominica from Barbadoes, you must steer N. N. W. till you have passed Martinique, and a N. W. course will then carry you to the northward of Dominica. Leaving Marie-Galante on the star-board side, haul up close in with the north point of Dominica; you will see a round bluff making like an island, at some distance; go round that bluff, and you open the bay; turn into the north part, and anchor in 7, 8, or 9 fathoms. You will see the mouth of a large river, which anchor to the northward of half a mile, and you will be opposite a small river, which you water at, the best in the bay; the great river is brackish. There is another river to the southward, where you may anchor in 6 fathoms, clear ground; but in 10 fathoms you will have coral rocks.

The north point, above referred to, is that called Cape Melville; and the bluff is Prince Rupert's Head, which forms the north side of the bay.

When turning into the bay its southern side will be in sight; which is a low point with a remarkable high hill over it, called Rolla's Head and Hill. Prince Rupert's Head, on the north side, is distinguished by two fortified hills, called the Cabrits, which are con-

\* Properly Desiderada. It was the first land which Colombo made on his second voyage to America, and he gave it the name of the Desired Island, because he had for a long time before been beating about in this vast tract of waters, without seeing any thing but sea and skies.

† This is the description formerly given, but Mr. Backhouse describes as follows:—"There is no danger in going in, and there are 6 and 7 fathoms at half a cable's length from shore. You lay one anchor in 7 or 8 fathoms, the other in 40 fathoms, very bad ground. The anchoring mark is to bring the fort N. E."

needed to the main by a low marshy neck. At the bottom of the bay, which is a mile deep, is the town of Portsmouth, consisting of houses irregularly placed: westward of Portsmouth, on a rising ground at the inner part of the marsh which connects the Cabrits to the main, there is a small plantation, called Cotton Hill, with a few small houses. Over the town appears two high sugar-loaf hills, to the southward of which is a high mountain, whose summit is involved in clouds. To the southward of Portsmouth, at the distance of nearly a mile and a half, and on low ground near the beach, is a plantation, called Picarde Estate; and nearly midway between Picarde Estate and Rolla's Head is a fine plantation, called that of Mount Allen.

Nearly mid-way between Portsmouth and Picarde Estate, in the valley on the southern side of the two sugar-loaf hills that appear over the town, is the river called Indian River, which falls into the bay.

When working into the bay, you may stand boldly over, from side to side, which is a distance of nearly three miles. The bay is rather more than a mile deep. Prince Rupert's Head and Rolla's Head, are both so steep that either may be approached to the distance of a ship's length. When off Mount Allen, you may stand towards it so as to bring a single tamarind tree, which stands to the northward of the middle of Portsmouth, on with the highest land behind it. You may stand towards Picarde Estate, until a little hill to the west begins to open with the cultivated part of Mount Allen Estate, without the western edge of Rolla's Hill. When standing towards the marsh, between the Cabrits and Cotton Hill, you should tack in 9 or 7 fathoms, according to the ship's draught.

From the inner part of the Cabrits, round the bay to the western side of the cultivated part of Mount Allen Estate, a shelf stretches from the beach, which is, in general, a cable's length broad; off Indian River, is a cable's length and a half; at about that distance there are 3 fathoms of water; thence it gradually deepens to 5, 7, and 10 fathoms, and then suddenly to 15, 20, and 25 fathoms. The clearest ground is in the shoal water; for without the depth of 10 fathoms it is rocky. The best anchorage is off the tamarind tree, as above mentioned, and the coast seen over the low land within the Cabrits, on with the western part of Cotton Hill, or on with the drain at the western end of it. Should you be to the southward of the tamarind tree, you must run in until the highest ground on the western side of the cultivated part of Mount Allen Plantation, is open without the western side of Rolla's Hill. With either of these marks the ground is muddy, and the depth is from 9 to 7 fathoms. There is anchorage farther out, in from 12 to 20 fathoms, fine dark sandy bottom, at from one to three cables' length from shore, with the tamarind tree E. N. E.

There is good fishing and good hauling for the seine throughout the bay. The water of the small rivers is to be preferred, that of the larger being brackish.

#### *Remarks from the Derrotero, &c.*

The Derrotero says that Dominica is the highest of all the Artillas: it has much wood and is very fertile. All its coasts are clean, and you may approach within less than a mile of them. On the west coast they experience great calms, which extend six miles out at sea; and here it is necessary to navigate under moderate sail, and with much caution, on account of the heavy gusts that abruptly proceed from the openings and valleys of the mountains; for, if caught, you may sustain serious damage from them. This island has neither harbor nor secure anchorages; the best are those of Roseau, on the south part of the west coast, and Rupert's Bay, in the northern part of the same coast; in both roadsteads they anchor at less than two cables' length from the shore, and in front of the towns; there is no need of instruction for going to them, for there is no hidden danger.

After what has been said of the calms and gusts of wind on the west side, it seems that the best way to avoid them will be for those bound to Rupert's Bay, to make the north part of the island; and for those bound to Roseau, to make the south. The channel between Martinique and this island, offers no danger whatever; and the currents set to the N. W., but they are of little importance.

ST. ESPRIT REEF, in lat.  $14^{\circ} 37'$  N. long.  $58^{\circ} 59'$  W., so named from having been discovered by the captain of the French ship St. Esprit, in 1817, and afterwards supposed to have been sounded on, as mentioned in the 12th edition of this work, from on board of H. M. ship North Star, Lord Wm. Paget, in February, 1833. It appears, however, that the reef does not exist, as Sir George Cockburn despatched the Ariadne, Sapphire, Vestal, Forte, and Victor, H. M. ships, then on the W. India station, in Jan. 1834, and after a close examination, the captains reported no such shoal could be found.

MARTINIQUE is about 12 leagues in length, and lies N. W. by N. and S. E. by S. Its breadth is extremely unequal, and scarcely any where more than four or five leagues;

and if you go beyond the land is very sugar-loaves of which have been seen from every point.

ur or five leagues;

and if you include the promontories, which project in many places one or two leagues beyond the rest of the island, its circumference will include above 30 leagues. The land is very uneven, and every where intersected with large hummocks, in the form of sugar-loaves. Three mountains rise above these innumerable hummocks, the highest of which has been a volcano; it appears like the crown of a hat, and may be plainly seen from every side of the island.

The principal towns are those named St. Pierre, (St. Peter,) and Fort Royal, both on the western side of the island. The latter, which is very advantageously situated near an excellent harbor, and under cover of a peninsula entirely occupied by a fort, is the residence of the Governor. It stands on the north side of a deep bay, called Cul de Sac or Royal Bay, and is situated to the N. W. of the fort. A little harbor on the east of it is called the Carenage. Here are all the conveniences for refitting ships of war.

On every side of the island are large bays containing good harbors and sandy coves, but some of them do not afford protection during the hurricanes.

The DIRECT and TRUE course from the north end of Barbadoes to Point Salines, the south point of Martinique, is N. W., distance 31 leagues; but the course to be taken, should be N. W. by N., to allow for a lee current. Point Salines is low, and has off it three rocky islets; when these bear west, you may see between them and the point. To the westward of the islets, there are several dangers.

The Diamond Rock, which lies off the S. W. point, is, according to the description of Captain Hester, about twice the size of the cupola of St. Paul's in London, and nearly as high. To the N. E. of it is Great Diamond Cove. There is no sailing within the rock, but on the south side it is bold.

Martinique: the Diamond bearing W. by N., and Point Salines distant 2 or 3 leagues.

Having made the Diamond, the course thence to Port Royal Bay is N. N. W. three leagues. The tract is free from danger, and the shores bold. When you see the bay open, haul up and the fort will be in sight; turn up towards it until it bears N. by E. or N., when you may anchor on a bank in 8 fathoms, or off the bank in from 14 to 17 fathoms, which is the best ground. The bank has coral on it, but is not rocky.

FORT ROYAL BAY.—The bay of Fort Royal, by its position on the west side of Martinique, affords a shelter from the reigning winds. During the whole of the dry season its different anchorages offer all the same degree of safety during this part of the year, and we have no other motive in preferring one place to the other for anchoring, than the superior facility of entering or leaving, which some places afford over others, and their neighborhood to places with which we wish to communicate. It is different during the rainy season, when we have to fear gusts of wind and sudden changes in the atmosphere. At this season we must renounce the advantage of coming to anchor in favorable situations for getting a ship under sail, and must seek a refuge in a situation sheltered by surrounding land, secure from the accidents to which we might otherwise be exposed. We shall presently point out, among these anchorages, the most secure ones, and the means of entering them.

The bay of Fort Royal is nearly  $5\frac{1}{2}$  miles wide, between Point Negro and Cape Solomon, which we shall regard as its western limits. It narrows, so that as we reach the middle of its length, it is reduced to two miles in width, and preserves about this mean breadth. Its greatest depth is nearly 7 miles, in an E. S. E. and W. N. W. direction. This great bay of water encloses a multitude of banks of gravel and coral, which encumber it, and greatly diminishes the navigable part. These banks produce a change in the color of the sea, by which they are easily known, and serve as a guide through the passes, which they limit. They are generally very perpendicular, and form irregular curves.

Fort Royal, the capital of the island, and the seat of government of the colony, is situated on the north side of the bay, and  $1\frac{1}{2}$  mile E. N. E. of Point Negro. This city, of which the population is nearly 4000 without including the garrison of Fort Bourbon, is built on a low, flat piece of ground, formed probably by the alluvial deposits of the River Madame, which forms its western boundary. It is bounded south by the sea, east by the careening place, north by a canal which serves to communicate with the ca-

reening place, the stores of the port, and the River Madame. The streets are straight, and crossed by others at right angles. At its eastern extremity, near the careening place, there is a fine parade called the Savannah, which forms the glacis of Fort Saint Louis, elevated, like the rest of the ground, only 3 or 4 feet above the surface of the sea.

Fort St. Louis (on which there is a light) is built on a peninsula terminated on all sides by steep rocks of a considerable height, especially on the western part. This peninsula extends 660 yards south of the Parade, and separates the careening place from the German Anchorage, which is situated between the city and Point Negro. It is not accessible from the land except by a narrow isthmus, which joins it to the Savannah. On the east side it is defended by a bank of gravel and madreporic rocks, which stretches S. and S. W. about half a mile.

The German Anchorage has for its limits to the north, after leaving Point Negro, a coast of middling elevation, whose almost perpendicular shores terminate before reaching Madame River, by a little wharf built for a landing place. Farther to the east, near the peninsula of Fort St. Louis, and on the site of the city of Fort Royal, we find the soil composed of grey sand, which is terminated by a handsome beach, where you can land with great facility at all times.

The anchorage extends westwardly, far as the Virgin Bank, situated 6 cables' length S. S. E. from Point Negro. It is bounded south by the Mitau Bank, and near Fort St. Louis by the banks from this fort. On the western extremity of these banks is a pier anchored in 19 feet water, and 6 cables' length S. 35 W. from the flag-staff of the fort.

From Virgin's Bank to the southward of the church of Fort Royal, the soundings decrease gradually from 154 to 41 feet, on a line, on which the flag-staff of Fort St. Louis bears N. 54° E. This line indicates the best place to come to anchor. If you quit this line, either to the N. or S., you will find, at different distances, the madreporic rocks, which are dangerous to come to anchor on, on account of the asperities of the bottom. Some of them rise suddenly fifty feet above the bottom of mud by which they are surrounded.

It is on this line of bearing relative to the flag-staff of the fort, and nearly S.  $\frac{1}{4}$  W. of Madame River, in from 90 to 110 feet water, that government vessels usually anchor. The vessels of commerce usually approach nearer the fort and the savannah.

You can, if necessary, anchor on the Mitau Bank, the length of which in an E. and W. direction, is half a mile, and the mean width three cables' length; but you should anchor about the centre of the bank, in from 8 to 9 fathoms, as this part offers few irregularities, and where the risk of damaging your anchor and cables is less. In anchoring too near the edge of this bank, you will expose your cables to be cut, and your anchors to be caught in the crevices of the rocks. For greater security, however, we advise you not to anchor on this bank, except with a chain cable.

The highest part of this bank is covered with 24 feet water, and is situated one mile S. 36° W. from the south extremity of Fort St. Louis.

We are not certain that Virgin's Bank is composed of madreporic rocks. The highest part of this bank has 51 feet water.

With the winds from E. to E. N. E., which almost always blow here, you cannot reach German Anchorage without making several tacks, but this offers no difficulty, for there is only one dangerous bank at the entrance of Fort Royal Bay, which is the Bank of Gros Islet, on the shoalest part of which are 21 feet of water. This bank is situated one mile and seven tenths north of Islet Ramiers, and about the same distance from Point Negro.

The permanency of the winds from the east, from November to July, makes the German Anchorage perfectly safe. It is only in the months of August, September, and October, that it is necessary to quit it and seek refuge in the carenage, at the Three Islets, or at the Cobe du Lamentin, which we shall presently describe.

The port of the carenage, by its situation east of Fort St. Louis, affords a shelter from all winds which would endanger a vessel at the German Anchorage. It is a little bay four tenths of a mile wide, bounded west by the peninsula of Fort St. Louis, and east by Point Carriere. A point of small height divides this bay, near the marine establishment, into two parts, one of which communicates with the canal which surrounds the city, and the other, which is more spacious, is enumbered with banks of gravel and madreporic rocks. The port of the carenage extends from the mouth of the canal to the north and south extremity of Fort St. Louis. Its width is scarcely a cable's length at its entrance, and diminishes gradually, so that vessels stationed there, the number of which is oftentimes very great, have not sufficient room, and are obliged to preserve their respective situations, to moor to anchors, secured to the foot of the walls of the fort.

There is, at the entrance of the carenage, a little to the north of a line from Point Carriere, to the extremity of Fort St. Louis, a coral bank, which narrows very much the

anchoring place, and a half's it, at its shoalest part.

The channel extends on one side three cables' for beating in.

We advise the shoalest part.

anchoring place. This bank is situated east of the barracks of the fort, is near a cable and a half's length from N. N. E. to S. S. W., and has only from 8 to 9 feet water on it, at its shoalest part. Its north part is marked by a pier.

The channel of the carenage is between banks of gravel and madreporic rocks, which extend on one side four cables' length south of Fort St. Louis, and on the other side three cables' length S. S. W. from Point Carriere. Small vessels find here space enough for beating in, but others should not attempt it except with a leading wind.

We advise you not to pass the Grand Seche Shoal. It is probable, however, that the shoalest part has not less than 20 feet water.

South of the mouth of Monsieur River, and in a bend of the Grand Seche Shoal, is an excellent anchorage, where you can anchor in 70 to 80 feet of water, with a bottom of clayey mud. This anchorage is bounded north by the banks extending from Point Carriere, at the entrance of the carenage, and south by the southern part of the Grand Seche Shoal.

Near Point Salle is the entrance to the Cohe du Lamentin, a bay extending  $1\frac{1}{2}$  of a mile N. N. W. and S. S. E. Its greatest width perpendicular to its length, is  $1\frac{1}{2}$  mile, and the entrance seven tenths of a mile wide. The River Lamentin winds through drained lands, and enters the bottom of this bay.

One quarter of a mile S. S. W. from the entrance of the River Lamentin, is Point Mill, remarkable for a handsome building situated on the highest point.

Many banks of gravel and rocks occupy a considerable space in the Cohe du Lamentin: the largest extends from Point Mill W. S. W. 4 cables' length, dividing the bay into two parts, where you can anchor on a bottom of mud, with excellent holding ground.

The next anchorage, that of the Three Islands, is one of the most important in the bay of Fort Royal. This anchorage is easily known from the appearance of the surrounding land, and particularly by a small island, called the Great Islet, which is situated half a mile from the south side of the bay, and south from Red Hill, 2 miles distant. Great Islet is composed of two distinct parts; the first part has a round summit and descends gradually to the sea; the second part, on the contrary, has an abrupt rise of 70 yards from the bed of the sea, and is terminated on the top by a little rocky plateau, covered by a slight vegetation, composed of small bushes and herbs dried up for the most of the time by the sun. The anchorage, as well as the village of the Three Islands, takes its name from three small islands situated near the coast, forming a triangle. By its position, defended by banks which break off the sea caused by westerly winds, this anchorage is a very safe one during the rainy season, but it contains a number of banks, which diminish the space of the anchorage. The place for anchoring to which we give the preference, is on the middle of a line drawn from the eastern of the three small islands to the top of Great Islet. In going farther south, we meet with banks reaching almost to Great Islet.

A bank of gravel and madreporic rocks covered with but two to three feet of water, surrounds almost entirely the western part of Great Islet, and extends to within five and a half cables' length of Point Rose. This bank limits to the N. and E. the anchorage of the Three Islets.

From Point du Bout S.  $56^{\circ}$  W. is the Isle Ramiers, a rock elevated 25 yards above the sea. It is separated from the coast by a channel about a cable and a half's length wide, and in depth 8 to 9 feet. A fort, built on the highest part, defends the entrance to the bay.

Between the Diamond Rock and Port Royal Harbor, there are three small coves, the southernmost of which is called Little Diamond Cove, and the others Grand and Petit Ance d' Arlet, or Arlet Coves. At the S. W. corner of the harbor there is a small green islet, strongly fortified, called Islet Aux Ramiers, or Pigeon Island, from which the fort bears nearly N. by E. In working into the harbor, by keeping the lead going, and having weathered Pigeon Island, you may anchor at pleasure.

On the south side of Pigeon Island there is a little roadstead for small vessels. In order to gain this place, those who are well acquainted go round the N. E. point of the islet, and turn in. The south shore is steep. The anchorage lies with the western part of the isle bearing north, N. by W., or N. N. W., in 7, 8, and 9 fathoms, clear ground. Be cautious of approaching too near the eastern shore, as a bank stretches from it, which breaks with a great swell.

#### *Description of the Bay and Harbor of Trinity, by Monsieur Monier.*

Leaving the island of St. Mary, the coast trends about E.  $60^{\circ}$  S. to the bottom of the Harbor of Trinity; which is distant from this island  $3\frac{1}{2}$  miles, and is defended by a border of reefs which surround it in almost every direction. It forms little bays of small depth, separated from each other in many places by high steep points, in other places of

but middling elevation, among others we distinguish Fort Point, situated towards the north part of the City of Trinity.

You will remark, before arriving at the bottom of the harbor, an islet, distant from the preceding coast three quarters of a mile, lying near a mile and a half north of Fort Point, and a little more than that distance from the islet of St. Mary, from which it bears S. 58° E. This islet, known by the name of St. Aubin, indicates the entrance of the harbor of Trinity, to vessels coming by the Dominica Channel. Its appearance and position make it easily distinguished. It appears high and steep in all parts, and its highest part is covered with bushes, mixed with a few trees. You can go on the north side as near as you please; for it is perfectly safe on this side, but on the south side it presents a great shoal of madrepore rocks, scattered towards the edges with projecting irregular rocks, many of which are at the level of the sea. At the south part of this shoal, which stretches near half a mile S. of the islet, is a bank of white sand, formed, probably, by the attrition of the blocks of coral detached by the violence of the waves.

The island of St. Aubin is also inaccessible at the E. S. E. side, because of a chain of shallows which extends about 2½ cables' length off, and on which the sea often breaks. This chain, covered with 14 to 21 feet of water only, forms the western limit of the channel which leads to the anchorage.

From whatever quarter you may come, you may be directed in the proper course to take for the harbor of Trinity, by the view of a rock, which, from a distance, appears like a vessel under sail, and for this reason is called Carvel Rock. This rock, elevated 96 feet above the level of the sea, is totally devoid of vegetation, and distinguished by a pointed summit, whitened by the dung of the numerous flocks of sea birds. It is an excellent distinguishing point for every vessel from Europe or the United States, bound to Trinity, or to any of the anchorages of the eastern coast, because it is to the windward of all the anchorages and ports on this part of the island. The depth of water around it being considerable, you can approach it as near as you wish, but the swell of the sea, caused by the direct and permanent action of the trade winds renders landing almost impossible.

A channel more than a mile and a half wide, exists between the Carvel Rock and the east part of a peninsula to which it has given its name. This peninsula, remarkable for its great projection from the east coast, forms the harbor of Trinity by its junction to that part of the coast near the Island of St. Aubin, and separates this anchorage from that at the bottom of Galleon Bay, by an isthmus, but little elevated and only half a mile wide, on which is the plantation of Beau Sejour, and also a wind mill, which is one of the most remarkable objects in the neighborhood of Trinity. The Carvel Peninsula extends in a direction E. 27° N. near six miles; the land increases in height towards the E. as far as Tartan Hill, situated about the middle of its length, the highest point of which is 623 feet above the level of the sea; from thence the land decreases in height, and again rises in a very sensible manner towards the east extremity: and throughout the whole extent, shows in general, a vegetation much less vigorous than the other parts of the island. To the north of the peninsula the reddish steep shores, of little elevation, form the edges of many straits; in other places are sandy bays, in which you cannot penetrate by reason of the reefs which border them, or the swell of the sea, which insinuates itself in the small intervals where the reefs are interrupted.

Tartan Bay, situated near the islet of this name, is the largest and deepest; but the coral rocks by which it is encumbered almost every where, leave only a narrow passage practicable only for boats.

Opposite the harbor of Trinity, a chain of madrepore rocks stretches from the extremity of the Carvel Peninsula towards the Sugar-loaf Rock, in a direction generally N. W. Its surface is unequal in many parts, forming shoal banks of great extent, which cause a very heavy sea. The most remarkable of all, is the Loup Ministre; we have sounded there in 10 feet, and profiting by the circumstance of very calm weather, we estimated the shoalest part at 7 feet. This shoal part is always indicated by heavy breakers, and in general they can easily be distinguished from a vessel's deck or masts, otherwise far from being an object of apprehension, it contributes the better to judge of the position of the dangers relative to the coast, and the distance it is necessary to keep to avoid them when bound into the harbor of Trinity.

The term Loup (Wolf) used at Martinique to designate the preceding shoal, is usually applied to all the banks covered by a small quantity of water, and on which the sea breaks at intervals. We shall have occasion to use this term frequently in a further description of the coasts.

Between the Loup Ministre and the north part of the Carvel Peninsula, the bottom is covered with banks of different sizes, on many of which we found but 3½ fathoms of water. It is not necessary to pass them in entering or leaving the Harbor of Trinity, but to pass the great chain of madrepore rocks, of which the Loup

Harbor of Trinity, for  
s, of which the Loup

Ministre forms a part, you might be exposed, in passing, to some dangerous rocks, which may not have been discovered by us in sounding, or receive a great shock from the sea, should the wind freshen ever so little.

There exists south of the Islet of St. Aubin, more than half a mile off, a bank extending S. S. W. and N. N. E. over half a mile, and on which we found 24 to 32 feet water. Here the chain of shoals, which lies off the Harbor of Trinity, ceases. A bottom of white sand is found, immediately on the west side, in 15 to 18 fathoms water, and stretches W. N. W. the general direction of the reefs, to the Loup St. Mary, situated N. N. E. of St. Mary's Islet, a mile distant. This shoal occupies a space of three cables in length by one in width, and the shoalest water we found on it was 32 feet. It is best, however, not to pass over it, notwithstanding the great quantity of water by which it is covered; for the sea there is always heavy, and oftentimes breaks, particularly when the winds blow from the E. N. E. to the N. E. strongly from these points; the soundings are at the least 25 fathoms less than a cable's length from the Loup St. Mary; and in the channel which separates it from the Islet, the depth of water varies from 18 fathoms to 9.

The passages between the Loup Ministre, the Loup St. Mary, and the Islet of St. Aubin, are at least a mile wide, and are frequented by vessels bound to Trinity; but it is very important not to get in with the chain of the Loup Ministre, for you would expose yourself in passing over the shoals where the soundings are scarcely  $4\frac{1}{2}$  fathoms, to very great danger from the sea. You will take the precaution to keep your distance until the Islet St. Aubin bears S.  $\frac{1}{4}$  E. (true) at the distance of nearly 2 miles. The directions given by this course being very near the west part of the banks of which we have just spoken.—You should not deviate from this course to the eastward, (whether you have a fair wind, or must beat in) till you bring the Island of St. Aubin to bear S.  $\frac{1}{4}$  E. at six or seven cables' length distance.—You may then stretch towards the southern limits of the Madrepore Rocks, and when you are W. N. W. of the Loup Ministre, and you have got sufficiently to windward to be N. E.  $\frac{1}{4}$  E. of the small island of St. Aubin, and W. of the Loup Ministre, you must steer S.  $\frac{1}{4}$  W. for this anchorage, guiding yourself, however, through the passage by the sight of the reefs which line it east and west. You may come to anchor east of Fort Point, between the two chains of reefs, and in the whole space comprised between this position and the bottom of the harbor the anchorage is excellent; it is sheltered from the prevailing winds, which generally vary only from the N. E. to the S. E. passing easterly. The winds from the N. and N.  $\frac{1}{4}$  E. are the only ones which cause any swell, because their direction is the same as that of the entrance, but these winds blow very rarely, and are not to be feared except in the winter season.

It is oftentimes more difficult to get out of the Harbor of Trinity than to enter, particularly when the winds are E. N. E. Taking care, however, to tow your vessels so as to approach as near as possible to the banks which limit the anchorage to the East, which may be done without inconvenience, as these banks are to windward: you will then be able to double a little rock detached from the reef which surrounds Fort Point, and on which there are but 7 fathoms of water, after having passed to the north of this danger, which is about two cables' length E. N. E. from the Fort, the passage will present much less difficulty, as the pass widens much and is marked through the greatest part of its extent by lines of breakers, which border it almost without interruption. The Mitau Bank, covered with 11 feet of water only, and the banks to the E. S. E. of the Islet of St. Aubin, are the only dangers which the breakers do not render always apparent; but it is not necessary to prolong your distance as far as the Mitau Bank to pass clear of the banks of the Islet of St. Aubin.

Once outside the Islet of St. Aubin you will make your course westward of the Loup Ministre; and in case you want to go towards the entrance of the Dominica Channel, you may pass inside of Loup St. Mary, or outside, opening the wind-mill of Beau Sejour a little to the east of the Islet of St. Aubin to avoid this bank.

The reef to the south of the Islet of St. Aubin, does not extend to the shore. Between it and the border of breakers which surrounds the coast, there is a channel of about a cable's length or more wide, and in which the soundings are from 5 to 6 fathoms, with a bottom of white sand. This narrow passage is frequented by boats, as for vessels they should not attempt it.

The Carvel Channel, which we have before mentioned, is used by vessels of a great draught of water, but as it does not shorten the route to the Harbor of Trinity, or the other anchorages on the east coast, and as there are great inequalities in the soundings, and the violent currents oftentimes cause a heavy sea, it is but rarely used. The least soundings we ever found there is 40 feet.

Trinity next to Saint Pierres and Fort Royal is the most commercial place in the colony. The city extends along a beach of sand which terminates to the north at Fort Point. Its length is about 3400 feet, its breadth is very small. Since the hurricanes of

1813. 1817, there is no remarkable edifice. The River Epinette crosses it towards the southern part, after having watered a narrow valley planted with sugar canes. It is a watering place which may answer for vessels anchored in the road; but to have pure and limpid water, it is necessary to go to the interior a considerable distance. During our stay at Trinity, the crew of the *Eclair* preferred procuring their water at a spring at the plantation of *Beau Sejour*."

**PORT ROYAL to ST. PIERRE.**—The N. W. point of the Port Royal Harbor is low, though bold, and has a masked battery on it. To the N. W. of this point, about 2 miles distant, there is a rivulet of fresh water, and a village called *Case des Navires*, off which there is excellent anchorage, from abreast of its westernmost houses to abreast of a battery east of it. The anchoring-ground, or bank, reaches only to the distance of a cable's length and a half from shore. Within half a cable's length of the beach, the water is shoal, deepening thence to three fathoms on the outer part, and to 5, 7, 10, 15, 18 and 25 fathoms, at a cable's length distance; off the battery the ground is clean, softening to soft mud abreast of the westernmost houses. Without the depth of 24 fathoms, the ground is hard and gravelly.

In order to anchor in this road, you must turn to windward before you stand in, until the easternmost cluster of houses in the village appears on with the middle of the valley behind them; then steer in with this mark. When the point between *Case des Navires* and the next village, called *Case Pilote*, opens without the land to the N. W., you will be entering on the bank in 43 fathoms; then steer so as to have the westernmost house of the cluster above mentioned on with the middle of the valley; and with *Le Grosse Pointe*, on the south side of Port Royal Harbor, shut in behind Point Negro, you may anchor a large ship in 18 or 20 fathoms. Small vessels may stand farther in, with the same mark, to the depth of 9 or 7 fathoms.

**ST. PIERRE**, (St. Peter,) the trading town of Martinique, lies about 4 leagues to the N. W. of Port Royal. It is built partly upon the rising grounds at the foot of a ridge of hills, and partly along the shore of a spacious circular bay, which forms an open road to the southward and westward.

The best anchoring place, called the *Frigate's Anchorage*, lies in the southernmost part of the road, (when you see some steep cliffs and rocks,) in 7 fathoms, gravelly ground. If you bring the highest steeple of the town N.  $\frac{3}{4}$  E., and Point Carbet (on the south side of the road) south, you will have 7 fathoms, oozy ground.

The French frigate *La Flore*, being moored in this road, in 1772, with one anchor in 25 fathoms, fine sand, and the other in  $4\frac{1}{2}$  fathoms, same ground, had the following bearings by compass, the variation at the same time, was  $3^{\circ} 52'$  E.

Point Precheur N. W. by N.  $3^{\circ}$  N., the Galley's End N.  $9^{\circ}$  W., the Black Friar's Tower N.  $3^{\circ}$  W., the Negroes' Chapel E.  $2^{\circ}$  N., Point Carbet, S.  $4^{\circ}$  W.

If you intend to stay some time in this road, it is proper you should lie with one anchor close to the shore, to the S. E. or E. N. E. (or even on shore) and the other to the N. W.

In the hurricane months, that is, from the 15th of July to the 15th of October, ships cannot lie with safety in this road, and the French ships are generally obliged to leave it on the 15th of July at farthest. If they are to remain for a longer time at Martinique they retire into Port Royal Bay, where they lie secure against the hurricanes; they may also find shelter in Trinity Bay to the windward and on the north side of the island.

Mr. Backhouse, in his description of the Road of St. Pierre, has observed that "there are 30 and 40 fathoms at two cables' length from the shore; but farther off than that you will be off the bank. They generally lay one anchor in 25 or 30 fathoms, and the other in 12. The marks with which we anchored were the fort S. by E; the great church N. off shore one cable's length, in 24 fathoms.

In sailing from *Case Navires* to St. Pierre, you will pass the village and battery of *Case Pilote*, and those of Fort Capet and Carbet. Between the latter is the promontory called *Morne aux Boeufs*, which bears N. N. W.  $\frac{1}{4}$  W., distant  $5\frac{1}{2}$  leagues, nearly, from the Diamond Rock.

The anchorage in this bay is far from offering adequate security to the many vessels that frequent it from Europe, West Indies, the United States and Gulf of Mexico. Its being exposed to all winds from S. S. W. to N. W. by W., renders it particularly dangerous during the winter months, as well as towards the commencement and at the end of that season, by reason of the sudden squalls of wind then frequent. The ground swell is then often experienced with a violence that afterwards causes great damage. In the other parts of the year, the road of St. Peter's is almost entirely exempt from those dangers, and it is a shelter from the reigning winds, which blow from the E. to the N. E., and the phenomenon of the ground swell is much nearer and less dangerous: the only inconvenience it occasions is to impede considerably the communications with the city, and sometimes to render them impracticable.

Vessels surprised at the anchorage by strong winds from the open sea, or from a heavy ground swell, find themselves in a critical situation. If they cannot tow out, or beat out, they are oftentimes thrown ashore by the enormous surges; if instead of attempting to go to sea they remain at anchor, their loss is almost certain, particularly if they have not chain cables; for the continual shocks of the sea cause them to drag their anchors, or if they hold, the agitation of the sea causes the cables to part, and in either case they drive on shore and soon go to pieces. With the intention of preventing such shipwrecks, the colonial government orders all French vessels to quit the road of St. Peter at the commencement of the winter, and obliges them to depart for Europe, or pass this season in the bay of Fort Royal, either at the carenage or at the port of the Three Islets.

The best anchorage in St. Peter's Road extends from Point St. Martha to the south extremity of Thurin's Bay. The soundings in this part have less declivity than in the other part of the road. They form relative to the depth which exists before the city a flat space of less depth, called the Plateau of Carbet. You may anchor on this plateau in 21 fathoms, two cables' length from the shore, but you must not anchor farther off, particularly if you are west of a little ravine where the steepness in the rocks round the Bay of Thurin is interrupted, as at this place we found 150 to 180 feet water, and a bottom of irregular rocks, on which many anchors have been lost.

The anchorage for merchantmen extends from Point St. Martha to the river Des Peres, which bounds the city to the north. French vessels occupy the space south of the Place Bertin, and foreign vessels north of this place. In these two parts of the road the soundings having a very rapid increase towards the sea, you are obliged to come to anchor at a cable and a half's length from the shore, and to moor by the head to an anchor carried on shore. It is important to bury your anchors very deep in the sand, that they may resist the violent shock to which vessels are exposed from the ground swell. It is also necessary to take the precaution to have your cables tight, to prevent your vessel from changing her position, and avoid falling on board other vessels.

A little distant from the Place Bertin, W. N. W. from the marine hospital, and at a cable's length distance from the shore, is a bottom of rock called Hospital Key, and on which foreign vessels are obliged to anchor. Its depth gradually diminishes in approaching the shore, but on the western side it terminates abruptly by an almost perpendicular wall; so that from 50 to 95 feet, the soundings found off the key, you suddenly have from 166 feet to 213 feet, which are immediately outside its western limits. It is necessary to sound before anchoring on this key, and let go your anchor in 50 feet water, as in going farther off, at a cable and a half's length for example, you expose your cables to be cut by the rocks which form the limits of this key.

North of this key, and in approaching it from the river Des Peres, the anchorage becomes more and more difficult, by reason of the declivity of the soundings. At less than 2½ cables' length from the mouth of this river, the depth is 550 feet, and farther off you will find no bottom with 600 feet.

Variation at Fort Royal Bay, 1824, 2° 47' N. E.

**NORTH-EASTERN SIDE OF THE ISLAND TO ST. PIERRE.**—Ships advancing from the eastward, off the north side of Martinique, generally take their departure from La Carvaille, or the Carvel, a remarkable rocky islet, lying about 1½ mile off the N. E. point. In running thence along the coast, you must cautiously avoid the effect of flurries, or sudden and partial gusts of wind, which frequently proceed from the narrow openings of the mountains; and if the top-gallants are up you must keep a good lookout after the halliards. For it is to be observed, generally, that the mountains intercept the course of the trade wind, and consequently occasion calms and variable winds to leeward.

This side of the island is well cultivated. You will distinguish the plantations to the very summit of the hills, which are themselves covered with trees and grass, excepting only the Mont Pelee, or Bald Mountain, the highest of those hills, and the only one that is barren.

Point Macouba, the northernmost point of the island, is distinguished by a waterfall, or kind of torrent, falling into the sea from the top of a high rocky coast. About five miles to the W. S. W. from Point Macouba lies a round rock detached from the land, called the Pearl, to the southward of which are the little isles, called those of Precheur, or Preacher. Next follows the point of the same name. Soon after Point Precheur presents itself, which ends in a flat hummock with a plantation on it, then the town of Le Precheur. Beyond Precheur Point you will discern two others in a line, namely, the Morne aux Bœufs, before mentioned, to the southward of the road of St. Pierre, and the Diamond Rock, to the southward of Port Royal.

Between the north end of the island and St. Pierre, there are several villages, protected by batteries. The coast is very steep and clear of danger.

Having doubled Point Precheur, you will descry the ships which lie at anchor in the Road of St. Pierre, as they all have awnings to protect them from the intense heat of the sun. You would take them at first sight for so many white houses, whose roofs are built like a terrace; you cannot come to anchor close hauled: for the winds, which always prevail from the E. and E. N. E., will compel you to traverse up to the road.

*Remarks on the Navigation about Martinique, from the Derrotero de las Antillas, &c.*

The land of this island is high and rocky, and may be discerned at about 15 leagues off. Its eastern part is full of bays, but they afford little shelter, and are frequented by coasters only. From the South Point, or Point Salines, along the western coast, to the North Point, Point Macouba, you may approach within a mile of the coast without any danger.

The principal anchorages of Martinique are those of Port Royal and St. Pierre. That of St. Pierre is an open roadstead, which affords shelter from the general breezes only; and vessels that are obliged to remain in Martinique during the hurricane season, go to Port Royal to pass it over. The Fortress, called Port Royal, is on a tongue of land, which runs nearly half a mile to the south into the sea; from the S. W. part of this tongue, a shoal of sand and rock stretches out, but it may be easily discovered by the color of the water. By the eastern side of this point is the harbor and arsenal, where vessels anchor in the greatest safety; but they enter into it only in the season of hurricanes, or for the purpose of careening; its bottom is excellent, with a depth of from 6 to 10 fathoms. The city is about one fourth of a mile to the north of this point, and at the sea side, on the west part, in Flamingo Bay, which is, therefore, the anchorage for merchant vessels; and, indeed, generally, for all vessels which are not to remain long at Martinique.

If you approach Martinique on the north side, and mean to anchor in the Road of St. Pierre, you may haul in as close as you choose for Macouba Point, and should run along the coast afterwards so as to pass outside of the Islets du Seron, which lie on the N. W. point of the island; and from these you may shave the Point du Precheur. (Preacher's Point.) within half a cable's length, in order to run and anchor in front of the town of St. Pierre, or a little to the south of it; keeping in mind that the coast is so steep, that half a cable's length from it you will have 4 or 5 fathoms water, and 35 or 40 fathoms at 3 cables' length. Vessels moor with two anchors, one to the west in 35 or 40 fathoms, and one to the east in 4 or 5 fathoms; it is, however, better to have a cable on shore in place of the anchor to the east, that you may not drag with the strong gusts of wind which come over the land.

If you are bound to Port Royal, you will steer from Pointe Precheur to Morne aux Bœufs, which is the south point of the Bay of St. Pierre: and from it you will sweep along the coast to shave Point des Negres, (Negro Point,) from which you must haul to wind all you can, in the understanding that, from the said point to Flamingo Bay, you may shave the coast without any risk.

As it is necessary to beat up from Negres Point to the anchorage, keep in mind that the shoal which runs out from Port Royal Point, extends to the west as far as the meridian of a brook which runs into the sea, to the westward of the city: and thus, when you mark the said brook at north you must not prolong the south tack further than to bring Port Royal Point a little to the northward of east, but ought rather to go about before you bring it to bear east, and anchor on the other tack opposite the city. If you have to enter the harbor, it is advisable to take a pilot.

Those approaching Martinique from the southward, must steer so as to pass close to the Diamond Rock and Point, and shave Cape Solomon, where the course is nearly north, but nothing to the east of it, until Pointe Noire bears east; from this situation you will haul by the wind to take Flamingo Bay, or enter into the harbor as may be requisite, it being well understood that you can anchor in any part of the great bay.

If coming from the south and bound to St. Pierre, you must steer from Solomon's Cape to Morne aux Bœufs, hauling in to anchor to the S. W. of the town as already directed.

It is almost a matter of indifference what part of Martinique you make: only in case of the winds being free from the N. E. you may consider it preferable to make the north side.

The strait between St. Lucia and Martinique is clear of all danger; the breeze is always steady in it, and its current is scarcely perceptible.

About a high peaks they lie ver both, on co

*The Island of St. Lucia.*

St. Lucia bearing N. W. by W. 3 or 4 leagues.

About a mile and a half to the west of the Sulphur Hill, on the sea shore, stand two high peaks, called by the French *Les Pitons*, and by the English the *Sugar Loaves*: they lie very near each other, but between them there is opening enough to distinguish both, on coming from the southward.

On the western side of the island, at the distance of about three leagues from its northern cape, is *Port Castries* or the *Careenage*, one of the harbors in the *Windward Islands*, having deep water and good ground all over it. These careening places have been formed by nature, which require no wharfs, and only a capstan to turn the keel above ground. Thirty line-of-battle ships might lie securely here unmoored, during the hurricanes. No ships can enter without warping in; but there is always a breeze to carry them out: and in less than an hour, the largest squadron may be in the offing. The shores are so bold, that a first rate man-of-war may approach within six yards of them.

Nearly a league to the southward of the *Careenage* lies the *Grand Cul de Sac*, or *Grand Bay*: and nearly two leagues to the northward of the same, is the *Bay of Gros Islet*: these places form excellent roads for ships of war.

When bound from the northward to the *Careenage*, you will see a bluff two leagues to the leeward, which may be approached boldly; you must haul close in to see the harbor, then run into it as far as you can fetch and warp in. When the sun shines all the dangers may be seen.

Should you have occasion to anchor off the south coast, you may do so in *Old Fort Bay*, (*Anse de Vieux Fort*), under the S. E. bluff, unto which you may turn till you bring *Point Moulacique*, the southern Point, to bear S. S. W. and then anchor in 7, 8, or 10 fathoms, good ground. At the north part of this bay there is a river, which runs into the sea. If you water here, it must be by proceeding half a mile up with the boat; unless after great rains, when you may fill at the entrance.

*Remarks on St. Lucia.*

[From the *Dernotero*, &c.]

The Island of *Santa Lucia* shows high, and in detached hills, with various peaks sufficiently visible: in particular two, at its extreme S. W. part, called the *Pitons*, which may be seen at the distance of sixteen leagues; they are black, and covered with wood.

At the N. W. point of this island there is an islet, named the *Gros Islet*, which is rather more than a mile distant from *Point Salines*, to the S. W. Between *Salines Point* and the *Gros Islet*, there is a rock named *Burgaux*. To the south of the islet is the *Bay of Gros Islet*, or *Roadstead of St. Croix*, with excellent anchorage for every class of vessels, having a depth of from 17 fathoms down to 5 fathoms, which are found at half a mile from the coast; between the coast and the *Gros Islet* there is a passage for small vessels only, it being impeded by a shoal, on which there are only 2 fathoms of water. The *Gros Islet* is foul, and you ought not to approach nearer to it than two cables' length.

Near *Brelotte Point*, to the south of *Gros Islet Bay*, there is an islet, which forms a strait, practicable for any vessel, it having 7 fathoms of water in it. This islet is, like the *Gros Islet*, foul, and you must not approach nearer to it than two cables' length; this coast, on the contrary, is clean, and a rock, which is also clean, lies about a cable's length out from it. On all this coast there are from 8 to 10 fathoms, at half a mile from it, and you may anchor in any part, though the safest anchorage is in the *Road of St. Croix*, where there is good shelter from the sea.

About a mile and a half to the S. by E. of *Brelotte Point*, there is a rocky shoal, extending nearly in that direction, which is a mile in length and about two cables in breadth; its distance from the coast is more than half a mile. This is the only danger on all the western side of *St. Lucia*, on which there are excellent anchorages, but principally in the *Careenage*, which is two leagues to the S. by W. of the great islet, and the best harbor in the *Lesser Antillas*, with excellent anchorage, very clean, and three natural

coves in the interior, and such steep shores that they might serve as wharves, or moles, at which the largest men-of-war may be hove down. This harbor has, however, the disadvantage that you cannot enter it except by towing or warping, it being impossible to beat in, on account of its narrowness; but, in exchange, it is easy to get out of it even with a large squadron; as you must enter either towing or warping, it is sufficient to say that the south point sends out a very shallow tongue of sand to the N. W., and that the North Point is deep and clean, and you may approach within a quarter of a cable's length of it, without giving a berth to more than the rocks which are seen.

The strait between this island and St. Vincent's is subject to tornadoes, and strong currents to the W. N. W.; and as Port Castries and the bay of St. Croix are towards the northern extremity of the island, it is advisable to make the land, when bound to them, from the northward.

*The Island of St. Vincent's.*

St. Vincent bearing S. by W. about 4 leagues.

From Bequia to St. Vincent's the course is north about two leagues. The channel between these two islands is very good to come through, if bound from Barbadoes to the Salt Tortuga, or the Spanish Main; and there are small trading vessels which work up through it. St. Vincent's is about five leagues long, and lies nearly N. and S. and E. and W. The north end, which is much higher than the south part, is inhabited by about 2000 natives or Caribs. On the north end there is a volcano, called La Soufriere, or Sulphur Hill, near Spanish Point. On the west side of the island, which is bold, are several bays, having all of them fresh water rivers, and on the S. W. side you make good anchorage, as near or as far off as you please, especially in Kingston Bay, where the chief town is situated. But the best bay of the island is Balair Bay. When you turn up between St. Vincent's and Bequia, you will see a large bluff of land, and just to the windward of that is Balair Bay, or Calliaqua. The shore is bold on each side. Run into 19, 20, or 15 fathoms and anchor. There are two rivers which run into the sea.

The course from Carlisle Bay to the south end of St. Vincent's is W., northerly, 33 leagues. If you intend to anchor in Kingston Bay, you will see a small high peaked island, called Young's Island; pass the bay to leeward of this island, and go round a long sloping point: you may borrow within pistol shot; but if the wind takes you short, you may anchor in 35 fathoms and warp in. There is a small ledge of rocks close on the weather shore, within 6 fathoms.

On the west side of the island, which is bold, there are several bays, all of them having fresh water rivers; and on the S. W. side, ships may anchor at pleasure, especially in Kingston Bay, on which the chief town of the island is situated.

The best bay, however, for shipping, is that called Calliaqua, or Tyrrel's Bay, at the south end of the island. This may be known by a high bluff, which will be seen when turning up between St. Vincent's and Bequia, which lies on the leeward side of the bay. The shore is here bold on each side. Run into 19, 20, or 15 fathoms, and anchor. There are two rivers, which run into the sea.

Kingston Bay is completely open to the S. W., and is more than a mile in breadth. The town is at the head of the bay, close to the water side; the anchorage good, the soundings regular, with a bottom of dark sand, apparently clean, and forming a good holding ground. The water is deep on each side of the bay, and you may round the eastern head, called the Old Woman's Point, as close as you please, there being 20 fathoms at not more than 20 feet from the shore. The best anchorage for a frigate is with the court-house bearing north, in 19 or 20 fathoms, not more than a quarter of a mile from the beach. There is a light current setting along the bay, but it is not regular. The tide rises about 4 feet. Fresh water is good and easily obtained.

PRINCESS OR BARAWALLY BAY.—This little bay lies five and a half miles to the north-westward of Kingston, and its north side is formed by rocks called the Bottle and Glass, between which and the main there is a passage for boats. There is no danger in going in; and, in coming from the northward, you may haul close round the Bottle and Glass. When round this point, luff up as much as possible, and you will open the town barracks, bearing N. E. by E.  $\frac{1}{4}$  E., which may be kept thus until the Bottle and Glass Point bears N. W.; you will then be in about 22 fathoms, with sandy ground.

e and a half miles to called the Bottle and here is no danger in ound the Bottle and n will open the town he Bottle and Glas- ly ground.

All along the Bottle and Glass side is rocky, but the bottom of the bay all sandy and good ground. If you moor in and out, which is used for ships of war, you may warp in, and lay your inner anchor in 12 or 13 fathoms of water, and your outer anchor will be in 32 fathoms. Moor a cable each way.

**THE GRANADINES, OR GRANADILLOS.**—The Granidines form a chain of innumerable rocks and barren spots, good for little, which extend to N. E. by N. for about 16 or 18 leagues. Some, however, are of considerable size and value, particularly Carriacou and Bequia, both inhabited, and producing good coffee and cotton. Carriacou lies about 6 leagues N. by E.  $\frac{1}{2}$  E. from the N. W. of Grenada. It is of a circular form, of about 6 miles in length and breadth, and has a commodious harbor.

Bequia, called also Little Martinique, is the northernmost of the Grenadines, and lies about 2 leagues south from St. Vincent's. On the west side it has a very good sandy bay, where you may ride occasionally; and wood is to be got there, with plenty of fish, but no water. The little islands to the southward of Bequia are very fair, and near them you may stand boldly, having neither rock nor dangers you need to fear.

N. by E. course from Point Laurent, or the N. W. point of Grenada, will carry you clear along the Granadines.

Observe that towards the south part it is rather dangerous to come near in the night.

**ISLAND OF GRENADA.**—There is good anchoring ground along the coasts, and on the eastern and western sides are several small bays and creeks, commodious for vessels, as well as for the landing and shipping of goods.

The principal town is that of ST. GEORGE, in the S. W. quarter of the island, which is situated on a bay of the same name, formerly called La Grande Bay. This bay is formed by a point called Molenier's Point, on the north, and Cabrit or Goat Point on the south. The distance between these points is  $3\frac{1}{2}$  miles. The space between is not entirely clear, as a coral reef extends out to a considerable distance from Point St. Eloi, which lies a mile to the south-eastward of Molenier's Point; and there is a sand bank, of only 17 or 18 feet of water, on which coral is beginning to grow, at some little distance off the fort point, on the north side of the entrance to the harbor.

The chief bay on the eastern side of the island, is that called Greenville Bay, which is open and protected by extensive reefs.

The town of GREENVILLE is a port of entry, having its distinct custom-house establishment. The villages are generally on the shipping bays around the island.

On the south side of the island, immediately on the western side of the Point of Fort Jendy, and 2 leagues to the eastward of Salines Point, lies the harbor called Calavine or Egmont Harbor, which is very deep, and where, it is said, sixty men of war could ride in safety without anchors. The entrance is nearly half a mile in breadth. Within, its peculiar conformation is such, that it may be considered as forming two harbors, namely, the Outer and Inner Ports. The entrance into the latter is narrow, and its length rather more than half a mile. The depth in the greater part is 7 fathoms, with excellent holding ground, being every where a soft oozy bottom. The ships may here lie alongside of the warehouses, and take in their lading with great ease and convenience; after which they may, with very little trouble, be towed into the outer harbor, which enjoys this peculiar advantage, that ships can sail in or out with the common trade wind.

In sailing off the south side of the island, there is little danger until you get to the westward of Fort Jendy Point. But thence to the rocks named the Grampuses, it is necessary to keep a good offing, as the ground in-shore is very foul, and full of reefs. The Grampuses lie about three quarters of a mile off the land, with the point called Pirogue Point bearing N.  $\frac{1}{2}$  W. They appear just above the surface, and there is a passage within them, but it is not deemed safe.

Off the north side of the island, in the channel between it and Redonda, or Round Island, there stands a remarkable rock, called London Bridge, (from its having a natural arch in it,) and from the south side of which extends a reef. This rock may be easily avoided by keeping over to the north side of the channel. Hence and along the west coast of the island, the shore is bold, all along to the point of St. Eloi, whence a coral reef extends, as before explained.

Islets off the north end of Grenada.

**ST. GEORGE'S BAY.**—When sailing into St. George's Bay, from the northward, give Molenier's Point a small berth. You may run within half a cable's length of it, in

8 or 9 fathoms. The point is low, with some straggling trees on it, and makes like an island. When near the point you will see St. George's Fort, bearing S. S. E. Keep your luff for the fort, and when you cannot fetch near enough to anchor, with the fort bearing east, tack, or you will be in danger of running on the three-fathom bank, before noticed. The soundings are very regular from Molenier's Point—some casts 20, 13, 9, and 12 fathoms; and in shore, towards the fort, from 9 to 5 fathoms, the bottom is foul.

To sail within the three-fathom bank or middle ground, you may be directed by two white houses, over the town, about half way up the hill. Keep them open with the north end of the fort, and run directly in, until you see a single tree to the southward, upon a little hill, open a good sail's breadth to the northward of a large tree close to the shore; you will then be within the bank, and may pass the fort point at the distance of half a cable's length, in 4 and 5 fathoms. In the mouth of the harbor there are 15 fathoms of water, but it shoals very fast to the southward.

The best anchoring ground in St. George's Bay, is off the mouth of the harbor, at about a cable's length from the fort, with the two white houses, above mentioned, open to the southward of the fort; but if you anchor in the bay off the town, the houses must be open to the northward of the fort and bear E. S. E.

In advancing towards St. George's Harbor from the southward, it must be observed that after passing Point de Salines, there is a very dangerous coral reef lying between that point and Goat Point, with only 2 or 3 feet over it, in the shoalest part. This bank lies with the signal staff of Fort St. George in one with a house that has two little turrets or pavilions, situated on the top of a hill a little to the eastward of the redoubts on Hospital Hill. With this mark you will be in a line with the reef, and must give it an offing. The bank is about a mile in length, lying parallel with the shore. Within it there is a narrow channel, through which small craft frequently pass.

In running from the eastward, towards Point de Salines, you will see islet Rameur, a very small island lying rather more than half a mile from the nearest shore, and nearly a mile from the point. Give that islet a berth of a mile, and do not attempt to pass within it, as the passage is shoal. To Point de Salines it is sufficient to give a berth of half a mile, as at that distance there are 7 fathoms water. So soon as you pass the point, the bay will be open. You must now carefully avoid the bank above described, which you will have passed, when a remarkable house, like a summer house, upon a high point close to the end of the reef, bears S. E. On the bank the sea frequently breaks.

To sail into the harbor you leave the three-fathom shoal, as before directed, on the starboard hand, and run in close under the fort, and then warp up. The ground is all clear, and the harbor capable of containing, with the utmost safety, a large fleet of ships of the line.

You will generally be obliged to work up into the bay, as it lies open to the westward, and the trade wind blows directly outward. The true entrance of the port is from W. S. W.

**GREENVILLE BAY.**—This port lies about half way down the island, on the eastern side, and all those bound for it must be very cautious, and not go to leeward of it; for if they do, they must pass round Point de Salines, and turn to windward, on the other side of the island, as the current sets so strongly to the southward that, with the prevailing winds, the fastest sailing vessel cannot lead up. They should heave to, a little to windward of the Greenville Rock, which lies to the north-eastward, (off Telescope Point,) and is round, pretty high and steep on all sides. Upon firing a signal, a pilot will come off, and take charge of the ship.

The marks for going in are two white beacons, formed at the head in shape of a diamond. One stands at the head of the bay, and south end of the town, at high water mark; the other a little inland on the side of the road leading over the mountains. They bear, when in a line, N. 74° W. By keeping them thus you may run directly in, under an easy sail. Be careful to steer very small, as the channel between the rocks is very narrow, not being a ship's length across. After you are through the narrow, if your ship draws more than 13 feet, you must come to at the mooring chain and lighten.

This harbor, to those acquainted with it, is safe and commodious, being sheltered from all winds. Yet it is impracticable to a stranger, the lead being no guide; and if you once get too near the rocks, the current sets so strongly that you cannot get off again.

#### *Remarks on Grenada.*

[From the Derrotero de las Antillas, &c.]

Any part of Grenada may be safely approached to within less than two miles. On its western coast are many bays fit for anchoring in, but the principal is that in which stands the town and harbor of ST. GEORGE, or Port Royal. This bay is about one league from the Salines, or the S. W. Point. Between that point and Fort St. George, there

is a rocky shoal from N. E. there are 6 fathoms from Point de Salines to Goat Point, George's Bay, the greatest breadth to it are 6½ miles. The western bank is three miles. The 59° W., true bank is three miles.

Behind the length in depth place is as with the can haul along.

two miles. On its  
hat in which stands  
about one league  
St. George, there

is a rocky shoal and banks of sand, with coral. The rocky shoal is half a mile in extent from N. E. to S. W., and its greatest breadth is two cables' length. On all its edges there are 6 and 7 fathoms. It bears N. 25° E., true, three quarters of a mile distant from Point de Salines, and the northernmost part of it lies nearly W., or W. by N. from Goat Point, at about three cables' length. Goat Point is the southernmost point of St. George's Bay. The first sand bank is a mile in extent, N. by E. and S. by W., and its greatest breadth is three cables' length. The least water on it is 3½ fathoms, and close to it are 6½ and 7 fathoms. Between it and the coast the depth increases to 10 fathoms. The western extremity lies nearly north from Goat Point, and at the distance of half a mile. The second bank, on which there are not more than 3 fathoms of water, lies S. 59° W., true, from the fort, at the distance of half a mile. The greatest extent of this bank is three cables' length.

Behind the point on which the fort stands, is the harbor, which is only three cables' length in depth, and into which vessels go to load and unload, or to be careened. This place is as well sheltered as the best harbor can be, and vessels of the greatest burthen can haul alongside the shore, in a depth of 8 or 10 fathoms.

Grenada may be seen at the distance of 7 or 8 leagues; and as the principal harbor is by the S. W. point, the best way is to make and haul in for its south side.

To the south of Point Pirogue, on the south coast, there are some rocks even with the water's surface, which are called the Grampuses, and which lie out about two thirds of a mile from the point. At night it is necessary to be certain how you run, that you may keep clear of them. To the westward of Pirogue Point, nearly half a league, there is an islet named Glover's Island, which is very clean, and has 4½ fathoms of water, at a cable's length from it. To take St. George's Bay, you ought to pass about a mile without Glover's Island, and at half a mile with Point de Salines, steering to the north so soon as you have passed the latter, until Goat Point bears east; then luff to the eastward, and place the prow to Point St. Eloi, which is about a mile to the northward of the Fort St. George. Thus you will pass safely outside the shoals. So soon as the point on which the fort stands bears east, you will have passed the last shoal, and may beat up between it and Point St. Eloi, taking care neither to prolong the tacks to the south of the fort, nor within less than two cables' length of St. Eloi's Point, which sends out some rocks to the west.

The anchorage is to the west of the town, at a quarter of a mile from the coast, where you may let go an anchor in 6 or 9 fathoms. The bottom is very various, for you may equally find clay, sand, or rocks. Vessels intending to make a short stay only, bring to in this place, with only one anchor; but those which have to make a stay and unload, go into the harbor, where they moor with four.

Some charts depict a bank and shoal to the S. W. of Point de Salines, with 13 and 45 fathoms. In the strait between Grenada and Tobago, the water has been found to set S. 70° W. with the velocity of a mile and a half an hour.

### *The Island of Barbadoes.*

Barbadoes bearing W. N. W. about 6 leagues.

Barbadoes, which lies out of the line, and to windward of the Caribbee Islands, is of moderate height, and generally level, although there are a few hills, of easy ascent. The island may be seen in fine clear weather 10 or 11 leagues off. The east end is much lower than the other parts; but on coming from the eastward, or when the north end of the island bears W. by N. and the S. W. point about W. S. W., then the eastern part appears the highest. From the eastern part to the southward, the land is even, and declines towards the sea; but between the eastern and northern points, it is uneven, rugged and broken.

The S. E. coast from South Point to Kitriages on the eastern point, is enclosed by a ledge of rocks called the Cobblers, from one of the most remarkable among them. They extend about a mile from shore, and you must be careful to avoid them in the night. At South Point, where the rocks terminate, there is a flat spit, which must have a berth, as it runs off above a mile to the W. S. W. In the daytime you may see how far it extends by the white water.

The principal town of Barbadoes is that called Bridgetown, situated at the mouth of a little rivulet on the north side of Carlisle Bay, upon the S. W. side of the island.

Those bound to Bridgetown should always endeavor to make the south side of the island by sailing on or near the parallel of  $13^{\circ}$ . In the latitude of Barbadoes, at about 70 or 80 leagues to the eastward, you will find the water discolored and thick, as if there were soundings, though there are none; by this indication, if met with, your situation will be nearly ascertained. When you approach the island, you may run along within three miles of the shore, until you advance towards Needham's Point, which forms the south side of Carlisle Bay. You may haul up and anchor in Osten's Bay to the westward of South Point, by avoiding the spit above described, where you will find ground in 7, 8, 9, or 10 fathoms water. This bay is rocky; but the best ground, which is tolerably good, lies with a mill close by the water side, at the head of the bay, bearing E. by N., or E. N. E.

In Carlisle Bay, also, the ground is foul, and apt to chafe the cables. In hauling in for this place, give Needham's Point a berth of a quarter of a mile, to avoid a reef which stretches from it, and always breaks. You may then run in till you bring Charles Fort, on Needham's Point, to bear S. E., and the steeple N. N. E.

There is, also, anchorage in this bay, in 25 fathoms, fine sandy bottom, with Needham's Point, S. E.  $\frac{1}{2}$  S. the church N. N. E. and the N. W. point of the bay N. W. by N.

The long mark for the reef of Needham's Point is a house standing upon the hill above the north end of the town, open with the outermost or southernmost flag staff on Needham's Point; and the thwart-mark is the three flag-staffs in one. With the above mentioned house on the hill open to the northward of the church, the ground is foul, but to the southward it is more clear; and with that house just open to the southward of the church, there is an anchorage in about 12 fathoms; the other marks for which are, a road to the eastward of the town directly open, the fort S. S. E.  $\frac{1}{2}$  E. and Pelican Point N. W. by N. The tide is almost imperceptible.

On the leeward side of the island, N. N. W. from the northern part of Carlisle Bay, are several shoals, called the Pelican and Half Acre Shoals, the outermost of which lie about three quarters of a mile off.

Before Speightstown, which lies between eight and nine miles to the northward of Bridgetown, and which is defended by three forts, vessels occasionally ride.

There is a bank lying about three hundred miles to windward of Barbadoes, called Glassionieres, from the name of the French Admiral who first reported it, but subsequent information confirms it.

TOBAGO, like Barbadoes, lies out of the line, and to windward of the Caribbee Islands. The land in the northern part is so high as to be seen, in clear weather, at the distance of fifteen leagues.

Though Tobago does not possess any harbors, properly so called, yet it has several good bays; which, considering that from their southern latitude they are never exposed to dangerous gales of wind, are equally convenient and secure to shipping. For this reason, the men of war stationed at the Caribbee Islands frequently repair hither for safety in the hurricane months.

The principal towns are Scarborough and Georgetown, situated on the south side of the island, and its best roadstead is in Man of War Bay on the north side. The vertical rise of the tide, on the full and change, is only four feet. The currents near the island, are very strong and uncertain, especially between it and Trinidad. The N. E. trade-wind prevails all the year round.

The course usually taken from the island of Barbadoes to the S. E. side of Tobago, is south rather easterly, so as to allow for the current, which sets most frequently to the N. W. and so as to get several leagues to windward of the island.

If you make Tobago towards the evening, and are afraid of running in with it, you must not, by any means, lie to, but stand to the southward under an easy sail, otherwise the current, which always sets either to the N. W. or N. E. may occasion your losing sight of the island; and it is possible that a N. W. current may carry you so far to leeward as to render it difficult to regain it.

Ships bound to the bays on the N. W. side, should always endeavor to make the north end of the island, which is bold and clear. A cluster of large bold rocks, called Melville's Rocks, lies off the N. E. point. Of these the westernmost is very remarkable, having a large hole in it, from north to south. You may run as near to these rocks as you choose, and along the coast hence to the Man of War Bay.

MAN OF WAR BAY.—This bay is not only the best in Tobago, but is one of the best harbors in the West Indies, having sufficient depth for the largest ships close to the shore. The distance from Melville's Rocks to North Point on the N. E. side of this bay, is about three miles. In sailing in, haul round this point, when you will have the bay open, and you must be careful not to be taken aback, the wind being very fluttering under the high land.

You will find no soundings until close up in the bay, and then from 40 to 10 fathoms.

Having entered the bay, you will find the water as you go, 17 fathoms. In Pirate's Bay, the water is 17 fathoms.

On the south side of the island, there is a grassy plain, the western end of which is the Cardina Bay.

Nearly two miles from the bay, are some hills, a half from the bay, which there are some of the rocks.

COURTNEY'S ISLAND, the island, the eastern point of which is Sisters. To the south of the island, there are breaks at low tide in 9 or 10 fathoms, only that the water hangs to the south. In the night, during night, the water is very good, and the soundings are very good.

To the south of the island, there is anchorage with smooth water here.

Between Martinique's Bay, there are some of one hundred fathoms.

At the S. V. point, there is an anchor in 6 fathoms without the reef. At the S. V. Point, and is the current in the breakers you have passed.

EASTERN ISLAND, lies the small island. Within these islands, you may anchor in 10 fathoms, and the ships must, the most constant.

At the distance of 10 miles, and raton, Queen's Island, anchoring ground. The water is from the eastward, out is early in the northward.

South-west of the island, called Richmond, is a lesser point of the island, dry rock, called the Roxburg Point, the N. W. of hereafter. From the bank and reef, several places,

Having entered, turn in and anchor as far to windward as you can. After you are shut in, you will see the little bay on the eastern side called Pirate's Bay: get as near to that bay as you can: you will find all clear ground, and may anchor in from 12 to 14, 16 or 17 fathoms. If you cannot turn in, you may anchor in 35 or 40 fathoms, and warp up. In Pirate's Bay, is the watering place in the rainy season.

On the south shore of the bay you may anchor in 16 or 18 fathoms, at a quarter of a mile from shore, and have good water at all times, half a mile from the anchorage; but there is a great surf which makes watering hazardous.

The western side of the bay is a good place for fishing; but there is a small shoal called the Cardinal, lying within half a mile of the shore on that side about half-way down the bay.

Nearly two miles to the westward of Point Corvo, the western point of Man of War Bay, are some bold rocks, called the Brothers; and in the same direction, at a league and a half from that point, are some others of the same description, called the Sisters, close to which there is a depth of 40 fathoms. All the coast hereabout is bold to. From abreast of the rocks, the south-west end of the Island, which is low and sandy, may be seen.

**COURTLAND BAYS.**—The first bay from the northward, on the western side of the island, excepting a few for small vessels, is that called Great Courtland Bay, the northern point of which, called Guana Point, lies thirteen miles to the south-westward of the Sisters. To this point a berth must be given, as a rock, called the Beef Barrel, which breaks at low water, lies just off it. There is anchorage in 6 fathoms, but good fishing in 9 or 10 fathoms, either with the seine or with the hook and line. The ground is clear, only that there are a few stumps of trees close up to the mouth of the river. If the wind hangs to the southward of east, you will ride very roughly, and if at N. E. will roll very much. In the bay you will have the common trade wind all day, and an off-shore breeze during night. If you arrive in the night, and do not care to push for the bay, you may find very good anchorage to windward of the cliff, in from six to twenty fathoms, regular soundings.

To the southward of Great Courtland Bay is Little Courtland Bay, having very good anchorage within the windward point, which is pretty bold. Vessels ride more safe and smoothly here than in the former.

Between Man of War Bay and Courtland Bay, are the bays called Bloody Bay, Peale-tuvier's Bay, Englishman's Bay and Castana Bay, which have safe anchorage for vessels of one hundred and fifty tons.

At the S. W. end of Tobago is Sandy Point Bay, in the bottom of which ships may anchor in 6 fathoms. When you weigh for this place, be sure of a breeze to carry you without the reef, called the Buckoo, which extends from Little Courtland Bay to Brown's Point, and is dry in some places, at the distance of two miles from shore. If it be calm the current may set you on this reef. At the distance of two cables' length from the breakers you will be safe to enter Brown's Point Bay, haul close round the reef, and having passed the point, anchor as above.

**EASTERN COAST.**—About three and a half miles S. S. E. from Melville's Rocks lies the small island called Little Tobago, near which there are several islets and rocks. Within these is the bay called Tyrrel's Bay, in the bottom of which vessels of 150 tons may anchor in 7 fathoms. The ground between Little Tobago and the main, is very foul, and the currents very strong and uncertain. In sailing off this part of the coast, ships must, therefore, keep well to the southward, allowing for a N. W. current which almost constantly prevails about Little Tobago.

At the distance of three and a half miles to the southward of Little Tobago is Pedro Point, and rather less than two miles from Pedro Point lies a high rocky islet, called Queen's Island. Between these points is the bay called King's Bay, which has good anchoring ground in every part within the windward point, in from 6 to 20 fathoms of water. The land on the eastern side, being high, intercepts the trade wind, and the swell from the eastward is apt to set a vessel down to the leeward point; the best time to sail out is early in the morning about daybreak, when the wind blows fresh from the land on the northward.

South-westward from Queen's Island at the distance of a league, lies a similar islet, called Richmond Island; and one league and a half from the latter, in the same direction, is a lesser islet called Smith's Island. These islets, being situated off projecting points of the coast, are conspicuous. Nearly a mile west of Queen's Island is a large dry rock, called the Roxburg, and between lies the bay, named Queen's Bay. Between the Roxburg Rock and Richmond Island is Hog Bay, in which the ground is foul. To the N. W. of Richmond Island is the little bay called Halifax Bay, which is noticed hereafter. From Halifax Bay, extending nearly to Smith's Island, there is a dangerous bank and reef, half a league broad, called the Great River Shoal, on which the depth, in several places, is only three fathoms.

In running down for Queen's Bay, which lies within Queen's Island, as above mentioned, give the latter a good berth until you open a large house, having a gallery on a rising ground fronting the quay, which is the only one of that description in the bay. Continue on this, without borrowing, until you bring this house in a line with one on the hill above; and keep this mark on, if the wind permits, until you are 2 cables' length from the shore; then haul your wind and anchor at about 150 fathoms from shore in 5 fathoms, fine ground, abreast of the watch-house on the beach. Should the wind be adverse, you must let go an anchor and warp up. In sailing outward, attend to the same mark as in sailing in, without getting over to windward.

The dangers are so numerous, from Queen's Bay to the west end of the island, that no stranger should venture without a pilot. The most accessible bays are those described as follow:

Halifax Bay, to the N. W. of Richmond Island, as before mentioned, is a good bay for vessels of 150 tons, but a shoal lies in the middle of the entrance. The next is called Barbadoes Bay, and lies to the leeward of Smith's Island. To avoid Great River Shoal in sailing for Barbadoes Bay, or to the westward of it, keep Little Tobago open without Richmond Island, with Smith's Island bearing N. W., you may luff up for the bay, on cautiously avoiding a reef of coral rocks, which stretches to the distance of a cable's length from Granby Fort Point, on the windward side. Within this reef, before Georgetown, there is good ground in from 12 to 7 fathoms; particularly with a silk cotton-tree on the beach in a line with the flag-staff on the top of the hill.

Rocky Bay, on which the town of Scarborough is situated, is a deep bay, generally safe; but a heavy swell rolls in with the breeze, especially when it is to the south of east. It lies five and a half miles to the westward of Barbadoes Bay. In sailing towards this place, keep Little Tobago open of Richmond Island, as above directed, to avoid Great River Shoal; and next observe that the Chesterfield Rock is a danger which must, also, be cautiously avoided. This is a sunken rock, having only 7 feet over it, and on which the sea frequently breaks. It lies at half a mile from shore, about two and a half miles to the southward of Granby Fort Point, and at the same distance to windward of the east side of Rocky Bay. You may sail clear within it, with Richmond Island open between Smith's Island and the main; and without it, by keeping Richmond Island open without Smith's Island; for Richmond and Smith's Islands, in a line, lead directly on it.

When past the Chesterfield Rock, you haul in for Scarborough Point, which is a bold bluff point, with a fort on the hill. There is no danger, provided you keep the weather shore well on board, till you open the main street, which extends directly up the hill. With this mark you may anchor in from 7 to 9 fathoms, being the only clear part of the bay. It is requisite, even here, to buoy up the cables. No stranger should attempt to leave the harbor without a pilot, as it would be extremely hazardous. The channel between Scarborough Point and the reefs is less than three-quarters of a mile in breadth, and the dangers extend thence to the end of the island.

In the Channel, between Tobago and Trinidad, is a bank or shoal, on which 5½ fathoms have been found, and the pilots assert that there are places on it with still less water; it has been sounded with great care, but less than 5½ fathoms have not been found. It is, however, advisable to run with caution; for it is not impossible that there may be some rock, of small extent, which has escaped notice. In this channel or strait, the current runs to the westward at the rate of two miles per hour; but so that when approaching Trinidad, the direction of the current is towards the N. W. and near Tobago, towards the S. W. On the N. E. part of Tobago the current sets to the north-westward with more velocity than is stated above.

## THE ISLAND OF TRINIDAD AND GULF OF PARIA.

*Compiled chiefly from the Directions and Survey of Captain Columbine.*

All the bearings given, whether points or degrees, are true bearings, unless otherwise expressed.

THE ISLAND OF TRINIDAD is of considerable magnitude, containing, according to computation, 1012 square British statute miles. It presents a front to the eastward of nearly 42 geographic miles, from Point Galere to Point Galeota, its N. E. and S. E. extremes; the latter bearing from the former S. 7½° W. From Point Galeota the South Coast extends 56 miles westward to Point Icaque, or Icacos; and from the

, containing, accord-  
s a front to the east-  
aleota, its N. E. and  
From Point Galeota  
cacos; and from the

later to Mono Point, which is the N. W. extremity of the island, it is 43 miles in a N. N. E. direction. The North Coast extends eastward from Mono Point, about 46 miles to that of Galere. A range of high mountains extends all along the North Coast, which may be seen at the distance of 11 or 12 leagues; and these stretch to the southward above 3 leagues on the East Coast. The south side is also bordered by a range of mountains, but considerably inferior in height to those on the north side; and near the middle of the East Coast is another range extending to the W. S. W. The other parts of the island are principally low and level land, with some savannas.

**GULF OF PARIA.**—Between the island of Trinidad and the main land, there is a large space or opening, called the Gulf of Paria, affording secure shelter to ships of all classes: as they may anchor in any part of it without the smallest risk, and in any convenient depth of water. This great Gulf may be entered by two channels, one to the north the other to the south: that to the north is divided into several small channels by some islands; and that to the south has an islet in it surrounded by rocky shoals, which are dangerous.

**NORTH COAST OF TRINIDAD.**—From Point Galere, the North Coast of Trinidad stretches first S. 85½° W. 29 miles to Point Chupara, and thence S. 76° W. 14½ miles to Point Coroza; whence it bends to S. 58½° W., about 4 miles to Point Mona. All this coast is bounded by rocky shores, and, with the exception of a small part, with steep mountains thickly covered with wood, close down to the sea, which breaks in a heavy surf along the whole extent, and renders landing impossible, except at very few places. The land immediately about Point Galere is not above 50 feet high; it rises towards the west, and about Toco begins to connect itself with the chain of mountains which extend along the whole North Coast, from Rio Grande to the Bocas. Of these, that of Maracass, called by the Spaniards Cerro de las Cuevas, is the highest, being 2947 feet above the surface of the sea, and not two miles from the sea coast: those to the eastward are estimated from 2000 to 2500 feet high, and those to the westward at less than 2000.

Between Mono Point and that of Chupara there are some bays; but so much swell sets into them, and the wind is so uncertain and light close to the shore, that it is dangerous to anchor a ship in any of them, except in Esconvas and Maracass. Of these, the first from the westward is Macaripe, a cove in which there are from 7 to 3½ fathoms water, sheltered from the N. E. winds, and defended by two batteries: this lies about 3 miles to the eastward of Mono Point, and one mile to the westward of Point Coroza. The next is Chute d'Eau, at the distance of 5 miles to the eastward of Point Coroza; this is also a small sandy cove, deriving its name from some rills of water, which, as they descend from the hills, are projected over the rocks in various directions. Off the east point of this cove is an islet of the same name; and about 1½ mile to the eastward of it is Isle aux Vaches, an islet lying close to the east point of another cove or bay, in which there is anchorage in from 12 to 8 fathoms, sheltered from N. N. E. winds. About E. 1½ mile from Isle aux Vaches, is the west point of Maracass Bay, having to the eastward of it a small bay called Mal d'Estomac, in which there is no shelter: this point lies 9 miles to the eastward of Point Coroza.

**MARACASS BAY.**—This bay is a mile wide, and about the same depth, having from 16 to 10 fathoms, on mud, at its entrance, decreasing gradually to 8 and 7 fathoms, on sand, near the middle. It is open to the north, but is capable of affording more shelter than any other on this part of the coast: the land about it is level for a considerable space. Two miles farther north-eastward is Esconvas Bay, five sixths of a mile wide, and about half that in depth, with from 10 to 5 or 4 fathoms water in it. The east point of this bay, on which there is a battery to defend it, is 1½ mile S. W. from the west part of Point Chupara. Here is anchorage at about one third of a mile from the east point, in 9 fathoms water, sand and mud, with the fort, (Abercrombie,) bearing E. N. E., and the large house on the south side of the bay S. by W. Esconvas is a better anchorage than Maracass Bay; the latter, although much larger, being more subject to calms and sudden shiftings of the wind.

**POINT CHUPARA.**—Point Chupara is scarped and clifty, and extends about a mile nearly east and west. At the distance of 700 feet to the westward of its west extremity, is a rock, on which the sea generally breaks; and the reef extends about half a mile eastward from its east extremity. From this point the coast inclines to the east south-eastward, being a sandy beach; and at the distance of three quarters of a mile, is the entrance of the Little River Chupara, fit only for boats. Here the coast again trends eastward, is partly composed of cliffs, and at the distance of 3½ miles is the mouth of the little River Macapou, similar to that of Chupara. Nearly 3 miles further, in the same direction, in the east part of a small sandy cove, is the little River Paria, of the same description as the two former: a small islet lies off the east side of the cove, close to the shore, called Paria Islet: 2½ miles to the westward of this islet, and about one

third of a mile off from the rocky points on the east side of the River Macapou, there is a reef of rocks: there are also several other rocks lying at a short distance from shore, between Chupara and Paria, but none so far off as the reef just spoken of. About two miles eastward of Paria Islet is Trou Boudé Ris: the shore between being chiefly rocky cliffs, with two islets lying near it. Nearly  $1\frac{1}{2}$  mile farther, in the same direction, and at the east end of a sandy beach, is the mouth of the little River Mandamus, having between a projecting rocky point: this, like the former, will admit nothing but boats. Hence the coast trends to east north-eastward 3 miles to Point Matelot, which lies  $1\frac{1}{2}$  miles N.  $87^{\circ}$  E. from Point Chupara.

From Matelot Point to Rio Grande Point, the bearing and distance are N.  $80^{\circ}$  E.  $7\frac{1}{2}$  miles: at about a mile to the eastward of the former is Le Petit Matelot, and between these, close to the eastward of a rocky spot, is the entrance of Shark's River, similar to those already described. The coast thence, to within half a mile of Rio Grande, is chiefly rocky and high, with a few sandy bays. Rio Grande, contrary to its appellation, is a small river, like those before mentioned; it lies about S. W. by S. three quarters of a mile from the point of that name, the shore between being scarped: from the entrance of the river a sandy beach extends westward about half a mile, having off its west extremity two islets or rocks, the outermost of which lies nearly one third of a mile from shore. A vessel may anchor in 9 fathoms water at one third or two fifths of a mile W. by N. from Rio Grande Point, (off which is an islet or rock,) with the east end of the sandy beach bearing about S. by E.  $\frac{1}{4}$  E. The coast from hence trends nearly E.  $2\frac{1}{2}$  miles to Point Sans Souci,—the shore being chiefly scarped.

From Point Sans Souci to Reefs Point, (called by the Spaniards Toco Point,) the bearing and distance are S.  $87^{\circ}$  E.  $4\frac{1}{2}$  miles. Here the coast bends in a little to the southward, and is of the same description as the anterior. About E. by S.  $2\frac{1}{2}$  miles from Sans Souci Point is Toco Point, with some islets or rocks lying close to it; and between it and Reefs Point, to the west south-westward of the latter, is Toco Bay, where a ship may anchor at about three quarters of a mile from the land, in 12 fathoms water, muddy ground, with Reefs Point bearing E. by S. Harris' house\* S. S. E.  $\frac{1}{4}$  E.; or farther southward, in 12 or 14 fathoms, with Reefs Point E. by N. and Harris' house as before: but this is not a good place to lie at, as a great swell sets in.

From Reefs Point the coast trends S.  $61^{\circ}$  E., nearly  $1\frac{1}{2}$  mile to Point Galere, which, as before noticed, is the N. E. point of the island. The land between is of a moderate height. A reef extends about one third of a mile from shore along all this space, and should not be approached nearer than the depth of 12 fathoms. There is also a rock to the eastward of Point Galere, about three fourths of a mile, often visible, but on which the sea always breaks; and there is reason to suspect that some sunken ones lie still further out, and also within it.

The whole of the north coast is bold, with the exception of the places already mentioned; and the soundings extend several miles off, and are almost regular. Four miles N. by W. from Point Galere there are 22 fathoms; half a mile farther off, 40 fathoms. sand and mud. Three and a half miles north from Point Sans Souci there are 23 fathoms; at the same distance N. by W. from Rio Grande, 20 fathoms; and at a similar distance N. N. W. from Point Matelot, 17 fathoms. N. by E.  $5\frac{1}{2}$  miles from Paria there are 13 fathoms; N. by W.  $2\frac{1}{2}$  miles from the River Macapou, 21; and N. three fourths of a mile from Chupara Point, 16 fathoms. There are 78 fathoms, 5 leagues N. by W. from Escouvas; and 43 fathoms  $5\frac{1}{2}$  miles north from Maraccas Bay, North, 6 $\frac{1}{2}$  miles from Point Corozal, there are 60 fathoms; and at 7 leagues N. by E. from Boca Mono, 93 fathoms. These depths decrease gradually towards the shore, very close to which are 8, 7, and 6 fathoms.

The bottom being every where good, sand and mud, a vessel having occasion to anchor, may choose her anchorage on any part of this coast, with the precaution not to go into any of the bays to leeward of Maraccas; as the high mountains there prevent the wind from blowing home, and the swell in such a case renders it difficult to manage a ship.

At Rio Grande, on the full and change days of the moon, it is high water at 4h. 30m.; and between this and Point Chupara, the last two hours of the ebb, and sometimes the whole of it, sets to the eastward along the shore.

**EAST COAST OF TRINIDAD.**—The range of high mountains extending along the north coast of this island, from west to east, continues on the east coast as far as Point Salibia. The highest part of the range, as before said, is near the meridian of Escouvas; on the east, the most elevated part is near Point Salibia.

\* Harris' house is situate on a little hill at the S. E. side of the bay, and easily distinguished, being the largest in that neighborhood.

The general appearance of the coast is rocky, with Point la Foie Point la Foie forms a bay, mana. From or 4 plantations sandy bay, exposed to the along whose fourths of a mile from the shore, consists of some to within three point itself, W. at the distance large or deep 4 fathoms. torrent discharge mile S.  $48^{\circ}$  and at the distance which is Salibia ter within a quarter or a third posed. Nearly Branche Moun about 1000 feet part of the coast

**COCOS B.** Manilla Bay, is abruptly to the

The general bearing of the east side of the island from Point Galere to Point Galeota is S.  $71^{\circ}$  W. about  $41\frac{1}{2}$  miles. Cape Galere, as before said, is comparatively low and rocky, with a heavy sea constantly breaking on it; and S.  $71^{\circ}$  W. from it  $1\frac{1}{2}$  mile, is Point la Forest, having between a rocky bay, in which there is no landing. From Point la Forest S.  $40^{\circ}$  W.  $4\frac{1}{2}$  miles, lies Point Guayaman. Between these the coast forms a bay, on the shore of which, and nearly midway, is the little settlement of Cumana. From Point Galere to Cumana the coast is very rocky. Cumana consists of 3 or 4 plantations, situated on land tolerably even, and rising with a gentle ascent from a sandy bay, which always affords good landing, although quite unsheltered, and as much exposed to the east, and to the consequent violence of the ocean, as the rest of the coast, along whose whole extent, except at this spot, a tremendous surf breaks. At three fourths of a mile off there are 9 fathoms water, whence the depth decreases gradually to the shore. From Cumana to Point Guayaman, a distance of  $2\frac{1}{2}$  miles, the shore consists of some points of rocks and sandy beaches. From the latter point it becomes clifly to within three fourths of a mile of Balandra Point, and then a sandy beach almost to the point itself, which terminates in a scarped rock, and bears from Guayaman Point S.  $40^{\circ}$  W. at the distance of 4 miles. Balandra Bay is to the westward of the point; it is not large or deep enough to shelter any vessel larger than a trading schooner, in from  $2\frac{1}{2}$  to 4 fathoms. The north part of this bay is a sandy beach, and at its west end a mountain torrent discharges; the shore thence is clifly as far as Salibia Point, which is nearly a mile S.  $48^{\circ}$  W. from that of Balandra. The coast now bends more to the westward; and at the distance of nearly 2 miles W. S. W.  $\frac{3}{4}$  W. is Patura Point, to the N. E. of which is Salibia Bay, where a small vessel drawing 8 feet water may find tolerable shelter within a small rocky islet on the north side. There is also anchorage about a quarter or a third of a mile to the southward of the islet, in 5 or 6 fathoms water, but more exposed. This islet lies four fifths of a mile from Salibia Point; the rocky shore extends nearly as far, and thence to Patura Point is a sandy beach. About W. by N. half a mile from the islet, is the entrance of Salibia River, fit only for boats, and a little to the westward of it is a tolerably good landing place. Patura Point has a small islet or rock near it, and the coast is clifly, though somewhat lower than before, for about two fifths of a mile, whence it turns abruptly to the southward. Salibia is at the foot of the range of mountains, which extends along the northern coast; and here ends the rocky quarter of Point Galere. From hence to the southward is a long sandy shore, the interior being a vast extent of land, apparently level and of a moderate height, with a few distant insulated hills arising out of the plain, the whole covered with a continued forest.

We have just said that the coast turns abruptly to the southward, and is a sandy shore. It continues of the same description so far as Manzanilla Point, which is  $9\frac{1}{2}$  miles S.  $8^{\circ}$  E. from Patura Point, with a surf breaking along its whole extent, so heavily as to render landing on any part of it totally impracticable. This is called Patura Bay; near the middle of it the River Oropuche discharges itself through the surf, and over a very bad bar.

At Manzanilla Point the coast turns suddenly to S. W. by W. and W. S. W. for about  $1\frac{1}{2}$  mile, chiefly rocky, but forming a small sandy bay or harbor of the same name, sheltered by some rocky islets lying near its east point. This bay has a depth of water sufficient for any vessel not drawing more than 9 feet; and although very small, it is the best on all the east coast of the island. A reef of rocks stretches from Manzanilla Point, eastward, rather more than half a mile; and nearly 2 miles S.  $49^{\circ}$  E. from the same point are three rocks, above water, over which the sea always breaks. Half a mile S.  $71^{\circ}$  W. from these rocks is another, so small, that it scarcely makes the sea break, and is not to be seen until you are close to it. Vessels from the north may run with great safety between the reef which stretches off from the point and these rocks; but the wind will scarcely permit a square rigged vessel to lie her course through this channel from the southward. There is also some foul ground about two fifths of a mile E. N. E. from the three rocks, on and near which the sea breaks in very bad weather. It shoals suddenly from 9 to  $4\frac{3}{4}$  fathoms. A ship may anchor off Manzanilla Bay, in 5 fathoms water, with the leewardmost of the rocky islets at the entrance of the bay bearing N. W. about the distance of 3 cables' length, and Manzanilla Point N. N. E. This is by far the best anchorage on the coast, as a ship from hence will always have plenty of room to make sail in case of necessity. Here the flood and ebb streams both set northeastward. Nearly W. S. W., about  $3\frac{1}{2}$  miles from Manzanilla Point, is the east end of Lebranche Mountains, which thence extend west, south-westward. This, by estimation, is about 1000 feet above the level of the sea, and forms a conspicuous mark to know this part of the coast by.

COCOS BAY.—Close to the westward of the clifly shore, on the west side of Manzanilla Bay, is the mouth of the little river Lebranche; and hence the coast again turns abruptly to the southward as far as the river Ortoire, a distance of  $10\frac{1}{2}$  miles; the shore

being all a sandy beach, nearly straight, with the surf breaking heavily on it. This is called Cocos Bay, from its shore being bordered by a narrow grove of cocoanut-trees 7 or 8 miles long. Near the middle of the bay the river Mitán discharges its waters. About half a mile eastward of the mouth of the Ortoire River, is a landing place behind a rocky point, on the north side of a scarped promontory, which advances  $1\frac{1}{2}$  mile into the sea, and presents a front of high cliff to the eastward, of about a mile in length N. N. E. and S. S. W. This is called Mayero Point, (but by the Spaniards Cape Guatara.) Several rocks and reefs lie off its N. E. part to a considerable distance; and it should not be approached from the east nearer than a mile, as there are only 3 fathoms at the distance of four fifths of a mile from it, in that direction; but a vessel may anchor, at nearly a mile to the northward of this promontory, in 5 fathoms, good ground, having the N. E. part of the point bearing S. E.  $\frac{1}{4}$  S., and the westernmost rocky bluff, which is near the mouth of the Ortoire, S. W.  $\frac{3}{4}$  S. Mayero Point is remarkable at the distance of 5 or 6 leagues, from advancing into the sea, and also from the almost equal elevation of the whole tongue of land that forms it. It lies nearly 11 miles S.  $13^{\circ}$  W. from Manzanilla Point.

**MAYERO BAY.**—From the south part of Mayero Point, the land continues high and scarped for about two thirds of a mile to the W. N. W., whence a low sandy beach begins, turning to S. by W. and S., and continues of the same description, with low land in the interior, as far as Point Galeota, which is  $12\frac{3}{4}$  miles S.  $8^{\circ}$  W. from Mayero Point. The space between these points is called Mayero Bay; and at its northern part the water is sufficiently smooth to afford good landing for two or three miles, although it is as much exposed to the east as the middle and southern parts, where a heavy surf breaks; and off this part, also, a vessel may anchor, as there are about 6 fathoms at  $1\frac{1}{2}$  mile off, and it shoals gradually to the shore. To the southward of Mayero point are some plantations, and at the distance of 3 miles a church.

**POINT GALEOTA**, as we have before said, is the S. E. point of the island. Several rocks lie off it, but they are all above water; and at the distance of three quarters of a mile to the E. and S. E. of it, is a depth of 10 fathoms. This promontory is of moderate elevation, and may be discovered from the north-eastward at the distance of 6 or 7 leagues. The soundings extend to a considerable distance off to the eastward, and shoal gradually to the land: these will be best understood by inspecting the chart.

**SUNKEN ROCK.**—Before we quit this part, we ought not to omit mentioning a dangerous rock that lies 6 or 7 leagues from the land, although we are not acquainted with its precise situation. The surveyor,\* when searching for it in the direction that was pointed out to him, found a bank of 16 fathoms, with deep water all around it, on which it is supposed to exist. This bank lies 7 leagues S.  $37\frac{1}{2}^{\circ}$  E. from Point Galere, and N.  $82^{\circ}$  E. from the mountain of Lebranche, distant  $6\frac{1}{2}$  leagues from Manzanilla Point. There is no doubt of its existence, a vessel having been wrecked upon it; and it has been seen by several persons at very low spring tides; it is a very small rock, and steep close to.

**SOUTH COAST OF TRINIDAD.**—From Point Galeota to the Point de la Grande Calle, it is 4 miles S.  $75^{\circ}$  W. The coast between forms Guaya-Guayara Bay, which is spacious, with a sandy shore, but so shoal that nothing can be sheltered in it, except very small vessels, there being only 3 fathoms water a mile from the land. A rocky shoal lies nearly in the middle of it, and there are several rocks near Galeota Point, but they are all above water. From Point de la Grande Calle the coast trends S. by W.  $\frac{1}{4}$  W., all scarped and rocky, to Point Casa Cruz, a distance of  $5\frac{1}{2}$  miles. All along this part there are 5 fathoms water at a mile and a half from the land. From Point Casa Cruz the coast runs nearly west, with several inflections, about 32 miles, to Point Tabaro, the shore being chiefly scarped with two or three spots of sandy beach, and a few rocks at the projecting points. From Point Tabaro the coast trends W. by N. about two and a half miles to Point Herin, a projecting point of sand, with some rocks lying off it. Nearly five miles west by north from the latter lies Islet Point. The coast between is sandy, and forms a small bay called Herin Bay, in which there are 3 or 4 fathoms water. The coast from hence trends W. S. W., nearly 6 miles, to Point Quemada, the shore being all sandy. About midway lies Point Chagnaramas. About 3 miles to the westward of Point Quemada is Point Icaeos, or Icaque, the south-western extremity of the island. We have already said that Point Galeota may be distinctly made out at the distance of 6 or 7 leagues. From this point the land begins to be more elevated, and continues so along the south coast. No part of this coast can properly be called mountainous, although it is very hilly; but these gradually diminish from the vicinity of Point Herin towards Point Icaeos, which is quite low and flat. The hill of

\* Captain E. H. Columbine.

Guaya-Guayara Bay from Point Galeota as a guide will be obtained about a mile from the coast; but it will be found 8 or 10 fathoms off Point Icaeos itself, but so Point Quemada is a risk.

**POINT ICAEOS** is a circular fort from its S. north-eastward.

**WEST COAST** of Trinidad, which is a distance, and from Point Galeota the coast between is a considerable distance, two thirds of a mile lies also of 14 miles from Point Galeota. Between Cape Brea and Point Galeota, within it is a bay, about a close to the bay.

From the north, N.  $69^{\circ}$  E.  $9\frac{1}{2}$  miles. The low water, into about  $1\frac{1}{2}$  mile two thirds of a mile, the water is 2 miles, the water and to the north to the northward of hills. The water is shallow with shallow water. Point de la Grande Calle, is a point, is that a mile to Port of the rivers Chaguanilla.

Here we discover the Bocas, and the Mono Point thence to Taitron's Bay. At three quarters of a mile from Taitron's Bay, the Careenage of 17 fathoms at the mouth of the river forms the east side of the bay, necessary to keep a ship of the line. Taitron's Bay Point, is about 3 miles from the beach at its head, these bays is 1 mile from the three islands, will be described.

**GASPAR** is a point of Gaspar Grande, 1 mile to Point de la Grande Calle.

Guaya-Guayara, at the eastern extremity of this range, and about  $1\frac{1}{2}$  mile N. W. by W. from Point de la Grande Calle, is 760 feet high by admeasurement. This may serve as a guide whereby to estimate the height of the others. There is a watering place about a mile to the westward of Point Casa Cruz, where, with a little trouble, water may be obtained from a mountain stream that falls into a well on the beach. Five fathoms will be found at a mile and a half from the shore, in which depth you may run along the coast; but it is more advisable to keep at two miles from the land. You will then be in 8 or 10 fathoms, and clear of all risk. At the distance of 3 or 4 leagues to the eastward of Point Icaos, a reef of rocks lies upwards of a mile from the land. It does not show itself, but some red cliffs on the shore will nearly point out its situation. After passing Point Quemada, you may approach the shore to a quartet of a mile without the least risk.

POINT ICACOS, OR ICAQUE, is a sandy promontory advancing into the sea in a circular form, but so steep that at half a cable's length there are 8 or 9 fathoms water. From its S. W. part it first runs northward about  $1\frac{1}{2}$  mile to point Corral, and thence north-eastward  $1\frac{1}{2}$  mile to Point Gallos, which has 2 or 3 islets lying off its west side.

WEST COAST OF TRINIDAD.—From Point Icaos to Port d'Espagne the bearing and distance are N.  $36^{\circ}$  E. 43 miles. All this part is low, excepting Mount Naparima, which is round, and 602 feet high. In clear weather it may be seen at 8 leagues distance, and is a good mark within the Gulf of Paria.

From Point Gallos, before mentioned, to Point Cedro, it is  $5\frac{1}{2}$  miles N.  $61^{\circ}$  E., the coast between forming a bay of the same name, the N. E. part of which is flat at a considerable distance off. From the point a spit projects westward, and at its extremity, two thirds of a mile from the point, is a rock called the Barrel of Beef. A shoal of 9 feet lies also about 3 miles N. E.  $\frac{1}{2}$  E. from the same point. N.  $62^{\circ}$  E., at the distance of 14 miles from Point Cedro, is the N. W. extremity of Cape or Point Brea, or Pitch Point. Between these the shore forms two shallow bays, separated by Gnape Point. Cape Brea presents a front of two or three miles in extent, projecting to the N. W., and within it is a wonderful lake of pitch or bituminous matter. In the bay to the southward, about a mile from Point Brea, there are two small rivers of excellent fresh water close to the beach.

From the north part of Point Brea to Mount Naparima, the bearing and distance are N.  $69^{\circ}$  E.  $9\frac{1}{2}$  miles, and from the latter to Point Cascaal, the coast trends N.  $6^{\circ}$  W. 11 miles. The shore between Cape Brea and Point Cascaal forms a deep bay, with shallow water, into which several rivers disembogue; of these the first is the Sibaira, at about  $1\frac{1}{4}$  mile to the S. W. of Mount Naparima. Between this river and the Mount, at two thirds of a mile from shore, lies a farallon, or rock, and to the W. N. W. of it, full 2 miles, the water is shallow. At the foot of the mount, on its west side, is Petit Bourg, and to the northward of it are the little rivers Taronga and Guaracaro. About  $2\frac{1}{2}$  miles to the northward of Petit Bourg is Stony Point, at the western end of the middle range of hills. The coast thence trends about N.  $\frac{1}{2}$  W.  $8\frac{1}{2}$  miles to Cascaal Point, bordered with shallow water to the distance of 4 miles off. About S. E. by S.  $1\frac{1}{2}$  mile from Cascaal Point, is the mouth of the little river Coura, and  $1\frac{3}{4}$  mile N. E.  $\frac{1}{2}$  E. from the same point, is that of Carapichina, of a similar description. From hence it is N.  $13\frac{1}{2}^{\circ}$  W. 9 miles to Port d'Espagne; the land between is low and swampy, through which the little rivers Chagonane, Aripo, and Aronca, discharge their waters.

Here we discontinue the description of this coast from the south, resume it again at the Bocas, and conclude at Port d'Espagne.

Mono Point, as we have before said, is the N. W. extremity of the island. From thence to Taitron's Point, or Punta del Diablo, it is little more than  $1\frac{1}{2}$  mile S.  $8^{\circ}$  E. At three quarters of a mile from the former, lies the north point of an islet, called the Careenage of Mono, which runs in north-eastward more than half a mile, and has from 17 fathoms at the entrance, to 4 and 3 at the extremity. At the head of this inlet, or bay, a ship of the line might lie secure to the shore, land-locked. Off the sandy shore which forms the east side of it, there is a bank which shoals suddenly: it will therefore be necessary to keep on the opposite shore, if you should have occasion to work up so far. Taitron's Bay, called also Eusenada del Infante, lies to the northward of Taitron's Point, is about one third of a mile wide, and of nearly the same depth, having a sandy beach at its head, and a depth of 15 fathoms at the entrance. The high land between these bays is 1400 feet above the surface of the sea. Westward from these points lie the three islands, Mono, Huevo, and Chaca-chacare, which form the Bocas, and which will be described hereafter.

GASPAR GRANDE.—S.  $4^{\circ}$  W. 1 mile from Taitron's Point, lies the west point of Gaspar Grande, named Espolon (Cock's-spur.) This island extends eastward nearly  $1\frac{1}{2}$  mile to Punta de la Reyna, the east point, and is about half a mile broad. Its eleva-

tion is considerable, the highest part being 337 feet; and its coasts form some coves, or little bays, in which small vessels may anchor.

From Taitron's Point the coast of Trinidad runs S.  $73^{\circ}$  E. four fifths of a mile to Punta de San Jose, whence it bends in to the N. E. and E.  $1\frac{1}{4}$  mile, and thence to the S. S. W. about two thirds of a mile to Punta San Carlos, being the west part of Chaguaramus Peninsula. This point lies almost 2 miles S.  $65^{\circ}$  E. from Taitron's Point, one and one tenth mile S.  $60^{\circ}$  E. from Punta de San Jose, and 740 yards to the eastward of Gaspar Grande. Gasparillo Island lies to the southward of Punta de San Jose, and has an islet on its north side. This island forms two passages: that on the north is 250 yards wide, with 5 to 15 fathoms water; and that on the south, between it and Gaspar Grande, is 740 yards wide, with from 9 to 14 fathoms water.

CHAGUARAMUS BAY is comprised between Gaspar Grande, on the S. W. the west side of the peninsula on the east, and the land on the north. It is spacious, and affords good anchorage. The shores are bold, except off the large plantation, which is situated in the principal valley on the north side, whence a shoal of 1 to 3 fathoms extends 600 yards off. Its outer edge trends to W. N. W., and is very steep. Vessels may anchor in this bay any where; but the most convenient spot for watering, is in 12 fathoms, with the east end of Gaspar Grande bearing S. by E. and Taitron's Point in a line with Punta de San Jose. There is a wreck of one of the Spanish ships of the line, that were burnt here at the taking of the island. It lies in 17 fathoms water, having the western Diego Island open  $1^{\circ} 10'$  of Punta San Carlos, and the north extreme of Gaspar Grande W. by S. Avoiding this wreck, a ship or two may water very well here.

At full and change of the moon, it is high water by the shore at 3 o'clock, and it rises about 5 feet; but at the anchorage the flood stream runs until half past 3 o'clock. The flood runs to the eastward, and continues only  $5\frac{1}{4}$  hours; the ebb runs to the westward.

ESCONDIDO HARBOR.—To the northward of Punta San Carlos, or Escondido, is a little harbor named Escondido. From this point S. S. E.  $\frac{1}{2}$  E. four tenths of a mile, is Prince's Point; and thence to the east end of Chaguaramus Peninsula it is about E. N. E.  $1\frac{1}{16}$  mile. From this latter point to another point at the west side of Lynch's Bay, it is N.  $55^{\circ}$  E.  $1\frac{1}{16}$  mile. To the N. W. of the east point of the peninsula, nearly half a mile, is an inlet, or bay, called the Careenage, an excellent harbor for merchant ships, but too shoal for men-of-war, there being only from 10 to 23 feet water. North-eastward from this bay is another with  $2\frac{1}{2}$  to 4 fathoms in it.

DIEGO'S ISLANDS.—To the S. and S. E. of Prince's Point, about one third of a mile, lie Diego's Islands, two in number, of about a quarter of a mile in extent each, and the same distance asunder, N. E. by E.  $\frac{1}{2}$  E. and S. W. by W.  $\frac{1}{2}$  W. There is a good passage between them of 9 to 12 fathoms water, and also between them and Prince's Point, of 20 to 25 fathoms.

COLORAS.—The Coloras are a cluster of small islands, five in number, occupying a space of four tenths of a mile. They lie  $1\frac{1}{3}$  mile E.  $\frac{1}{2}$  S. from the easternmost of Diego's Isles, and  $1\frac{1}{3}$  mile S. E. from the east point of the peninsula. There appears to be a passage between the two southernmost and the others.

PORT D'ESPAGNE.—From the point on the west side of Lynch's Bay, the coast, with some inflections, trends E. S. E. a distance of  $5\frac{2}{3}$  miles to Port d'Espagne, and there turns about S. S. E.  $1\frac{1}{2}$  mile to the river Caroni, which in the rainy season pours out a furious stream. The water in the road of Port d'Espagne is very shallow, there being only  $3\frac{1}{2}$  fathoms at a mile and a half off. It is extremely foul and muddy there, and nearer to the shore it is proportionably more so. At about  $1\frac{1}{2}$  mile off from the shore, with the round white tower on a hill near the town, bearing N. E. by E., there are  $3\frac{1}{2}$  fathoms, very soft mud, but ships may anchor any where. The ship will turn the soft mud up long before she gets into a good anchoring place, which should be in about 3 feet more water than she draws. The water is always perfectly smooth.

The tide flows here on full and change days of the moon, at half past 5 o'clock: the flood comes from the west, and the ebb from the S. E.; and the water is slack about 11 hour, both at high and low water. The course of the tides, both ebb and flood, being each checked by an opposing shore in this corner where the town is situated, they naturally must deposit there much of the mud which they carry along with them: hence the quantity of mud in the anchorage.

The coast of the main land is low and swampy, opened by a great number of rivers and channels falling into the Gulf; of these the deepest and most frequented, is the Guarapiche, by which a trade is carried on with the interior of Cumana; it is navigable for schooners and large balaxues.

#### *Description of the Islands which form the Bocas.*

mbus called Bocas de

Bragos, from the velocity of the current which he found setting through them. This, however, is very various in its strength, though constant in its direction to the northward.

**MONO ISLAND.**—The three islands which form these passages, are Mono, or Ape's Island, Huevo, or Egg Island, and Chaca-chacare. The first is about 2 1/2 miles in length from N. E. to S. W., and 1 1/2 mile in breadth: it consists of two lofty hills, from which the land on the south side shelves down to the sea, in ridges singularly sharp: the highest of these hills, at the north part, is 1013 feet above the surface of the sea. On the east side of the island are two bays; the northernmost named Morris' Bay, the other Debert's, besides some coves: to the westward of these, on the south side, are some others. The N. E. point of this island bears about S. W. by W. distant half a mile from Mono Point, and the S. E. point W. N. W. 1/3 W. 1330 yards from Taitron's Point; but in the narrowest part, the channel is not quite one third of a mile wide. This is called Boco Mono: it lies nearly north and south, and has from 23 to 47 fathoms water in it. A cluster of rocks lies about 300 yards E. N. E. from the N. E. point of Mono Island; these have 8 fathoms close to them.

**HUEVO, OR EGG ISLAND,** is the next: this is of a semi-circular shape, forming a bay on its S. W. side. Its N. E. point, near to which lies the Umbrella Rock, is distant one and one tenth mile W. by S. from the N. W. part of Mono Island, and thence extends 1 1/2 mile about N. W. by W. 1/2 W. Its south point lies one mile W. N. W. 2/3 W. from the S. W. point of Mono. Huevo, near its N. E. point, is 655 feet above the surface of the sea. The channel between it and Mono is called Boco Huevo, or more commonly the Umbrella Passage, from the rock of that name; the course through is about S. W. by S. and N. E. by N.; and its narrowest part, which is near the S. W. entrance, is about three quarters of a mile wide, with a depth of more than 100 fathoms.

**CHACA-CHACARE** is the westernmost of the three islands: Point St. Jago, the east point of this island, lies three quarters of a mile nearly W. S. W. from the south point of Huevo; and thence extends about N. W. 1/2 N. one and four fifths mile to the north point, near which is an islet; and thence turns about S. by W. 1/2 W. nearly the same distance to its S. W. point. From the latter to Point Antoine, the S. E. point, the coast runs about E. 1/2 N. 1 1/2 mile; and from this point to that of St. Jago, N. E. by E. about three quarters of a mile. Between the latter points a deep bay is formed north-westward, with safe anchorage, but difficult to get in or out of, except by warping. At the further end of this bay of Chaca-chacare, which nearly divides the island into two parts, is a low sandy neck or isthmus. To the southward of this beach, and on the west side of the island, are some scattered rocks, at about a cable's length from shore; and there is a small rock, with 2 1/2 fathoms on it, lying one third of a mile west from the S. W. point of the island, and S. 25 1/2° W. from its N. W. extremity.\* The whole of the high land of the peninsula of Chaguanarus open to the southward of the rock at the S. W. point of Chaca-chacare, clears it on the south side: the angular altitude of the high hill on that point, from the top to the sea, at its foot, taken in a boat anchored on the rock, is 7° 50'. This hill is 426 feet above the surface of the sea: the north part of the island has an elevation of 810 feet. Here it is high water on full and change days of the moon at 30 minutes after 2 o'clock.

The Channel formed by Chaca-chacare and Huevo, is called Boca Navios, or Ship Passage: it lies S. E. by S. and N. W. by N. and is, at the narrowest point, the S. W. entrance, two thirds of a mile wide. To the westward of this island is Boca Grande, of great extent, and almost free from danger.

#### *Description of the Bocas.*

The great depth of water in the three largest of the Bocas, namely, Nuveo, Navios, and Boca Grande, prevents anchoring in any part of them, except in case of absolute necessity, very close to the shore. A ship may anchor any where in Boca Mono, but in 30 or 40 fathoms, in mid-channel. The beds of these channels are much deeper than the bottom, either within or without them; as if they had been thus worn away by the constant operation of the Northern Current which runs through them. In autumn its rapidity at times is so great, that ships are frequently driven out again, after having en-

\* There is another rock lying off the S. W. point of Chaca-chacare, with only 9 feet water on the shoalest part of it, at low water, with very deep water all around; it is about 40 yards in circumference. This rock was discovered on the morning of the 26th of June, 1809, by Captain Sughrée, of the ship Samuel, of London, drawing 17 feet of water, who struck and remained fast upon it for several hours. While this ship was aground two others passed, one on each side, without touching, although not at 25 fathoms distant. The bearings by compass from the ship were, Chaca-chacare, S. W. point, E. N. E., El Plata, or Goose Island, S. W. by W. 1/4 W.; and the S. E. end of Cuamana, or Paria, W. by S.

tered one of the passages with a good breeze: during the rest of the year, its rate may commonly be estimated to be about 2 or 3 knots; but close to the S. W. point of Chacacachare, it runs much stronger. Except in autumn, the tide of flood which sets through them into the Gulf of Paria, has a considerable power towards the top of high water, in checking this current; and at spring tides, the water is frequently perfectly slack in Boca Mono for an hour; and very nearly so in Boca Huevo.

*Boca Mono.*—In the Boca Mono, (the eastern mouth,) at ebb tide, the current runs outward with a velocity of  $1\frac{1}{2}$  or 2 miles an hour, and something less at ordinary flood; so that, with the exception of about an hour near the top of a spring flood, it always runs outward. For this reason, and because it is subject to calms and eddy winds, occasioned by the great elevation of the coast, from being very narrow, (not exceeding one third of a mile in width,) long and winding, and consequently full of eddies, it should not be attempted by a ship except in a case of necessity, although it is the windward one: but either of the others should be preferred. It is high water here on full and change days of the moon at 50 minutes after 3 o'clock.

A ship may anchor any where in the south part of this passage, and all along the south side of Mono. Deher's Bay affords excellent anchorage, and there is deep water far into it: a ship anchored off the mouth of it in 15 fathoms, on clay, with the south point bearing S. W. by S. and found the ground so tough that it was with great difficulty the anchor was heaved.

*BOCA HUEVO, EGG PASSAGE*, (or, as it is now more commonly called, the Parasol, or Umbrella Passage,) is safe to attempt to run in at, if the wind hangs to the N. E., as it will then, probably, blow quite through the passage; but at any rate, if the ship cannot stem the current, there is ample room to back and fill her out again. The shores are bold, but care must be taken to avoid a rock at the S. W. point of Mono; although it is not above a ship's length from the point, the eddy of the flood tide at the springs sets directly over it. At ebb tide the current sets through with rather less velocity than in the former; and during the last two hours of flood, it is nearly slack water: on this account, it being the shortest, being to the windward of the other two and being entirely clean, it is considered the best for entering the gulf. It is advisable to keep closer to the island of Huevas than to that of Mono, to avoid being becalmed by the high land of Mono, and also because the current inclines to the N. E.

*BOCA NAVIOS, OR SHIP PASSAGE*, may be safely entered, if, when a ship hauls round the N. W. end of Huevo at a quarter or one third of a mile distance, she can lie up high enough to bring the south end of the island on her starboard bow, so as to have the current under her lee; otherwise it will be improper to attempt it, as the current does not run fairly out, but rather inclines down on Chacacachare. With a flowing tide, it runs with a velocity of  $1\frac{1}{2}$  mile per hour; but at the ebb, frequently at the rate of  $3\frac{1}{2}$  or 4 miles. It is high water on full and change days of the moon at 39 minutes after 3 o'clock. Although the entrance by this channel is practicable only under the above circumstance with a flood tide; yet, on the other hand, it is far superior to the Boca Huevo for getting out of the Gulf; but it is necessary, in so doing, to pay attention to the set of the current, as we have just mentioned, and also to the following:—

On June 5, 1804, at 7 P. M., His Majesty's ship Ulysses weighed from Chaguaramas Bay: but falling calm, it was 10 o'clock on the following morning before she reached the south point of Huevo, with an intention of going through Boca Navios. Here was found such a strong current setting round that point to the E. S. E. that being unable to stem it, she was let drive out through the Umbrella Passage, which took up two hours to perform, owing to a number of eddies and opposite currents, formed by the tide of flood setting into the Gulf, and contending against the usual stream setting outward. It was high water in the Bocas that day, at about half past twelve o'clock, being three days before the new moon.

*BOCA GRANDE.*—In this channel, at ebb tide, the current runs with less velocity than through either of the others, and at flood there is scarcely any. It is also very clean, with the exception of the sunken rocks lying off the S. W. point of Chacacachare, and of sufficient breadth to tack at pleasure; but being the leewardmost, it is only resorted to in case of having failed to effect a passage by either of the preceding.

*Remarks on the Currents on the Coasts of Trinidad and in the Gulf of Paria.*

*CURRENTS IN THE VICINITY OF TRINIDAD.*—We have already stated that the western Equinoctial or Tropical Current, occasioned by the Trade Wind, being confined by the trending of the Coast of South America, is thrown in a collected force upon Trinidad, and runs there with great strength; we have now further to observe, that the force of this current, is still further increased along its shores by the obstruction which the island itself presents against the free course of the stream; and by the waters of the

Orinoco, which flowing through vast plains, subject to periodical inundations, and discharging itself into the ocean near this island, greatly increases the current in its vicinity, particularly about the months of August and September, when that river is at its greatest height. The river Amazon also, collecting the waters of almost half the Southern continent, may, perhaps, though at the remote distance of 280 leagues, contribute somewhat to its strength.

These currents vary much in their velocity at different times, without any apparent cause. It is said they run strongest in the declining quarters of the moon; but of this no satisfactory proof has hitherto been obtained. Adapting itself to the coast, the current runs to the northward, along the east side of Trinidad, and takes a western direction between the island Tobago and Point Galere, round which it runs with such accumulated strength, that it is scarcely possible for a square-rigged vessel to beat against it, round that point, although there are instances of its having been effected.

Passing Point Galere, it runs along the North Coast, close to the shore, for a few leagues, as far as Rio Grande; but there it often quits the shore, and takes a W. N. W. direction, increasing its distance from the land till it gets to the northward of the Bocas, where it seldom prevails within 5 or 6 leagues, being repelled by the current which runs out of these passages: there the two streams blend and run to the westward.

Along the South Coast it always runs to the westward, seldom less than  $1\frac{1}{2}$  or 2 knots, near Point Galeota, but often more; and as the opposite shore of South America contracts the channel towards Point Icaque, or Icaos, its velocity is much accelerated there, and may be estimated generally at 3 knots, but it frequently runs still stronger.

The channel between the Coast of America and the S. W. point of Trinidad, is called the *Serpent's Mouth*, through which the current enters the Gulf of Paria, dispersing itself over it. Near the shore of the Gulf it is subject to the influence of the tides, but in the middle, it always runs to the northward towards the Bocas; where its channel being again contracted, its velocity is proportionally increased. Having passed these Straits, the body of this water preserves its westerly direction for 5 or 6 leagues, before it falls into the common course of the stream of the ocean, which is there W. N. W. But it is to be observed, that so soon as it has passed the Bocas, a considerable part diverges to the E. N. E. and either runs with some rapidity to windward, or so thoroughly destroys the effect of the western current, that a ship will seldom fail of working up, at least to Point Chupara, with ease, by keeping within a moderate distance of the shore. This easterly current frequently extends to a considerable distance farther along the North Coast, as was experienced in the month of June, 1804, when His Majesty's ship *Ulysses* worked up to Rio Grande from Huevo, in 25 hours, although she never went more than 3 knots.

That part of the stream which goes out of the Boca Grande on the west side, turns round the N. E. point of Paria, and runs down that Coast with such velocity, that if a ship bound to Trinidad should fall in with the land to leeward of this point, though ever so little, she must immediately stand to the northward again, at least so far as  $13^{\circ}$  of lat. out of the great force of the current, and work up to Grenada before she again attempts the Bocas. Even then, if she cannot lie S. E. by S. at least, her reaching them will be very doubtful; and her best mode of proceeding will be, to go through the passage between Kick'em Jenny and Carriacou, in order to weather Grenada, before she gets into the strong lee current that prevails between that island and Trinidad. This current renders it very difficult for ships to fetch Point Saline in Grenada from the Bocas: they generally only reach about 4 or 5 leagues to leeward of that island; hence the necessity of working to windward on the North Coast of Trinidad.

*Practical Directions for making the Island of Trinidad, and for entering the Gulf of Paria.*

[From the *Derrotero de las Antillas.*]

It has been already observed, that from July to November is called the rainy season in this country, in which the General Trade Wind is very light, and veering to E. S. E. and S. E.; and that in the other months it blows fresh from N. E. or E. N. E.; this circumstance, and the two channels by which the Gulf of Paria may be entered, occasions the preference to be given to the south entrance during the rains, and to the other during the dry season. It is therefore obvious that Trinidad should be approached with due regard to the season: from December to June the object is to make it about Point Galere; and from July to December, about Point Galeota. These two points being the N. E. and S. E. extremities of the island, cannot fail of being known. A ship coming from the eastward, and making the body of the island, will see the mountain of Lebranche ahead of her; and a flat low shore extending from thence about 4 leagues to the north-

*Gulf of Paria.*

It has already stated that the Wind, being collected force upon to observe, that the obstruction which by the waters of the

ward, where it is bounded by the northern range of high mountains. To the southward of Lebranche will be seen another, and more extensive low shore, at the extremity of which are the hills of Guaya-guayare. The range of high mountains which extend along the Northern Coast, may be seen in clear weather at the distance of 11 leagues, but Point Galere cannot be distinguished at more than 3 leagues, the being low.

The soundings off the eastern coast of the island to the distance of 17 leagues, furnish a safe method of rectifying the place of a ship arriving from the eastward, and under circumstances of night or cloudy weather, will save much time; for being in the parallel of the island, it is necessary to try for soundings, which may be done without more delay or inconvenience than that of trying at about every 20 miles, when the ship is supposed to be nearing the land. The depth of water and the latitude will give the situation of the ship with tolerable precision. Knowing this, no more is requisite than to steer for the Points Galere or Galeota, according to the season of the year, for entering the gulf either by the north or south passage.\* But as it frequently happens that two or three days elapse without obtaining a meridian altitude, it is very possible that the mariner, supposing himself to be in the parallel of Trinidad, may actually be in that of Tobago, or even of Grenada, as the current sets with such violence to the N. W.: for this reason no opportunity of observing the latitude either by the moon, a star, or by altitudes of the sun before and after he has passed the meridian, should be neglected. It is also advisable to make the land rather to the south than to the north of either of the points, as the currents will always favor working to the northward. The facility is still greater in times of the N. E. winds for getting up from Point Galeota to Point Galere. The passage may also be made from the latter to the former, but not with so much ease. So soon as one of the points or capes has been made out distinctly, the route to the mouths of the gulf is as follows:

From Point Galere a ship may run along the coast at the distance of two miles, with an understanding of its being quite clean, as before described.

Point Corozal may be approached to half a mile. It will then be better to close more upon the land, to reach the mouths with greater facility.

#### *Directions for the Bocas.*

From the description already given of the islands which form the Bocas, and also of the Bocas, it is evident that the Boca Huevo, or Umbrella Passage, should be chosen for entering the gulf, and that the best time is with a flowing tide, and with a wind that will ensure the ready working of the ship; but if there be a four-knot breeze, there is no necessity to wait for the tide. At night, if the weather be clear, there is no inconvenience in entering the Huevos Channel, as the only risk is of getting too close to one of the little islets, and which is almost impossible to happen; but if calms, scant winds, want of tide, darkness, or excess of caution, should determine the mariner to wait for a more favorable opportunity, he may anchor about two thirds of a mile from the coast in 18 or 20 fathoms, except the wind be N. E., which raises a heavy sea: in such a case he will do better by keeping under sail, and making short tacks on and off shore. Along the coast from Point Toco to Point Chupara, the bottom is soft mud; on the meridian of the latter point it is coarse sand and fine gravel; and to the west of it, so far as the mouths, it is mud of a greenish color. These differences in the bottom will point out with sufficient accuracy what part of the coast the ship is on.

When a ship has passed through either of the channels, she should be kept close to the wind, on the larboard tack, in order to get away from the mouths, and near the coast of Trinidad; and she should, in general, be continued on this tack so long as the flood tide lasts, that she may go on the starboard tack so soon as the ebb begins, with a certainty of reaching the anchorage, or at least within a very little of it. It may probably appear to some persons, more eligible to make several tacks after entering the gulf, and particularly so if the larboard tack is not the most advantageous; but it must be remembered that the strongest currents are in the narrows, and therefore from remaining near the mouths, in consequence of having made several tacks, it would not be extraordinary if the ebb tide should force them through the channel again, or compel them to anchor to prevent it; and even if neither of these circumstances should take place, the ebb will be found unfavorable for gaining the Port d'Espagne. On the other hand, by having stood on the larboard tack within the gulf, if necessary, as far as the parallel of Mount Naparima, the ebb tide will then very favorably assist the ship on the starboard tack, perhaps, so much as to reach the anchorage, or it will be gained by another short board. If calms or very light winds prevent gaining ground by keeping

\* It is necessary to be cautious of the sunken rock that lies about 7 leagues S. E.  $\frac{1}{2}$  S. from Point Galere.

under sail, strength of the wind; because, in weighing anchor, the ship will be liable to be blown to leeward.

At about 17 fathoms; the bottom is soft mud, and a half mile from the shore, the water is 2 miles out. Go to the latter town of Breogama, or S. by E. 10 miles from the shore, the water is 2 miles out. Go to the latter town of Breogama, or S. by E. 10 miles from the shore, the water is 2 miles out.

Running 10 miles from the shore, the water is 2 miles out. Go to the latter town of Breogama, or S. by E. 10 miles from the shore, the water is 2 miles out. The following is a list of the names of the towns of Breogama, or S. by E. 10 miles from the shore, the water is 2 miles out. Samuel Chacabuco tried the route, but when he had not the opportunity of observing the latitude either by the moon, a star, or by altitudes of the sun before and after he had passed the meridian, should be neglected. It is also advisable to make the land rather to the south than to the north of either of the points, as the currents will always favor working to the northward. The facility is still greater in times of the N. E. winds for getting up from Point Galeota to Point Galere. The passage may also be made from the latter to the former, but not with so much ease. So soon as one of the points or capes has been made out distinctly, the route to the mouths of the gulf is as follows:

So soon as the island is made out, in from 7 to 10 miles, the water is of different depths, no reason to fear. On clearing the channel, the least risk, to the westward, is convenient.

The First of the Bocas, distant from the coast with  $1\frac{1}{2}$  fathoms, as before described, is so steep, that the channel is very narrow. W. with the wind.

The Second of the Bocas, distant from the coast with 10 fathoms, as before described, is so steep, that the channel is very narrow. W. with the wind.

The Third of the Bocas, distant from the coast with 10 fathoms, as before described, is so steep, that the channel is very narrow. W. with the wind.

The Fourth of the Bocas, distant from the coast with 10 fathoms, as before described, is so steep, that the channel is very narrow. W. with the wind.

The Fourth of the Bocas, distant from the coast with 10 fathoms, as before described, is so steep, that the channel is very narrow. W. with the wind.

under sail, the kedge anchor may be let go; it will be sufficient to hold against the strength of the tide, and the use of large anchors should be avoided as much as possible; because as they bury themselves so deep in the soft mud, there is considerable trouble in weighing them. In Port d'Espagne ships may anchor in the S. W. part, in 4 or 5 fathoms, according to the ship's draught: moor N. W. and S. E.

At about 4 miles within the Bocas, soundings may be got with the hand line, in 20 fathoms; from whence, in standing southward, the water soon shoals to 14, 13, and 12 fathoms, which depths will continue several miles; but the soundings are not quite regular, though nearly so, there being some small banks with 6 or 7 fathoms on them, 5 or 6 leagues from the shore. When about 6 or 7 miles from Point Brea, the depths will increase suddenly to 17 and 18 fathoms: the latter will continue until about  $2\frac{1}{2}$  miles from the shore: the water then shoals gradually to 3 fathoms, about the length of a cable and a half from the beach. The best anchorage off this part of the island is with the town of Brea, which consists of 5 or 6 old houses near the beach, bearing about south, or S. by E. one mile off the shore, in 6 or 7 fathoms.

Running down the coast to the southward from Port d'Espagne, observe that about 8 miles from it, and off a point of mangroves, there are only  $2\frac{1}{2}$  fathoms, at  $1\frac{1}{2}$  mile from the shore. To the north-westward from Naparima Hill about 7 miles, there are  $2\frac{1}{2}$  fathoms 2 miles distant from the land, and this bank is steep, with 10 fathoms not far without it. Go into no less than  $4\frac{1}{2}$  fathoms between Point Brea and Point Cedro; from the latter to Point los Gallos, the shore is flat, and a ship may be guided by the lead.

"The following remarks on Boca Huevo were made in September, 1826, by Captain Samuel Chambers, of his Majesty's ship *Druid*. He says—'As had been recommended, we tried the second passage two different evenings, approaching it with a fine breeze; but when almost through, both times, the current forced her out; and the second night, had not the boats been ready down, and she a quick ship, she must have gone on shore. According to calculation, this was at flood tide. We immediately bore up for the Great Bocas, where we soon got through;\* therefore I by no means recommend any passage but the large one, as the advantage is trifling comparative with the safety of your ship. For when through either, in less than an hour, with a moderate breeze, you come in 13 fathoms water, when you may anchor.'"

#### *Description of and Directions for the South Channel.*

So soon as the ship has reached Point Galeota, she should be kept along the shore of the island at the distance of two miles or less; at the distance of two miles she will be in from 7 to 9 fathoms, clear of all risk; and although it may be perceived that the water is of different colors, particularly to the eastward of Point Herin and about it, there is no reason to be suspicious of shoals, as the variety of colors is occasioned by the current. On clearing Point Quemada, she may near the shore to a quarter of a mile, without the least risk, to gain that channel which, under the existing circumstances, may be most convenient.

The First Channel is formed by Point Icaeos, or Icaque, and a shoal lying to the west of it, distant about half a mile, and which is from east to west about two cables' length, with  $1\frac{1}{2}$  fathom, rocky bottom. In the channel there are 9 fathoms water. Point Icaeos, as before said, is a sandy promontory, advancing into the sea in a circular form, but so steep, that at half a cable's length from it, there are 7 or 8 fathoms. The current in this channel sets to the S. W. at the flood, with a velocity of  $2\frac{1}{2}$  miles per hour, and N. W. with the ebb, at the rate of 3 and  $3\frac{1}{2}$  miles.

The Second Channel is formed by the rocky shoal and a bank of rock and gravel lying to the N. W., upon which there are 4 fathoms. This bank bears from Point Gallos S.  $60^\circ$  W., distant 3 miles, and from Icaeos N.  $73^\circ$  W., distant 2 miles. The greatest extent of it is three quarters of a mile N. W. and S. E. The currents in this channel set in nearly the same direction as in the preceding one. Its breadth is about a mile.

The Third Channel lies between the bank last mentioned and the Isote del Soldado, (Soldier's Islet,) with the reefs and shoals on the south and S. E. of it. This channel is about two short miles from east to west. About  $2\frac{1}{2}$  cables from the reef off the east part of Soldado, there are 6 fathoms water, in mid-channel 8, and near the bank  $5\frac{1}{2}$ . At flood tide the current sets W. by S. with the velocity of  $3\frac{1}{2}$  miles; and with the ebb N. W. and W. N. W. at the rate of 4 and  $4\frac{1}{2}$  miles per hour.

The Fourth Channel is formed by the Soldado with the reefs and shoals on the south of it and the main land. The breadth of it is about 4 miles. The currents always set to

\* In going through this passage be careful of the rock that lies W. S. W. from the S. W. point of Chaca-chacare, as well as that which lies one third of a mile due west from it.

the N. W. and W. N. W. with a velocity of  $4\frac{1}{2}$  or 5 miles per hour, in mid-channel, and near Soldado; but at half a mile from the main it runs only from  $1\frac{1}{2}$  to 2 miles.

To enter the First Channel, it is only necessary to near Point Icacos at about a cable's length, luffing up by degrees as it is passed, and then steering north, to pass at a convenient distance from the Points Corral and Callos. This passage can never be attended with difficulty, either by day or night, especially at ebb tide, as the current will keep the ship clear of the shoal; and if it should be necessary to anchor, there will be no risk of getting aground, as the shoal will be at least 3 cables' length distant from the ship.

To enter the Second Channel, it will be necessary, after having passed Point Quemada, and approached the coast to a quarter of a mile, to place the ship's head towards Soldado, and keep her so until Point Gallos comes open of Point Corral, and then luff, but without going to the N. N. E. until Point Corral bears east; she may then be kept along the coast of Trinidad.

To pass through the Third Channel, the ship's head ought to be placed towards the Soldado, in the same manner as for the second, and kept in that direction until Point Gallos bears N.  $67^{\circ}$  E.; then luff up to N. until the south front of Point Icacos bears S. E. by E., and Point Gallos N.  $83^{\circ}$  E.; then run along the coast of the island.

To pass through the Fourth Channel, you have only to pass at 2 miles S. of the Soldado, and when it bears N. E. luff up to N., and keep luffing by little and little to coast along the island of Trinidad. Care must be taken not to get within two miles of the Soldado, observing that the current will set the ship strongly to the N. W.

Hence it results, that at any time a ship may enter the gulf by the South Channels, even by night, if not very dark; that the First Channel is the best, not only because it is the windward one, but by keeping the luff, every danger will be avoided, especially with the ebb tide. In fact, there can be no danger whatever, if an anchor be ready to let go in case of a sudden calm, or other cause, that might carry the ship towards the shoal. In the night time either of the channels can be more easy to enter than the first; for as the point must necessarily be passed within a cable's length, every impediment from darkness will be avoided, because at so short a distance it can be very distinctly seen.

But however easy the entrance into the gulf by these channels is, if any circumstance, either of calm or want of daylight, may render it advisable to wait some time before attempting it, the ship can be anchored on the south coast of Trinidad; for if kept under way and tacking, as the current always sets inward, it will be very difficult to maintain a determinate position.

On getting through the channels into the gulf, steer for the west coast of Trinidad, and keep along it, at  $2\frac{1}{2}$  or 3 miles distant, as far as Brea Point. Port d'Espagne is not above  $8\frac{1}{2}$  leagues from this point, and by steering N. by E.  $\frac{1}{2}$  E. the buildings in it will soon be discovered. If this course cannot be made good, recourse must be had to tacking; but the boards must not be stretched within 4 miles of the shore, on account of the shoal that lies off it; and if standing into the Bay of Naparima, it will be necessary to be careful of two shoals, one west of the mount, distant about  $2\frac{1}{2}$  miles, and the other S.  $75^{\circ}$  W. of it, distant 4 miles. In proceeding from Brea Point to Port d'Espagne, the depths are from 7 to 12 fathoms, at the distance of 3 miles from the point; then 14 fathoms for about a mile; after which, 18 or 19 fathoms for nearly 10 miles; and then a gradual decrease to 5 fathoms, at the distance of  $2\frac{1}{2}$  miles S. S. W. from the town.

Good fresh water may be obtained from two small rivers in the bay, about a mile to the southward of Point Brea; at high water, a boat may land close to it. Wood can be procured in abundance with little trouble, as the trees are very large, and close to the water side.

In September, 1821, his Majesty's ship Forte, Capt. Sir T. J. Cochrane, passed over a bank with only 4 fathoms water on it, at about 4 or 5 miles northward of the Soldado, and the same distance from the shore. The Captain says, "I felt a very strong smell of tar, or pitch, and observed some of the former floating on the surface, which, no doubt, oozed from the bank below. I have since learned it is composed of pitch, and that there is a spot on it with only 3 fathoms water; but being suddenly called from the station, I had not time to ascertain that fact."

## THE COAST OF COLOMBIA, FROM THE GULF OF PARIA TO CARTHAGENA.\*

In the description of the island of Trinidad, and the Dragon's Mouth, (Bocas de Dragos,) it was said that the fourth, or Boca Grande, is formed by the island of Chaca-chacare and the main land. The most projecting, or N. E. point of the coast forms a lofty steep islet, called the Morro. This lies about 4 leagues, N. 78° W., from Point Mono, in Trinidad. From the Morro the coast runs westward, with a little inflection to the south, for the distance of 19 miles, to the Bay of Mexilones, whence it trends a little northward to Cape Tres Puntas, (Three Points,) which is distant from the Morro 50 miles due west. The whole of the land along this space is high and mountainous, and the shore perfectly clean, so that it may be run along by at half a mile distant. At the distance of a mile there are from 20 to 40 fathoms, on a bottom of muddy sand.

Cape Tres Puntas is the most northerly cape of all this part of the coast, and it continues to be equally as clean and deep as the preceding part, to the Bay of Unare, a distance of two miles.

Unare Bay presents a good anchorage, sheltered from the trade wind. To enter it, it is necessary to keep about a mile from the N. E. point, which is fronted by a rocky shoal extending half a mile out; then stand in and anchor in 5 or 4½ fathoms, sandy bottom, immediately on getting round within the point. A little river falls into this bay, and on the hill to the east of it, there is an Indian town named San Juan de Unare. The S. W. point of the bay sends off a reef, with several islets upon it, to the distance of half a mile. Passing outside of them, and at about two cables' length from the most northerly one, will clear every danger.

From Unare Bay the coast continues to run west, with some inflections to the south, for the space of 10 miles, whence it turns gradually to the northward of west, for 9 miles farther, to Cape Mala Pascua, between which and Cape Three Points all the shore is clean, and may be coasted at a mile's distance, in 8 fathoms, sandy bottom. The bearing and distance from Cape Three Points to that of Mala Pascua, are S. 83½° W. 20½ miles.

**TESTIGOS ISLANDS.**—Nearly N. ½ W. from this cape, at the distance of 40 miles, lie the little islands called the Testigos. These consist of seven principal islands, besides several farallones, or high rocks. The passages between the islands are free and clean, and may be run through without any risk whatever; but the contrary is the case with those between the rocks, for they are very narrow. All those islands may be approached to the distance of two cables' length, or even nearer, if necessary, excepting that which lies most to the north-eastward. This is surrounded by a reef extending half a mile from it. Between the islands the bottom is sandy, and will admit of anchoring in case of necessity. The principal island, called Testigo Grande, (Great Testigo,) lies N. W. and S. E., about 2½ miles in length. The S. W. part affords good anchorage, sheltered from the trade wind, with a depth of 8 to 15 fathoms, coarse sand. It may be approached either by the N. W. or S. E. side. If by the former, it must be on the outside of the rock that lies off it; if by the latter, the passage is between the great island and another lying S. W. of it. The channel is sufficiently spacious; for at the narrowest part, between the rock at the east side of the little island, and another about a cable's length from the S. W. coast of the large island, it is half a mile wide, with a depth of 8½ to 9 fathoms, on red gravel.†

Between these islands and the coast, there are soundings. About 5 miles to the S. S. E. of them, lies a large bank of sand, with 4½ and 5½ fathoms water on it, which should be avoided by large ships.

From Cape Mala Pascua the coast runs nearly west 7 or 8 miles to the Morro of Porto Santo. This Morro is joined to the shore by a little low sandy tongue; and very near to

\* From the *Derrotero de las Islas Antillas*, &c. &c. &c., segunda edicion, Madrid, 1820.

† The Testigos may be seen from the distance of 5 leagues. The Great Testigo, called Goat Isl. and, abounds with land tortoises. It is not inhabited, except in the season, by turtles. It appears a bold shore, and has a sandy beach near its north end. August 27, 1826, his Majesty's ship *Valor*, under the command of Captain the Earl of Huntington, anchored here in 16 fathoms, on sandy bottom, about 1½ mile from shore, the north end of the island bearing N. ½ E. and the south end E. S. E. ½ E.; found the current setting west north-westward, 1½ mile per hour. No fresh water to be had.

the Morro on the west, lies an islet called Porto Santo. To the westward of the Sandy Tongue, is an anchorage sheltered from the trade wind, in  $4\frac{1}{2}$  to  $5\frac{1}{2}$  fathoms water, sand and mud. The north side of the Morro and island may be approached to 2 cables' length, if necessary. To gain the anchorage, immediately after passing the island, steer S. or S. by W. and anchor in  $4\frac{1}{2}$  or  $5\frac{1}{2}$  fathoms, so soon as shelter from the wind is obtained; but taking care not to get to the eastward of the western part of the islet, because there lies a bank in that direction with only 3 fathoms water on it. Southward from the Morro, and about 2 leagues inland, stands the mountain of Porto Santo.

From this bay the coast inclines to W. S. W. for the space of  $3\frac{1}{2}$  miles, and sends off a bank with little water on it, about half a mile, and extending all the way to the point of Hernan Vasquez, which forms another little bay with an anchorage of  $5\frac{1}{2}$  to  $6\frac{1}{2}$  fathoms water, sheltered from the trade wind. From a river that disembogues into the Bay of Hernan Vasquez, fresh water may be obtained; and to the southward of its western point, off which is a small islet, stands the town of Carupano: two miles west of Carupano are the point and Morro of Salines, or of Jarro, with an islet near to it, which, with the point of Hernan Vasquez, forms the bay of Carupano, including that of Hernan Vasquez. There are two shoals at the entrance of this bay, lying a little to the northward of the parallel of Point Hernan Vasquez, and westward of the meridian of Carupano: of these, the first has  $2\frac{1}{2}$  fathoms on it, with  $5\frac{1}{2}$  close to, and lies one mile W. N. W. from the point; the other lies  $1\frac{1}{2}$  mile W.  $\frac{3}{4}$  N. from the same point, and  $1\frac{1}{2}$  mile N. E. from Point Salines: this has  $1\frac{1}{2}$  fathom on it, with  $4\frac{1}{2}$  fathoms close to it. A third shoal, of  $3\frac{1}{2}$  fathoms, with 5 close to it, lies within the bay, at three quarters of a mile W. S. W.  $\frac{1}{4}$  W. from Point Hernan Vasquez, and the same distance north from the town of Carupano; and westward of the town there is a bank with little water on it, extending from the shore northward nearly three quarters of a mile, and one mile E. N. E. from the islet at Point Salines.

**MORRO BLANCO.**—From the Point and Morro of Salines to Morro Blanco, a distance of three miles nearly west, the coast is clean, with several patches of small rocks lying close to the shore: nearly south of this Morro, and about 3 leagues inland, the Mountain of San Jose, or St. Joseph, may be seen.

From Morro Blanco to the westward, a bank runs off, with little water on it, that does not permit the coast to be approached nearer than 2 miles: on this part of it, there are, 1st, the Point and Morro of Padilla, known by an islet and several rocks extending to a little distance from it: 2d, the Point and Morro of Taquien, which projects farther northward than the preceding, and is also surrounded by several islets: 3d, the Morro of Lebranche, which is joined to the main by a low sandy and swampy tongue of land; and 4th, the Morro de la Esmeralda, or Emerald Morro, which is an islet separated from the coast by a channel of about half a cable's length wide. Between Lebranche and the Emerald Morro, at a moderate distance from the land, lie the Garrapotas Islets; but from rocks and shoals there is no passage between them: there is, however, between the most southerly islet and the main land, a good passage; but the better way always, is to go on the outside of them, especially with large ships. From Morro Blanco to the point of Taquien, the distance is  $3\frac{1}{2}$  miles N.  $83\frac{1}{2}^{\circ}$  W. and thence to the Emerald Morro,  $8\frac{1}{2}$  miles S.  $75^{\circ}$  W. Southward of the latter, and about 13 miles inland, will be seen Mount Redondo.

**ESMERALDA BAY.**—To the westward of the Emerald Morro there is formed a large bay, but it is obstructed by a bank, with very irregular soundings, which extends from the middle of the Morro about south, and S. W. nearly a mile, then S. W. by S. to within one third of a mile of the coast, whence it turns to the westward, and runs parallel to the shore, at about that distance from it. In the bay and on the bank, there are three islets, called the Cascabels, lying nearly east and west. On going to anchor in this bay, ships may pass as close as may be necessary to the north and west of Emerald Island, and anchor under shelter of it, at the distance of 2 cables' length, in  $5\frac{1}{2}$  to  $6\frac{1}{2}$  fathoms water, sandy mud.

From this bay the coast runs west about 5 miles to the Point and Morro of Manzanilla, all the way bounded, at the distance of one third of a mile, by a bank which extends from the Emerald Isle. The Point of Manzanilla forms a bay; but it is obstructed by the same bank of which we have spoken, and which terminates at the first steep point, about two thirds of a mile to leeward of the bay; it not only impedes entrance into the bay, but also prevents steering to the southward before getting to the westward of the said steep point. From this situation, west of the point, the coast is quite clean for the space of 8 miles, to Point Guaraputuro, where another bank begins, and extends two thirds of a mile from the coast. About one mile N. E. of Point Guaraputuro lies a sunken rock that must be carefully avoided. A little eastward of this point, and about a league inland, will be seen the peak of a mountain called Pico del Este, Peak of the East.

Three miles westward from Guaraputuro Point, is that of Escudo Blanco, or White Shield Point, the coast being steep and high; but from that the coast runs out about N. W., very low and swampy, for the space of  $2\frac{1}{2}$  miles, where there rises a Morro called Chacopata, which forms a point, projecting into the sea almost 2 miles. From this point the coast takes a southerly direction and forms a great bay, in which, at  $1\frac{1}{2}$  mile west from the middle of the said Morro, there is a little island called Caribes; at about a mile west of Caribes Island is an islet called De Lobos, or the Wolf, with a rock close to the east part of it. The shoal bank that begins at Guaraputuro Point, also borders this part of the coast, and reaches about one third of a mile from the Morro Point; it thence continues to Caribes Island, whence it turns to the south, bearing so close up on the shore that at Cayman Point, the southernmost and westernmost of the bay, it does not extend more than half a mile.

N.  $82^{\circ}$  E. from Chacopata, at the distance of 17 miles, lies the eastern point of the Island Margarita, forming with the main land a channel 11 miles wide. In the middle of this channel are the Coche, or Coeh, and Cuagua, or Cnagua Islands; and as a description of the coasts on both sides of this channel will be necessary, we will first proceed along that of the main, so far as Araya, and then return to Margarita and the other islands.

From the Point and Morro of Cayman, the coast is level toward the west, the only salient points being those of Tuua, a mile and a half from the preceding, and the Point and Morro del Castillo, 2 miles beyond Tuua. From Castillo Point, the coast inclines somewhat to the north, as far as the Point and Morro of La Pena, a distance of 4 miles: this point lies S.  $77^{\circ}$  W.  $14\frac{1}{2}$  miles from the Morro of Chacopata. From the Point of La Pena, the coast descends somewhat to the southward of west to Point Gorda, a distance of  $2\frac{1}{2}$  miles, from which it forms a bay with a very flat shore and beach to Point Guachin, or Guaranache, forming a piece of steep and high land, which rises above the low land and seems insulated by it; along the shore of the bay, there is a steep point of little extent, called Minas. From Point Gorda to that of Guachin, it is  $6\frac{1}{2}$  miles.

From Point Guachin the shore continues low and flat, so far as Punta del Escarceo, or Eddy Point, where it rises a little: the distance from one to the other is  $3\frac{1}{2}$  miles: the latter bears from the Point of La Pena N.  $85^{\circ}$  W.  $12\frac{1}{2}$  miles. Point Escarceo presents a front extending half a mile, the western extremity of which is called Point Cardon, whence the coast bends to S.  $49^{\circ}$  W. a distance of  $2\frac{1}{2}$  miles, to Point Araya, the whole space being a very low sandy beach. About half a mile from Araya Point is another, called Point Chica. On Araya Point there are a few small houses, inhabited by people employed in the salt works. All the coast, from Point Cayman to that of Escarceo, sends off a bank about half a mile from shore, and which from the latter point extends four miles westward, forming what is called the Araya Shoal, the south edge of which terminates at Point Chica, to the southward of Point Araya. This will be cleared on the south side by bringing the most southerly of the houses on the Point to bear east. Thence southward the coast may be approached at 2 cables' length; for although the sandy beach is very flat, at that distance there are 5 or 6 fathoms water. The beach continues for 2 miles about S. S. E. to Punta de Piedras, formed by the western extremity of the Ridge of Guaranache; this Point shows a front of about half a mile, and immediately within it the land rises to a lofty hill; on the south part of it stands a chapel, or sanctuary, dedicated to the Virgin of Agua Santa. The coast continues in the same direction of S. S. E. to Point Barragon; at first it is low and sandy, and afterward steep, but all of it is so clean that it may be coasted at a cable's length. On the south point of the little bay of Araya, where the high land of Point Barragon begins, there is a castle in a ruinous state. From Point Barragon the coast continues high and very clean, about S. E. by S. a distance of 2 miles, to Point Caney, from whence it changes its direction to S. E. by E. and continues for rather more than a mile to Punta de Arenas, or Sandy Point, which is the southernmost part of this coast, and northernmost of the Gulf of Cariaco. From Point Caney there is a bank extending along the coast as far as half a mile south of Point Arenas.

Here we suspend our description of the coast and return to

**THE ISLAND OF MARGARITA.**—The greatest length of this island is, from east to west, about  $37\frac{1}{2}$  miles; it is mountainous, and, when seen at a short distance from the north, it appears like two islands, from a space of low swampy land in the middle of it. On the eastern part there are several heights, that may be seen in clear weather from Cape Three Points, a distance of 24 leagues; and on the west part a ridge of heights called Macanao. The eastern point is named Bullena, and, as before said, lies N.  $8^{\circ}$  E. from Chacopata Morro; the coast runs thence N. N. W.  $\frac{1}{2}$  W. to Cape La Isla, a distance of 13 miles, forming the N. E. side of the island. The whole of it is clean, only sending off a bank of about 3 cables in breadth; two islets, named Isles of the Cape, lie about a mile and a half south-eastward of the Cape, and about half a mile from shore.

From Cape La Isla the coast runs S. W. by W. to Point La Galera, a space of 7 miles, all clean; there is also an islet lying  $1\frac{1}{2}$  mile N. E. by N. from the point, named La Galera, having between them 14 fathoms water, on sand and shells. From Point La Galera to Point Maria Libre, it is S. W.  $\frac{3}{4}$  S.  $3\frac{1}{2}$  miles; between these points there is a large bay\* with a bank edging the shores of it, which in the centre runs off nearly a mile. On the shore opposite to the widest part of the bank, stands an *Inc.* a village.

Point del Tunar bears from that of Maria Libre N.  $83^{\circ}$  W., at the distance of 11 miles: in the intermediate space there is a very large bay, running about 5 miles inland. The whole of this bay is very clean, and presents no other danger than the bank which borders it, which, at the widest part, extends only about half a mile from the land: the shore at the extremity of the bay is a low swampy beach. A reef of considerable extent runs off in a N. N. E. direction from Point del Tunar. From this point the coast trends about W. by S. for 8 miles, to Point del Tigre, the whole very clean, and may be coasted within half a mile; from the latter point the land bends to S.  $72^{\circ}$  W. for  $2\frac{1}{2}$  miles, to the Morro of Robledar, and thence S. S. W. a distance of  $4\frac{1}{2}$  miles, to the Punta de Arenas, which is the western extremity of the island. The bank of shallow water which surrounds the coast, extends about  $1\frac{1}{2}$  mile from this western part of the island, between the Morro of Robledar and Point Arenas. About N. W.  $\frac{3}{4}$  N.  $4\frac{1}{2}$  miles from Point Arenas, and W.  $\frac{1}{4}$  S. 4 miles from the Morro of Robledar, lies the eastern edge of a rocky shoal, named the Ostial, having on its shallowest part  $4\frac{1}{2}$  fathoms; it thence extends about N. W. by W. 3 miles, and is nearly a mile wide. Between it and the Morro of Robledar, there are from 5 to 7 fathoms, on sand and mud; to the northward and westward, the soundings extend to a considerable distance; but on the S. W. side, at a short distance, the water is very deep.

Three miles and a half about S. W. from Ballena Point, are Point Moreno and a Morro; the intermediate coast forms a spacious bay, on the north side of which stands the town of Pampatar. Nearly in a line between the two points, and about midway, lies the little islet called Blanco, which is very clean; the passage between it and the land is very safe. All parts of this bay afford anchorage in 7 and 8 fathoms water, at two thirds of a mile from the beach: with the trade wind blowing fresh it is rather exposed, as there is no shelter; and although such a wind does not send in much sea, it will be advisable to anchor in such a position that, in case of necessity, there may be room to run freely for the Morro Moreno, which, if occasion require, may be passed on the east side, at the distance of a cable's length.†

From the Morro Moreno, the direction of the coast is S. W.  $\frac{1}{2}$  W. for a space of 6 miles, to Mosquito Point; the land between forming a great bay, on the north part of which stands the town, so called, of La Mar, but more correctly, a cluster of straw huts. The coast from Morro Point to that of Mosquito is so *foul*, that it would be hazardous to get within two miles of it: the same character may be given to that farther westward. From Mosquito Point to Punta de Mangles, or Mangrove Point, the bearing and distance are S.  $83^{\circ}$  W.  $10\frac{1}{2}$  miles: the coast between is very foul, from a rocky shoal that extends off about a mile. From Mangles Point the shore turns to the northward, forming a bay between it and Point Piedras, a distance of  $3\frac{1}{2}$  miles; from the latter point it runs farther northward, forming another bay with Point del Pozo, which is distant  $6\frac{1}{2}$  miles from the preceding. Point del Pozo lies 10 miles N. W. by W.  $\frac{1}{2}$  W. from Point Mangles; and from the former to Point Arenas, the bearing and distance are W. by N. 12 miles. All that part of the coast from Mangles Point to Arenas Point is, like the preceding, *foul*, and should not be approached to less than 2 miles.

THE FRAYLES.—Nine miles E. N. eastward from Cape la Isla in Margarita, lie

\* Mr. William Waddy, Master of H. M. S. L'Aminable, in his remarks on this bay says, "In approaching it from the northward and westward, the soundings will be regular, from 30 fathoms at the distance of 4 leagues to 6 fathoms. Pass the islet of Galera at a discretionary distance, and in rounding Point la Galera, which is high and bluff, you will see a fine open bay, where you may ride at anchor in safety, in from 10 to 4 fathoms, with Point la Galera bearing about N. E.  $\frac{1}{4}$  E. distant about 2 miles."

† His Majesty's sloop Barbadoes, John Fleming, Esq. commander, anchored here in January, 1816. He says, "Ships from the eastward having approached Ballena Point to about a mile, should edge away to the S. W. sounding in 12 and 10 fathoms water until Fort La Carranta comes open: this fort is on a point of land over the sea, about half a mile to the east south-eastward of Fort St. Carlos, which is situated in the middle of the town. With Fort La Carranta bearing N. W.  $\frac{1}{2}$  N. by compass, distant one mile, there is good anchorage in 8 fathoms water; but this is not a safe and advantageous bay for a fleet to rendezvous in, there being little shelter against any weather, and a great scarcity of water and every species of provisions. The forts command the anchorage."

"In sailing out of Pampatar Bay and bound to the westward, pass to the westward of Blanco Islet, on account of a reef lying off its S. E. side, which makes it dangerous to borrow near it in that direction."

ward of Blanco Islet, low near it that direc-

group of islets, called the Frayles, or the Friars, of which the southernmost is the largest: they are all very clean, except the northernmost, which is surrounded by a reef, extending about two cables' length from it.

**SOLA ISLET.**—About 12 miles N. E. ¼ E. from the largest of the Frayles, lies the little islet called Sola, which is very clean: from Sola to the Testigos, the distance is 27 miles. The passages between the Testigos and Sola, Sola and the Frayles, the Frayles and Margarita, are all so clear, that ships of all sizes may use them in any kind of weather.

**Channel between Margarita and the Main.**—In this channel there are two large islands: the easternmost one is called El Coche, or the Coach; and that on the west, Cubagua, or Cuagua. Coche Island is low, lying W. N. W. and E. S. E. about 6 miles in length, and 2½ miles wide. It is surrounded by a rocky shoal and reef, which extend from the N. W. and S. E. points about a mile and a half, and forms two channels: that on the north, with the Island of Margarita, which, in its narrowest part, is two miles across: and that on the south, with the main land, of nearly similar breadth in its most confined part. In both of them the passages are perfectly clear, the bottom very good, and a vessel may ride at anchor in either of them as securely as in a harbor.

Cubagua is smaller than Coche Island, and lies nearly east and west: it is about 5 miles long, and 2 miles wide. From the east point there are a shoal and a reef, extending out about a mile: the north and south sides are very clean: but on the west side, a rocky shoal extends about one third of a mile from the shore. This, like Coche Island, forms two channels,—one on the north with Margarita, and the other on the south with the main land,—both very clear. In the narrowest part, which is between the shoal and reef which stretches out from the east end Cubagua, and the bank that extends off from Mangles Point in Margarita, the width is 3½ miles.

In navigating the North Channel of these islands no other care is necessary than that of keeping in the middle of the passage; for, by so doing, the banks of Margarita, that from the N. W. of Coche Island, and that from the east end of Cubagua, will all be cleared: but for greater certainty, the most northerly little point of Cubagua may be brought to bear west; which course may then be kept on to pass Mangles Point, and then edging a little to the northward, so as to pass a cable's length to the northward of the said north point of Cubagua, every danger will be avoided.

To navigate the South Channel, † you ought to pass near to the Caribes and Lobos Islands, by which you will clear the bank that extends to the S. E. from Coche Island, and thence shape a westerly course without fear, as the three Tuna Islets, lying off Tuna Point, are very clean, and may be passed between, if necessary. From these islets westward, the channel widens considerably, and consequently requires less care. In all these channels it is advisable to anchor at night, in any part of them, when the ship is bound to Araya or Cumana, lest the current should carry her to leeward; and also because these ports should always be entered in the day time, that the shoal off Point Araya, and the shallow bank of Cumana, may be avoided.

To sail to the ANCHORAGE of ARAYA, the only danger to be avoided is the shoal off Point Araya, which, as before observed, extends 2½ miles to the N. W. of it: this may be effected by standing on about 3 miles from the point before the course is altered to the southward; or, what is nearly the same thing, to make no southing until having

\* His Majesty's sloop *Sapphire*, A. Montgomerie, Esq. Commander, when beating to windward in the South passage, on the 29th of April, 1821, struck on a shoal of 15 feet water; the Morro of Chacopata, bearing about E. S. E. ¼ E. by compass, distant 22.3 miles, and the west end of Caribes Island about S. ¼ E. 2 miles.

† His Majesty's sloop *Bellefleur*, J. Leith Esq. Commander, ran through this channel on the 7th of March, 1825. He passed three quarters of a mile to the northward of Point Chacopata, in 7½ fathoms water (having gradually shoaled from the depth of 19 fathoms to the eastward), and steered directly for the Island Lobos, in which track he had not less than 4½, nor more than 5 fathoms, until arriving abreast of the said island. After passing it, the water began to deepen fast, but the wind blowing strong from the east, with an appearance of foul weather, he hauled towards the S. W. side of Coche Island, where the shoal extends only a short distance off, shortened sail and anchored in 9½ fathoms water, on mud, about 3 miles off shore; \* with the west end of Coche, a low sandy point, bearing N. W. by N. by compass; the S. E. end S. ¼ E., Lobos Island S. E. by E. ¼ E. and Morro de Pena S. W. ¼ W. On the 8th, at 6, 30 A. M. he weighed; and after running 22 miles W. by S. from the anchorage, saw white colored water on Araya shoal ahead; hauled up to N. W. to avoid it, having found that a W. by S. course would not clear it; at 11 A. M. passed close round its western edge, and gradually hauled in for Point Piedras, &c.

‡ His Majesty's ship *Valorous*, Capt. J. Murray, anchored off the west end of Coche Island, at about 1½ mile off shore, in 7 fathoms, muddy bottom; with the N. W. end of the island, a low sandy point, bearing N. E. by N. its S. W. point east; Cubagua Island W. ¼ N. and Point Mangles in Margarita, N. N. W. ¼ W. this anchorage is very good.

got out of soundings. But if it should be thought preferable to use landmarks, be careful not to cross the parallel of Point Escarceo, but the westernmost peak of four, on the height of Macanao, in Margarita, bears north, a little easterly; for when it bears N. 5° E. it will clear the west extremity of the shoal about half a mile. The Island of Cubagua will also afford a mark; for, by bringing the west point of it to bear N. E., the western edge of the shoal will be cleared two miles.\* Hence it appears, that a ship bound to Araya, and having run down the South Channel between Coche and Cubagua on the north, and the main land on the south, should pass about a mile to the northward of Point Escarceo, and steer west until the west point of Cubagua bears N. E., when, by altering the course to the southward, she will pass two miles distant from the west edge of the shoal; and if it be desirous to keep closer to it, to avoid getting so much to leeward, it may be done by steering west, until the westernmost peak of Macanao bears N. 5° E., or rather more easterly; then bring her head to the southward, and she will pass at the distance of one mile from it. Keep on the south course, until she gets abreast of the southernmost house on Point Araya, then haul to the wind, in order to fetch into the little Bay of Araya, which will be known by the Fort on the south side, and the Sanctuary of Our Lady of Agua Santa on the north side, and on the south slope of Guaranche. In this bay, and also on every part of this coast, as far as Point Arenas, a ship may be anchored in any convenient depth, and, if desirable, at a cable's length from the shore.

In like manner, in doubling Point Araya from the northward, that is, from Cubagua or Margarita, the parallel of Point Escarceo should not be crossed to the eastward of the bearings before given; and if by any accident you happen to do so, you should immediately steer in an opposite direction, until you are due west from Point Escarceo; and then west, until the proper bearings come on—namely, the westernmost peak of Macanao N. 5° E., or rather more easterly; when you should steer south, so as to be able to haul to the wind on getting abreast of the southernmost house on Point Araya. On coming from the north, the soundings will also be a good guide, either by keeping out of them altogether, or, at least, by not getting into less than 35 fathoms, until after crossing the parallel before mentioned.

There are a shallow bank and reef stretching about half a mile south from Point Arenas, which have been already spoken of as the North Point of the Gulf Cariacou, which runs 35 miles inland to the eastward; at the broadest part it is 8 miles across, and may be considered as a spacious, well-sheltered harbor, there being good anchorage in every part of it; but the best is in 36 fathoms. The shores are very clean, and may be approached to half a mile, or even a less distance, except in the vicinity of Cumana, where a shallow bank extends about two thirds of a mile from the shore. On the north side there are two harbors, called the Little and the Great, or Bishop's Lagoon; the former is very small, but the latter is spacious: and, besides having from 8 to 18 fathoms water, is so clean that there is no danger except what is visible. Its entrance is 12 miles from Point Arenas. Within the Gulf there is no town of consequence, or other inducement for ships from Europe to visit it; the main object of attraction for all is Cumana, which is situated on the South Point of the entrance into the Gulf. This point is low and sandy, with a bank running from it to the west and south, so steep that, from 10 fathoms, there are almost immediately 5; and from 5, a ship would be aground before getting another cast of the lead. The edge of the bank running eastward, lies nearly east from the point, about 4 miles, to Punta Baja, or Low Point, whence it turns to south-eastward with the coast, narrowing by degrees to the vicinity of Mount Blanco, where it terminates on a clean shore.

The edge of the bank that runs southward from the point is very close to the shore, forming with it the mouth of the River Manzanares, or Cumana, whence it increases in breadth to the S. W. so much that, N. W. of the Escarpado Roxo, a little mount, with

\* His Majesty's sloop *Esk*, Edward Lloyd, Esq. Commander, ran aground on this shoal, on the 20th of August, 1821, having at the time Araya Point bearing S. E. by E. by compass, distant 6 miles by estimation. Subjoined is an extract from the Log Book, whence we have obtained the information:—

"P. M. Fresh breezes and fine, running along the land between Margarita and the main. At 4h. Point Araya south 6 or 7 miles; at 4h. 15m. trimmed sail and hauled more to the wind; at 4h. 25m. the ship under a press of sail, running at the rate of 10 knots, S. S. W. by compass, being about 6 miles from Point Araya, and (by the leadsman in both chains) in 9 fathoms water, suddenly shoaled, and immediately afterwards struck the ground. Shortened and furled sails; hoisted out the boats, and sounded in every direction round the ship; laid the stream anchor out N. W. in 3 fathoms; at 6h. parted the stream cable, of which 90 fathoms were lost: Point Araya then bearing S. E. by E."

It farther appears that the sea broke very high within a quarter of a mile of her; and that the soundings all round were very irregular. On the 23d, after being lightened, she got off.

a red cliff, south of the town, it reaches about a mile from the shore: from this point it narrows again, and terminates at Point Piedras.

The TOWN and FORT of CUMANA, stand on the high land of the point, on the banks of the Manzanares, or Cumana River: on the low land, and near to the beach, stands an Indian town, separated from Cumana by the river. The anchorage is nearly in front of, or to the westward of, the river's mouth, on the south point of which is another fort. In order to fetch this anchorage, ships should steer from Point Caney towards Escarpado Roxo, but not more to windward, until the bank off Punta de Arenas is cleared. Having passed it, they should keep to the wind, and steer direct for the mouth of the river, which will be known by the fort already spoken of. Keep the lead going; and on getting a depth of water suitable for the size of the vessel, let go an anchor, with which, and a stream anchor towards the shore, the ship will be moored.\* If, from a scant wind, or from the current having set the vessel to leeward, it should be necessary to work to windward to gain the anchorage, when standing to the southward she should tack before Fort St. Antonio, which is situated on the most elevated part of the town of Cumana, bears to the northward of east, in order to keep clear of the projecting point of the bank off Escarpado Roxo; to the northward there is no danger, and the board may be prolonged according to judgment.

To the S. W. of the Escarpado Roxo, and a little to the eastward of Punta de Piedras, the River Bordonos disembogues its waters; and from this latter point the coast lies nearly west for the distance of  $3\frac{1}{2}$  miles, in some points scarped, and in others a sandy beach, to Port Escondido, which is a bay running about half a mile inland, and 3 cables' length wide at the entrance. In the middle of it the depth is  $4\frac{1}{2}$  fathoms, on sand, but nearer to the shore, only 3 and 2. Off the West Point there are some rocks, which may be avoided by passing at a little more than a cable's length from it.

From the West Point of Port Escondido, the coast trends about west for the distance of  $1\frac{1}{2}$  mile to Punta de Campanarito, all of which is scarped, and very clean, except one sunken rock, about half a cable's length from the coast, and 2 or 3 cables' length to the westward of the West Point of Port Escondido.

From Point Campanarito to the Morro and Vigia, or Signal Tower of Mochima, the distance is  $\frac{2}{3}$  of a mile; between them is a very fine bay, varying in depth of water, from 16 fathoms to  $5\frac{1}{2}$ , which will be found within a cable's length of the shore. Every part of the bay is clean; and only off the north and west sides of Point Campanarito there are a few rocks, extending somewhat less than half a cable's length from it, but nevertheless, it ought not to be passed nearer than one.

About W. S. W. from the signal tower of Mochima, a little tongue of land projects, and forms the east point of the Harbor of Mochima, which is capacious, beautiful and well sheltered. The shores are indented with several coves, or little bays, which are so many natural docks. The depth of water is very regular, no where exceeding 14 fathoms, or being less than  $4\frac{1}{2}$ ; the latter from one to one cable and a half's length from the shores, which are generally very clean. By keeping at the distance of  $1\frac{1}{2}$  cable's length from every visible obstruction, all danger will be avoided. To these good qualities may be added that of sailing in and out with the trade wind,† altogether making it the best harbor in this part of America; indeed it may be reckoned one of the best in the world.

\* His Majesty's ship Valorous, Capt. J. Murray, anchored here, in Feb. 1821, at about  $2\frac{1}{2}$  or 3 cables' length from the shore, in 14 fathoms water, on mud and clay; with the low sandy point at the entrance of the river, bearing N.  $\frac{1}{2}$  E. by compass, distant 3 cables' length; and Fort San Antonio on the hill above the town, east. The bank shelves off very suddenly, which occasions vessels to anchor near the beach, in 14, 8, and 6 fathoms, on good ground. To the northward, and off the fort on the beach, it shelves off quicker still; but to the southward, the shoal water extends farther off shore. The Bellette sloop, J. Smith, Esq. commander, in March, 1825, anchored in 20 fathoms, on mud, with the castle on the hill and church in one, E.  $\frac{1}{2}$  N. by compass: the Fort on the beach N. N. E.  $\frac{1}{2}$  E. and the Red Cliff (Escarpado Roxo) S.  $\frac{1}{2}$  E. This is about  $\frac{2}{3}$  of a mile off shore and is quite an outside berth; it is necessary to steady the ship with a stream to the S. W. The rise and fall of the tide is from 4 to 5 feet. Good water may be obtained in the little river to the northward of the fort on the beach. The wind always blows off the shore.

† His Majesty's sloop Sapphire, A. Montgomerie, Esq., commander, visited this harbor in April, 1821. Capt. M. observes, that though the anchorage is good throughout, the most secure is in either the two first eastern bights, mooring with a cable or hawser to the shore. The harbor may be entered with the trade wind; and as there is generally a land-breeze during the night, it is easy of egress; though from the first eastern bight, a ship may sail out at any time with the sea-breeze. Water may be obtained at the south end of the harbor from the River Mochima, though it by no means deserves that appellation, being only a small stream at any time; and though, if cleared a little above its mouth, enough might be had for any number of ships, yet it can at no time be accounted a good watering place.

About a mile to the westward is the Harbor of Manare, which is also an excellent port. The depth of water is from 14 to 4½ fathoms, the latter at half a cable's length from shore. It is very clean, and as the entrance is spacious, it may be entered with the trade wind at any time, and quitted with equal facility. The west point of the harbor is called Point Manare.

From Point Manare the coast runs about W. S. W. for the distance of 1½ mile, to Punta de Tigrillo, which sends out a reef on every side, to the distance of half a cable's length from it. The coast thence trends to the southward and eastward a distance of 2½ miles, whence it returns to W. by S. for 5 miles, to Punta Gorda, forming what is called Tigrillo Bay, at the farther extremity of which there is a canal communicating with the Harbor of Mochima. In the entrance of this bay there are three islands: the first or easternmost one is named Venados; the second or middle one the East Caraca; and the third the West Caraca. The shores of the bay, as well as those of the islands, are very clean, there being only off the north point of Venados, called Point Campanario, a rock which extends about a cable's length from it; and from the S. W. part of the same island, a small shallow bank running off a similar distance. All the passages or straits between these islands, and also between them and the main land, are free and navigable for ships of any class; and although some of them are narrow, there is sufficient room for anchoring, in case of necessity.

The only danger to be avoided is a rocky shoal, called the Caracas, which lies about N. W. at the distance of rather more than a mile from the East Caraca. It is about half a mile in extent from east to west. There is not, however, much risk; for in passing between it and the Caracas, it will be avoided by keeping near to the latter, and in going outside of it, keeping to the northward of Point Manare will clear it in that direction.

To the southward of Punta Gorda, distant 3 miles, lies Punta del Escarpado Roxo (Red Slope Point.) These form the entrance of the Gulf of Santa Fe, which runs about 6 miles inland to the eastward. All its shores are very clean; but at the entrance, at about one third of a mile from the north coast, lies a foul rock, that should not be approached within two cables' length. The depth of water in this gulf is from 27 to 15 fathoms, on mud bottom.

From the Point of Escarpado Roxo the coast inclines to the southward, and then to the westward, for 2½ miles, to Punta de la Cruz, forming a bay that is very clean, and affords excellent anchorage, called the Bay of Santa Cruz. About W. S. W., one mile from the latter point, lies the easternmost of the little islands called the Arapos, extending altogether to the westward about half a mile. They are very clean, except in the strait between them, which is impassable on account of a bank and reef that unites them together. The passage between the easternmost one and the coast is open, and without danger. Off the western part of the westernmost island there are two rocks, but they are very clean.

From Punta de Cruz the coast continues westward, inclining a little to the southward, nearly 4 miles to Punta Comona—the whole of it clean, and navigable within two cables' length of the shore, without the least risk. Westward from Punta Comona, almost 2 miles, is Punta de Pertigalete, in which space there is a fine bay, with 12 fathoms water within a cable's length of the shore. In the farther part of this bay there is a sandy beach where two small rivers discharge their waters. It is all very clean, except on the eastern part, which sends off a reef about a cable's length from the shore.

**MONOS ISLAND.**—In front of this bay, and about 3 cables' length to the northward of Pertigalete Point, lies the south coast of the Island Monos, or Guaracaro, the shores of which are steep and clean. About 2 cables' length from the north side there is a rock and a foul reef, which should not be approached nearer than half a cable's length: the channel between Monos and the rock is very clean, with 25 fathoms water; and in sailing through it will be best to keep closer to the island than to the rock. The channel between Monos and the coast is also very clean, with 45 to 50 fathoms water in the middle of it, and nearly the same depth near to the island, which should be kept close on board, if any thing prevents running through mid-channel.

One mile and a half to the westward of Pertigalete Point is Point Guanta, and between them is formed the Bay of Pertigalete, within which there are several islets, and a little river discharges into it. In case of anchoring here, it will be necessary to keep clear of the west side of Pertigalete Point, passing it at a cable's length at least, to avoid a reef which runs out from that part. It is also necessary to be careful to avoid a reef and shoal from the centre of the bay; which will be cleared by not getting anything to the westward of the most easterly part of the first islet to the north. With this attention a ship may be anchored nearly north from the mouth of the little river, in 4½ fathoms water, at about 1½ cable's length from the beach on the east side.

length to the northward, or Guaracaro, the north side there is half a cable's length; the water is deep; and in the rock. The channels are 20 fathoms water in the bay, could be kept close on

Guanta, and between several islets, and a little necessary to keep clear of at least, to avoid a reef and anything to the westward. With this attention a vessel, in  $4\frac{1}{2}$  fathoms wa-

To the westward of Punta de Guanta, and three miles distant, is Punta de Bergantin: between the two, and about a mile from the first, is the little bay of Guanta, in the mouth of which lie several islets and rocks, with very narrow channels between them, though very clean and navigable. Within the bay there are from 15 to 9 fathoms water, at half a cable's length from the shore: at the west front of the bay a reef runs off about 2 cables' length; but, by keeping over to the eastern side, which is very clean, every difficulty will be avoided.

THE PUNTA DEL BERGANTIN has a foul reef, which runs off about a cable's length, and extends about a mile to the southward. On the S. W. side of the Point there is an islet, so very foul all round as not to leave a clear passage between it and the point, from which the coast continues west, forming Bergantin Bay, the southern side of which has a foul reef that borders the coast westward as far as the Morro of Barcelona. This Morro is high land, lying nearly north and south one mile in extent: and joined to the main land by a very narrow isthmus, or tongue of sand, rather more than a mile in length.

The distance between Punta del Bergantin and the Morro of Barcelona, is  $4\frac{1}{2}$  miles, and the coast inclines to the southward, forming a large bay called Pozuelos Bay: all this tract of shore, which is a sandy beach and very low land, sends off a shallow bank a mile into the sea. Therefore, in navigating on this part of the coast, it is advisable to steer directly from Bergantin Point for the north point of the Morro, which is steep and clean, and may be passed within a cable's length; or, should it be thought preferable to go into the bay, the lead must be kept going, to avoid getting into less than  $7\frac{1}{2}$  fathoms water, sandy bottom.

The western side of the Morro of Barcelona is foul, and ought not to be approached nearer than 2 cables' length: from its north point to Punta Maurica, which is to the southward of it, the distance is about 4 miles: the coast, a low sandy beach, rounds in to the eastward; and in this part the River of Barcelona discharging itself into the sea, forms a large bank of sandy mud. About  $1\frac{1}{2}$  mile inland, on the left bank of the river, stands the City of Barcelona. To anchor in the bay, the lead will prove the best guide, for being very shoal, each ship may take a berth suitable to its draught of water.

On the coast from Cape Manare, besides the Caraca Islands already noticed, there are several others, called the Picudas, the Chimanas, and the Borracha. The Great Picuda lies to the westward of the west Caraca, with which it forms a channel rather more than a mile wide, free from all danger, except a sunken rock that lies about 2 cables' length to the eastward of the east point of Picuda. This Island lies about S. W. and N. E. and is little more than a mile in length: its shores are very clean: to the northward of its east extremity there are two rocks,—the first about one and the other 3 cables' length off. About S. W. by W. from the Great Picuda, at the distance of  $3\frac{1}{2}$  miles, lies the second Picuda,—an islet of a circular figure, about 3 cables' length in extent, and very clean. About S. S. E. from it at the distance of a mile, is the East Chimana, another islet less than the preceding, and equally clean. Two miles further west, is the east point of the second Chimana, which lies east and west about  $1\frac{1}{2}$  mile in length, and also very clean; to the eastward of it are two little islets, the nearest being about one cable's length off, and the other 5 cables; and on the west side is another little islet about a cable's length distant. About S. W. 2 cables' length from the west point of the second Chimana, lies the east point of the Great Chimana, which island is of a very irregular figure, and in its greatest extent, about E. by S. and W. by N.  $3\frac{1}{2}$  miles. To the westward of it, about one third of a mile, lies the West Chimana, joined to the Great Chimana by a shoal of rocks and sand, extending a full half mile to the northward of the north extremity of the Great Chimana; on this shoal, and midway between the two Islands, there is an islet, also another at a short distance from the west extremity of the West Chimana; and, finally, to the southward of the east part of the Great Chimana lies the South Chimana, that in its greatest extent from N. E. to S. W. measures 2 miles. This island forms two channels: one on the north with the Great Chimana, about a cable and a half wide, and very clean, with a depth of 20 fathoms, on mud; and the other to the south, between the Island and Punta del Bergantin, half a mile wide, and very clean: in passing through it the reef, which extends about a cable's length from Bergantin Point, is the only danger to be avoided. Between the Great and the South Chimana, there are several islets, all very clean.

From a recapitulation of what has been said of the Picudas and Chimanas, it appears that these islands and their islets are clean and steep to; the only dangers being the rock on the east of the Great Picuda, and the shoal in the channel between the Great and the West Chimana; consequently all the channels or passages between these islands and their islets are navigable, although some of them from being very narrow, are not so eligible for large ships: this circumstance, however, is a matter of choice for the navigator; in other respects he has no hidden danger to guard against.

**BORRACHA ISLAND**, (Drunken Woman's Island,) is about 3 miles to the westward of the West Chimana: it lies nearly north and south, in which direction it is rather more than 2 miles in length, and  $1\frac{1}{2}$  at its greatest breadth. All the east and north sides of it are clean: but on the N. W. a very foul rocky bank, with very little water on it, extends to a considerable distance, having on it several little islets; all of which should be passed on the outside, at 2 cables' length distance from the most westerly. From the south extremity of the island a large sand bank runs off about S. S. W. on which are situated an islet called Borracha, near the island, two small islets, called the Borrachitos, at the distance of two large miles from the Borracha. They should always be passed on the south side, at the distance of 3 cables' length from the southernmost of them; for between them and the Borracha, as well as between it and the principal island, the water is very shallow.

From the anchorage of Barcelona the coast trends to the S. W. and westward for the space of 32 miles, to the Morro of Unare, which lies about W. S. W.  $\frac{3}{4}$  W. 34 miles from the Morro of Barcelona. It thence inclines to the northward of west, then N. W. and lastly north to Cape Codera, distant from the Morro of Unare 57 miles N. W. by W.  $\frac{3}{4}$  W. and from that of Barcelona 85 miles N.  $76^{\circ}$  W.

The whole of this coast is low land, on which are seen the Morros of Piritu and of Unare, distant 7 miles from each other. The water is shallow along it, but it is very clean, and in approaching it the lead will be a sufficient guide. The two islands of Piritu lie nearly 12 miles to the westward of the anchorage of Barcelona, and about 3 miles from the shore: they lie nearly E. S. E. and W. N. W. are low like the coast, and have a reef extending a cable and a half's length from them. There is a passage between the two islands, but it is hazardous to attempt on account of the reefs on each side, which leave a channel of only 2 cables' length wide, with  $5\frac{1}{2}$  fathoms water. The passage between the islands and the main land is free for ships of any size; and in going through it there is no necessity for any other guide than the lead.

About due north from the Morro of Roldar, at the N. W. point of Margarita, about 40 miles, lies the southernmost of seven islets, called the Hermanos, or Brothers, which southernmost, at the distance of 2 miles therefrom, is called Pico; and from it the next, which is the largest and called Orquilla, the distance is 3 miles: the others lie to the north and N. N. W. of it: they are all very clean and steep to; so that there are no soundings in the passages between them.

**BLANCA.**—To the westward of the northernmost of the Hermanos, at the distance of  $7\frac{1}{2}$  miles lies the Island Blanca,\* or Blanquilla, about 6 miles in extent from north to south, and 3 from east to west: it is very flat and sterile, and the coasts are very clean, except the S. W. point, where there are several ridges of rocks extending about 3 cables' length from the shore; some parts of the west side, and off the north point, where there are some foul rocks extending 2 cables from the shore. On the N. W. part there is an anchorage, in from 18 fathoms at a mile from the shore, to 6 or 7 at 3 cables' length from it; all the bottom being sand. On the west side about half way, at a cove in the beach, there is a Cazimba, spring, or well, where fresh water may be obtained.

**TORTUGA.**—Westward from Margarita, at the distance of 47 miles, lies the east end of the Island Tortuga, (Turtle Island,) which thence extends about 12 miles to the westward, and is about 5 miles at its greatest breadth. All the east and N. E. sides are very clear, except at Punta Delgada, the N. E. extremity, where a reef extends off about 2 cables' length: the south side is also clean; but at the S. E. part are several islets. The west point of the island is named Punta de Arenas, from which to the north point, called Punta Norte, there are so many banks, that it will be necessary to keep the lead going while passing that space. On this side there is, first, Anguila Key, lying about half a mile from the shore, the intermediate channel being very foul with reefs; second, Cava Herradura, or Horse-shore Key, forming, with the coast, a channel of one mile wide, but too dangerous to be attempted by large ships; from the N. E. point of this Key, a ridge of rocks extends about  $2\frac{1}{2}$  cables' length eastward; thirdly, the Tortuguillos Keys, two in number, entirely surrounded by a bank, with little water on it. The anchorage at this island is between the Tortuguillos and its coast: it may be entered from the S. W. or from the north, through the channel formed by the Tortuguillos and Herradura Key. At the anchorage, and in all the channels, the greatest depth of water is from  $6\frac{1}{2}$  to  $7\frac{1}{2}$  fathoms, with sandy bottom in the middle. In going in the only care required is not to get into a less depth than  $6\frac{1}{2}$  fathoms.

\* Mr. AV. Waddy, Master of His Majesty's Ship L'Aimable, in his remarks says, "This island appears low, with white cliffs. You may sail round it without the least danger, and may anchor in the depth of 8 or 9 fathoms in Dampier's Bay, having the S. W. point of the island bearing N.  $\frac{3}{4}$  E. about the distance of a mile: the ground is a white sandy ooze. The current sets regular from E. to West."—March 9, 1796.

*Description of the Coast of Caracas and the Frontier Islands from Cape Codera to Cape St. Roman.*

CAPE CODERA, a place well known on this coast, is a very round morro, or hill, to the north of which about a mile, a tongue of low land projects, and is so clean that at half a cable's length from it there are 9 fathoms water, on sandy bottom. On the west side this tongue forms a very fine anchorage, named Puerto Corsarios, or Privateer's Bay; to enter which it is only necessary to double the west point of the tongue, close to which there is a farallon, or rock, and anchor so soon as there is shelter from the wind, wherever the depth of water may be suitable; with an understanding, that at two cables' length from the shore there are 7 fathoms water, on sandy bottom. At the south extremity of the bay, the coast, for a space of about 3 cables' length, is a low swampy beach, to the westward of which it is foul, with a reef stretching about half a cable's length from the shore. The west point of the bay, named Caracoles, has on the north side a rock close to it, from which a reef extends about a cable's length.

From Cape Codera the high mountains of Caracas are visible, extending east and west many leagues. Nearly 14 miles N.  $\frac{1}{2}$  W. from the Cape lies an islet, which appears like a ship under sail: it is very clean, except about a musket shot to the north, where there are two sunken rocks, having between them and the islet a channel of great depth.

From Point Caracoles, the coast runs in the direction of W. N. W. a distance of  $9\frac{1}{2}$  miles to Point Maspa, whence it trends W. by S.  $2\frac{1}{2}$  miles, to Point Chuspa, which is the eastern extremity of an anchorage of the same name. All this space is bordered by a reef, which extends one mile northward from Point Maspa and terminates at Point Chuspa; for this reason it should not be coasted at a less distance than 2 miles.

The anchorage of Chuspa is excellent: from the Point Chuspa, which is the N. E. point of the bay, the coast runs about S. W. for a mile and a half, to the mouth of the River Chuspa, on the east bank of which stands the town of Chuspa, about 2 cables' length from the beach.

From the mouth of the river the coast rounds to the westward for the distance of  $1\frac{1}{2}$  mile to Point Curuan; to the southward of which, at about one third of a mile inland, stands the town of Curuan. From Point Chuspa to that of Curuan all the shore is very clean, and the only guide required for entering the anchorage will be the lead; but from Point Curuan the coast is very foul with a reef extending 2 cables off, and continuing so to la Punta del Frayle, (Friar's Point,) with a farallon, or rock of the same name, about a cable's length from it. This point is nearly 4 miles from Point Curuan; between the two points there is a projection to the north, called de Sabana; and to the north of it lies a bank, the south edge of which is about a mile from the shore: its greatest extent is about a mile from S. E. to N. W. on rocky bottom; and although the general depth on it is from 8 to  $4\frac{1}{2}$  fathoms, in some places there are only  $3\frac{1}{2}$ , and even less than 3; for which reason it should be carefully avoided. It lies 3 miles from the anchorage of Chuspa; and as in fetching that place it will be necessary to pass near to Point Chuspa, there can be but little risk in approaching it; it will, however, be entirely cleared, by taking care to be to the northward of the parallel of Point Chuspa, before crossing the meridian of Curuan.

From Point del Frayle the direction of the coast is S.  $86^{\circ}$  W. for the distance of 29 $\frac{1}{2}$  miles to the anchorage of La Guayra,\* on every part of which a ship may be anchored at half a mile, or even at a musket shot's distance, from the shore.

THE PORT OF LA GUAYRA, with respect to its commerce, is the principal one on this coast: it cannot properly be called either a harbor or a roadstead, but a continued coast, with a little sinuosity between Point Carabellera on the east, and Cape Blanco in the west; consequently, it affords no shelter from winds in the N. E. and N. W. quarters; and the trade wind from the eastward, which constantly prevails, sends in a heavy sea. To prevent ships from thwarting the sea when the wind subsides, or falls calm,

\* About 3 miles to the eastward of La Guayra, is the little village of Macuto, situated in a small bay of that name, and is an excellent place for watering. The water is procured from three iron pipes or spouts, distant about 84 feet from the beach. There is good anchorage all over the bay, and the soundings are very regular in approaching the watering place. On going in towards the village, keep the watering place in a line with the N. W. corner of the chapel, and the highest cocoa-nut tree, over the east angle of the fort west of the village.

There is a depth of 20 fathoms at about three quarters of a mile from the shore, with a street of the village, close by the watering place, open or end on; and the easternmost point about a sail's breadth open of the point to the westward of it. Remark book of H. M. S. Salisbury, Captain John Wilson, 1819.

they are generally moored with a cable astern to the westward: the bottom is good holding ground, and at a cable's length from the shore there are nearly 3 fathoms water. In this anchorage, it is seldom that any other wind than the trade is experienced, which, however, sometimes, for short intervals, does veer to the west; in which case, the position of the ship should be changed, and her head placed to the westward: there are seldom any land winds, but there are squalls from the S. E. during the rainy season. Although, from the nature of its locality, La Guayra cannot be considered as a port or an anchorage, yet, from the nature of the climate, it is both, in which with fresh, or indeed with hard gales, ships at anchor are not exposed to danger.\* Ships from sea bound to the anchorage of Lagnayra, will have a good mark in a very high and steep peak, called the Peak of Cares, situated about 9 miles inland, and 20 miles to the eastward of the anchorage. At about 10 miles to the westward of this peak is another called the Peak of Niguatar; and thence a range of mountains extending towards Lagnayra, among which the Silla de Caracas, (Saddle of Caracas,) and Mount Avila may be very well distinguished; the latter being about 2 miles inland, and nearly on the meridian of the anchorage. It is advisable to make the land well to windward; there will then be no danger in running down to the anchorage. Cables are sometimes injured here by some anchors lost by the English in one of their expeditions against this place.

From the anchorage of La Guayra the coast first runs west for the distance of six miles, and thence west by south twenty and a half miles, to the little harbor of Cruz, and is sufficiently clean to be run down at the distance of a mile. This port is a small indent in the coast, with an entrance about one and a half cable's length wide, and two cables in extent inward; very clean, for at half a ship's length from the coast, all round, there are  $4\frac{1}{2}$  fathoms water. At its south extremity a little river discharges its water; and off its eastern point, called Point la Cruz, there is a rock close to it. Were it of greater capacity, this anchorage would be excellent, but it is so small as to be eligible for small vessels only.

From Port la Cruz the coast trends S.  $82^{\circ}$  W., a distance of 23 miles, to the Bay of Cata. It is all very clean and may be approached with safety to the distance of a mile, or less. About 2 leagues to the eastward of this bay, and 5 miles inland, will be seen Monte de la Meseta, (Table Mountain,) and at about the same distance inland, on the meridian of Cata, another, called Mount Ocumare. These will serve as marks for taking Cata Bay, or the anchorage of Ocumare, which is farther to the westward.

Cata Bay is half a mile wide at the entrance, and about as much in depth. At the eastern point there is an islet lying almost close to it; and from this point the shore trends to the south to the extremity of the bay, where a river falls into it, throwing up a bank, with little water on it, which extends almost a cable's length from the shore. Every other part of the bay is clean, with a depth of water from 25 to  $4\frac{1}{2}$  fathoms, about  $1\frac{1}{2}$  cable's length from the beach.

Two thirds of a mile westward from the west point of Cata Bay is the eastern point of the Bay of Ocumare, in which there is very good anchorage. An islet lies off the east point, in a N. W. direction, forming with it a strait, or channel, of about half a cable's length wide, very clean, and with a depth not less than 6 fathoms. In taking the anchorage in this bay, pass close to the islet, and steer to the south until shelter is obtained from the wind; then anchor in 6 or  $6\frac{1}{2}$  fathoms, on sand, at about a cable's length, or a little more, southward of the islet. The bay has many banks in it, but the lead is a good guide. Care must however be taken; for as the anchorage narrows to the southward, a large ship may possibly touch the ground, unless attention be paid to luff and stop her headway in time. A river falls into this bay to the southward of the islet, having on its banks a few fishermen's huts.

Two miles and a half westward from the islet of Ocumare lies the east point of a bay, called Cienega de Ocumare, (the Bog or Quagmire of Ocumare,) which is, in fact, no more than a swampy opening in the land, and which, between shoals of a reef, has a channel of 12 to  $4\frac{1}{2}$  fathoms water. The west point of this bay is formed by an isolated

\* Captain F. Chamir says, "La Guayra cannot be called any thing else than a dangerous roadstead; but as the trade wind blows right along shore, by being prepared, a ship may always clear the land. The town and fortifications, which may be distinguished at a long distance, mark the anchorage; the former bearing S. by E., in a depth of 10 fathoms, at  $1\frac{1}{2}$  mile from the shore, is as secure as any other. The Rollers are very heavy, and oftentimes it is dangerous to attempt landing. The ground is very bad for holding, and in a good strong sea breeze you may expect to bring your anchors home."

Capt. G. G. Lennox, in his remarks on this place, observes that, "although during the hurricane of 1815, at the Leeward Islands, they did not experience any wind here, yet there was a very heavy swell at the anchorage, which drove the vessels from their anchors on shore, and dashed them to pieces against the rocks."

morro that rises on the low land. The anchorage is very bad, and fit only for small coasting vessels.

One mile and a half to the westward of the Morro of Cienega is the Harbor of Turiamo, which is excellent, and capable of receiving every class of ships. At the exterior points it is about a mile broad, but decreases inwards to two thirds of a mile. From the entrance to its south extremity is about two miles, and the general depth in mid-channel is from 25 to 18 fathoms, on mud and sand. All its shores are bordered by a reef, extending off about one third of a cable: therefore, by not approaching nearer than half a cable's length, all danger will be avoided. At the farther extremity of the harbor the River Turiamo discharges itself on a sandy beach. Off the east point, at a cable's length in a N. W. direction, lies Turiamo Islet.

From the Harbor of Turiamo westward, at the distance of 9 miles, is Porto Cabello. This part of the shore is very clean, and may be coasted at the distance of a mile. There are various detached islands lying off it to the eastward of Porto Cabello; and for sailing by or between them, sufficient information will be obtained by inspecting the Plan of the Port, published at the Hydrographical Office, which includes all these islands.\*

Porto Cabello is a channel formed by several islets and tongues of low land, covered with mangroves. Ships desirous of entering must be warped into it; and those of the largest size may be made fast to the mole, not requiring even the use of a plank to land from them. The mouth of this channel opens into a spacious bay, with excellent anchorage, in 10 to 12 fathoms, sandy mud, and well sheltered from the trade wind. Being in  $4\frac{1}{2}$  fathoms will be near enough to the beach, which is rocky and foul. The best berth is about west from the harbor's mouth, at the distance of 3 or 4 cables' length, in 11 or 12 fathoms. In this harbor all Spanish merchant ships that go to La Guayra are careened, and winter. Each ship, so soon as she has delivered her cargo at La Guayra, proceeds to Porto Cabello for greater security, to receive such repairs as may be necessary, and take in part of the homeward bound cargo. She then returns to La Guayra to complete her lading. At Porto Cabello there is always a body of good shipwrights, &c., although it is not very numerous. Ships of war should only enter the harbor when it may be necessary to careen them: for other purposes it is not only useless, but it is prejudicial. They should therefore always remain in the bay; for the excessive heat in the harbor, the mangroves with which it is surrounded, added to any degree of intemperance, occasion almost immediate attacks of putrid fevers and the black vomit, both of which are very fatal to Europeans.

The coast to leeward, or to the westward of Porto Cabello, forms a great bay, called Tucacas, or the Gulf of Triste, (Doleful or Dreary Gulf,) in which there are several islets. With the trade wind it is a lee shore, and rather dangerous. Ships from Europe should keep clear of it, as there can be no inducement to take them in. Point Tucacas, the north point of this gulf, bears N.  $28^{\circ}$  W., 25 miles from the mouth of Porto Cabello: therefore vessels bound westward from that port should steer about N. by W. until they are abreast of Point Tucacas, or N. N. W. if they intend to keep close in with the point, in order to take the anchorage at it, called Chichiriviche.

Point Tucacas is formed by a low swampy land, covered with mangroves, which projects out from the high land about a mile. On the east side of it there is a key, about a mile in length from S. E. to N. W., called Sombrero, between which and the coast there is a channel barely half a mile wide; and although there are 11 fathoms water in it, it is dangerous from shoals, and the reefs extending from the coast. A key on the N. E. side of it is also surrounded by a reef of two cables' breadth, which should not be approached at less than a mile distant. From Point Tucacas, which is to the westward of the most northerly part of Sombrero Key, the coast runs about N. W. It is low and foul, with a reef half a mile broad, which extends so far as the mouth of the harbor of

\* It appears by the remarks of Captain James Murray, of H. M. ship *Valorous*, that there is a very good and spacious anchorage between Isla Larga, or Long Island, and the main, and about  $3\frac{1}{2}$  miles to windward of Porto Cabello. There is plenty of room for a large fleet, in 10 or 12 fathoms water. You may sail into, or out from, this anchorage, through between any of the islands; but the best passage is considered to be round the east end of Long Island, between it and the main, in order to take a berth well to windward.

The *Valorous* anchored here on February 27, 1823, in eleven fathoms, with the S. W. end of Long Island bearing N. N. W. by compass, distant two cables' length; the east end of the island east, and the fort on the hill above Porto Cabello W. S. W., distant 3 or 4 miles. This is a very good place to get wood; and fresh water may be procured from the river on the main a little to leeward.

It is necessary to be cautious of a shoal that lies about a cable's length to the southward of the west end of Long Island.

Chichiriviche, distant 3 miles from the point. This harbor is formed by low lands covered with mangroves, and although well sheltered from all winds, with  $6\frac{1}{2}$  fathoms, good holding ground, the entrance to it is a little difficult on account of shoals and reefs. The east point, called Chichiriviche, presents a front of rather more than a mile in length, from which a reef runs off about three cables' length, having on it several islets that must be passed on the outside. To the north of these there is a key, called Peraza, with a foul reef all around it, half a cable broad. This key, and the islands off the point, form a channel two cables' length wide, with upwards of 7 fathoms water. To the westward of Peraza Key lies another, called Chichiriviche Key, larger than the former, and also surrounded by a reef of a cable's length broad. Between these two there is a channel rather more than two cables' length wide, with 6 and 7 fathoms water in it. To the west of Chichiriviche Key lies the west point of the harbor, forming between them a channel of  $2\frac{1}{2}$  cables' length wide, with  $5\frac{1}{2}$ , 6, and  $7\frac{1}{2}$  fathoms. There are, however, two shoals in it, with only 2 fathoms water over them. At half a mile north from Chichiriviche Key, there is a large one, called Salt Key, from the salters in it. This key is also surrounded by a reef, nearly a cable's length broad, except on the S. W. part. Finally, about N. by E., at the distance of  $1\frac{1}{2}$  mile from Salt Key, lies Borracho Key, which is very foul, with a reef extending half a mile from the N. E. and S. points of it. All this part of the sea just described is of so regular a bottom, that at somewhat more than one half a mile from the coast there are  $6\frac{1}{2}$  fathoms, which depth continues so far as 2 miles north of Borracho Key, where there are 14 fathoms, on sandy mud. To enter this harbor, observe that on getting abreast of the northernmost part of Sombrero Key, which should always be passed on its outside, place the ship's head toward Peraza Key, and on approaching it steer west, so as to pass in the middle of the strait between it and the islets off the point, until Peraza Key bears N. E. by E., and then S. W. by W., edging towards the south, so soon as the largest islet off Point Chichiriviche bears east; thence run under shelter of the point, luffing up to S. S. E. and there anchor in  $6\frac{1}{2}$  fathoms, mud. The plan of this harbor will show all that is necessary to be done, either in going in or coming out.

From the Harbor of Chichiriviche, the direction of the coast is N. N. W.  $\frac{3}{4}$  W. for the distance of 18 miles, to Point St. Juan: the ground in all that tract is so regular, that at the distance of 4 miles, there are only 14 fathoms water: the only danger is a small shoal, called La Piragua, lying off a little point, named Manatie, about four and a quarter miles before arriving at Point St. Juan: it does not, however, extend more than a mile from the shore.

Point St. Juan forms, on its west side, a large bay, but so shallow, that at a mile from the beach, there are no more than  $3\frac{1}{2}$  fathoms water. N. W. of the point there are two Keys: the first, half a mile distant, called St. Juan's Key: and the second, nearly 2 miles farther, named the N. W. Key. On the N. W. side of Point St. Juan, a reef stretches off about 2 cables' length; and the Key of St. Juan is surrounded by another about half that breadth. The N. W. Key is also surrounded by a reef that extends out about half a mile from its S. E. point, having on it several keys and islets. The anchorage is to the S. W. of St. Juan's Key: in order to take it, it will be necessary to pass to the northward and westward of that Key, and anchor in any depth of water suitable to the ship's draught. It is directed to pass outside of St. Juan's Key, because the channel formed between it and the Point is eligible for small vessels only; not alone from its narrowness and the foulness of the reef, but because the greatest depth of water is only  $3\frac{1}{2}$  fathoms.

From Point St. Juan the direction of the coast is about N.  $60^{\circ}$  W. for the distance of 19 miles, to Point Ubero, the whole space being clean, and the depths regular; but there is a farallon, or rock, lying near a rocky or cliffy part of the shore, about 8 miles from Point St. Juan, called Penon del Soldado. On the west side of Point Ubero there is a bay, but being very shallow, it scarcely affords any shelter for large ships, from the Trade Wind. About N. N. W. one and a half mile from this Point, there is a bank, over which the least depth is four and a half fathoms: on it there are some loose rocks.

From Point Ubero to that of Zamuro, the distance is 12 miles, N. W. by W.: and from Point Zamuro the coast runs N.  $77^{\circ}$  W. forming various sinuosities for the distance of 25 and a half miles, to Point Manzanillo, and thence S.  $83^{\circ}$  W. 14 miles, to Point Taymatayma. All this coast is clean, and the soundings regular, requiring no other guide than the lead to run along it at half a league distance; and in the interior are several heights that may be seen far at sea. Between the Points Manzanilla and Taymatayma the coast bends in to the southward; and at the distance of 5 miles S.  $62^{\circ}$  W. from the former, is the Bay of Cunnarebo, being a sandy beach so called: the town of the same name standing on a hill at the distance of 3 miles S. E. from it. N. N. W.  $6\frac{1}{2}$  miles from the sandy beach, and N.  $65^{\circ}$  W.  $7\frac{1}{2}$  miles from Point Manzanilla, lies the rocky bank of Cunnarebo, with  $5\frac{1}{2}$  fathoms water on it, and from 11 to 18 fathoms very near to it. From Point Taymatayma the coast trends S. W. by W. about 4 miles, to Point des Frayles,

by low lands covered with  $6\frac{1}{2}$  fathoms, of shoals and reefs, more than a mile in length, on which several islets are, called Peraza, and off the point, Peraza. To the westward of the former, and to the north, there is a channel in it. To the south, between them are, however, two more, from Chichiriviche. This key is also W. part. Finally, the Key, which is the largest of it. All this is more than one mile long. To enter this harbor, which is Peraza Key, and on the west side, and the islets by W., edging to the east, there is a shoal in  $6\frac{1}{2}$  fathoms, either in going

N. N. W.  $\frac{3}{4}$  W. for the distance of 12 miles, the danger is a small one, at four and a quarter miles, and more than a mile

at a mile from the point there are two more, nearly 2 miles long, a reef stretches off to the northward, about half that length, and about half a mile long. The anchorage is to the S. W. of the northward, to the ship's draught, and is formed between it and the narrowness and the shoals,  $3\frac{1}{2}$  fathoms.

For the distance of 12 miles, the danger is a small one, at four and a quarter miles, and more than a mile at a mile from the point there are two more, nearly 2 miles long, a reef stretches off to the northward, about half that length, and about half a mile long. The anchorage is to the S. W. of the northward, to the ship's draught, and is formed between it and the narrowness and the shoals,  $3\frac{1}{2}$  fathoms.

For the distance of 12 miles, the danger is a small one, at four and a quarter miles, and more than a mile at a mile from the point there are two more, nearly 2 miles long, a reef stretches off to the northward, about half that length, and about half a mile long. The anchorage is to the S. W. of the northward, to the ship's draught, and is formed between it and the narrowness and the shoals,  $3\frac{1}{2}$  fathoms.

on the east side of the Bay of La Vela de Coro. This bay has an anchorage, and, in proceeding to it, no other guide than the lead is required, as the bottom is regular and clean. At the S. E. part of the bay stands the town of La Vela de Coro; and about two miles inland to the eastward of it, an Indian village, called Carrizal. The River Coro falls into the sea  $1\frac{1}{2}$  mile west of the town.

From the River Coro the coast turns abruptly to N. W.  $\frac{3}{4}$  N. forming a chain of sand hills about 19 miles in length, uniting the Peninsula of Paraguaná with the coast; these sand hills are called the Isthmus of Medanos, or Sand Hills. The Eastern Coast of this Peninsula trends true north for 15 miles, to Point Auricula, which bears N.  $24^{\circ}$  W. from the Bay of Coro, and distant 33 miles: all the coast has very regular soundings, there being 18 fathoms at the distance of 10 miles from it.

From Point Auricula the coast trends from N. by W. to N. W.  $\frac{1}{2}$  N. a distance of  $16\frac{1}{2}$  miles, to Point Tumatey, and thence about W. N. W.  $3\frac{1}{2}$  miles, to Cape San Roman, the northernmost land of the Peninsula. The mountain of Santa Anna, on the Peninsula Paraguaná, may be seen from the sea at the distance of many leagues.

Due north from Cape Codera, at the distance of  $23\frac{1}{2}$  leagues, lies the Island of Orchila, rather flat, its greatest extent is from east to west. On its North Coast are some peaks, the highest of which is at its western extremity. Off the east end a Key runs to the northward about 3 miles; and, to the westward of it, a great reef extends in that direction, nearly half the length of the island: there are several keys on the reef. All the rest of the coast is clean, and may be approached to a cable's length. On the S. W. part near the western extremity, there is a very clean sandy beach, in front of which there is a good anchorage, well sheltered from the trade wind, in 6 and 7 fathoms water, within a cable and a half of the beach. Half a mile W. N. W. from the west point of the island, there is a high rock, very clean and steep, forming a passage eligible for ships of any burthen.

S. W.  $\frac{1}{4}$  W. from Orchila, and S. E. by E.  $\frac{3}{4}$  E. from the east end of the Roccas, there is a shoal with 3 fathoms water; the form of the shoal is nearly round, and is about  $1\frac{1}{2}$  mile round. Long, corrected by the Roccas,  $66^{\circ} 27'$ , lat.  $11^{\circ} 42'$ .

The ROQUES.—Twenty-two miles to the westward of Orchila lie the Roques, an assemblage of low keys raised on a very dangerous reef. This group occupies a space of 12 miles from north to south, and 23 from east to west; of which the S. E. Key, named Grande, is 6 miles from east to west, and nearly the same in breadth. To the westward of it is Key Sal, upwards of seven miles in length nearly east and west, very narrow; and to the northward and westward of Key Sal, there lie a great number of smaller ones, without any passage between them. The northernmost group consists of El Roque, nearly two miles in length E. by S. and W. by N., the French Keys, four in number; the N. E. Key, Naman's Key, and Pirate Key. All the exterior keys on the edge of the reef may be passed at a mile distance, except on the eastern side, where the reef extends upwards of three miles beyond them. The passages between the keys must not be attempted, as most of them are barred by the reef, except on the west side of El Roque Key, where there is an entrance into a very fine bay, formed by the other keys and reefs, in which there are from 13 to 20 fathoms water; but a foul rocky bottom frequently does great damage to the cables. The anchorage is on the west side of the key, in 17 or 18 fathoms water, on sand and mud, and about three cables' length from the beach. The Roque Key may be easily distinguished by several peaks on it, that may be seen at a moderate distance. It will be most prudent to give all these keys a wide berth, as the vicinity of them will be perilous to a ship, particularly at night.

PORT EL ROQUE.—In October, 1827, while his Majesty's sloop *Arachne*, captain W. R. A. Pettman, lay at the above anchorage, a very fine harbor was discovered to the eastward of El Roque, and surveyed by lieutenant, now commander, E. O. Johnes: it is sheltered on the north by the French Keys, from the east by the N. E. Key and the reef, and on the south by Pirate and Naman's Key, and their reefs. From the Plan published at the Hydrographical Office, it will be seen that there is a space of about two miles in length, and half a mile wide at the narrowest part between the reefs, where ships may anchor in from 12 to 14 fathoms, and five entrances, or outlets, quite clean.

The Instruction says, "Port El Roque presents considerable advantages, as a safe and convenient anchorage, over that which seems to have been heretofore made use of by ships of war, and in which his Majesty's sloop *Arachne* came to anchor; as it will be evident by a reference to the Plan, that from whatever quarter of the compass the wind might blow, a vessel could scarce find a difficulty in getting to sea. Nor, from the manner in which it is locked in, by the keys and reefs, (a circumstance, of course, productive of a constant smoothness of water,) is it probable she could receive any injury, should her commander deem it necessary to ride out a gale at her anchors.

"Beside which, a ship will find another important advantage over the old anchorage—that of having, almost invariably, a clear unobstructed trade breeze across the reef, which can bring with it no decaying vegetable, or other impure effluvia, to render the place un-

wholesome: a circumstance not unlikely to occur, to the detriment of a ship's company's health, in the road where the Arachne lay, from its leeward proximity to a mangrove marsh.

"The channels are clean, and, without an exception, steep to the reefs on either side, which are of coral, and have scarcely sufficient water on their edges for a four-oared gig; thus displaying, by the contrast between the shades of deep and shallow soundings, a secure guide to a stranger on entering. The bottom is mostly of a hard sandy nature, though there was found a patch of stiff clay off the N. E. point of Pirate Key, in thirteen fathoms.

"The islands, with the exception of El Roque, appear to be of a coral formation, with a light sandy soil, thickly covered with the sapphire plant: most having salt marshes, either in their interior or just within the reefs, which are skirted with mangrove and other timber trees, affording shelter to innumerable families of boobies, and other aquatic birds; as the marshes likewise abound in several delicious kinds of the snipe genus, that are by no means difficult to be got at.

"Fish of excellent quality may be caught in plenty, either with a seine (the method we adopted) or by anchoring in a boat near the reefs, and employing hook and line for that purpose. The only quadruped that came under observation, was a small description of rat, several of which were met with in visiting the peaks of El Roque. Those heights are of limestone, which is removed by slaves, and burnt in a kiln at their foot, (the property of a Dutchman,) and then conveyed to the island of Curazao, to be made use of in the erection of forts, and for other government purposes. Turtle are met with, but not numerous.

"Ships requiring small plank, fine wood, boats' knees and breast hooks, can be well supplied, for the labor of cutting them, though it is recommended, should time admit of it, to have it always barked, split, or sawed up, before embarkation, as, should the sap lodge upon decks or any thing else, the stains would be found difficult to eradicate. There is a well of water upon the S. W. end of El Roque. The supply is uncertain, never, however, exceeding 80 gallons a day. The lime burners obtain what they make use of, by digging wells in the sand; and although that which was tasted was of an indifferent quality, it is not improbable that by a deeper excavation, better may be procured.

"A stranger, in running for the harbor, is recommended to pass to the westward of the peaks, and then stretch across towards Blackman's Key, which may be easily known, as appearing, without the use of a glass, like a single large rock, (though actually a low islet with bushes on it,) until he can fetch through the south channel, which will open clearly to sea at the bearing of N. 16° E., per compass, when he can pass with safety between Pirate Key on the larboard, and a small dry sand bank on the starboard side, both of which are bold within the channel; but a reef extends 333 fathoms off the S. S. W. end of the former, which, like all others, is easily traced from a vessel's deck by the eye.

"On the full and change of the moon, it is high water at 4h. 30m. P. M. Spring tides rise 3 feet perpendicular."

**ISLAS DE AVES.**—Thirty miles to the westward of the Roques are the Islas de Aves, (Bird's Islands,) which are two groups of keys, rising upon two distinct reefs, and forming between them a channel of 9 miles in breadth. These keys are very low and flat; and as the east group has a reef extending 4 miles to the north from it, and the western another, extending 6 miles in the same direction, it results that an approach to them, especially from the north, is extremely dangerous; and therefore they ought to be given as wide a berth to as any other dangerous shoal.

**BUEN AYRE ISLAND.**—To the westward of Aves, and at the distance of 33 miles, is the island of Buen Ayre. It is of moderate height, with several mountains and peaks on it, the most elevated of which is close to the north point. The south point of the island is rather low and flat, and called Point Rasa del Lacre. About the middle of the west shore, there is a town and a small fort. There also is the anchorage, which is so steep that at  $1\frac{1}{2}$  cable's length from the shore, is a depth of 17 fathoms, and it increases so rapidly that at a cable's length further out there are 60 fathoms. For this reason it is necessary to run out and make fast a cable to the shore. Small ships should always be prepared, in order to prevent the anchor from dragging; for should she be driven from the anchorage, it will cost much trouble to regain it. From the west part of the anchorage, at the distance of a mile, lies an island named Little Buen Ayre; and although the passage formed by it on the N. E. will admit ships of any size, yet it will be preferable to use the S. W. channel, as being more free, both inward and outward. There is no danger whatever to be apprehended at the distance of a cable's length from all the coast of Buen Ayre, except on the east side, where a reef runs out in some places more than half a mile; but the N. E. and S. E. points are very clean.

**CURAZAO ISLAND.**—Twenty-seven miles westward from the south point of Buen Ayre lies the S. E. point of the island Curazao. It thence extends about N. W.  $\frac{1}{2}$  W.

35 miles, but some mountains are very close by E. from the sandy island, dangerous of this island, that on the than the reef (1826) in c and bearing mountain c passed with no bottom.

35 miles, but the greatest breadth does not exceed 6 miles. It is moderately high, with some mountains, that may be seen from a considerable distance at sea. All its coasts are very clean, and may be passed at the distance of a cable's length, without risk. S. E. by E. from the S. E. point, named Canon, at the distance of 4 miles, there is a little low sandy island, named Little Curazao, which, although very clean, is, from its lowness, dangerous at night and in thick weather. Lieutenant D. F. Campbell says, "No part of this island appears elevated more than 6 or 8 feet above the level of the sea, except that on the west end there are two small clumps of mangrove bushes, showing higher than the rest of the island. The crew of a Dutch National Corvette had been employed (1826) in erecting on the east end a large cairn of stones, having on its top an old tree, and bearing at a distance a great resemblance to a martello tower. It bears from the mountain of Sta. Barbara, on the S. E. side of Curazao, E. by S. by compass. He passed within half a cable's length of the N. E., N. and N. W. sides of the island, and got no bottom with a line of 40 fathoms."

The island of Curazao has many bays and harbors, the principal of which, where the whole commerce of the island is carried on, is St. Anne's, on the west coast, situated at the distance of  $14\frac{1}{2}$  miles from Point Canon. To the eastward of this, about six miles, is another bay, named Sta. Barbara. In proceeding to the Harbor of St. Anne, it will be proper to make Point Canon, so as to run down the coast at one or two miles' distance, taking care not to get to leeward of the harbor's mouth, as the current sets with considerable strength to the westward. The entrance is very narrow, and formed by tongues of low land. That in the inner part also forms large lagoons. On the eastern point stand Fort Amsterdam and the principal town of the island, inhabited by Protestants and Jews. On an islet close to the west point there is a battery, which, with Fort Amsterdam, defends the mouth of the harbor; and on the western shore stands the town inhabited by the Catholics. The channel leading into the bay runs in about N. E. by N., is three quarters of a mile long, and a cable's length broad, except between the forts at the entrance, where it is barely half that breadth. The towns, wharfs, and magazines, are on the banks of this channel, where also ships anchor and are careened. To enter the channel it is necessary to keep the windward coast close on board, but not within half a cable's length, as there are rocks and also a reef, extending about one third of a cable from it; and on getting abreast of the batteries on the point of Fort Amsterdam, luff enough to bring the ship's head towards the battery on the islet at the west point, and then stand inward through the middle of the channel. The Dutch always have a launch ready to assist in towing ships into the harbor.

ORUBA ISLAND.—At the distance of 43 miles to the westward of the most northerly part of Curazao lies the S. E. point of the island of Oruba, which extends thence nearly N. W. 17 miles, and is 4 miles wide. Although low there are some heights upon it, that may be seen at a moderate distance off, particularly one, which, from its resemblance to, is called the Sugar Loaf. All the eastern coast is very clean, and has some islets close to it. On the western coast there is a chain of keys, extending almost so far as the west point. These may be coasted on the outside, at the distance of two cables' length, if necessary. This island lies to the northward of Cape St. Roman, the intermediate channel being 13 miles wide, and very clear.

Lieutenant D. F. Campbell, commanding his Majesty's schooner *Monkey*, visited Oruba in September, 1826. From his remarks we extract the following:—"The island is moderately high; the east part even, and gradually lowering to a point. The west end, at a distance, appears like broken hummocks. The Sugar-loaf Hill, which is about 7 miles to the N. W. point, is the highest in the island, and may be seen at the distance of 18 or 20 miles. A chain of low bushy keys stretches along the south shore, bold to, having, at a cable's length off, no sounding with the hand lead. These keys terminate in a rocky islet, considerably higher than the rest, about three miles to the westward of the east point, and two cables' length off shore. About three miles to the westward of the Sugar Loaf there is a projecting point, having an opening between the keys to leeward of it. To take the shelter afforded by this point, it is necessary to get close in with the land so far to windward as the Sugar Loaf, and run along shore till the port bears N. N. W., when the flag-staff will come on with a small red house standing by itself on a hill behind. These marks kept in a line, will lead clear of a rocky ledge at the extremity of the point. To leeward it is all clear. When far enough in to be sheltered from the breeze, you may anchor in 4 to 5 fathoms, on sandy bottom. There are, however, some rocky patches to be carefully avoided. It is particularly necessary for a stranger to get close in with the keys well to windward, otherwise the current will sweep him so far past the opening, as will require half a day to beat up again. There is also good anchorage in from 5 to 12 fathoms under the west end of the island; but as procuring provisions, or temporary refit, can be the only inducements for visiting Oruba, it is advisable to go into the harbor, which is distinguished by the town along the beach, close to

leeward of the sandy point, and named Port Caballos. The pilots are skilful and attentive; and the anchorage within the reefs and close to the town, in 3 fathoms water, sandy bottom, is very good. Fresh water is scarce, there being no spring. It is collected in tanks in the months of September and October, but is good and wholesome."

The following is from the remarks of Capt. T. W. Carter, of his Majesty's ship *Emulous*, October 1, 1815:

"The best anchorage about this island is on the south side, about 4 or 5 miles to the north-westward of the village. You may anchor on a white shoal in about 7 fathoms, with a low and very white sandy point bearing N.  $\frac{1}{2}$  E., a remarkable mountain, nearly resembling a sugar-loaf, at the back of the town E. by S., and the easternmost extremity of the land S. E., at three quarters of a mile off shore. You must look for a clean spot to drop your anchor, as some parts are rocky. Water may be procured here by digging a few feet in the sand, at a short distance from the beach."

#### *The Gulf of Venezuela, or of Maracaybo.*

From Cape St. Roman the coast runs S. 62° W. a distance of 13 miles, to Point Macolla. It is all shallow and clean,\* and may be safely approached by the lead. This point, and Point Espada, (Sword Point,) which lies nearly west from it, at the distance of 50 miles form the entrance of the Gulf of Venezuela, or of Maracaybo. The south extremity of this gulf opens into the Great Lagoon of Maracaybo, by a Delta that has but one mouth navigable, and that only for vessels drawing no more than 12 feet water, as there is a bar, upon which there is no more than 14 feet. Hitherto no chart of the coasts of this gulf has been drawn from actual survey, nor is the situation of the bar accurately laid down; yet, from practice, the course to it is tolerably well known, both from Point Macolla and Point Espada. The Hydrographic Commission, under the command of Captain Don Joaquin Francisco Fidalgo, surveyed and drew a chart of that part of the east coast from Point Macolla to Point Arenas, which is a little to the eastward of the bar. The inspection of this chart will prove a sufficient guide; and as the water is shallow, but without banks, or detached islands, the lead is the best guide that can be recommended. The same may be recommended for the west coast, which, though not surveyed, has been well explored; and it is ascertained that it may be safely approached to the depth of 6 or 5 fathoms, in every part. Those who enter this gulf have generally no other object in view than to proceed to the lagoon, for the purpose of loading with cocoa, tobacco, and other produce. We shall, therefore, now proceed to give some instructions for navigating it with certainty.

Being four leagues to the westward of Cape St. Roman, and thence steering S. W. by S. will take a ship in sight of the Mesas of Borjo, which are some level hillocks, or sand hills, situated to the east of the Bar. From this situation steer about west, keeping at the distance of 2 leagues from the coast, and in from 4  $\frac{1}{2}$  to 5  $\frac{1}{2}$  fathoms water, until the Castles of Zapara and San Carlos appear in sight: these defend the entrance of the Lagoon, and are placed, the first on the eastern point, and the second on the western.—They are not, however, on the Bar, but rather to the southward of it; the Bar itself being formed by the shoals, which extend out W. N. W. to the distance of 2  $\frac{1}{2}$  or 3 miles from the Bajo Seco, or Dry Shoal. The sea breaks on all these shoals, and the deeper water is easily distinguished by its having no breakers. This will be found by keeping at one and a half cable's length from the outermost breakers off Bajo Seco. This Bajo Seco is an islet of sand, which is about a cable and a half over in every direction: it lies N. N. E. at the distance of one and a half mile from San Carlos Castle, and at about east from it will be seen the other, named Zapara. The island of this name has some very high mangroves; and outside of it, in 5 and a half or 6 and a half fathoms, the bottom is hard mud, mixed with sand; and this is where ships ought to anchor, in case of necessity; observing that the ground tackle ought to be good, as the prevailing wind blows very fresh at the place.

Being off Point Espada, at the distance of 2 leagues, and bound to the bar, steering a S. S. W.  $\frac{1}{2}$  W. course will take a ship to the N. E. of the islet named Bajo Seco.

\* By the remarks of Capt. T. W. Carter, of his Majesty's ship *Emulous*, we find that on the 30th of September, 1815, when standing towards the shore, Cape St. Roman bearing E. N. E.  $\frac{1}{2}$  E. distant from 12 to 15 miles, and off shore about 3 miles, they fell in with a shoal on which the water broke, having close to it 15 fathoms. He further adds, "The land being very low about this part of the coast, it would be dangerous to beat up along shore during night; although, with the westerly current running through the channel, a strong counter current will be found along the shore, and with the very strong breezes that you frequently get in this channel, it is difficult to get up, except by beating in shore. You will, however, find good anchorage all along this part of the coast, in from 5 to 10 fathoms; and during the day you may see all your danger."

"The ent

"The Bar Zapara, on t southward o and of some have settled The whole E stream ancho we love it u

On this course, as well as the former, the depth diminishes very gradually as you advance southward; and it will be advisable not to approach the bar in the night, but to run out again, or make short boards about 4 leagues from it, until daylight comes on. The breezes in this Gulf are fresh, and from N. N. E. which cause a heavy sea on the bar and all the south shore; so that there is great risk of getting aground, which must be guarded against.

High water on this bar takes place, on full and change of the moon, at a quarter after 5 o'clock afternoon; on spring tides, the water rises from 2 to 2½ feet. The least water on the bar, at high water, in the season of the breezes, is 14 feet 8 inches; and 16½ feet in the rainy season, which is in August, September, October, and November.

The Bar cannot be crossed without a pilot; and therefore, so soon as the ship is nearly north and south with the Castle of San Carlos, and in 5½ fathoms water, the course should be altered to the west, until in the depth of 4½ fathoms, when the breakers on the shoals will be seen in a line, about W. N. W. Continue steering to the westward, keeping the same depth, until getting abreast of the last breakers, which will be near the mouth, heave to on the starboard tack; or what is better, make short tacks off and on, until the pilot gets on board.

Steering for the bar, the first object that comes in sight, as being the highest thereabout, is the Island of Todas, or Todos, which lies about 3 miles to the southward of the Castle of San Carlos: shape a course towards this island, until the Castles and the Bajo Seco can be seen, and then proceed as before directed.

A knowledge of the *exact situation* of the mouth of the bar is very essential: that is to the westward of the meridian of the Castle of San Carlos; because, without this information, every person would suppose it to be between the Bajo Seco and the Eastern Coast where Zapara Castle stands. By such a mistake, the ship might be cast away on the shoals; or, if attempting to enter, it would be a prodigy if every person on board did not perish: unfortunately, such accidents have sometimes occurred.

Vessels drawing from 9 to 12 feet water, should endeavor to be at the entrance at high water, to avoid all danger of even touching; for if she would not answer the helm immediately, the peril would be imminent. In such an event, from the narrowness of the channel, shipwreck would be inevitable.

A pilot is also requisite for getting over the Bar outward, and clearing the shoals: after which, particular instructions for sailing out of the Gulf are necessary; for although it must be done by working out, yet every navigator knows how to regulate his tacks, so that they may be more or less favorable; and here he may prolong either tack without any other guide than the lead. It is, however, necessary to remark, that in the Gulf the wind generally shifts to the north, or nearly so, at 4 or 5 o'clock, P. M.; therefore endeavors should be made to get near the Western Coast about that time, in order to take advantage of it for a long board to the E. N. E.; and to go on the other tack again, so soon as the wind rounds back again to the eastward; not only to gain northing by it, but also to get again over to the West Coast, to make the best use of the next shift of wind to the north.

*Directions for Navigating from Santa Martha to the Bar of Maracaybo, by Capt.*

*Frederick Chamier, R. N. 1826.*

"In sailing from Santa Martha for Maracaybo, I rounded Cape Aguja quite close, and by keeping within 5 miles of the foot of the Snow Mountains, carried the easterly set of the Magdalena up to Cape la Vela, and had likewise light winds from the westward.

"On nearing Rio de la Hacha, you must keep the lead going, as you will be in 5 and 7 fathoms water the whole night. After passing Cape la Vela, the best plan is to make one good stretch to sea, and the next morning you will in all probability weather Cape Chichibacoa: in which case you will weather Punta Espada, and be able to stand for the Bar of Maracaybo. You will run the greater distance from Punta Espada in 9 and 10 fathoms, and the shoaling of the water will be a guide to shorten sail for daylight.

"The best anchorage is with the Castle of the Bajo Seco in a line with that of St. Carlos, and distant from the latter about 7 miles, in about 6 fathoms water.

"The entrance of the Bar is in lat. 11° 2'; long., by chronometer, 71° 43' W.

"The Bar of Maracaybo is a shifting bar; formerly the entrance was by the Island of Zapara, on the west end of which stands the Old Fort. It then formed its channel to the southward of Bajo Seco (which at that time was not above water, although now an Island of some magnitude, and the principal defence of the entrance,) but now it seems to have settled into a permanent channel of 13 feet depth, to the N. W. of the Bajo Seco. The whole Bar is a quicksand, and when the Britomart grounded in passing, although the stream anchor was towed in the cutter a cable's length astern, and dropped instantly, yet we hove it up without starting the vessel in the slightest degree. Having ultimately

been obliged to heave the guns overboard, the sand covered them so deeply, that the buoy rope, which was the same as is allowed for an anchor of 16 cwt. snapped before we could raise the gun sufficiently to sweep it, and that only the next day.

"To pass the Bar, a pilot should always be taken: the difficulty is to get one; an old Spanish ordinance being still in force, that no foreign man of war is to be taken across.

"The town of Maracaybo stands 21 miles up the lake, and you have to pass over the Tablazos, shoals of soft mud, with about 10 feet, in some places, which you may drag through with ease.

"I came out over the Bar against a head sea, drawing eleven feet fore and aft, and never touched.

"Water can be procured, if you are outside of the Bar, from the main land, exactly opposite the fort of the Bajo Seco; and, if inside, the lake is fresh water 10 miles above the Bar. The seine may be drawn any where in the sandy bays; but the alligators are very plentiful.

"Although the Derrotero de las Antillas and others mention the depth of water on Bar in the rainy season, from August to November, to be  $16\frac{1}{2}$  feet, yet no more than 14 feet, and that only in one place, could I succeed in finding. The tides are very strong indeed."

*Continuation of the Coast from Point Espada to Cartagena.*

It has been already said that Point Espada is the west point of the entrance to the Gulf of Venezuela, or of Maracaybo; from it the coast trends about N. W. by N. a distance of 13 miles, to Cape Chichibacoa, and is all so clean and shallow, that the lead is a sufficient guide; and, although the coast is low, there are several peaks which rise inland, the highest of which are named Sierras de Aceyte.

From Cape Chichibacoa, N.  $75^{\circ}$  E., at the distance of 10 miles, are the Monges del Sur, or Southern Monks, which are two very small and perfectly clean islets, so that they may be passed at the distance of half a cable's length without any fear. About N. E. by E. from them, at the distance of 3 miles, there is another, named Monge del Este, or East Monk, which is also very clean; and at the distance of 8 miles N.  $\frac{1}{2}$  W. from the first is another group of seven islets, named Monges del Norte, or Northern Monks; these are *foul with a reef*, and ought not to be approached at less than a mile. The channels which the Northern Monks form with the east and with the Southern Monks, as well as between them and the coast, are very free and clean; therefore there is not the least risk in navigating them.

From Cape Chichibacoa the coast bends nearly W. N. W. 25 miles to Point Gallinas,\* which is the most northerly part of all this coast. From Point Gallinas the coast bends to W. S. W. a distance of 5 miles to Point Aguja, from which a shoal bank extends a mile out to sea. At Point Aguja the coast turns to the southward, and forms a bay of small extent, named Bahia Honda Chieha, or Little Bay Honda, which has very shallow water, and affords no shelter: next to this is the Harbor of Bahia Honda, the eastern point of which is 4 miles from Point Aguja.

BAHIA HONDA is a bay of great extent, and its mouth is 3 miles wide. In entering this bay you have only to be careful to avoid a shoal which lies in the mouth of it, and in a line with the two points of the entrance, and which is distant from the west point three quarters of a mile, and from the east point a mile and two thirds. This bank, whose greatest extension is nearly E. and W., is about one third of a mile in length, or a little more; and the least depth of water on it is at the east end, where there is only one foot; upon which, with the slightest wind, the sea breaks. In other respects the bay is shallow and clean; so that no other guide than the lead is required for choosing an anchoring place in it, the depths being from 4 to 8 fathoms. The coast from Cape Chichibacoa to this bay, is low and level, but clean and shallow, so that no other guide than the lead will be required.

From the west point of Bahia Honda the coast runs about S. W. for the distance of 11 miles, to a large Bay, named El Portete, the entrance of which is very narrow, and the depth of water in the interior will admit none but small vessels. From El Portete the coast trends about west, for a distance of 14 miles, to Cape la Vela: the coast is

\* A shoal of  $4\frac{1}{2}$  fathoms, or less. On the 7th of July, 1827, his Majesty's ship Druid, Capt. Samuel Chambers, running along shore to the westward, suddenly shoaled the water from 10 fathoms to  $4\frac{1}{2}$ . Capt. Chambers says, "I understand there are only 2 fathoms on it, and it is not in any chart that I have seen. Its latitude is  $12^{\circ} 30'$  N., longitude  $71^{\circ} 46' 30''$  W. Point Gallinas bears from it S. S. E., distant 5 miles, and Bahia Honda S. S. W.  $\frac{1}{2}$  W. Ships of a large draught of water should not go nearer than to bring the low sandy hills on the shore in sight. If clear weather, the high land of Chiniaro will be seen."

clean, and from Bahia Honda the land begins to rise higher. One league before arriving at Cape la Vela there is a little hill, in form of a sugar-loaf, against which the sea breaks, and which projects about half a mile to the northward of the rest of the shore. From this hill the land continues of a good height, rounding southward so far as the west point, which is that properly named Cape La Vela: about  $2\frac{1}{2}$  cables' length to the westward of this point, there is an islet, or rock, very clean and steep to, which may be passed at a ship's length, if you please. The channel between it and the cape is quite clear, and may be run through without risk of danger, there being  $5\frac{1}{2}$  fathoms in the middle of it; but it is better to keep near the islet than the cape, because there are  $5\frac{1}{2}$  fathoms water close to the former, and only 4 or even less than 3, near the latter. The land about Cape la Vela is very sterile, and S. E. from it, about 7 miles inland, there rises a mountain, named Sierra del Carpintero, the Carpenter's Mountain.

**ANCHORAGE OF CAPE LA VELA.**—From the cape the shore trends to the southward, forming a large bay, where there is shelter from the trade wind: to enter it no other guide than the lead is necessary, for all the bottom is clean and so shallow, that at 2 miles from the coast there are  $5\frac{1}{2}$  fathoms, and from that the depth gradually diminishes towards the shore.

**CAPE LA VELA TO POINT MANARE.**—From Cape la Vela the coast runs about south, with some inclination westward 23 miles to Castilletis Point, where there is a grove, or group of mangroves, from which the cape bears N.  $21^{\circ}$  E. From this point it trends S.  $74^{\circ}$  W. 14 miles, to Manare Point, and between the two bends a little to the southward, with some projecting points. S.  $72^{\circ}$  W. at the distance of  $12\frac{1}{2}$  miles from Manare Point, is that of La Cruz, the intermediate coast being nearly straight, although the Points of Almidones, Pajaro and the Fouton de Jorote, project out a little. Between the two latter, at a mile and a half to seaward, lies the Pajaro, or Bird's Shoal, with 2 fathoms water on it, on sandy bottom.

From Point de la Cruz, at the distance of 4 miles S.  $54^{\circ}$  W. is Point Vela; and at 7 miles from it S.  $42^{\circ}$  W. are the city and river of La Hacha. The coast thence trends S.  $61^{\circ}$  W. and S.  $53^{\circ}$  W. to Punta Dibulle, which is  $31\frac{1}{2}$  miles distant from the city of La Hacha. From Dibulle Point the coast runs west, and N.  $75^{\circ}$  W. to Cape San Juan de Guia, which is distant  $38\frac{1}{2}$  miles from Dibulle Point. All this coast from Cape la Vela to 12 miles east of San Juan de Guia, sends out a bank of soundings, more or less projecting into the sea, as may be seen in the charts published at the Hydrographical Office; but it is dangerous on account of several shoals on it, which extend a considerable way off to sea. The first shoal, which is already noticed, is that named Pajaro; and the second, named Navio Quebrado, or Wrecked Ship, is situated at  $2\frac{1}{2}$  miles from the coast, between the Laguana Grande and the Laguana Navio Quebrado, in latitude  $11^{\circ} 26' 15''$ , and longitude  $73^{\circ} 14' 30''$  W.; therefore ships should not approach the coast nearer than 4 leagues; and care should be taken not to get into a less depth than 20 fathoms. The shore is generally low; but somewhat to the westward of the city of La Hacha, the celebrated Sierra Nevadas, or Snowy Mountains, begin to rise inland, well known, not only for the great elevation, but also because the summit terminates in two peaks like sugar loaves, which are always covered with snow. These mountains extend to the westward, and terminate under the meridian of Cape Aguja.

**Instructions for taking the anchorage off the CITY OF LA HACHA.**—Although we have said that it is not advisable to approach this coast, but to steer a direct course from Cape la Vela to Cape Aguja, and take care to get into no less depth than 20 fathoms; nevertheless, as vessels bound to La Hacha must of necessity stand in for the shore, it is requisite to give some rule by which they may do it without risk. To take the anchorage off the City of La Hacha, and being near the rock or farallon at Cape la Vela, it will be necessary to steer S.  $53^{\circ}$  W. or  $55^{\circ}$  W., with which course run in sight of the coast; and having run 51 miles they will be on the meridian of the city of La Hacha, in  $5\frac{1}{2}$  to  $6\frac{1}{2}$  fathoms water, on sandy bottom, and may then direct themselves to the anchorage without more attention than by the chart appears necessary, observing that large vessels ought to steer for the anchorage N. N. W. of the city, in 5 or 6 fathoms; and when they sail from it, they ought to follow this course until they are three leagues out.

The taking of this anchorage, as well as all others which have no secure distinguishing marks, demands some vigilance; and as a case may happen in which a vessel may pass it, the bank of  $4\frac{1}{2}$  and 5 fathoms, on gravel, sand, and rock, which lies  $15\frac{1}{2}$  miles to the westward of the city of La Hacha, may serve as a mark for ascertaining her situation. The snowy mountains of Santa Martha may also serve as good marks for the same purpose.

From Cape San Juan de Guia the coast runs W. N. W., W., and W. S. W. a distance of  $12\frac{1}{2}$  miles, to the north part of the islet of Cape Aguja, which forms a prominent or projecting front of high hills, scarped, and with deep water close to, with several

coves or small bays, and good anchorages. The islet of Cape Aguja forms, with the cape, a channel of three tenths of a mile in breadth; but the passage is very narrow, on account of the reefs which extend out both from the cape and the south part of the islet; so that, although there is water enough for any vessel, yet none should attempt it, as by so doing they would run the risk of being wrecked.

To the N. W. of the islet of Cape Aguja there are three rocks, or farallones, very near each other; and the one which extends farthest out, which is also the largest, is at the distance of three cables' length. There is another, to the westward of the west point, which is higher than either of the former, and is also at a short distance; they are all clean, and steep to. From Cape Aguja the coast trends S. 31° W. 3½ miles, to Betin Point, which is the north point of the Bay of Santa Martha, and the south point of the Bight or Ancon of Tagango: the coast is high and scarped, with some beaches and indentments.

**SANTA MARTHA.**—The harbor of Santa Martha may be considered as one of the best on this coast. To the westward of its northern point, called Point Betin, at the distance of half a cable, there is a farallon, or rock, named El Morrochica, which is very clean, so that it may be passed at half a ship's length, if necessary: between it and the point there are from 5 to 8 fathoms water; but we advise that no one should attempt this passage, which is so very narrow, as there is nothing to be gained by it. About 4 cables' length to the westward of the same point lies an islet, called the Morro, also very clean, so that it may be passed on either side at the distance of half a cable's length. There is a fortification on this island, which, with other batteries on the coast, defends the harbor and city. The channel between the Morro and the rock off the point is very open and clean, with a depth of water from 13 to 27 fathoms. The bay is also very clean, and the bottom good: there is nothing in it to avoid, or give a berth to, but a bank before the city, which extends out about half a mile from the beach: but as the depth diminishes gradually from the edge, the use of the lead will be sufficient to avoid all risk from it. The best anchorage is to the northward of the city, as much as possible within the cove, or basin; to enter it, pass at about half a cable's length outside of the Morrochica, steering thence so as to pass at about the same distance from some rocks which extend southward from the point;\* having passed them luff as much as possible and anchor where most convenient, with the precaution of being guarded against the edges, which extend from the coast and the Points, exhibited in the particular plan of the harbor. On entering into this anchorage, be particularly attentive to the sails, &c. for the gusts of wind come off the land very heavy. The River Manzanares disembogues a little to the south of the city, which, although not large, has very good water.

**FROM SANTA MARTHA TO THE RIVER MAGDALENA.**—From Gaira Point, which is the south point of Santa Martha, the coast trends nearly south 13½ miles, to the Cienega, which is a lagoon, formed by some of the branches of the river Magdalena. From this Cienega it bends to the west, and W. N. W. a distance of 34 miles, to the western mouth of this celebrated river, named Boca de Ceniza, leaving at 8 miles to the eastward another, named Boca de Rio Viejo, or Old River. These streams form an island in form of a Delta, named Isla de los Gomez, which is six miles from north to south, and eight from east to west. By the two directions which the coast takes from Santa Martha, it forms a very large bay, in the bottom of which is the Chienga. At this coast is low and shallow; and from the Cienega towards the west, it forms the Isla de Salamanca, the west point of which is formed by the Boca de Rio Viejo. The waters of the Cienega, and those which form this island, communicate with the Magdalena by several small channels. The current of this great river is so powerful, that at more than five leagues out at sea it gives a *greenish color* to the water, resembling that over a shallow bank. All the bay may be coasted by the hand lead, for it is all clean. The west part of Isla de los Gomez, and the east part of Isla Verde, or Green Island, form the Boca de Ceniza of the River Magdalena; and in the middle of this mouth there are two keys.

The Isla Verde stretches from east to west a distance of 5 miles, and to the southward of it is another, of greater extent, called Sabanilla, at the S. W. end of which is a harbor of the same name, with 4½, 5½, and 6 fathoms water, on sand and mud.

\* Probably there are sunken rocks lying at a greater distance from Point Betin; for Captain S. Chambers of His Majesty's ship *Druid*, says, that "having been driven out from the anchorage by heavy squalls twice; on the morning of the 27th of February 1828, in again taking the harbor, the ship grounded on a rock not laid down in the chart, and which he had passed inside of on the previous morning. It bore from the east end of El Morrochica S. 55° E., from the S. E. of Point Betin S. 46° W., and from the West Point S. 10° W., all true bearings. On its inside it is quite perpendicular, with 5 fathoms, decreasing gradually to the shore: its outside is a quick descent to 9, 12, and 15 fathoms; and on the top of it are exactly 12 feet."

The Derrotero being silent on this harbor, we introduce the following account of it from documents in the Hydrographical Office:

"The Harbor of Sabanilla is situated about 7 or 8 miles to the south-westward of the Boca de Ceniza, of the Magdalena River, and is formed by the main land on the south side, and by the islands Sabanilla, Verde, and others, on the north side. Its entrance is between the point of Morro Hermoso and a shoal bank that extends about 4 miles south-westward from the Isla Verde, and nearly 2 miles from the west end of Sabanilla Island. The extremity of this bank has about 7 feet water on it, and lies about 3 miles north-eastward from Morro Hermoso Point."

*Directions for Sabanilla Harbor, by Sotrell Leigh, Esq., Commander of his Majesty's sloop Ontario, 1820 and 1821.*

"On making Sabanilla, it may be known by a remarkable table land lying about two miles to the westward of the fort. On the east end of the table land is a square hummock resembling a battery. Bring this hummock to bear S. E.  $\frac{1}{2}$  S., and a red cliff will be seen, which steer directly for, and you will pass to the westward of a shoal, with only 7 feet water on some parts of it, that extends 4 miles from Isla Verde. Its bearings are, the Red Cliff S. E. by S.; Morro Hermoso Point S. W. by S.; the west extremity of the land S. W.; and the N. W. point of the island N. by E.  $\frac{1}{2}$  E. These bearings were taken in a boat, in 7 feet water, on the edge of the bank; and at the distance of 30 yards from it, there are 5 fathoms, increasing regularly.

"When the west extremity of the land is shut in with Morro Hermoso Point, you will have passed the point of the shoal, and may haul up towards the fort, in from  $5\frac{1}{2}$  to 3 fathoms. The bearings at the Ontario's anchorage were, the fort N. E.  $\frac{1}{2}$  E.; west point of the island N. by W.  $\frac{3}{4}$  W.; and Morro Hermoso Point S. W.  $\frac{1}{4}$  W. at a quarter of a mile from shore.

"When turning into this harbor, care must be taken to avoid a shoal on which the Ontario tailed when in stays. It lies about a quarter of a mile from the Red Cliff, with the following bearings:—The outer part of the island N. N. W., and the fort E. N. E. On the inside of this bank is a reef of rocks, some of which are above water. On the outside the depths are from 6 to  $3\frac{1}{2}$  fathoms, and on it there are from  $3\frac{1}{2}$  to 2 fathoms. It is composed of sand and mud, and is, perhaps, formed by the freshes of the small rivers throwing the mud into the current, which, setting to the westward, carries it against the rocks, and there being stopped, forms a spit or bank.

"There is also another shoal, or oyster bed, on which the schooners Kate, and Experiment, lost their rudders. Its marks are the magazine in the fort, open a little to the eastward of the guard-house, also in the fort, and a remarkable notch in the bottom of the bay on with a bluff point to the northward of the custom-house. Ships of war have no occasion for going so far up, as the anchorage is equally good a mile below it.

"As the wind generally blows from the N. E. ships are obliged to work up to the anchorage. They ought not to stand inshore to less than 5 fathoms, nor to the northward into less than  $5\frac{1}{2}$ , as the bank is steep to, and on the shore side, abreast of the Red Cliff, is the reef above mentioned.

"I have been informed that heavy gales, or great freshes from the Magdalena, cause the banks to shift. During several visits to this harbor, we found the current setting to the westward, owing, perhaps, to the easterly current, which from Galera de Zamba meets the freshes from the Magdalena, causing an eddy over the outer bank into Sabanilla Bay, which, not being able to escape to the eastward, returns along the south shore of the bay, and round the S. W. point to sea.

"There is no regular tide at this part of the coast, but the water sometimes falls and rises 4 or 5 feet.

"Water of an indifferent quality may be procured here from the S. W. mouth of the Magdalena; but the bar is so shallow that nothing but small boats can get in. Fire wood may be easily obtained in any quantity, the beach near the river being nearly covered with drift wood."

*Directions for entering Sabanilla Harbor, by Capt. W. B. Bigland, R. N., 1821.*

"The land to the eastward of the anchorage is quite low, and full of trees. It consists of small islands lying about the mouth of the River Magdalena. The shore on the north side of them, I believe is safe, by attending to the lead; but I would not advise any person to approach it nearer than  $2\frac{1}{2}$  miles.

"Coming from the eastward, and having a distinct view of the S. W. part of the low islands, and the high land to the southward over them, go no nearer than  $2\frac{1}{2}$  miles, but continue steering westward, until the point of Morro Hermoso bears about S. by W., and then steer directly towards it, until you bring a small hummock upon the table land

to the southward to bear about S. E. (some yellow-faced cliffs close to the water will then be seen, and nearly on with the said hummock.) You may then with safety haul up for it, and it will lead you clear to the S. W. of the shoal that stretches off  $2\frac{1}{2}$  miles S. S. W. from the low islands, with only 5 feet water on it. Keep this latter mark on, and run S. E. until you get a small whitish looking house to the right of the fort, and close to the water, a little to the eastward of the highest part of the highest of three hills at the back of the fort, bearing E.  $\frac{1}{2}$  N.; then haul up for it, which is about as high as a ship will lie, as the wind is generally at N. N. E.

"But if, in going in, you should happen to get into 7 fathoms water, before you have the latter mark on, bear up to S. W. immediately until you deepen to 9 or 10 fathoms, which you will soon do. The reason for this precaution is, that if you are without the bank, you may have 6 fathoms, and before another cast of the lead can be had, the ship be on shore.

"On a line with the S. W. part of the shoal and the main land, there is not more than  $6\frac{1}{2}$  fathoms water. Ships of a small draught may anchor close to the fort, in 3 fathoms.

"There are good turning marks for working up to the fort, but rather difficult for strangers to understand. In standing south-eastward, be careful to keep a good look-out for a small red or yellow spot in the land to the N. E. of the custom-house, and keep it open of the fort. In standing northward keep a very small hillock on the land, a considerable distance off, just open of the south-easternmost low land, though this will not be known unless pointed out. A frigate may work in by standing no farther to the S. E. than the depth of 5 fathoms, nor to the northward than  $5\frac{1}{2}$  fathoms. In mid-channel above the line of the S. S. W. part of the reef, there are no more than  $6\frac{1}{2}$  fathoms, on muddy bottom. The soundings are very regular, but in standing towards the reef it is steep to.

"The fort is not very conspicuous, but may be seen 8 or 9 miles. It has 6 guns, which cannot be seen one mile off, and a small howitzer. It is situated on a rising bluff under the high land.

"His Majesty's ship *Euryalus* anchored on May 4th in  $5\frac{1}{2}$  fathoms, on soft mud, with the northernmost island bearing N.  $43^{\circ}$  E.; Point Morro Hermoso S.  $50^{\circ}$  W.; higher red bluff S.  $55^{\circ}$  E., distant nearly a mile; the fort N.  $46^{\circ}$  E.; and the custom-house N.  $41^{\circ}$  E. On the 16th of the same month, she anchored in 7 fathoms, on soft mud, with the northernmost small island N.  $2^{\circ}$  E.; the custom-house N.  $40^{\circ}$  E.; the lower house at the fort N.  $58^{\circ}$  E.; the double highest red bluff S.  $60^{\circ}$  E.; and Point Morro Hermoso S.  $40^{\circ}$  W.

"A frigate might work up a half or three quarters of a mile nearer the fort, and anchor in 5 fathoms, to windward of all the red-faced land. About 3 cables' length off lies a rock just above water, with two others close to its north side, with 2 feet on them; and another 20 yards N. E. with 4 feet on it. There are 4 fathoms close to their N. W. side, and  $2\frac{1}{2}$  fathoms between them and the shore. The custom-house kept open of the fort clears them. Although these rocks are out of the track of vessels working up, it has been thought proper to notice them, as they are dangerous for boats."

**COAST BETWEEN ISLA VERDE AND GALERA POINT OF ZAMBA.**—From the Isla Verde the coast trends S.  $58^{\circ}$  W. for a distance of 33 miles, to Galera Point of the Island of Zamba, or Zamba Point: the shore between forms a bay of five or six miles in depth, all of it being shallow: for, at 3 leagues from the shore, there are only 26 fathoms of water, on muddy bottom. The Cascajal and Palmarito Shoals are in it; the first, very near the coast, in the middle of a little bay formed by the Morros, or hills of Damas and of Inasco: the second is more dangerous, for it lies at a league off shore, N.  $26^{\circ}$  W. from Morro Pelado, or Bald Hill.\*

**ANCHORAGE OF GALERA DE ZAMBA.**—The Galera Point of Zamba is so low that, when there is a fresh breeze, the sea washes over the greater part of it. To the west, W. N. W. and N. W. of its western extremity, and at the distance of 2 miles from its most projecting part, there are four small banks, of different sizes, with  $5\frac{1}{2}$  fathoms water, on black sand. Between these banks, and between them and the coast, the depths are 7, 8, 9, and 10 fathoms, black sand. This Galera Point of Zamba projects

\* Captain J. F. Chapman, when commanding the *Nautilus* sloop, on the 8th of July, 1821, while working to windward on this coast, and being about  $3\frac{1}{2}$  miles from the nearest shore, with Morro Hermoso bearing about E. N. E. distant 5 or 6 miles, struck on an *unknown rock*, not three times the size of the ship; it had 11 feet water on it, and 6 fathoms all round it. In a subsequent account he describes it bearing S. W. from Morro Hermoso, at the same distance from it, and from the nearest shore.

The difference in the given bearings of Morro Hermoso precludes the possibility of assigning to that rock a place in the chart; but it has been thought advisable to insert the above account, in order to excite the vigilance of those who may hereafter have to navigate on this part of the coast.

ability of assigning to the above account, in order of the coast.

into the sea about 8 miles, and forms on its south part an anchorage, sheltered from the breezes; but in taking it, great care is necessary, on account of the banks in it, and of the Isla de Arenas, or Sandy Island, which lies in the middle of the Bay of Galera de Zamba; therefore every one intending to enter into this anchorage, must pay great attention to the haul lead.

At S.  $26^{\circ}$  W., distant  $14\frac{1}{2}$  miles from Point Galera of Zamba, is the Point of Canoas, which is low at the water's edge, but hilly very close to it. Between these two points the coast is of moderate height; and at about one third from Point Canoas there rises a hill, forming table land at its top, with several barrancas, or reddish colored ravines, upon it, called Bujo del Gato. On the intermediate coast there are several dangerous spots. Of these, the first is the islet Cascajal, which lies from the Point Galera of Zamba S.  $6^{\circ}$  E., at the distance of 6 miles, and from the coast a long mile and a half. North, and N.  $6^{\circ}$  E. from this islet, at the distance of one mile and three tenths, and eight tenths of a mile, are two little banks, with 2 and 4 fathoms water on them; and there is another, of equal depth, lying N.  $58^{\circ}$  W., at the distance of two short miles from the Cascajal. S.  $14^{\circ}$  W. from the Point Galera of Zamba, and at the distance of seven short miles, is the west rock of Bujo del Gato Shoal, which extends a long half mile from north to south. At about N. N. E. from its north extremity, distant half a mile, there is another rock, called the N. E. rock, or Una de Gato, Cat's Claw. The depth on the outside of this shoal is 7, 8, 9, and up to 14 fathoms, at the distance of  $2\frac{1}{2}$  miles. There is also, at the distance of  $3\frac{1}{2}$  miles N.  $31^{\circ}$  E. from Point Canoas, a rocky bank, of 3 fathoms water. This lies in the middle of the bay of Bujo del Gato. We ought to warn the navigator that going into this bay is dangerous, especially by night, and if he is compelled to do so, he ought not to go into a less depth than 20 fathoms.

NEGRILLO SHOAL.—The Point of Canoas has lying off it at the distance of one long mile and a quarter, S.  $49^{\circ}$  W.\* a shoal called the Negrillo, of one quarter of a mile extent. It is composed of three rocks, at a short distance from each other, in a triangular form, with from 2 to 5 feet on them. All around these rocks, and very near to them, there are 6, 8, and 9 fathoms water, on a bottom of rocks, small gravel, and sand; and the channel between them and the coast would be practicable, were it not for three sunken rocks, which make it difficult to pass. From the Negrillo Shoal, the hill of La Popa, at Carthagena, bears S.  $4\frac{1}{2}^{\circ}$  W. distant  $7\frac{2}{3}$  miles; and this bearing may, if necessary, serve to guide the navigator clear of it. At S.  $50^{\circ}$  W., a short mile from the southernmost Morrito, is the Cabeza Shoal, with 2 feet of water on its shoalest part.

CARTHAGENA.—From Canoas Point the coast trends to the eastward a long mile; and thence it bends round to the southward 3 miles, where rise some little hills, called Los Morritos. From these, the coast, which is low, and covered with mangroves, trends S.  $33^{\circ}$  W.  $5\frac{1}{2}$  miles to the city of Carthagena, which is built upon the western part of this swampy land. About one mile and three quarters to the east of the city rises the hill of La Popa, on the summit of which there is a convent of Augustine Monks, and a chapel or sanctuary dedicated to the Virgin of La Popa. In clear weather, this hill may be seen, from the quarter deck of a line-of-battle ship, at the distance of 10 leagues.

HARBOR OF CARTHAGENA.—The little tongue of land on which the city is built, extends S. S. W. two short miles from it; then turning round to the east, it forms, with the main land, a basin, which is the anchorage or harbor, and which is as well sheltered as the best arsenal. One mile to the southward of the exterior point of the little tongue, of which we have just spoken, is the north point of the island called Tierra Bomba, and the passage which is formed between the two is called Boca Grande, and which is artificially closed in such a manner that only boats, and vessels drawing very little water, can enter by it. Tierra Bomba Island is about 4 miles from north to south, and its south point is the north point of Boca Chica, which is the only entrance to the harbor of Carthagena. The south point of this entrance is the north point of another large island, named Baru, and which is separated from the main land by a creek

\* SUNKEN ROCKS OFF CANOAS POINT.—On May 27th, 1829, H. M. B. Spey, W. James, commander, struck on a reef of rocks, Canoas Point bearing N. E.  $\frac{1}{2}$  N., distant about three miles. On examining this reef, it was found to consist of several heads of rocks about 100 yards in length, with 3 to 5 fathoms between them, 7 fathoms all round them, and on the tops, which are sharp pointed, from 4 to 5 feet. The current was setting to the N. N. E. one mile per hour.

On May 5th, 1826, H. M. S. Isis, Capt. H. Patton, struck on a rock, with Canoas Point bearing N. E., the estimated distance from the land about  $2\frac{1}{2}$  or 3 miles. When she struck there were  $7\frac{1}{2}$  fathoms under the main chains.

These rocks are evidently the continuation of the Negrillo Shoal, which, therefore, has not been correctly placed in the Spanish surveys. Measures have been taken to ascertain its extent and position.

named Pasa-Caballos, navigable by canoes only. On both points of the Boca Chica there are castles to defend the entrance. That on the north side is named San Fernando, and that on the south San Josef. This boca or entrance is rather more than two cables' length in width; but there are parts of it where the bank of shallow water which extends off from the southern castle (San Josef's) narrows it one half.

This entrance opens first into a large and well sheltered bay, where there is a depth of 13 and 15 fathoms. To the north of this the eastern coast of Tierra Bomba inclines towards the main land, leaving a channel of a mile in width, at the entrance of which, and in its middle, are some shoals, which lie to the westward of an islet called Brujas, and which is very near to the main land. Through this strait is the entrance into a second bay, which corresponds with, or is opposite to, the Boca Grande, and in which there are also 14 and 15 fathoms. To the north of this second bay there is an entrance of less than half a mile wide, defended by other castles, and which conducts into the harbor. This channel or entrance has a shoal in the middle, which forms it into two very narrow channels, but with 8 to 12 fathoms water; and the depth in the anchorage no where exceeds 11 fathoms.

Having given an idea of the harbor, we shall now speak of the exterior coast and the shoals.

**BANK OF BOCA GRANDE.**—From Point Canoas to Boca Grande there is a large bank, on which the depth of water diminishes gradually; and there are 9 fathoms at 4 miles, or somewhat less, from the land. This bank is named the Playa Grande, and ships may anchor on it, in 7 or 8 fathoms water, on a bottom of grey sand, in front of the city. After passing the most northerly part of Tierra Bomba, the depth increases to 20, 30, and 40 fathoms; and at 2 cables' length from the shore there are 6. To the westward of Tierra Bomba, at the distance of 4 miles, there is a shoal, called the Salmadina, which has been much spoken of, on account of the great loss of ships which it has caused. This shoal, which is little more than a mile in extent from north to south, and a little less from east to west, lies with the following bearings:\*

*The Head, or North Edge of it.*

The Castle del Angel.....	S. 64° E.
Hill of La Popa.....	N. 68 E.
N. W. Point of Tierra Bomba.....	N. 80 E.
Point Canoas.....	N. 35 E.

*The South Head, or Edge, on which the sea generally breaks.*

The Tower of the Cathedral.....	N. 55° E.
Hill of La Popa.....	N. 62 E.
N. W. Point of Tierra Bomba.....	N. 70 E.
Point Canons.....	N. 33½ E.

In addition to these marks, by which it may with certainty be avoided, in running from Playa Grande for Boca Chica, ships ought to get into from 6 to 8 fathoms, to the west of the city, and at the distance of three short miles from it, and then steer south, without inclining anything to the westward; and so soon as the depth increases, keep more to the larboard hand, in order to close in with Tierra Bomba to the distance of half a mile; and run along thus, closing to within a pistol shot of the north shore, at the entrance of Boca Chica, avoiding the south shore, which is foul. To enter Boca Chica, and navigate within the bays, up to the harbor, requires a pilot, and one may always be obtained at Boca Chica.†

As the Harbor of Cartagena may be made by ships from the southward, it is necessary to give some description of the south coast, as far as the islands of Rosario, in order to connect all the information required for making the land with correctness and safety.

We have already said that the south coast of Boca Chica is the north coast of the Isl. and Barú. The exterior coast of this island from the point forming the entrance of Boca Chica, trends S. 35½° W. for 13 miles, to Barú Point. This coast is sufficiently clean as far as an islet, named the Farallon of Perico, from which to the south it is very

\* These bearings do not agree with the position of the shoal in any of the charts.

† According to the remarks made by Mr. J. Whidbey, when master of his Majesty's ship Europa, it appears that ships having occasion to anchor and stop in Boca Chica, should haul round the S.W. point of Tierra Bomba at the distance of half a cable's length, and run along by the beach until the centre of San Fernando Castle bears N. E., true, and then drop an anchor in 13 fathoms, at about 100 yards from the beach. They may then moor with two thirds of a cable on the N. E. anchor, and half a cable on the S. W. in 16 fathoms, which ought to be the bearings of the anchors. When moored, the centre of San Fernando Castle will bear N. E., as before, the centre of San Josef Castle, E. S. E., and the extremity of Tierra Bomba, W. N. W.

foal, with a reef. To the westward of this latter part of the coast, that is, from the Fa-  
rallon of Perico southward, are the islands of Rosario, of which there are four principal  
ones, with several small islets. The easternmost and southernmost of these, which is  
also the smallest, is named Isla de Arenas, and it is distant from the shore of Baru  
scarcely one mile and a half; but the channel between them is reduced to three quar-  
ters of a mile, by the reefs and shoals which extend from both sides. W. N. W.  $\frac{1}{2}$  W.,  
at the distance of  $3\frac{1}{2}$  long miles from Arenas Island, is the Island of Rosario; and to the  
northward of these two, is that named Isla Larga, or Long Island, which is the largest,  
and which, with its banks, shoals, and islets, extends out to the westward farther than  
Rosario Island. To the northward of the middle of Isla Larga, at a little more than 3  
miles distant, lies the islet Tesoro, with a reef to the westward. The channel between  
them has from 17 to 25 fathoms water, on a bottom of sand and rocks, from which Boca  
Chica bears N. 63° E.,\* distant  $10\frac{1}{2}$  miles.

The Rosario Islands are very foul, and no one should sail among them unless well  
acquainted; but always keep at a sufficient distance to the westward, in order to avoid  
the shallows, which extend out from them. About S. S. W., distant 7 miles from Ro-  
sario Island, there is a shoal called the Tortuga. These islands are fertile in trees, and  
to the southward of them there is good shelter from the trade wind. Besides the Bank  
of Rosario Island, there are two others, one  $3\frac{1}{2}$  miles to the W. N. W., and the other  
 $2\frac{1}{2}$  miles S. W. by S. Both are rocks and sand, with 6 and 7 fathoms water on them.

*Observations and Reflections on navigating on the Coast of Colombia, from the Dragon's  
Mouth to Cartagena.*

Reflecting on what has been stated respecting the winds that are experienced on this  
coast, it would appear that nothing further need be added to the description already  
given, to enable the navigator to prosecute his voyage with the greatest safety. In fact,  
as there is on this coast only the general breeze, or trade wind, neither hurricanes nor  
hard norths are to be feared, the first being absolutely unknown, and the second, if they  
do at any time occur, never exceed the strength of the ordinary breeze. If in the rainy  
season, that is, from May to November, there are sometimes strong southerly winds,  
they must be considered rather as squalls with heavy rain, of short duration; and as  
they blow off shore, do but little injury. This coast, therefore, especially as far as Cape  
la Vela, may be considered as a continued harbor, as far as climate is concerned; and  
no more is necessary, to enable us to avoid every danger upon it, than a reference to  
the description given; for we are sure that the loss of a vessel upon it, has been very  
rarely the effect of a storm.

From Cape La Vela westward, it is proper to give some notices; for as the breezes,  
especially from Cape Aguja, or rather from Point San Juan de Guia, are exceedingly  
strong, so much so, that they may be considered as real gales, it becomes necessary to  
present some rules for making the different harbors, to prevent as much as possible those  
inadvertencies that, during such unmanageable winds, might prove of the most serious  
consequences. The shifting of the wind, which we have before said sometimes changes  
to S. and S. W., from June to November, raises some doubt with respect to the navi-  
gation, and therefore the following reflections will not be considered irrelevant; for  
though they may not be necessary for those who are acquainted, they cannot fail of be-  
ing beneficial to those who are not so.

The principal commercial establishments on this coast, and towards which vessels  
from Europe in general direct their course, are Cumana, Barcelona, La Guayra, Porto  
Cabello, Maracaybo, Santa Martha, and Cartagena; Pampatar, in the island of Mar-  
garita, and Santa Ana, in the island of Curazao. It being a general rule on this coast,  
as well as in the whole sea of the Antillas, or Caribbean Sea, to make the land to  
windward of the port of destination, as a matter of necessity, to prevent the trouble con-  
sequent upon getting to leeward of it, we may say with safety, that, being once within the  
Sea of the Antillas, all those who intend to anchor at either Margarita or Cumana,  
should close with the coast about Cape Mala Pasqua, or Cape Three Points, passing in  
preference through the channel which Margarita forms with the main land, as we have  
before stated in the description. This route also appears preferable for those who are  
bound to Barcelona, although there certainly can be no inconvenience in their going to  
the northward of Margarita.

Those who are bound to La Guayra, from Cumana, or Barcelona, should shape a di-  
rect course for Cape Codera, passing always between the island Tortuga and the coast;  
but those who, from Enrope, or any of the Antillas, are bound to that port, should na-  
vigate to the northward of Tortuga, to approach the coast about the same cape, or a

\* By the Chart it bears N. 57° E.

little to leeward of it, taking care, if they choose to make the rock called the Schünel, which lies to the northward of the cape. For those bound to Porto Cabello, it will not be so necessary to make Cape Codera, as any other point on the coast will answer the same purpose, provided it be sufficiently to windward of their port.

To make Cape Codera, or any harbor upon the coast to leeward of it, every one may do it in the manner that is easiest, or that he considers best; that is, he may pass through any of the straits or passages that are formed by the islands to the northward of the coast; in doing which, nothing more is necessary than to attend to the description of the one that he takes.

Those bound to Maracaybo from the east, should get sight of Cape St. Roman, and those from the westward should make Point Espada. In running for Cape St. Roman they may pass either to the northward or southward of Curacao; and from that cape they may run along by the coast, until they get about two miles to the westward of Point Macolla, which is the situation from which the course to the bar is certain, as has already been stated in the description.

Should the navigation to Cape St. Roman be made outside the islands, it should be recollected that the Roques and the Islas des Aves are extremely dangerous on their north sides; and to the end that they may be careful to keep themselves at a sufficient distance from them, especially by night, they must not forget to apply to their reckoning for the night a correction for currents which they experience during the day, as deduced from the comparison of the dead reckoning with the points of departure and landfalls. The due observation of this remark is very important, as from what has been before said relative to the currents, they in this place require particular attention.

Those bound direct for Santa Martha, or Carthagena, ought, unquestionably, to navigate outside all the islands, so as to make that of Oruba and the land about Cape la Vela; for, having obtained a sight of the latter, they may with safety shape a direct course for Cape Aguja, in order to reach the anchorage of Santa Martha, as before directed. We speak of the propriety of navigating to the northward of all the islands, because by so doing a more direct course may be shaped, and the distance be thereby shortened, which is well known to every skilful navigator.

Those who, without touching at Santa Martha, go on to Carthagena, will shape a direct course from Cape Aguja for the mouths of the River Magdalena, whence, by passing about 2 leagues to the westward of Point Zamba, and one and a half from Point Canoas, they may proceed direct to the Boca Chica, or else anchor off Point Canoas, or on the bank of Playa Grande, if they should not be able to effect an entrance into Boca Chica with daylight. Calculation ought to be made, in order that the distance may be proportioned to the rate the vessel sails at, or the sailing of the vessel to the distance to be run, so as to reach Point Zamba, and thence take the Boca Chica by day; or anchor off Point Canoas, or on Playa Grande, in order, if possible, to avoid the necessity of hauling the wind for the night, which will be troublesome and injurious to the ship and her rigging, in the time of the hard breezes; but if there be no means of avoiding it, the situation must be maintained by short tacks off and on; or if the wind and sea will permit, let go an anchor.

When we advise a direct course to be shaped from point to point on the coast, as Aguja, Zamba and Canoas, it is not only on account of distance, which would be greatly lengthened by following every turn of the coast, but also for the purpose of avoiding the various shoals and dangers which lie between Cape la Vela and Point Agrija, as noticed in the description of the anchorage of the city of La Hacha, as well as those lying between Point Zamba and Point Canoas, among which we recommend no one to go with a large vessel.

If during the season of the breezes, it is necessary to follow the route which we have described to Carthagena, from any place situated to the eastward of it, you ought in the season of the rains, or during the Vendavales, to steer true west from Cape la Vela, in the parallel of  $12^{\circ}$ , or somewhat more, in order to retain the breeze, until you get so far as  $75^{\circ} 45'$  or  $76^{\circ} 15'$  west longitude; and from that situation to steer south, coming up by degrees to S. E. on getting into the limits of the rains; observing also, that it is better to make the land to the southward of Boca Chica than to the northward of it; because in this season the current sets to the N. E., though in the season of the breezes they run to the S. W. Particular care should likewise be taken, not to run in upon the land by night, but only by day; for at such times the land is very hazy.

In working to windward on this coast, from Carthagena to Margarita, or Trinidad, haul close by the wind, and make the boards as long as convenient. The proper time of tacking ought to be decided by the daily variation of the trade wind, which, at about 12 at night, or somewhat sooner, comes off the shore from about E. S. E., or even S. E., if it has been raining before, and the ground is soaked; and from 9 to 11 in the forenoon, the sea-breeze, or that from E. N. E., comes on. At all distances from the shore

argarita, or Trinidad, nt. The proper time wind, which, at about E. S. E., or even S. E., n 9 to 11 in the fore- tances from the shore

these variations take place; and the navigator may, and ought, to take advantage of them in working from leeward to windward: therefore when at night the breeze gets to the S. E. it will be proper to tack, and stretch off from land until the morning; and when the wind gets to the northward of east, he ought to tack and stand in towards the land again. And if on account of hearing the land he cannot continue on the same tack until the breeze changes, he ought to make short tacks along shore, until the breeze again changes to E. S. E., and then again stand out to sea. By these means two long stretches may always be made, one to the N. E., the other to the S. E.; that is to say, both of them within eight points of the compass. By working to windward on short tacks along shore, this advantage cannot be obtained, because the breeze always blows along the coast, unless sometimes there may be a light land-wind in the night, and before the sun rises during the season of the rains; but they do not last, and such variations afford but little assistance.

Very small vessels cannot proceed upon this system, when the breezes are very fresh, which from point Agula to Isla Fuerta are like storms, with a rough sea; so that they cannot make any way: in these cases, it is most advisable for them to keep in near the coast where the water is smoother. But large vessels, well equipped, and capable of resisting these gales, or when the breezes are moderate, ought to make long stretches when the wind will admit of it, in the manner already described.

#### *Observations by Captain Don Tarquato Pridrola.*

On the coast of Carthagena de Indias, of which I can speak with certainty, the breezes do not begin until the end of November, and generally with little strength until the middle or end of December, from which time they are powerful both day and night; only they frequently, but not always, moderate a little between sun-rise and nine or ten in the morning, when they recover their ordinary force. When you are very near the coast, especially if it be high, you may often find them moderate at the dawn of day, and at sun-rise veer to E. N. E. until 9 or 10 o'clock, when they again blow in their usual direction, which on this coast is from N. N. E. to N. E. Of these variations, those who are acquainted with the coast, and sail near it, may take advantage; and it may be better, at night-fall, to anchor at the various points which offer, even for large vessels. In the season which is not of the breezes, that is from April or May until December, they experience the wet season, but not in the other seasons, as has been made manifest; adding, that a vessel which attempts to get to windward outside, will not accomplish it without great difficulty and damage, as much from the strength of the breeze, because the sea is very rough and short as far as 30 or 40 leagues from the coast, when it becomes longer; and because being forced in the night to take in reefs, and that the current draws towards the N. W. quarter, it results that the little gained by tacking is lost by these causes.—These facts have been proved by continued experience.

## **COAST OF COLOMBIA, MOSQUITO, HONDURAS, AND YUCATAN,**

*From Carthagena to Cape Catoche.\**

THE ROSARIO ISLANDS and ISLAND OF BARU have been described in the preceding section, and it has also been noticed that the latter is separated from the main land by a narrow channel, named the Paso Caballos (Horse Pass.) The north end of the channel opens into the first Bay of Carthagena, the south end of it into the N. E. part of a great bay between the Island Baru and the coast, which extends inward north-easterly nearly 12 miles: the points which form its entrance are the S. W. end of the Island Baru on the west, and Barbacoas Point, on the main land, on the east. This bay is named Barbacoas, or the Little Gulf of Baru; it has several shoal spots in it, but is generally clean, with a depth of 3 to 9 and 10 fathoms, on fine sand and ooze; the most general depth being from 4 to 5 fathoms. In it there is very good shelter from the breeze; and, in entering, care must be taken to avoid the edges of the shoal ground that extends from the Rosario Isles, and not to forget the Tortuga Bank, which lies at the distance of 10 miles S. 42° W. from Rosario Island, with 7½ fathoms water, on sand and rock.

\* From the Derrotero de las Antillas, &c. &c.

At one mile N.  $41^{\circ}$  W. from Barbacoas Point, is a shoal, the least water on which is two fathoms; and there is another lying S.  $80^{\circ}$  W.  $2\frac{1}{2}$  miles from the same point, with from  $1\frac{1}{2}$  to 2 fathoms on it; these are named the Barbacoas Shoals. Besides these, there are two others, named Atillo and Manilla: the first lies N.  $25^{\circ}$  W. distant  $3\frac{1}{2}$  miles from Barbacoas Point, with the depth of one foot, on rock; and the second lies N. E. by N., nearly 5 miles from the same point, and has very little water on it.

From Barbacoas Point the coast runs about S.  $8^{\circ}$  W.  $15\frac{1}{2}$  miles, to the Fronton, or Bluff of Tigua: this is easily known, because a cerro or hill rises on it, which is the highest of any on this part of the coast. From this Fronton a bank, with little water on it, extends to the north a little westerly, about 4 miles, the extremity of which opposite to Point Comisario (the first projecting point to the north,) extends  $2\frac{1}{2}$  miles from shore. From the Fronton or Bluff of Tigua to the Boqueron or Point San Bernardo, it is 12 miles S.  $25^{\circ}$  W. To the north-eastward of Point San Bernardo, and in the direction of the coast, are two islets; the northernmost named Isleta de Jesus, and the southern one, Cabrana; they lie respectively at 4 and 3 miles from the point.

The Point of San Bernardo is the S. W. point of a drowned mangrove key; between it and the coast there is a narrow channel, called the Boqueron, frequented by canoes and pirogues. S.  $20^{\circ}$  E. from the Point San Bernardo, nearly 2 miles, lies a rocky bank, called the Pajarito (Little Bird Rock;) the least water on which is  $3\frac{1}{2}$  fathoms, and the most  $4\frac{1}{2}$  fathoms.

To the westward of San Bernardo Point lie the islands of the same name, which are eleven in number, including those of Jesus and Cabrana, already mentioned; but without including some other small islets of little consideration. The edge of the banks on which these islands are situated, extends to the westward 15 miles, and nearly 10 from north to south. Various little channels are formed between them. The depth on the bank to the west and south of these islands is very unequal; for you may suddenly pass from shallow into deep water. All the islands are low and covered with trees.

**SALAMANQUILLA CHANNEL.**—The Salamanquilla Channel lies to the eastward of the San Bernardo Islands, or rather between the bank on the E. and S. E. side of the Island Salamanquilla, and that on the west side of the islet Cabrana. Its direction is N.  $47^{\circ}$  E., and contrary, and in the narrowest part is only three tenths of a mile wide; but the depth is from 9 to  $12\frac{1}{2}$  fathoms, on clay, with 5 fathoms at the edges of the banks. The banks have but little water on them, and therefore, unless precisely in the middle of the passage, there is great danger of grounding. The channel is nearer to Salamanquilla than to Cabrana; therefore it is necessary to pass nearest to the former; and if the weather be clear, the banks may be seen, by which ships may sail through with less risk; but, in thick cloudy weather, the hand lead is the only guide.

**SAILING THROUGH THE SALAMANQUILLA CHANNEL.**—To sail through this Channel from the north; so soon as you have passed to the westward of the Rosario Islands, steer towards the Cerro, or Hill of Tigua, bearing in mind that the shallow bank, called the Tortuga, lies N.  $63^{\circ}$  W. from that hill, which will be a sufficient guide for giving it a suitable berth: that is, you must not steer towards Tigua Hill when, in that direction, but either to the southward or eastward of that bearing. Stand on until the easternmost of the Rosario Islands, named Salamanquilla, bears south: from which situation you may steer S. S. E. until the Hill of Tigua bears N. E.; and then steer S. W. keeping the same bearing on; and keeping in mind what has been previously said of this channel, have persons on the look-out for the banks, which stretch off from both sides, and which, as we have before said, show plainly.

**GULF OF MORROSQUILLO.**—Having passed through Salamanquilla Channel, and being opposite to San Bernardo Point, you will discover the great Bay of Tolu, called also the Gulf of Morrosquillo, which is formed by the islands of San Bernardo on the north, and the Island Fuerte on the south. The latter lies with the southernmost key of the former, bearing N.  $46^{\circ}$  E. distant 26 miles. All this Gulf has a good depth of water, there being from 9 to 23 fathoms, on green ooze; therefore a ship may anchor in any part of it during the season of light breezes, calms and variable winds.

**TOLU.**—Thirteen miles S.  $33\frac{1}{2}^{\circ}$  E. from Point San Bernardo, in the bottom of the Gulf, is the town of Santiago de Tolu, situated close to the sea: this town lies 13 miles N.  $63^{\circ}$  E. from the mouth of the Harbor of Cispata, and is in lat.  $9^{\circ} 30' 56''$ . The land in the vicinity of this town is plain, with savannas, which extend to the north, east, and south, terminated on the east by a chain of mountains, over which there rises one mount, forming two round hummocks, named the Tetras de Tolu: these lie 12 miles to the eastward of the town, and are useful marks for recognizing the coast.

In order to pass to the westward of the Islands of San Bernardo, it is necessary to keep at about six miles from the northernmost of them, named Tintipan; and then not steer to the eastward of south, until the point of San Bernardo bears E. by N., in which direction you may steer towards . . . . . It is very convenient for those bound

letes, or Little Trees; San Juan, and Savanilla: that of San Juan is high and scarped, the others are low to the water's edge, with beaches from one point to the other. The interior is a low range of hills, terminating near the cerros or hills of Savanilla, which are about 4 miles S. S. E. from the point of that name. All this coast has a bank lying along it; so that, during the season of light breezes, or of variable winds and calms, ships may anchor on it, at any convenient distance from the coast, according to the size of the vessel. There are no other obstructions on it than a farallon, which lies S. 39° W. a long mile and a half from Broqueles Point; the Island Tortuguilla, which lies 16 miles S. 37° W. from the same point, and nearly west from the Fronton or Hill of Tortugon, rather more than 4 miles; and the Gigantones Shoal, which lies S. W. from Savanilla Point, at the distance of a long mile; this lying near the shore, presents no danger, except to those who run near that point, or Gigantones Point. Tortuguilla Island is low, and covered with trees; a small reef extends from it northward, with very little water on it.

**CARIBANA POINT.**—*Gulf of Uraba, or Darien.*—Point Caribana, as we have already said, is the northernmost point of the Gulf of Uraba: it is low, with trees on it, and surrounded by rocks close to it. It is readily known, because from it the coast trends to the south to form the said Gulf, and also by the Cerro de Aguililla, or Eagle Hill, which is near it: this hill is in latitude 8° 37' 50" N. and longitude 76° 56' 30" W.; and from it, Cape Tiburon, which is the western point that forms the Gulf of Darien, bears N. 84° W. 29 miles distant.

Aguila Hill, although of moderate height, is remarkable from being insulated in the middle of low land.

**SHOALS OFF CARIBANA POINT.**—The shoals off Caribana Point are at the S. W. end of the bank, already described, as generally extending along the coast; the outer corner of which, with 4½ fathoms water, is 4 miles N. W. by N. from the point.

In this extent, and nearly in that direction, there are two rocks; one, at a little distance from the point, partly shows itself; and the other farther separated from it with very little water on it. From the edge of the bank, in 5 fathoms, the depth increases outwards to 6 and 7 fathoms, on sandy bottom, and successively to more; so that 6 miles N. W. from Caribana Point, there are 9 and 10 fathoms, on oozy sand; at 11 miles, 21 fathoms, ooze; and, lastly, at 14 miles, 32 fathoms, also on ooze. These soundings, with the bearings of Aguililla Hill, may serve to direct those who are bound to the Gulf; observing that so soon as Aguililla Hill bears east, they will be entirely free from the shoals of Caribana Point, and may steer freely for the Gulf of Darien, nearly to Arenas Point, which lies 5½ miles S. 35° W. from that of Caribana; all this part having a good depth of water.

**GULF OF URABA, OR OF NORTH DARIEN.**—This Gulf, as above stated, has its entrance between Caribana Point on the east, and Cape Tiburon on the west. All the eastern and southern coasts of it, to the Bay of Candelaria, offer secure anchorage at every season of the year; but the other parts to Cape Tiburon are very wild in the season of the breezes, and without any shelter, except for small vessels; but in the season of the Vendavales, when there are light breezes, variable winds and calms, you may anchor in any part of the Gulf, without either wind or sea to incommode you.

**ARENAS POINT.**—The north and south points of Arenas form a low front of two miles extent, and they bear from each other S. 19° E. and N. 19° W. These two points form the eastern dyke of Aguililla Lagoon, which extends from thence eastward 5½ miles, and is 3 miles from north to south, with various low islets in it: this lagoon commences at the southern extremity of Aguililla Hill, heretofore described.

**RIO SALADO.**—From Arenas Point southward, the coast trends eastward a distance of 5½ miles to the Rio Salado, and thus forms a tongue of sand, projecting into the sea, and which, although it is low, has a sufficient depth of water near it, and may be coasted at less than a mile.

From the Rio Salado the coast takes a southerly direction, with some inclination eastward; it is all low land, with hillocks at intervals; and the depth on the bank all along it is so regular, and the bottom so clean, that it may be coasted without any other care than due attention to the lead. From the Point and Hill of Cayman, which are distant from Rio Salado 14 miles S. 14° E. the shores to the southward on both sides of the Gulf, so far as the principal mouth of the Rio Atrato, are swampy, without even one hill on it; and, from the Rio Suriguilla, which is in the southernmost part of the Gulf, to the north and west, may be considered as the Delta, where the great river Atrato or Darien disembogues. The Bay of Candelaria, which is formed by the swampy land at the mouths of the river, bears from the Hill of Cayman about S. 49° W. at the distance of 12 miles. For navigating all along this coast of the bottom of the Gulf, from Cayman Point on the east to the Bay of Candelaria on the west, there needs no other direction than that of attending to the lead; nor is there any danger, for a ship may be anchored wherever it may be convenient, or necessity may require.

me inclination eastward on the bank all along out any other care, which are distant on both sides of the throat even one hill part of the Gulf, to the river Atrato or the swampy land at the, at the distance of 10 miles, from Cayman, no other direction may be anchored

The principal, indeed the sole object for entering into the Gulf of Darien, can only be to avail yourself of the facilities which the River Atrato affords for conducting into the interior the imports, and withdrawing therefrom the exports: thus, notwithstanding this river branches into the sea by many mouths, extending over a great distance, and forming the swampy and inundated lands just spoken of, yet only eight of them are navigable for boats and launches; and of the whole of them, not one of them offers the same advantages as the Little Faysan, or Pheasant, which discharges into the southern part of the bay of Candelaria: inasmuch, as ships anchoring there, will be sheltered from the sea, and be near to the channel by which their freights are to be conveyed inland.

**BAY OF CANDELARIA.**—The coasts of the Bay of Candelaria are so very low, that the greater part of them are inundated, even at low water, and bordered with mangroves, reeds, and rushes, so that only the N. W. point of the bay appears dry. The mouth or entrance of the bay from the N. W. point to the S. E. where the branch called the Little Faysan falls into it, is about 2 miles in width; but there is a sand bank which borders the whole circuit of it, and extends out a mile to the S. E. from the N. W. point, which reduces the entrance to scarcely a mile in breadth. This shoal also stretches off from the S. E. point, but only to a cable's length and a half; within the bay it narrows on the south shore, but widens considerably on the N. W. side. The clear space of good anchorage is about a mile and a third each way.

**Instructions for entering CANDELARIA BAY.**—To enter this bay, caution and a careful use of the lead are necessary, taking care not to get into less than 17½ or 17 fathoms in its entrance, nor 12 within it. This caution is very necessary, because the sand bank that surrounds it is so steep, that it shoals immediately from 13 to 5 fathoms, and from 5 to getting aground. By taking care to preserve the proper depth, you will go in mid-channel, at about 4 cables' length from the S. E. point. It will also be advisable to have a man upon the lookout, on one of the yard arms, as the color of the water indicates the channel and the shoals. On the Bar of the Little Faysan branch, there are 3 feet water, and the tides rise 2 feet, throughout the whole of the Gulf of Darien.

**CHOCO POINT AND ANCHORAGE.**—From the N. W. point of Candelaria Bay the coast continues low, and covered with mangroves, in the direction of N. 10° W. nearly 5 miles, to Revesa Point; thence W. N. W. 7 miles, to the Tarena Keys; on all this coast the shallow bank, thrown up by the waters from the mouths of the river, extends outward. The principal mouth of the Atrato lies at about one third of the distance from Revesa Point towards Terena Keys; and it is necessary to keep at two miles distance from the coast. Revesa Point, which is also called Choco Point, forms a curve that presents a fine anchorage, well sheltered from the north winds and breezes; to enter it you have only to keep about 1½ cable's length distant from the south side of the point; and when you are abreast of it, or to the westward of it somewhat farther into the bay, you may anchor in 13 or 14 fathoms.

**PEAKS OF TARENA, CANDELARIA, DE CABO, AND GANDI.**—On this coast, and to the southward of the Tarena Keys, will be seen a mount, or hill, called the Peak of Tarena, whence lies a very lofty ridge, extending to the N. W. of the various peaks of these heights, the southernmost is called Candelaria, and the northernmost, which is over Cape Tiburon, is called Pico de Cabo, or Peak of the Cape; the peak next to it southward is named Gandi.

**ISLETS TUTUMATES, TAMBOR AND BOLANDEROS.**—From Tarena Keys the coast runs about N. 28° W. a distance of 10 miles, to the Bolanderos: it is all high, and there are various islets lying along it. The first of these, named Tutumates, is a group of three islets, very clean, and lying about half a mile from the coast. To these follow another named Tambor, which is separated from the coast rather more than half a mile. Although this is clean, it must be borne in mind, that at the distance of half a mile N. N. E. from it, there is a rocky shoal which shows itself, between which and the islet there is a passage; but it is always better to pass outside. To the west of this islet the coast forms a bay called Puerto Escondido, or Hidden Harbor, which on account of its small capacity, admits small vessels only. To Tambor follow the Bolanderos, consisting of a larger islet, with other small ones at its south part: all these are clean, with deep water around them, and do not lie farther than three quarters of a mile from the coast.

Three miles N. 55° W. from the Great Bolandero, and at the distance of half a mile from the coast, lies the Piton Islet, which is very clean; from thence N. 65° W. 6 miles, lies Gandi Point, forming a beachy bay, named Tripo Gandi. From Gandi Point the coast follows about N. N. W. for the distance of 1½ mile, to the point of the River Gandi, with which, Gandi Point forms the bay of Estola, or Gandi, where the rivers of these names disemogue: this bay is of little importance.

At N. 16° W. 6½ miles from Gandi Point, lies the Tonel Islet, very clean with deep water, especially on its eastern side: it is rather more than a mile from the coast. From this islet to Cape Tiburon it is 6½ miles N. 42° W. All this coast from the Tarena Keys to Cape Tiburon, is high and steep, with deep water: but it is very wild in the season of the breezes: for which reason it is most prudent to avoid it during these seasons, and to keep on the eastern side of the Gulf, as it not only affords security and the accommodation of anchorage in every part, but, as there is no inconvenience arising from the sea, it is much more easy for working to windward; and much time may be saved by it.

**CAPE TIBURON.**—This cape, as before said, is the N. W. boundary of the Gulf: it is rocky, high, and scarped; and projects out in a N. E. direction forming an isthmus, on the south and west sides of which are two little harbors. The first of these is so narrow as to be of little importance; the second is larger, and called Miel Harbor, in which there is good holding ground, and the greatest depth is from 11 to 12 fathoms, on sand and clay.

**POINT AND PEAK OF CARRETO.**—Thirteen miles N. 62° W. from Cape Tiburon is the Point and Peak of Carreto, which is the eastern point of a little harbor of that name. Between the two points a bay is formed of about 2½ miles in depth, which is called the Bay of Anahuana; all its shore is beachy to the foot of the high mountains, without any remarkable point. In the N. W. part of this bay, and at the distance of two miles to the southward of Point Carreto, is a little harbor, called Puerto Escondido, fit for smugglers only.

**CARRETO HARBOR.**—The Point and Peak of Carreto are, as before stated, at the eastern part of the Harbor of that name, the western part being formed by a cluster of islets of various sizes; and between these points the greatest distance is a mile and a half, but the narrowest part of the mouth is only a mile. This harbor is of a semicircular form, and extends inward about a mile: the depth of water in it is not less than 3 fathoms, nor more than 8 fathoms. Notwithstanding these good qualities, it is, on the contrary, open to the N. E. breezes and the seas they raise, and has little shelter from the N. W.; it is, therefore, only of use during the season of the calms and variable winds.

**CARRETO SHOALS.**—To the north of this harbor, at the distance of a long mile, there are two little shoals near each other bearing N. E. and S. W. with 5½ fathoms over them, on rocky bottom, and near them from 20 to 25 fathoms; with fresh breezes the sea breaks over them.

Seven miles N. 48° W. from the point and peak of Carreto is Punta Escoces, or Scott's Point: on this bearing there are clusters of islets of different sizes, extending out to N. N. E. a long mile from Punta de los Islotes: to this point, which is three miles south-eastward from Punta Escoces, the coast is high and scarped; but from thence to Punta Escoces, it is lower, with a beach.

**CAROLINE BAY.**—Punta Escoces is the S. E. of a bay, named Caroline Bay, the great islet of Oro, or Santa Catalina, being the N. W. point, bearing from the former N. 40° W., distant 4 miles; and from this line of direction, the bay falls inward about one mile and two thirds. In the S. E. part of this bay is Puerto Escoces, or Escondido. (Scottish or Hidden Harbor,) which extends inward in that direction nearly three miles, and forms good shelter. There are some shoals in it, which are represented in the particular Plan of the Harbor, by which any vessel may run in for the anchorage, where they will find 4½, 5½, 6, and 7 fathoms water, on sandy bottom.

**GRANDE DEL ORO, SAN AUGUSTIN, AND PIEDRAS ISLET.**—The Isla Grande del Oro is high; and at one mile and eight tenths to the south of it, there is a smaller island, called San Augustin; and on the same bearing, a little more than a cable's length from San Augustin, is Piedras Islet, which doubtless takes its name from the many rocks with which it is surrounded.

Between Piedras Islet on the north, the west point of Aglatomate River on the south, and that of San Fulgencia to the S. W. is formed the Ensenada, or Bay of Carolina, or Caledonia, and the channel of Sasardi.

**CALEDONIA BAY.**—The Bay of Caledonia is, strictly speaking, formed by the points already mentioned, which bear from each other N. 25° W. and contrary, distant one mile. This bay is clean, and has a good depth of water; the greatest part of its shore is beach, and near the middle of it disembogues the River Aglaseniqua. The front or point of San Fulgencia is salient, scarped, and clean; and it also has a little bight at its western part, with little depth of water, bordered by mangroves and various keys.

**SASARDI CHANNEL, S. E. ENTRANCE.**—Between San Fulgencia Point, the Great Oro Island, Piedras Islet, and the Mangrove Keys which lie to the west of them, the Channel of Sasardi is formed; whose S. E. entrance from edge to edge, is about four cables' length wide, a little more or less, and with a depth of 8 to 11 fathoms, on

ooze; and farther in, from 7 to 9 fathoms; as also between the edge of the bank off Pie-  
dras Islet, and the Bay of Caledonia, the depth is from 6½ to 14 fathoms; and the space  
of sea between this bay and Puerto Escoeces, is of a good depth; but at S. 55° E. a short  
mile from Piedras Islet, the sea breaks when the breeze is fresh.

These harbors are equally sheltered from the winds and seas of both seasons, and have  
a good depth of water; but the channel of Sasardi and Bay of Caledonia are prefera-  
ble, because you can either enter or sail out from them with all winds, with more facility  
and less risk than you can either into or out of Puerto Escoeces.

**SASARDI CHANNEL, N. W. ENTRANCE.**—At the distance of 4½ miles, N.  
52° W. from the east end of the Great Oro Island, is the west extremity of two larger  
islands, which, with the reefs, shoals, and multitude of smaller islets extending thence  
to the N. W., form, with the coast, the channel of Sasardi. The N. W. mouth of this  
channel is formed by the said western point of the two large islands and the front of Sa-  
sardi, with an opening of three quarters of a mile: this channel has many shoals in it,  
and is, therefore, of no utility; neither is there any population near it. Those who  
wish to enter it must have a free wind for that purpose.

Between the eastern point of Great Oro Island and the N. W. mouth of the channel  
of Sasardi, some reefs project out, with two islets at the extremity, which bear from the  
said eastern point of Great Oro N. 25° W. two miles distant, and from the S. E. ex-  
tremity of the two large islands already mentioned, about N. E. Also, at the distance  
of a mile and a half to the westward of the front or point of Sasardi, there is a bank  
with little water on it.

The front of Sasardi is projecting, round, scarped, and surrounded by reefs close to  
the shore. From the most salient part of this front, the S. E. part of the Isla de Pinos  
bears N. 5° W., distant two miles; and in the intermediate space the coast forms vari-  
ous open bays, of little importance, the points of which are scarped, and surrounded by  
reefs. Off the west part of the said island is the Cienaga of Navagandi, with its mouth  
shut by reefs; which, with the island, form a channel of two cables' length wide in the  
narrowest part, with a depth of from 1½ to 5 fathoms water.

The Isla de Pinos is high, with a hill extending along it, on which rise two remarka-  
ble points, covered with wood: its greatest extent is N. E. by N. and S. W. by S. rather  
more than a mile, and its greatest breadth is scarcely a mile: its N. E. and south sides  
are scarped, and bordered by reefs, very near the shore. The N. E. point of this island  
is in latitude 9° 1' 30", and longitude 77° 50' 10". At the distance of two miles N. by  
W. from the north end of the Isle of Pines, is the Isla de Pajaros, or Bird's Island,  
which is low, narrow, covered with brushwood, and surrounded by reefs, which have a  
depth of 7 or 8 fathoms close to their edges, on rocky bottom. From this point com-  
mences the immense Archipelago of the Mulatas, composed of islands, keys, shoals,  
and reefs, forming between them and the main land many anchorages and well sheltered  
channels, secure in all weathers, and terminating at Punta de San Blas. The interior of  
the coast is a high mountain range, with notable peaks, whose situations are exhibited in  
the chart of the coast, and may serve as marks to direct to the various anchorages, &c.  
which it comprises.

The channels which are formed in this space, are those of Pinos, Mosquitos, Cuiti,  
Zambogandi, Punta Brava, Cocos, Rio de Monos, Ratones, Playon Grande, Puyadas,  
Arevalo, Mangles, Moron, Caobos, Holandes, Chichime, and San Blas. These are more  
or less free, as may be seen by inspection on the chart.

A ship, at the distance of one league to the northward of Pajaros Islet, and steering  
N. W. 25 miles, and N. 65° W. 38½ miles, will pass clear of all these dangers, and will  
be to the north of the easternmost keys of the Holandes Group, at the distance of 4½ or  
5 miles. With these courses you will, in the beginning, pass at 1½ or 2 miles outside the  
reefs, and afterwards at 4 and 5½ miles; but it remains at the option of the navigator to  
pass at a greater distance, if more convenient.

**GULF OF SAN BLAS.**—Seventeen miles to the westward of the easternmost keys  
of the Holandes Group lies Point San Blas, in lat. 9° 34' 36", and long. 79° 1' 24". It  
is low, and forms the N. E. boundary of the Gulf of San Blas, the mouth of which ex-  
tends N. and S. to the anchorage of Mandinga 6 miles, and from that line an equal dis-  
tance to the westward. Its coasts are low, with mangroves which advance into the sea.

From Point San Blas eastward, to the distance of a mile and three quarters, extend  
some reefs, with various keys, the easternmost of which is called Cayo Frances. From  
this, extending to the S. W. and westward, there are twelve other keys; and to the east-  
ward of them are many banks and islands, which make part of the Archipelago of the  
Mulatas, and form various channels.

To run into and anchor in the Gulf of San Blas, whether it be in Bahia Inglesa, which  
is to the S. W. of Point San Blas, or at Mandinga, which, as before said, lies to the  
south of it, the most commodious passage is by the channel of Chichime and that of San  
Blas.

THE CHICHIME CHANNEL is formed to the west by the keys off Point San Blas, to the east by the reef and group of keys of Chichime, and to the south by another group surrounded by reefs, which some call Cayos de Limon or Lemon Keys.

THE CHANNEL OF SAN BLAS is formed by the Cayos de Limon to the S. E., and those of San Blas to the N. W. The first is three miles in extent between the steep edges of the reefs; and the second one mile and three quarters.

DIRECTIONS FOR ENTERING THE GULF OF SAN BLAS.—To enter this gulf it is necessary to open the mouth of the channel of Chichime, until you are on the true meridian of the second islet, counting from the westward to Cayos de Limon; from which situation steer south towards it, until abreast of, or rather before you get so far to the south as Cayo Frances; then steer S. 50° W. through the middle of San Blas Channel, which, as already noticed, is a mile and three quarters wide between the reefs of the west south-westernmost islet of the Lemon Keys, called Gallo, or the Cock, and the reef which extends to the southward from Cayo Frances; thus directing yourself to the anchorage, whether it be to that on the north side of the gulf, or in Mandinga Bay. To proceed to the latter, the keys which lie to the north of Mandinga Point will serve for a mark. Of these, the outermost, called Cabras, lies a mile from the point; and it should be noticed, that at nearly a mile N. 10° W. from Cabras there is a little sandy key, to which a berth must be given, and there is a bank, with 1 and 1½ fathom on it, lying N. 69° W., distant a long mile and a half from Cabras Islet. The passage is between this bank and the little sandy key. The anchorage of Mandinga is sheltered, and has depth sufficient for any class of vessels. In the gulf, and extending out from the bottom of it to the distance of 3¼ miles, there are various islets, keys, and banks, the easternmost of which is called Cayo Maceta. To all of these a berth must be given, if desirous of going far into the gulf.

HOLANDES CHANNEL.—This is the largest of all the channels that are formed by the Muktas Islands. Its mouth is formed on the east by the western extremity of the reefs of the Holandes Group, and on the S. W. by Icaos Key. The distance from one key to the other is 2¼ miles N. 55° E., and S. 55° W., and the least depth in the channel is 14 fathoms, on a bottom of sand; but W. N. W. from Holandes Key, at the distance of a little more than 1½ mile, there is a shoal, which extends half a mile N. and S., with 6 and 6½ fathoms on it, over rocks. The sea breaks over it when there is but little swell. It may be passed either on the east or west side, but it will be always best to pass to the eastward of it, and near to the reefs of the Holandes Group, the breakers of which will serve as marks. Proceed afterwards toward the east part of Icaos Key, and give it a berth in passing. This key or island is of firm land, covered with high wood, and named from the abundance of Icaos trees growing on it. From the meridian of Icaos Key, on its south side, the direction of the Holandes Channel is about S. 75° W., to the bottom of the Gulf of San Blas. It is clean, and has a depth of 21 to 25 fathoms, on oozy bottom, with a breadth of 2½ to 3 miles, between groups, detached keys, and reefs, but free and commodious to turn in, in case of necessity, towards the anchorages already described.

FROM THE POINT OF SAN BLAS WESTWARD.—At N. 49° W., rather more than half a mile from Point San Blas, is the north part of its front, low, and covered with mangroves; and in the intermediate space is a little key, called Piedras, and other shoals, connected with Cayo Frances. At the distance of a quarter of a mile N. 34° W. from the north point of San Blas, is a key named Cayo Perro, also united to the reefs extending westward from Cayo Frances, and which terminate at an island lying in front of Cineaga, a mile and a quarter farther west.

From Perro Key the coast continues nearly 10 miles S. 88° W. to Cocos Point, on the east side of the mouth of Escribanos Harbor. The intermediate coast continues low, with reefs along shore, and somewhat of a bay. The most visible objects on it are Magote Point, which is small, a little salient, and has a hillock on it; that of Cerro Colorado, which is round, scarped, and projects out but little; and that of Playa Colorado, which is round, and surrounded by reefs, which extend out to a cable's length.

POINT ESCRIBANOS.—Cocos Point advances into the sea, and from it the point of Escribanos bears S. 80° W., one mile and a third, and in this space a bay is formed, in the middle of which is Escribanos Harbor, extending inward to the south, from its mouth, half a mile. This harbor is very shallow, having no more than 1 and 1½ fathoms water. Without, on both sides, there are reefs with very little water on them; and in the channel, which is formed by them, there are from 3½ to 6 fathoms.

ESCRIBANOS SHOALS.—To the north-eastward of the mouth of this harbor are the shoals named the Escribanos. They are two in number, and are composed of reefs with very little water on them, and lying near each other. On the reef nearest to the coast is an islet lying rather less than two miles from Cocos Point. This reef extends a mile from W. S. W. to E. N. E. The other lies about W. N. W. from the said

N. W. from the said

islet or rock, and extends nearly a mile from E. to W. Both are steep to, with 3 and 4 fathoms water; and on the bank are from 8 to 12 fathoms, on gravel and coarse sand. In the channel formed by the south-easternmost shoal and Cocos Point, there are from 9 to 12 fathoms, diminishing to 6 and 5 fathoms on each side.

Escribanos Bank lies nearly N. W. by W. from the shoal of that name, distant  $5\frac{1}{2}$  miles. This extends N. 56° W., and S. 56° E., nearly 2 miles, and has from 5 to 8 fathoms water, on rocky bottom. To the northward of its edge, about 2 cables' length, from 16 to 31 fathoms are found. In heavy seas, the water breaks on this bank, which may serve as a guide; and when it does not, a lookout must be kept at the mast heads. In the channel between this bank and the Escribanos Shoal, there are from 8 to 17 fathoms water, on sand, gravel, and rocks. The N. W. part of it lies N. 32° W., distant  $8\frac{1}{4}$  miles from Escribanos Point.

TERRIN POINT.—Nineteen and one third miles N. 81° W. from Cocos Point, lies Terrin Point and Pescador Islet. Between the former and Quingongo Point, which are distant from each other  $8\frac{1}{2}$  miles, and on the meridian of Escribanos Bank, is Culebra Islet, distant from Culebra Point two thirds of a mile about N. N. W. Following on to the westward, the point and islet of Quengo are met with. Part Escondido, which is somewhat to the westward of this point, is only a little cienaga, or lagoon. Point Chaguachagua, and that of Macolla, are the most remarkable points on this part.

The range of mountains which extends along this coast, from those of Darien to those of Porto Bello, are sufficiently remarkable, that called Cerro de la Gran Loma, or Gordo, being rather more so than the others. It lies S. 42½° W. from Culebra Islet, distant full 7 miles, and may serve as a mark for keeping clear of the Escribanos Shoals and Bank. This hill is a little higher than the Cordillera, in which it is situated. Its top is large, and of some extent.

Pescador Islet lies about 2 cables' length N. 43° W. from Terrin Point, and the point is surrounded by reefs, which extend a cable's length to the north, and half a mile to the west, continuing to S. S. W. so as to surround three islets, which lie between that point and the N. E. point of the harbor of Nombre de Dios.

Between Point Terrin, on the east, and the Islet Martin Pescador and Manzanilla Point, on the west, the first of which bears from Terrin Point N. 64° W., at the distance of 4 long miles, and the second N. 72° W., 5 miles, a great bay is formed, which extends in nearly 3 miles to the S. W. and to the W. and N. W. 2 miles, to the bottom of the bay of San Cristoval. At  $1\frac{1}{2}$  mile S. 49° W. from the eastern extremity of this bay, lies the western point of the harbor of Nombre de Dios, surrounded with reefs, as is also the eastern point, although at this part they extend farthest off. This harbor is small, and the greatest part of its shores are bordered with reefs and shallows. Its clear depth is  $3\frac{1}{4}$ , 4, and 5 fathoms, in the mouth. The other parts of the great bay of San Cristoval are useless in the season of the breezes, and the reefs from the bottom of it extend out nearly a mile towards Point San Cristoval.

From Point San Cristoval, distant 2 long cables' length to the N. E., lies an islet, called Juan del Pozo, surrounded with rocks; and about S. E. from it, at the distance of half a mile, is a bank named the Vibora. Between this bank and the Islet Juan del Pozo, and between the latter and Point San Cristoval, there is a depth of 9, 10, and 13 fathoms, on gravel and coarse sand.

Point San Cristoval lies S. 88° W.  $3\frac{2}{3}$  miles from Terrin Point: also, from this point the Buey Shoal bears N. 60° W., distant nine tenths of a mile. Between this shoal and the reefs of Terrin Point there are from 9 to 12 fathoms water, on rock, sand, and clay; and 9, 12, and 14 fathoms, on ground of the same quality, between the Buey and Vibora Shoals. The coast between Point San Cristoval and that of Manzanillo is high and scarped.

The Point of Manzanillo is the northernmost of all the coast of Porto Bello. It is also high, scarped, and projecting out, with two hummocks on it. Near this point are several islets and a shoal. The greatest of these, named Manzanillo Islet, is high and scarped, and lies four fifths of a mile to the east. It has three farallons to the north, of which the farthest out is distant a long cable's length. At S. 30° W. from the same islet, there are three small islets, surrounded with reefs, which extend N. E. and S. W.; and also to the east there is another small one, distant about a cable and a half; and, lastly, to the N. N. E. of the said Manzanillo Islet, at the distance of four tenths of a mile, lies the islet of Martin Pescador, extending about a cable's length N. and S. All these islets are high and scarped, and between those of Manzanillo and Martin Pescador there are from 10 to 14 fathoms water.

Manzanillo Shoal lies N. W. of the point of the same name, at the distance of four tenths of a mile. It has very little water on it, and 5 and 6 fathoms close to it; and in the strait between it and the point there are 13 fathoms water.

Among the mountains on this coast, two are remarkable, named Saxino and Nombre de Dios, and which may serve as marks for recognizing the harbor of the last name. The first, which is high, terminates in two peaks near each other, and the north-easternmost of them is about S. 22° E. from Terrin Point, distant nearly 7 miles. That of Nombre de Dios, which is to the south of the harbor, terminates in one peak, and is distant from Terrin Point 8 miles S. S. W.

N. 65° W., at the distance of a mile and a half from Manzanillo Point, is the highest part of Tambor Islet, which is high, round and scarped, and which is connected by a reef of two cables' length, with the northernmost part of Venados or Bastimentos Islet, and. This island is nearly a mile in length, N. E. and S. W., and forms, with the main land, the N. E. channel of Bastimentos Harbor, the greatest extent of which, between the reefs, is one and a half tenth of a mile, with 5 and 5½ fathoms water, on sand. This island of Bastimentos is foul on its S. E., S., and S. W. sides; and the latter, with Cabra Islet, which lies somewhat to the southward of west, forms the N. W. channel, the narrowest part of which, between the reefs, is three tenths of a mile wide, with from 3½ to 9 fathoms, on mud. The harbor of Bastimentos is of little importance, although sheltered, with a depth of 3½ to 7 fathoms. All its shores are bounded by reefs; and the customary anchorage is to the S. W., S., and S. E. of the south or sandy point of Bastimentos Island.

**GARROTE HARBOR.**—At S. 51° W. from the highest part of Tambor Islet, at the distance of 2½ miles, lies the mouth of Garrote Harbor, formed by the main land to the south, by Great Garrote Island in the east, and by Pelado Island, and other islets which follow to the westward one mile and a half, to the mouth of the Boquerones. The mouth of Garrote Harbor is scarcely three tenths of a mile wide between the reefs to the west of Great Garrote Island and Pelado Islet. Its first direction is from north to south, and afterwards to S. E., with a depth of from 6½ fathoms in the interior of the harbor, to 12 and 18 in the mouth, on mud. Between this harbor and that of Bastimentos, rises the Hill of Garrote. It is of middling height, and its top terminates in a peak, at the distance of seven tenths of a mile from the coast.

At the distance of 3½ miles S. by E. from the little bay of Garrote, is the Mountain of Capiro or Capira, high, and almost always covered with clouds. This mountain is situated nearly east from the city of San Felipe of Porto Bello.

At a short distance to the southward of Capira is the Sierra or Mountain Ridge of Llorona, extending nearly east and west. It is the highest of all on the coast of Porto Bello. On the eastern part of its top it appears as if cut down vertically, forming a peak called the Campana, or the Bell. From this peak the ridge descends gradually to the west, to near the Peak of Guaniche. The appearance of this ridge is such, that it cannot be mistaken for any other. In clear weather it may be seen at the distance of 45 miles; but in the season of the fresh breezes it is generally covered with haze; and in the season of the vandravales and variable winds it may often be seen between 8 and 10 in the morning, and 4 and 5 in the afternoon; but in the rest of the day it is covered with clouds.

The Lavandera Shoal lies N. 6° E. seven tenths of a mile from the north extremity of Pelado Islet, and N. 85° W., distant one mile, from Cabra Islet, at the mouth of Bastimentos Harbor. This shoal is of rock, with very little water on it, and steep to, with 7½ and 9 fathoms close to a rock on which the sea breaks. The channels between it and Cabra and Pelado Islets have a depth of from 14 to 17 fathoms, on mud.

**BOQUERONES POINT AND ISLETS.**—S. 64° W. from the highest part of Tambor Islet, at the distance of three miles and eight tenths, lies the point of Boquerones, which is salient, high and scarped; and from it, almost on the opposite bearing, that is, N. 64° E., there are 5 islets, called the Boquerones, which extend out about 3 cables' length. Here terminate the reefs and islets which extend westward from Pelado Islet.

**CASIQUE HILL.**—Boquerones Point has to the south, at a long mile's distance, a hill, named Casique, which terminates in a point, and is of middling height. It may serve as a mark for keeping clear of the Farallon Sucia, or Foul Rock, which lies N. 33° W. nearly 2 miles from Boquerones Point. The Foul Farallon is at the west end of two groups of islets and shoals, which from S. W. to N. E. extend six and a half tenths of a mile, forming a channel between both, with 4 to 6 fathoms water. The north-easternmost islet, or farallon, bears N. 88° W. from the highest part of Tambor Islet, at the distance of nearly 4 miles; and in this space there are from 16 to 30 fathoms water, on clay and sand; and 16, 21, 22, and 25 fathoms, between the said farallon, the islets of the coast, and the Lavandera Shoal.

**DUARTE ISLETS.**—Three miles S. 69° W. from Boquerones Point, lies the north end of the Duarte Islets, which are 4 in number, and extend S. 25° E. and N. 25° W. six tenths of a mile. From the north-easternmost one a reef extends a cable's length in the

same direction as the cables' length from that of the straits there; the coast is high out, and is su rocks.

At the distance of 1½ miles, is Drake Islets, is high, and bordered by the reefs, and is high out, and is su rocks.

**PORTO BELLO.**—The capability of the entrance, which is on the south N. by W. The rather more to the W. From the mangroves at the reefs and rocks, the length; and advances 2½ cables from the city, and 1½ fathoms, diminishing regularly by warping on the anchorage is on clay and sand, the little shoal.

The reefs of the Lavandera Shoal, the point of the shoal, all connected by a mile, lies the middle that at W., at the distance of 1½ miles, the shoal, and the other around it, and water, on clay.

At three miles from Point Farnes, the water on it, on the channel between the islets on clay.

**Fresh Water.**—The islets descend from that which is according to the of San Gerónimo.

To the south of the Cove of Boquerones.

To enter Porto Bello, approach the islets, the length to the, but never attempt to enter, Drake, steer toward in that direction.

If bound in the Bay of Buenaventura, N. E. and nearer the north.

 the said farallon, the

s Point, lies the north  
 E. and N. 25° W. six  
 a cable's length in the

same direction. The southernmost of these islets is separated a little more than two cable's length from the Point of Duarte on the main land to the southward of it; and from that of Sabanilla, which bears N. 64° E. nearly half a mile. Between the two straits there is a depth of from 3½ fathoms, close to the islet, to 15. The intermediate coast is high and scarped, with some bays. The Point of Josef Pobre extends farthest out, and is surrounded with rocks and reefs. Sabanilla Point has also a reef, and some rocks.

At the distance of two long miles S. 24° W. from the northernmost part of Duarte Islets, is Drake's Point, which is the N. W. point of Porto Bello. The intermediate coast is high and scarped, with a little harbor, called Leon, of very little importance, and bordered with reefs, which terminate to the N. N. W. at a little farallon, distant four tenths of a mile from its mouth.

**PORTO BELLO, OR PORTO VELO.**—The name of this port aptly defines its capability of receiving and accommodating ships of every class. The widest part of its entrance, which is between Drake's Point on the north, and the Islet of Buena Ventura on the south, is one mile and one fifth; and these bear from each other S. by E. and N. by W. The narrowest part between Todo Fierro Point and that of Farnesio, is rather more than half a mile wide, and these lie in the direction of S. 2° E. and N. 2° W. From the last mentioned points the harbor extends inward E. N. E. 1½ mile to the mangroves at its bottom. The north shore is clean; but from the south shore some reefs and rocks, with very little water on them, stretch off to between 1 and 1½ cable's length; and in the bottom or east part of the harbor there is a sand bank, which advances 2½ cable's length from the mangroves towards the west; and also at N. 26° W. from the city mole, one and a half tenth of a mile, there is a very little sand bank, with 1 and 1½ fathom water on it. The rest of the harbor is clean, and sufficiently deep, diminishing regularly from 16 to 8 fathoms. Ships of the line ought to enter this harbor by warping or towing, because there are regularly either head winds or calms. The best anchorage is to the N. W. of the Battery of Santiago de la Gloria, in 9 or 10 fathoms, on clay and sand; but smaller vessels may go nearer to the city, taking care to avoid the little shoal already spoken of.

The reefs on the south shore continue to the W. S. W., and W., to the Islet Buena Ventura, the N. W. point of which bears S. 55° W. three long cables' length from the point of the same name; and between this islet and the point, there are two smaller ones, all connected by reefs. S. 37° W. from Drake's Point, at the distance of one fifth of a mile, lies the middle of Drake's Islet, which is clean all around, and has a break in the middle that appears to divide it into two parts. From this break to the west, and N. 65° W., at the distance of three fifths of a mile, lie the south and north ends of the Salmedina Shoal. The south part consists of rocks above water, over which the sea breaks; and the other parts have from 2 to 3½ fathoms water, on rocks. There is deep water all around it, and in the channel between it and the islet there are from 11 to 26 fathoms water, on clay.

At three fifths of a mile south from Drake's Islet, and three and a half tenths west from Point Farnesio, lies the Farnesio Shoal, of a triangular form, with 3½ to 5 fathoms water on it, on a bottom of rock. There is no passage between it and the coast; but in the channel between it and the Salmedina Shoal there are from 16 to 21 fathoms water, on clay.

**Fresh Water.**—This harbor is surrounded by high hills, from which some rills or rivulets descend on both coasts, and from whence vessels may procure water, particularly from that which runs into the bay to the westward of the Fort of San Fernando. According to the determinations of Brigadier D. Joaquin Francisco Fidalgo, the Battery of San Geronimo, at the city, is in latitude 9° 24' 22" N., and longitude 79° 43' W.

To the southward of Porto Bello, at the distance of a long half mile, is the Ensenado, or Cove of Buena Ventura, much bordered with reefs, and consequently of little use.

To enter Porto Bello when approaching it from the north-eastward, it is advisable to approach the Farallons of Duarte, and from them to steer so as to pass at about a cable's length to the N. W. of Drake's Islet, by which the Salmedina Shoal will be avoided; but never attempt to pass between Drake's Islet and the shore. Having passed the Drake, steer to the south and east, to gain the middle of the harbor, and proceed inward in that direction, or rather nearest to the north shore.

If bound into this Harbor from the southward, pass at about half a mile from the Islet Buena Ventura, and thence towards Drake's Islet, to clear the Farnesio Shoal; then steer N. E. and more easterly as the harbor opens; and lastly, run in mid-channel, or rather nearer the north side, as before directed.

**FROM PORTO BELLO TO CHAGRES.**—About S. 50° W. at the distance of nearly 15 miles from Drake's Point, is the western extremity of the front of Longarremos, which, with the north-easternmost of the Islas de Naranjos, or Orange Isles,

form a bay in which are two creeks, called those of Minas; the Orange Isles lie N. 66° E. at the distance of 4½ miles from Longarremos Point. The Minas Creeks are formed among mangroves, and the easternmost one extends inward 3 miles to the S. S. E. is of various breadths, and its shores are bordered with *reefs*. The western creek is narrower and shorter; it extends inward to the south, rather more than a mile. At the S. E. part of the Orange Isles, which are low, covered with trees, and surrounded with *reefs*, there is an anchorage with 4½, 6, and 7 fathoms water, on sand.

In the intermediate part of this coast, Point Gorda is the most projecting, and there are several coves of little consideration. To this point the coast is high, with banks or ridges, and between it and Buenaventura Cove, the River Guanache disembogues; Guanache Hill bears from Point Gorda N. 82° E. distant 3½ miles. From Point Gorda to the S. W. the coast gradually diminishes in height, and the remainder from the Point of Rio Grande and the Creeks of Minas, is a low coast, with mangroves. The Fronton of Longarremos is likewise low, with mangroves, and bordered with *reefs*, as are also the points which form the Minas Creeks; these *reefs* extend somewhat more than a cable's length off, are steep to, and at the distance of one third of a mile there are 11 fathoms water, on clay.

**MANZAÑILLO POINT.**—From the Fronton of Longarremos, the mangroves extend to the S. W. nearly 1½ mile to the Point of \* Manzanillo, which is also of mangroves, round, and bordered with *reefs*, to the distance of a long cable, with a little *shoal* that is distant 3 cables from it, N. W. by N.

**MANZAÑILLO HARBOR** is formed between the islet of that name to the west, and the main land to the east, extending in nearly 2 miles S. S. E. from Manzanillo Point; this Harbor is clean, from 2½ to 6 fathoms water. The best anchorage for every class of vessels is a little to the south of its mouth, and on the east coast, in 5 fathoms water, on sand and clay.

Five miles S. 68° W. from the front of Longarremos is Toro Point, which is the western point of Naos Harbor, the eastern one being the north end of Manzanillo Island, which is distant from Toro Point 2½ miles. Toro Point is salient, high, scarped, and bordered with *reefs*, extending out about two cable's length, † with an islet near them. Naos or Navy Harbor extends inward nearly 4 miles to the south from the middle of its mouth; its breadth is nearly equal, narrowing somewhat from two thirds of the said distance; it is clean to the parallel of Point Limon, with a depth from 3½ to 6½ fathoms water, on sand and clay; from Point Limon to the south it is shallow. As this Harbor is open to winds from N. E. to N. W. round by north, it can be of use in the season of the variable winds and calms only.

From Toro Point the coast trends S. 67° W. nearly 2½ miles to Brujas Point, which is of moderate height, and, like the intermediate coast, bordered with *reefs* which extend only a short distance out, but surround an islet, named Mogote de Brujas, which lies to the N. E. of the point of the same name, about 2 cables' length.

From Brujas Point the coast that follows is lower than before, and in the direction of S. 35° W. for 2 miles to Barata, or Vigia Point, so named from having a guard-house on it: from this point that of Chagres is a cable's length distant, and is lower than the former, bordered with low rocks which show above water, and *reefs* which extend out to a short distance.

**CHAGRES.**—From Chagres Point to the west point of the Penon or rock, on which stands the Castle of San Lorenzo, is about 1½ cable's length S. by E. The Penon is scarped to the N. W. and south, and the Castle of San Lorenzo, as we have said, is situated on it, in latitude 9° 20' 57" N. and longitude 80° 3' 53" W. This Penon to the north with point Arenas to the south, form the mouth of Chagres River, which, at the widest part, is two cables' length across, and 1½ where narrowest.

To the E. S. E. at a short distance from the Castle of San Lorenzo, is the little town or village of Chagres, consisting of huts covered with thatch. The mouth of the river narrows between the penon and bank, which extends out from Arenas Point in a N. W. direction to the distance of a cable's length. In the mouth, and to the south of the penon, there are 2½ and 3 fathoms water; and the same depth continues, a little more or less, to

\* SHOALS NEAR PORTO BELLO.—H. M. S. Tribune, Captain Sir Nesbitt J. Willoughby, K. C. B. on the 10th of November, 1821, struck on a rock off Manzanillo point with the Island of Bastimentos bearing S. W. by W. by compass, distant 3 miles, and Monkey Island S. E. There were 3 fathoms water on it, and 7 or 8 fathoms round it. This was accidentally omitted in its proper place. His Majesty's ship Harpy, in February, 1829, having Manzanillo point bearing S. W. by compass, Tambor Island W. ½ S. distant 4 miles, and being about 3½ or 4 miles off shore, had only 6 fathoms water on rocky bottom; and then hauling to the N. W. gradually deepened to 20 fathoms.

the distance of half a mile up the river. To the west of the Castle of San Lorenzo, at the distance of 200 varas, or 92 English fathoms, is a shoal named Laja, which extends from north to south 70 fathoms, and is of rock, with very little water on it. To enter and to sail out of this river is very dangerous, and can only be effected by very manageable vessels, which do not draw more than 12 feet: both operations must be performed with a fair wind, for otherwise the current of the river, and the various eddies it forms, from the opposition of the Penon, Laja, and the west shore, will carry vessels on either one or the other of these dangers.

From Point Arenas of the River Chagres, the direction of the coast is S. 65° W. one mile to the point of Morrito, or Little Hill Point; and from thence S. 33° W. nearly 2 miles, to the Point of Animas: all the shore being low with a beach.

S. 36° W. at the distance of 2 long miles from the last mentioned point, there is another equally low; and is the last point of the surveys of Brigadier Don Joaquin Francisco Fidalgo; from whence proceeding onward, although we have various accounts, they do not merit that confidence which would entitle them to be named Directions.

*Descriptions of the coast from Porto Bello to Chagres, with directions for Chagres and Navy Bays; by Capt. G. Sidney Smith, late Commander of H. M. Sloop Bustard.*

"The land of Porto Bello is very high and full of hummocks, whilst all that to the westward is comparatively low, and in the vicinity of Chagres offers nothing remarkable; that to the eastward of Manzanillo Point is rather high and uniform. The Castle of Chagres, from the nature of its position, cannot be seen from the eastward until you arrive close to it.

"CHAGRES BAY.—Point Brujas forms the N. E. point of the Bay, and when within 4 or 5 miles of it, in nearly an east or west direction, it cannot be mistaken; it appears to have lying off it a small island, with its sides of perpendicular rock, and top covered with bushes, which, on nearer approach, is found to be connected with the main land.—About half way between this point and the Castle (the whole of that part of the coast being steep to) is a remarkable *white patch* in the cliff, and close to it a fine fall of excellent water: but unless in very fine weather and smooth water, it cannot be approached without danger of staving the boat. When running in for the anchorage during night or day, after passing Brujas Point, keep it open of the point S. S. W. of it. The best anchorage for a large ship is with Brujas Point N. E. about three miles. The Bustard anchored in 5½ fathoms with the Flagstaff in the Castle S. E. ½ E. and Point Brujas N. E. ¾ N. A strong current sets out of the river to the N. N. E. with greater or less force, according to the season, whether rainy or dry; but at all times it prevents your riding with any great strain with northerly winds. Should it come on to blow heavy, it would be well to slip and shift round to Navy Bay.

"The Bar of Chagres Harbor or River has 2½ fathoms on it, at low water: the entrance is rather difficult, and at all times requires a fair wind, but when in, you are perfectly secure. I would not recommend its being entered, if the measure could possibly be avoided, or to suffer the boats to be there at night. It is, perhaps, the most unhealthy place known. The Bustard's cutter was, by stress of weather, obliged to pass a night in the harbor; the consequent loss was a lieutenant, and seven men: only one of the number attacked recovered. This happened between the 27th and 30th day of November, 1827.

"NAVY BAY is about 4 miles in depth, and 3 in breadth, open to the north, and formed by Point Manzi, which is the N. W. point of the Manzanillo Island, to the eastward, and Point Toro to the westward. Off the latter lies a dangerous reef, extending about a mile to the N. E. which should not be approached to a less depth than 5½ fathoms water; Point Manzi on the opposite side may be approached with safety by the eye, within half a cable's length. The shores of the Bay on both sides are bold for nearly 2 miles inward, having 3 fathoms close to the beach or bushes. The depth of water decreases very gradually between Toro Reef and the south end of the bay, being from 7 to 2½ fathoms, so that persons may select their berth according to their draught of water: but reference ought to be had to the season of the year. In the rainy season, by far the greater portion of the year, it is best to anchor on the west side, as the winds, though variable, are generally from that quarter; and during the season of strong sea breezes, which are generally from the N. E. with occasional westing, it is better to anchor under Point Manzi. The latter bore from the Bustard N. ½ W. by compass, one third of a mile distant, where the holding ground was found very good at 4½ fathoms water, with a little outset from the bay.

"Point Limon is bluff, and is on the west side of the bay, about three miles within Toro Point, having a hut erected on it, where there is generally a guard of a few soldiers, who communicate with Chagres by an intricate foot path; for although the distance is

not above 4 miles, it takes several hours to accomplish it. When Point Limon is well open, bearing S. by W. by compass, the Bay may be entered with safety.

"The soundings on the coast between Points Toro and Brujas at a full mile off shore are  $7\frac{1}{2}$ , 8,  $8\frac{1}{2}$ , 9, and 10 fathoms, and thence to half a mile off Chagres, or Batata Point, 10, 9, 7,  $6\frac{1}{2}$ , and 6 fathoms; there are  $5\frac{1}{2}$  with the white patch before mentioned bearing E. S. E. always keeping Brujas Point just open of the point S. S. W. of it.

"Navy Bay has not a single resident on its shore besides the guard before spoken of. Landing, except at a few places, is very difficult. Wood and cocoa-nuts are to be had in abundance: fish are scarce.

"Some persons have pointed out different spots where fresh water may be obtained; but the Bustard's boats during her stay here, from the 30th of November to the 11th of December, 1827, were employed surveying and visiting every part of the bay; and although heavy rains had fallen, water was not to be found, except in small quantities in stagnant pools."

*Directions for sailing from Jamaica, to and upon the Coast of Colombia, between Escudo Island and Carthagena, including Chugres and Porto Bello, by Capt. J. Mackellar, R. N. 1816.*

**JAMAICA TO ESCUDO ISLAND AND CHAGRES.**—"The current between the Island of Jamaica and the Spanish main, or Coast of Colombia, is not always to be depended upon as setting to the westward, as is generally supposed; for in crossing from Jamaica to the main, ships have been known to be driven to the eastward by the current 50 or 60 miles in 4 or 5 days; which can only be guarded against by lunar observations, or good chronometers. From the month of May till the middle or end of November, the east and N. E. Trade Winds seldom blow home to the main; therefore ships should never go to the southward of the parallel of eleven degrees, until they are 40 or 50 miles to the westward of their intended port; after which they may make a south course good, allowing half a point easterly variation, and with the winds, which in the aforementioned months blow from S. W. to W., and sometimes in the morning after daylight till 10 o'clock, even at south, together with the current, will set them to the eastward, and thereby gain the anchorage. If, however, upon making the land, they should find that the current has set them to the eastward of the intended port, and light winds prevail, they should immediately stand to the northward so far as  $10^{\circ} 30'$ , or even  $11^{\circ}$ , of latitude, in order to meet the N. E. trade wind, and with it to make good the necessary westing again.

"The land to the westward of the River Chagres, within the Island Escudo, is high, and unless you are close in shore, it is impossible to discover that island; but in a clear day, a remarkable high hill will be seen to the eastward of it, which makes like a sugar loaf. Steer in towards that hill, until you are within 3 miles of the shore, and then run to the eastward at about that distance from it, free from danger, until you see a fort on a small bluff, which is the entrance of the river, bearing about E. by S. or E., according to your distance from the land. The mouth of the River Chagres is strongly marked, by the land to the westward forming a bluff, and the fort on the eastern side: the latter, however, cannot be seen at a greater distance than 10 or 12 miles. You have good anchorage by bringing the fort to bear E. S. E. or E. S. E.  $\frac{1}{2}$  E. in from 10 to 6 fathoms, sand and mud: the Sugar Loaf to the westward will appear about one third above the low land between Chagres and Escudo, and the two high hills of Porto Bello open of Point Brujas. In mooring, lay your small bower to the westward, and the best to the eastward, as the offset of the river will generally keep the hawse clear during the prevalence of westerly winds." Variation  $6^{\circ} 10' E.$

**CHAGRES TO PORTO BELLO.**—"From the Road of the River Chagres to Porto Bello, the course by compass is N. E.  $\frac{1}{2}$  N., but if you run 3 or 4 miles to the northward, then a N. E. course will take you into the harbor: the distance is about 28 or 30 miles. I strongly recommend, should light winds prevail, which is generally the case from May to the end of November, that ships bound to the eastward should get a good offing, as the current runs at the rate of from  $1\frac{1}{2}$  to  $2\frac{1}{2}$  miles an hour, to the northward and eastward, and sets right on the rocks to the N. E. of Porto Bello, particularly in the rainy months, that is, as above stated, from May to November. In this season the River Chagres has a discharge which discolours the sea 6, 7, and 8 miles off; and this water meeting the sea current, causes a strong set to the eastward.

"If you intend going into Porto Bello, the entrance of the harbor may be known by two remarkable trees on the top of the hill, on the starboard or south side; and on a hill, on the larboard side, is a small signal post. In coming from the westward keep within 3 miles of the shore, until you open the town of Porto Bello, on the starboard or south side of the harbor, which will lead you in; but observe, should you have light

winds, to keep Drake's Islet, upon it. Take land on the starboard side. You may anchor going into the bay, generally between 10 and 12 fathoms in breadth. It bears from the eastward about  $30^{\circ}$  from the eastward.

"During the day, there is danger to be apprehended of the length of the day, we found from the town, care must be taken to shut the town gates, to avoid the sun."

"There are supplies of provisions a mile below the town, you will be able to procure wind, keep the thoms, or even the town."

"During the day, there is danger to be apprehended of the length of the day, we found from the town, care must be taken to shut the town gates, to avoid the sun."

**CHAGRES TO PORTO BELLO.**—"From the Road of the River Chagres to Porto Bello, the course by compass is N. E.  $\frac{1}{2}$  N., but if you run 3 or 4 miles to the northward, then a N. winds, to keep well up on account of the Salmedina Shoal, which lies in a line with Drake's Islet, on the larboard hand, when going in, as the current may set you down upon it. Take care, however, that you do not shut the town of Porto Bello in with the land on the south side, as a shoal extends off from the Islet Buenaventura, on that side. You may anchor in from 10 to 18 fathoms, on soft mud. There are no other dangers in going into the harbor besides those stated. The Salmedina is frequently visible, and generally breaks: it is from 50 to 60 fathoms in extent N. N. E. and S. S. W. and 50 fathoms in breadth, with 6 fathoms all round it, at 25 fathoms distance from the breakers. It bears from Drake's Islet, on the north side of the entrance, W.  $\frac{1}{2}$  S. by compass, distant about 300 fathoms; and between is the passage generally taken by ships coming from the eastward, for Porto Bello.

"During the N. E. trades blowing home, that is, from December to May, there is no danger to be apprehended in going through this passage, as you may keep within a ship's length of the Islet, and within half a cable's length of the Salmedina; between which we found from 7, to 14, and 22 fathoms of water. In turning up to Porto Bello, great care must be taken, when within 3 or 4 miles of the harbor's mouth, that you do not shut the town in with the land on the south or starboard side of the harbor, in order to avoid the sunken rocks off Buenaventura Islet.

"There are no particular marks for anchoring; but when ships require refreshment, and supplies of water and wood, I would recommend their anchoring about a quarter of a mile below Fort Fernando, which stands on the north shore, and is easily seen; then you will be abreast of the only watering place in the harbor. In going in with a leading wind, keep the town well open on the starboard bow, and anchor in from 30 to 15 fathoms, or even in 12 or 10, according to the size of your ship.

"During the months of May, June, &c. to November, light airs prevail in the harbor from the S. W. and W.; and, early in the morning, light winds from the N. E. down the harbor: therefore, be prepared with boats ahead, to be under way by the dawn of day. In mooring, let the small bower be to the northward, and the best to the southward."

**CHAGRES TO CARTHAGENA.**—"When at the river Chagres, during the months of the rainy season, or from May to the end of November, stand out to the northward 4 or 5 leagues, so soon as you can; because the winds during these months are in general light, and the current very strong, setting directly on the rocks which lie off Porto Bello, and thence along the line of coast from E. by N. to E. N. E. and E. S. E. and seldom less than at the rate of  $1\frac{1}{2}$  or 3 miles an hour. Should you, however, be unavoidably drawn in near the land of Porto Bello, be constantly on your guard, but particularly in the evening and at night, against squalls, which frequently shift from the land, round the compass, with torrents of rain and gusts of wind so as to oblige you to clew all up.

"When you get to the eastward of Point St. Blas, and open the Gulf of Darien, the current appears to have less effect, and generally draws in to the south, S. by W. and S. by E.; but I strongly suspect that it is much influenced by the prevailing winds at the different periods of the seasons. After passing the Gulf, you may see the islands of San Bernardo, which lie to the eastward, and form a cluster, the centre of which we observed to be in latitude  $9^{\circ} 27' N.$ \* longitude by chronometer,  $75^{\circ} 52' 30'' W.$  These islands are low, but very remarkable, when at the distance of 10 or 12 miles off, and bearing from E. to E. by S.  $\frac{1}{2}$  S. several parts of them will appear like small rocks between the islands: but at the south end of the northernmost island there are two remarkable trees, which may be mistaken for a vessel at anchor. These islands, like the whole of the coast, are covered with wood, and may be seen about 5 leagues off.

"As you proceed further to the eastward you will make the islands of Rosario, which may always be known from those of San Bernardo, as they lie in a triangular form, and are long and low. Having passed these islands, if the weather be fine, you will see the hill over Carthagena, called Popa, on which a convent and castle with a signal staff stands, and forms not unlike a gunner's Quoin. After you get to the eastward of the Rosario Islands, you will find a current setting to the N. W. and N. N. W. at the rate of from 1 to  $2\frac{1}{2}$  miles in an hour.

"In proceeding to your anchorage you must steer to the northward, until you open the town of Carthagena to the southward of the Popa, which may be seen at the distance of 10 or 12 leagues off. In running in from sea, you must never bring the Popa to bear to the northward of east: either of the above marks or bearings will lead clear of the Salmedina Shoal, which has only 8 feet water on it; and bears from the Popa S. W. by W. about 8 miles.

\* According to the survey of Don J. F. Fidalgo, the centre of these Islands lies in  $9^{\circ} 45'$  north latitude.

"The anchorage of Carthagena is very good, sand and mud, and from 8 to 6 fathoms of water. Here you are about  $3\frac{1}{2}$  or 4 miles from the city, and may see a gateway on the face of the bay, named the St. Domingo Gate, where you may land, keeping a little to the westward, where there is a good sandy beach. In the fine season the winds generally blow along shore, and seldom bring in much sea. The marks for anchoring are the citadel on with the lower or south part of the Popa, or the Popa E. by S. and the Boca Chica S.  $\frac{1}{2}$  E."

[From the Journals and Remarks of Officers in the British Navy.]

*The Coast from Chagres to Boca del Toro of the Chiriqui Lagoon, by Captain John George Graham, when Commander of H. M. sloop Icarus, 1824 and 1825.*

**ESCUDO ISLAND.**—The course from Chagres to the Island Escudo is W. by S. by compass, about 75 miles. The island lies 9 miles from the main land, and its east end, by sights taken with two well regulated chronometers, was found to lie in  $81^{\circ} 29'$  W. longitude. It is low and covered with cocoanut trees, and is about  $1\frac{1}{2}$  mile in length, with a reef of rocks extending from each end.

Point Valencía bears from this island W. by S. 22 miles, and may be seen in clear weather. To the eastward of the point there are two small keys, named the Plantain Keys, and are covered with trees. To the westward, about three miles, are the three Tiger Keys, between which and the main is a passage about a mile in breadth, having from 7 to 16 fathoms water. Here the current was found setting strong to the westward.

**GREEN BAY.**—Six or seven miles to the westward of the Tiger Keys is the entrance of the Chiriqui Lagoon; and 8 miles S. E. of this entrance is Green Bay, where you may anchor in 10 fathoms, about a mile from the shore, abreast of an old hut in the middle of the bay. At about half a mile from the shore, the water shoals suddenly. Fresh water may be procured in abundance: it runs out of a hollow rock nearly 500 yards to the westward of the hut. There is also a pool of water close to the hut, but it is not so good as that obtained from the rock. Wood is plentiful. There are no inhabitants within 7 or 8 miles.

In working out of Green Bay, two small keys will be observed: they are named the Zapadillas, and bear W. N. W. from Point Valencía. To these a berth must be given on account of a reef which stretches to the south-eastward from them about two miles, on which the water breaks in most parts.

Boca del Toro, another passage into the lagoon, is about 10 miles W. by S. from the Zapadilla Keys. This may be known by a remarkable rock, standing near the middle of the entrance. Ships going into the lagoon, should keep the rock open at about a cable's length on the starboard side, until a reef appears on the larboard side, which must not be approached to a less depth than 4 fathoms, it being very steep. Pass the end of the reef in 7 fathoms, and haul up for the bay, where you may choose your anchorage in from 8 to 4 fathoms, well sheltered.

The only supplies to be obtained here, are turtle, fish, and wood.

*The Chiriqui Lagoon, by Douglas Cox, Esq., Commander of his Majesty's sloop Sheerwater, in 1819.*

[The courses and bearings are magnetic.]

Chiriqui Lagoon is about 26 miles long, and in some places 12 or 13 miles wide, with several rivers falling into it. The principal entrance into this lagoon is called the Valencía Channel, which is about two miles wide, lying north and south, with from 23 to 14 fathoms water. Its latitude is about  $9^{\circ} 16'$  N., and longitude  $81^{\circ} 58'$  W. The western side of this channel is formed by the Zapadillas and Water Key; the former having a reef on the north side of them, from the S. E. end of Provision Island to about 2 miles S. E. of the easternmost Zapadilla Key. Off the east end of Water Key, a reef extends about half a mile. The eastern side of the channel is formed by the Tiger Keys and Valencía Point. The Tiger Keys lie  $1\frac{1}{2}$  mile from Valencía Point, and are four\* in number, three having trees on them, and the fourth perfectly bare, to the S. W. of which is a rock just even with the surface of the water. On this the sea always breaks, and there are 17 fathoms within half a mile of it. There is little or no danger in going into this channel, by keeping a good lookout from the masthead, until you get within Water Key; then there is a rocky bank with 11 feet on some parts of it. The marks to avoid this bank, is to keep the two Zapadilla Keys open of the east end of Water Key, N. N. W.  $\frac{3}{4}$  W. In going across to the south side of the lagoon to Chiraco Mola River, the soundings are very irregular, there being in some places not more than 3 fathoms. By observing the following directions, you will not have less than that depth.

\* Capt. J. G. Graham notices only three.

When abreast of the Zapadilla Keys just at the bearing of the North Valencía W. S. W. until the North end of three fathoms, then fast to 10 fathoms, the Mola River will be within 2 or 3 fathoms, on the end of Water Key.

At the head of the fowls, and perfectly fresh at the head of the fowls.

There is very fresh water giving the reef guide for you.

The north end of the lagoon is  $54^{\circ} 18'$  W.

Remarks on the lagoon.

In his Majesty's eastward of the most remarkable a gun quoin, a distinguish, was about 10 miles from this to We sounded the shore. The water mile an hour, discolored for will often obscure by the outsets there being 9 fathoms would not be trying, but most generally blue.

Point San Juan the North Fort which gives it a mile, as I observed northerly directed remarkably high, and of a vessel.

From Point river, and as no fathoms, about at the entrance in 5 and  $4\frac{1}{2}$  fathoms length from the distinguish from river, in  $4\frac{1}{2}$  fathoms I did not observe.

The soundings my opinion, there are a sergeant and two out a passport.

When abreast of Water Key, steer to the southward until you bring the two Zapadilla Keys just open of the east end of Water Key, bearing N. W. by N.; keep them on that bearing until the small keys which lie off Valencia South Point come on with the North Valencia Point, and you will have from 18 to 5 and 6 fathoms; then steer to the W. S. W. until the eastern Zapadilla Key comes within half its breadth of the east end of Water Key, bearing N. N. W.  $\frac{1}{2}$  W., and keep it thus open, or in that direction, until the North and South Valencia Points appear in a line. You will then be on a bank of three fathoms, which is about half a mile wide; and when over it the water will deepen fast to 10 and 12 fathoms. When you are on the bank of three fathoms, Chiraco Mola River will bear about S. E. 4 or 5 miles distant. It is not perceptible until you are within 2 or 3 miles. Nine fathoms is near enough to approach on the river side. It has, however, two entrances. The best anchorage is off the northernmost, in 9 or 10 fathoms, on muddy bottom, with Valencia Point bearing N. by W.  $\frac{1}{2}$  W., and the east end of Water Key N. W.  $\frac{1}{4}$  N., or you may go farther eastward, in 9 fathoms.

At the head of the river a tribe of Indians live, from whom you may purchase hogs, fowls, and plantains, by going up to their village about 25 miles. The water is perfectly fresh at a quarter of a mile from the sea.

There is very good anchorage on the south side of the Zapadilla Keys, in 12 or 13 fathoms water, about one mile off either of them, and little danger in going in there, by giving the reef off the S. E. key a berth of about a mile. Your eye will be the best guide for you here.

The north entrance of the Chiraco Mola River is in lat.  $9^{\circ} 1' 36''$  N., and long.  $81^{\circ} 54' 18''$  W. Variation of the compass  $5^{\circ} 50' E.$

*Remarks on the Coast of Nicaragua, by Sir William S. Wiseman, when Commander of H. M. S. Sophie, in May and June, 1820.*

[The courses and bearings are magnetic.]

In his Majesty's sloop Sophie, we made the coast of Nicaragua, about 30 miles to the eastward of the River San Juan and close to the River Tortuga. Near the latter is the most remarkable land on the coast. It is a high hummock, shaped at the west end like a gun quoin, and called the Turtle Bague. The land to the eastward, as far as I could distinguish, was very low, and perfectly level. To the westward it was the same, for about 10 miles, where there are three hillocks rising inland near the River Colorado. From this to Point San Juan, it is uniformly level, very low, and covered with trees. We sounded in 50 fathoms, on blue mud and small shells, at about 10 or 11 miles off shore. The wind variable from N. to N. E., a current running to the S. W. about one mile an hour. Off this part of the coast, particularly after rain, the water will be much discolored for a considerable distance from the land; and if the wind blows on shore, you will often observe a ripple that has the appearance of broken water, which is occasioned by the onsets from the many rivers on the coast; but the soundings are very regular, there being 9 and 10 fathoms from 3 to 4 miles off shore. Nevertheless, at night it would not be prudent to go into less than 7 fathoms, as the currents are constantly varying, but mostly set on shore. The anchorage is good all along this part of the coast, generally blue mud and clay.

Point San Juan, bearing N. W. by W., distant about 5 miles, has the appearance of the North Foreland. The land, though low, is thickly covered with very high trees, which gives it a bluff and a bold appearance; but it should not be approached within a mile, as I observed the breakers extending half a mile or more from the point, in a northerly direction. Standing towards Point San Juan from the eastward, many remarkably high trees are seen; one in particular, stripped of its branches, has the appearance of a vessel's mast, and may be seen at a considerable distance.

From Point San Juan the land takes a south-westerly direction to the mouth of the river, and as near as I could judge, about 8 or 10 miles. You may run along in 8 or 9 fathoms, about two miles off shore, till abreast of a low sandy point on the larboard hand, at the entrance of the river, when you may haul round at about a cable's length from it, in 5 and  $4\frac{1}{2}$  fathoms. On the starboard hand, just within the river, at about three cables' length from the point, there is a bank with only 4 or 5 feet on it, which you may plainly distinguish from the ship. We anchored in the Sophie about a cable's length within the river, in  $4\frac{1}{2}$  fathoms water, on blue mud.

I did not observe any shoals or dangers upon the coast, or near the river San Juan. The soundings are regular, and a good lookout, with the lead constantly going, are, in my opinion, the principal requisites for approaching this coast.

There are no inhabitants at or near the river, but the Spaniards have a guard of a serjeant and twelve soldiers at a short distance within it, to prevent boats going up without a passport from the commandant at Grenada.

Very excellent fresh water, and plenty of wood, may be easily procured; and there appeared to be abundance of fish.

*From Chagres to Cape Catoche.*

[Continued from the Derrotero.]

The description which we have given of the coast thus far, we have presumed to call by that name, because we can safely say that the data from which we have compiled it, is essentially good, and therefore contains no error but of a very trivial nature; but hence proceeding onward, we cannot speak with equal certainty, and therefore have thought it necessary to apprise the navigator with the distrust with which we proceed. And although the general course of the coast may be considered as moderately exact, yet we are in want of the details that are indispensably necessary for coasting along the shore. Therefore, until correct charts come to hand, we shall content ourselves with giving such information as appears to us to approximate nearest to the truth, and which may be sufficient to enable mariners to make those points of the coast that are most frequented.

**THE COAST BETWEEN PORTO BELLO AND VALENCIA POINT.—**

From the last low point without a name, of the surveys of Brigadier John J. F. Fidalgo, the coast trends about S. 70° W. a distance of 53 miles, to the River Belen, from whence it bends N. 55° W. 8 leagues, to Point Escudo; and thence it runs west another eight leagues, to Valencia Point. All this coast is generally low, excepting some parts which rise a little; and the water is deep, so that at the distance of 3 or 4 miles off, there are from 20 to 40 fathoms, the bottom being chiefly mud and sand. Several rivers disembogue upon it, two of which, besides Chagres, namely, that of Indios, and that of Coclet, are navigable, and have communication with the interior. The river Coclet is 42 miles to the westward of Chagres; and between them are 4 remarkable mountains, two of them inland, and the other two on the coast; and as they may serve for recognizing the land by, we give a description of them.

1. The Caladeros Altos of Chagres are two mountains situated on the River Chagres, and some distance inland. They lie E. N. E. and W. S. W.,\* and appear separate from each other as you come from Porto Bello. They seem only as one when they bear S. E., and thus apparently united they have the same bearing from the Castle of San Lorenzo, at Chagres; therefore those bound to Chagres from sea, have only to bring these two mountains in one, and steer S. E. for the port.

2. The Pilon of Miguel de la Borda is a single mountain, so named from its resemblance to a sugar loaf, which is seen inland, at about 9 leagues to the S. W. by S. from Chagres. When this mountain bears S. by W. it will be in a line with the river Indios, which is 5 leagues to the westward of Chagres.

3. The Sierra of Miguel de la Borda is of moderate elevation, and rises upon the same coast. It extends north and south, and is 13 leagues to the westward of Porto Bello.

4. The Sierra of Coclet, which is somewhat lower than the former, lies to the S. S. W. of the river Coclet.

*The Cordillera of Veragua and Serrania of Salamanca.*—Besides the mountains above described, there are others about 7 leagues inland, very well known, and celebrated for their great elevation, named the Cordillera de Veragua, which commence nearly to the south of the river Coclet, and unite with the Serrania of Salamanca, nearly on the meridian of Bocas de Toro, which ends a little to the westward of the meridian of the river Matina. Both are so elevated as to be seen 36 leagues out to sea in clear weather. At the east end of the mountains of Veragua there is a gap resembling a riding saddle, and is called the Silla, or Saddle of Veragua, and which lies south from the river Coclet. Therefore to find that river from sea, you have only to bring the Silla to bear due south, and steer in for the shore. To the westward of the Silla there is a mount on the highest top of the same Cordillera, of the figure of a house or castle, and is called the Castle of Choco, from which the island named Escudo de Veragua (Shield of Veragua) bears N. 38° W. Therefore, when the mount bears S. 38° E., the island will be found by steering in that direction.† Upon the west end of the same mountain may be seen a remarkable peak, called Pan de Suerre, so called from the village at its base. This may serve as a mark for finding Matina.

The Island of Escudo is low, covered with cocoa and other trees, and surrounded on the east and north parts with various keys of a chalky clay, also covered with trees.

\* We presume this should be N. W. and S. E.

† By another chart the bearing is N. 20° W., and S. 20° E.; but as we have not the means of ascertaining which, or if either, is correct, we advise the navigator to use it with caution.

\* See, however

From the east side a reef extends off about half a league, on which the sea generally breaks. All the island and its keys are surrounded by a bank of sand and gravel, which extends out about 5 miles, on which, and very near to the land, there are  $4\frac{1}{2}$  fathoms, and the depth gradually increases outward. The island is situated about three leagues from the main land, and in case of emergency water may be procured from its various rivulets, but not without considerable trouble, from the scantiness of the streams, and from their distance above the beach. On the S. and S. W. sides of this island there is good anchorage, sheltered from the norths and the breezes. There is also anchorage on the bank to the eastward, but this is not so commodious as the other, not only because it is not sheltered from the breeze, but also because the bottom is rocky, and may chafe the cables.

From Point Valencia, already noticed, and which, according to the Pilot Patino, is situated in  $9^{\circ} 13'$  of north latitude, the coast forms a great bay, shut in by various keys and islets, which extend from that point W. N. W. a distance of 14 leagues, to Punta Gorda de Tirbi. This great bay is separated into two parts, by several interior keys. The eastern part is called the Lagoon of Chiriqui, and the western part Almirante Bay. They are connected by various arms and creeks of little depth of water. The Lagoon of Chiriqui may be entered through the channel which is formed by Point Valencia and the easternmost keys of the group; and according to our information, although shallow, there is depth of water sufficient, both in the channel and within the lagoon, for vessels of all burthens. Almirante Bay must be entered exclusively by the channel which is formed by Punta Gorda de Tirbi and the westernmost key. In this mouth, and within the bay, there is, from the same authority, depth of water sufficient for all classes of vessels. This channel is called the Dragon's Mouth, Boca del Dragon, to distinguish it from another more to the eastward, called Boca del Toro, by which only small vessels can enter. Within both bays the anchorage is as well sheltered and secure as the best harbors; but as we possess no information respecting them, we shall say no more than that to enter in or go out by the Dragon's Mouth, you should give a good berth to the western coast, or that of Punta Gorda de Tirbi, on account of a rocky reef that runs out from it to mid-channel.\*

The pilot Patino places the northernmost key off Point Valencia, called Zapadilla, in latitude  $9^{\circ} 15' 30''$  N., and the northernmost of those of the Island Bastimentos, in  $9^{\circ} 29'$ .

#### COAST BETWEEN PUNTA GORDA AND SAN JUAN DE NICARAGUA.

—From Punta Gorda de Tirbi, the coast trends about N.  $56^{\circ}$  W. a distance of 14 miles, to Point Carreta, which is the eastern point of a bay that falls into the S. W., W., and N. W., a distance of 13 miles, to Blanca, or White Point, which has an islet near it. Thence the coast trends N.  $32^{\circ}$  W., 26 miles, to the Point of Arenas, which forms the Harbor of San Juan. All this coast is clean, and the water deep, and several rivers disemboque in it, of which the principal is that of Martina or Port Cartayo, or Cartago, and that of San Juan. The last discharges its water by several mouths, one of which enters the very harbor.

**SAN JUAN DE NICARAGUA.**—The Harbor of San Juan, or St. John, is formed by a low island, which, with the coast, encloses an extensive bay. On the east part the island is nearly joined to the main land, and the entrance to the harbor is on the west. The west point of the island is called Arenas Point, which is situated in  $10^{\circ} 56'$  N. lat. The bay is very spacious, but is incommoded with a large bank, with little water on it, which limits the extent of the anchorage to 5 cables' length from north to south, and to  $2\frac{1}{2}$  from east to west.

To take the anchorage, you have only to coast Point Arenas at the distance of a half, one, or one and a half, cable's length, according to the ship's draught of water, and proceed inward towards the east, so as to take the round of the point, with an understanding that at a cable's length from the south coast of the island, which is where you ought to anchor, there are  $4\frac{1}{2}$  fathoms water. The lead is the best, in fact the only guide into the harbor. Vessels in it are securely sheltered, there being no sea to occasion inconvenience, except when the wind is in the N. W. quarter, which is common on this coast, from September to the end of January or beginning of February.

The mouth of the River St. Juan is exactly on the meridian of, or true south from, Point Arenas, and by it there is a communication with the Lake of Nicaragua. A little to the east of Point Arenas, upon the island, are some pits, or wells, where fresh water may be obtained; it may also be procured in the river.

From the Harbor of San Juan de Nicaragua the coast trends to the north, a little easterly, a distance of 80 leagues, to Cape Gracias a Dios, (Thanks to God,) and is what is properly called the Mosquito Shore. It is all low land, for the high lands terminate

\* See, however, another account of this lagoon, and some other places, given hereafter

at St. Juan's; and in this extent there are numerous rivers and lagoons. A bank of soundings extends all along it, being about 8 miles from the shore at Point Arenas, and running off in a north-easterly direction into latitude  $16^{\circ} 33' N.$ , and to longitude  $81^{\circ} W.$

Upon this bank there are a number of keys and reefs, and those off Cape Gracias a Di are very dangerous. Of them we possess no written description, but we may remark that this coast has been recently surveyed by order of the British Admiralty, by Capt. R. Owen and Lieut. Barnett, and that the results are published on the General Chart of the West Indies, 1837, E. & G. W. Blunt.

**COAST BETWEEN ARENAS POINT AND THE PIGEON KEYS.**—North of Point Arenas, 40 miles distant, is Point Gorda; the coast between forms an extensive bay, called the Gulf of Matina. About Point Gorda and near it are several islets which, with the coast, are clean; and the soundings are so regular, that no other guide is necessary than the use of the lead.

From Point Gorda the coast trends to N. about 3 leagues to Point Monos, S. E. of which there are several keys, very clean; and between them and the coast there is an anchorage in 3 fathoms water: this anchorage ought to be entered from the southward of the islets. To the N. N. E. of these islets there are others which rise upon the bank and reef, called the Pigeons, extending about 12 miles from north to south. To the eastward of all these, and without the bank, lies a key, which with the Pigeons, forms a channel; but it is best to avoid it, by sailing on the outside, as the Pigeons' Reef will thereby be entirely cleared, although it extends about two miles north from the islands.

**BLUEFIELD'S, OR BLEWFIELD'S LAGOON.**—Abreast of the Pigeon Keys, on the coast, is the southern point of Bluefield's Lagoon, which is a bay extending inland to the westward, about 10 miles, and receiving in its northern part a considerable river called Rio Escondido. From the southern point of the bay, or lagoon, to the northern one, called Bluefield's Point, the distance is 13 miles N. N. E.; the latitude of this point is  $11^{\circ} 56' 20'' N.$  it being the mean of several observations. Nearly on the line, between the two points, is a key 11 miles in length, which forms, with the points, two channels: of these the northern is the principal one, and has, in the season of the breezes, about 2 fathoms water; but at that season it is dangerous, because there is a fall (Alfada) of 3 feet. In the time of the Vendavales, or rainy season, there are  $2\frac{1}{2}$  fathoms, without any fall, or Alfada.

Having passed this bar, or channel, there are within the bay 5 and 6 fathoms water, upon clay: the anchorage is near the town on the N. E. side. To enter the lagoon you have only to keep along by Bluefield's Point, at the distance of a stone's throw, for it is very clean; and the point may be known from its being the highest land on this part of the coast. When within continue on near the north shore, for the south is very foul, and requires the utmost caution: it will be indispensably necessary in going up to have anchors and cables all clear, to let go at an instant when the current, which is moderately strong, may render such an expedient necessary.

**PEARL LAGOON.**—From Bluefield's Point the coast trends north, inclining a little to the west, for the distance of 18 miles, to the entrance of the Pearl Lagoon. Off this part of the coast is a key, called the Cayman, lying at the distance of 7 miles from Bluefield's Point, and somewhat more than half a league from the shore. A reef extends from the north part of this key to the distance of 4 miles; but as every vessel ought to pass to the eastward of it, there can be no danger if the lead be kept going. The entrance of Pearl Lagoon has deeper water than that of Bluefield's: there is also anchorage on the outside of it, under shelter of the north coast, which rounds to the N. E. a distance of 11 miles to Point Loro.

To the eastward of the Pearl Lagoon, and well out from the coast, lies the Pit Key, which is 7 leagues from it; the Lobo Marina, or Sea Wolf Key,\* which lies 12 miles N. E. by E. from Pit Key; and lastly the Islas de Mangle, or Corn Islands, which lie about 12 miles to the eastward of the latter.

The Pit and Sea Wolf Keys are somewhat foul, and should not be approached nearer than half a mile: they are dangerous to navigation, because having 14 fathoms about them, and no bank near them with less depth, the soundings will give no indication of their proximity in the night, or in thick weather. The channels which they form with the Corn Islands and the coast, are clean and free.

[The Courses and Bearings are magnetic.]

**ISLAND OF ST. ANDREW.**—On the 1st day of September, 1818, His Majesty's sloop Beaver anchored in a fine bay or cove on the west coast of this island; of which

\* According to various modern charts, these two Keys appear to be of doubtful existence; but we do not venture to alter these directions until we have better accounts and data to convince us of it.

abful existence; but data to convince us

the following information was obtained, while lying there. The bay is spacious and clean, sheltered from N. by E. round by east to S. by E.; and it appeared that a S. W. wind would not send in much sea. The bottom is rocky without the depth of 7 fathoms; so that you must run in until you get upon the white bottom, which consists of white sand, and bounds the bay, stretching off a long mile, having good anchorage on every part of it. The Beaver laid with a small inlet laying nearly east, distant three quarters of a mile off shore; the north point of the bay bearing N. by W. and the south point S. by W.  $\frac{1}{2}$  W. in  $6\frac{3}{4}$  fathoms.

No other directions are necessary for entering this bay, than to steer directly in, and anchor where convenient. To find the situation of the bay from the offing, look out for the highest part of the island, near the south end, on which are two cocoa-nut trees, very conspicuous by their overtopping the other trees, and by being the only cocoa-nut trees that show themselves on the high land: bring them to bear N. E. or N. E. by N. and you will find the bay by steering in that direction.

It is flat to the distance of two cables' length from the north point, with no more than 2 and 3 fathoms, deepening suddenly to 8 fathoms; but this lying so near the shore, is out of the way of sailing in from the southward. But if from the northward, running along shore, with a scant N. E. wind, it will be necessary to give it a berth, going no nearer to the shore than 8 fathoms; and keeping the south point of the bay a little open of the larboard bow bearing nearly south; and when the two cocoa-nut trees come over a remarkable withered tree which stands near a sandy place on the point, bearing about N. E. you will have passed the point of the flat, and may haul in S. E. for the anchorage. We sounded the north shore, and found 5 fathoms close to; so far as we sounded, the bay was all bold and clear.

There is an inlet in the N. E. corner of the cove, which would answer for a careening place for small vessels; it is also a snug harbor for boats. At the entrance it is 27 fathoms wide and has  $4\frac{1}{2}$  fathoms water; but this depth does not continue more than a cable's length, when it shoals to 3, and then suddenly to 6 feet. Two brigs and a frigate might be moored in the entrance, in which situation they would appear as in a wet dock, having hawsers made fast on shore from their bows and quarters; but a vessel must be warped in stern foremost, having a bower anchor a cable's length to the westward, as a security against the winds from that quarter, which blow right in. The north part of the cove is also a good place to moor ships, having a bower anchor toward the sea; they might be moored with their sterns to the shore, by the stream cable, or a good hawser.

The island in general presents a pleasant fertile appearance; it is of moderate height, and may be seen 18 or 20 miles off: when seen from the eastward, it makes in two hummocks, of which the north one is the highest. As we sailed along the east coast, we observed it to be bounded by a reef, which appeared to extend off 4 or 5 miles; the south point of this reef, with the shore inside of it, forms what is called the Eastern Harbor, the entrance of which is from the southward. The north end is very dangerous, having a low key with a reef off it, on which the sea breaks as far as can be seen from the deck, probably 7 miles; it joins with the eastern reef, and they together encompass all the north end and two thirds of the east side of the island, ending a mile or so south of the entrance to the Eastern Harbor.

The south end is bold, as is the west side: you may anchor in a bight near the shore to the northward of the cove, near some chalky cliffs: we got soundings of 9 fathoms in it, but the ground was coarse. There are no soundings until you come very near the shore.

From the hills you can see the E. S. E. Keys, which lie 7 leagues from St. Andrew's; the S. S. W. Keys 10, and Old Providence 18 leagues.

The currents about these islands are very irregular, setting occasionally in every direction, but generally to the northward and southward. In going there, we experienced a strong easterly current; in returning, a southerly one; and a vessel had arrived from the Indian coast a short time before, having had calms nearly all the passage, and was brought along by a strong N. E. current.

THE S. S. W. KEYS, are the southernmost and westernmost of the keys around St. Andrew's Island, being S. by W. 20 miles from the south point of St. Andrew's Island. These are three islets, which afford good anchoring ground, and so clean that there is nothing to be guarded against, except what is in sight; for although there are a few rocks round them, they are too near to be of any interruption.

THE E. S. E. KEYS.—About E.  $\frac{1}{2}$  S. from St. Andrew's Island, at the distance of 5 leagues from the south end of it, there are three keys, called the E. S. E. Keys. They are surrounded by a reef and a bank, of 7 miles in extent, which is very dangerous, and although there is anchorage for small vessels on it, it is necessary to have a pilot.

LITTLE CORN ISLAND lies about 20 leagues W. S. W. from St. Andrew's, and has a reef round the east side of it, about a mile from the shore. The isl-

and appears to be all savanna, bordered round the beach with trees: all round the east side there are a great number of cocoa-nut trees. There is good anchorage in a bay on the S. W. side of the island, where you may lie sheltered from north winds; from the north and south points of the bay there are reefs run off to the distance of two cables' length, but there is good room to work in, and regular soundings. You may anchor in 3 or 4 fathoms, sandy ground, at about a mile from the shore. In approaching this bay from the northward, it is necessary to give the north point of the island a berth of a mile in order to clear the reef. The tide rises and falls about 3 feet, and there was a current off the bay setting to the southward, but not very strong. Latitude of the bay by observation is  $12^{\circ} 17' N.$  Variation of the compass,  $9^{\circ} 20' E.$  At the Porcupine's anchorage the south point of the bay bore E. S. E., and the north point N. W. by W.

**GREAT CORN ISLAND.**—This island lies S. S. W. 10 or 11 miles from Little Corn Island: it has a reef off the N. E. end of it, that runs along the east side about a mile and a half from the shore. The N. W. part of the island is pretty bold; in the N. W. bay called the Brigantine Bay, there is good anchorage with the sea breeze, but no shelter from norths. There is another called the S. W. Bay, where we anchored in 3 fathoms. Off the point between the two bays lies a very dangerous ledge of rocks, stretching from the point to sea, nearly east and west, about 2 or  $2\frac{1}{2}$  miles, and having from 10 to 13 feet water on it: it does not appear to be more than 2 cables' length across in any part, and on the outer end there is a spot with only 9 feet on it, where the sea broke when it blew strong. Over this ledge we were carried by the unskilfulness of the pilot, and beat our rudder off, close by the point, where I think we had the best water: this ledge breaks off the sea from the bay, when the wind is to the westward of north. In going down the west side of the island for the bay, it is necessary to give these rocks a good berth, and not haul in for the bay till the S. W. point of the island bears about E. S. E.; but by keeping a look out from the mast head, you may see the rocks and round them, taking care to go no nearer to them than 6 fathoms: you may then work up into the bay, the soundings being regular from 6 to  $2\frac{1}{2}$  fathoms, on a fine sandy bottom. You may sail along on the outside of the reef to the eastward of the island, and go round the S. E. point, which is pretty bold; then haul into the bay, and fetch farther to windward than by going to the westward round the ledge. The Porcupine lay in 3 fathoms water, about half a mile off shore, with the north point of the bay bearing N. by W., and the S. W. point S. E.  $\frac{1}{2}$  S. We always found a great swell in the bay, setting from point to point whichever way the wind blew; but it had been constantly blowing strong without. The patch of 9 feet on the outer end of the ledge, where the sea broke, bore W. by N. from the anchorage. The latitude observed at the anchorage is  $12^{\circ} 13' N.$  and the longitude  $83^{\circ} 3' W.$  We observed a regular rise and fall of the water by the shore; but the current off the bay ran moderately to the southward.

This island is very conveniently situated for those bound to the Harbor of Bluefields, which bears from it W. by S. distant 14 leagues, and which it is very dangerous attempting, in blowing weather, with the wind on shore, as there are only 12 or 13 feet water on the bar; but here, as was our case, they may stay in safety till the weather settles, that they can get in.

**DANGEROUS ROCK.**—To the southward of the Great Corn Island, at the distance of about 7 miles, there is a rock which appears above water, and the greatest caution should be taken to avoid it; for we do not believe that its situation is correctly known, and even if it were, it would still be dangerous to navigation at night, or in thick weather.

**THE ISLANDS OF SANTA CATALINA AND PROVIDENCE**, separated only by a narrow channel, may be considered as one island. They are situated about 15 leagues N.  $23^{\circ} E.$  from St. Andrew's. Catalina is scarcely any thing more than a rock, extremely craggy, and mostly covered with stones. The highest parts of it are excessively irregular, so that it is of no value, and is therefore uninhabited. Providence is about 4 miles in length from north to south, and 2 from east to west. From the level of the sea, at the most salient points, it begins to rise with a very gentle acclivity towards the centre, where, resembling an amphitheatre, it forms four hills, crowned by a high mountain. From the summit or cusp of the easternmost hill, four streams descend from the same source, and run down to the shore in different directions, subdividing in their course into smaller rivulets of most excellent water. The most abundant of these streams in the dry season, is that which runs down on the west side, into what is called Freshwater Bay, Ensenada de Agua dulce. In clear weather the island may be seen from 10 to 12 leagues off. It is, as well as Catalina, surrounded by a reef, that will not admit of coming within a league of it, and on the north side, not nearer than 4 miles. It is inhabited by three or four families, who cultivate some portions of it. Vessels not drawing more than 10 or 11 feet, may get in between the reefs, but it is necessary to have a pilot for the purpose.

**MUSKETEERS.**—This shoal, of which we have no written description, is dangerous, and has an extent of 8 miles, in a north-westerly direction. The centre lies in  $13^{\circ} 33'$  N. lat., and  $80^{\circ} 03'$  W. long.

**QUITA SUENO.**—This is an extensive bank, of 35 miles in length from north to south, and 13 miles in width from east to west, having on it from 7 to 20 fathoms water, excepting on the eastern edge, which is dangerous, being a range of shoals and reefs, for an extent of 23 miles, ranging nearly north and south.

South point of the bank is in.....	$14^{\circ} 2'$	N. lat.,	$81^{\circ} 15'$	W. long.
North point.....	$14 37$	"	$81 7$	"
South point of the shoal ground.....	$14 7$	"	$81 7$	"
North do. do. do. ....	$14 30$	"	$81 7$	"

**SERRANA.**—East, 42 miles from the eastern edge of Quita Sueno, is the Serrana Bank. It is of a triangular shape, longest from N. E. to S. W., being 20 miles long; on which point there is a key. The N. E. and S. sides are bounded by reefs.

North point.....	$14^{\circ} 28'$	N. lat.,	$80^{\circ} 17'$	W. long.
East point.....	$14 24$	"	$80 8$	"
S. W. point.....	$14 16$	"	$80 23$	"

**SERRANILLA.**—This is a bank of 25 miles in extent from east to west, and 20 miles from north to south, of different depths, from 3 to 30 fathoms. The S. E. side is a range of keys and breakers; the western side is clean and clear, with the exception of one small spot called the Western Breaker.

The N. E. Breaker, which may be called the N. E.

point of the bank lies in.....	$15^{\circ} 47'$	N. lat.,	$79^{\circ} 42'$	W. long.
The west point of the bank in.....	$15 45$	"	$80 7$	"

**THE NEW SHOAL** is a bank extending about 13 miles from N. E. to S. W., and 7 from east to west. All the eastern part is a reef, very steep to; but on the west side the depth diminishes gradually. On the bank, at a mile and a half from its northern extremity, there is a sandy key, situated in latitude  $15^{\circ} 52' 20''$  N. and longitude  $78^{\circ} 33'$  W. Three or four miles W. N. W. from this key, you may anchor; but take care not to get into less than 9 fathoms water, because at  $2\frac{1}{2}$  miles W. N. W. from it, a rock has been found, with only 7 feet water on it; and S. by E. from it, at the distance of a mile, there is another, with no more than 4 feet water on it. Both of them stand in 5 fathoms. They are very steep, and not larger than a boat.

**THE BAXO DEL COMBOY** does not exist; for particular search has been made for it, but it could not be found.

The above have all been surveyed by Capt. R. Owen and Lieut. Barnett, and are published in the General Chart of the West Indies, by E. & G. W. Blunt, 1837.

**GREAT RIVER.**—From Point Loro, already mentioned, the coast trends about north, a distance of 27 miles, to the Rio Grande, or Great River. This part of the coast is very foul, with a reef which stretches off from it about 6 miles. On the southern edge of the reef, and east from Point Loro, there are two keys, the easternmost of which is called Marron. To the north, a little westerly from this key, and at the distance of 9 miles, there is another, which is outside the reef. Without these two keys there are others, of which the southernmost are called the Pearl Keys. To these follow three others, called the King's Keys, which lie east from the mouth of the Great River, at the distance of about 13 miles. Finally, to these follow the Mosquito, Man of War, and Sea Wolf Keys, the last being to the eastward of the Man of War Keys. The northernmost of the Man of War Keys lies about 20 miles distant from the Great River. Between all these keys there are good channels, with from  $5\frac{1}{2}$  to 9 fathoms water, on clean mud; but to take them it is necessary to have a pilot, and if you have not one, you ought to go outside the whole of them. To enter the anchorage of Great River, you should pass between the Man of War Keys and the coast; in which channel, until you arrive at Great River, there is nothing to fear or attend to but the lead.

**PRINCE AMILCA RIVER.**—To the N. by W. from Great River, at the distance of 11 miles, there is another river, called Prince Amilca,\* from which, in the same direction, and at the distance of 9 miles, is the Black Rock River. From this the coast trends north a little easterly, for 11 miles, to the River Tongula; in front of the mouth of which, about 5 miles to the eastward, there are some rocky shoals, which are the only dangers along the coast, between this river and Great River.

\* There is great variety in the charts in the names of this and other rivers on the coast, and also of the keys.

**THE COAST TO BRACMA POINT.**—From the River Tongula the coast trends about N. by W. for the distance of 17 miles, to the River Warva; whence it continues to the north for 9 miles to Bracma River; and thence it rounds to the N. E. a distance of 8 miles, to Bracma Point. This last part of the coast, called the Barrancas, or Bragman's Bluff, forms a bay sheltered from the norths, and westerly winds, and in it you may anchor, in any depth that suits you, understanding that at 2 miles from the land there are 4 fathoms, upon coarse gray sand and small shells. Great care should be taken in landing on this beach, as there is a bank before it, on which, with ever so little wind from the east, the sea breaks with great force.

**THE COAST TO GRACIAS A DIOS.**—From Bracma Point the coast trends about N. N. W., a distance of 6 miles, to the River Tupapi, or Housetan, which is known by a town situated about three quarters of a league from the beach, and discernible at a good offing, as the ground is level and bare. From Tupapi the shore runs about N. N. E. a distance of 20 miles, to the Governor's Point, which is known by being more salient eastward than any other on this coast, and thickly covered with trees. From this point the coast trends to the N. N. W., a distance of 12 miles, to the mouth of Arenas, or Sandy Bay, in which there is so little water, that, in the time of the breezes, launches pass with difficulty; but within, there is a deep and spacious bay. From Sandy Bay the coast trends to the north, 10 miles, to the River Guanason, and thence to the Bay of Gracias a Dios, it is 13 miles in the same direction.

**THE BAY OF GRACIAS A DIOS** is formed by a tongue of land extending to the eastward more than 4 miles, and which affords a good roadstead, with winds from S. S. W. round by W. and N. to S. S. E. The easternmost and southernmost point of this tongue of land is that which is called Cape Gracias a Dios; and from it to the south there are several keys, of which the last or southernmost is called San Pio; and the south point of it, called Arenas Point, is also the east point of the bay. The depth of water in the bay is from 20 feet, which is found at the entrance, to 16, which is found well within it; and in all parts of it the bottom is soft, slimy clay.

**INSTRUCTIONS FOR TAKING THE ANCHORAGE OF GRACIAS A DIOS.**—To anchor in this bay, if approaching it from the north and west, you have only to pass the sandy point of Key San Pio, and then run into the bay, and anchor in the number of feet suitable to the vessel's draught of water, for all of which you have only to attend to the lead. The only thing which demands a little care, is not to mistake for the Key San Pio, that which comes before it, called Troncoso; for having a strait of a mile in breadth between them, and the Key San Pio being very low, any one coming from sea may be deceived, and take the strait between the keys for the entrance; but this mistake may be avoided, if you bear in mind that Key Troncoso is very small, and, on the contrary, that Key San Pio is a mile in extent from N. E. to S. W., and farther, in this strait, there is so little water, that scarcely a canoe can pass, which is the cause of the sea generally breaking in it. To those coming from the southward, in order to enter this bay, we have nothing farther to recommend.

Such is the description of this bay, given in 1788, by Don Gonzalo Vallejo, who anchored in it in the corvette San Pio, under his command; but we ought also to add what Don Josef del Rio reports of it, after visiting it in 1793. "I ought to make known that the anchorage in the bay of Cape Gracias a Dios, is becoming lost; for the cut of communication made by the English from the Great River Segovia, across the tongue of land that forms the bay, for the purpose of conveying into it the timber which they bring down by that river, has increased so much in width that, from a narrow canal, it has become a branch of the river, and brings with it so much soil, and so many trunks of trees, which has diminished the depth of the bay so much, that since the year 1787, there are three feet less water in the vicinity of Key San Pio; and it is very probable, that, within a few years, the depth will be filled up, and vessels will be obliged to remain on the outside, deprived of the shelter they at present have, and which is of so great an advantage to those who navigate on this coast during the season of the Norths."

All the coast from the River Tongula is clean, without any other keys or reefs on the bank than those already described; and those which are between the parallels of Governor's Point, and Cape Gracias a Dios, which are named the Mosquitos and Thomas' Keys. These keys, with their reefs, form with the coast, a channel four leagues in breadth where narrowest; and although between them there are passes with a depth of 6 fathoms or more water, yet it is not advisable to attempt them, but always run to the westward, between them and the coast; for there can be no risk in this channel, as the lead will give timely warning, either in sailing with the wind large, or working to windward; for at half a league from the coast there are  $4\frac{1}{2}$  fathoms and 9 in the vicinity of the keys; therefore, by not getting into less than  $4\frac{1}{2}$  when standing westward, or into more than 8 fathoms to the eastward, there will not be the least risk or cause of anxiety.

From the Bay of Gracias a Dios, you may steer S. S. E., which course will take you in sight of the westernmost key of this group, which is a dark brown rock, that may be seen at the distance of 5 or 6 miles. On this route you will have from 7 to 8½ fathoms, and the course must be kept without going anything to the eastward of it, until you are well clear of the southernmost keys; the surest indication for which, will be your getting the depth of 11 fathoms, and thence you may shape a course for your voyage.

**FROM CAPE GRACIAS A DIOS, WESTWARD.**—From Cape Gracias a Dios the coast runs about N. W. for the distance of ten leagues, to Cape False, which may be known from being the highest land on this part of the coast. From the False Cape a bank, with very little water on it, projects out to the N. E. to the distance of 6 miles; but the coast bank preserves its regular soundings, and it even seems as if they extended to the Serranilla; but however that may be, it is so little known, that 9 fathoms is the greatest depth that you ought to navigate in, because there are various shoals, of which the positions are very doubtful; and, therefore, to navigate with safety, you ought not to get into deeper water than 9 fathoms, nor into a less depth than 5½ fathoms; and this rule will hold good, either in steering a direct course, or working to windward; for you will thus be sure of navigating in a clean channel of 20 miles breadth.

From False Cape the coast trends about W. N. W. for a distance of about 35 miles, to the Lagoon of Cartago, or Caratasca, which is easily known by its wide mouth. All this coast, like the preceding, is clean, with regular soundings along it; and, to navigate on it, the lead is a sufficient guide, so that you may not get into less than 5½ fathoms when standing towards the shore, or into more than 9 when standing off; by doing which, you will evade falling on the Vivorilla,\* &c. as they lie about 8 leagues off the coast northward.

From Cartago Lagoon the coast trends about W. N. W. for a distance of about 20 leagues, to Brewer's Lagoon; and thence, almost on the same bearing, a distance of 8½ leagues, to the Rio Tinto, or Bla River.

**BLACK RIVER, AND METHOD OF ANCHORING OFF IT.**—Black River is distinguished by the mountains of La Cruz, which are very lofty, and are the first to be seen on all the coast, after passing Nicaragua. These mountains are a little to the eastward of the river's mouth: on the same river there is a peak, named the Sugar Loaf, because it is of that shape. To anchor off this river, bring the mouth of it to bear south, and Cape Cameron west, taking care not to get into less than 11 fathoms; because in less depth there are many lost anchors, left by ships obliged precipitately to make sail when the norths have set in.

This anchorage is an open roadstead, where, even with the winds of the breeze, it is necessary to ride with two thirds of a cable out; and so soon as the wind falls, to heave in to nearly a-peak, in order to avoid fouling the anchor. When lying in this anchorage during the season of the gales, which, as we have said, is from October to February, the utmost attention must be paid to the state of the weather; and when you see the wind gets to the south-east and then veers to south, and south-west, you ought immediately to weigh the anchor, and make sail off shore well clear of the land, for a gale will surely succeed. Cloudiness, or a foul appearance in the N. W. quarter during these months, is an almost infallible sign of an approaching gale; a swell from the north is an indication equally certain, that precedes the gale at a moderate interval. In any of these gales, the loss of a ship remaining at anchor is inevitable; frequently the wind will not give time to weigh the anchor; in which case the cable must be slipped, with a buoy upon it, or even cut, that you may immediately make sail, and get clear from the land, in order to encounter the gale under sail. These gales are very violent, and raise a heavy sea, and therefore, if a ship is very much distressed, she has the resource of running to the Bay of Gracias a Dios for shelter, and riding out the gale at anchor; and it has been already observed, that the lead is a guide, which there, will carry you clear of all danger. As these gales occur more frequently from the N. W. and W., than from the north, the result is, that ordinarily, the anchorages of Gracias a Dios may be considered as a port to leeward, to which you can bear away: in which resource there will be found the advantage of being to windward of the Black River when the hard weather ceases; because then the breeze blows from the east, and therefore in a short time, and almost without trouble, you can return to your former anchorage.

**BLACK RIVER BAR.**—The Bar of Black River is extremely dangerous, and boats run great risk of being upset on it, and the crews on board of them of perishing, from the very heavy sea there is generally upon it. Therefore, either to enter or come out of it, it is necessary that it should be done in the calm of the morning, before the sea breeze sets in, and after the land breeze has blown the preceding night. If the breeze

\* There are many charts in which this and other rocks do not appear; but we do not think proper to alter these directions until we have a more correct account of the situation of all of them.

has been tolerably fresh, neither going in or coming out can be effected; so that communication with the shore is far from frequent, and is always very troublesome and dangerous.

**COAST TO CAPE CAMERON AND PUNTA CASTILLA.**—From Black River the coast trends west, with some inclination to the north, for a distance of 9 miles, to Cape Cameron, which is formed by a low tongue of land projecting into the sea. From this Cape the coast trends W. 3° S. a distance of 20 leagues, to Punta Castilla, or Cape Honduras: it is all clean, and also deeper than the anterior coast, so that it should not be approached into less than  $7\frac{1}{2}$  fathoms water.

Punta Castilla is low; and a small sand bank, with very little water on it, extends from it one quarter of a mile to the westward. Castilla is the north point of the Bay of Truxillo, which at the entrance is about 7 miles wide. This bay is easily entered, as there is nothing to be guarded against except the little bank off Point Castilla. On the south coast of the bay there is a high mountain, called Guainoreto, which may be seen at the distance of 24 leagues. In making the bay from the offing, this mountain is a good mark for running in by; for, by bringing it to bear about S. S. E., or S. E. by S., it will lead clear of Point Castilla, and up to the anchorage off the mouth of the River Cristales, which falls into the south side of the bay. This anchorage seems preferable, not only because its contiguity to the river affords the opportunity of procuring water conveniently, but also, because from this spot Point Castilla may be easily cleared, in case of being obliged to get under way by a gale from W. S. W., west, or W. N. W.; whence it blows most frequently from October or November until February. With such winds a simple inspection of the plan of the bay will show that there must be a heavy sea in it; and this was experienced in the ship Maria, in December and January 1800, which having rode out one or two of these gales at anchor, was afterwards under the necessity of quitting and taking shelter in Port Royal, in the Island of Rattan, as her captain considered the anchorage of Truxillo too hazardous to remain at during the season of the Norths, which was the season he was in it.

To enter in or sail out of this bay, no particular instructions are necessary, as there is plenty of room for working without the smallest risk, observing only not to approach Blanquilla or St. Lucas Key, nearer than half a mile: this key is off the south coast, about two miles outside the bay, and is surrounded by a bank, with little water on it, the best guide towards which is the lead. Take care not to get into less than  $5\frac{1}{2}$  fathoms in its vicinity, and you will avoid every danger. Blanquilla lies about a mile from the coast, and you may run through the channel between, without any other guide than the lead. It was heretofore believed that this bay was well sheltered, and a good place of refuge during the storms of winter; but this is not the fact, and any vessel stationed on the coast at that season ought to prefer Port Royal, in Rattan, to it.

**GUANAJA, OR BONACCA.**—North from Point Castilla, at the distance of eight leagues, is the Island of Guanaja, about three leagues in length N. E. and S. W. It is entirely surrounded by keys and reefs, which extend a league off from it. On the east side of the island there is a very good anchorage, particularly during the north winds; but it will be necessary to pass between the keys and reefs to enter it. The best passage is to the southward, leaving the southernmost key on the larboard, and another key lying N. by E. half a mile from it on the starboard. Endeavor to pass in mid-channel, and steer towards another key that lies two thirds of a mile west from the northernmost of those you have passed. It will bear from you about N. 71° W. You ought always to pass between the two last mentioned keys, and then nothing remains but to coast along the island to the N. E., and anchor at any convenient place after getting under shelter of the land; observing to keep about the middle of the channel between the island and the keys, in 7, 8, and 9 fathoms water, on muddy sand. It may be necessary sometimes to run for this anchorage in blowing weather from N., N. W., or W., which will not permit of entering it on one stretch. In such a case, however, it may be observed that you may work between the three keys before mentioned, on the supposition that it will be sufficient to give them a berth of a cable's length. The plan of the harbor will clearly elucidate what has been said of it.

**RATTAN.**—Westward of Guanaja is the Island Rattan, about 10 leagues in length from E. N. E. to W. S. W. A reef runs off eastward from the east point, to the distance of 12 miles, on which there are several keys and islands; of these, the easternmost is called Barburet. The distance from Barburet to Guanaja is about 10 miles; but the channel is reduced to 5 miles only, by the reefs which extend from both islands: without great experience, the passage through it will be attended with great danger. All the North Coast of Rattan is bordered by reefs that prevent its being safely approached nearer than a league; and those not well acquainted with the coast, should keep at a still greater distance. On the South Coast there are several good roadsteads, but most of them are difficult of access from the foul reefs at the entrances. Of all these harbors,

that called Port Royal, on the eastern part of the island, is the principal; and of which mention was made when describing the Bay of Truxillo, as being well adapted for affording shelter during the season of the norths. It is formed by the coasts of the island on the north and west, and by some reefs and keys on the south and east: the entrance to it is by a narrow channel, scarcely half a cable's length wide, between the reefs; but fortunately, this narrow pass is not more than a cable and a half's length. The east side of this channel is formed by a reef extending from the west side of the island called Lein, which is easily distinguishable from its size, and cannot be mistaken for the other keys, which are very small. In attempting to enter this harbor without a pilot, it will be necessary to mark the entrance by boats or otherwise; and it ought always to be done with the wind from N. E., easterly, or from west, southerly, in order to get clear within the reef: we refer to the Plan of the harbor, but it must be mentioned, we cannot guarantee the correctness of it. In approaching the island from the southward, great caution is required to avoid a rocky shoal nearly opposite the western extremity of it, at the distance of more than 4 miles from the coast: the channel between it and the coast is also obstructed by several other shoals; and although there is a passage for large ships, yet without an experienced pilot, they should always pass on the outside of it.

FROM TRUXILLO WESTWARD.—From the River Cristales, in the Bay of Truxillo, the coast trends about S.  $75^{\circ}$  W. a distance 32 leagues, to Triunfo de la Cruz, or Triumph of the Cross. This coast is dangerous, on account of several reefs and shoals which extend from the south side of Utila; for which reason, if there is no cause for keeping near the shore, or you have not the requisite experience for making the passage without risk, we strongly recommend a course always to the northward of both the Cochinos and the Island Utila.

THE COCHINOS are two rather large islands, clean on the north side, but with various foul keys and reefs on the south: between these islands and the keys there is a regular anchorage, respecting which, the only information we possess is a plan, that, on examination, will present all the instructions requisite.

UTILA ISLAND lies about N.  $75^{\circ}$  W. from the Cochinos, at the distance of 23 miles: the north, south, and west coasts of it are foul, but the East Coast has a good anchorage; to enter which safely, much experience is requisite. To the S. W. of this island, lies a shoal, called the Salmedina, of more than 5 miles extent; on account of which, when going to the northward of Utila, observe to approach it no nearer than two leagues until you are abreast of its western points; you may then run down for the coast about Punta Sal: in doing which, a S. W. by W.  $\frac{1}{2}$  W. course will counteract the effect of the current, that hereabout sets N. W., and might otherwise drift the ship into some difficulty with Long Reef.

THE TRIUNFO DE LA CRUZ is a point whence the coast rounds to S. S. W. and S. about 7 miles, and then bends to the N. W. for a space of 22 miles further, to Punta Sal, forming a great bay, sheltered from the breezes, and with good anchorage for ships of every denomination. To the north of Cape Triunfo, at the distance of half a mile, there are some islets, two of which are tolerably large, and may be seen at the distance of two leagues; they are clean, and by passing at half a mile from all that is visible, you may proceed direct to the anchorage in the eastern part of the bay, a little to the southward of the point, in  $5\frac{1}{2}$  to 8 fathoms water, on sand.

PUNTA SAL.—The point at which the bay terminates is called Punta Sal, or Salt Point; and at about half a mile to the northward of it, lie some high rocks, called the Bishops, forming a channel navigable for boats only. The Point appears with some hillocks and broken ground, and to the southward of it there is a little harbor, called Puerto Sal, but of which we have no details: however, off the mouth of this harbor, and at the round of Punta de Sal, you may anchor under shelter from the breezes; but it will be necessary not to come to in more than 12 fathoms, because in 17, 16, 15, and 14, the bottom is rocky; while, on the contrary, in less than 12, it is clean clay.

From Puerto Sal the coast lies about W. S. W. a distance of 8 miles, to the River Lua, which is large and deep: in front of this river there is anchorage on excellent holding ground of clay, but without the least shelter from the norths.

About 8 miles W.  $\frac{1}{2}$  S. from the River Lua is that of Chamalacon, off which there is also anchorage on good holding ground, but also unsheltered from the norths.

PORT CABALLOS, OR CAVALLLOS, lies about W. S. W. from the River Chamalacon, and at the distance of 4 leagues. This harbor is formed by a low point of sand to seaward, on the west side of which there is an anchorage in  $5\frac{1}{2}$  to  $4\frac{1}{2}$  fathoms, on sand. The harbor may be known by a high round hill, which is situated close to the sea on the eastern coast, and at about two leagues to the eastward of the port. To enter this port, you have only to keep clear of what is visible.

From Porto Caballos to Omoa, the distance is 7 miles S. W. by W. Within this space there is a small bank, with little water on it, lying north of some red gullies or

or cables are liable

to be cut by them, or in heaving up, to hook one; in which case you seldom fail losing your own, as it is good holding ground; this was the case with us on the 27th of November, 1786. For the above reason, it is advisable to lie somewhat to the eastward of the usual anchoring place, where you will have clear ground. Should the wind come to the westward of north, you must run to Cape Gracias a Dios; but if it should be to the eastward, you may go either to Truxillo or Bonacca. The north prevails from October to February.

We anchored in 12 fathoms directly off the river, with the Sugar-loaf of Poyer Hills bearing south, and Cape Cameron west; but with the Sugar-loaf bearing S.  $\frac{1}{4}$  W. there is less risk of getting foul of anchors. When the trees on the low land are seen from the deck, you will have 80 or 90 fathoms, from which it shoals regularly to 9 fathoms, on muddy bottom. The entrance into the river is narrow, and distinguishable from the other land; it has a dangerous bar across it, which can very seldom be passed, except in the morning, before the sea breeze sets in; and then only in *their* craft: though it is sometimes smooth enough for a ship's boat to go over in safety. Being over the bar, and in the entrance of the river, you must proceed up a lagoon on the right hand, about  $1\frac{1}{2}$  mile to the town, or Bank, as they call it, which is the principal settlement, and is very pleasantly situated on the left side of the lagoon, going up. The town is about a mile long, and consists of only one street; at the east end of it there is a battery of 12 guns en barbette.

Good water may be obtained a little way up the river, and plenty of wood; but both must be got off in the country craft on account of the bar.

From the Black River to Cape Gracias a Dios, we kept alongshore, sounding in from 7 to 10 fathoms. Off Patook River, which lies at a considerable distance to the eastward of Black River, we observed the fresh water, where it joined the sea, form a distinct line as far as we could see, being very brown and muddy, and had the appearance of a shoal. When in it, we found the water nearly fresh; at the time of this alarming appearance there was a flood in the river.

Off the Caratasca Lagoon it is shoal to some distance; we passed it in 6 fathoms, keeping off and on, as we shoaled or deepened the water. On passing the False Cape, be careful to give it a good berth, keeping in 5 fathoms, as a dangerous shoal runs off from it; then keep alongshore in 5 fathoms for the cape, which appears like a bluff point, with level low land to the westward of it. As you proceed to the southward, keeping in  $4\frac{1}{2}$  or 5 fathoms, you will see near the cape three small islands, with moderately high trees on them; but they all join the land by a narrow beach: beyond them is a low sandy key, connected with the other by a reef, and forming the entrance of the harbor, it appears to lie across the mouth of it. As a spit runs from this key, you must give the point a berth of about 2 cables' length. There is good anchorage within the spit point in 4 fathoms, the said point bearing S. E. distant three quarters of a mile, where the Porcupine anchored, having little wind, and there being a great outset occasioned by a fresh in the river. You may bring the southernmost point of the Spit Key to bear S. and the northernmost point S. E. by E. distant three quarters of a mile, and anchor in 4 fathoms.

In working up the harbor the soundings are regular, from 4 to 3 fathoms, muddy bottom. The town, which is only a few huts built for the convenience of the wood-cutters squaring and shipping off their mahogany, is situated on both sides of the Hanlover, which is a cut they have made from the river Wanks across into the harbor, the river running into the sea by the cape. Through this cut, great trees and logs have been drove, which have lodged round it, and formed a bar about two cables' length off, over which there is barely water for a boat; and it is increasing, so that it is very probable it will in time spoil the harbor. Before this cut was made, there was deep water close in, and they brought their wood through another opening to the eastward into the harbor. There being a flood in the river, and consequently a continual outset, could make no observations respecting the tide. Latitude observed,  $14^{\circ} 59' N$ .

SANDY BAY is the residence of one of the Mosquito Chiefs, and lies about 9 leagues from Cape Gracias a Dios to the southward; it is low level land, and only to be distinguished by a gap among the bushes near the beach, which the Indians have cut through for nearly a mile, to open a passage into a spacious Lagoon for their craft, directly across which is their town, very near the water side, in the midst of a plantain walk, on which, and some cassada roots, with turtle that they catch in the season, is their chief dependence for support. The coast here trends nearly north and south; the Porcupine lay in 6 fathoms, about two miles from the shore, with the Creek bearing S. S. W.  $\frac{1}{2}$  W. at the distance of 3 miles; here we were obliged to ride out a gale of wind, with a heavy sea setting right on the shore. The Bar, which is off the Creek, is not above a cable's length from the shore, and has a continual breach over it, without any very heavy surf; I went over it in one of *their* craft, which the Indians are very expert in managing. Nei-

ther wood nor water can be procured, except from the Indians, and brought off in their craft, for the ship's boats cannot go over the bar. Latitude observed,  $14^{\circ} 30'$ .

It is better to anchor farther southward off the Creek, bringing it to bear W. by S. or W. S. W. for the convenience of getting off from the shore. The water rises and falls here a little, but there is no regular tide.

TREBUPPY is about 7 leagues to the southward of Sandy Bay, and is the residence of the Indian Chief Governor, who is considered to be the most powerful chief on the Mosquito shore. On running down you will see houses a considerable way inland, which is the Governor's Town, off which we anchored. The land is not high, but has the appearance, from the ship, of being cultivated. The Porcupine lay in 5 fathoms, between 2 and 3 miles from the shore, and 3 from the Bar, and found three fathoms very near in. The Bar is at the entrance of a small river, that runs winding up to the town, and is only safe to be passed in the country craft. It is no better lying here than at Sandy Bay, as it is a straight shore. The bearings at the anchorage were Brangman's Bluff (Point Braema) S. W.  $\frac{1}{2}$  W., the river's mouth W., and the northernmost land N. by E. Latitude observed,  $14^{\circ} 8' N.$  Found a current setting to the southward.

Neither wood nor water to be had here, except procured from the Indians, and brought off in their craft.

BRANGMAN'S BLUFF (Point Braema) makes out in a point from where we lay off Trebuppy, about the distance of 5 miles, and has somewhat of a bay to the southward of it. We ran in till the bluff bore N. N. E.  $\frac{1}{2}$  E. and anchored in  $4\frac{1}{2}$  fathoms about 2 miles from the shore, with the river's mouth bearing N. W. and the southernmost land S. W. by S. At about half a mile within the ship there were only 3 fathoms. The appearance of the land is much the same as at Trebuppy; there is a bar at the river's mouth; and at about 2 miles up the river are the few houses of the inhabitants, who have a number of cattle and good pasturage, some of which we procured. There are no Indians living here. There is a considerable rise and fall of the tide in the river, but at the anchorage we could only perceive a small southerly current. Latitude observed,  $14^{\circ} 3' N.$  variation  $8^{\circ} 50' E.$

Wood and water may be got here, but they must be brought off by the inhabitants in their craft.

*DESCRIPTION of the Swan Islands, &c. with Directions for Navigating from Half Moon Key to Balize; and from English Key Northward past Mauder Key, Turneff; by Capt. G. Sydney Smith, while Commander of H. M. Sloop Bustard, 1827-1828.*

The Swan Islands, two in number, are low, but may be distinguished from the mainland in clear weather, at a distance of 5 leagues. They are in extent about  $4\frac{1}{2}$  miles, in an E. N. E. and W. S. W. bearing, and have a passage between them, in which there is only sufficient water for a boat: they may be approached on either side with safety to a distance of three quarters of a mile; and at the S. W. end of the western island there is a fine sandy bay, and clean bottom, where a ship may anchor in safety in from 7 to 10 fathoms, at half a mile off shore. Farther west, at from  $1\frac{1}{2}$  to 2 miles distant, the bottom becomes foul, with very irregular soundings from 10 to  $4\frac{1}{2}$  fathoms. A bank of this description has been said to exist off the east end, where the Bustard obtained soundings in 12 fathoms, on rocky bottom, at a mile distant from the point, whence the depth decreased gradually to 5 fathoms, at half a cable's length from the shore, the boats being dispatched to sound round both islands. The easternmost island is infested with innumerable Boobies, its shore not accessible without great danger, or injury to the boat. The western island, on the contrary, is well wooded, with several good landing places in small sandy bays, which abound in turtle; some hundreds of their eggs were collected on the beach in the space of a few minutes; and several large snakes were killed by the boats' crews, found feeding on the eggs. Cocoa-nuts were in great numbers on the north side. Search was made for water, but without success, though it might probably have been found by digging.

Observed latitude of the West Island,  $17^{\circ} 24' N.$ , longitude by chron.  $83^{\circ} 53' W.$

MISTERIOSA BANK.—North, 90 miles distant from the Swan Islands, is the Misteriosa Bank; this bank has been partially examined by Capt. R. Owen of H. M. Ship Blossom, and is inserted on the Chart published by E. & G. W. BLUNT.

Mr. Allen, formerly first Lieutenant of the ship, says, in a note to the author of this work, we have not entirely completed the examination of this bank, but believe there is a small key on the north end of it.

THE MISTERIOSA BANK was met with by D. Tomas Nicolas de Villa, in his passage from Truxillo to Bataviano, in April, 1787, having sounded in 11 fathoms, on white sand and stones. The latitude deduced from that observation at noon, places this bank in  $18^{\circ} 48' 42'' N.$  Its longitude is  $77^{\circ} 29' 24'' W.$  from Cadiz, as deduced from

Punta Castill for the errors April, 1805, sounded on the observations, the  $53^{\circ} 36''$ . The eastern edge of after making Misteriosa by that the bank the two long be that in whi THE ALB are without do GLOVER'S

\* Copy of a no ing been lost on th

Punta Castilla, at Truxillo, (well ascertained by Gen. Don Tomas Ugarte,) allowing for the errors which Villa might have made in 5 days' navigation. Also, on the 11th of April, 1805, D. Josef Maria Merlin, Captain of a particular frigate, called the Flecha, sounded on this bank in his passage from Cadiz to Vera Cruz. According to his observations, the depths of 9 and 13 fathoms were in north latitude  $18^{\circ} 52' 42''$ , and  $18^{\circ} 53' 36''$ . His longitude was deduced from the spot where he had 16 fathoms, on the eastern edge of the Seranilla (well ascertained by B. D. J. F. Fidalgo;) and it seems, after making all the corrections for the action of the currents, &c., the longitude of Misteriosa by Merlin is  $77^{\circ} 39' 30''$ , which, differing only  $10'$  from the former, shows that the bank is well fixed, and not very far from its true situation, taking the mean of the two longitudes,  $77^{\circ} 34' 37''$  west of Caliz ( $83^{\circ} 51' 37''$  W. of Greenwich) will be that in which we place it.

THE ALBION AND MAUD'S BANK, described in a former edition of this work, are without doubt the Misteriosa Bank.

GLOVER'S REEF.—This is laid down from the surveys of Com. R. Owen, of his Majesty's ship Blossom, and published by E. & G. W. Blunt, 1833. The bank is in general very dangerous. With the common trade wind the current sets strongly over it to the westward. The following description has been communicated by Capt. J. Burnett.

"Glover's Reef, which has two sand spots on the north end, lies nearly south from Hat Key, distant 15 miles, trending thence S. S. W.  $\frac{1}{2}$  W. to the south end of the reef, on which there are five islands or keys. These may easily be known from the southern four keys, as they are quite bold on the south side. The keys are very little detached, and nearly all of the same height, with numerous cocoa-nut trees on them. If, from want of observation, and strong current, you may have gotten to the southward of Glover's Reef, and the wind be so far to the northward that you cannot sail north for Key Bokel, night coming on, you should anchor to leeward of the key, where there is good ground, in from 7 to 17 fathoms, within half a mile of the keys, and there either wait for a wind, or till you send into English Key for a pilot."

BALIZE, OR BELIZE.—Pilots for Balize are always in readiness at Half-moon Key, (the S. E. Key,) on the east end of which stands the lighthouse, whose lantern is elevated about 50 feet above the sea, which may be seen in clear weather when 4 leagues distant—a circumstance that causes this route to Balize to be generally preferred—though in the season of the north winds, that is, from October to March, it is considered by some, and with apparent justice, best to make Manger Key, the northern key on Turneff, from which you may run with a fair wind S. S. W. 6 leagues to English Key; whereas, by approaching Half-moon Key at this season, the prevailing winds will not allow you to fetch Key Bokel from Hat Key Reef, and also gives you a dead beat to English Key. It has been recommended by some to make Bonacca in lat.  $16^{\circ} 35' N.$ ; but this island is surrounded by reefs, which circumstance, combined with the strong southerly currents at the season alluded to, when gales from the N. and N. W. may be frequently expected, renders it a coast rather to be avoided, particularly as the only port under your lee would be New Port Royal, in the south side of Rattan—a most desirable port for persons acquainted—but the entrance lies between reefs, and is intricate, and pilots are seldom to be obtained.

Observed latitude of the lighthouse on Half-moon Key,  $17^{\circ} 12' 30''$ ; longitude by chronometer,  $87^{\circ} 27' 10''$  W.

HAT KEY AND REEF.—W. S. W. of Half-moon Key lies Hat Key, which is wooded, and resembles, in form, a coronet. A dangerous reef extends from this key S. by E. 3 miles, to clear which, when 2 miles south of Half-moon Key, they steer S. S. W.  $\frac{3}{4}$  W. 10 miles. From the edge of the reef to Key Bokel, the course is W. or W.  $\frac{1}{2}$  N., according to the wind, 7 leagues.

KEY BOKEL AND ANCHORAGE.—Key Bokel may be known by its fine sandy beach and three or four cocoa-nut trees, and may be rounded at half a mile distant, but not nearer. Should you wish to anchor, a clear sandy bottom will be found, with from 10 to 4 fathoms, the centre of the key bearing from E. by S. to S. E.: the E. S. E. bearing is preferred. It is advisable to give a good scope of cable at once, as from the edge of the bank being very steep, you are liable, in case of squalls or fresh breezes from the eastward, to drive off it before you could have time to veer.

ENGLISH KEY.—The course and distance from hence to English Key is N. W. by N. 4 leagues. It has three cocoa-nut trees on its centre, is sandy on the N. E. side, and bushy to the water's edge on its S. and S. W. sides, lying at the south side of the entrance of the channel to Balize.\* Goff's Key is situated on the north side of the

\* Copy of a notice, dated Lloyd's, 10th May, 1823.—"Many vessels, at different times, having been lost on the main reef, when going into Honduras, from being unable to distinguish Eng-

channel; is very small and bushy, with one cocoa-nut tree in the centre, and surrounded by a sandy beach. To the eastward about half a mile is a sand patch, called by the pilots "Sand Bore," nearly even with the water's edge, and requires a good berth in rounding. The anchorage is in from 8 to 4 fathoms, with Goff's Key bearing from N. by W. to N. by E., or the keys to the northward and Goff's Key in one. From this place, unless perfectly acquainted, you cannot proceed without a pilot.

There is also anchorage in 4 fathoms at "Joe's Hole," under Turneff, as far north from Key Bokel as to have English Key bearing N. W. by W. The depth of water between English and Goff's Keys is 20 fathoms. Pilots are generally found on the former of those keys, waiting the arrival of vessels coming in from the northward.

The course in mid-channel from English Key to Balize is about W. N. W. till the west end of Water Key bears north; then haul up to N. by W. or N. N. W. till Goff's Key is on with Water Key, which is the mark to run over the narrows in  $2\frac{1}{2}$  fathoms; then N. W. and N. W. by W., hauling to the northward after passing the middle ground, which has only 10 feet water on it, and lies from 2 to  $2\frac{1}{2}$  miles from Balize. From the Narrows you will find 7 fathoms, decreasing gradually as you approach the anchorage. The marks for anchoring off Balize are the steeple of the church on with the centre of Government House, and the south end of Fort George, situated on a low flat island, bearing N. W.  $\frac{1}{2}$  W., where you will have  $2\frac{1}{2}$  fathoms, on muddy bottom. Ships of a greater draught of water lie at a considerable distance from the town, and proceed to it through a wider and deeper channel than the one described, having in it 3 fathoms and upwards.

The current in the anchorage sets to the southward, at the rate of one mile per hour, with a rise and fall of two feet.

Supplies of all sorts are of a very inferior description. Vegetables are seldom to be procured, and never but in very small quantities. Beef is also inferior and very scarce. Turtle alone is abundant. The water is not good for a voyage, unless taken from about 14 miles up the river, except during the rainy season, when it may be had perfectly fresh two miles from its mouth.

**MAUGER KEY.**—The course from English Key to Mauger Key is N. E. by N. 6 or 7 leagues. It lies in latitude  $17^{\circ} 36' 15''$  N., and longitude  $87^{\circ} 42' 30''$  W., being the northernmost key on Turneff, with a reef extending from it N. N. W. two miles. To the S. S. W. is Crawl Key, at the S. W. end of which there is anchorage during the regular trade winds, in 4 or 5 fathoms. To the eastward of Crawl Key lies Three-cornered Key, all having a great resemblance to each other, Mauger Key being the smallest, and, as before stated, the northernmost.

*From Port Royal, Jamaica, to the Bay of Honduras, and thence to the Island of Cocumel; by Capt. Wm. Sandom, R. N., in the years 1826 and 1828.*

[The courses and bearings are magnetic.]

**SWAN ISLANDS.**—Left Port Royal for Balize, Honduras, on the 24th of June, 1826. Having some doubts as to the true situation of the Swan Islands, as they are laid down directly in the track from Jamaica to Balize, I determined on making them, which was done at 8h. 30m. A. M. of the 26th. After making the east end, I ran down the north side, which is bold, and may be approached with safety to the distance of half a mile, until within three quarters of a mile of the west end, where shoal water and dangerous rocks lie off full one mile and a half. The easternmost of these islands is not low, and may be seen in clear weather 18 or 20 miles off. I observed from the mast-head, in coasting along the north side of these islands, that the discolored water extended a full mile off from the E. S. E. part, along the south side to the west end, where it extended off full  $1\frac{1}{2}$  mile. They are two distinct islands, connected by a reef of rocks, and well wooded, the trees on the easternmost being moderately high. The latitude of the eastern end is  $17^{\circ} 22' 30''$  N.; the longitude, by chronometer, from Port Royal, being  $6^{\circ} 56'$ , makes this end in  $83^{\circ} 48'$  W.

From the Swan Island towards Balize, it is necessary to guard most particularly against the influence of the currents in running down to the shores of Honduras. They are entirely influenced by the winds, and change their direction when the wind changes; but on approaching the shoals, reefs, and keys, south of Balize, you will generally find a strong current setting to the northward, which must be guarded against by frequent observations during the night. The south-easternmost of the southern four keys is

lish and Goff's Keys (between which is the only ship channel into Balize) from the many other keys on the main reef, Major General Codd, his Majesty's Superintendent, has caused a flag-staff, 60 feet high, with an octagon figure on the top, to be erected on English Key.

The south end points, between

Half-moon Key, so called from the form of the sandy shoal projecting from it. On this key the lighthouse is placed, in lat.  $17^{\circ} 12' 30''$  N., and long.  $87^{\circ} 27' 10''$  W., by chronometer. Here the pilots for Balize reside.

The approach to Balize from the Outer Keys is too difficult to be attempted by any one not having a thorough and practical knowledge of it.

On leaving Port Royal, January 21st, instead of steering to the southward of west for the purpose of making Rattan, and thereby ensuring a more certain route to the lighthouse, (on Half-moon Key,) off Balize, I was under the necessity of keeping to the northward, to communicate near Cozumel; consequently ran down on the eastern reef, and found myself much perplexed in consequence of a very strong current, which ran to the N. N. W. upwards of 2 miles an hour. I could not ascertain the latitude of the North Key on the Eastern Reef; but ran along by the eastern edge of the reef.

The pilot was received as usual at the lighthouse, and sail made for English Key, past Hat Key, and Key Bokel. At this time the remarkable cocoa-nut trees, with a space between, showing the clear light, sufficiently point out English Key. I weighed from English Key, and sounded along the shore of Turnell to Manger Key, and now confirmed an opinion I formed two years since, namely;—that rather than beat about outside, I would endeavor to make Manger Key, (which I would also do, if I had made the North Key on the Eastern Reef,) and run along the western side of Turnell, at the distance of from 2 to 4 miles off. When about 12 miles to the southward of Manger Key, you will see two or three remarkable hillocks on Turnell; from these hillocks English Key will bear about W. by S. From hence you may steer across to English Key, with less chance of mistaking it, attending to the foregoing remarks,—namely, the space between the cocoa-nut trees. The course from Manger Key to English Key is S. S. W. 20 miles; but I imagine there is a great risk of a stranger's being bewildered, from the similarity of the Keys near English Key, by steering directly for it; and therefore recommend running along the Turnell shore, as above, in preference.

**ANCHORAGE AT ENGLISH KEY.**—In anchoring at English Key, take your soundings from Goff's Key, and round towards English Key, as there is a dangerous spit off the latter, called by the pilots, the Sand Bore. With English Key bearing S. W.  $\frac{1}{2}$  S. and Goff's Key N. by W. there are 5 fathoms.

I have several times worked from the above anchorage to Manger Key, and always found a southerly set; it is, however, influenced by an ebb and flow of the water, but not very strong. In the *Espiegle* I worked close to the edge of the reef off Manger Key, and consider it about 2 miles off; and at night made the edge of the reef when about 2 miles to the northward of it, and 4 from Manger Key. Therefore, unless very dark, by keeping a good look out, you may see it in time to avoid danger.

I must here caution navigators against a strong current, which almost always sets between Manger Key and the opposite keys, about N. W.: when standing to the northward, I have most unexpectedly been set on the lee shore, when I thought myself many miles off it. This current sometimes sets westerly, and then to the southward.

I beat up to the northward during the night, keeping much to the southward and eastward, to avoid the danger of going near the Triangles. Early in the morning sail was made to the northward, and the northern end of Ambergris Key closed on, without having seen the Triangles: nor had we much northern current during the night. I must here remark, that the whole of the shore of the Ambergris Key has a reef about a quarter of a mile, or a little more, off, in many places dry, and the sea breaking on all of it.

I continued working to the north towards the Island of Cozumel. The coast of Bacalar is bold, and may be approached in some places within one mile; there is a reef all along it, which, both by the color and breaking, plainly indicates itself; and off some of the projecting points they are plainly seen breaking at a considerable distance off. You have no soundings outside the reef, nor any means of ascertaining your approach to it in the night.

**AMBERGRIS KEY.**—The long isle called Ambergris Key, to the northward of Balize, is said to abound with extensive fresh water lakes; to produce logwood, and the more valuable kind of dye-wood, named Brasiletto. In most seasons it is plentifully stocked with many kinds of game.

**EL CHINCHONO.**—The shoal called the **NORTHERN TRIANGLE** lies at the distance of 13 leagues to the northward of Manger Key. Captain Burnett says, when the trade wind prevails, a current, often very strong, sets down between Manger Key and the Triangle; there dividing itself, it sets to the southward, between Turnell and the Main Reef, and, to the northward, between the Triangle Reef and Ambergris Key. With a wind from E. to E. S. E. as you sail to leeward of the Triangle, you will have a strong current in your favor.

The south end of the Triangle Reef is from four to five miles broad; it makes in two points, between which there is a sandy spot. From the S. W. point, the reef trends N.

by W.  $\frac{1}{2}$  W. to the great key on the centre of the reef; from thence N. by E. to the two keys on the north end. The course along shore to Cozumel is N. by E.  $\frac{1}{2}$  E. and the shore pretty bold.

**COZUMEL ISLAND.**—On first making the Island Cozumel, from the north-west end being much higher than the southern, you are inclined to think the island lies nearly east and west: but, on a nearer approach, it will be found to lie nearly in a N. E. and S. W. direction. There is good anchorage all along the west side of the island at about three quarters or  $1\frac{1}{2}$  mile from the shore, on stiff sand and clay: the anchor may be seen. The bank running all along the western side is free from danger, and very steep to, having from 13 to 10 fathoms at one cast of the lead. On approaching the shore you plainly see the edge of the bank, which shows itself by the discolored water, and a very strong and turbulent motion, caused by the stream of current which sets very strong to the northward outside, at one mile from the shore, coming in contact with the eddy current, which sets in a contrary direction along from the edge of the bank. On first seeing this, I was somewhat alarmed; but on finding the cause, the alarm ceased.

**ANCHORAGE.**—The *Espiegle* anchored in the first bend of the coast to the southward of the N. W. point, having that point bearing N. by E. and the southern extreme S. S. W. distant off shore about half a mile. It is necessary to remark that the land from the N. W. to the north point falls in to the eastward, forming a long deep bight of 8 miles. About 8 miles to the southward from the N. W. point there is a small lagoon, the entrance to which is not discernible till very near it, having about 5 or 6 feet of water at the mouth; there are many small islets all about it, and an abundance of fish of the finest quality. All along the coast there is an abundance of wood, and fish may be caught: in some places the seine may be hauled, but generally speaking, the beach is lined with small rocks near the water's edge. The south end of the island is low, and has a long sandy spit projecting from it. I have heard that fresh water is to be found, but did not see any.

*Cursory Remarks on the Northern Part of Cozumel Island, by Anthony de Mayne, R. N. Surgeon, February, 1820.*

**COZUMEL ISLAND** is of a moderate height, extending N. E. and S. W. upwards of 7 leagues, and is about 2 leagues in breadth. Its east side appeared to be free from danger; but off the N. E. point a reef runs out in a N. E. by N. direction upwards of 3 miles: this reef is steep to in every part; and there are 10 and 11 fathoms close to the breakers on the N. E. extremity. We passed the north-eastern breakers at a distance of half a mile, having 12 fathoms, and rounding them gradually, stood into a bay on the west side of the island, and there anchored in 6 fathoms, on rocky bottom, at about  $2\frac{1}{2}$  miles from the beach; with the N. E. point bearing east, distant 5 miles. From this spot we could plainly see the main land of Bacalar to the westward, which is rather low, with a number of large trees along the shore.

From observations made at this anchorage, we found the N. E. point of Cozumel situated in latitude  $20^{\circ} 32'$  N. and longitude  $86^{\circ} 44' 52''$  W. The north part of the island is low and swampy, covered with thick underwood, but we observed no other than small trees; on the south part, the trees appeared much larger, but of the fustic or log-wood kind.

We could not perceive any discolored water or soundings off the east side of the island; but off the north part, or end, the soundings extend to a considerable distance northward from the reef before mentioned. We found 13, 14, 20, and 16 fathoms, on rocky bottom. In latitude  $20^{\circ} 50'$ , and longitude  $76^{\circ} 40'$ , we had 16 fathoms, on rocky bottom; with strong rippling caused by the current, similar to the Gulf Stream, the set being N. by E.  $2\frac{1}{2}$  knots; at this point the bank appeared to terminate.

We found the current to the eastward of Cozumel setting N. by E. at the rate of 2 knots; but to the westward, between the island and the main, it ran south-westward at the rate of  $2\frac{1}{2}$  knots.

From several observations, the variation of the compass was found  $7\frac{1}{4}$  degrees easterly.

The main land opposite to Cozumel trends about N. N. E.  $\frac{1}{2}$  E. to the island Muger, and is all low and woody.

## THE COAST AND RIVERS OF GUYANA, FROM THE EQUATOR AND THE AMAZON, WESTWARD TO THE GULF OF PARIA, OR TRINIDAD.

**THE COAST OF GUYANA IN GENERAL.**—The country comprehended under the name of Guyana, extends southward from the river Orinoco to the river of Amazons. The coasts of it are generally low; as the numerous rivers bring down vast quantities of alluvial matter, which, accumulating on the shores, has formed a border of low ground. This ground, between the high and low water marks, is commonly covered with mangroves; at low water, it appears like an inaccessible bank; but with the rising tide, it is inundated.

**PORTUGUESE GUYANA.**—The Amazon is considered as the first or largest river in the world. Mr. Pinkerton has said, "among the grand rivers which water the globe, and diffuse fertility and commerce along their shores, the Amazon will ever maintain the preference." The truth of this averment seems to be unquestionable; the sources of this river being within two degrees of the Pacific Ocean, about the parallel of  $11^{\circ}$  S. and several great rivers fall into it, these again having innumerable branches. The course of its grand stream is nearly east across the continent, until it falls into the Atlantic under the equinoctial line. The river is said to be navigable through nearly its whole length, though impeded by many banks of sand, some of which extend 30 or 40 leagues. Below its confluence with the river Xingu, at 40 leagues from the sea, its opposite banks are invisible from each other. At Ovidos, more than 140 leagues from the sea, its breadth is about 1000 fathoms. The tide is perceptible to the distance of 150 leagues.

The declivity of the bed of the river, from Ovidos, has been computed at only four feet; yet the immense body of interior water gives it an astonishing impetus; so that it rushes into the sea with amazing velocity; and is said to freshen the ocean, at times, to the distance of nearly 80 leagues from the shore. This rapidity, on the return of tide, occasions a bore, called by the Indians *pororoca*, which is chiefly observable towards Cape North, and which surpasses those of others great rivers. This phenomenon always occurs two days before and after the full and change of the moon; when at the commencement of the flood, the sea rushes into the river, forming three or four successive waves, that break mountains high on the bar, and raise the tide within to its greatest elevation in one or two minutes. It has been said that the elevation of these ridges of water has amounted to not less than 200 feet; but the ordinary rise over the bar, is from 12 to 15 feet. The noise of the irruption may be heard at the distance of two leagues.

**FRENCH GUYANA.**—The coasts of French Guyana are much like those of the Portuguese or Brazilian territory, and present nothing remarkable to the navigator; the whole being lined by drowned mangrove isles and mud banks, which bar the mouths of the numerous rivers. The rains on this coast prevail from January to June, and form stagnant ponds and marshes, which render the climate very unhealthy. The currents along the coast are strong and irregular.

The only town is that of Cayenne, situated on an isle or rather delta, called Cayano; hence the whole territory is commonly styled Cayenne. The situation of this place was ascertained by M. la Condamine, in 1774, from four eclipses of the first satellite of Jupiter, &c. who has given it as in  $4^{\circ} 56' 15''$  N. and  $52^{\circ} 16' 30''$  W. a position since generally adopted.

The coast is in many places dangerous; having extensive banks of sand and mud with numerous rocks, some of the shoals reach to the distance of two leagues from shore. The isle Cayano lies between the rivers Onya and Cayenne; the latter has near its entrance, only 12 and 13 feet of water, with soft mud interspersed with rocks. The town is situated on the N. W. side of the island; it is generally described as a wretched place, the streets steep and narrow, and paved with sharp stones. The harbor, which is a tolerable one, is supposed to have determined the choice of settlers, in fixing on this situation.

There are several islets off Cayenne, as exhibited on the charts; of these the outer ones, called the Constables or Gunners, are the most conspicuous; they being barren rocks whitened with birds' dung. The Malingre, and other isles to the eastward of Cayenne, are very steep. On one of these is an hospital for lepers, a malady very common on the Cayano Island. These isles, &c. are more particularly described hereafter.

**DUTCH AND BRITISH GUYANA.**—Dutch Guyana or Surinam, extends from the Marrowyine to the Corantine, an extent of 170 miles; and British Guyana, from the Corantine to Essequibo, an extent of about 120 miles.

*General Directions for the Coasts of Dutch and British Guyana.*

Ships bound from the windward or Caribbee Islands to these coasts, should steer as far to the eastward as S. E. if the wind will permit, on account of the strong indraught or current, setting all times of the year to the westward, into and through the gulf of Paria. The moment you come on to the outward edge of the ground, you will perceive the color of the water change to a light green, and will have from 35 to 35 fathoms. If in that depth you should be so far to the southward as  $7^{\circ} 25'$  or  $7^{\circ} 30'$  north latitude, you may steer in S. W. and make the land; but if more to the northward, keep your wind till you attain that latitude, you will have very gradual soundings quite to the shore, but very shallow; you will be in 9 fathoms when you first get sight of the land about Demerara; but you may run in without fear in 4 fathoms, being attentive to your lead.—As it is the general opinion that there are many unexplored sand banks on this coast, a great attention to the lead and the quality of the ground will be necessary, as by that only you will be apprised of the danger; for, on most parts of this coast to the eastward of the river Oronoco, the bottom is of very soft mud; if, on a sudden, you find hard sandy ground, be assured some danger is near, and immediately haul off, till you again find soft ground as before.

The making of the land all the way from the Oronoco, as far to the eastward as Cayenne, is very low and woody, and therefore appears in all parts so much alike, that the most experienced pilots are frequently deceived. Your chief dependence therefore is in a true altitude; if that, by reason of thick weather, cannot be obtained, it will be advisable to anchor in about six fathoms, which you may do with great safety, having good ground, and in general moderate gales and smooth water.

The making of the land about Demerara is the most remarkable of any part of the coast; the woods in many places being burnt down, and cleared for cultivation, makes the land appear in large gaps, where the houses, &c. are plainly to be seen; and if there are any ships lying at the lower part of the river, their mast-heads may be plainly seen above the trees, for some distance at sea.

If bound into the Demerara, you must run to the westward till you bring the entrance of the river S. S. W. or S. by W., and either lie to, or anchor for the tide, in 4 fathoms of water; but be very cautious not to be hauled farther to the westward than these bearings, for the flood runs very strongly into the river Essequibo, at the mouth of which, and at a great distance from the land, lie many very dangerous sand banks, on some of which there are not more than 9 or 10 feet of water, and the flood tide sets directly on them.

On many parts of this coast, particularly off Point Spirit, a league to the eastward of the Demerara, the flood tide sets directly on the shore, and the ebb sets off to the N. E. It will be advisable, when calm and near the land, to anchor there.

In the month of December, there is, at times, particularly in shoal water, on the coming in of the flood, a great sea, called the rollers, and, by the Indians, Pororoca. It is often fatal to vessels at anchor. The early navigators have been puzzled to assign a cause for this phenomenon, which is occasioned by the northern winds blowing on the shoal water.

It is to be observed, generally, that on a great extent of the coast of Guyana, the sides of the rivers and creeks are almost every where covered with thick forests. The immense plains of natural salt swamps, which lie between these forests and the sea coast, (commonly called savannas,) were also formerly covered with forests, which have been destroyed by means of fire. Much brush wood, however, has since grown up, the branches and roots of which are so interlaced with each other, as to prevent penetrating through them even in boats. The greatest part of these savannas contain so much water, which flows into them during the rainy season, that the greatest heat of the dry season is insufficient to drain them. The land therefore cannot be cultivated.

At the distance of between 12 and 40 leagues from the coast, the wind generally prevails from the E. S. E., but within 12 leagues the wind is variable—in the morning S. E., and E. S. E. towards noon, drawing round to the east; and between 2 and 8 it is generally to the N. E. and N. N. E. or north. In the night it varies from E. by N. to E. by S.

To get to the windward on this coast, care must be taken not to suffer the southerly winds to take you more than 10 leagues from the land, at which distance you should be about noon; for by two hours after, the wind may prevail so far to the north as to lay you along shore. By 8 in the evening the north wind has generally subsided, and the wind then blows along shore from the eastward: therefore, with a whole ebb before you, it may be best to anchor and stop for a tide. By daylight the wind will be found to have

changed to west, southerly : hence the advantage of being near shore. Thus proceeding, and taking advantage of the tides, a ship may beat from Demerara to Surinam in the space of three or four days.

**SURINAM, OR DUTCH GUYANA.**—The River Marowynne forms the eastern boundary of the province. This river, which is but little frequented, empties itself into the sea by channels formed between several alluvial banks. The mouth of the river above these is three miles in breadth, and the stream is navigable to a great distance.

OF SURINAM RIVER, the entrance is three miles broad, and there is a depth over the bar of from 12 to 18 feet at low water, and from 21 to 30 at high water. The depth within is greater; but this is interrupted by two bars within the river, which are exhibited on the charts.

**PARAMARIBO**, the chief town, is on the western side of the river, between 4 and 5 leagues from sea.

The approach to the town is defended by several works on each side of the river. Of these, Fort Amsterdam, at seven miles up, on the eastern side, is the most considerable. Fort Zeelandia, below the town, is separated from it by an esplanade, and protects the shipping, in the reach of the river before it, which will contain 100 sail.

The river is navigable for large ships to the distance of 12 miles within land, and 60 miles higher for small vessels. The banks, quite down to the water's edge, are covered with evergreen mangroves, which render its navigation extremely pleasant.

**RIVER SURINAM.**—It is advisable for ships bound for Surinam, when coming from the eastward, or long voyages, to get into latitude  $5^{\circ} 55' N.$ , in the longitude of  $50^{\circ}$  (unless they have a time keeper, or lunar observation, which may be depended upon;) as by that means they will have an opportunity, from observation to observation, of ascertaining the current, which almost constantly, off the Marowynne, runs to the N. W.; and you are also to observe that, during the rainy season, you cannot always depend on a meridional observation.

When you have gained ground in the above latitude, (and be sure to sound in time,) 60 to 40 fathoms, fine sand, you will be 40 to 20 leagues to eastward of Marowynne Shoals; and you may not, in the night, approach nearer to them than 10 fathoms, when the soundings will be gradually coarser. In hauling to the northward you will have deeper water and finer sand; and in 10 fathoms water, heaving to with your head to the northward, you will drive clear enough of the shoals to the N. W. You will always know whether you are to the eastward, and consequently to the windward, by those soundings; for the ground, six leagues to leeward of the Marowynne, all the way to Bram's Point,\* is soft mud. Your best landfall will be between Post Orange and the Marowynne: indeed it is absolutely necessary that you should make the land thereabout. The Marowynne is known by the only high land near the coast, and appears, when you make it, at a great distance inland, and bringing it to bear south of you, you will be clear of its shoals; and had better then stand in until you are in 3 fathoms of water.

In making Post Orange, which has often been mistaken for Bram's Point, and which error has occasioned the loss of many ships,† observe that there are many large white houses, which are barracks; and in the middle of them, appears a large tree, which, when bearing south of you, makes like a ship with top-gallant-studding-sails set; and the flag-staff also appears among the trees; and those trees show to be nearer the houses; whereas Bram's Point has two large houses, a beacon erected in 1817, and the trees are on the other side of the river, as shown on the Chart of Surinam.

**SURINAM.**—You will then keep on the edge of the Mud Bank, (well described on the Chart,) in from 3 to  $2\frac{1}{2}$  fathoms, or as near as your draught of water will permit; and you need be under no apprehension in steering along the coast, if you touch, as the mud is very soft; and, on the Mud Bank, the moment you haul to the northward, you deepen your water; for, on the whole of this bank, it deepens gradually, from 2 to  $3\frac{1}{2}$  fathoms, and then you are on the outward edge of it.

The next mark you have (for you must be very attentive in keeping a good lookout) is a break in the land, which has been cleared for a plantation, with two houses; the trees on each side having been burnt, appear very brown, and in making it in 3 fathoms of water, 4 leagues off, you will be from 3 to 4 leagues to the eastward of Bram's Point,

\* Bram's Point is the eastern point of the entrance of Surinam River. A beacon, 70 feet high, has been erected about a mile to windward of the point, on which is a broad tin vane, painted white. When this vane is first distinguishable from any vessel coming from the eastward, she may be reckoned on the edge of the mud bank. The body or frame of the beacon is boarded around, and painted white. There are also two flag-staffs, the eastern one for signals, and on the western the colors are hoisted, and at a distance appear to be almost in the water.

† As the name of Post Orange does not appear on some charts, it may be proper to notice that it lies 13 leagues to the eastward Bram's Point.

which forms the eastern entrance of Surinam River. If it be evening, or ebb-tide, you had better haul to the northward, and must anchor when you have 4 fathoms of water, as the current would, during the night, drift you, (should you lie-to) as far to the westward as the Saramacca; and many ships have been three or four weeks beating back to Bram's Point, although the distance is only 7 or 8 leagues. Nay, heavy sailers, after beating many weeks, have borne up for Berbice, finding it unavailing to contend against wind and current.

BRAM'S POINT may be readily known by the beacon with a vane, at a mile to the eastward of it, and two flag-staffs, which have already been noticed. You will, on the flood, when it bears S. S. E. haul in, keeping the point open to the larboard bow. Steering thus, you will clear the shoal that runs out to the northward of it; and you are in the fair channel way, and may go within hail, when there is good anchorage in 4 fathoms of water; observing the best anchorage is within the point half a mile. The course up the river from its entrance to Fort Amsterdam is S. E. On getting within this point, keep the eastern shore on board, as then, all the way up, until you reach Paramaribo, is the deepest water. About three miles within the point, you have only 2 fathoms at low water; and from thence to within two miles of the entrance of the Comowinie, may not be improperly termed the lower bar; it extends about three miles.

In approaching close to Bram's Point from the sea, you may naturally, if a stranger, apprehend danger from several wrecks that lie on the point; but these are old vessels that have been brought from Paramaribo, and placed there as break-waters; as, at some seasons, the sea breaks upon the point.

Having reached nearly to the entrance of the Comowinie, which branches from the Surinam, you must be very particular in guarding against the flood, which sets strongly into the Comowinie, and which, without great precaution, would set you on a spit of sand, which extends from Fort Amsterdam, almost across the Comowinie. On the other hand, you must guard against some sunken rocks which lie a little below Fort Amsterdam, on the western shore, so as to keep between the two. Having passed the flag-staff, you will have 18 feet at low water; and from thence to the edge of the bar, the deepest water in the river. It is here that those ships complete their lading, which draw too much water to pass over the bar.

At Tiger's Hole there are 6 fathoms of water, which is just above Governor Frederic's plantation, called Voorburg. Here you will then have a leading wind up; and by keeping three quarters over to the eastern shore, you will have the deepest water, 11 feet at low, and 18 feet at high water. You may anchor abreast of Paramaribo, in 4 fathoms, observing that the deepest water is close to the town.

We shall conclude by these general descriptions:—That you will be near, and to windward of the Marowynne, with coarse ground; that, hauling to the northward, the ground will gradually become finer and the water deeper; and to leeward of the shoals, a sandy coast and ooze: that it is necessary to keep on the edge of the bank, in from 2½ to 3 fathoms, and in the rainy season, rather anchor too soon; or if you are in the least doubtful, or should you sail a few leagues to leeward, even in a fast sailing vessel, you would have much difficulty and length of time in turning back; and that, in observing these precautions, you cannot fail to make the land properly.

It is high water, at full and change, at Bram's Point, at 6 o'clock. The flood sets to the westward, ebb to the eastward.

BRITISH GUYANA.—The River Berbice, as a harbor, is of minor importance, there being a depth of only 7 feet on the bar at low ebbs. This bar is two leagues from the entrance of the river. The low isle within, called Crab Isle, is so named from the number of land-crabs which are found upon it.

New Amsterdam, the chief town, is situated at two miles above Crab Island, on the eastern bank. It is intersected by canals, which have the advantage of the tide. The government and public houses are of brick, and handsomely built. The entrance is protected by three batteries.

In sailing for the coast of Demerara from the northward, you must keep well to windward, as the general set of current along the coast is W. or W. N. W., about two miles an hour.

At the distance of 20 miles off shore, the currents vary according to the wind, and it may be observed as a general rule, that when there is any westing in the wind, a strong easterly set will be found along the whole coast; and that when the wind inclines to the eastward, the set will then be westerly.

The trade wind blowing between N. N. E. and S. E. causes the westerly set usually found; but as the wind occasionally veers to the northward, and even so far as N. N. W., particularly in the winter months the easterly current above alluded to sometimes exists.

The flood-tide sets along the coast S. W. and the ebb N. E. Their influence is not felt beyond eight miles off shore.

eir influence is not

As the passage from Demarara to Berbice, or other ports to windward, exposes you to the general westerly current, it is well to keep close inshore, and take advantage of the inshore tides; and should the winds be light, it will be necessary to anchor with the flood.

Cruising to windward in the Arachne, we found the trade wind incline so much to the northward as to enable us to lay up E. and E. by N., when we found the easterly set, as before mentioned, running at least  $2\frac{1}{2}$  knots an hour. This, however, is not common, and ought not to be calculated upon in making a passage to windward, unless the wind, as previously noticed, enables you to lay E. by N. or east.

The color of the water along the coast, to 19 miles off shore, is thick and muddy, and on many parts of it there are very dark patches, apparently shoals, but the soundings on them are the same as the water surrounding them.

Off the mouths or entrances of the different rivers, the bottom is hard, but in general along this coast it is mud.

In working to windward, stand no nearer the shore than four fathoms, nor off beyond nine. You will then be enabled to take advantage of the regular ebb and flood inshore.

*Appearance of the Land on the Demerara Coast.*—Nine miles to the eastward of Cocobano Point are five or six single cocoa-nut trees; ten miles farther to the eastward are two rows of the same trees, appearing like white cliffs.

Twenty-six miles to the eastward of the river there is a hillock, formed by a large cotton tree. This towers above the low land, and forms like a sugar loaf: it is called General Murray's tree.

General Murray's Tree, S. W. by S. 12°.

Forty-six miles to the eastward of the river are two hillocks close together. They also form like sugar loaves, and show themselves above the low land.

Two Cotton Trees, S. S. W. 11°.

Vessels on the coast of British Guyana, and bound to Demerara, will clearly make these objects, as they alone alter the appearance of the low land.

Crab Island, at the entrance of the river Berbice, will point this part of the coast out, there being no other island between Demerara and Sarinam.

Fourteen miles to the eastward of Berbice there is a building close down to the water; its sides and top are white, and a little to the westward of it is a deep gap in the land.

Fifty miles to the eastward of Berbice there is a patch of burnt trees, having the appearance of vessels at anchor.

The intermediate coast between these objects is low; patches of trees, and a few dispersed houses, alone altering its appearance.

There is no danger, if the lead is kept well going.

Unless standing in for a harbor or river, do not go into less than 5 fathoms, as there are many banks but little known inside these soundings. There is anchorage along the whole coast, but be careful, if you anchor off Berbice, to have sufficiently deep water to prevent touching the bottom between the hollows of the rollers, which break.

The pilotage going in and out of Demarara being so heavy, it is advisable to anchor outside, being 4 or 5 miles off shore, and Cocobano Point bearing W. S. W. 6 or 7 miles, is the best anchorage.

*THE HARBOR OF DEMERARA.*—This harbor is formed at the entrance of the river of the same name, Point Cocobano, which has a lighthouse on it, being the eastern point of the harbor.

It is a bar harbor, the bar running north and south from Point Spirit, which is 5 miles to the eastward of Cocobano Point.

At high water you will have on it 15 feet; high springs  $16\frac{1}{2}$  and 17. The rise and fall is 9 feet.

*Directions to sail for the River.*—Being to windward, and running for the river, keep at the distance of 4 or 5 miles off shore, in  $4\frac{1}{2}$  and 5 fathoms. Sixteen miles to the eastward of the river are two very remarkable rows of cabbage trees. Three miles to the westward of them are seven single ones. These trees have the appearance of white cliffs.

Having passed these, stand on with the same soundings until you see Cocobano Point, which is low, and the northernmost point of land, and has a lighthouse on it. Steer about west, until the lighthouse bears S. S. W.; then steer S. W. until the lighthouse bears south; then steer S. W. by S. until it bears S. by E. You will then have the river and ships open; steer for the lighthouse and you will have a white buoy on your

left, and a black on your right. Your anchorage is abreast of the lighthouse; it will bear E.  $\frac{1}{2}$  S.; at low water you will have 17 feet. The flood runs two knots and a half, and the ebb three knots an hour. The holding ground is good, being mud and clay.

In working out you must not bring the lighthouse to the westward of S. W. by W. or to the southward of S. by W.

The water that is generally used is rain-water. In the dry seasons it would be necessary for a ship in want of water to go 15 or 20 miles up the river, where it is quite fresh and good.

The pilots for this harbor are very good, and keep a sharp lookout for vessels coming down, picking vessels up 15 and 20 miles to the windward of the river.

It is high water (spring tides) at George Town at 4h. 45m. P. M. Rise at ordinary springs, 9 feet; at neaps, 8 feet. The tide continues to flow on the surface 1h. 10m. after high water, and during s. runs about three knots per hour at the anchorage, in the dry season, from July to November.

The distance from George Town to the Sandhills up the river is about 25 $\frac{1}{2}$  miles, by Capt. Owen's survey. In going up to the Sandhills, keep the eastern shore close on board, after passing the flats off Providence, until abreast of Howeroenie Creek; then haul over towards the point on the west shore above Glasgow.

The lighthouse is in lat. 6° 49' 20" N., long. 58° 11' 20" W.; variation 5° 43' E., by Capt. Owen's observations.

**SPANISH OR COLOMBIAN GUYANA.**—The most remarkable feature of Spanish Guyana is the course of the River Oronoco. A great part of the upper portion of this river was explored, in the year 1800, by the celebrated Humboldt, who proved its communication with the Rio Negro and, consequently, with the Amazon. The mouths of the Oronoco are of dangerous navigation, and require an expert pilot. Seven of them are navigable; but the chief is the Great Mouth, (Boca Grande, or Boca de Navios) which is about six miles in width. This is most to the southward, and in the direct course of the river. The isles of the Oronoco, or rather its Delta, which is of prodigious extent, are possessed by the Guaraunas and the Mariusas, two independent tribes of Indians. The northern part opposite to Trinidad, is overflowed from the middle of January to the middle of June; and, during this season, the Guaraunas dwell upon the palm-trees with which it is covered.

The seven navigable channels into the river, already mentioned, have been described as follow, commencing northward:

The first of the navigable mouths is the Grand Manamo, in the Gulf of Paria: the second is the Cano or canal of Pedernales, three leagues south of the Soldier's Island, at the entrance of the gulf: it is fit for long-boats only: the third mouth, named Capura, is seven leagues to the eastward of Pedernales, and, likewise, is fit only for boats: the fourth, named Macareo, is six leagues eastward from Capura, and is navigable by small craft: Mariusas, the fifth, is 12 leagues to the south-eastward of the fourth; but between are many mouths navigable when the river is high: the sixth mouth is eighteen leagues to the southward of Mariusas, and is navigable for small vessels: the seventh, Boca Grande, or Great Mouth, is eight leagues S. E. from the sixth: its breadth is six miles between the Islands, Congrejo, (Crab Isles,) on the N. W. and Point Barma, on the S. E. but the navigable channel is not above three miles, and is crossed by a bar, with 17 feet at low water: the approach to this entrance is dangerous, from the shoals running off seven miles eastward from Congrejo Island, and two miles northward from Point Barma.

The Flux and Reflux of the tide, are felt in the month of April, when the river is lowest, beyond Angostura, at a distance of more than 85 leagues in-land. At the confluence of the Carony, 60 leagues from the coast, the water rises one foot three inches. These oscillations of the surface of the river, this *suspension* of its course, must not be confounded with a tide that flows up. At the Great Mouth, near Cape Barma, the tide rises to a height of two or three feet; but further to the N. W. towards and in the Gulf of Paria, the tide rises 7, 8, and even 10 feet. Such is the effect of the configuration of the coast, and of the obstacles presented by the Bocas del Drago, &c.

The currents on the whole of this coast run from Cape Orange towards the north-west; and the variations which the fresh waters of the Oronoco produce in the force of the general current, and in the transparency and the reflected color of the sea, rarely extend farther than three or four leagues E. N. E. of Congrejo, or Crab Island. The waters in the Gulf of Paria are salt, though in a less degree than in the rest of the Caribbean Sea, attributed to the small mouth (Bocas Chicas) of the Oronoco, and the mass of water furnished by the River Guarapiche. From these reasons there are no salt pits on this coast.

The navigation of the river, whether vessels enter by the Great Mouth or by the labyrinth of the Bocas Chicas, requires various precautions, according as the bed may be

full or the water has long been dried, the plumb similar, and at the vernal equinox the increase of the regions. This Negro, appeared at progress of (the people say) it is, at first, obtains its maximum at the end of July slowly than it is.

The general velocity mated at two miles sary to make it in

full or the waters very low. The regularity of these periodical risings of the Oronoco has long been an object of admiration to travellers, as the overflows of the Nile furnished the philosophers of antiquity with a problem difficult to solve. The cause is similar, and acts equally on all the rivers that take their rise in the torrid zone. After the vernal equinox, the cessation of the breezes announces the season of rains. The increase of the rivers is in proportion to the quantity of water that falls in the different regions. This quantity, in the centre of the forests of the upper Oronoco, and the Rio Negro, appeared to me to extend 90 or 100 inches annually. The following is the usual progress of the oscillations of the Oronoco. Immediately after the vernal equinox, (the people say on the 25th of March,) the commencement of the rising is perceived. It is, at first, only an inch in 24 hours; sometimes the river again sinks in April; it attains its maximum, or greatest height, in July; remains full, (at the same level,) from the end of July till the 25th of August, and then decreases progressively, but more slowly than it increased. It is at its minimum, or least depth, in January and February.

The River Amazon, according to the information which I obtained on its banks, is much less regular in the periods of its oscillations than the Oronoco: it generally begins, however, to increase in December, and attains its greatest height in March. It sinks from the month of May, and is at the lowest height in the months of July and August, at the time when the lower Oronoco inundates all the surrounding land. As no river in America can cross the equator from south to north, on account of the general configuration of the ground, the risings of the Oronoco have an influence on the Amazon; but those of the Amazon do not alter the progress of the oscillations of the Oronoco. It results from these data, that, in the two basins of the Amazon and the Oronoco, the concave and convex summits of the curve of progressive increase and decrease correspond very regularly with each other, since they exhibit the difference of six months which results from the situation of the rivers in opposite hemispheres. The commencement of the risings only is less tardy in the Oronoco. This river increases sensibly so soon as the sun has crossed the equator; in the Amazon, on the contrary, the risings do not commence till two months after the equinox.

Foreign pilots admit 90 feet for the ordinary rise in the lower Oronoco. M. de Pons, who has, in general, collected very accurate notions during his stay at Caracas, fixes it at 13 fathoms. The heights naturally vary, according to the breadth of the bed, and the number of tributary streams which the principal trunk receives. It appears that the mean rise at Angostura does not exceed 24 or 25 feet.

When vessels that draw much water, sail up towards Angostura, in the months of January and February, by reason of the sea breeze and the tide, they run the risk of taking the ground. The navigable channel often changes its breadth and direction; and no buoy has yet been laid down to indicate any deposit of earth formed in the bed of the river, where the waters have lost their original velocity.

#### *General Description of, and Directions for, the Coast of Guyana.*

[From the "Derrotero de las Antillas," &c.]

The coast, which extends from Cape North to the Great Mouth of the Oronoco, which is in latitude  $8^{\circ} 41' N.$  is very low, and soundings off it reach out a great way to sea. This circumstance is the only mean of ascertaining with certainty the proximity. Any other mode of recognizing the coast is very difficult: for, in the clearest day, it is not possible to discern the land at five leagues off; and the nature of the coast itself impedes a nearer approach than two leagues, on account of the shoalness of the water, and the banks of sand and mud of great extent with which it is obstructed.

The harbors on this coast are the mouths of rivers only, all of which have bars, more or less navigable; and to enter, a practical knowledge is necessary.

From North Cape to Cape Cassapana, the land is very low and wet, and covered with a thick wood, without any other mark to recognize it by, than the hill or mount of Mayes; a kind of platform, insulated and hilly, which may be seen, in clear weather, at the distance of five or six leagues. Its latitude is  $3^{\circ} 5' N.$  The soundings hereabout extend far out to sea. You may sail along the coast at three leagues from it, and at that distance have from 8 to 10 fathoms. At 10 leagues from land, the depth increases to 15 and 20 fathoms; and, at 15 and 20 leagues distance, there are from 25 to 30 fathoms, with bottom of soft clay, or of fine sand of various colors. The current runs N. N. W. but, close to the shore, varies according to the tide, of which the flood runs W. N. W. and the ebb N. E. at the rate of about three miles an hour. It flows at six o'clock on full and change days, and rises from 12 to 15 feet.

The general velocity of the current, outside the influence of the tides, may be estimated at two miles an hour. On this account, in making this coast, it is always necessary to make it in less latitude, (i. e. more to the southward,) than that of your port of

destination. It is the custom of those bound to Cayenne, to endeavor to strike soundings about N. E. from Cape North, and 20 or 30 leagues from it, at which distance they find from 40 to 50 fathoms of water.

Cape Cassepour lies in latitude  $3^{\circ} 50'$ : near it there is a great bank of clay which extends 5 or 6 leagues out to sea: its extent from N. to S. is about 4 leagues: with 4 and 5 fathoms of water upon it. On account of this, vessels from the southward making this cape, ought not to run along the shore nearer than 5 or 6 leagues. After having passed this bank, Cape Orange bears W. by N. distant from 6 to 7 leagues; and although from this place it cannot be discovered, yet its proximity may be ascertained without any doubt: for, steering north, you will deepen the water from 5 to 10 fathoms in running less than a mile; when you find this latter depth, you ought to steer W. N. W. (or even west, if necessary,) to preserve the same depth. It is to be remarked that, when a vessel is near Cape Cassepour, and in 5 fathoms of water, she ought not to be steered so as to maintain that depth; but that it is necessary to steer north, or even N. by E. until you get 7 fathoms of water, when you will no longer be able to see the land from the deck, as it is very low. After steering the same course for a short time, in 7 fathoms, you may steer N. N. W. and N. W. with the same depth: with these courses you will near Cape Orange insensibly, and make it at the distance of 2 or 3 leagues, when in 8 or 9 fathoms of water. Between this cape and Cape Cassepour the river of that name disemboques itself.

Cape Orange may be known by a cut point, (Punta Cortado,) or rather, more properly, a point which seems to have been cut or shortened, which is on the side next to the sea, and is the highest land to the S. E. of the same cape; and also by the Silver Mountains, which form various peaks, appearing insulated and detached the one from the other, and which are the more remarkable as they are the first high land discovered in coming from Cape North. Approaching Cape Orange, you may discover various remarkable hills, over the point which forms the entrance of the River Oyapoc.

Beyond Cape Orange the coast forms a bay, of 4 leagues in breadth, in which the great river Oyapoc disemboques itself, and into which also two other rivers of small consideration discharge their waters; the one to the eastward is named Coripe, and that to the westward is called Wanari. The Silver Mountains serve not only as a mark for Cape Orange, but also for this bay; because, beginning to rise on the west coast, in a swampy country, they come down almost to the edge of the sea.

The River Oyapoc is two leagues wide at its entrance; and you may anchor in it in 4 fathoms, clayey bottom, keeping Wanari west, at the distance of three quarters of a league. Mount Lucas is a small, but tolerably high hill, on the point which divides the rivers Wanari and Oyapoc. One league up the river, (Oyapoc,) there is a low island, named Isla de Venados, which is covered by very high tides. You may pass to the westward of it, where you will have 4 fathoms of water close to the shore. After the Isla de Venados, there are some other small islands, which do not embarrass the navigation of the river. After sailing up the river 5 or 6 leagues, there is a fine bay, which serves as a harbor, and in which you may anchor in 4, 5, or 6 fathoms of water, and as near the shore as you please. At this place there is a small fort and a country-house.

About 12 leagues to the N. W. from the River Oyapoc is the River Apronak, which, also, is of some importance. Its entrance is two leagues wide, and it has from 3 to 4 fathoms of water. The lands which form it are very low, marshy, and covered with mangroves. Two leagues up the river, and in the middle of it, there is a low and very narrow island, of about half a mile in length, covered with wood and named Fisherman's Island. To the north of it a bank of sand stretches out more than two miles, to which it is necessary to give a berth when you enter into the river. There is a channel on each side of the island. The one to the eastward has 3 fathoms of water, but that to the westward not more than 2 fathoms.

Five leagues north of the mouth of this river there is a tolerably high bare island, in shape resembling a half-orange; it is called the Great Constable, to distinguish it from a smaller island, which lies half a league from it nearer the coast, almost level with the water, and which is called the Little Constable.\* The Great Constable, (or Gunnet,) may be discovered 8 or 10 leagues out at sea. Vessels bound to Cayenne direct their course to these islands from Cape Orange, from off which they bear N. N. W., distant 18 leagues. In this passage it is necessary to keep in 8 or 9 fathoms. The Great Constable has 3 fathoms of water all round it, and is very clean. The little one lies E. N. E. and W. S. W. with the great one. You may pass between them in 8 or 9 fathoms of water, observing to keep within two musket-shots of the great one, and to leave the little one on the larboard hand.

\* The

N. N. W. from the Great Constable there is a rocky shoal, which some place at two, others at three, and others even at four miles distance from it. To avoid this shoal is the principal reason for passing between the Constables. The French ship of war *La Gironde*, bound to Cayenne, in 1738, after having passed between the Constables, leaving the great one on the starboard hand, steered N. W. by W. for the Mother and Daughters, and soon after discovered the water breaking upon what appeared to be rocks, which bore N. by W. about a league distant. At the same time the Great Constable bore E. by S. and the little one S. by E. From this it appears that the shoal lies N. 39° W. true, from the Great Constable, at the distance of four miles. Its extent may be about five cables' length, and it lies N. W. and S. E.

The course from the Great Constable, to pass outside the Mother and Daughters, which lie about 6 leagues distant from it, is N. W. by W.; with this course you will shoalen the water, and will not have more than 6 fathoms near the Malingre, (one of the Mother and Daughters,) near the N. N. E. part of which you may anchor in 3 fathoms, at low water.

Four leagues \* N. W. from the Apronak is Kan River, and from it to the River Orapu is reckoned 5 leagues more. The River Orapu separates Cayenne on the east from the main land. It is a fine river, its entrance being about a league wide, and has 3 fathoms, at low water. The banks are pretty high, and covered with large trees.

CAYENNE.—The island of Cayenne is about six leagues in extent, from north to south, and its greatest breadth may be 3 or 4 leagues. On the north it is bounded by the sea; on the west by the River Cayenne; on the east by the River Orapu; and on the south, by a branch formed by the rivers Orapu and Cayenne, which here unite.

The City and Fortress of Cayenne are situated on the N. W. point of the island, the north part of which has various hills and eminences, but the south part is low and wet, in the season of the rains. The harbor is to the westward of the city, in the mouth of the River Cayenne. The hills, or high lands, of which we have spoken, are named Du Pont, Remontabo, Mount Joly, and Mahuri; and all these are close to the north coast. A little inland are those of Baduel, Tigres, Papaguay, and Mathory; and upon the banks of the Onya, that of the Franciscans.

At about a league, or league and a half, or something more, from the Island of Cayenne, are the Islets of Remire: they are five in number, viz. the Child, the Father, the Mother, and the Two Daughters. The last are two little rocks, very close together, and about a mile distant from the Mother, to the E. S. E. The Father is the largest of all these islets, and bears E. N. E. true, from Mount Joly, on the eastern coast of Cayenne Island, 4 miles distant. It may be about half a mile long, E. S. E. and W. N. W.

The Child is very small, and lies about a league E. N. E. from Mount Remontabo, and four miles from the Father. You may pass without them at three miles, or a little less distance, without any risk, and with a certainty of not having less than 5 or 6 fathoms of water. Betwixt these islets and the coast there is about fifteen feet of water, at low ebb, but the passage is dangerous, on account of a rocky shoal which lies in mid-channel, almost even with the surface of the water. There is also a shallow, which extends between the Father and Child: this shoal lies N. N. W. from Mount Joly and nearly east from Mount Remontabo. Round the Malingre, the bottom is very shallow, and it is said that a reef stretches out about two cables' length N. N. W. from its western extremity.

Besides these isles there is another, at about three leagues to the W. N. W. of the Child, called the Forlorn Hope, or the Lost Child, which lies nearly on the meridian of the town of Cayenne, at the distance of seven miles.

In order to enter Cayenne, it is first absolutely necessary to anchor between Malingre and the Forlorn Hope, both for the purpose of receiving a pilot, and to wait for the tide, so as to pass the shallows at the entrance of the harbor. Between the Child and the Father, the anchorage is very incommodious; for the N. E. winds raise much sea in it, which, catching vessels on the beam, makes them roll as if in a storm. An anchor is very apt to drag, and it is necessary to have another all ready to let go; and often three or four days elapse, in which no communication can be had with the shore. In this anchorage there are from twenty to twenty-five feet, at low water, the bottom being of clay.

In general, vessels anchor to the E. N. E., N. E. or north, of the Child, at the distance of two miles; but there are some who anchor to the E. N. E. or N. E. of the Forlorn Hope, at about two miles distant from it. From the east to the south of the latter, the depth of water diminishes to 15, 12, or even 10 feet; and you must take good care not to place yourself between it and the coast, because there is even less depth.

\* The original says six leagues, which distance appears to be too great.

In this place the tides rise 7 or 8 feet; and it is high water, on full and change days, at 5 o'clock.

N. W. by N. from the Forlorn Hope, at the distance of 8 or 9 leagues, are three small islets, which are so placed as to form a triangle. They are called the Devil's Islets. They form a fine and well sheltered harbor. The best anchorage at them is E. S. E. of the most southerly islet, in 5 or 6 fathoms of water, with a hard clay bottom, at about a musket shot's distance from the islet. In this islet there is a reservoir of fresh water; but it is necessary to get the water with small kegs, which can be carried, as the roughness and steepness of the ground render it impossible to get it with large casks.

Between these islets and the Forlorn Hope there are 5, 6, and 7 fathoms of water, at 3 or 4 leagues from the land; near the Devil's Islets are 9, and leaving them to the S. or S. E. you will have 20, 30, and 40 fathoms, increasing your depth as you increase your distance from the islets.

Six leagues N. W. from Cayenne is the River Macouria. The coast between is low, level, and has many handsome houses. At 15 leagues N. W. from Macouria is the River Sinamari. This river affords excellent anchorage at 2 or 3 leagues from its mouth, in which vessels are not incommoded by the sea, because the bottom is of very soft clay.

Nineteen leagues N. W. by W. from Sinamari is the River Maroni, which is very considerable. Its entrance is about 2 leagues wide, but is of difficult access, on account of the shoals of sand and clay which are in it. In this space of coast the rivers Sinamari, Aracoubou, and Amanibo, disembogue themselves, and shoals and banks of clay stretch out about 3 leagues to sea, along the whole of it; so that it is indispensably necessary to keep at least 4 leagues from the land, in 5 or 6 fathoms of water. It is also to be remarked that between Cayenne and Maroni there are many single or detached rocks, some of which are even two leagues from the shore.

From the River Maroni to Surinam River, the distance is about 34 leagues. The coast trends W. by N.; it is all so much alike, and so low, that it is totally impossible to distinguish one part from another, so as to rectify the position of any vessel: hence it is absolutely necessary to make the Maroni, in order to be sure of falling in correctly with Surinam. This coast, also, has various banks of clay stretching from it, which render it necessary to keep at four leagues off it. The entrance of the River Surinam, when coming from the eastward, may be known by its Crow's-hill Point, which may be seen at 4 or 5 leagues off, and is the only land which, under these circumstances, can be discerned. It has a beacon on it, as before mentioned. The east shore is that which is first seen: the opposite cannot be discerned until you are in the entrance of the river, it being remarkably low land, which, as it were, hides itself to the west.

To anchor in the entrance it is necessary to bring the east point, of which we have spoken, to bear S. E. or S. E. by S., at the distance of three leagues, anchoring then in 3½ fathoms at low water. The tides flow at six o'clock, on full and change days; and at the anchorage, at the entrance of the river, the flood tide sets from S. to S. S. E., and the ebb from N. to N. N. W. The least water is two fathoms and a half. When the wind is favorable for entering the river, steer S. E. or S. E. by E. until the east point bears east; then steer E. S. E. to anchor in 5 fathoms, on a clay bottom, at a quarter of a league from the east point, which is named Bram's Point, with that point bearing N. 9° W.

At one league up the River Surinam the River Comowinie discharges its waters into it. The entrance is defended by Fort Amsterdam, on the south side, and by a battery, which is on the north part, so situated as to defend the River Surinam also. On the west bank of the latter there are various batteries, which cross their fires with those of Fort Amsterdam. A little further up is the bar, upon which there are not more than two fathoms at low water. After passing this, you find, on the west shore, Fort Zeeland, and the town of Paramaribo, which is the capital of this colony.

Four leagues west of the River Surinam, the River Saramacca and Copename enter the sea by the same mouth. Their banks are uninhabited, and in their mouth are two fathoms at low water.

Ten leagues west from these rivers, the River Corentine disembogues itself. Its entrance is about a league in width, but of difficult access, on account of the sand banks off it, which extend three leagues out to sea. Within the river are three islands, which are very clean, running north and south: between you may anchor in 5 fathoms of water. The entrance and anchorage are on the west side. The small River Nikesa also discharges its waters by the same mouth as the Corentine.

Five leagues west from the Corentine is the River of Berbice. Its mouth is about a league in width. Its banks are very low, and covered with trees. In the very mouth lies Crab Island, which divides the entrance into two channels. This island is low and bushy, and is surrounded by a bank of sand and clay, which prevents a nearer approach to it than at least a long musket shot. It is in length about a mile, and half a mile in

breadth. The A rocky shoal tion, as you m two fathoms a

breadth. The bank which surrounds it stretches about a league to the northward of it. A rocky shoal extends from its east point, to which it is necessary to give much attention, as you must enter by the east channel, on the bar of which there are not more than two fathoms at low water.

[Directions for the Demerara have already been fully given.]

The River Essequibo is very large. Its mouth is three miles wide, but it is full of islands and shoals, which obstruct the passage, and render it difficult to enter; and although the islands and shoals form channels deep enough for all classes of vessels, yet it requires much care and practical knowledge to enter them. The islands are numerous, low, and bushy. The greater part of them are a league or two leagues in length, but very narrow, and lie north and south. There are two principal channels for entering the river, viz., the east and west channels. The eastern is the best: there are in it from 15 to 35 fathoms. After having passed the islands at the entrance, you will see another cluster of them, which it is proper to pass on the east side, where they form so deep a channel that there are from 40 to 70 fathoms in it.

At ten leagues from the entrance, the fort is situated, upon an island in the middle of the river. The town, or rather village, is situated on the west side, in front of the fort.

At fifteen or sixteen leagues from the Essequibo, is the mouth of the River Pauroma, which is about half a league in width; its shores are low, and covered with trees. The east point of the entrance is named Cape Nassau. Six leagues up the river, on the eastern side, is the fort named New Zealand; the town or village, named Middleburgh, stands at the foot of the fort.

From the River Pauroma the coast trends, without varying its appearance, to Coco Point, which forms a bay to the south, and to the westward has some very high coconut trees, which are the only ones on all this coast, on which, in general, there is nothing else than mangroves.

From Coco Point, you ought to steer N. W. and N. N. W. with the precaution of keeping in 5 or 6 fathoms of water, in order to shun a bank of mud, which lies about two and a half leagues N. N. W. from it. Having run twelve leagues on these courses, you will see the mouth of the Guayama, situate in  $8^{\circ} 25'$  N. latitude. The making of this mouth is very necessary for those who seek the great entrance of the Oronoco, as there is no other point which can be used with certainty as a mark, and it cannot be mistaken; not only because it is the sole entrance or opening which can be seen, but also on account of three little hills or hillocks, which may be seen, if the day be clear, bearing about S. W. at some distance inland.

N. E. from this mouth, about three leagues distant, there is a shoal of fine sand, with two and a half fathoms of water on it; and to avoid it, you must take good care not to shoalen the water more than to 5 fathoms, muddy bottom.

From the mouth of the Guayama the coast is woody, level, and low, and trends for eight leagues about N. W. to the point of Mocomoco; after which comes the coast named Sabaneta, which trends west about four leagues: it also is covered with wood, level, and lower, and the water on it shallower, than the former. All this coast is bounded by a shallow bank of soft clay and shells, and sand with clay and shells.

**RIVER ORONOCO.**—The Isle Congrejo (Crab Island) of which the N. E. point is in lat.  $8^{\circ} 51'$  N. has a shoal of hard sand, of the color of ground coffee, which extends six leagues from its eastern part, and about two leagues from the northern part of the island; and this renders the entrance of the river dangerous: for between it and the coast of Sabaneta is formed the Bar of the Grand Entrance of the River Oronoco, the depth of which at low water, is 15 feet, and at high water only 16 feet; the bottom soft clay. The bar is about three leagues in extent from N. to S. and a little less from E. to W.

The coast, which is rather higher than the former, though still woody, trends S. W. from Point Sabaneta, about three leagues, and ends at Cape Barma, which forms the boundary of this line of coast; as after this it forms a great bay, into which the river empties itself.

The coast which follows, from Isla de Congrejo to leeward, is very distinct from the former; low, and all broken, forming different mouths, by which the small branches of the Oronoco discharge their waters. They are fit for small vessels only, which have pilots, because they are full of dangerous sand banks.

**GRAND MOUTH of the RIVER ORONOCO.**—After what has been stated, we need only say that, having recognized the Boca de Guayama, you may run along the coast at the distance of five or six leagues, in 4 or 5 fathoms, in soft clayey bottom, until Cape Barma bears S. by W., when you may shape your course for the bar; still, however, keeping the lead going, in order to preserve the soft clayey bottom, although even in shallow water; as it is better to get ashore on the clayey mud, than to run the risk of falling on the shoal of hard sand off Isla Congrejo. If you catch that quality of sound-

ings, (hard sand, like ground coffee,) you must immediately steer south, to recover the soft bottom. Following these directions, you will near Cape Barma; and, when about two leagues from it, you will see a large island covered with trees, which is that called Isla de Congrejo; and, having passed the bar, you will begin to augment the depth of water until you find 5 fathoms. When it is proper to steer from S. W. by S. to S. W. by W. to keep mid-channel, understanding that, if you are in less than 5 fathoms, soft bottom, you are too much on the mainland-side of the channel, and must steer more to the westward to recover the mid-channel; but, if you find less than 5 fathoms of water, with a sand bottom, you are getting upon the shoal off the Isla de Congrejo; and, in this case, must steer more to the southward to recover the mid-channel. With these directions, and attention to the soundings, you may run in, until the S. E. point of Isla de Congrejo covers some woody islets, which lie off the N. E. point of it; you may then run close to the island, and anchor in 5 or 6 fathoms of water, the bottom soft clayey mud. Moor with a cable ashore, and, in this situation, every vessel will be secure and well-sheltered; and it is necessary, at this place, to wait for a pilot, to conduct any vessel up the river; for, without one, they may be certain of experiencing some misfortune or other. A pilot may be engaged from any of the small vessels of the country.

On all this coast the tides are rapid and irregular. They are said to be felt as high up the river as Imataca, a village of the Guaraunas Indians. As to the times of high water, all that the pilots remark is, that, at one-third ebb, at the rising of the moon, the water of the Oronoco increases from April to September, and decreases during the other months of the year. It is navigable for large vessels up to the capital only, between the months of May and December; during the rest of the year, they must stop sixteen leagues farther down, not being able to ascend higher; in consequence of a bar or pass, named del Mamo, which at that time has not more than 4 or 5 feet of water on it; and large merchant vessels, therefore, must employ lighters to load and unload them, which, although there are plenty of them, occasions much expense.

The magnetic variation, at the mouth of the river, is 4° East.

From this mouth the Delta of the River Oronoco extends itself to the interior of the Gulf of Paria, rendering this portion of the coast useless, either for trade or navigation, being no more than a labyrinth of low muddy isles, which are drowned in the season of the floods, in the river. The number of them is unknown; and it is not easy to make a plan of them, for they are all formed by the various channels into which the Oronoco divides, and which may be considered as useless for any thing, except boats and canoes. The termination of this coast may thus be fixed at the Grand Mouth of the Oronoco, which we have described; and we now proceed to make some general remarks, which follow:

**GENERAL REMARKS ON THE COAST OF GUYANA.**—Although the whole of this coast may have no great errors in the situation on the charts, yet it must not be supposed that every point of it is accurately placed: for instance, Point Barima had an error of 22 minutes of latitude in its position. The points which have been observed are inserted in the table of latitudes and longitudes:—

The mariner may confide in the situation of these points; and it is necessary to remark, also, that, on a coast, of which there is scarcely a possibility of recognizing the different places, except by the latitudes, it is very easy to make a mistake, and get to leeward of your port of destination. For this reason it is proper to run down the coast from windward to leeward, taking good care to make the various places out distinctly. It is also proper to examine the mouths, or embouchures, of the rivers: and what renders this more and more necessary is, that, in the season of the rains, there are often days on which the latitude cannot be observed.

2d. If such is the uncertainty as to the positions of the points, it is no less in respect of the soundings at the mouths or entrances of the rivers. It ought always to be remembered that all these rivers form bars, and that the bars generally have very little water on them. The best way for those who have not a practical knowledge of these entrances, is either to obtain such by means of their boats, or not to enter a river without a pilot.

3d. The wind, which from E. N. E. to N. E. or E. S. E. and S. E. always prevails upon this coast, and the current, which always runs W. N. W. make the lesser latitude to windward; and hence, on all this coast, it is very easy to increase your north latitude, but almost impossible to decrease it.

4th. The general current, of which we have spoken, must not be confounded with that which is produced by the tides, the influence of which is principally felt near the coast; and twelve leagues out at sea, or 9 fathoms of water, may be considered as their limits: as at that distance out at sea, no other current but the general one is felt: but, between that and the land, no other currents than those caused by the tides are felt. The flood sets towards the coast, and the ebb away from it: the tide flows on full and change days, at Cape North, at 7 o'clock; on the coast of Mayez, at 6 o'clock; at Cayenne, at 5 o'clock; and at Surinam, at 6 o'clock.

5th. In adding Europe to Guyana, the River Amazon is at sea; and what phenomenon, or Bore, is here called.

6th. Having lead constantly water, from fear although with tides in clear weather, of your place of sight the land. only to keep moor be extremely careful your destination tides, (described the coast.

7th. Getting a bottom is always gate this part with sions much work even when a vessel the mud, as if placed ness such a thing.

8th. The island points of this coast them. In order not drive you upon with a free wind; or to pass outside ken, a sufficient light.

9th. On the wh mouths of rivers, on account of the coast, storms are deems it to be necessary, but rather w sufficient practical take the vessel in.

10th. When an wishes to go from with the ebb tide, may be shouldered to the S. E. or E. and current being.

11th. Those wh their larboard tacks ward of their port according to the practice all this coast, especially unable to ascertain observations for larboard and leeward.

The environs of trees being burnt and have been cleared houses, &c. may be up your doubts; as keep still to windward cost you much time.

12th. DEAD RECKONING the greatest uncertainty in reckoning, caused by correct, it is advisable leaden weight, weighing

5th. In addition to what has already been said, it is advisable for vessels bound from Europe to Guyana, to make the land about the coast of Mayez; shunning the vicinity of the River Amazon, because it produces vast swellings, which are felt a great distance out at sea; and which, near the mouth of the river, might prove most fatal to a vessel. This phenomenon, which is known in the Ganges, and other great rivers, by the name of a Bore, is here called the Pororoca, as already noticed.

6th. Having made and recognized the coast, it is necessary to run along it, keeping the lead constantly going, so as to keep in 7, 8, or 9 fathoms, taking care not to get into less water, from fear of striking on some of the shoals which stretch out from the coast; and although with that depth, in some places, the land cannot be seen from the vessel, even in clear weather, this can occasion little or no inconvenience; as, when near the latitude of your place of destination, it is easy to put the vessel on the larboard tack, and run in to sight the land. Nor is there any difficulty in examining it, when necessary, as you have only to keep more away on the larboard tack; but, in such cases, it is very necessary to be extremely careful with the lead. When night comes on, and you are near the port of your destination, it is proper to anchor: as also when it is calm, within the limits of the tides, (described before,) as the current, or set of the flood tide, carries a vessel towards the coast.

7th. Getting aground on this coast is not generally attended with much danger, as the bottom is always of clay, more or less soft. Notwithstanding this, no one ought to navigate this part without due care, as getting ashore not only causes a loss of time, but occasions much work in carrying out anchors, &c. to get a vessel off. We notice here that, even when a vessel is in the regular track, although in 9 fathoms of water, she will raise the mud, as if ploughing it with her keel. This may cause uneasiness to those who witness such a thing for the first time, though it is the consequence of a very natural cause.

8th. The islands of Remire, the Constables, and the Health Islands, are the only points of this coast which are likely to cause the loss of a vessel, if it gets ashore on them. In order to avoid this, it is needful to pay attention to the currents, that they do not drive you upon them; and not to attempt to pass between the Constables, unless with a free wind; with the contrary, it is better to anchor at three leagues from them, or to pass outside of them, taking care to give the shoal, of which we have already spoken, a sufficient berth.

9th. On the whole of this coast there are no other harbors than those formed by the mouths of rivers, the greater part of which require practical knowledge to enter them, on account of the bars and shallows which run out from all of them; but as, on all this coast, storms are unknown, and there is not the smallest risk in anchoring where one deems it to be necessary, there can be no necessity to run rashly for one of these anchorages, but rather wait at anchor outside for a pilot, or till such time as you can obtain a sufficient practical knowledge of the place by means of your boats, so as to be able to take the vessel in safety yourself.

10th. When any one wants to beat to windward on this coast, or, what is the same, wishes to go from the Oronoco or Surinam to Cayenne, he must work along the coast with the ebb tide, in from  $3\frac{1}{2}$  or 4 fathoms water, out to 8 or 9 fathoms: for though you may be shouldered away by the current to the N. E. you will gain very well on the tack to the S. E. or E. S. E., but with the flood it is necessary to anchor; for then, both wind and current being against you, you will irremediably be driven upon the coast.

11th. Those who from the Antillas are bound to any port in Guyana, ought to keep their larboard tacks on board, until in a convenient latitude to make the land to the southward of their port of destination, which ought to be more or less to the southward, according to the practice and knowledge of the navigator who directs the vessel; but, upon all this coast, especially from Cayenne to the Oronoco, even the most experienced are unable to ascertain the places where they find themselves; and without the assistance of observations for latitude, and of prudent conjectures on the different appearances to windward and leeward, they would often commit very serious mistakes.

The environs of Demerara are the parts of the coast easiest known, on account of the trees being burnt and cut down to clear the land for cultivation; and where these trees have been cleared away, there are clear spots or gaps in which, (as already stated,) houses, &c. may be plainly seen. When at a loss, it is best to anchor till you can clear up your doubts; as, although you lose the time in which you are at anchor, yet you keep still to windward, which is what interests you most; and which, if lost, it would cost you much time and labor to recover.

12th. DEAD RECKONING in Shoal Water as on the Coast of Guyana, &c.—As the greatest uncertainty in the situation of a vessel arises from the errors in the dead-reckoning, caused by currents, to diminish such errors, and render the computation more correct, it is advisable to take off the log-chip from the log-line, and to substitute a leaden weight, weighing 4, 6, or 8 pounds, as may be judged necessary: this, taking the

bottom, (when the log is hove with it, in place of a log-chip,) will not so easily follow the vessel, or be influenced by currents. By this mode it is clear that the log will show the whole distance which the vessel runs, whether caused by winds or by currents. Then, having made fast the log-line, before you haul it in, mark the bearing of it, and the opposite point or direction will be the course which the vessel makes good. It is clear that, by this mode, the course and distance ought to be as exactly found as if no current existed. If you heave the log with a chip, in the usual manner, as well as a log with a lead attached to it, and compare the distance by it, and the course which the vessel appears to make by compass, with the distance and course found by the proposed method, you will be able to ascertain the direction and velocity of the current.

## SOUTH AMERICA, SOUTH OF THE EQUATOR.

We now commence south of the Equator, with the island of Fernando Noronha and the Rocas, as they are often fallen in with in the route to South America.

**FERNANDO NORONHA.**—This island is remarkable by a high rocky peak on its north side, called the Pyramid, very barren and rugged; and by its S. W. point, named the Hole-in-the-Wall, which is pierced through, and gives a free passage to the sea. The Pyramid appears, at a distance, like a very high steeple or tower. The south side is distinguishable by a little rocky isle, that appears like a statue. The island is about 7 miles long, and 2 or 2½ broad. It has been the rendezvous of vessels employed in the southern whale fishery, &c. for procuring supplies of cattle, sheep, poultry, wood, &c.; but water is frequently scarce. East India ships, have, also, occasionally touched here, when they have been horsed to the westward by the currents.

On approaching the island, no soundings will be found until very close in. There is no danger but what may be seen, excepting a rocky spot off the south side between two and three miles from the shore, and a rock at about a quarter of a mile from the S. W. point.

The road or principal anchorage is on the north side of the island, being sheltered by the north-eastern land, and several islets in that direction. The anchorage has from 10 to 12 fathoms, loose sandy ground, at about half a mile from the citadel point or nearest shore. It is unsafe to lie in with northerly or N. W. winds, which are said to prevail from December to April; in the other months the winds are mostly from the S. E. or easterly; sometimes at N. E.

Fernando Noronha was formerly appropriated exclusively, by the Brazilian government, as a place of exile for their vilest criminals, under the control of a garrison. All the little sandy bays and anchorages are defended by forts.

Water may be obtained here; but in the dry season it is sometimes very scarce. In seasons of drought, which are not uncommon, the rivulets are dried up, and the vegetation parched. There are but few vegetables, but plenty of live stock and fish, with an immense quantity of doves. The fresh water is obtained from a well near the Governor's house, in the cove called Water Bay; but the cask must be rolled over some rocks and swung off to the boat over the impeding surf.

Wood is cut on the larger islet to the N. E., called Wooding or Rat Island. This islet is nearly surrounded by rocks, and there is risk of staving the boat when taking off the wood, as it is heavy, and sinks if thrown into the water. Should the governor permit wood to be cut on the main island, it may be conveyed without much danger from the fine sandy bays to the westward of the road.

In 1805 Captain Mortimer found but a small supply of water, few vegetables, but plenty of live stock and fish, and an immense quantity of doves. On the 9th day of April, 1827, H. M. Ship Cambridge, Capt. T. J. Maling, touched here, and there were at that time about 200 inhabitants on the island: of these 60 were soldiers under the government of a Prussian officer, who with the assistance of an engineer was repairing the fortifications and erecting new points of defence.

From Tobacco Point, or the south point of the island, a reef of rocks, even with the water, extends half a mile to the southward; and to the S. E. by E. 2½ miles from the same point, is the centre of a rocky patch, on which the sea always breaks. Within a line with these rocks the pyramid is shut in with the highest hill on the south side of the island. Between this reef and the shore is a channel of from 10 to 15 fathoms.

The current here commonly sets strongly to the westward, for which due allowance must be made in rounding the islands to the N. E.

**THE ROCCAS.**—These are dangerous low keys, 16 or 17 leagues to the westward of Fernando Noronha, and on which the Britannia East India ship and King George transport, deceived by the currents, were lost in 1805. The keys or islets are sandy with shrubs upon them; they cannot be seen from the mast head in the clearest weather at the distance of more than 3 leagues. At their N. E. end is a high rock, and the sea breaks exceedingly high all round them. The ship *Glory*, at two miles to the west of the reef, found bottom at 28 fathoms, coral rock. The current here was found to set 2 1/2 miles hourly, to the westward. Rise and fall of tide 6 feet.

**COAST OF BRAZIL.**—By *Baron Roussin*. The appearance of the coast of Brazil is very different. From the island of Santa Catharina up to Olinda Point, (60 leagues north of Cape Frio,) the land is very high and woody, and can be discovered in fine weather from 50 to 60 miles distance, and consequently, with little care, a vessel can make land without danger. North of this in many places the land is very low, and not to be perceived from that distance; as for example, between Espirito Santo and Mount Pascal; between the bay of Porto Seguro and the bay of All Saints; between the Torre de Gracia de Arica and Cape St. Augustine; and finally, every where between Olinda and the Island of Maranhão: In all these places the land is more or less low, few mountains can be perceived, being so far in the interior.

Sounding in general is of very little service to indicate the distance from the land, particularly from Point Santa Catharina Island up to Olinda, on account of the great depth even at a short distance from the shore, except in the neighborhood of the Abrolhos. It may be generally stated that the depth under the following parallels, is nearly this; 70 fathoms at 18 leagues distant from the land of Santa Catharina; 40 fathoms at 12 leagues from the Paranaíba; 50 fathoms at 12 leagues east from the island of San Sebastian; 35 fathoms at 5 leagues south-east of Joatinger Point; 77 fathoms at 18 leagues south-east of Rio Janeiro entrance: Finally, more than 60 fathoms at 7 leagues only from Cape Frio. The depth of the sea is very great N. E. of Cape Frio, for at 30 leagues distant, in a direction E. 1/4 S. of Cape St. Thomas, we did not find the bottom even with 100 fathoms. Soundings increase again E. and S. E. of Abrolhos; generally speaking, it is in few instances not to be depended on, that a less depth than 100 fathoms is to be met at 30 leagues from the coast.

No bottom is to be met even with 200 fathoms, eight leagues only S. E. of St. Salvador, nor at 12 miles south of this, although at a distance of 4 miles, there are but 20 fathoms; and finally, E. from Cape Morro San Palo, we did not find the bottom with 120 fathoms, although at 9 leagues distant. From Bahia de Olinda the coast is not less bold, for at 9 leagues east of Torre de Gracia de Avilla the sounding is over 180 fathoms; at the same distance 9 leagues east of the bar of Itapieracu it is over 200 fathoms; the soundings are over 190 fathoms 20 leagues from Rio Real, and 15 fathoms are found 10 leagues east of Rio San Francisco. Finally, every where up to Pernambuco, there are not less than 30 to 40 fathoms at 9 or 10 leagues distant from the shore, and between Olinda and Pernambuco, from 18 to 20 leagues distant from the shore, the bottom is not met over 120 fathoms. Though the sounding be less north of Olinda, yet it is too great at a small distance to be of service.

North of Cape San Roque, the land being more low, and extending into the sea, the soundings decrease gradually towards the shore.

From Monte Melancia up to the village of Amufadas there are but 15 fathoms at 16 leagues distant, and farther north the soundings increase, but it may be taken as a general rule, that 10 fathoms are to be met with at the distance of 10 or 12 miles, between Amufadas and Jericacoara. Opposite the village of Camoa there is a spot where 24 to 25 feet only of water are to be met, over an extent of three leagues, but it is the only place up to Maranhão.

The coast of Brazil offers this particular, viz., that there are two banks or shoals at no great distance from the shore, the first of which is not far distant from the land, and in many places rises over the level of the sea, and in some other places form the breakers or shallow waters. The other bank, farther distant from the shore, is not equally distant anywhere. It cannot be stated as forming shallow water, but it is a fact that between this bank and the former, there is a deep channel separated from the main sea by this bank and the small islands of Figuera, Castillo, Guemado, los Alcatrazes, los Abrolhos. Manuel Luis Shoal may be considered as the prominent point of this second bank.

The temperature of Brazil varies. In the southern latitudes the winter is pretty severe. Frost and snow are not uncommon at Rio Grande. The seasons may be divided into two, viz., the rainy season and dry season, the last of which is from September to February. The rainy season continues from March to September, but the only months in fact which may be considered as rainy are May, June, and July.

On the Brazil coast the south monsoon is from March to September. The northern one from September to March. The prevalent winds, according to the saying of the na-

tives, during the south monsoon, are from E. S. E. and S. S. E., and during the northern monsoon are from E. N. E. and N. N. E.; this may be the case at sea. I will not oppose this fact, having no reason for it; but I can assure, from my own observation, that at a short distance from the shore I did not find the monsoon so regular as it is supposed; in fact, the most prevalent wind at all times, is from the eastern part of the compass. The Rabajos are very strong winds, blowing from the S. W. during the rainy season. They last three or four days with great force, not so great when it rains, but very heavy in dry weather. This begins at the change of the moon. The grains are squalls, and are met more frequently in the neighborhood of Abrolhos Islands, and called for this reason, Abrolhos squalls. They are more frequent in the months of May, June, July, and August, and in very rainy seasons they blow from E. S. E. They say they arise from a white cloud of a round shape, and of a little appearance at first, and by and by increase to such a force as to be dreadful.

Land-breezes are very regular on the whole extent of Brazil coast, but not equally regular and strong, but more so as you approach the equator. At Rio Janeiro they are not very regular, and very often not at all felt. The land-breezes are more powerful in the northern monsoon, and in the southern monsoon very often the land-breeze has quite the same direction as the sea-breeze, this part coming from the S. W.

It is a general rule, that the land-breeze will be more powerful in proportion as the sea-breeze is so. It may be stated, that a vessel can depart from Brazil any day it pleases.

Generally the more you proceed south along the coast, the more you must expect to find the wind coming from the south and west in the rainy season. In this time of the year, from Abagoados Patos up to Cape Frio, they blow with great violence from S. E. to S. W., and even N. W. In this case they turn into hurricanes, and are called *Pampeiros*. In the River Plata they are very dangerous. If at sunset, foggy clouds, and the land appears more distinct at a small distance, it is an omen the wind will blow from the S. or S. W., and they will be powerful in general. They last in proportion as they are more heavy, and last longer if not so dreadful. When they turn into a hurricane, they will never last over twenty-four hours. When the wind hauls towards the east, you may expect fine clear weather. It is to the contrary when it nears towards the west; easterly winds bring clear weather; westerly winds bring fogs.

Nothing positive can be said respecting the regularity of the currents: they generally follow the direction of the wind, for there is no river of a sufficient magnitude on the whole extent of the Brazilian coast capable of causing a current, according to numerous observations. The average running of the currents is at the rate of six tenths of a mile an hour; in the monsoon time never over that rate, and in many instances below it, even no current at all. It is only north of Pernambuco, that the current can be considered as permanent, and capable of causing some errors in the day's work of a ship, and, even in this case, it is only when you go along the coast at no great distance, for if distant at sea no current exists. From what has been said respecting winds and currents, we may infer that no impediment exists in navigating the Brazilian sea, from Santa Catharina to Olinda Point, and it is entirely useless to endeavor to make land more south than the place bound to, as formerly prescribed. If going to Olinda, or any other place more north, up to Maranhão, it is better to keep east of the place bound to, in order to counteract the effects of the currents, which run generally W. N. W. as will be more particularly stated when describing the several harbors, and the manner to reach them.

#### *Description of the Cape and Banks of St. Roque.*

The Cape of St. Roque admits hardly any description, for nothing particular exists by which this cape may be distinguished from the sandy beach. The color of the sand is white, but in some places appears of a reddish tinge, owing to the reflection of the light, and by this reason is not a very certain guide. From place to place bushes are to be seen on the top of the beach, and some trees can be discovered far in the interior, which is not the case in coming from the south. Cape St. Roque is not in fact the most extreme end of this great elbow of the South American land, for the direction of the shore remains nearly the same 20 miles farther, and it is only at Calcanar Point that it changes its course to N. N. W.

From St. Roque the land lowers more and more, and 8 miles distant it forms Cape Petetinga, which cape offers no more particulars than St. Roque, and the beach is of the same white sand.

\* A lighthouse, which exhibits a revolving light, has been erected at the entrance of Pernambuco, by which that part of the coast may be recognized.

The Portuguese good watering

The Portuguese cosmographer, Pimentel, admits that near Cape Petetinga there is a good watering place for ships, but we had no chance to ascertain that fact.

Near Cape Petetinga the soundings begin to indicate the shallow water of the Banks of St. Roque. This shoal runs in a direction parallel with the shore, nearly 60 miles, and the average breadth may be considered 6 miles. The channel between them and the main land is from 5 to 6 miles wide, and it is reported that vessels of a less draught of water than 7 or 8 feet, can pass without the least danger. The greatest distance from the northern shoal to St. Roque is 20 miles.

Notwithstanding the small height of the shore near these shoals, in fine and clear weather, it may be discovered before you reach them.

The whole extent we ascribe to the shallow water is not equally dangerous, and it is reported that places exist where large ships may cross them. As the whole coast is of very little interest, one will do better to keep at a distance from it.

The eastern breaker stands 12 miles distant from Calcanar Point. The sea seldom breaks over it. The next west of the former, and 8 miles distant from dos tres Irmaos Point, is called the Lavandera, and the third one, called the Urcas, stands 12 miles N. N. E. from Tubaroa Point, and opposite St. Alberto Bay. The sea breaks constantly with great force on these two last, particularly when the wind blows from the sea.

By keeping at a reasonable distance there is not the least danger to be apprehended. We found the soundings increasing regularly and very fast, towards the sea, the surest proof that no more shallow water is to be met, though in many charts another shoal is marked E. 20° N. of this place. This we consider as an error, for the reasons previously stated.

The soundings are of no service to indicate the approach of this place. The nature of the bottom seems to be the same every where, and we found it always a mixture of white madrepores, intermixed with sand, and in some instances with gravel.

The green color of the water, like every shallow water, deserves more notice, and you may consider yourself safe as long as you have not reached this green water.

The current runs N. N. W. and N. W. at the rate of nearly 2 miles an hour; and the tide rises from 6 to 10 feet, according to the new or full moon.

From Cape St. Roque to Ponta Petetinga, is 5 leagues to the N. W. and N. W. by N. At the foot of this hill, or eminence, is a stream, where you may obtain water; and at about a musket shot from shore, is a high reef, near which you may anchor in 3 or 4 fathoms; bottom of sand and mud. The coast in general is flat and barren.

At 3 leagues from Petetinga, westward, are some rocks on the shore called Pedra da Garca, near which any ship may anchor; and at about 15 leagues to the west, is the Ponta das Pedras, or Point of Rocks, with the rocks called the Three Brothers. Of all the coast between, the country is bare and black, its surface covered with sand, and it appears like small islands.

Off the Pta. das Pedras are three shoals of rock, having a channel between them and the main, of 3 and 4 fathoms. At 3 leagues outward are reefs above water.

Of the River Guanare to the S. W. the distinguishing marks are two inland sugar loaf mountains, of unequal heights. To the west is the island Tubaroa; then follow the rivers Amargosa, Cavallos, and Conchas: of these rivers the first two lead to the Salines or Salt Ponds of Assu; whence many parts of Brazil have been supplied. The coast hence trends to the Ponta do Mel, or Honey Point, as shown on the chart. The point may be known by its high red cliffs; and hereabout were, and probably still are, some palm or cocoa trees.

the River Upanema, situate as shown on the chart, are natural salinas, which, like those of Assu, require no artificial means for crystallization. Its entrance has a bar of little more than one fathom at high water, although within there is a depth of 8 fathoms. Here the land is very level; and on the west of the river, there are, as far as a field-piece can carry, red cliffs. Within land is Monte Vermelhos, a sugar-loaf hill. Ships, however, should not advance into the bay, as it is full of shallows.

From the River Upanema to the N. W. the next river of any consequence is the Iguaripe, which may be known by a round bare hill of sand on the N. W. terminating in a rock below, and within land a mountain, having seven sugar-loaf points.

Five leagues inland from the Iguaripe rises the range of the Guname Mountains, which extend ten leagues in the direction of east and west.

Commencing at about three leagues from the River Iguaripe, the land for nearly four leagues, close to the sea, appears dark and full, with several openings like bays. At about half a league from the commencement of these openings are some white cliffs, in shape like a schooner, with all sails set, and head at east. So soon as this full land terminates, the coast assumes a more flat and level appearance.

Upon the south bank of the River Iguaripe at the distance of about nine miles from the entrance, is the town of Aracati. At the entrance is a bar, narrow and dangerous, owing to sand banks on each side; and upon these the surf is very violent. The sand is

so loose at the mouth of the river, that, even with the coasting vessels of the country, every precaution is required. The river widens immediately within the bar, and forms rather a spacious bay; but the port cannot, from the uncertainty of its depth, ever become important, and it has, at times, been nearly choked up.\*

Pimentel describes the Bay of Iguaire to the south-eastward of Seara, which, he says, forms a small harbor to the westward of some low level land. The bay is surrounded by very high perpendicular cliffs, against which the sea breaks at half-tide. It has a high round rock, behind or within which is shelter and anchorage in two and a half or three fathoms. On the N. W. of this bluff rock you may anchor in the very roll of the sea, as it has 4 and 5 fathoms, and on the strand are pits for watering. Along side of the rock of Iguaire, on the east, the river Xaro falls into the sea: and, on its west side, three leagues out to sea, is a shallow of green water, of 5 to 7 fathoms, with bottom of mixt sand, and, in some places, small shells.

SEARA—is the most important town upon this part of the coast. The bay on which it stands is formed by Point Macoripe (in lat.  $3^{\circ} 40' 30''$  S. and long.  $38^{\circ} 27'$  W.), to the eastward, and by the River Papina to the westward, an extent of about 4 leagues. It is extremely open; its greatest depth being 3 miles.

Abreast of the town, and at the distance of half a mile from the shore, extends a ridge of rocks, level with the water's edge, and within which small craft generally anchor, the entrance to the anchorage being around the eastern end of the reef.

The land within Point Macoripe is a high and irregular sand-hill, terminating in the point, which has a tower near the extremity. Ships advancing from the N. E. should not approach the point nearer than three miles, and should choose a berth without the points which form the bay. Tolerable anchorage may be obtained by bringing the point to bear S. E. by E. and the town of Seara S., about 4 miles distant from shore, in 5 fathoms, sand and mud. His Majesty's ship *Inconstant*, in 1814, was the first English ship of war that had anchored here within the memory of the oldest inhabitants; having brought up in a spot which had previously been occupied by the American frigate *Constitution*.

The Recife, or Reef, forms a complete ridge, at a considerable distance from the shore, and is to be seen at low water. It extends parallel with the shore for about one quarter of a mile, with two openings, one above and the other below the town. A small vessel may come to anchor between it and the shore; but a ship can bring up only in one of the openings of the ridge, or on the outside of it. A vessel coming in from the northward should make Point Macoripe, which is a league to the eastward of the town, with a small fort on it, and may thence bring up in 6 or 5 fathoms. On the appearance of a ship, the town fort displays a white flag upon a tall flag-staff.

North-eastward of Seara, between the reef and shore, is a rock, called *Pedra da Velha*, or the Old Woman's Rock, which may be known by the breakers over it. When a vessel leaves the port she may pass between this rock and the shore, giving berth to a shoal which lies about 100 yards to the northward, or she may run out between the rock and the principal ridge or reef.

On the 1st of January, 1824, a vessel, commanded by Mr. J. W. Matthewson, was wrecked by striking on the *Pedra da Velha*, while lying-to for a pilot. The rock appeared to be in size not more than two or three times the length of the ship. It lies about one-third of the way between Point Macoripe and the inner anchorage, and the depth all round it is  $3\frac{1}{2}$  fathoms.

Captain Matthewson says, "In going into the bay, I kept the lead constantly going; and when in  $3\frac{1}{2}$  fathoms wore ship, with her head off shore; at the moment before she struck we had this depth of water. She struck only twice, did not stop, and, as quick as the lead could be hove, we had  $3\frac{1}{2}$  fathoms again. The vessel drew scarcely nine feet of water.

The breach may be seen on the rock at low water; but in the daytime, when the sea-breeze sets in, the water generally tops and shows so much alike that it is not easy to distinguish the place of the rock in the general swell.

The inner anchorage above mentioned, is between the Recife or reef and the shore. You enter by the eastern channel and go out by the western, when you cannot fetch out by the eastern one. Here a vessel lies at low water, surrounded by breakers, except in the channels; and as the pilots are very inattentive, it is, altogether, very dangerous. This is, nevertheless, becoming a place of very considerable trade.

"From Seara the coast trends N. W. by W. to Jericoacoara,† the depth gradually

\* Koster's Travels in Brazil, vol. 1, p. 175.

† "Jericoacoara is a bay covered with sea weed, and its coast bare and barren. It is full of shallows, having near the shore only 2 fathoms. number, from two to quite visible under w water. They are no with a sea on. The for a vessel to pass cl are in 10 fathoms wa

increasing off shore; but a N. W. course should be pursued, to avoid a spit, the base of which extends from Mount Melancias to Jericoacoara, and terminates in a N. E. direction from the latter, at the distance of 6 or 7 leagues off shore. Having run 100 miles upon the above N. W. course, including a mile and a half per hour for the current's assistance, in soundings varying from 11 to 20 fathoms, change the course to W.  $\frac{1}{2}$  N., which is nearly the direction of the coast from Jericoacoara to Mangues Point, and it will give you a sight of the land as far as the island of St. Anna.

"When ships are bound to Maranhão, from seaward, it is absolutely necessary to make the land considerably to the eastward, as the currents, in general, set very strongly between W.  $\frac{1}{2}$  S. and W. N. W. If, in endeavoring to make the land, you should be in lat. about  $3^{\circ} 3'$  S., on discovering it you will be off Mount Melancias, or between it and Seara; if the latter, three other mountains will be observed to the S. S. E., lying nearly S. E. and N. W. of each other, which mountains are about 7 leagues to the westward of Seara, and are easily seen from that place. About this part of the coast you will have a bottom of fine sand and shells.

"If you should make land when you consider yourself in from lat.  $2^{\circ} 15'$  S. to  $2^{\circ} 30'$  S., and have a bottom of small red and white stones, you will be off Jericoacoara; if the bottom consists of yellow, blue, and red stones, you will be off Parnahiba or Tamonia; and three mountains, lying nearly in the meridian of each other, in the neighborhood of the latter, will be seen.

"The whole coast from Point Macóripe to Parnahiba is sandy to about half a league inland, whence it appears well cultivated; so that it is easily distinguishable from the coast between Parnahiba and Green Mangues (Mangroves) Point, which consists of nothing but sand, without the least sign of vegetation."

That part of the sea coast of the province of Palmyra, extending from the Barra de Iguaçu, the easternmost branch of the Rio de Parnahiba to the Barra de Tutoia, is incorrectly laid down in all our charts. The distance between these two mouths is about 35 miles, in which extent the Rio de Parnahiba discharges itself by four others. Two of the mouths of this river, namely, those of Iguaçu and the Barra Velha, are only laid down in the charts, while the position of the four others is unknown. *Now this harbor of Tutoia is the only one along this extensive line of coast from Bahia de Todos os Santos to the River Amazons that admits of the bar being crossed at all times of the moon by vessels drawing 14 or 15 feet water.* Notwithstanding this, the position of the harbor of Tutoia is not only incorrectly laid down in some charts, but in many which are tolerably correct in other respects, Tutoia is not even mentioned.

The bar of Tutoia is between 7 and 8 miles wide. The masters of two English vessels who sounded on it, never found less than 5 or 6 fathoms water, which corroborated the extract of a log of a large Brazilian brig of war that had entered the harbor a short time previous to our arrival.

The bars of Iguaçu and Barra Velha are not navigable. Tutoia, as above mentioned, is the only port accessible, and is highly important in a commercial point of view.

"Inclining to the shore and observing the sand banks well, as you pass along, the entrance of the River Perguicas will easily be distinguished. The sand will now begin to assume a higher and more irregular appearance: this height and irregularity does not, however, deserve the appellation of hills. When the Perguicas bears S. S. E. you will begin to shoal your water to 8 or 9 fathoms, but a steady course should be pursued, as you will presently pass the spit formed by the sand washed from the river, and which, meeting the natural course of the current in the offing, inclines it to the N. W.

"If the day should be far advanced when you are off this part of the coast, haul to the wind under topsails and foresail for the night; standing off into 22 or 24 fathoms, and on into 12 or 14. It would not be advisable to haul the wind before you are past the Perguicas, as, otherwise, you may be short of daylight for the operations of the ensuing day. At daylight you may bear up under all sail, pursuing the former course and distance from the shore, and towards the conclusion of the sand banks the land will begin to appear a little more fertile, and Green Mangues Point will easily be distinguished.

ANGERSTEIN'S ROCKS.—Lat.  $4^{\circ} 28'$  S. long.  $37^{\circ} 6'$  W. soundings 11 feet.

Extract of a letter from Mr. John Bouch, master of the Brig Angerstein, dated Rio Jaguaribe, 15th December, 1830.

"In lat.  $4^{\circ} 28'$  S. and long.  $37^{\circ} 6'$  W. I came through a cluster of rocks, thirteen in number, from two to three fathoms under water. I ran close along side of one; it was quite visible under water, and I have the lead on it myself, and had not more than 11 feet water. They are not dangerous by day, but I should not like to be among them by night, with a sea on. The rocks being of a dark brown color, they show themselves sufficiently for a vessel to pass clear of them; and before the second cast of the lead can be got, you are in 10 fathoms water. They lie in a triangular form, about 11 miles from the land,

with Ponto do Mel, S. S. E.  $\frac{1}{2}$  E., the Red Mount on the Return, W. by N.  $\frac{1}{2}$  N. 7 or 8 leagues."

*Description of St. Marco Bay.*

St. Marco Bay is that part of the sea comprised between the western coast of Maranham and the main land; its entrance lies N. N. E. and S. S. W.; its length is over seventy-two miles, and its width six miles: every where the depth of water is sufficient for large vessels, even for frigates, which may cast anchor near the harbor of St. Luis, situated on the western coast of the island of Maranham.

The prevalent winds being from the east, vessels bound to Maranham must endeavor to make the first land east of the island, except in case of a fair and favorable wind from north to west.

The white sandy beach, called Lancos Grandes, is the first land a vessel bound to Maranham must endeavor to make: but it is proper to observe, that, by an error in the day's work, you may be deceived, and mistake the Lancos Pequenas for the Lancos Grandes, and in such case consider yourself west of the Perguicus, when in fact you will be on the east of this shallow water: to prevent such an error, the surest way will be to keep at ten or twelve miles distance from the shore, with from 6 to 10 fathoms of water, and sail along the coast until you reach the green Mangel shore; from this point you must steer west; and very soon after you will discover the breakers of St. Ann Island, and the island itself. Now you must direct your course round the breakers of St. Ann at two or three miles distance, until north of them, and you will be certain to have passed them when St. Ann Island shall stand south a few degrees east of you.

Having passed the northern breakers of St. Ann, you must steer again west, a few degrees north, until you discover the breakers of Corao Grande, which you may approach as near as the former. From this point you may proceed to the harbor by two different courses: if you intend to follow the first course, then you must steer round Corao Grande, keeping at a regular distance, with 10 or 12 fathoms of water: if the second, you coast along the western shore of Maranham Island. Maranham Island is easily distinguished from Santa Ann Island by its greater height, and its white shore towards the north.

The first point to be discovered, when keeping close to the Maranham Island, is Cape St. Marcos, from which the bay derives its name. It is a high land of very great declivity, on the top of which a house is to be discovered, with a mast for a signal. This cape and land project into the sea, and 800 yards from the sea-shore there are many rocks and sandy breakers, which you must not approach, being very dangerous.

Keeping always the same course, S. W. and S. W.  $\frac{1}{2}$  S. you will very soon reach the parallel of the small fort of San Antoni de la Barra, situated at the point of Areias, which forms the northern point of St. Luis Harbor. That point being part of the rocks and sandy bank above stated, it will be dangerous to approach too near, as long as you stand west of it, but when you shall have sailed beyond this cape, you may cast anchor.

**SHOAL OF MANOEL LUIZ.**—At the distance of 77 miles N. 8° E. from Itacoti, you will find one of the most dangerous shoals that you can possibly meet with at sea: this is called the Shoal of Manoel Luiz, and was only known by the number of wrecks that happened before we were able to discover or assign its true position. It consists of many groups of conical rocks, nearly even with the water's edge, separated by intervals, irregular both in distance and in depth.

This shoal, being situated in a sea rarely exposed to violent winds, breaks only for an instant, and that when the tide is quite low, so that it is almost impossible to perceive it even when passing very near. Nevertheless, the rocks on the surface which we have explored, are not more than from 5 to 15 feet under water at low tide, while there are 8, 12, and 10 fathoms close to them; thus you may encounter this danger suddenly, and be wrecked without the hope of assistance.\*

The instantaneous breakings rise in appearance like the back of a whale, when the sea is calm; and when these disappear, they leave masses of white foam, which are visible for some time. When the sky is clear, you may discover the rocks under water, which appear in large black patches; but as these patches are not perceptible until you are too near, you must not wait for such indications. After two hours of flood, and at the distance of only half a mile, it is probable you will not see one trace of this danger, if the sea is calm.

The survey which we made of this shoal, has enabled us to be well acquainted with its approaches from the east, the south, and from the west, so as to be certain that nothing

coast of Maranhão is over seventy-two fathoms deep, sufficient for large vessels. Luís, situated on

Maranhão must endeavor to catch a favorable wind from

the east, by an error in the bearings for the Lancer when in fact you will find the true way will be to the north of 10 fathoms of water, from this point you will see the breakers of St. Ann's Island, and be certain to have passed it.

Again west, a few degrees, you may approach the harbor by two different routes: round Coroa Grande; if the second, you will find the island is easily distinguished from the shore towards the

Maranhão Island, is Cape São João, of very great declivity, which is a signal. This shore there are many dangers.

Very soon reach the point of Areias, which is the part of the rocks and shoals, as long as you stand off, you may cast anchor.

8° E. from Itacolumã, you will meet with at least the number of wrecks in this position. It is on the edge, separated by

reefs, breaks only for a short time, impossible to perceive the surface which we have under the tide, while there are dangers suddenly, and be

of a whale, when the sea is calm, which are visible from under water, which is not visible until you are too close to the flood, and at the time of this danger, if the

well acquainted with the coast, be certain that nothing

having struck upon the rocks in 12 minutes.

dangerous exists in these directions. I wish I could state the same with confidence respecting the approach from the north; but this examination would have occupied me eight days more, and we had not the opportunity of making it; for the following day, after we had discovered this shoal, the bad season set in with violence. The weather would not allow us to make any more astronomical observations.

All the accounts that I could collect of these rocks of Manoel Luiz agreed, in the midst of contradictions, in placing them more to the southward of the place which I discovered them in, and confined them to much narrower limits than those in which I found them: it was therefore most probable that I had seen them all. Nevertheless I do not affirm this; and our survey having included the approaches to these dangers in the directions the most important to vessels which frequent Maranhão, I am pleased to have resolved the question of the actual position of this danger in its most essential parts, agreeably to the instructions given me; leaving to a more favorable opportunity the chance of discovering whatever may be further interesting, for the benefit of navigation in general. From our observations, made at the anchorage 400 toises to the south of the most westerly rock of Manoel Luiz, and under circumstances which assure us of its correctness, I place these rocks in latitude  $0^{\circ} 51' 25''$  S., longitude  $44^{\circ} 14' 45''$  W. and the variation observed at the same anchorage, Jan. 29, 1820, was  $0^{\circ} 57'$  E. The same day, in the evening of which it was full moon, we found the rise of the tide was 12 feet, and that it was high water at five o'clock; that the flood ran for six hours, at the rate of six tenths of a mile per hour, to the S. W. and the ebb ran N. E. for the same period, and with the same velocity. Lastly, the nature of the rocks which form this danger, appears to be of the same kind as those of the Abrolhos, and are similar to most of the other rocks and islets at a little distance from the coast of Brazil, which we have already described.

Such were our observations, according to our surveys, of these shoals of Manoel Luiz, when, in 1825, we were told that another group of rocks had been discovered nearly 7 leagues more to the northward, and almost on the same meridian as ours. This discovery, entirely accidental, was made by Mr. Da Silva, an officer in the Brazilian Navy, who, on his route to Para, saw the breakers on his passage, and discovered these rocks. I am not acquainted with the particulars of this discovery; but the position given to this new danger is said to be latitude  $0^{\circ} 32'$  S., longitude  $44^{\circ} 17' 21''$  W. and according to the account we received, there does not appear to be any doubt, at least of their latitude.

One question here presents itself, that is, to which of the two shoals, Mr. Da Silva's or mine, ought we to give the name of Manoel Luiz? If you consult former charts which notice this shoal, you will find so little agreement among them, that it will be impossible to decide in favor of one or the other. They are marked as only one group of rocks, and not any of them are placed in the position given either by Mr. Da Silva or myself. I am therefore inclined to think that these two dangers ought to be considered as a continuation of the same shoal. Its extent, which would be 7 leagues north and south, having occasioned its being met with in many parts, will explain, in some measure, the different positions that have been assigned to it. I agree that this hypothesis would not justify all these accounts, because I am informed that the popular opinion at Maranhão, for example, places the shoal one degree more to the southward than where we found it, and where we are confident there exists no sort of danger; and we may say the same respecting the danger discovered by Mr. Da Silva; however, it appears, beyond all doubt, that what is called the Shoal of Manoel Luiz, is only one of the points of the extensive shoal that Mr. Da Silva and myself have fixed the northern and southern limits of.\*

We conclude this subject, by observing that it appears to us difficult to determine from the soundings, your distance from the shoal of Manoel Luiz; the depth and the nature of the ground being so variable, at a certain distance from the danger, that you can deduce from them only very uncertain conclusions. The soundings of white sand, speckled black and red, as before mentioned, being the most common in that part of the sea, between the meridian of the Coroa Grande, and that of the eastern coast of the adjacent continent, extend 10 or 15 leagues to the northward of the entrance to the Bay of St. Marcos; but these are not without exceptions, as you will often find soundings of a very different appearance.

Beyond this limit, as well as to the eastward of Coroa Grande, sand and broken mad-

\* It is remarkable that Captain Appleton, in 1817, discovered a dangerous shoal in latitude  $0^{\circ} 45'$  S. and about 4 leagues to the westward of the reputed situation of the Bank of Manoel Luiz, which would appear to be placed somewhere between Roussin and Da Silva's Rocks, and probably will prove to be a continuation of the same dangers. He states them to be composed of sharp-pointed coral rocks, with only 14 and 15 feet water over them in some places, while close to these shallows the lead will fall into 40 fathoms; this description, in its principal features, very much resembles that of the Baron.

reporea are the most commonly met with. These are nearly the same which you so constantly meet with all along the coast of Brazil from the Abrolhos. We found them at the extremity of all our routes to the eastward, and on the parallel of this shoal; and it is probable they extend much farther to the northward and eastward.

In fact, broken madrepora are most common in the vicinity of this danger, to the east, south, and west of it; but they are mixed sometimes, though rarely, with coarse gravel, broken shells and rocks, but varying in depth so much, that you cannot, by the soundings, determine your distance from the shoal to within 5 or 6 leagues.

*Directions for Vessels bound to Maranham, by Lieut. E. Stopford, commanding H. M. Schooner Pickle.*

Vessels bound to Maranham may cross the equator in long.  $40^{\circ}$  W. which will enable them to fetch the Lancoes Grandes, a landfall deservedly recommended by Baron Roussin. It has been customary to make the lighthouse on the island of Santa Anna, but an error in the longitude will be of less importance by making the Lancoes Grandes.

A vessel arriving off Santa Anna, and not having sufficient daylight to find her way into the bay of St. Mark, may lay to for the night off and on the lighthouse, keeping it as near south of her as possible, distant 6 and 7 miles. The light is revolving, and can be seen distant about 15 miles.

As there is constantly a heavy swell on the coast, anchorage should be avoided if possible, as it is both difficult and dangerous to recover the anchor.

From Santa Anna a vessel should steer W.  $\frac{1}{2}$  N.; by doing which she will pass the breakers of Coroa Grande, at the distance of about 3 miles, and Mount Itacolomi will be discovered bearing about west. When distant about 10 or 11 miles from the Mount, alter course to S.  $\frac{1}{2}$  W., till the fort and flag-staff of St. Mark's are made out nearly ahead. St. Mark's point should not be passed at a greater distance than a mile and a half, that the bank of De Cereia, (on the starboard hand going in,) may be avoided; a reef of rocks runs off from the point; and to avoid these, it should not be approached, within three quarters of a mile. Within these limits a vessel may coast along until Fort Antonio bears E. or E. by S. when she should anchor and wait for a pilot.

A vessel by following the above route to Maranham, will avoid getting entangled among the swash-ways on the Coroa Grande shoals, mentioned by captain Courtenay as being so very dangerous to strangers.

The inhabitants of Maranham, in consequence of their harbor filling up, expect to be obliged to transfer their port of shipment to Alcantra. Lieut. Stopford visited this port, and is of opinion that it is preferable in every respect to Maranham, being easier of access, capable of containing more ships, and allowing them to get in or out, at any time of tide, with the prevailing winds. The depth of water is also greater. The Pickle was anchored about one third of a cable's length from the shore, in 7 fathoms at low water, being more than in any part of the harbor of Maranham, even at high water.

Captain Courtenay represents the bottom, along the whole line of coast, as being composed of quicksands, to which he attributes the frequent loss of anchors by vessels. Lieutenant Stopford is of a different opinion, having frequently anchored on all parts of the coast, between Maranham and Para. It is, however, indispensable, that vessels should ascertain the quality of the bottom before anchoring, as it is foul in many places. The Pickle lost her small bower before Lieutenant Stopford was aware of this, by anchoring on rocky ground. Vessels should be careful not to anchor off St. Mark's point, as the ground is foul, and many anchors have been lost there.

**ROUTE FROM MARANHAM TO PARA.**—A vessel bound from Maranham to Para, during the rainy season, should get to the northward of the equator as soon as possible. She will thus avoid the light baffling winds and calms which prevail in this season; and also the current, which sets from E. N. E. to S. E. about 2 or 3 miles per hour, occasioned by the waters from the various rivers and bays of the coast.

To the westward of the island of Salina there are some white cliffs so nearly resembling those to the eastward of that island, that they have been frequently mistaken for each other. Vessels mistaking the western cliffs for those east of Salinas, have stood on until they have become lost on the Braganza shoal, or in that equally dangerous place called the Well. The utmost caution therefore is necessary to attend to the following directions for anchoring at Salina.

Bring the town of Salina to bear S. by E. and anchor in 9 fathoms. The whole coast from Turnivissa is woody, and the white sand hills are very remarkable.

Information obtained from Senhor Saramanbas, the chief pilot, Lieutenant Page, commander of the U. S. Schooner Boxer, at Para, South America.

signal that a pilot may

2. If the pilot should not, however, come off during the day, and at night there be shown two lights, the pilot may be expected off the following morning.

3. If there be three lights shown, the pilot has no boat, and must have one from the vessel to bring him off; in which case the vessel must bring the village of Salinas to bear S. S. W. in soundings of five or six fathoms water, when point Atalaia, (improperly called in the charts, Atasia,) will be distant about 5 miles. You may here dispatch a boat, well manned, which must keep close in with the shores of Atalaia, clear of the surf, until it meets with an opening in the reef which lines the coast in front of the village, through which it must pass. Inside the reef, the water is quite smooth, and you may land any where upon the beach.

4. The boat should be sent at half flood, in order that it may return the same tide. It is high water on full and change at 7 o'clock, and off shore at 8. Para, June 1, 1832.

H. M. S. Pickle remained at anchor one night in 7 fathoms, with the town bearing S. by E. and had no difficulty in regaining her anchor in the morning. Lieutenant Stopford observes, that accidents have frequently happened, and lives have been lost by boats going for the pilots being swamped in the surf. They have frequently landed immediately under the town, which is very wrong, and Lieutenant Stopford recommends them to pass to the westward of the island; by doing this a river will be observed, which leads up to the town, where boats may land in safety, and thereby avoid the surf outside.

MARANHAM TO PARA.—Para, or Grand Para, is the northernmost province of Brazil, and is celebrated for its cotton, sugar, vanilla, chocolate, and coffee. The coast from the bay of Maranhão to Para, is generally low and sandy, and has many little isles, of the same description, with numerous coves and rivulets. Pimentel has described the whole, but his description is not adapted to the use of the modern navigator, unused to creep along the shore. Some of it may, however, be useful. A vessel, he says, bound from Maranhão to Para, should take her departure in the morning, advance to the anchorage off the Arneaji, or cliff, already described, thence stand out to sea, to beyond the shoals of Cumã, (or Carnaveros banks,) which may be effected in a run of 8 leagues. Having passed these, you approach the sand bank stretching from the western shore, and over which there are 6, 10, 7, 6, 5, 7, and 8 fathoms. Thus, you may proceed to the N. N. W. or N. W. by N. to the distance of 22 leagues, when the ground of the bank, white sand with black specks, will be succeeded by coarse sand and stones, or brown sand and broken shells, with 13 to 17 and 20 fathoms of water.\* Here you will be off the island of St. João, or St. John, and near the parallel of one degree south.

The island of St. João is nearly level with the sea, and about 3 leagues long from E. N. E. to W. S. W. Between the N. E. end of this island and Point Turivazo to the W. N. W. the distance is about 9 leagues. The bay between affords shelter, and vessels may anchor on the N. W. side of St. John's island, in from 6 to 4 fathoms, sandy ground.

At the distance of 18 leagues W. N. W. from Turivazo point is Cape Gurupi, over which is a mountain, insulated and therefore remarkable. This mount is several leagues inland, and near it is another, somewhat smaller and rounder. The coast here, as in other parts, is, however, low, level and sandy, covered with a dark brush-wood, and from the point a shoal, with breakers, extends 3 miles out to sea.

From Cape Gurupi to the River Cayte, on the western bank of which is a small town of the same name, the distance is 24 leagues, on a course nearly west. At the entrance of this river, on the eastern side, are several low islets, of the same name. Off the shore, throughout this extent, the bottom is generally flat, and there is commonly 7 and 8 fathoms at 3 leagues off, with clear ground.

From the Cayte to the inlet of Maracão, the distance W. by N. is  $12\frac{1}{2}$  leagues. In sailing along it is proper to keep 2 or 3 leagues off shore, in soundings of 7 and 8 fathoms. The coast here is distinguished by a range or chain of white sand-hills, the highest of which, Pirassu Hill, is about  $3\frac{1}{2}$  leagues westward of Cayte Point, the western point of the mouth of the Cayte. Pirassu Hill appears like a high bluff, and perpendicular point, close to the sea, with red cliffs on its eastern side.

At  $5\frac{1}{2}$  leagues W. by N. from Pirassu Hill is Point Atalaia, distinguished by a watch-tower, having a gun which is occasionally fired when a vessel is approaching. On making this, and keeping a good look-out, the smoke may be seen. At this place are two eminences of white sand, and immediately west of the point is the inlet or bay of Maracão, having 5 and 6 fathoms of water, and good ground.

RIO PARA.—Point Tigioea, the eastern point of the mouth of the Para, is 9 leagues west from Atalaia Point; and within this, at the distance of 7 miles to the S. W. is Point Tapua. Here an extensive bank extends 2 leagues from shore between the two points, and to the northward are the Tigioea shoals and breakers, the positions and nature of

\* According to a late survey.

which can be understood only by reference to the charts. The passage is between these shoals, and has a depth of 12, 11, and 15 fathoms, at about 11 miles from the southern shore, in latitude  $0^{\circ} 23' S$ . There is, also, a channel for small vessels, at 5 miles from shore, and along the edge of the Baxo do Boronoco, the bank which extends from Point Tigioea, as already noticed.

**DIRECTIONS FOR PARA.**—Vessels bound to Para should endeavor to make the land about Salina or Cayte, which lies to the eastward of Salina, and is remarkable for its white sand hills, steering to the westward, keeping the land in sight 6 or 7 miles distant, you will make the Point Atalaia, which has a house near its extreme point, and immediately after will see the village of Salina, which faces the sea, and easily perceived in clear weather by its white buildings. Here vessels take a pilot for Para, and if one should not come off by making a signal, you will have to send the boat on shore for one.

Should you not see Salina, or find any difficulty in procuring a pilot, by attending to the following directions you will find no difficulty in passing the shoals, or going up the river.

The land between Salina and Tigioea runs about W. by N. about 4 leagues. To the westward of Salina you will see a point of land, S. W. of which are two remarkable white sand hills, and by keeping a good lookout at the mast-head you cannot pass them without seeing them, they being the only thing remarkable between Salinas and Tigioea, and is a good departure to run between the shoals. Tigioea lies about 17 miles to the westward of this land, and is a low point. You will have running along 11, 12, 14 and 15 fathoms water channel-way, and be careful in sounding; come no nearer the land than 9 or 10 miles, as you approach Tigioea, for fear of getting into the Well, which is a dangerous place, and oftentimes deceives strangers by supposing it to be a good channel inside, as most of the books and charts represent, but should never be attempted by any. The Well (or entrance of do.) is about 5 or 6 miles to the north and eastward of Point Tigioea, and has from 20 to 28 fathoms water: by getting that soundings you may judge immediately you are in the Well, for there are no such soundings any where about that part of the coast. Haul off as soon as possible to the south and east, to avoid the Braganca Bank, for in that soundings you are not far off danger: perhaps the next soundings you may not have more than 2 or 3 fathoms and less, as I have found it to be the case in going through that channel with a boat, and sounded all the way, sometimes not 6 feet, and breakers both sides. I have been the more exact in pointing out the danger of this channel, that it may never be attempted by any, and if unfortunately you should happen to get in, and your water shoalens, if flood tide, come to anchor and wait for the ebb, and then you should not haul off the land too sudden, for fear of the Braganca Bank, which is inside of you, and which you cannot avoid seeing, as it breaks constantly unless at high water, and the sea perfectly smooth, which seldom happens to be the case, that a vessel can pass it without seeing.

#### *Running for the Channel between Tigioea and Braganca Banks.*

When you make Tigioea Point from the mast-head, and running along the land so that you can see it plain from the deck, (say 9 or 10 miles,) you will soon discover the Braganca breakers from aloft, which break very high on the larboard hand going in, and is the best mark to run in by. The tide runs very rapid in this channel, and the sea at times, and for the most considerable. The ripple caused by the tide at times appears to a stranger like shoal water, where there are probably from 14 to 15 fathoms water, and while the Braganca is in sight you need not be apprehensive of any danger, for the bank is steep close to the breakers, and you should pass within 2 miles of them, or even less, and when Tigioea Point bears about S. E. by S. Braganca distant about 2 or 3 miles, you may haul up about S. W. to avoid Tigioea Shoal, which lies outside of you, and stretches to the south and west, and breaks heavy at the east part, but seldom seen going through this channel, and should your water shoalen, approaching said shoal, (which will not be the case whilst the land is in sight plain from the deck,) haul more to the south, and your water will deepen immediately; you may then proceed up the river by keeping the Braganca in sight, which will always be a sure guide for going in, keeping them at a distance about 2 miles, more or less, as the courses given may be affected more or less by the tides.

The land between Tigioea and Point Taiper is broken, appearing in spots of small islands, which makes them more remarkable, and near to Taiper is a dry sand bank about 5 miles from the land, and to the south of which, abreast of Point Taiper, is good anchorage, in about 7 or 8 fathoms water, and is where pilots come to anchor outward bound to wait an opportunity of running out between the shoals on account of being less exposed to the heavy sea which sets in with the flood tide, and out of the strength of it.

Point Taiper, is good  
e to anchor onward  
s on account of being  
d out of the strength

Point Taiper is about 11 miles from Tigioa Point. The land between Taiper and Vigia lies about S. W. by W. and N. E. by E. distant about 17 miles, between which, keeping at a distance from 5 to 4 miles, you will have 9 to 10 fathoms water, and as you approach Vigia your water will shoalen gradually to 8 and 7 fathoms. The point of Vigia is remarkable in coming from the northward, and as you draw to the southward another point will open which shows the entrance of Vigia. Be careful not to approach too near Vigia, as there is a shoal stretches off about N. W. by N. 2 miles from the northern part of the land, which forms the entrance; and north from the southern part which forms the entrance to Vigia,  $2\frac{1}{2}$  or nearly 3 miles, hard sand. Vigia is a small fishing town, and cannot be seen in passing, as there is an island in front of it, which stands some distance from the entrance.

Running along the land, at the distance of 4 miles, you will have 7, 8, and 9 fathoms towards Colares, it being a small village which faces the water, and is very easily distinguished by its white buildings, distant from the south point of the land 6 or 7 miles. Off this village, or between it and Vigia, is good anchorage about 3 miles from the land, sticky bottom. Be careful not to come too close to Colares, as there is a reef of rocks that stretches off nearly two miles.

If night is coming on, it is advisable not to pass Colares, but come to an anchor and wait until morning, and to know when you pass Colares, your water will deepen very soon after as you approach the Bay de Sal, which will be open to your view. Bay de Sal is a large deep bay, being about 4 or 5 miles wide at the entrance.

Be careful not to get into this bay, as it is dangerous, being full of rocks, and no safe anchorage, and has sometimes been taken for Bay St. Anthony. Between Bay St. Anthony and Colares there is no good anchorage that can be recommended with safety, the water being very deep, particularly abreast the Bay de Sal, where you will have from 16 to 18 and 20 fathoms water, which is not the case anywhere else in the river. Colares bearing west about 5 miles, steer from S. S. W. to S. S. W.  $\frac{1}{2}$  W. You will then pass two small islands on your larboard hand, one abreast of the land, which forms the Bay de Sal, (S. part,) the other about 3 miles to the S. and W. In approaching these islands your course will draw you towards the land, but come no nearer than two miles, as there are rocks which stretch off about  $1\frac{1}{2}$  mile, with 7 fathoms close to them; therefore 8 or 9 fathoms is near enough. As you draw up with the south island, you make the island of Tatuock nearly ahead. Be careful in drawing up to this island not to come too close to it, as there are rocks stretching off it to North Tatuock, between 2 and 3 miles. Leave this island on your starboard hand after passing the small island previously mentioned, 4 or 5 miles; you may then haul in for the land which forms the Bay St. Anthony. The shore becomes bold and without danger. The Bay St. Anthony is a fine clear bay, good anchorage all through from 5 to 7 and 8 fathoms, and by hauling into the bay if you want to anchor, particularly the southern part close in, which forms a lee, you will have the sea perfectly smooth, good shelter from the wind, and out of the strength of the tide; but if you want to proceed to town, steer across the bay, the wind being always fair for going up: you will then see several islands: keep between them and the point which forms the south part of the bay, (or Point Penheiro,) which is close to. You will soon see a small island called Paraquet Island, open to your view, and appears at a distance to be close in to the main land. When you pass Point Penheiro, steer directly for it, leaving it on your larboard hand close aboard, as it is on the very edge of the channel. It is so bold close to this island that you need not be afraid to pass within the length of your vessel of it, and it is requisite you should pass close to it, as the channel becomes narrow as you pass it, having a shoal flat of sand on your starboard hand. The fort, which stands on a small island, will open plain to your view. About two miles distant from this island steer for it, giving it a berth of half a cable's length on the larboard hand, where you must send the boat on shore with your papers, or come to anchor: the latter is preferable for a stranger, as the channel is very narrow. When you weigh anchor steer for Para, or city of Belem, which will be open and plain to your view, distant about 5 miles from fort, keeping the land distant about one mile on your larboard hand, and as you approach the town, haul in for the shipping, or custom-house, the next large building to St. Anthony's Church, which is the first or nearest church in coming up the river: then you may anchor abreast the custom-house, where you will have to land your cargo.

N. B.—There is a shoal of considerable length runs between the island of Parajo and the main land that runs nearly north and south, which the sea constantly breaks on. Nearest distance of said shoal from the main land, being abreast of Colares, or that part of the land which forms the Bay de Sal, distant 7 or 8 miles.

High water, full and change, at Para, 12 o'clock.

Do. entrance between the shoals, 10 do.

From the mouth of the river, within Point Tigioca, the distance to the basin or anchorage of Para, is 20 leagues. All the western side of the river is shoal, but on the eastern side are even soundings of 8, 7, 8, 9, 10, 7, 10, 12, 9, 7, and 6 fathoms. In the basin itself are from 5 to 3 fathoms.

A vessel direct from sea, with good observations, may cross the equator on the meridian of  $45^{\circ}$ , where soundings, from 50 to 40 fathoms, may be found. A course hence W. by S. will lead towards Maracuno Inlet, on the east of which a pilot may be obtained. The soundings over the bank decrease gradually, from 40 to 15 fathoms; and it is to be observed that the flood tide sets strongly to the west, while the winds are from the east.

The flood sets into the Rio Para at the rate of 4 miles an hour. The beginning from the eastward is very rapid, and it veers gradually to the N. E. and N. The vertical rise is 10 feet.

*Vessels outward bound*, from point Tapua, steer according to the tide, keeping that point S. E. to the distance of fifteen or sixteen miles. With Cape Magoary then in sight, haul up N. E. or N. N. E., taking care to avoid the banks of St. Rosa on the west. The wind here being generally from the eastward, with frequent squalls, great caution is required. In thick weather, when Cape Magoary cannot be seen, the approach to St. Rosa's Bank may be known by the soundings becoming irregular, which is not the case to the eastward of the channel. The weather shoals should be kept on board as much as possible.

#### *Description of Pernambuco Bay, and Instructions to sail in and out of it.*

Cape St. Antonio is the land vessels bound to \*Pernambuco must endeavor to make first. The coast north of Cape Antonio forms a bay, in the centre of which lies Pernambuco. At the extreme end of this coast, N.  $17^{\circ}$  E., stands Olinda Point; half way from Olinda Point to Semanibus, the church of Nossa Senhora Do Rosario is built on a height; its two towers are easily distinguished when coming from the main sea; going along the coast at two to four miles distance, there are 12 to 19 fathoms water.

When you have ascertained Cape St. Antonio, you must keep at two or three miles from the shore, until you perceive the Fort of Picao, between the N. W. and W. N. W. and then steer in a straight line to the Fort built on the breakers, and you will near it until the Cocoa-tree of Olinda (which stands between the two highest buildings of the city) appears N.  $\frac{1}{2}$  E. of you. In this situation you will stand within two or three thousand yards of the breakers, which form a key. This anchorage is not of the best, large ships ought never go nearer, and it is prudent never to cast anchor in bad weather. West of the meridian of the Cocoa-tree of Olinda, notwithstanding the contrary is generally prescribed, going to Pernambuco during the northern monsoon, it is best to make land on Olinda Point. From Olinda Point up to the Fort of Picao, there is a shoal extending two miles from the shore towards the sea, which makes it necessary to keep at three miles distance, and by a depth of water from 8 to 10 fathoms, until the Fort Picao stands west, a few degrees towards the north, by which you will avoid the English bank, which is formed by sandy rocks lying at the southern end of Olinda bank. That does not extend further east than the meridian of Olinda City, nor farther south than the parallel of Fort Ciesco. The sea breaks there with great violence in heavy wind, though there are 2 fathoms of water. Small vessels may avoid it to the west and north, keeping at half a mile from the main land from Pernambuco up to Olinda Point, but this vessel shall not require over three to five fathoms, and it is indispensable to have on board a pilot for the place.

The harbor of Pernambuco is not a very safe one, for vessels of a great draught of water are not able to cross the bar; for the swell of the sea is very great outside, and if too near the shore, there will be great danger should the anchor drag or the ship fall to the leeward, when getting under sail, which may become indispensable should the wind turn S. S. E. or E. N. E. as is the case in the month of March and September. During the northern monsoon the prevalent winds are from the east, particularly at the time of new or full moon, and though the weather is clear and fine generally, yet it requires to be careful in the anchorage, and the surest will be not to cast anchor too near the shore, the bottom being very rocky, and requisite to make use of chain cables in this place more than in any other. Large vessels will do well to be all times in readiness to get under sail, and prudence requires to let fall every evening a second anchor for safety during the night.

If there is any necessity to remain a long time at Pernambuco, the best way will be

to cast the two anchors off the cat-head, toward the main sea, with another toward the W. N. W. on the stern of the ship, in order to prevent the ship from swinging during the calm which comes after every squall of wind.

The harbor of Pernambuco is sufficiently spacious and deep for vessels from 10 to 12 feet draught of water; it is divided into two parts; the interior part, which is called the Poco, (the Well) is an anchorage situated on the northern end. The entrance is formed by several rocks or banks of small stones. There are from 17 to 30 feet water on the bar, as well as inside. The shore is sandy, and the water decreases in depth, in proportion as you go toward the land. The only guard vessels have from the winds coming from the sea, are the rocks or breakers before stated; but they are very deficient for that purpose, and during the southern monsoon this place is not at all safe. The second part of the Fort is called Recife Port: it is comprised between the natural quay of rocks and the city: it is also called Mosqueirao. This harbor is better guarded than the former, by the quay of rocks, which, at low water mark, are from 8 to 10 feet above the sea; but to reach in the Mosqueirao, it is necessary to cross the bar, on which, at low water mark, there are but 7 feet water.

If you wish to carry your vessel in the Poco harbor, you must proceed as follows.—Being situated as we have already stated, inside of the English bank, the cocoa-tree of Olinda N.  $\frac{1}{2}$  E. of you, you must see a small pyramid built on the shore, in a straight line with the church of San Amara, which is surrounded with cocoa-trees; in this situation the church and pyramid stand very near the west of the wood, and you must follow that direction until you perceive south of you the Fort Picao. If you wish to go into Mosqueirao you will have to steer S.  $\frac{1}{2}$  W. from that place.

Small vessels sometimes used to pass through the south entrance to reach Mosqueirao, which is at the northern end of the quay of rocks, whereon Fort Picao is built. The mark to direct your course in this case is, to keep the two corner towers of the southern end of Fort Brun in the same direction, and consequently the one covering the other, and true west; sail in this direction until you see the Fort Picao south of you; then steer along the western side of the breakers, and you will reach the harbor. There is no great danger in going near the breakers; it is customary with pilots, when called, to come to take vessels lying in the bay. We again repeat, that vessels trading with Pernambuco must not draw over from 10 to 12 feet water.

The two harbors of Pernambuco are safer than the bay, ships being sheltered from the too great swell of the sea by the breakers or quay of rocks; but when the wind stands east and blows hard, it requires to be well secured.

The prevalent winds are, as in the tropical climate, from S. S. E. to N. N. E.; from March to September, they are more toward the south, and sometimes S. W.; during the other six months they stand E. N. E. and N. N. E.

*Description of the Coast comprised between Cape St. Antonio, and Olinda Point, the mouth of the St. Francisco River, and Cape St. Augustine.*

From Itapuanzinho Point up to Itapuan, the coast bears no longer the same appearance as it does previous to your arrival at Bahia. Here the shore is but sandy and low, few trees are to be perceived at a distance, and from place to place some cocoa-trees. All along the shore a ridge of rocks are to be met, and in many instances they rise above the level of the sea; the one at the Itapuan Point particularly, seems like small islands. Thirty-eight miles farther N. 45° E. of Itapuan Point, you are opposite the Torre de Garcia of Avila, a kind of fort, built on the top of the coast, among the trees, and which is now used as a house for signals. The coast viewed from 9 to 10 miles distant, appears like a wall of great magnitude and equal height, except where the two rivers San Joannes and Jaculype discharge into the sea, where a large cut appears in this wall. The depth of the sea is very great opposite this place, for being only 10 miles distant, no sounding is to be met. From Torre of Avila up to Oiteras of San Miguel, the shore is more high, but with small hills.

All the coast from Rio Real up to Rio St. Francisco is low and sandy, with small broom bushes, and small hills are discovered at no great distance in the interior. A vessel may approach very near the land, the bottom is sandy, with gravel and broken rocks. The next river after Rio Real, is Rio Sergipe, which is 21 miles distant from Vassa Barris. The mouth of this river, when viewed at no great distance, is easily distinguished by the three small hills of an equal height, all covered with briars, lying 9 miles S. W. of the bar. These hills are called the Ostres Irmaos, (or Three Brothers.)

At the mouth of the Sergipe River, a very white sand beach is to be seen, whose color contrasts with the green ground of the coast all around. At the bar the sea breaks with great force at the time; from which we must infer a shallow water. The rivers which come next in succession are, Cotombeda River, near the Miserias Point, and Japarutuba

Points, south of the mountains of Pacatuba; the country round Colindiba River, is one of the most productive in sugar, cotton, tobacco, &c. There are but 7 feet water at the bar. When viewing the bar W. the Mount Aracajou stands a few leagues N. W. and in the west Morro Teilha is discovered. The Mount Aracajou seems to run in a parallel direction with the coast, and in its northern extremity a deep cut is to be perceived. The second mount bears the shape of a Quaker's hat. The coast from Rio Idaparutuba up to St. Francisco River, is very dangerous in a strong S. E. wind, for vessels going near the land, they having no good chance to escape the wind, and the bottom too hard for the anchor to have a good hold in it. Prudence requires to keep at some distance from it.

Near St. Francisco River the land is very low, and cannot be seen even at a short distance, for which reason great care is required to make land near St. Francisco. The only mountains to be discovered at a distance are the Itabayanna and Pacatuba, but only in fine clear weather, and when exactly opposite the River St. Francisco. The entrance of this river lies south of Manguiha Point, which is very low, and all covered with Mongel trees. It projects E. S. E. and, at  $1\frac{1}{2}$  mile distant from it, in its direction, there are dangerous breakers. The north of the entrance is formed by a land more low than the former, having a white sand, and in its projection into the sea there are no less dangerous breakers than on the other southern points. It is between these breakers you must cast anchor until a pilot comes on the bar. There are from 12 to 13 feet water, the country is very populous, well cultivated, and produces great quantities of sugar; when near, the land from St. Francisco River up to Alagoas is low and sandy, and a ridge of rocks at no great distance from the shore is to be seen. Many small rivers discharge into the sea, but none of a sufficient depth to be navigated; they may be approached very near without danger.

Opposite Cururippe, three miles distant from the shore, stands the rock of Dom Rodrigo. This rock, as well as several smaller ones to be seen only at low water marks, have been designated by some as the Cosmographer Banks of St. Francisco, and stated to be very dangerous, but without the least reason. We found all around this place a great depth of water, and the shallow water will not extend over 3 miles. In supposing it to extend as far as the Iquia, as there is no reason to keep so near the land, one will do better, at all events, to remain at a greater distance than 4 miles. An important observation is to be made on this part of the Brazil coast, and agreed to by the natives, which is this, that the land-breeze during the night time is hardly perceived, when 4 or 5 miles from the land, but at daylight it begins to reach that distance, and seems to attract the eastern wind towards the north until 12 in the morning; and afterwards the eastern wind returns gradually towards the east: from that fact vessels may derive some benefit on either course, when obliged to beat. Near San Miguel the shore is very bold, and nearly 80 feet high, and the top perfectly even and horizontal for an open space of 15 miles. When coming from the southernmost, the village of Macayo is to be discovered on the top of a highland. The church is easily distinguished; and for this reason the place deserves notice. The Jaragua River empties below Macayo, and the point which forms the northern land of the mouth is covered with cocoa trees, and very animated breakers are to be seen at some distance in its direction. North of Macayo and from the interior, the mount of Marambaya is discovered even at 45 miles distant. This mount offers this particular, that the country on which it stands, though high, is very level on every side of its base. The shore north of Macayo is sandy, and from place to place of a reddish color; low trees are seen not far distant from the shore. The Fort of Tamandare, though not very important, deserves some notice, being the only place affording a safe shelter between Bahia and Pernambuco. This anchorage is formed by a deep cut into a bold shore, and is sufficiently large and deep for admitting large vessels.

Nine miles N.  $\frac{1}{4}$  N. E. of Tamandare Harbor, lies the small island or rocks of Alexo, situated at the mouth of the small river Serenhen. Previous to your arrival there, the bar of Rio Feroso is discovered. When you observe the two rocks of Alexo together, they stand N.  $6^{\circ}$  W.; then north of these two rocks Monte Do Sella is discovered in the interior, which derives its name from its shape, (Little Saddle,) and may be useful to ascertain the situation of a ship.

Being a few miles east of the rocks of St. Alexo, you will distinctly perceive the Cape of St. Augustine, lying 16 miles N.  $18^{\circ}$  E. This cape is hardly covered with wood, and not very thick; it is of a moderate height, which decreases gradually towards the sea. It offers the particular remark, that a steep beach of a red yellow color is to be seen in many places of it: it has a barren prospect when nearing it; on its top there is a church towards the north side, a little below the church, fortifications are to be seen.

*Description of the Bay of All Saints, or Bahia—Instructions to go in and out of this Harbor.*

Vessels bound to Bahia during the southern monsoon should make land near San Paulo. If during the northern monsoon they will do better to make land north of Itapuan, which is a little further north than Cape St. Antonio. Upon the whole this will depend on the accuracy of the day's work, the actual situation of the vessel, and the wind to be met with when near the coast. The main entrance of the Bay of Bahia, called likewise St. Salvador, is formed by the cape or promontory of St. Antonio on the east, and by the Island of Itaparica on the west. The mean distance from the Cape St. Antonio to Itaparica Island is not less than 4 miles, but the one half only of this channel, which is towards the main land, is safe for navigation of large ships. If from the Morro San Paulo, you steer N. 46° E., with a favorable wind, you will pass at the proper distance of the bold shore of Itaparica Island, and of the breakers of St. Antonio; but if you are obliged to beat, it requires care to avoid both places.

Nothing is to be feared by keeping at equal distance from the main land, on which stand San Paulo, Mount Arod, Itaparica, until you discover towards the north, the Jaburu Point, which is the eastern end of Itaparica Island. Arrived opposite Point Aratuba, you are now 7 miles from Jaburu, and 5 miles S. 41° W. of Cape St. Antonio, and nearly 3 miles W. of the southern extremity of the breakers of St. Antonio. From that situation you must direct your course straight towards the Cape of St. Antonio until two miles only from the shore: from thence steer straight towards the church of Boni Fim, (situated on the Point of Montferrate,) until you reach the Fort Do Mars, or Sant Marcelllo, near which is the usual anchorage.

The Flat of St. Antonio, lying 4 miles S. W. of Cape St. Antonio, there is no difficulty to avoid it, and is altogether not very dangerous. It is a sandy bank of a reddish color: no rocks are to be met there, and 4 fathoms of water are to be found every where. Such is the opinion of the natives, and of the most experienced men; but having perceived some places where the sea breaks on this bank during strong wind, I would suggest to keep a distance from this place with a large ship, which is the case when following the course we have described. The general anchorage for merchant vessels is inside of the line drawn from the Fort of Marto Montferrate Point. It is necessary when going to this anchorage to avoid the sandy bank of Panella, which we had no chance to ascertain, but it is reported by the natives as a very shallow water of 3 to 3½ fathoms only, lying W. ¼ N. W. from Fort Do Mar.

It is generally the case that the wind permits you to come to anchor in front of St. Salvador, the most prevalent wind being from E. and from S. E., and vessels can generally go in by plying small board. During the night time, the breeze comes from several points of the compass, but more generally from the land side. The tides are perfectly regular from St. Salvador, and the flood and low water last an equal time. The harbor is very safe, and there are only a few instances when a strong wind from S. W. blows, that the water is much swelled, and the ships do not ride easy.

The course to follow when going out of St. Salvador, is very near the reverse to the one to proceed in. When one mile distant west of Cape St. Antonio, and steering 4½ miles S. S. W. of the same, the shallow water will be avoided, and afterwards you may go round the cape into the open sea. All the lands near Cape St. Antonio are tolerably high, if compared to those of the opposite side. They are of a pleasing appearance, being covered with trees, and a luxurious vegetation of a green color. This shore in fine weather can be discovered from 30 miles distant. On the end of St. Antonio Cape, stands a lighthouse, not very high, which in night time can only be seen from 12 to 15 miles. In the day time, when the lighthouse bears W., the fort of St. Antonio appears as separated at a small distance from the main land. Two and a half miles east, a few degrees south of the lighthouse, there is another land point, on the top of which stand the poles for signals. This last point forms with the Itapuanzinho Point, which stands one mile east of a small bay. Many houses are to be seen along the sea coast.

**ISLE OF TRINIDAD AND MARTIN VAS' ROCKS.**—*Descriptions and Directions.*—In approaching Trinidad from the eastward, when running on its parallel, you will make the three islets or rocks of Martin Vas', which may be seen at the distance of eight or nine leagues from a ship's deck. These rocks are very remarkable, and cannot be mistaken. They lie north and south of each other, the distance from the outer rock being about three miles. The central rock is very high, with tufts of withered grass scattered over its surface. The other two are entirely barren. There is a passage between the southernmost and central rocks. The northernmost almost join. In clear weather Trinidad is distinctly seen from the rocks of Martin Vas', and may be descried 16 leagues off.

The island is about 6 miles in circumference, the land very unequal, and at best no more than a cluster of rocks, with some shrubs in the valleys. The northernmost side is quite barren, but to the southward all the interstices of the rocks are filled with evergreens of several kinds. There is also a quantity of sea-fowl and rock-fish, and many wild hogs. The generality of the wood is very small, though the trees of eighteen inches diameter towards the extreme heights.

Trinidad is surrounded by sharp rugged coral rocks, with an almost continual surge breaking on every part, which renders the landing often precarious, and watering frequently impracticable; nor is there a possibility of rendering either certain, for the surge is often incredibly great, and has been seen during a gale at S. W., to break over a bluff which is 200 feet high.

The island is supplied with very good water from two small streams down the E. and S. W. sides of it; besides a small issue from the rock which forms the S. W. extremity, not one of them will fill a tube of 6 inches in diameter, and there is a doubt whether these run temporary or perennial, though they always produce a small quantity of water, sufficient to preserve the existence of a few wretched inhabitants. Lieut. Thomas Harrison, from whose account this detail of Trinidad is chiefly extracted, speaking of the anchorage, says that they anchored off the west side of the island, at a mile from the shore, to be able to weather it on any tack, should the wind happen to blow on, "being directed," continues that gentleman, "to do so by Captain De Auvergne, who informed us of the wreck of the Rattlesnake, and the miraculous escape of the Jupiter and Mercury." They prudently avoided the common anchorage, which is about a musket shot from the shore, in 18 or 20 fathoms water. On that side there stands a stupendous arch or hole in the rock, like that of Fernando Noronha, and two very remarkable rocks, one called the Monument and the other the Sugar-loaf.

The Monument is 850 feet high, of a cylindrical form, and almost detached from the island, with large trees growing on its top. This had been named in 1700, by Dr. Halley, the Nine Pin. The Sugar-loaf, at the S. E. end, is 1160 feet high, of a conical form, with trees likewise on its summit, and whenever it rains hard, a cascade of 700 feet, makes there a beautiful appearance. The arch is a natural passage made by the sea through a high bluff of about 800 feet high. It is 40 feet in breadth, nearly 50 feet in height, and 420 in length; the depth of water above 3 fathoms. When the sea is moderate, you may see through this arch into the only bay in the island, and have a view of a distant rock covered with trees, which renders the prospect extremely picturesque.

Lieutenant Hamilton says "we first saw the island on the 5th of June, on our passage to the Cape of Good Hope, we had then variable winds and calms: and on making it a second time on the 8th of November we had exactly the same winds and weather, accompanied with a heavy squall of wind from the westward. During our stay there, above two months, the prevailing wind was from N. N. E.: hence I conclude the S. E. trade wind is not to be depended upon, although the island is so far within the tropic of Capricorn.

The American commander, Amasa Delano, visited Trinidad in 1803, and he again describes it as mostly a barren rough pile of rocky mountains. What soil there is on the island he found on the eastern side, where there are several sand beaches, above one of which the Portuguese had a settlement, and have he says done much to work streets or roads over the valleys, levelling down small hills to make the roads good. They had walled in a number of enclosures for the purpose of making fields at the expense of much labor.

This settlement was directly above the most northerly sand beach on the east side of the island, and has the best stream of water on the island running through it. It might be possible, he adds, in pleasant weather to get it off from this place, but we got ours off the south side from the next best watering place or stream. This falls in a cascade over rocks some way up the mountain, so that it can be seen from a boat when passing it. After you have discovered the stream you can land on a point of rocks just to the westward of the watering place, and from thence may walk past it, and when a little to the eastward of the stream there is a small cove between the rocks, where you may float your casks off.

Wood may be cut on the mountain just above the first landing place, and you can take it off if you have a small oak boat. The method in which we filled our water was carrying it in kegs and buckets to the place where we floated our casks on shore.

All the south side of the island is indented with small bays, but the whole is so inclosed a shore, and such a swell surging against it, that it is almost impossible to land a boat without great danger in staving it. The south part is a very remarkable high square bluff head, and is very large. There is a sand beach to the westward of this head, but should caution against landing on the beach till it is well examined; for just at the lower

end of the beach are amongst the rocks which had been the crew shot. The latter were some cats, and some other kinds. A ship must not lose her anchor. The navigation of Martin Vas' rocks do not appear.

Between Cap perceived at son top of one of the

end of the beach and amongst the breakers it is full of rocks, which are not seen till you are amongst them. Where we landed we saw the remains of at least two or three boats which had been knocked to pieces by landing. We found plenty of goats and hogs.—The latter were very shy, but we killed some of them and a number of goats. We saw some cats, and these three sorts of quadrupeds were the only animals we saw on the island. If a ship is very much in want of wood or water, it may be got at Trinidad; or if the crew should have the scurvy, it is an excellent place to recruit them in, as you can get plenty of greens on the S. E. part of the island, such as fine purslane and several other kinds. These, together with the fine sweet water, would soon recruit a crew. A ship must never be anchored at this place with common cables, or she will be likely to lose her anchors; but if she has chains for her anchors, the rocks cannot cut them. The navigation is safe for a ship all around the island within the distance of a mile. Martin Vas' rocks, or more properly islets, lie about east, nine leagues distant, but there do not appear to be any dangers between them and Trinidad.

**MARTIN VAS' ROCKS.**—These rocks, as noticed above, are high and barren. The central one is the largest, and it may be seen from a ship's deck at the distance of ten leagues. When bearing south, the rocks seem nearly in a line. The northern and central rocks are near each other, but between the central and southern rocks is a good channel. Here the *Chesterfield*, in 1800, observed the latitude  $28^{\circ} 28'$ , when she hove to in twelve fathoms, with the largest rock E. N. E. about a mile, the bottom then visible, and caught plenty of rock-cod and other fish. The boat in sounding found the depth decrease gradually over a rocky bottom to a fathom and a half, close to the largest rock.

The north rock is small and most westerly, all are steep and inaccessible; the distance between the extremities is about three miles; that to Trinidad, as already noticed, about nine leagues.

**ASCENCAO, or PORTUGUESE ASCENSION.**—An island distinguished by this name, has formerly been described, and said to be at the distance of about 100 leagues to the westward of the Isle of Trinidad. Doubts have long since been entertained as to its existence, and we have the best reason to believe that they are verified. *La Perouse* in 1785 sought for it without success, as far as the longitude seven degrees west of Trinidad, and *M. Krusenstern*, in 1803, prosecuted the search so much further to the westward, that its non-existence within  $37^{\circ}$  west appears certain. Add to this that the Governor of St. Catharine's informed *M. Perouse* that the Governor General of Brazil had dispatched a vessel in the preceding year, to survey the island, but it could not be found, and it had consequently been expunged from the charts.

Notwithstanding this, it has been said that land was seen by the commander of the Steamer *Telica*, on her passage to Peru in 1825, which appeared to lie in latitude  $20^{\circ} 35'$  and long.  $37^{\circ} 8'$ , or nearly so. At noon the vessel was in or about  $20^{\circ} 20'$  S. and long.  $37^{\circ} 28'$ . The island (if land) bore S. E. by E.  $\frac{1}{2}$  E. by compass, distant by estimation about 8 leagues. But we mark this as very doubtful.

**CONGRESS BANK.**—In *Brackenbridge's* account of the voyage of the U. S. Frigate *Congress* to Buenos Ayres in 1817, it is reported that *Commodore Sinclair* found some extensive rocky (coral) soundings of 35 fathoms, and lost them in latitude  $20^{\circ} 30'$  S. and  $37^{\circ} 30'$  W.

*Description of the Coast between Rio Janeiro and the Bay of All Saints, showing the Anchorage in the Harbor of Espirito Santo, Porto Seguro, &c. &c. and near Capes Frio, Thomas, St. Paul, and St. Antonio, with a description of the banks and small islands of Abrolhos.*

Leaving the bay of Rio Janeiro to proceed eastward, 14 miles distant, E.  $15^{\circ}$  S. of the Sugar Loaf, you will find the two islands of Marice, situated nearly one league from the sea-shore; they are not very high, their southern shore is quite perpendicular, and there is no danger in going near them.

At 14 miles farther N.  $77^{\circ}$  E. of these islands, you meet Cape Negro, which is formed by a hill not very high, adjoining to the highest mountains to be met with between Rio Janeiro and Cape Frio, which, with its dark green tinge, (from which it derives its name,) are quite sufficient to distinguish it. There is not the least danger in nearing it, for even at the distance of three miles, the soundings are from 30 to 40 fathoms, muddy bottom.

The sea-shore from Rio Janeiro to Cape Frio is low and sandy: the mountains which surround that bay run first E. N. E. until you reach the meridian of Cape Negro, and afterward N. E., leaving an empty flat between, over 10 leagues in extent, which is to be seen from the sea in fine weather only.

Between Cape Negro and Cape Frio the land is low, and a few small hills are to be perceived at some distance from the sea-shore, which is there sandy and bushy. On the top of one of these small hills, 9 miles E. N. E. from Cape Negro, stands a church

dedicated to Nostra Dama de Nazereth. At no great distance from the shore a ridge of rocks and sand are to be seen at low water, and considered dangerous by the coasting traders, but without good reason, as there are 30 and 40 fathoms water at 6 miles distant, muddy bottom, the depth increasing very fast toward the sea, and at 10 leagues distance, from 70 to 90 fathoms, bottom sandy, rocky, and muddy.

Though of little importance, it is proper to state that inside the beach, a flat of water can be seen. The depth of the sea near Rio Janeiro is very great, varying from 76 to 90 fathoms, at the distance of 10 or 15 leagues, diminishing gradually toward the land. The bottom is a mixture of coarse sand, gravel, broken shells, rocks and mud. In some charts, S. S. E. from Cape Frio, distant 10 or 12 leagues, from 20 to 25 fathoms have been marked, but we believe it incorrect.

CAPE FRIO, (on which there is a lighthouse with a revolving light, which is visible 2 minutes and eclipsed 2 minutes, and can be seen 40 miles in clear weather,) is the southern end of an island lying on the eastern end of the beach of Maranbaya. This island is rocky; there are trees only in some places, and no where is green grass to be seen. In fine weather it may be discovered from 15 leagues distant. Viewed from E. and N., two different hills are to be perceived on Cape Frio, the northern one of which is the largest and highest, and on the southern one a kind of rock seems to project and hang over. Viewed from the N. N. E. and S. S. E. these two hills appear to be but one with tops, and at a small distance from the cape, in an E. S. E. direction, lies a small island of a conical shape. All this shore is so bold that 30 and even 40 fathoms are to be met in every direction, even at one mile distance, bottom almost every where mud.

Between the island of Frio and the main land there is a good channel for small vessels, and a good anchorage for others of any size. The channel runs N. E. and S. W. It is not frequently used, on account of its narrowness at the southern part, but the depth of water is every where more than sufficient. The northern passage is very spacious and safe against any wind except N. E.; but by anchoring more north toward the Island dos Porcos, you may consider yourself perfectly safe, the anchorage being firm, and often resorted to by coasting traders who wait there for favorable winds, and for a chance to put to sea through the southern or northern passage. In time of war this place may be useful to get information. Var.  $2^{\circ} 3' E.$  1819.

The northern part of the coast of Cape Frio, together with the islands, runs N.  $35^{\circ} E.$  up to Anchora Islands, and forms with this last a deep bay, in the inside of which stand the numerous islands of Papagaros; several of them afford very safe anchorage in case of contrary wind.

The island of Ancoras stands at 4 miles E.  $\frac{1}{2}$  S. from Cape Busios; the eastern one has the appearance of a quaker's hat. I do not doubt, as reported by native mariners, the practicability for a large ship to pass between them and the main land.

North of Cape Busios lies the small island of Branca, from whence another beach extends to the Morro San Joao or San Joam, and at no great distance the island of Feno. The land now runs easterly up to Cape St. Thomas. This gulf, formed by the coast between the Capes Busios and St. Thomas, is very near 30 leagues in extent, and in the middle of it, at 3 leagues distance from the shore, lies the island of Santa Anna.

The Morro San Joam is easy to be distinguished, being entirely separated from the chain of mountains lying in its rear, and its top having a warlike appearance.

At twenty miles N.  $\frac{1}{2}$  W. of Morro San Joam, another hill is to be perceived, which offers this particular, that its northern side is quite perpendicularly cut, and its top ends in a sharp point. It is known by the name of Father de Macaye, or Macahe.

The islands of St. Ann are three in number. Viewed from S. S. W. and N. N. E., they appear as one only. The southern one is the highest. The anchorage in the channel is one of the safest and most convenient for any kind of repairs, and to refit vessels of any description. Good water and timber are to be found, and at the distance of four to five miles from the shore, there is, in every direction, from 19 to 30 fathoms of water, and a good mud bottom.

From the parallel of the island of St. Ann up to Benevente, which stands in latitude  $20^{\circ} 53' 50'' S.$ , a flat land projects considerably into the sea. That low land is known by the name of Granes. Some navigators bound to Rio Janeiro, state that they have been deceived by the similar appearance between the coast north of Cape Frio and the coast forming the bay of Rio Janeiro. Such an error appears very extraordinary, for the entrance of Rio Janeiro is on the angular point of two chains of mountains, the eastern side running E.  $\frac{1}{2}$  N., and the western side running W. S. W.; whereas the land north of Cape Frio runs N. and S., which is quite an opposite direction. On the whole, a single observation will relieve the doubts in that respect.

CAPE THOMAS.—From the island of St. Ann to Benevente End, the land extends more and more to the sea; and at Cape Thomas the mountains appear to be thirteen leagues from the sea shore. This part of the Brazilian coast is very low; a few trees

and small sand-hills seem as buried in the sea water. This beach extends far in the sea, and forms what is called the banks of Cape Thomas. The chart shows how far the shallow water extends. At the distance of five miles we found from 10 to 21 fathoms, increasing regularly towards the sea. By keeping fifteen miles from the shore there is not the least danger.

Though some coasting traders state that places on the banks are to be met with, having 2 or 3 fathoms of water only, yet the pilot we had on board thinks differently, and nothing has been perceived by us to indicate such a shallowness.

The nature of the bottom near Cape Thomas is not of a muddy nature, but white sand and broken shells. It should here be observed, that this white sand, which extends so far north, appears to begin only there, and is never met with farther south.

At a short distance from Benevente you meet, in succession, the Barra Guarapaya, (Bald Island,) La Rosa, and the small islands of Guarapari.

The River Guarapari empties into the sea between two hills covered with trees. On the top of the southern hill there is a church with a steeple, many houses, and cocoa trees. The other hill is called Perro de Cao. To proceed up the river, it is necessary to keep Guarapari Hill N. W.

The surrounding coast is tolerably high, and every where covered with small trees, and in several places a yellow steep beach not perceived to the southward of Benevente. The mountains in the interior deserve particular notice, being of a conical shape, and appearing to incline on one side, which is not to be observed the south or north.

ESPIRITO SANTO.—The Island Calvada lies 4 miles distant from the shore. There is no danger passing in the channel, being from 12 to 20 fathoms water. Outside this island, and off the Island Rosa, the depth varies from 12 to 20 fathoms up to Espirito Santo Bay. Keeping at the distance of 2 to 7 miles from the shore, at nearly two thirds the distance from Guarapari Santo, you meet the rocky island Jien, and a little farther distant the Pacotes rocks, which indicate the entrance of the bay of Espirito Santo. The particulars which distinguish Espirito Santo Bay, are Monte Moreno and Mertue Alvara. Monte Moreno is a mountain on the southern end of the bay, its northern base forming the southern entrance of the river of Espirito, is of a conical shape, covered in part with wood; no green grass to be seen on its eastern side, and may be discovered 10 leagues distant. Vessels going up the river must range along it at no great distance. The two Pacotes rocks stand  $2\frac{1}{2}$  miles, and are of unequal size. The inside channel is used only by small vessels.

Nearly one mile distant from Monte Moreno, S. 60° W., stands the Morro de Nozza, (Sembora de Porcia,) a rocky hill with little wood. The church, which is built on its top, can be discovered 5 leagues distant. What distinguishes the hill called the Mastre Alvaro, is its great height on a low ground, appearing as entirely separated from the other mountains.

The greatest part of the bay of Espirito Santo is occupied by two islands, in a direction N. N. W. of Monte Moreno. Though the space between this island and the mountain appears to be wholly obstructed by banks, and the two rocks, the Balea (the Whale) and the Casello, (the Horse,) yet a vessel not drawing over 16 feet water may easily go through there without danger, as you will not have less than 18 feet water. The anchorage we occupied in the bay of Espirito Santo was not the best one, because we had no knowledge of a submarine rock not more than two cables' distance from us, where, from time to time, the sea was breaking. The safest place to anchor is the one pointed on the chart, with an anchor.

Espirito Santo is of some importance to navigators. At one league's distance from the city of Victoria, there is good water. Wood and cattle can be got in plenty, and cheap. The climate appears unhealthy, being extremely damp. A rock called the Pao de Hanuar, (Sugar-loaf,) about 2000 yards from the city, is of some service to mariners, as you steer in its direction after weathering Monte Moreno, if you intend to get into the river. The tides are not more than 4 feet, and are regular but in the inside of the bay.

The coast north of Espirito Santo is low and covered with trees; and the shore, which runs N. 32° E. from the Tubaron (the Shark) up to the bar of Rio Doce nearly 16 leagues distant, is of a yellow red color.

From Rio Doce (Soft River) the coast runs north and south up to the bar of San Matheo, a distance of 20 leagues. The country in the interior does not appear so low as the sea shore, but from Rio Doce to Mount Pascoal the country is very flat. There is consequently no more difficulty in recognizing Espirito Santo Bay when coming from the south or from the north, as in the first instance Mount Mastre Alvaro comes next to the flat land, and in the second instance it ends a land tolerably high.

The shore from Tubarao end up to San Matheo, may be approached every where at the distance of 2 or 3 miles. From 9 to 10 fathoms water are to be found at such a distance, bottom sandy, sometimes muddy, and with broken shells.

It is reported Rio Doce runs far in the interior, but its mouth does not admit of large vessels. It is to be observed here, that the numerous islands pointed out in some charts, as existing at its mouth, is not correct.

The bar of Rio Seca lies ten leagues north of Rio Doce. Rio Seca is a stream only in the rainy season. Two miles east of Rio Seca we found no variation in the compass, July, 1819.

The bar of San Matheo is 10 leagues distant from Rio Seca. Being far at sea, this bar may be distinguished by the breakers of the sea, which are greater than on the surrounding places. The shallowness of the water, the impossibility for a ship to cross over the bar, and above all, the little benefit to be derived from this place, are more than sufficient reasons to keep at a distance from it.

**ABROLHOS.**—At a distance of 4 to 5 leagues from San Matheo, in a northern direction, and at 3 to 4 leagues from the land, the soundings begin to indicate the shallow water of the Abrolhos. This shallow place may be considered to extend north and south from 18 to 20 leagues, and east and west not less than 20 leagues; and though the whole extent is not to be considered equally dangerous, yet a vessel not particularly bound to this place, will do well to keep away from it.

The Abrolhos Islands, or Sante Barbara Islands, are four in number, not including two or three flat rocks. The two northern islands are the highest. The western one is nearly 130 feet above the sea; the other 115. They may be perceived from the top of a frigate in fine weather, from 20 leagues distance.

Nothing is to be found on this island except some reeds and cactus. Numerous tribes of birds inhabit them. A few turtles are to be met with. Fishes are in plenty, and the fishermen of Porto Seguro repair there to fish, and dry what they call garoujas. This is consequently the only thing a vessel can expect thither.

We have already stated that the whole extent assigned to the shallow water is not every where dangerous. In the same extent, by our observations and soundings, it appears that from the E. S. E. up to S. by N., and W., large ships may approach from 1 to 8 miles, in fine weather. The only part we had no chance of sounding, and which remains consequently doubtful, is that part comprised between the S. and S. S. E.

West of this island there is a channel, of nearly 3 leagues wide, where the soundings show from 10 to 15 fathoms, except in a few places where it shows only 8 fathoms. The western side of this channel is formed by more shallow water, called the Paredas, (or Walls,) which is very dangerous. According to the report of the native mariners, the tides are irregular on the Abrolhos; the current runs according to the wind, and does not run over  $\frac{3}{10}$  of a mile an hour. The sounding shows no mud over the whole extent we ascribed to the shallow water of Abrolhos, and if any is to be perceived, it is a certain sign you are no longer there. The nature of the bottom in the Abrolhos is white sandy stone, mixed with broken madrepora\* in a powdered state. Sometimes that sandy gravel is very firm and combined with sand and rock, particularly in the N. E. direction. In the direction of S. S. W. or N. E. by W., the bottom is very firm and like tough mortar, in which the anchors have a good hold, though they enter very little into it. We have no correct information respecting the Paredes, which are stated in the chart, according to the saying of the native mariners, beginning at the bar of Portalegra, and ending at Alcobaca.

*Extract of a letter from Capt. Fitzroy, of H. M. Sloop Beagle, to Capt. Beaufort, R. N. on the subject of the Abrolhos Banks,† dated "Rio de Janeiro, April 10, 1832.*

"On the 18th March we sailed from Bahia, and worked our way slowly towards the eastern limit of the Abrolhos Banks. The winds, being light and easterly, favored our soundings frequently, and taking good observations.

"Having reached the parallel of the islands, to the eastward of the easternmost soundings laid down in the charts, and finding no ground with 300 fathoms of line, I began to steer westward, sounding continually, and keeping a sharp look out at the mast-head. At 2 P. M., on the 26th, we had no bottom with 230 fathoms, and at 4 P. M. we found only 30 fathoms, without the slightest change either in the color of the water or in its temperature, or any indication of so sudden a change in its depth.

"I directly hauled to the wind, and worked back again to the eastward, to have another opportunity of confirming the place of the edge of the bank. We lost soundings suddenly as we found them; and in standing to the westward a second time, with a grapple towing astern by 200 fathoms of line, we hooked the rocky bottom, and straightened the grapple: but my object in ascertaining the exact beginning of the bank was gained.

\* Every kind of stone supposed to be formed by insects, is called by the French, madrepora.

† From the Journal of the Geographical Society.

"From that spot we had soundings in less than 40 fathoms, until we anchored near the Abrolhos Islands.

"I passed to the southward and eastward of them, because that side had not been examined; but time would not allow of my doing what I wished while so favorable an opportunity offered.

"At least a fortnight would be necessary to complete the survey of Baron Roussin, which appears, so far as we have examined, to be extremely correct. The soundings are so irregular, that little dependence can be placed on the lead. It is only by a multitude of soundings, by watching the sea when there is much swell, and traversing every part, with a sharp look out at the mast-head, that the neighborhood of the Abrolhos, particularly to the south-east, can be thoroughly examined.

"More than once we had four or five fathoms under one side of the vessel, and from fifteen to twenty under the other side. The *sauts de sonde*, as the French express it, are surprising.

"The tide, or rather current, which we experienced, set continually to the southward for the three days we were near these islands, varying from half a mile to a mile and a half an hour.

"I supposed that the bottom was chiefly composed of coral rock, but was surprised to find no coral excepting small fragments growing on the solid rock, which is chiefly gneiss and sandstone. As the charts say '*coral rock*,' I have sent a few of the soundings for your inspection; and you will see by them that what has here been called coral, is the coating of a solid rock, formed by the deposit of the sea-water, mixed with coralline substances, and what a sailor generally calls '*barnacles*.'

"My meridian distance of the Abrolhos Rocks from Bahia, their latitude, and their size, agree precisely with those given in the French survey; but between Bahia and Rio de Janeiro, and consequently between the Abrolhos and Rio de Janeiro, there exists a difference of from four to five miles between us, this being the only point on which I have found any such difference, either on this or on the Beagle's former voyage.

"Having made both passages, I venture to observe, that going within the Abrolhos certainly shortens that between Rio and Bahia very much; but yet I should not recommend it to any vessel unless she has reason to make unusual haste. The soundings are very irregular, varying suddenly from 20 to 6 fathoms; and there are both reefs and currents."

The little city of Prado lies on the mouth of the river Incumen, a very deep cut amongst the trees, which are numerous on the shore, at the place where the river discharges into the sea. There is no danger near the mouth; even at three miles there are from 10 to 14 fathoms of water. This depth remains the same as far as the village of Columbiana, situated E. S. E. of Mount Pascal. Mount Pascal is to be perceived even from the Abrolhos.

E. by S. 28 miles from Mount Pascal, in a direction north and south, and at 12 miles distant from the coast, the water is very shallow, intermixed with rocks. That dangerous place is called the Itacolomis, and runs E. S. E. and S. by W. There is not the least danger by keeping away 13 miles from the shore, and when north of Mount Pascal the land may be neared to 3 miles, the depth being from 11 to 24 fathoms.

Mount Pascal, as we stated before, is the highest of the mountains perceived from the Abrolhos. The chain it belongs to runs nearly S. E. and N. W. The southern part of this mountain seems as if a large square tower had been built on its top. Viewed from the east, Mount Pascal appears of a conical shape, and being the highest of the whole, it cannot be mistaken.

The shore from Villa Prado up to Mount Pascal runs N. 10° E. It is low, woody, and its general appearance is very much like the shore between Itacolomis and Mount Pascal; it differs only in its yellow red colors. This red color increases more and more towards Porto Seguro, and the shore more high, and steep, and the cow-tree is more numerous amongst the trees which cover the land. If going along the coast, you will pass in succession the bars of Gramminau, of Joasima, of Frade, the small bay of Tranoso, and the church of Mossa. In Senhorada Judea, distant only two miles from Porto Seguro: the walls of that church being perfectly white, it is perceived amongst the trees at some distance; there is a small river which empties in the harbor of Porto Seguro; on the bar there are 18 feet at high water, and only 11 inside: moreover, there are many banks, extending very far; taking the whole together, Porto Seguro is not a good place for vessels of small size, and of no use for large ones.

From Porto Seguro to Rio Grande, there are twelve leagues distance; the coast runs N. 14° E. very woody; sandy banks and shallow water, are to be found at three miles distance. A new city called Belmonte, stands on the southern bank of Rio Grande: there are but two fathoms of water on the bar.

From Belmonte to Fort St. Georges dos Ilheos, there are twenty leagues distance, steep shore and equally woody; depth of water from seven to twenty fathoms: and at 5 miles distance, muddy bottom and broken madrepore. At half the distance from Belmonte to Fort St. Georges, you meet the Seras de Itaraca, a group of mountains on which terminates the flat country beginning after Mount Pascal; the southern mountain bears the name of Commandatuba, from which the small river derives its name. From thence up the bay of All Saints the coast offers the finest prospect, being well cultivated in the valley, and the small hills covered with wood.

From Fort St. George, up to the two Castelhanos Ends, 19 leagues distance, the coast is perfectly secure: the largest ships may approach it within two miles, without the least danger.

The Dos Castelhanos Ends, belong to a high land joining to Ponta de Muta, at the extremity of which stands the small island of Quipe. The Muta point and the island of Quipe form a kind of basin, into which empties the small river Acarahi, at a short distance from the small town of Camamu. The breakers which obstruct the bay, do not permit vessels to go into it.

Beginning at this place the coast seems divided into two, and appears like two islands. This appearance is produced by the low land existing between the two hilly parts, and remains the same, till you arrive at cape or Morro San Paulo.

Morro San Paulo, from the east end of the bar of Uha's River, may be very easily distinguished, though not very high, being higher than the highland, which stands on its rear, in the northern direction; there is on its top, two separated groups of cow-trees very apparent. Morro San Paulo offers this particular, that when near it, the green verdant color of its top seems spotted on the northern side with large white stains: in fine weather these white stains may be seen from fifty-four miles distance. Two miles east of Morro San Paulo there are 17 fathoms, with good muddy bottom. North of San Paulo the coast is low, sandy, and a reef of rocks runs along within a short distance of it. This coast appears at first connected with the island of Tamaraica; but the land on this island is higher: the space between the western side of Itaporica Island, and the main land, forms what is called the false entrance of Bahia. This channel is very crooked, narrow, and too difficult to admit vessels to pass.

A vessel may steer in a straight direction from Morro San Paulo to Cape St. Antonio; but if the wind blows too strong towards the land, it is better to keep a little more to the N. W. until the eastern point of Tamaraica Island stands north of you.

*Description of the Mountains and other objects which show your approach to Rio Janeiro.*

At the eastern end of the beach of Maranbaya stands the large point of Guaratiba, where begin the high mountains which surround the Bay of Rio Janeiro. From this point, in clear weather, the Island Redonda (Round Island) can be seen, although eight leagues distant. That island stands at the entrance of the Bay of Rio de Janeiro, and is easily distinguished by its round shape, and by the green and white color of its shores. From the same point the mountain called the Gabia, or Main-top, which by its peculiar shape cannot be confounded with any other, and is, by this reason, the surest mark of Rio de Janeiro. When arrived near Round Island, there is not the least difficulty in reaching Rio Janeiro. It is unnecessary to undertake the course towards that place, unless you are sure to reach it before night time, and for that to wait for the sea breeze, which generally begins at 12 or 1 o'clock.

Some say that it is better to make land near Cape Frio, when bound for Rio Janeiro; though it will do well for vessels coming from the north or east, yet in every other instance, it will be wasting time.

The Grand Island, the Morro Maranbaya, and particularly the Main-top Mountain, are the surest guides for nearing Rio Janeiro, as they may be seen at a great distance, and no fear in nearing the land.

There is something peculiar which distinguishes the appearance of the Bay of Rio Janeiro from every other place. When coming from the E. S. E. up to the S. W. the tops of the mountains bear a perfect resemblance to a man lying on his back, in a direction W. S. W. and E. N. E., the Mount Main-top seeming to form the head, and Mount Sugar-loaf the extremities of the feet.

The Main-top Mount is flat on its top, and seems not so large at its base as at its top, from whence it derives its name. Eight miles distant from the mountain lies the Paçoá-sucar (Sugar-loaf) Mount, a large rock, which, although generally indicated as the best mark to ascertain the bay of Rio Janeiro, is not so, according to my observations, being not so high, so distinct, or so near the shore, as the Main-top Mount. It offers this particular, that its shape is very conical, and it appears above all the other mountains of a like shape around it, and it seems to incline a little towards the N. W.

It is very prudent to keep at some distance from the shore, when navigating between

Rio Janeiro and in like manner when it blows stronger in the afternoon.

We must stand at the head of the harbor, situated, in the middle of the harbor.

To enter the harbor of Rasa\* (Bare) is 12 miles from the bold shores, between the 23 fathoms. The end of the mountain during 7½ miles situated at the head of the bay, passed on your way to the Round Island, half mile distant from the head of the bay, keep at a proper distance, the water is 7 fathoms deep, few yards from the shore.

The way we enable you to put to sea, the flat island thirdly, to come to anchor.

The passage is, and the one of water, but it is safe, in case of a storm.

When at 60 fathoms anchorage is N. W. pass at only 60 fathoms, (Rat Island) in from 10 fathoms.

If you draw that line will see the best for you, drawn from Rasa, is near the city, are separated from the pass, and over the sea.

The sea and breeze begins in the morning; a calm commences.

Vessels going to Rio Janeiro, it is best to take the breeze, which, from the islands, and reach the city the day after, to sea the day after, be better to cast anchor.

*Description of the*

VOLAGE H. 12½ to 14 fathoms.

\* On Rasa Island.  
† A fixed light.

Rio Janeiro and Cape Frio, because the sea-breeze blows generally towards the shore, and in like manner the waves generate a current, having the same tendency, particularly when it blows from S. W., and then in case of a sudden storm, there will be some danger in the anchorage, not being there very safe.

We must repeat that it is very prudent never to approach too near the islands which stand at the entrance of the bay of Rio Janeiro, except in case you are certain to reach the harbor during day time; for if engaged amongst them you may be dangerously situated, in case of a squall of wind, which is often the case; then if not enabled to reach the harbor in daylight, it is better to put to sea again.

*Directions for going in and out of the Harbor of Rio Janeiro.*

To enter the harbor of Rio Janeiro it is preferred generally to pass between the Island Rasa\* (Bare Island) and the Island of Para, (Father and Mother,) the first one nearly 7 miles from the Sugar-loaf, the two last  $5\frac{1}{2}$  miles N.  $41^{\circ}$  E. of Bare Island. They have bold shores, and may be approached very near; and even if necessary a vessel can pass between them and the shore. The depth of water between these islands is from 13 to 23 fathoms. Standing one mile abreast of Bare Island, you must perceive the western end of the most western island (Paya) N.  $47^{\circ}$  E. from this point. Direct your course during  $7\frac{1}{2}$  miles N.  $5^{\circ}$  E., until you arrive at 800 yards west of the fortress of Santa Cruz, situated at the eastern extremity of the entrance.† During that course you will have passed on your larboard hand several small rocks and small islands, which lie between the Round Island and the land on the Main-top Mount side, and you will pass at one half mile distance from the small island Toucinho, (Ham Island,) which is not far distant from the Sugar-loaf Mount. There is not the least danger. You have only to keep at a proper distance from the rocks which are to be seen. The least depth of water is 7 fathoms at the entrance; but when in the harbor it increases very fast, and at a few yards from the Santa Cruz Battery there are over 12 and 16 fathoms.

The way we prescribe to go into the harbor possesses many advantages. First, it enables you to approach the Santa Cruz fortress sufficiently near to answer the questions put to you by the guard; second, to keep the ship at a reasonable distance from the flat island lying in the middle of the entrance, on which is built the Fort Lage; and thirdly, to correct the effect of the current, which sets towards the N. W. with the tide.

The passage between Fort Santa Cruz and Fort Lage is the only one used in passing, and the one formed by San Joao Point is never used; not on account of deficiency of water, but because it is narrower, more crooked, and the bottom being rocky, is not safe, in case of necessity, to anchor. They say the passage through it is prohibited.

When at 600 yards distance west from Fort Santa Cruz, the course to reach the best anchorage is N.  $35^{\circ}$  W. until you arrive E. N. E. of Fort Villegagnon, which you may pass at only 600 yards distance. From that place you will steer toward the Island dos Ratos, (Rat Island,) and now, being in sight of the city, you may choose your anchorage in from 10 to 20 fathoms.

If you draw a line from the flag of Fort Villegagnon to the Cobras (Snake) Island, that line will separate the anchorage for vessels of war from that of the merchant vessels. The best for vessels of war is towards the E. N. E. of the palace, and south of a line drawn from Rat Island to the main church in the city, and the best for merchant vessels is near the city. The largest reach that place by passing north of Snake Island, and they are separated from the vessels of war by a bank, or shallow water, where boats only can pass, and over which the sea is constantly breaking at low water.

The sea and land-breezes are regular, and each last one half of the day. The land-breeze begins in the evening, continues during the night, and stops at nine or ten in the morning; a calm of one hour generally succeeds it, and at about eleven the sea-breeze commences.

Vessels going to sea will follow the course opposite to that pursued when going in. It is best to take your departure in the morning, in order to take advantage of the land-breeze, which, lasting 3 or 4 hours during daylight, enables you to clear all the small islands, and reach the open sea. Vessels used sometimes to go at some distance from the city the day previous to their departure, in order to have a better chance of getting to sea the day after, with the land-breeze. In case the breeze should subside, it would be better to cast anchor.

*Description of the Coast comprised between the Island of St. Catharina and the Bay of Rio Janeiro.*

VOLAGE BANK, on the coast of Brazil, lat.  $26^{\circ} 44'$  S., long.  $48^{\circ} 15'$  W. Soundings  $12\frac{3}{4}$  to 14 fathoms.

\* On Rasa Island there is a lighthouse with a revolving light.

† A fixed light is exhibited on the fortress of Santa Cruz.

His Majesty's ship *Volage*, on her way to St. Catharines, on the coast of Brazil, in September, 1832, struck soundings in 14 fathoms, mud, on a bank which is not laid down on the charts in the above latitude and longitude, calculated from the noon observation. From thence, while the ship was sailing two miles west by south, bottom was found with 14 to 12½ fathoms; after which, on steering W. and W. S. W., the water deepened suddenly to 23 and 29 fathoms; and these depths were preserved until the island of Anhero, at the north end of St. Catharines Island, was passed.

The above position of the shoal depends on that of Fort San Jose, which was considered to be in lat.  $27^{\circ} 26' 30''$  S., and long.  $48^{\circ} 39'$  W. The variation was found to be  $7^{\circ}$  easterly. Roussin passed inside of this shoal, and does not lay it down.

**FROM RIO JANEIRO TO THE RIVER PLATE.**—On quitting Rio Janeiro, the shore bends W. by S. towards the great Point of Guaratiba, where the range of mountains terminates which surrounds the Bay of Rio Janeiro. From this point you may in fine weather clearly perceive Redonda, or Round Island, distant eight leagues, which island is distinguished by its form, and the deep streaks of white and dark green which slope down on every side. You will also discern La Gabia at the distance of 6 leagues, bearing E. N. E., which is a remarkably formed mountain, as already described, and cannot well be confounded with any other. It therefore is the most certain mark for Rio Janeiro, particularly when coming from the southward.

From the Point of Guaratiba, a W. S. W. course will lead along the low land of Marambaya, the western point of which terminates in a little hill, called the Morro de Marambaya, at the entrance to the Bay of Ilha Grande. The eastern point of the Praya de Marambaya, or Marambaya Island, is separated from the land of Guaratiba by a small channel, which boats only can enter. This island occupies a space of 8 leagues E. and W. It is very low, and you must not approach it without the greatest caution, especially when the weather is not clear. This circumspection is the more necessary on account of a rock, surrounded with shallow ground, which projects 3 miles to the southward from the coast, about midway. By keeping about 4 miles from the coast at this part, you will have from 22 to 30 fathoms water, with a bottom of sand and gravel.

**BAY OF ILHA GRANDE.**—The great Bay of Ilha Grande, formed between the continent and the island of this name, has two entrances. The western one is bounded by the Point of Joatinga and the Island of Grande; the eastern one by the same island, and the promontory or low land of Marambaya. Either of these entrances conducts you into the bay, which is calculated to receive the largest vessels. The pilots say, "whole fleets may enter there, and find shelter from every wind. The soundings vary from 30 to 7 fathoms in the greatest part of the bay, and you may readily procure wood and water from many parts of the coast."

At the distance of 2 miles from the south part of Ilha Grande is the little island of Georgi Gresco, which has a barren appearance, but will furnish you with both wood and water. The largest vessels may find anchorage on its northern side, and refreshments may be procured at the little village of d'Angra dos Reos, which is there situated.

It does not appear that Baron Roussin penetrated into the interior of the Bay of Ilha Grande; and the information Europeans at present possess of this bay is very imperfect.

This bay is bounded on the N. E., and also on the S. W., by the main land, comprehending a length of full 60 miles, and is studded with numerous islands and places of anchorage, having many villages on the northern shore. The Eastern or Marambaya Channel, leading into this bay, is 8 miles wide, and may be known by the single ball mountain about 700 feet high, which stands on the low point of Marambaya. The sandy flat, or island of Marambaya, is about 20 feet above the level of the sea. In most parts, especially near the middle of the island, it is quite barren; in others it is covered with various creeping plants, which keep the soil together. It exhibits on its summit a little brushwood, and at its northern extremity some mangroves. Towards the sea it is steep, and the surf breaks with violence against it; but towards the bay it is level and smooth. This latter side abounds with shell-fish and sand-larks. The herbage shelters many armadillos, and there are numerous deer and other animals of chase. There is a church, and some few springs of good water.

The Island Grande, which bounds the western side of the channel, is 14 or 15 miles in length, and lies in the centre between the two channels. The Western, or Gaioso Channel, is 3 leagues wide, and both channels have deep water within them. On entering this passage there are said to be several small bays at the western shore; and in entering the eastern channel there are also the bays of Palmas, Albroo, and Eschella, all situated on the eastern side of the Isle of Grande. Palmas Bay is reported to have good anchorage, inasmuch as a vessel may lie landlocked within it, and ride in 6 or 7 fathoms water. The other two are smaller, and have a depth of 5, 6, and 7 fathoms.

The following directions are from the Journals of Mr. Bruce, Master of H. M. Ship *Diamond*, in 1826:—

"The western channel between the Ilha Grande and Joatinga Point may readily be known by a remarkable hill inland, called the Friar's Hood; this you should endeavor to bring N. by E.  $\frac{1}{2}$  E., and then steer towards it until you get within  $2\frac{1}{2}$  miles of the Point. Keep at this distance from the island, in order to avoid the sunken rock, which is laid down in the chart about mid-channel: we kept about 2 miles off, and saw a great number of islands over towards the main. After passing Starling Point, we perceived a low and barren island, lying about  $1\frac{1}{2}$  mile from Ilha Grande; this we left on the starboard side, carrying 9 and 10 fathoms close to it. We then discovered what is called Terville Island, and also the Town of Villa Grande; steered for the Island Terville, and had no where less than  $6\frac{1}{2}$  and 7 fathoms. Green Island lies so very close to Villa Grande, that until you get close to it, it cannot be distinguished as an island. We left this on the starboard side, and Terville Island on the larboard, and had 9 and 8 fathoms between them; kept close to Ilha Grande, until Gabia Grande was distinctly perceived; then steered towards it, gradually deepening our water to 12 and 13 fathoms." Mr. Bruce observes, "I have no hesitation in saying the whole of these islands are laid down too far to the westward in all the charts: for if they had been correctly delineated, we must have seen Barren Island, Ekam and Green Islands, the moment we rounded Starling Point; instead of which, they were not visible until we had passed Vermeille Point, so that they must be nearer to Eschella Point. We rounded close to the Island Gabia Grande in 9, 10, and 11 fathoms, and then steered for the cluster of islands which lies round Jagenos, or Jagenos Island, and came to for the night in 14 fathoms, sandy ground, the extremes of the islands bearing S. E. and N. E. by E., distant  $1\frac{1}{2}$  mile from the shore. We passed through between the islands Fortada and a small, low, round, and well-wooded one, which lies nearly west, distant 2 miles from the former, in 16 and 17 fathoms water. This is a very safe passage with a leading wind; but due east from the woody island a dangerous reef runs off about the length of 3 cables, upon which are only 12 feet water; this therefore must always be carefully guarded against.

"The best, most common, and by far the safest passage to Sapatiba, is by keeping the main land on board, leaving the whole of the Islands of Tacruen and Madeira on the larboard side, and those of Jagenos on the starboard: you will then have 10 and 9 fathoms of water until you get abreast of Madeira; it then gradually shoalens towards the anchorage of Santa Cruz, off which we anchored, with the following bearings:—Madeira Island W. by N.  $\frac{1}{2}$  N. distant  $2\frac{1}{2}$  miles; Tacruen Island W. by S.  $\frac{1}{2}$  S.; entrance of Tagna River N. W.  $\frac{1}{2}$  N., distant  $1\frac{1}{2}$  mile; Mount Marambaya S. W., and Point Sapatiba E. by S.  $\frac{1}{4}$  S. in  $5\frac{1}{2}$  fathoms, muddy ground.

"In sailing from hence, we kept the main land on board, and when we were between the Islands of Gabia Grande and Fortada, caught a westerly wind. You may stand towards Gabia Grande into any depth you choose; but you must be cautious in approaching the shores of Marambaya. Stand not into less than 10 fathoms, lest you get upon the reefs on that side; you will have 15, 17, 10, and in two casts only 5 fathoms; then, before you get the ship round, you will be in 4 fathoms: with the above soundings, Gabia Grande bore N. N. W., and Point Marambaya S. by E. It appears by the water having shoaled gradually when standing towards the reef, from 17 to 15, 10, and 7 fathoms, that the western edge of it lies with Point Marambaya S. E.  $\frac{1}{2}$  E., and Gabia Grande N. E.  $\frac{1}{2}$  N.

"The Marambaya or Eastern Channel, is upon the whole very safe, and may be navigated with common prudence, with very little danger. Should the winds be light when you get within Point Marambaya, and the flood or easterly current is making, you should not bring Gabia Grande to the northward of N. E. or N. E.  $\frac{1}{4}$  N., for the tides set strongly over Marambaya Reefs, and there are plenty of places for anchorage."

Point Joatinga, which is the western point of the Gairoso Channel, has a small islet before it. This island, according to Baron Roussin, lies in  $23^{\circ} 18' 30''$  S. and longitude  $41^{\circ} 39'$  W. This Point, with that of Carioca, terminates the southern part of the high land which forms the vast Bay of Ilha Grande: both are very lofty, and may be approached with safety by all sorts of vessels.

From Point Carioca the land runs W.  $23^{\circ}$  S. about 9 leagues towards the Islands of Porcos: this group comprehends an island somewhat high, and is accompanied by three other smaller ones: one of these lies to the southward, the others to the eastward. The pilots assert "that between this island and the continent there is a very fine channel, through which large vessels may pass, and anchor in perfect safety. You may at many parts of the coast procure wood and water, also cattle and other necessaries; but you should not attempt this passage without having the advantage of a fair wind."

Mr. Bruce says, "When I was near the shore about the Island of Porcos, I took the following bearings of a very interesting cluster of islands; between the whole of which there appear to be good and safe passages, with excellent anchorages inside, sheltered from all winds. The Island of Porcos bore S. W.  $\frac{1}{2}$  W. distant 12 miles; the first or

inshore island about half a mile from the main, and situated abreast of a very fine sandy beach, N. by E. distant three-quarters of a mile; second island N. E. by E. distant 1 mile; a rock which is 10 feet above the level of the sea, E. N. E. distant  $1\frac{1}{2}$  mile; and an island, which appeared to be  $2\frac{1}{2}$  miles in length, and forming a sort of cape to this little bay, E. by S. distant  $3\frac{1}{2}$  miles; with 6 smaller islets inside of it, running to the N. eastward in a semicircular form.

Mr. J. Engledue, of H. M. Ship Bedford, observes, "The bay in Porcos Island forms a good roadstead, being sheltered from all winds, except those from the N. E. to the E. by N. which seldom continue long enough to occasion a sea of any consequence; it may therefore be considered the best and safest of any on this part of the coast. There is no regular tide, and the water does not rise or fall above 1 foot. Shark's Road also has good anchorage with all winds except those from the southward, which occasion a heavy tumbling sea, and render large vessels unsafe."

**SAINT SEBASTIAN'S ISLAND.**—Point Pirasonungo, \* which is the S. eastern point of the Island of St. Sebastian, bears from Redonda Island W. S. W.  $\frac{1}{2}$  S. distant  $40\frac{1}{2}$  leagues, and from the Point Cariocu S. W.  $\frac{1}{2}$  S. distant 49 miles. It is about  $4\frac{1}{2}$  leagues in diameter, and the mountains are as lofty as those upon the main land, from which it is separated by a narrow channel. This island is visible 15 leagues off in clear weather: the shores are very steep, the south point projects sensibly, and the coast turns directly to the E. S. E. so far as the S. S. E. point of the island. The eastern coast runs nearly in the direction of the meridian. The whole island is in the form of a triangle, and the coast opposite to the continent forms with it a strait, or channel, with deep bays, where you will find excellent anchorage on a bottom of mud, having from 5 to 8 fathoms. "While mentioning the qualities of the soundings," says the Baron, "I may observe that on the Coasts of Brazil, muddy ground is most always to be found near the highest lands."

Many islands, or groups of islets, situated to the northward of the Island of St. Sebastian, contribute to shelter the vast basin which the island forms with the continent. The most contiguous is the Island of Victoria. Six miles E.  $28^{\circ}$  N. of Victoria are the three little Islets of Buzios; and 11 miles N.  $15^{\circ}$  W. of these lie the Porcos Islands, already noticed. The passages between these islands have water sufficient for the largest vessels, like that between the Island of St. Sebastian and the main: however, the passage between Victoria and St. Sebastian's being contracted by a reef, which stretches 2 miles to the S. S. W. of the former, it is somewhat hazardous for large vessels to pass through it.

**THE STRAIT OF ST. SEBASTIAN** is formed between the island and the continent, and offers a safe and commodious port for the largest vessels: its general direction is N.  $30^{\circ}$  E. and S.  $30^{\circ}$  W., but this course cannot be followed exactly throughout the strait, on account of the banks which run out from the continent two thirds of its length from north to south. Vessels coming from the northward, and leaving a point situated half a mile from L'Armacao, which is built at the head of the northwest side of the island, should first proceed S.  $16^{\circ}$  W. for about 5 miles, and then S.  $45^{\circ}$  W. until they get out of the strait. In this passage, which is about 11 miles in length, the least water will be 10 fathoms, but more frequently from 15 to 20 fathoms, the ground being always of mud, which holds well. The greatest breadth between the island and the main is about three miles, and this is at the northern entrance; but two thirds of this space is occupied by the banks just mentioned, over which there are not above three fathoms water; so that you must range along the shore of St. Sebastian's Island, at the distance of 500 or 600 fathoms.

The southern entrance is much narrower: nevertheless, all the natives assure you that the largest ships may navigate it, by only following the direction of the channel. You could not wish for a harbor more tranquil than this of St. Sebastian; for, environed by high land, the vessel rides on water which is as smooth as though it were in a basin.

You will find at St. Sebastian the advantages of a good supply of cattle, poultry, arrack, and other provisions customary to the countries situated within the Tropics. You may obtain these very easily, and at moderate prices, either at the two principal establishments, or at the habitations of the natives, which are scattered about in great numbers in the interior of the coast. Fish are seldom very plentiful, but they are of a good quality.

The ancient town of St. Sebastian is on the continent, at the narrowest part of the strait. Since 1817 the Brazilians have projected another, to be called Villa Nova da Princeza, situated near the north entrance on the island. It is 400 fathoms S. W. of this new establishment, where there is the best anchorage for mer de war, having 17 fathoms water on a bottom of grey sand. There are a great many watering places on the Island of St. Sebastian: one of the best is at the entrance to the new town and L'Arma-

The winds at St. Sebastian follow, almost always, the direction of the Strait, except at night, when the land breezes blow alternately from many points, without following any regular law. During the day the winds generally come from the N. N. E. and the S. S. W., following the direction of the land; but are frequently interrupted by intervals of calm.

The currents follow the same directions as the winds, and their velocity is proportionate to the force of the latter: the most common in the Straits, is from  $\frac{1}{10}$  of a mile per hour, to 1  $\frac{8}{10}$  of a mile.

The tides have no regularity within the Strait; nevertheless, we thought we could reckon that it is high water on the days of new and full moon, at 2 o'clock. The rise of the tide has been estimated at 4 feet.

The anchorage is situated in latitude  $23^{\circ} 47' 26''$  S. and in longitude  $45^{\circ} 27' W.$  The variation was  $3^{\circ} 25' E.$ , in June, 1819. We have observed that the land of St. Sebastian's Island, and that of the neighboring parts, is much elevated; the hills are covered with wood up to their summit, and have a most agreeable aspect. The coasts are steep, and you may anchor any where at a little distance from them, on a good bottom; and there is, in general, no danger but what appears above water.

About W. S. W.  $\frac{1}{2}$  W. from the southern entrance of the Strait of St. Sebastian is that of Santos, the distance being nearly 50 miles. Between them you will perceive the deep bay which forms the coast, and also a number of islands near the shore, of which the Monte de Trigo, (Stack of Corn,) is the most considerable. The Monte de Trigo is nearly conical, high, and woody to its very summit. At 2 or 3 miles from it, as well as at the same distance along the neighboring coast, you will find a good passage with from 12 to 25 fathoms, on an excellent bottom of mud. Due east from this island, at about 14 miles distance, is a small rocky islet, called Toquetoque; it lies just off the western entrance of the Strait of St. Sebastian; and in coming out or going in, should always be left to the northward. Some small rocky islands also lie close to the shore, and to the N. E. of Monte de Trigo.

**LES ALCATRAZES.**—The group of Alcatrazes is composed of several barren rocks above water, the largest of which may be seen 7 leagues off. Viewed from the E. S. E. it has the appearance which painters commonly give to the dolphin; whose head, joined to two little rocks, is turned to the W. S. W.; another rock, larger than the two latter, lies at the distance of 2 miles to the W. N. W., while 2 or 3 others are situated about a similar distance to the north-eastward. The pilots say the bottom is not safe in the parts adjacent to this group of rocks, and that it will be prudent not to approach them nearer than 4 or 5 miles, and that with a fair wind. This precaution may be rendered necessary by the vicinity of the Strait and Island of St. Sebastian, which cause the currents to be very considerable at this part. Mr. Bruce asserts, that vessels beating to windward from Santos, may pass close to the Alcatrazes, which are steep to, and visible 10 or 12 leagues off in clear weather.

The summit of the principal island of the Alcatrazes is in latitude  $24^{\circ} 6' 5''$  S. and in longitude  $45^{\circ} 46' 32'' W.$  The variation in 1819, was  $5^{\circ} E.$

It will here be proper to mention a rock first seen by Manoel Madeiros, a Portuguese commander, on the 13th of February, 1811, who sounded round it at 100 fathoms' distance, and was unable to reach the ground. He entertained no doubt of the real existence of this danger, and described it to be a round naked rock, sometimes above water, and often covered by the swell of the sea. The mariners of Brazil seem to allow the reality of this danger, which is said to lie 35 leagues S. by E. from the S. E. Point of St. Sebastian, and 72 leagues E.  $29^{\circ} N.$  from the N. E. Point of St. Catharine's Island; or in lat.  $25^{\circ} 41' 20'' S.$  and long.  $44^{\circ} 59' W.$  from Greenwich.

Baron Roussin observes, this danger appeared nearly in a similar situation on two MS. charts of the Portuguese, then in his possession; and therefore he thought it ought to be placed on all maritime charts in future.

W.  $\frac{1}{2}$  N., distant 11 leagues from the Alcatrazes, is the Island of Moela, upon which a lighthouse is erected.\* The island is situated off the eastern point of the Harbor of Santos.

**SANTOS.**—The Port of Santos was formerly much frequented by Portuguese vessels, but is now only of secondary importance; for the riches of the provinces of Rio Janeiro, Bahia, and Pernambuco, acquire every day a predominance more considerable than all the southern provinces. This port is formed by the continent and the Island St. Amaro, being only separated from the former by the little River Bertioaga. There are two entrances, but only that of the south is navigable by large vessels; for the other,

\* This lighthouse shows a fixed light, and is of great assistance in entering this port.

formed by the River Bertioga, is only fit for small craft. The Harbor of Santos will admit large ships, which may ride sheltered from all winds, except those from the S. S. W. to the S. E.

The Point of Taypu, which forms the western point of the entrance, is in lat.  $24^{\circ} 11' S.$ , and in long.  $46^{\circ} 30' 20'' W.$  The Point of Manduba is to the eastward; and on the same parallel, about a mile to the south-eastward of which is the little Island Moela, which may be approached without danger.

The following directions are by Mr. Bruce, whose name has frequently been introduced in the course of this work.

"In steering for Santos from the southward, you may pass close to the Island Redonda, (the Queimada Grande of Roussin,) bearing N. E.  $\frac{1}{2}$  N. distant 1 mile; it is 2 miles long and narrow, and lies about N. N. E. and S. S. W.; the highest part is to the S. W. which appears lofty and bluff, and, with the above bearing, seems to be round. N. W. from this island is another, distant nearly 6 miles: this is small and quite round, being thickly wooded, and visible 20 miles off. After passing between these islands, I perceive a rock 12 or 15 feet high, and a little larger than a line of battle-ship's launch; (neither of these two last appear in the charts.) The following are their bearings and estimated distances:—Large Island, perhaps Redonda, S. E.  $\frac{1}{2}$  E. distant about 6 miles; small round Woody Island, S. W.  $2\frac{1}{2}$  miles; and the Rock N. E.  $\frac{3}{4}$  N. about 6 miles; the Rock in one with Redonda, S.  $\frac{1}{2}$  E.; Rock and Woody Island in one S. W. by S. When going into Santos Bay, I took the following bearings: Bird or Dnty Island, (the Laage de Santos of Roussin,) S. E. distant 4 leagues; Alcatrazes, E.  $\frac{3}{4}$  N. 12 or 13 leagues; supposed Redonda, S. W.  $\frac{1}{2}$  W. 10 or 11 leagues; and Point Engenho, north, nearly 9 miles: at this distance we could not see either the Woody Island, or the Rock.

"In advancing into the River Santos, you will have 10, 9, 8, and 7 fathoms water, until you near the bar, upon which there are only 4 $\frac{1}{2}$  and 5 fathoms; the entrance is narrow, but the starboard side is much the boldest, and has 19 fathoms water close to the shore. After passing the first Barra Grande, the water deepens to 15 and 16 fathoms, within 12 fathoms of the shore. Keep the starboard land close on board, until you get abreast of a few huts; then steer mid-channel, keeping gradually on towards the highest or northernmost hill, there being two on the westernmost bank of the river, and these are the only ones, therefore you cannot be mistaken. Steer from the huts before mentioned towards these two hills. The reach is shallow, with not more than 3 fathoms on it; there the starboard side will be found the shoalest; keep therefore close to the hills, and your water will deepen to 6 fathoms; but having passed the hills, you may again run toward the starboard shore, and when you have passed about 2 cables' length, then steer for the fort on the starboard bank of the river. This is erected upon a perpendicular rock, close to which are 20 fathoms water; and when you arrive abreast of this fort, you will see the town of Santos nearly open of the point on the larboard side. Steer towards it, keeping about 2 or 3 cables' length from the shore, and you will then avoid the shoal which runs from it, and be perfectly clear also of the bank which runs off the fort in the direction of the town, on the starboard hand, and when almost up to the town, you can anchor. The best anchorage will be abreast nearly of the centre of the town, in 7 fathoms, on a bottom of mud. Provisions are abundant, and good water may be obtained by sending a boat about 7 or 8 miles further up the river.

"To enter this port a pilot is not absolutely necessary; for the above directions, if well attended to, will be fully sufficient to carry you in, clear of every danger. When you get abreast of the town, you will observe the high land opposite, on the northern side of the river. You may pull towards this, and round Carvalho Point pretty close, by which you will open the Lago de St. Rita. This lake is about four miles in circumference. Steer right up it for the distance of a quarter of a mile, and stretch directly over for a low round island, thickly covered with brushwood; and when you get near to this, you will perceive another island, somewhat similar in appearance. Keep nearer to the first island, and pass between them; then you will open the entrance of the river, and also will observe another branch or opening on the starboard side. Keep the starboard shore on board, and pull up about 3 or 4 miles. You will then find the water freshen. A boat may with ease make two trips a day; but as the atmosphere is hot and sultry, all boats should endeavor to get on board before half after 3 o'clock; for at this time it commonly begins to rain, and continues to do so until 10 at night. Wood is in abundance.

The Barra de St. Vincent is on the west side of the entrance to the Port of Santos, and was once a good channel; but the continual increase and accumulation of sand have choked its entrance up, for now it will scarcely admit canoes to pass.

Le Laage, or Rock of Santos, lies  $16\frac{1}{2}$  miles S.  $14^{\circ} E.$  of the Island Moela: it is a smooth white stone, elevated about 6 or 8 feet above the surface of the sea; it lies in latitude  $24^{\circ} 18' S.$  and in longitude  $46^{\circ} 17' W.$  Midway between this danger and the

Port of Santos, there are 19 and 20 fathoms, with a bottom of sand and mud, which is the usual quality of the ground hereabout.

Leaving the Port of Santos, the coast runs S. W. towards the Village of Conceicao, a distance of 8 leagues. The land is generally low at the water's edge, but high in the interior; for a chain of mountains runs along 4 or 5 leagues inland, and the shore is intersected and broken by several rivulets, which, in sailing along at a distance, gives to it the appearance of islands. This chain of mountains is broken by the Harbor of Santos, but continues to run E. by N. so far as the Harbor of St. Sebastian.

The Village of Conceicao is situated on a little mountain near the shore, 4 miles off which you may anchor in 10 or 12 fathoms water. To the S. W. of Point Taypu, distant 20 miles, is an isolated rock, elevated about 10 or 12 feet above the surface of the sea, which the Portuguese call Laage de Conceicao, at a pistol-shot distance from which are from 12 to 14 fathoms, sand and mud. Off this part you may distinctly perceive the port of Santos. This rock lies 7 miles to the E. 31° S. of the Village of Conceicao, and 15 miles to the N. 4° W. from Queimada Grande.

The Islands of Queimada are two masses of rocks, nearly barren, and distant from each other 10 miles, in a S. E. and N. W. direction; the largest, which is farthest to the S. E., and may be seen 7 or 8 leagues off, has a little rock lying to the northward of it: you may, without danger, go between the two Queimadas, or pass between them and the land.

In sailing along the shore to the south-westward, you will recognize successively the River and Hill of Pirube, the two Isles of Queimada, the Isles of Guarahu, the Barra de Unha, the Point da Jurca, and the River Iguape. At the distance of from 3 to 10 miles off the land, you will have a depth of from 8 to 15 fathoms. The coast near the shore becomes rather high, and runs in the direction of S. 50° W., and the soundings opposite increase in proportion to the elevation of the adjacent coast.

**IGUAPE AND CANANEA.**—The coast, from the entrance of the River Iguape to the River Cananea, is called the Playa de Iguape; it is a low sandy flat, except about the middle, and cannot be seen unless you are a very little distance off; therefore, in sailing along it, you ought never to come nearer the land than 2 leagues, nor into less than 10 or 12 fathoms water, with a bottom of sand. This Playa de Iguape is separated from the continent by a lake, or natural canal, which communicates with the Bar of Cananea, and is called by the Portuguese, Mar Pequena, or the Little Sea. This lake has depth sufficient for large vessels, but the Bar of Iguape will only admit of boats. You must not confound this opening with the Bar of the River Iguape, which is situated 3 leagues further to the north-eastward, and forms the entrance of the River Iguape, situated in latitude 24° 35' S.

You may anchor all along this coast at the distance of 2 or 3 miles off the Playa, on excellent muddy ground, with from 6 to 10 fathoms water; but there are no ports on this coast accessible to large ships, and there can be no necessity to anchor here, unless in a calm, when you have no occasion to expose yourself to danger.

After passing along the Playa de Iguape, you will arrive at the Bar of Cananea, and at the Island Bom Abrigo, which lies to the southward of the Bar of Cananea, within which the Brazilians construct their large vessels: and the natives say, that to enter the river, "you may pass with a pilot to the southward of the Island of Bom Abrigo; but the common channel is to the northward, although it is encumbered with many shoals." The Island Bom Abrigo is very high, and covered with trees; and vessels may anchor at a little distance off to the eastward. There is a little island lying to the southward of it, about 2 miles to the eastward from which there are 11 and 12 fathoms water, on a bottom of sand.

The Bar of Cananea may be known from seaward by two objects, both equally conspicuous: one is the Mountain of Cardoz, situated inland, about 5 leagues W. N. W. from Bom Abrigo; the other is the Playa de Iguape, or flat, consisting of little downs of white sand, interspersed with brushwood, which extends all the way from the Bar of Iguape, a distance of 10 leagues. Notwithstanding the short distance, and the height of the chain of mountains, of which Mount Cardoz constitutes a part, and predominates so remarkably, the fogs that prevail throughout this part of the coast in the south monsoon, will prevent your discovering the land, and large vessels should therefore approach the low coast with the greatest precaution. Mount Cardoz is the highest mountain upon this part, and is situated in lat. 24° 54' 45" S., and in long. 48° 12' 26" W. The variation, 6 leagues off the land, was 7° E. in 1819.

Pimentel, in describing this part, proceeds thus:—"From the Barra de Iguape to the Barra de Cananea the distance is about 30 miles, the shores being low and flat. Opposite to the entrance to the latter, lies the Island Abrigo, dividing it into two channels, both of which are dangerous, on account of the breakers and shoals thereabout. The northern entrance, called Barra Falsa, is narrow and shallow. Corvettes and small boats

only enter there. The southern entrance is wider and deeper, and in this channel ships of burthen find a passage. Sail in towards the southern shore, keeping close in 3 and 4 fathoms water; but observe the bar is shifting, and consequently dangerous to all strangers. The bar is about a mile in breadth. When you are within you will deepen your water to 5, 6, and 7 fathoms, and may anchor as most convenient for your purpose.

From Cananea southward, you will fall in with a small island, called Castillo. This is nearly opposite to the River Arrepira, which is now not navigable. Further on is Figuera, another small island; and coasting along, you will reach the Barra de Superagui, admitting canoes only. This creek is divided from the main entrance to the Bay of Paranaguá by the Island of Pecas, near a mile from the southern part of which are some rocks. These rocks form the northern boundary of the channel, while the Island do Mel lies to the south. The passage between is near a mile in width. A league off at sea are only  $3\frac{1}{2}$ , 4, and 5 fathoms; but as you approach the bar, it deepens to 5, 6, 7, and 8 fathoms; in the channel are  $4\frac{1}{2}$  and 5 fathoms; and when within you will have 5, 6, and 7 fathoms. There is another entrance to the southward of Mel Island, called Barra do Sul; but, like the Barra de Superagui, it is fit only for boats. The course to Paranaguá Town and the Villa Antonina is due west. The former is on the larboard side, almost 4 leagues from the bar, while the latter is rather to the northward, and about 6 leagues up the river. There are several islands scattered about, but the channel is generally clear, and every known danger is visible."

Roussin says, that in following the land to the S. westward of Bom Abrigo, to the distance of 10 miles, you will meet the little Island Castillo, the bar, and  $8\frac{1}{4}$  miles beyond that, in the same direction, the Island of Figo, or Figuera, both which have obtained their names from their peculiar appearance: the former is somewhat less elevated than the latter, but broader, and has a ridge rising up in the middle, which may be mistaken for a castle; the latter resembles a fig. They are both nearly barren, and bear from each other  $S. 35^{\circ} W.$  and  $N. 35^{\circ} E.$  In drawing near to them, you will have, at the distance of  $\frac{1}{2}$  mile, from 15 to 10 fathoms, fine sandy ground.

**PARANAGUA.**—Having passed to the southward of Figuera about 8 or 9 miles, you will open the Bar of Paranaguá. This is a bay of 3 or 4 leagues diameter, receiving many brooks and little rivers: the entrance is sheltered, and at the same time divided into channels by a low island, upon which are many little hills, appearing, when seen at a distance, like several islands. This island, named Isle do Mel, has on its northern side, three little Islets das Palmas. The southern entrance is enumbered with breakers, and not navigable. The northern channel will admit of brigs, and many are built in the bay, which is surrounded by forests. In navigating the northern passage, the pilots say you ought to leave the Islands of Palma to the starboard: these you will recognize by the palm-trees with which they are covered, but a pilot must always be employed for the interior navigation.

The water which runs out of the Bay of Paranaguá, constantly carries with it the alluvial soil of the country, which sensibly is diminishing its depth, but there is otherwise nothing material to obstruct its navigation; and 2 leagues from the two entrances there are from 5 to 9 fathoms water, the bottom being grey sand and mud. The coast from hence to the Island of St. Catharine, generally speaking, runs south.

The summit of the southern hills on the Island of Mel is in latitude  $25^{\circ} 32' 43'' S.$  and in longitude  $48^{\circ} 25' 40'' W.$  The variation was  $6^{\circ} 1' E.$  in 1819.

**GUARATUBA.**—S. S. W. from the Barra do Sul de Paranguá is the Point of Joao Diaz, the eastern point of the entrance of Rio San Francisco: 16 miles N. by W. from which is the entrance to the River Guaratuba, from the northern point of which a parallel, or shoal, runs up to the Barra do Sul: this shoal extends 4 or 5 miles from the shore, and is bounded to the eastward by the little Islets of Coral, and by two great rocks, 20 feet high, called the Itacolomis. The shoal is not navigable except by boats; but you may approach the rocks to seaward to the distance of one or two miles, where you will have from 10 to 12 fathoms water, the ground being sand and mud.

Pimentel says, "the entrance to the River Guaratuba is on the north side, near a large rock, where you will have a deep channel with 6 and 8 fathoms water; but from this is shoal to the southward. This river is remarkably rapid, and famed for its fisheries. Whoever runs for the harbor from the northward, should keep close to the land, not for the point of the rock above mentioned, and when about to enter, keep the small island astern: this island lies about  $\frac{1}{2}$  mile to sea, and your anchorage will be immediate behind the hill to the northward, or opposite to the hill on the south side. This river is supplied by several others, of which Rio St. Joao is the most considerable, and is said to be navigable for upwards of 12 leagues."

**RIO SAN FRANCISCO.**—"About 16 miles south from Guaratuba is the northern entrance to the Rio San Francisco, capable of accommodating any vessel, and having from 6 to 13 fathoms in its channel. To sail in, it is advisable to coast up the land which

up the land which

to the southward, in 6, 7, and 8 fathoms; and when you arrive at the headland where this coast ends, you should make for the northern point, taking care to avoid a bank running to the N. E., which is shoal, having not more than one fathom at low water; and as soon as this north point comes abreast, stand S. by W. for the town, or for the church of St. Joze, built on an eminence, opposite to which you may anchor in clear ground. This entrance may be known by the high woody land of San Francisco, which terminates at the hill; and also by the three islets lying two or three miles to the westward of this hill. The other entrance to the river, called Aracary, is six leagues to the southward, and fit only for canoes; but opposite are some islands with anchorage and shelter from the sea, in 4 and 5 fathoms water, on a bottom of whitish sand."

The Islands of Garcia lie on the parallel of the Point of Joao Diaz, which forms the eastern extremity of the Bay of San Francisco, and are situated about 2½ miles from the point. Fourteen miles to the southward of this group of Garcia are the Tamborettes Islands, from abreast of which the coast turns more to the westward, so far as the River Aracary; near the bar or entrance of which is another group, called the Remedios: all these islands lie at the distance of 2, 3, or 4 miles from the coast, and are said to have passages between them. The islands are covered with trees; but between the Remedios and the mouth of the River Aracary, the passage is said to admit of small vessels only; and even then it is not to be depended on.

The River Aracary, after running a considerable way up, and separating the Island of San Francisco from the main, turns N. E. easterly, and runs into the sea at a spacious bay of the same name, where you may anchor in several places. At 2 leagues from the shore, N. N. E. of the entrance of Rio San Francisco, you will not find more than 6 fathoms water, on a bottom of fine sand. The coast is flat, the land adjacent but little elevated, but interspersed with desolate spots, which are rather remarkable. A few leagues in the interior are the Sierras of Maratuba, a chain of very high mountains.

Directly south of the Remedios Islands, distant 6 leagues, is the Point Itapacoroya, the eastern extremity of a bay, rather deep, and sheltered by the winds from the south and west; here are an *armacao*\* and two little rocky islands, near which you may anchor in sufficient depth of water. At the bottom of this bay the land runs N. ¼ E. so far as the Islands Garcia, where you will see another *armacao*, the whole distance being 13 leagues.

S. S. E. 7 leagues and a half from Point Itapacoroya is the Point of Bombas, and between them are the Points of Cambeundo, Camboriu, Ytapeba, and Garopas, forming several bays. You may safely sail along these points at the distance of 2 or 3 miles.—Pimentel says, "the entrance to Garopas Bay is 8 or 9 miles broad, and well sheltered from all winds, with depth of water enough for any ship. Two rivers discharge themselves into this bay over beds of white rocks, and the surrounding land is covered with thick woods. To the southward is Point Manduri, from whence you proceed on south-easterly to the Island of St. Catharine."

#### *Description of the Island and Anchorages of St. Catharine, by Baron Roussin.*

THE ISLAND OF ST. CATHARINE is situated at a little distance from the continent, upon the parallel of 28° S.; it is sufficiently elevated to be visible 15 leagues off in fine weather. At the above distance you will find 70 fathoms; thence the depth diminishes gradually to within 4 cables' length of the coast, where there are 4 fathoms.

In approaching from the eastward, this island appears very uneven, being intersected with mountains and deep valleys: its elevation is greater at the southward than at the northward. Across it the mountains on the continent are a little more elevated than those on the island; and you will distinguish among these principally the Morro de Camborella, which is a branch of the eastern Cordilleras, which extend from Rio Janeiro to this island.

About the middle of the island, and near the edge of the sea, is a large lake, which presents an opening that may serve to distinguish it is a landfall. At three leagues from the eastern coast, if you bring this opening to bear west, the N. E. point of the Island will be about 3 leagues to the N. W. All the eastern side of this island is safe and rather steep to, and you may run alongside many large rocks on the coast without danger.

The Island of St. Catharine may be entirely circumnavigated, and many anchorages will be found between the western coast and the continent; but the northern part of the channel is the only one fitted to receive vessels which draw much water, and it is to this part we shall limit our description.

To enter by the North Channel into the Gulf or Bay of St. Catharine's.—The passage most frequented, leading to the anchorage, is between the north point of St. Catharine's

\* An *Armacao* is a building used for the purpose of converting the blubber of whales into oil.

and the Arvoredo, a woody island situated N. N. E. from the northern point called Point Rapa. This passage is rather less than 2 leagues in extent, and does not contain any danger. You may approach it on either side, observing only to keep clear of the Mo-leques\*, which you will leave to the southward: these are large rocks, and lie near the shore. We may say the same of all the points which surround this passage, for you may sail close, and beat up to them without the least risk or danger. There are 26 feet water at 600 toises distance from the N. W. coast of St. Catharine's, which is the deepest water in this part of the channel.

*The anchorage for large vessels in the Bay of St. Catharine's.*—When you are within the bay, you may anchor any where, agreeably to the size of your vessel; by keeping in the middle of the channel, the depth will be sufficient for the largest ships, to 1000 toises S. by E. off the little Island Anhatomirim. Having passed this point, in advancing to the southward, the depth gradually decreases; and S. of the Raton Islands there are not more than 10 or 12 feet water. There is little more depth west of these islands, in the large bay called by the natives Sacco Grande: it is a quiet place to ride in, and principally frequented by vessels in the whale fisheries: but ships drawing any great quantity of water could not have access to it.

There is plenty of water in all the anchorages in the Bay of St. Catharine. In that which vessels of war most commonly frequent, you will have the following bearings: North Point of St. Catharine's, N. 69° 30' E.; middle of the Fort of Santa Cruz, S. 63° 30' W.; the Fortress St. Joseph, S. 55° 30' E.; and the point of the Armacaco, on the continent, N. 16° 50' E.

The depth of the above anchorage is 30 feet; and the bottom is mud of a greenish cast, and holds well.

Here you enjoy almost always a perfectly tranquil sea, under shelter of the high lands with which it is surrounded, the only exposed part being to the N. eastward; but the winds from this part are here very seldom dangerous.

Many places for obtaining water are in the vicinity of this anchorage: the best is about 2 miles north of the Island Anhatomirim, upon the continent, which is supplied day and night with excellent water, of which you can obtain an ample quantity. You may get permission at a cheap rate to take fire-wood either on the continent or on one of the Isles of Raton, and also for repairing your vessel, if needful. In short, the principal town of the island, and the habitations near this anchorage, furnish, at moderate prices, all kinds of refreshments, &c. which the country produces. The provisions consist of bullocks, pigs, fowls, maize, rice, spirits, farinha, dried meats, sugar, coffee, all tropical fruits, &c. The Island of St. Catharine is therefore one of the best ports at which a vessel can be supplied with necessaries, after or before a long voyage.

The anchorages of this island are sometimes plentifully supplied with fish; but the success of the fishing depends upon a variety of causes, with which we are not well acquainted. La Perouse found abundance of fish in November, but I was less fortunate in the same month, and also from May to August. Most of the shores are besides covered with the bones of whales, which it becomes difficult to avoid in hauling the seine.

When you provide yourself with fire-wood from the country, it is better to prefer the young trees; for the old trunks are commonly hollow, and filled with insects and the eggs of reptiles, which are very often venomous, and might be highly dangerous on board your vessel. It will therefore always be prudent to throw the wood into the sea before you take it on board.

The winds most frequent in the Gulf of St. Catharine follow the direction of the channel, whether inwards or outwards, but these are seldom violent; and the storms are not dangerous to vessels which are well moored.

From March to September, that is during the time called winter, or the southern monsoon, the winds in the neighborhood of the islands blow generally from the south or S. S. W. Sometimes they come on with very great violence, and are accompanied with rain; but these gales seldom last more than 48 hours. Towards the month of October the winds approach towards the E. and N.; the six following months form the summer, and are the hottest throughout the year. There are frequently storms, which come from the N. and S. E. round by the west; and if in this season the winds blow from the S. E. they are accompanied with considerable rain: but in general, however, the greatest quantity of rain falls during the months of August and September, although even at this period many years have been exempt from it. The tides are regular at the anchorage; and it may be remarked that as they blow into the north and south entrances of the strait at the same time, meeting at the anchorage near the town, they return in a similar manner, with more or less velocity, according as they are accelerated or retarded by the prevailing winds.

The common rapidity of the current seldom exceeds three tenths of a mile an hour at half-tide: and the rise of the water does not in general exceed 3 feet; but at the springs the currents run sometimes one mile and a half per hour, and then the water rises 6 feet. It is high water at the above anchorage at 40 minutes after two on full and change days.

If you should find yourself under any circumstances to require the protection of the forts, this anchorage will not suit: you must in that case draw nearer to one of the defences adjacent: these are the forts of Santa Cruz on the Island of Anhatomirim; St. Joseph, on the Island of St. Catharine; or the Fortress of Raton, erected upon the largest of the two islands of that name. But the shot from these fortifications do not cross on any of these points effectually, at least with the artillery with which they are at present protected.

The Governor of the province resides in the town of Nossa Senhora do Desterro, situated about 4 leagues to the S. S. E. of the Fort of Santa Cruz. The passage to it being in a strait, well sheltered, is almost always easy for small vessels; and the communication between all the points is quick. Your depth decreases from 6 to 2 fathoms in going from the above anchorages southward.

The position of the flag-staff of Fort Santa Cruz on the Island Anhatomirim is 27° 25' 32" S., and the longitude 48° 41' W. Point Rapa, the north point of St. Catharine's, is in latitude 27° 22' 31" S., and in longitude 48° 32' 7" W. The variation at the anchorage in 1819, was 7° 29' 26" E.

The Island of St. Catharine may be made indifferently upon all parts of the island, and it rarely happens that either the winds or the currents are strong enough to occasion any difficulty in correcting your route; however, you ought to prefer making the southern part of the island in the south monsoon, and the northern part in the contrary monsoon.

Many little isles are visible to the northward of St. Catharine's: the largest of these is Arvoredo, which has been already described. Its distance from Points Ganxos and Zambo on the continent, and from the Isle Pedra de Galle, is nearly the same as from the Point Rapa in St. Catharine's; and you may pass through, in great safety, all the channels formed between these islands and the continent. The depth varies from 24 to 12 fathoms, on a bottom of mud and grey sand: you have only to avoid the rocks and breakers of San Pedro, situated rather less than 3000 toises (about 3 miles) W. N. W. from Arvoredo.

Directly to the northward of the entrance to the harbor of St. Catharine's, is the Bay of Tijoucas, where there is good anchorage. Three leagues to the eastward of all the islands, the depths are from 27 to 31 fathoms.

To the above we here add the remarks of Mr. Bruce, who says, "There are no particular dangers in going to the anchorage of Santa Cruz; and in entering you will carry regular soundings, 13, 12, and 9 fathoms, gradually shoaling towards St. Catharine's Island, until you get abreast of Papagaios Island. It then shoals abruptly from 7½ to 5 and 4½ fathoms. The best leading mark for a large ship to enter, when she is abreast of the above island, is to haul over to the westward until Great and Little Raton Islands are in one; then steer for them until you are nearly abreast, or a mile from Santa Cruz, when you may haul over to the eastward, until you get the southernmost Raton Island, which is the smaller of the two, open of the great island. Keep it just open, and you may anchor within a mile of them in 6 or 7 fathoms, good holding ground, and well sheltered. In working out from this anchorage, when you are standing to the westward, do not stand into less than 5 fathoms, for there is a bank of 4 fathoms on its eastern edge, and only 3½ and 3 fathoms on its inner part. It lies rather less than 2 miles to the southward of Santa Cruz. Standing to the eastward, you may bring the Island of Arvoredo on with Point Groca, (St. Jose,) and when you get nearly so far as the Points of Groca and Santa Cruz, you may stand into any depth you please. There is good anchorage under Santa Cruz, where ships commonly touch for water; but the best anchorage is with the small Island Ratonces just open to the eastward of the larger one, in 5½ fathoms. The deeper water will be found on the eastern side; but when off Santa Cruz the western side will be the boldest. There is but a scanty supply of water inside of Santa Cruz, which comes from a small rivulet close to the beach. Here you may fill your casks in the boat, by baling with buckets; but this supply in dry weather sometimes fails. Wood may be either cut or purchased."

The Island of Santa Catharine is of such height as to be discovered in fine weather from 45 miles distant, at which distance there are 70 fathoms water, diminishing gradually towards the shore. Nearing it from the east, it appears with high mountains and deep valleys. Taking the whole together, the southern part appears higher than the northern side. The Morro Camborello is a mountain which appears above every other. Vessels may go round this island with safety. The channel between the main land affords good anchorage, but the best place to cast anchor is on the northern part.

Santa Catharine affords the best place to refit a vessel. There is an inexhaustible quantity of good water, to be got without any expense; fuel, and provisions of every kind at a cheap rate—such as beef, pork, poultry, corn, sugar, dried beef, arack, &c. &c. It is then the most convenient place for a ship to stop, in case of want, and for repairs. When taking on board wood for fuel, it is necessary to take young branches only, and even to let them float in the sea water, in order to destroy the numerous worms, as their eggs are very dangerous on board of a ship.

The coast north of Santa Catharine is every where very high. Woody mountains and deep valleys are to be discovered all round. From Santa Catharine to the Bay of San Francisco, you meet several small islands and rocks, and the last are the small Garcia Islands, 2 miles distant from Joao Diaz Point, (which point forms the eastern extremity of the River San Francisco,) San Francisco River is not very deep. Its mouth is turned N. N. E., and empties in a large bay, in which you may anchor any where. The shore of this bay is flat, the surrounding land not very high, but from place to place small hillocks are to be seen, which render that place remarkable, particularly by the chain of a very high mountain, to be seen nearly at 9 miles in the interior. The Island of San Sebastian is to be seen 45 miles distant. The shores are very bold. The whole island taken together seems of a triangular shape. The channel affords good anchorage, but is not to be followed in a straight line from end to end. Banks connected with the main land, existing nearly two thirds of the whole extent, in the direction of N. to S., and consequently, when coming from the north, and starting from a point situated one half mile from the Armacao, which is constructed at the head of the island, it is necessary to steer first five miles S. 16° W., and from thence S. 45° W., until you are out. This route is nearly 11 miles, and the depth of water from 10 to 20 fathoms. The greatest distance between the opposite lands, is nearly 3 miles, but two thirds of that space is not safe for navigating. It is necessary to near the shore of San Sebastian Island, at no less distance than from ten to twelve hundred yards. The southern entrance is more narrow. The natives say that very large ships may pass through. San Sebastian Harbor is one of the safest in the world, and offers the same facilities as Santa Catharine for provisions of any kind.

**No. 1. FROM THE NORTH POINT OF ST. CATHARINE TO CAPE ST. MARTHA GRANDE.\***—The land of the Isle St. Catharine, and the neighboring continent to Cape St. Martha Grande, is very high and woody. The highest mountains perceived from this island, are of the Cubatao chain, covered with clouds when the winds from the south prevail, and clear in N. E. winds. At sea with a clear horizon, these coasts can be easily perceived at 12 leagues distance. The soundings are there from 70 to 80 fathoms, with a muddy bottom. In approaching the coast, the soundings diminish gradually. At 3 leagues distance the soundings are still from 37 to 40 fathoms, and 20 to 30 at 4 miles distance.

The whole coast is safe. The Emulation coasted it at 3 or 4 miles off, and passed between the Irmaos Islands and Moleques do Sul, in 17 fathoms water. The only dangers to be avoided are the islands and islets, which can be perceived 3 leagues off, and round which there are 15 fathoms water.

The usual anchorages are at Isle de Campexe, Point Pinheira and La Laguna.

The two first form shelters from southerly winds; the third is only practicable for small vessels, drawing at the most from 7 to 8 feet of water, by reason of a bar at the entrance of the Lagune, near the borders of the lake where the city of Laguna is built.

The Island of St. Catharine is about 9 leagues long, and its greatest width does not exceed 10 miles. It forms, with the continent, a strait in which vessels find excellent anchorages.

The points to distinguish the two entrances into the strait, are the following:

**THE NORTH ENTRANCE.**—The Island of Arvoredo, which rises in the form of a sugar-loaf with two summits (seen at a distance.)

The Islet Badejo, which is in the form of a tiller, and without vegetation.

**THE SOUTH ENTRANCE.**—The islet of the Great Moleque do Sul, which resembles a steep beach when seen from the S. E., and for this reason is perfectly delineated on the coast, which is woody.

The Isle Coral stretching from north to south, and round when perceived in this direction. It is covered with trees, and is about 1½ mile long.

If you wish to come to anchor north of St. Catharine's, where large ships ought to anchor, you must follow the directions given by Admiral Roussin; but if you wish to come by the south bar to the city of Nostra Senhora do Desterro, the capital of the is-

and, you cannot do it with a vessel drawing over 13 feet water. You may govern yourself by the following directions :

Steer for Cape Quebra Cabaco, leaving the two Ratone Islands on your larboard hand, not less than a mile and a half distant ; when you bring the small Ratone Island to bear east 2 miles distant, steer S. E. until the two rocks of Itapitinga do Norte are in a line with Cape Quebra Cabaco. You will then have on your starboard hand a flat rock, on which, at low water, there are but 4 or 5 feet. As soon as you open this cape to the south of the rocks of Itapitinga do Norte, steer S. W. and proceed on this course until the rocks bear N. N. W.

From thence steer so as to pass within 4 or 5 cables' length east of the rock of Cape Tres Henriques, a wooded cape, and more apparent than Cape Quebra Cabaco. Then steer direct for the little strait of the city, taking care to pass 3 or 4 cables' length from the islet of Point do Lial. From this islet you will enter the little strait defended by Fort Santa Anna on your left, and by the battery of San Joao on your right. You will find there a bottom of 12 to 18 fathoms, and you will perceive, in approaching, the Islet of Gato and the Islet of Vinhas, situated before the city. You will leave the first on your larboard, and come to an anchor in 19 to 20 feet of water, the Island of Gato bearing by compass N. N. E., the Islet of Vinhas S. S. E., and the steeple of the Cathedral N. E.

The city of Nostra Senhora do Desterro is situated in  $27^{\circ} 35' 25''$  S. latitude, and in  $48^{\circ} 34' 9''$  W. longitude. The variation of the needle in October, 1831, was  $5^{\circ} 29'$  N. E.

In coming from the north bar to the city, we frequently found but 7 feet of water, and a muddy bottom ; but the mud is at least 5 feet deep, and a vessel lies easy ; at high water the passage is made. The Emulation, which drew 13 feet 4 inches, was 3 days coming up to the city. She was dragged through the mud by her anchors, when the water was low or the tide weak.

In coming in by the South Bar, you must have a fair wind, high water, smooth sea, and fine weather, without which the currents may throw you on Fort Isle, or on the Point dos Naufragados, distant from each other only 280 fathoms. The vessel should draw less than 15 feet. The following is the route to take : steer on a line drawn from Coral Island to Fort Island, towards the last Island ; when you are abreast of the two Islands dos Papagios, (they are on your left,) you will have the three Irmaos Islands, and the Moleques do Sul on your right, and you will bring the Cape to the N. E. to open the passage ; arrived at this point, you will steer directly in the middle, until you find yourself south of the Isle dos Cardos, remarkable by a single tree, elevated on the summit. Steer then so as to pass E. of the Isle dos Cardos one or two cables' length distant, and from thence continue until you find yourself E. or W. with the south point of Enceada do Brito, half a mile distant. Follow the coast of the continent, until you come up to Cape Pesqueiro Fundo, at 4 cables' length distant. You will pass the village of Enceada do Brito, and at a little distance forward, is a group of houses or cabins forming the little Village dos Cedros. On your right at a great distance, you will perceive the village of Robeirão, situated on the Island of St. Catharine's, and almost before you Isle Largo.

Before arriving to this last, you will have to avoid a reef of rocks always under water. You are on this reef when the towers of the cathedral in the city are W. of the Isle Largo, and those of Cardos by the fort of the south bar.

From the Isle Largo steer N. until you are off the Isle das Cascas, and then steer for the steeples of the City, till you come to the anchorage indicated between Isles Gato and Vinhas.

There are on the coast of the Island of St. Catharine, from Point Rupa, the north extremity, the following islands and islets :—The North Moleques, the Islet Badejo, (the outward one,) the two Aranhas Islands, Pavier Island, (of a middling height and without trees,) Campexe Island, the three Irmaos Islands, the South Moleques, three large white rocks which touch each other, (composing the Grand Moleque.) On the coast of the continent, commencing at the south bar, are the following islands and islets :—Coral Island, S. E. of Point Pinheira, Araras Islands, (S. E. of Point Bituba,) Tocoromi Islet, (an elevated and perpendicular rock,) S. E. of Araras Island, Lobos de la Laguana, (S. W. of Araras and Tocoromi.)

In passing along the coast, we find the following points and capes :—Point Pinheira, Cape Guaratuba, Cape Cirui, Cape Uvidor, Point Viraquera, Point Bituba, or Embituba, Morro-da-Barra, Morro-da-Fora, Cape Santa-Marta-Pequeno, and Cape Santa-Marta-Grande.

At Point Bituba commences the beach, behind which is a lake and the cities of Villa Nova, Santa Anna, and La Laguna. This last is situated on the south side of the lake, at one mile from the bar within, in latitude  $28^{\circ} 28' 23''$  S. and  $48^{\circ} 50' 17''$  W. longitude. This position has been determined on shore.

CAPE SAINT MARTA GRANDE is remarkable on account of several large white rocks, situated on the summit of the cape, which may be taken at a distance for a number of houses. The latitude is  $28^{\circ} 39' S.$ , and the longitude  $48^{\circ} 49' 49'' W.$  The variation of the needle in November, 1831, was  $7^{\circ} 20' N. E.$

No. 2. FROM CAPE SANTA MARTA GRANDE TO RIO GRANDE DE SAN PEDRO.—This space of land, about 95 leagues in extent, has a coast extremely low, having, at intervals, little sand hills and brambles. The land can hardly be perceived in clear weather, from the mast head, at the short distance of 7 or 8 miles, and from the deck at 3 miles distance at the farthest. It may be divided into three parts. The first runs N. E. and S. W., true; we will call it the Beach das Torres. The easterly part is in  $48^{\circ} 49' 49'' W.$  longitude, and the situation of the westernmost part is in  $49^{\circ} 58' 45'' W.$  longitude.

The second part runs N.  $\frac{1}{2}$  E. and S.  $\frac{1}{2}$  W., true, and is called the Beach of Fernambuco. The easterly part is in  $29^{\circ} 52' S.$  latitude, and  $49^{\circ} 58' 45'' W.$  longitude.

The third part runs N. E. and S. W., true, and is known by the name of the Beach of Destretto. The easternmost part is in  $31^{\circ} 12' S.$  latitude, and  $50^{\circ} 39' 45'' W.$  longitude.

BEACH OF TORRES.—We will remark here that a chain of mountains, distant about 15 leagues from the sea, stretches along in the interior, and ends abruptly at Torres, 25 leagues from Cape Santa Marta Grande.

This beach may be approached within 3 or 4 miles, and has been coasted, at this small distance, by the Emulation. It was impossible to find any remarkable points on this route to form a triangulation. I confined myself to fixing the position of the vessel, by frequent observations, and from thence deduced the coast, by estimating our distance.

We found 30 fathoms of water, bottom of sand, mud, and shells, 4 miles S. of Cape Saint Marta Grande, and from thence to Torres, the soundings decrease to 5 fathoms, almost to touching the shore at this last place. You can judge of the decrease of the soundings, as the distance between the first soundings in 30 fathoms, and the soundings at 5 fathoms, was 25 leagues.

BEACH OF FERNAMBUCO.—This is also more perpendicular than the first, especially in the latitudes of  $30$  and  $31$  degrees. The Emulation found 40 fathoms water, with a bottom of sand, mud, and shells, 4 to 5 miles from the shore. She coasted along for half a day.

In steering off shore to the distance of 15 leagues, the soundings augment progressively to 95 fathoms, with a bottom of muddy sand: at a greater distance, no bottom is found with 100 fathoms; at 10 leagues distance, the soundings are about 83 fathoms.

BEACH OF DESTRETTO.—It terminates at Rio Grande de San Pedro. You will find 10 to 15 fathoms in coasting along, at the distance of 3 or 4 miles. The Emulation coasted along 17 leagues at this short distance, over a bottom of sand. It is not higher than the beach of Fernambuco, but there are hills of sand and less vegetation. Twenty to 24 leagues S. E. of this beach we find 38 and 39 fathoms water, bottom of mud and sand, and in sailing towards the land, these soundings gradually decrease.

We will also remark that of the three beaches, that of Fernambuco, the easternmost, has more water towards the shore, and also at a distance; on the contrary, that of Destretto has the least.

RIO GRANDE DE SAN PEDRO.—The approach to Rio Grande de San Pedro, is difficult on account of the want of elevation of the neighboring land, it being low for a distance of 95 leagues north, and 40 leagues south. You should not attempt the bar except when the wind is N. E., the weather very fine, and appearing as though it would last several days. You should coast along the beach of Destretto at a small distance, until you perceive the tower, which is situated at the north point of the bar, two miles inside. You must not, if possible to avoid it, get embayed or wind bound on the south side, because the sea breaks in the shoal water.

The bar is not practicable for vessels drawing more than 10 or  $10\frac{1}{2}$  feet in ordinary tides.

As soon as they perceive from the tower, a vessel, they hoist a red flag. It is the signal given to the pilot boats to go to the bar and sound it out.

The vessel ought, on her side, to show her draught of water by means of white, red, and blue flags, and a blue pendant.

	Blue.		Red.
	White.		Red.
			Blue.

These signals are repeated by the tower; and the pilot boat, on perceiving them, makes a signal, if there is water enough on the bar. If the bar be impassable, the tower strikes the red flag, and the vessel should steer off; if there be sufficient water, the boat hoists a flag; if you ought to steer for it, it keeps the flag in the same situation; if it lowers it towards the right you must keep to the starboard; if it lowers it towards the left, you must keep to the larboard.

The bar changes every year, during the winter; and as soon as the pilots have well ascertained the channel, the president of the province, notifies the government at Rio Janeiro. It sometimes happens, that it is impossible to cross the bar for a long time, after a great S. E. gale.

The geographical position of the tower is  $32^{\circ} 07' 20''$  south latitude, and  $52^{\circ} 8' 45''$  W. longitude. The variation of the needle, in the month of November, 1831, was  $8^{\circ} 30'$  E.

**No. 3. FROM RIO GRANDE DE SAN PEDRO, TO CAPE SAINT MARY.**—In this part of the coast the soundings are very shallow and variable, you are therefore obliged to keep off. The *Emulation*, in  $33^{\circ} 30' 30''$  S. latitude and  $52^{\circ} 19' 45''$  W. longitude, passed at once from 22 fathoms, sand and mud, to 18 fathoms, sand and shells; she soon ascertained the edges of a great bank extending from the coast 7 or 8 leagues and extending to the Castillos.

The Castillos are black and scarp'd rocks, situated at a very small distance from the land, in  $34^{\circ} 24'$  S. latitude and  $53^{\circ} 40' 45''$  W. longitude. At the north is found an immense bay, in which you find shelter from S. W. winds, but you should quit this anchorage as soon as the winds vary to the E. and the N. E.

South of the Castillos is *Bahia Falsa*, of which we shall speak hereafter.

Some time before arriving at these rocks, if you coast along the land 11 to 12 miles in coming from the N. the soundings show 11 to 12 fathoms water, with a bottom of sand; when shells are mixed with sand, you are still on the Great Bank, and you steer a little more to the larboard; you will then perceive two hills having the form of teats, the only ones which can be seen to Cape Saint Mary.

**No. 4. WINDS, TIDES AND CURRENTS.**—At the Island of St. Catharines, the prevailing winds are N. E., N. W., S. W., and S. E. The winds from N. W. bring fine weather, and the winds from S. E. in the winter, are extremely rainy.

The tides are not regular in the strait until the approach of a new and full moon. The difference between high and low water, is there, scarce above 5 feet.

The sea rises in the S. basin from the S. to the N. and it rises in the N. basin from the N. to the S. in such a manner, that the waters meeting from two sides accumulate towards the city, built near the little strait, which serves as a limit for the whole strait, of which the two basins are composed. It falls also in a contrary manner from which it rises.

About the beach of Rio Grande de San Pedro, the winds from the S. W., N. E., N. W., and S. E., are equally the most frequent, and those from the S. E. the most violent and dangerous. A vessel surprised by a sudden squall from this quarter, on the coast, cannot get away from it. By a wind from the E. S. E. the *Emulation*, under top-gallant sails, would have been obliged to run on shore on the beach of Torres, if the wind had lasted several hours; the sea broke in 30 fathoms of water, and the vessel ran great risk of being dismasted by reason of the great shocks that she experienced. During these winds from the S. E., the sea runs extraordinarily high, and the currents run rapidly towards the shore.

The winds blow usually from the S. E. after having blown from the S. W. These last winds do not usually blow until after the N. E. winds have varied to N. W. and W. N. W.

**RIO DE LA PLATA.**—The River Plate is 55 leagues wide at its mouth, and runs nearly W. N. W. and E. S. E., true. It is formed by the waters of the Uruguay and the Parana, two great rivers which receive the waters of an immense number of other

\* The palm is 94 English inches.

ivers, among which may be mentioned the Paraguay, the Picolmaya, and Rio Grande de Curitiba.

The capes which mark the entrance are those of Saint Maria and St. Antony; the first is situated on the northern side, and the second on the southern.

The coast of the northern side, comprised between Saint Maria and the mouth of the Uruguay, is in general high.

The coast on the southern side, comprised between Cape St. Antony and the mouth of the Parana, is on the contrary very low; it is on this side those immense plains known under the name of Campas, are found.

The river sensibly diminishes in width from its mouth to the confluence of the Rivers Uruguay and Parana. It may be divided in two parts, nearly equal in length.

The first extends from Cape Saint Maria and Saint Antony on the north, to the River of Santa Lucia, and to the south to Point das Piedras de San Borrombon \* the water of the river is there brackish. The second part extends from these last points to the confluence of the Uruguay and the Parana; the water is here generally sweet.

The depth of the water in the River Plate increases in going from this confluence to the sea, and the bottom between the banks is generally composed of mud, and frequently of soft sand-stone, to the meridian of Monte Video; from this place it is of oozy sand, sand only, sand and shells, and sand and gravel, as far as Cape St. Antony, except towards the north side, and towards Ensenada-de-San-Borrombon, where it is formed of mud. The south side, from near the River Salado to near the borders the Ensenada de Barragan has a border of soft sand-stone two to three leagues wide, on which it is very shallow.

We may consider the bottom of sand, sand and shells, and sand and gravel, situated east of the meridian of Monte Video, as forming an immense bank, the highest part of which is known by the name of the English Bank.

The bottom of hard sand found west of the same meridian, forms sundry banks, on which the depth of water is from one to one and a half fathoms at the most.

Three cities are built on the north bank; the first, after leaving Cape St. Mary, is Maldonado, the second, Monte Video, and the third the colony of San Sacramento; they belong to the Republic of Banda Oriental of Uruguay, the chief of which is Monte Video; from Monte Video to the colony of Uruguay is 10 leagues.

The city of Buenos Ayres is the only one situated on the south side of the river; it is the chief city of the United Provinces of La Plata; the distance to Parana is 5 leagues.

From Cape St. Maria to Maldonado, is 6 leagues; from Maldonado to Monte Video, 21 leagues; and from this last city to Colonia, 28 leagues; the distance from Cape Saint Maria to the Uruguay is thus 75 leagues.

From Cape St. Antony to Buenos Ayres, is 45 leagues, and from thence to Parana, 50 leagues; the south side of the river is thus 25 leagues less in extent than the north side.

On the north side there are many islands, and a number of rocks, above and under water; there are none on the opposite side as far as Buenos Ayres.† These islands are Lobos, 8 miles S. E. of Maldonado, Goriti, in the Bay of Maldonado Flores, E. of Monte Video, 15 miles; San Gabriel, Farallon, Lopez, before Colonia and Hornos, 5 and 6 miles west of this city. The rocks are all a short distance from the shore.

No. 6. BANKS.—The first we meet with coming from the sea, is the English Bank, which breaks in  $35^{\circ} 11' S.$  latitude, and  $55^{\circ} 54' 45'' W.$  longitude; it is 11 miles south of the Island of Flores.

The second is Archimedes Bank, on which an English frigate of this name touched. It is very small, and is situated S.  $\frac{1}{2}$  E. (true) from Monte Video, at 19 miles distance.

The third is New Bank, formed within a few years, very probably by the sand drifted from the little bank of Ortiz. It is situated on the southern side of the river.‡

The fourth and the largest of the whole is the Ortiz; its eastern extremity is only half a mile wide, and is north of New Bank; its western extremity stretches to within a very short distance of Colonia; it is nearer the north than the south side of the river. Its greatest width is 11 to 12 miles.

\* The Point das Piedras de San Borrombon forms with Cape St. Antony a great bay, called the Ensenada de San Borrombon, in which two small rivers discharge themselves, the San Borrombon and the Salado: this last is the largest, and during the war between Buenos Ayres and Brazil, served as a refuge to a great number of privateers; it is difficult to discover its mouth; the following however serves as an indication of it. The south side is covered with bushes which terminate at two brick towers used formerly as lime kilns; and at the N. part of the entrance are two banks of sandy land, on which two batteries are built.

† The islands situated at the Point of Santiago of Ensenada being very small we do not mention.

‡ The American Corvette Vandalia touched on this new bank.

† At the beginning current from the wind and all sa

The fifth is the Chico Bank, a dangerous bank, by reason of the irregularity of the soundings on the edges. It is placed between the Ortiz Bank and the south side.

The sixth and seventh are the Banks of Santiago and of Lara, and the eighth, ninth and tenth, those of Ciudad, Camerones, and the Palmas, all situated on the same side, except the Palmas, which is between the confluence of the Uruguay and Parana, on the way from Buenos Ayres to Colonia.

In going to Maldonado, there is no bank to fear, but in going to Monte Video, you must avoid English and Archimedes Bank; in going to Buenos Ayres you have to pass all the banks. Vessels do not generally take a pilot in going to Monte Video, but they rarely omit to take one in going to Buenos Ayres.

The pilots who conduct vessels to Buenos Ayres, live at Monte Video or Point Indio. They keep under sail, or at anchor near the coast in schooners or cutters.

The government of the United Provinces of La Plata, caused to be placed several years since, large buoys on the edges of most of the Banks, but bad weather and the strong currents have caused them to disappear. The government of Monte Video, have erected a tower with a good light, on the Isle of Flores, elevated about 120 feet above the level of the sea; it can be perceived in the night at 15 or 16 miles distance, and serves to avoid the English and Archimedes Banks.

No. 7. WINDS, TIDES AND CURRENTS.—At the entrance of the river, and at Monte Video, the prevailing winds are the N. E. and S. W.

At Buenos Ayres and at Colonia, they are N., N. W., S. E. and S. W.

During summer, and in fine weather, the winds blow in the whole river, with considerable regularity, from the E. to the S. E. from ten o'clock in the morning, until sunset. In the night the winds vary to the north.

The winds from S. W. and S. S. W. are known about the River Plate, by the name of the Pamperos, from the Pampas from which they come.

The Pampero lights up the sky, the same as the N. W. winds in Provence, and the N. E. on the coasts of Brittany; it blows usually after rain, or when the wind has varied from the N. to the N. W. and to W. N. W. and in summer after a calm and very hot day. Oftentimes it comes all at once with a strong wind from the N. E. when the sky is covered with clouds; the explosion is then sudden and very dangerous; and it is best for vessels in the River Plate, or the entrance, to get under easy sail, as soon as there are any indications of a Pampero.\* The barometer falls previous to the Pampero and rises afterwards.

As it rains oftener in winter than in summer, this wind is more frequently in the winter, and lasts each time from two to three days. In summer it blows with more violence and ceases sooner; it is then called in the country the Turbonado (Tornent.)

When the weather is fair, and the wind light and constant, the tides on this coast are regular; on the contrary, in bad weather and strong winds, the tides are irregular, and form currents which oftentimes run from 4 to 5 miles per hour.†

At Buenos Ayres the sea is high with the winds from the S. E. and low with the winds N. W. and S. W. At Monte Video and the remainder of the northern side, the river rises with the winds from the S. E. and S. W. and falls with those from the north. The difference between high and low water on the borders of the river, rarely exceeds 4 or 5 feet; but in strong gales from the S. W. they sometimes rise 10 feet.

In the months of March, April, and a part of May, the River Plate is higher than in the other months of the year, occasioned by the rivers Parana and Uruguay. It then brings down trees and shrubs, which form little islands of verdure sufficiently remarkable. This is the epoch of the finest season in this interesting part of South America, of moderate breezes and a mean temperature. During the spring, summer and winter, the winds are very strong, and the temperature of the atmosphere very variable.

No. 8. ANCHORAGES.—Wherever the lead shows mud, you can anchor, having care however to anchor far enough from the banks, not to be driven on them.

With the winds from the S. the anchorages on the south side are best, with the winds from the N. the opposite side is preferable.

Large vessels and frigates may go up to Monte Video; vessels drawing less than 17 feet, may go up to Buenos Ayres and the Hornos Islands.

The anchorages which shelter from the N. W., N. E., S. E., and S. E. are Maldona-

\* The Emulation, in the night of the 31st of August, 1830, 35 leagues off from Lobos Island, under foresail and topsails, was surprised by a Pampero, which in two minutes carried away the top sails and forced her to send under bare poles; a brig was upset in the river and an enormous whale cast on shore.

† At the beginning of March, 1831, the Emulation explored the south side; she could not stem the current from the N. W. in sight of Point des Piedras-de-San-Borrombon, although she had a fair wind and all sail set, and a four knot breeze, she was obliged to come to anchor twice.

do, Monte Video and Hornos. Those which give shelter from S. W. winds, are Ensenada de Baragan and Buenos Ayres.

Small vessels may anchor at Cape St. Mary, at the entrance of the River Santa Lucia and at Colonia on the north side; at Rio Salado within Ensenada de Baragan and at Riachuelo near Buenos Ayres on the south side.

You can come to anchor at Maldonado in 6 to 8 fathoms of water; at Monte Video, in the road in 5 to 6 fathoms, in the port in 3 to 3½; at the Hornos Islands in 3½ to 4½ fathoms; in the road of Ensenada de Baragan in about 5 fathoms; at Buenos Ayres in the road in 3½ to 4½ fathoms; and near the city in 2 to 3 fathoms.

In the anchorages on the north side, you should moor for the S. W. winds; in the others for the S. E. winds.

Of all these ports and roads, the best holding ground is at Maldonado. It is much covered with sand. In the other places the bottom is of soft mud, through which the anchors drag in sudden flaws of wind. During the Pamperos, the Hornos Islands offer an excellent anchorage, because the sea is broken off by the Palmas Bank. This last anchorage was not known when the *Emulation* was there in September, 1830.

No. 9. DEPTH OF THE RIVER AT THE ENTRANCE AND OFF THE MOUTH.—When in the parallel of Cape St. Mary, and in the longitude of 52° 8' 45", which is that of Rio Grande de San Pedro, the soundings at the distance of 33 leagues from the cape are 90 fathoms, mud; at 25 leagues the bottom is sand or mud mixed with shells, and show 40 to 28 fathoms only. In going towards the cape, the soundings decrease irregularly.

On the parallel of Castillos, at 33 leagues distance, the depth of the water is 58 fathoms, and the prevailing quality of the bottom is sandy.

In sailing on parallels farther south than Cape St. Mary, you will find less water in the same longitude, and the depth diminishes more regularly. At 15 leagues from Cape St. Antonio, the depth is 17 fathoms, bottom of sand. At 28 leagues S. E. from the same cape, you will have 45 fathoms, same quality of bottom. North of the cape, and 3 leagues from the land, you will have 7 to 8 fathoms water.

If you shape your course for the English Bank, that is to say, in the parallel of 35° 11' S., you will find 6 to 7 fathoms, and a sandy bottom, 5 leagues before arriving there. You are then nearly in 55° 39' 45" longitude.

On the parallel of 35° 30', when you reach the longitude of 50° 39' 45" W., the bottom is of fine sand, and the depth 8 fathoms. On the parallel of 35° 35', and to the parallel of Cape St. Antonio, the bottom is sand mixed with shells and gravel.

In the latitude of 35° 20' S., when you have passed the longitude of the English Bank, the soundings do not reach above 8 fathoms; on the parallel of 36° it reaches to 11 and 12 fathoms; west of the bank, on the same parallel, there are 5 and 6 fathoms only.

At 20 leagues distance from the entrance to the river, the water loses its blue color, and becomes green, tinged with yellow.

In coasting along the north side, in sight or near the land, you will have mud soundings; running on a parallel greater than that of Lobos Island, you have no soundings of mud except in the neighborhood of the meridian of this island; at two miles south you have 16 and 17 fathoms of water; and at 6 miles, 23 and 24 fathoms, mud bottom. In going from Lobos to Monte Video, the depths diminish gradually, but irregularly. In the passages formed by the hard sand banks, situated between Monte Video and Buenos Ayres, there are from 3½ to 5½ fathoms of water.

No. 10. POINTS TO RECOGNIZE IN MAKING THE LAND.—There are three, Cape St. Mary, Lobos Island, and Cape St. Antonio.

CAPE ST. MARY.—Its position determined on shore, is found to be 34° 39' 1" S. lat., and 54° 9' 45" W. longitude. The variation of the needle, in the month of February, 1831, was 10° 7' N. E.

Although of but little elevation, the cape is distinguished by the neighborhood of two little islands named Tuna and Palonna, distant from each other only 260 feet. The separation forms a passage for small vessels drawing less than 10 feet water, and is the entrance of a bay which is sheltered by the cape and the two islands. You find there from 11 to 12 feet of water. It will contain perhaps 7 or 8 vessels.

The Island of Tuna, the smallest and the nearest to the cape, is covered with the cactus, which is peculiar to a sandy coast. You will remark also in coming from from sea, a large sand hill with a double peak, S. W. of the cape, near a very flat beach. At the north, on a hill, is seen an establishment consisting of a group of houses called an Estancia, for raising cattle. Near to these houses are many trees, and all about them many enclosures.

The coast to the north forms a large bay, 14 miles in extent, with a point surrounded by the Palmarone and Castillos Islands. The island of Palmarone, the nearest to the point, is verdant: the Castillos are barren. Otherwise, this resemblance to Cape St.

a point surrounded  
e, the nearest to the  
blance to Cape St.

Mary has caused sometimes one to be taken for the other, and has caused many ship-  
wrecks. It has been named, for this reason, False Bay.

At two miles east of the Castillos, are found 16 fathoms of water, bottom of sand.  
From these islands to Cape St. Mary, at the same distance, are found 11 to 14 fathoms,  
same kind of bottom. At the east of the cape, 11 fathoms, a bottom of sand, or sand  
and gravel; S. at 3 miles distance, 20 fathoms, sand; and S. W., from 18 to 22 fathoms,  
bottom of mud.

ISLE OF LOBOS.—It is situated in  $35^{\circ} 0' 51''$  S. lat., and in  $54^{\circ} 54' 15''$  W. long.,  
and is only a mile in extent. It can be seen 15 to 16 miles off. It is inhabited by a  
great number of seals, from which it takes its name. The eastern part ought to be  
avoided, by reason of a chain of reefs which extends 3 miles off.

This island is without vegetation. Large vessels pass easily in the strait between it  
and the main land, and find there 17 fathoms of water.

Its position has been determined from the sea and the island of Goriti by triangula-  
tion. The variation of the needle is the same as at Cape St. Mary.

CAPE ST. ANTONIO.—We comprehend under this name a large collection of  
little mountains, or hills composed of sand, which stretch to the E. and S., and which  
are terminated in the west by a low coast covered with bushes.

Its position, determined at the anchorage, is in  $36^{\circ} 19' 36''$  S. lat.,  $56^{\circ} 47' 15''$  W.  
long. The variation of the needle was in the month of December, 1831,  $13^{\circ} 30'$  N. E.  
The point determined is that where the separation takes place between the sand hills and  
the low verdant coast.

This cape is surrounded by a bank of sand which breaks oftentimes at a considerable  
distance from the land, extending N. and E., and ought to be carefully avoided.

No. 11. NAVIGATION AT THE ENTRANCE AND IN THE RIVER  
PLATE.—The description that we have given of this river, naturally indicates the pre-  
cautions necessary to take to ascertain the points of the entrance. We think it prefera-  
ble to make the north side, as the land is the highest.

Some navigators pretend that they can always judge of their situation, out of sight of  
land, by the depth of water and the quality of the soundings.

We do not partake of their security in this respect, because in exploring the south  
coast of Brazil, in 1831, we found soundings on all the coast, nearly of the same depth  
and quality as towards the entrance of the river. Besides the Great Bank, whose posi-  
tion we have determined between the Rio Grande de San Pedro and the Castillos, has  
the same sort of soundings we meet with west of Cape St. Mary, and causes by this re-  
semblance numerous errors.

We advise mariners bound to the River Plate, to be well assured of their position by  
frequent observations of latitude and longitude, and to take them with the greatest pre-  
caution, as the currents may deceive them between the hours of observation.

If the winds are well established from the N. E., making the land about Cape Mary  
has this advantage, that you can recognize a larger extent of land before entering the ri-  
ver. But in all other circumstances Lobos Island has this advantage, that it offers more  
chances of success, by the position of the island, to avoid being wind-bound on the north  
coast, and to beat up with greater advantage. Making the land at Cape St. Antonio,  
should be considered the most difficult and dangerous.

No. 12. COURSE TO MONTE VIDEO.—Being south of Lobos Island, at 2 or 3  
miles distance, the direct course for Flores Island is W.  $7^{\circ}$  N., true, or W.  $\frac{1}{4}$  S. by  
compass. But we know the River Plate is subject to very variable currents; and  
you should steer in such a manner as to approach the north border of the river, rather  
than the south side, on account of the English Bank. You will perceive in good sea-  
son the Tower of Maldonado, and the elevated land to the east. In sailing along at a  
distance of 5 or 6 miles, you will distinguish a point formed of black rocks, on both sides  
of which, to the right and the left, are sand beaches. This is Black Point, or Point  
Negro, situated 14 miles from Maldonado, near a vast sandy bay. The high lands on  
the city side are remarkable for a great white band, which shows itself on both sides of  
Whale Point.\*

When Point Negro bears N. 6 miles distant, the Island of Flores bears W.  $7^{\circ}$  N.,  
true. The Island of Lobos is then on the same bearing about 37 miles distant, and the  
soundings are from 13 to 14 fathoms, with a muddy bottom.

The land N. of Point Negro makes a deep bend, and becomes lower. In steering  
along in sight of land, you can distinguish the hills of Afilar, situated in  $34^{\circ} 47' 15''$  S.  
lat., and  $55^{\circ} 31' 8''$  W. long. When they bear by compass N. by W., and the nearest hill

\* Whale Point is the west extremity of the bay of Maldonado. It is very near the same parallel  
of the tower of the city, although the Spanish and English charts place it W. S. W. of the tower.

bears E.  $45^{\circ}$  N., you are then 27 miles distant from Flores. The soundings are then 12 to 13 fathoms, bottom of mud, and still on the same rhumb with Lobos. The hills of Afilar are isolated, and resemble two tents.

In running W.  $\frac{1}{2}$  S. by compass, you have to run only 12 to 13 miles to perceive from mast-head the tower built on Flores. This island at first resembles three islands, then the lower part gradually shows itself, and at the distance of 5 miles, if the sea is low, the whole island is seen. If the sea is high, the island at the same distance appears in two parts.

If it be night, as soon as you perceive the light on the tower, steer direct until within 4 miles distance.

From thence keep on the larboard side, leaving the island on the starboard hand, and passing within 2 or 3 miles south of it.\*

Between Flores and English Bank, the bottom is mud, and the depth of water 7 to 8 fathoms.

From Flores to Monte Video is 16 miles in a straight line, and you must steer by compass W. by S.; avoid Point Brava.

Point Brava, situated east of the city, is formed by a long line of rocks stretching off from the land. You must give a good berth to a rock detached from the rest. A large white house is built N. of Brava, and another, a smaller one, is situated towards the middle of the rocks. In quitting Flores you can, at the same time, if the weather be clear, perceive the Cerro or hill of Monte Video, and soon after the steeples of the Cathedral in the city.

If the wind is from the N. or N. E., you ought to steer in the night, W. by S. to double Point Brava. But if the wind is from S. E. or E. S. E., it is prudent to steer W. S. W. You should, by way of precaution, in either case, bring the light of Flores to bear E. by N., or E. N. E., to be assured that the currents have not set you towards Point Brava.

When the hill of Monte Video bears N. W. by compass, the point is doubled, and you steer gradually towards the starboard hand, if you would anchor in the harbor. A large vessel, which can only anchor in the open road, should steer W. by S. from Brava, and anchor in 5 fathoms.

South of Brava, one mile distant, there are from 5 to 6 fathoms of water.

On the passage from Lobos to Monte Video, and also in the navigation of any part of the river, you must estimate the distances run by a ground log, that is to say, by a log of which the "chip" has been replaced by a piece of lead. If you throw the common log immediately after the deep log, the difference given by the two logs shows if the currents are in favor of, or against the vessel.

As any part of the coast between Point Negro and Flores, may be approached within 5 or 6 miles, it may be well, in the night-time, to steer wide to the starboard. The revolving light on the island, in this case, may be perceived on the larboard side, but it will be easy to rectify the vessel's course in steering directly for it, and then leaving it on the starboard hand, when you estimate yourself 4 or 5 miles distant. You will by this means certainly go clear of the English Bank.

The Cerro of Monte Video is 475 feet high. They have established there a fixed light, which can be seen in clear weather at only from 5 to 6 miles distance.

If you wish to go to Monte Video, S. of the English Bank, you must, in entering the river, place yourself on the parallel of  $35^{\circ} 30'$ , and steer W. by S. with northerly winds, and W. S. W. with southerly winds.

The soundings are at first fine sand, then sand of the usual kind, farther on mud, sand, and again mud. You will be in this last case on the meridian of Monte Video, and you ought then to see the hill of Monte Video, which can be seen in the day-time in clear weather, 9 leagues distant. The geographical position of this hill is  $34^{\circ} 52' 2''$  S. latitude, and  $56^{\circ} 16' 30''$  W. longitude.

If in spite of your precautions you should get in 5 or 6 fathoms of water, in passing S. of English Bank, it will be necessary to steer more to the larboard, and keep in from 7 to 9 fathoms.

Monte Video is in  $34^{\circ} 54' 11''$  S. latitude, and  $56^{\circ} 13' 18''$  W. longitude. The variation of the needle in September and December, 1831, was  $11^{\circ} 42' 24''$  N. E.

In a thick fog, or in the case of uncertainty of the true position of the ship, it is best to anchor, rather than pursue your course up the River Plate.

\* You can pass north of Flores, taking the precaution to pass at a good distance from the eastern point, to avoid a bank of rocks under water, and which extends a mile and half north. You can anchor only north of the tower one or two miles distant. The Emulation anchored here in a gale of wind, in January, 1831.

**No. 13. COURSE TO BUENOS AYRES.**—Vessels that do not wish to take the passage by the Island of Flores, must run on the parallel of Point Piedras de San Borrombon, and steer true W. until they make it. Its geographical position is  $35^{\circ} 27' 40''$  S. latitude,  $57^{\circ} 9' W.$  longitude. This point is very low, and can only be perceived in clear weather. You will remark on the right, many woody hills, among which the highest bears nearly N. W.\*

From Point Piedras de San Borrombon the course is the same as when the vessel has passed Monte Video.

Vessels that draw less than 9 feet of water, pass generally over all the banks between this last city and Buenos Ayres.

Those drawing 13 feet may pass between Chico Bank and the south side.

Those drawing 15 feet may pass between the channel formed by Ortiz Bank and the north side.

Those drawing 15 or 17 feet should choose the passage between Ortiz Bank and Chico Bank.

**PASSAGE BETWEEN CHICO BANK AND THE LAND.**—On leaving Monte Video, steer S. W. by compass 30 miles, to avoid being drifted on the Ortiz by the currents. You must then head W. S. W. until you make Point Indio, or rather Salvador Grande.

Point Indio is in  $35^{\circ} 15' 20''$  south latitude, and  $57^{\circ} 11' 42''$  west longitude, and 52 miles from Monte Video, it is very low, and can only be known by the woody hills in the east part, while the coast to the west has no hills. When you reckon yourself 9 to 10 miles from Point Salvador Grande, head W. N. W. along the land. You will soon perceive the three Ombu Trees† of the Magdalena, and then the church of the same name. When the first Ombu Tree bears S. by E. by compass, you are then N. and S. true, from the east point of the Chico Bank; when the church is on the same rhumb, you are in the middle of the channel. You will distinguish in a short time a large single Ombu Tree on a hill, and more distant, three other Ombu Trees forming a single group.

In sailing along with the land in sight, it is better to steer first one side and then the other, to ascertain the limits of the border of soft sandstone, which we have said exists in this part of the river, and not to quit it more than 2 or 3 cables' length, in obtaining with the lead alternately soft sandstone and mud, by this means you will avoid the Chico Bank.

When you distinguish two small elevations covered with bushes and trees, and an Ombu Tree by the side of two low houses, you have passed the narrowest part of the channel. When you are N. and S. true, with these elevations, you are entirely clear. From thence you may follow the coast, or steer N. W. until you make the edges of the Ortiz.

In the first case it is necessary to steer at a distance from the land, twice as great as before, to avoid the Banks of Santiago, Lara, and Ciudad. In the second case, which is the most prudent, you must pay great attention to the soundings. The depth increases at first to 5 fathoms at the least, and then diminishes gradually to  $3\frac{1}{2}$  and 3 fathoms. As soon as you have these last soundings you are on the edge of Ortiz, and you must then head to the west.

This course will bring you towards the south side. You will soon see the village of Quilmes, situated on a little hill on which there are many Ombu Trees, and the towers of Buenos Ayres, and the vessels anchored in the open road. It is as well when these different objects are well distinguished to steer W. N. W. to avoid the Ciudad Bank. As soon as the Towers of the Cathedral bear S. W. you are in the outward road of the city.

The city of Buenos Ayres is in  $34^{\circ} 36' 18''$  S. latitude, and  $58^{\circ} 23' 57''$  W. longitude. The variation of the needle, in March, 1831, was  $12^{\circ} 30' 59''$  N. E.

**PASSAGE BETWEEN ORTIZ AND THE NORTH SIDE.**—In leaving Monte Video, you may follow the land along 6 miles distant, taking care to avoid the Panella Rocks, near which is a large iron buoy‡ secured by means of a strong anchor and chain.

The Panella Rocks are situated in  $34^{\circ} 54' 15''$  S. latitude, and  $56^{\circ} 26' W.$  longitude. You are on them when you see Point das Yeguas of the hill of Monte Video with the

\* This hill is called Salvador Grande. It is situated between Point Piedras de San Borrombon and Point Indio; the hill situated E. of Salvador Grande, is called Salvador Chico. The pilots confound Indian Point with these hills.

† The Ombu is a tree which thrives on the borders of the River Plate; it is as thick and bushy as a walnut tree; its wood is so peculiar, that it is good for nothing, not even to burn. It grows very rapidly.

‡ This buoy was placed by the Emulation, in May, 1831, by request of the government of Monte Video, to replace one carried away by bad weather.

steeple of the city, and Point Espinillo bears N. by E. by compass, distant 5 miles. These rocks are never uncovered, but when the water of the river is very low, it occasions a long eddy which may be easily distinguished.

Point Espinillo, though low, is apparent, because it terminates the coast of the hill of Monte Video, and it forms the entrance of the river of Santa Lucia, 11 miles from Monte Video.

Being N. and S. true with Point Espinillo, you must steer W. by N. by compass, and follow the land always at the distance of 6 or 7 miles, to avoid the little banks of sand on the borders of the river. You will soon perceive the high scarped mountains, called Barrancas de San Gregorio, or Santa Lucia. When you are N. and S. with their east extremity, called Point de Jesus Maria, steer W. N. W. until you bring this point to bear E.  $\frac{1}{4}$  N. by compass. You must then head to the W. until you make Point Sauce, the only part of the coast which is woody. The latitude is  $24^{\circ} 25' 20''$  S. and the longitude  $57^{\circ} 26' 21''$  W.

From thence you may coast along at a short distance, until you pass north of you a great bank of rocks, of which some are out of water, and are known by the name of the Pipas. You will thus arrive off Point Colonia, with a considerable depth of water, but in a very narrow channel between this part of the coast and the Ortiz Bank.

When you are before the city of Colonia, you leave in good season on your right the San Gabriel Islands, Farallon and Leper, and steer then S. W. for Buenos Ayres.

The navigation south of the Chico Bank, and north of the Ortiz Bank, is not practicable except with a fair wind and a favorable current.

#### PASSAGE BETWEEN THE CHICO BANK AND THE ORTIZ BANK—

You may leave Monte Video until within 9 or 10 miles of Salvador Grande, then you bring the vessel's head W. N. W. to bring the first Ombu Tree of the Magdalena S. E., and avoid by this course the new bank. From this the course is N. W.  $\frac{1}{2}$  N.

This course leads directly to the edges of the Ortiz Bank, and as soon as you come up to this bank and have  $3\frac{1}{2}$  to  $3\frac{3}{4}$  fathoms, bring the head W. until you perceive the village of Quilmes and Buenos Ayres.

If the winds are ahead and the currents favorable, you may beat between Chico and Ortiz Bank, but the tacks should be short, and you should prefer the neighborhood of the Ortiz, because this bank is announced by the progressive and regular diminution of the soundings. If the currents are contrary, you should anchor between the banks, taking care to avoid the soft sand bottom which you often meet in the River Plate.

No. 14. COURSE FOR THE HORNOS ISLANDS.—If you are before Colonia, going from Monte Video to the north of the Ortiz, leave the islands on the right, and when you bring the island of Farallon to the north, steer N. N. W., and then N. by W.: you will soon see the Hornos Islands on the same line, the last islands after leaving Colonia, and covered with small trees, and very bushy.

You will anchor N. W. from the outward one, and at from 1 to  $1\frac{1}{2}$  mile off.

In going from Buenos Ayres, you must steer so as to bring Farallon north of you, and then steer as in the preceding case.

Colonia is situated in  $34^{\circ} 28' 14''$  S. latitude, and  $57^{\circ} 50' 37''$  W. longitude. The variation of the needle was, in September, 1830,  $11^{\circ} 8'$  N. E.

#### Additional Remarks, by Capt. Heywood.

At the entrance of the River Plata, the prevailing winds, during the summer months, from September to March, are north-easterly, with tolerably clear weather over head, but a dense atmosphere near the horizon. These winds haul gradually to the eastward as you advance up the river; and, about the full and change of the moon, strong breezes from the south-eastward are common at this season, accompanied with rain and foul weather. At Buenos Ayres, during the summer months, the S. E. winds are generally fresh in the day-time, hauling round to the northward in the night.

\* This point is so named from a little river of the same name, before which small vessels bound to Colonia, or from the Uruguay, anchor. The brig Star of the South, came near being lost in attempting to approach this point, on some rocks covered with water, which were not seen or indicated on any chart. Fortunately a brig anchored near, prevented the loss by making us a signal.

† *Shoal off the Rio de la Plata.*—The Laurel, McDonald, from London to Valparaiso, put into the river of La Plata, on the 19th of June, 1822, having been obliged to bear up to repair some damage sustained by a heavy sea breaking on board of her. The master reported as follows:—That, on the 15th of June, he discovered a shoal in lat.  $36^{\circ} 28'$  S., long.  $51^{\circ} 30'$  W.; that it appeared to be about a mile long, and the same in breadth, with a sea breaking very high over it, that it had the appearance of sand, and little water on it. He passed within half a mile, and then hove to, sounded with 90 fathoms of line, and found no bottom. He further states, that he had a good chronometer on board, and was six miles out of his longitude when he made the port of Monte Video.

"During the winter months, from March to September, the prevailing winds, at the entrance of the Plata, are S. W. or more westerly; but, up the river, more generally from the northward, than the southward, or west.

"The winter season is the best, in point of weather, at Buenos Ayres; for, the winds being chiefly from the N. W. to S. W. the water is smooth, and the communication can be kept up between the shore and the shipping with more facility. The weather is sometimes, but not frequently, foggy. Fogs are most common in the months of July, August, and September, and prevail more at the entrance of the river, as far up as the S. E. tail of the Ortiz, than above the banks.

"As it cannot be said that there are regular tides in the Plata, but currents as uncertain in their duration, as they are irregular in their rate and direction, no certain allowance can be made for them; therefore a ground-log should always be used, to know the course made good, and distance run.

"The tides, generally speaking, when the weather is fine and settled, and the winds moderate, do not, in any part of this river, rise or fall more than 5 or 6 feet; though at Buenos Ayres, at the distance of 8 miles from the city, we found, in his Majesty's ship *Nereus*, when the winds were strong at N. W. so little, sometimes, as 15 feet water; while with strong breezes from E. S. E. to S. S. W. the depth was upwards of 5 fathoms; but, except on such extraordinary occasions, we had between 17 and 22 feet water. I have heard, however, some marvellous stories of the river having been almost dried up across from Buenos Ayres to Colonia, during heavy westerly gales.

"The River Plata has many singularities, which I think may, in a great measure, be accounted for, from its formation being so different from any other known river. Its entrance being very wide and very shallow, it is affected by every change of wind in a most extraordinary manner; so much so, that a shift of wind may be predicted almost to a certainty, by observing carefully the state of the mercury in a barometer and the set of the currents, which usually shift before the wind. In calm weather the currents are generally very slack; and then as regular, almost, as tides: setting up and down the river alternately. When the winds are variable, the currents are equally so; and I have known the *Nereus* to be current rode four different ways in less than six hours. When the current comes in from the eastward, along the north bank of the Plata, a north-easterly wind may generally be expected to follow; and at the same time (should the wind have been previously to the S. E.) the mercury in the barometer will fall a little; but much more if the transition be quick from south-west, without stopping in the south-eastern quarter.

"When the wind continues in the north-east quarter, the mercury is more depressed (according to its strength) than with any other wind, and there is usually, then, a set into the river on the north bank, and out on the opposite. Indeed, whilst the winds are between N. E. and S. S. E. the current generally runs to the westward past Monte Video, though without much augmenting the depth of water off that place, but filling the river above the banks.

"The winds between N. N. E. and W. N. W. make the water lowest: the out-set being then strongest along the south bank of the river, past the Points del Indio and Memoria; but very inconsiderable along the north bank.

"Before the setting in of a S. W. gale, or Pampero, the weather is usually very unsettled, and the winds unsteady and variable in the northern and north-western boards, preceded by a considerable fall in the mercury, though it usually rises a little again before the wind shifts to the south-west, and often continues to rise, even though the wind may increase from that quarter.

"Before these winds set in at Buenos Ayres, the current runs up, and fills the river unusually high; at the same time as strong an out-set is experienced along the north bank, which continues whilst the winds are strongest from W. S. W. to S., seeming to prove that these winds force up, from the southward, a large accumulated body of water past Cape St. Antonio, which can only find a passage out again by the north shore, where they increase the depth of water, as well as up the river, and particularly in the shallow harbor of Monte Video.\* Whilst these S. W. winds blow the air is cold, and the atmosphere clear and elastic, in a degree rarely to be met with in any other part of the world. They are generally succeeded by some days of fine serene weather, the wind continuing moderate from the southward, or varying to the eastward.

"I have never known the velocity of the tide or current, in the River Plata, any where to exceed three knots per hour; but I have heard it said, by some, that they have found it to run at the rate of six or seven miles an hour!

\* There is a lighthouse at Monte Video, the lantern of which is four hundred and seventy-five feet above the level of the sea.

"As the winds outside the River Plata, and particularly about Cape St. Mary, are most frequently from the north-eastward and northward, except when the S. E. summer and S. W. winter gales blow, about the times of new and full moon, I consider it, on the whole, most advisable, for ships bound into the river, to get in with the land about the latitude of that cape.

"In latitude  $33^{\circ}$  S. the bank of soundings extends off the land full thirty-six leagues, where the depth of water, in longitude  $50^{\circ} 20'$  W. is 94 fathoms, and the quality of the bottom dark olive-colored mud, or ooze, as it is all along the outermost verge of the bank.

"In lat.  $34^{\circ}$  S. and 30 leagues from the land, the bank is steep, and the soundings decrease quickly; in standing to the westward, to 25 fathoms, 20 leagues from land.

"In lat.  $34^{\circ} 20'$  S. and long.  $51^{\circ} 50'$  W. or about 30 leagues east of the Great Castellos Rock, the depth is 63 or 64 fathoms, dark mud. In standing in for the land, between the Great Castellos and Cape St. Mary, the water shoals, in a short distance, from 60 to 25 fathoms; and the quality of the bottom changes to sand, which grows coarser as you approach the coast; and, as far as seven leagues off shore, is intermixed with shells. This bottom is found only in, and to the northward of, the latitude of Cape St. Mary, except very close in with it.

"To the southward of  $34^{\circ} 40'$  S. the bottom is chiefly mud, intermixed with fine sand or gravel; and if a ship happen to be set to the southward of Cape St. Mary, as she hauls in for the land, yet keeps to the northward of Lobos, she will get out of fine sand into dark mud, which is the quality of the bottom, chiefly, between Cape St. Mary and Lobos, as well as 8 or 9 leagues to the eastward of that island; and the depth of water between them is generally 26 to 20 fathoms.

"In lat.  $35^{\circ}$  S., and long.  $52^{\circ}$  W. or 42 leagues true east of Lobos, there are about 90 fathoms water, dark sandy bottom; from whence the bank of soundings takes a S. W. direction. East of Lobos, 27 leagues, the depth is 25 fathoms; and, in steering in, on its parallel, the same depth nearly continues till very near that island. But, if set a little to the southward of Lobos, the water will shoal even to 10 fathoms, perhaps, on a knoll sandy or gravelly ridge, that extends all the way from the English Bank, in its parallel, as far as long.  $52^{\circ} 30'$  W.; or full 18 leagues to the eastward of the meridian of Lobos.

"Thus the approach to this river cannot be considered dangerous, if proper care be taken in navigating, and due attention paid to the lead, and to the course steered.

"I shall here insert the honorable Capt. Bouverie's description of Cape St. Mary, &c. which I believe to be very correct, and his directions judicious.

"Cape St. Mary is a low point, with rocks all about it. The direction of the coast, to the westward of this Cape, becomes more westerly than at any other part northward of it. About six miles northward of it is a house, with a row of trees northward of the house, (probably a fence of high prickly-pear bushes,) which is very remarkable.

"About a mile south of the house is a bluff point, with a few rocks at the foot, which is remarkable, being different from the rest of the coast, the general character of which is a sandy beach. One cannot fail of knowing the Cape by these marks, running down the coast near it. If you are at any distance off, you will not perceive them. The water off Cape St. Mary is shallower than to the northward. Off the Cape, in a S. E. direction, you have 8½ fathoms at the distance of 4 or 5 miles."

I am inclined to think Capt. B. may have been somewhat deceived in his estimation here; for in his Majesty's ship *Nereus*, I found more water at the distance he mentions. On the 17th of November, 1810, at noon, in lat.  $34^{\circ} 42'$  S., and long. about  $2^{\circ} 20'$  E. of the Mount Video, had light winds from S. by W., and fine weather. At half past 1 P. M., tacked in 23 fathoms, to stand in shore, and carried from that depth to 15 fathoms, when sights were taken for the chronometer, which made  $2^{\circ} 13' 21''$  east of Mount Video, Cape St. Mary bearing N.  $66^{\circ}$  W., and standing on, laying up W. and W. by N., tacking in 12½ fathoms water, the prickly pear hedge (mentioned by Captain Bouverie) being on with Cape St. Mary (which is formed by a low rocky islet nearly joining the shore) bearing north by compass, and the breakers stretching to the S. E. of the cape, N.  $7^{\circ}$  E., about 3 miles was our distance from the cape.

Captain Bouverie, in continuation, says, "To the northward of the cape, between it and Palma, you have 10 or 11 fathoms at a little distance from the shore.

"Ships in general make the land with N. or N. E. winds: therefore it is best to keep in the latitude of the cape, or a little to the northward of it, till you get soundings, as the current sets to the S. W. It is better not to make the land north of the cape, nor that I believe there is any absolute danger, but the water in many places is shoal a long way off the land, and would alarm any one not acquainted with that circumstance.

"In lat.  $33^{\circ} 27'$  S., and long.  $52^{\circ} 9'$  W. is a shoal, where we found 9 fathoms water. I believe it is a ridge running in that parallel of latitude all the way to the shore. In latitude  $34^{\circ}$  S. is some tolerably high land, on which is a Spanish fortress, called Fort Terresa. It is a square, with bastions at the angles. It has three guns in the face and one

in the flank, and it is a mark set up.

"Being in the fine sand and shoal fathoms, sand on the land before a ship to allow for the current mentioned N. a little other way.

"I am inclined with off the mon south-westward,

in the flank, and stands about a mile from the beach. About 6 leagues N. N. E. from it is a mark set up, as the termination of the Spanish territories.

Being in latitude of Cape St. Mary, and having got ground in 28 or 30 fathoms water, fine sand and shells, you may reckon yourself 20 leagues off shore; with from 15 to 20 fathoms, sand and clay mixed, you are not far off the land. When you have not seen the land before night, be sure to keep to the northward of the cape by your reckoning, to allow for the current, which sets to the southward. This is the case with the above-mentioned N. and N. E. winds. With S. and S. W. winds the current runs strong the other way.

I am inclined to think that the strong north-easterly currents which are to be met with off the mouth of the Plata when the wind is about to blow, or blowing, from the south-westward, do not extend much, if at all, beyond the bank of soundings.

Agreeing in opinion with Captain Bouverie, that, generally speaking, it is advisable to make the land about Cape St. Mary, I would also recommend, if the wind should be any where between S. E. and N. N. E., to enter the river on the north side of the English Bank, passing Lobos, on either side, according to the wind and state of the weather. There is a good passage between Lobos and the main, having 17 to 14 fathoms water. Variation 13° easterly (1813.)

When within 3 or 4 leagues of Cape St. Mary, in 17 or 18 fathoms, S. S. W., by compass, is a fair course to steer for passing outside of Lobos in the night time; for, with the wind from the eastward, or N. E. the set along shore into the river must be guarded against. Steering this S. S. W. course, the depth of water will increase to 20 and 22; and some casts, perhaps, of 25 or 27 fathoms, (if you are set neither to the westward nor to the southward of it,) and the bottom will change, first to sandy mud, and then to dark blue mud, as you approach the latitude of Lobos. If you are set to the southward, in steering S. S. W. you will not deepen so much. The bottom will keep sandy; and when you approach the latitude of Lobos, you will have no more than 19, 18, and 17 fathoms; but if you are set to the southward of Lobos a few miles, you will have hard casts of from 16 to 10 fathoms, and may rest assured of being on the parallel of the English Bank, and may therefore make a west northerly course, true, till you find the bottom soften, as it is all dark blue or greenish mud, in the channel, between the foul ridge of the English Bank and the north shore, all the way up to Monte Video, in the fair way from Lobos. When off Lobos, if the weather threaten, and it should be likely to blow, a ship will find safe anchorage in the harbor of Maldonado, sheltered from southerly winds by the Island of Goritti, which bears N. 42° W., true, 11 or 12 miles from Lobos. As I have never been in Maldonado myself, I shall insert here what Captain Bouverie says about it.

The Spanish surveys of this bay lay down a sufficient depth of water for any ship between any part of the island and the main; however, it cannot be safely entered, but by small vessels, except to the westward; and you must not go farther in than to bring the N. W. point of Goritti to bear S. S. W.  $\frac{1}{2}$  W., or S. W. by S., by compass, with  $4\frac{1}{2}$  or 5 fathoms, good strong clay. With southerly winds there is, in the east passage, a heavy swell; and the water, from the ground being uneven, breaks almost the whole way across in bad weather. The *Dionede* (fifty-gun ship) passed through it to the anchorage before its dangers were known, and had not less than 18 feet; but there are places where there is so little as  $1\frac{1}{2}$  fathom; and it is very irregular. There is a bed of rocks to the south of Goritti; the marks for it are, the Tower of Maldonado north, and the outer part of Point del Este E. N. E.  $\frac{1}{2}$  E.

In the direct line of the entrance of the bay, from the westward, is a bed of rocks where there are parts having only 3 and quarter less 3 fathoms. The bearings, taken on the rocks, are N. E. point of Goritti, E.  $\frac{1}{2}$  S.; N. W. point of ditto, E. by S.  $\frac{1}{2}$  S.; S. W. point of ditto, S. E. by S.; Point Ballena, W. by N.  $\frac{1}{2}$  N.; the hill of Pan de Azucar, just within the extreme of Point Ballena.

In mid-channel, between these rocks and the island, are  $6\frac{1}{2}$  and 7 fathoms. Their distance from the island is about three quarters of a mile. There are 7 fathoms close to them, all round the western side. The watering place is on the main, close by a battery. The stream loses itself in the sand, except when swollen by heavy rains, and you have to roll your casks about 60 yards over the sand. The water is very good.

Having Lobos bearing N. by W., by compass, distant 3 or 4 miles, you will have about 18 fathoms; and, in making a compass course, W.  $\frac{1}{2}$  S., by ground log, (having due regard to the wind and current at the time,) you will make the Island of Flores ahead of you. In this track your soundings will gradually decrease from 18 to 12 fathoms due south of Black Point, and to 7 or 8 fathoms when you approach within nine or ten miles of Flores.

Though Captain Bouverie says, 'You may run quite up to Monte Video, either by night or day, by making a due west course, first trying the current to make allowance for

it; and though I have frequently done it myself, yet I would not recommend it as a general rule to be followed by strangers to the River Plata. Great care and attention to the course made good, and to the soundings, are indispensably requisite in those who attempt to conduct vessels during the night, in any part of this river; and even these have been but too often insufficient to save ships from destruction. But, in merchant vessels, I fear we cannot always expect to find those qualities; and, therefore, I withhold my opinion of its being advisable for them to run in the night; neither can it be done by men of war, without some risk.

"Flores bears, by the world,  $W. 4^{\circ} 30'$  N. from Lobos, distant 52 miles. It lies nearly N. E. and S. W., has a small hummock in the middle, and one at each end; that to the S. W., being 39 feet high. Between these the land is low and marshy, and overflowed sometimes from the central and N. E. hummock. It may be seen at the distance of five or six leagues from a ship's deck in clear weather.

"There is good anchorage all round this island, but a reef extends in a N. W. direction from the north point about a mile. Seals and sea lions, and various aquatic birds resort to the small island as well as to Lobos; and in the months of August and September, great quantities of very excellent eggs may be procured. With the wind easterly, boats may land on the western side of Flores, particularly in a small cove very near the S. W. part of the island. From Flores,  $W. N. W.$ , the Caretas Rocks (above water) are distant about five miles, and there are 5 fathoms between them. True south, at the distance of 11 miles from Flores, is the north part of the English Bank, on which, in that latitude,  $35^{\circ} 8' S.$ , there are about 12 feet water. The depth of water between Flores and the English Bank is 7 fathoms all the way across, to within a very little distance of both. The English Bank, in lat.  $35^{\circ} 12'$ , generally breaks, and, with a low river, is above water in some places. Its extent, to the southward, has not yet been accurately defined; and for 70 or 80 miles to the south-eastward of it the ground is said to be foul and uneven, and has not been explored.

"Between the Archimedes and the English Bank there is a swatch of 5 fathoms water, (according to Capt. Beaufort, of the Royal Navy, who explored these banks in 1866,) and as many miles wide.

"The shoalest part of the Archimedes Bank, about  $2\frac{3}{4}$  fathoms, is 4 miles in extent, about north and south, and there are 4 fathoms all round it. The centre of it is in latitude  $35^{\circ} 12' S.$ , and the Monte Video bears N.  $22^{\circ} W.$ , by the world, from it, distant 20 miles. Besides this bank, there is a small knoll, in lat.  $35^{\circ} 14' S.$ , which is true S. from the Monte Video 21 miles, and has not more than  $3\frac{1}{2}$  fathoms of water on it, and about 4 fathoms all round it.

"Passing to the southward of Flores, at the distance of a couple of miles, you have  $6\frac{1}{2}$  or 7 fathoms, and may steer  $W. \frac{1}{2} S.$  to pass Point Braba, which bears true  $W. 4^{\circ} N.$ , distant 4 leagues from the S. W. end of Flores. This point is bolder to than the land to the westward, between it and the town of Monte Video, and may be passed close, in  $4\frac{1}{2}$  or 5 fathoms, at a mile or a mile and a half distance. The best anchorage for a frigate, off the town of Monte Video, is with Point Braba bearing  $W. by N. \frac{1}{2} N.$ ; the cathedral N. E. by N.; and the mount about N. W. by N., in  $3\frac{1}{2}$  and 4 fathoms, two miles or more from the town, with the harbor quite open. The bottom is all soft mud.

"The harbor of Monte Video is very shoal, having only from 14 to 19 feet water; but the bottom is so very soft that vessels receive no damage by grounding there. Captain Bonverie says, 'A S. S. W. wind, which blows right into the harbor, and causes a good deal of sea, always occasions the water to rise a fathom or more.'

"In a long continuance of fine weather, the tides sometimes assume the appearance of regularity; but this is not often the case. They are governed entirely by the winds. The winds from the southward cause the water to run out on the north shore strongest. Fine weather and a N. W. wind make the water lowest. It is usual, in Monte Video harbor, to have an anchor to the S. E. and another to the S. W. and to take one in about from the northward; for the water, forced in by the southerly wind, sometimes rushes out with astonishing rapidity; when the anchorage to the north is of the greatest service.

"The Mount Video is in latitude  $34^{\circ} 53' S.$  longitude  $56^{\circ} 3' W.$  of Greenwich; being  $1^{\circ} 24' W.$  of the island of Lobos, and  $2^{\circ} 10' E.$  from the Cathedral of Buenos Ayres. On the summit of this mount is a fortified building, whose base is 42 feet 6 inches by 20 feet, used sometimes for a light-house.\* The diameter of the lantern is 1

\* A lantern, with lamps and reflectors, for Monte Video, was prepared in London, by order of the Portuguese government, and shipped in May, 1819. It was then stated that the lighthouse was to be erected on the Isle Flores; but, on the 26th of October following, an official notice was issued from the British Admiralty, stating that "the lighthouse, which formerly stood upon the mountain of Monte Video, had been re-established, and is to be lighted every evening." The light has, therefore, been materially improved.

feet 6 inches, and its elevation above the level of the sea, 475 feet. At the base of the mount are several runs of excellent water, particularly in two small, smooth, sandy bays, on the S. W. part of it, where ships in the outer road may supply themselves with ease; and another on the east side of the mount, just abreast of Rat Island, adapted to ships in the harbor.

"Giving the preference to the passage on the north side of the English Bank, especially when the wind is any where between S. S. E. and N. N. E. on passing Lobos, because it may be expected most probably to shift, if it does at all, round by the north to the westward; though, perhaps, not before that wind, and the inset, together, might carry a ship up to Monte Video; yet if the wind should be to the north-westward at the time of making the land, it may be pretty confidently expected to shift next to the westward or S. W., and therefore a ship should not strive to beat up, round Lobos and the north channel, against an outset, but stand at once over towards Cape St. Antonio, where, by the time she could stretch across, she would, most likely, find a S. S. W. wind and N. W. current to run up with, along a weather shore, to Buenos Ayres; or to Monte Video, if bound thither, passing to the westward of the bank of Archimedes, in about 5 fathoms water; or, if the mount should be seen in good time, never to bring it to bear to the westward of north, till within 5 leagues of it.

"In standing to the southward, from abreast of Cape St. Mary, with the wind south-westerly, a ship will have from 18 to 24 or 25 fathoms when in the latitude of Lobos, and about 12 or 13 leagues to the eastward of it; and, making a S. S. E. course, the water will then shoal to 18, 16, 12, or 11 fathoms, in crossing the ridge, which is generally composed of sand, grey speckled, mixed with stones, hereabouts; after which the depth increases gradually to 35 or 36 fathoms, over a sandy bottom, in latitude  $35^{\circ} 40'$  S. and longitude  $53^{\circ} 25'$  W. In the latitude of  $36^{\circ}$  S. and 15 or 20 miles farther to the eastward, you will deepen off the bank entirely. A ship, having got as far to the south as  $36^{\circ}$  S., may consider herself in the fair way for proceeding up on the south side of the English Bank; and, if the wind serve, a true west course may be made good.

"In latitude  $36^{\circ}$  S. the depth of water on the meridian of Cape St. Mary, is 38 fathoms, and the bottom fine grey sand, like ground pepper.

"Keeping still to the westward, on that parallel of  $36^{\circ}$  S. the depth decreases to 19 or 18 fathoms, true south of Lobos; and for 10 leagues farther you have from that to 15 fathoms. But if from the latitude of  $36^{\circ}$  S. on the meridian of Lobos, you make a W. by N., or W. by N.  $\frac{1}{2}$  N. course, true, you will shoal the water to 8 or  $7\frac{1}{2}$  fathoms, in latitude  $35^{\circ} 45'$  S. on the meridian of the English Bank. The quality of the bottom, generally, in this track, is sandy, mixed with small stones; and the nearer you approach to the ridge of the English Bank, it is intermixed with bits of shells, and sometimes with clay or mud.

"From latitude  $35^{\circ} 45'$  S., due S. of the English Bank, a W. N. W. true course to latitude  $35^{\circ} 33'$  S. will bring Mount Video to bear N. by the world, in about  $6\frac{1}{2}$  fathoms, mud, at the distance of 13 leagues from Point Piedras; and from this position the same true course may be made to raise the land about Point del Indio, if bound up to Buenos Ayres; or N. W. or more northerly, to get sight of the Mount Video; having due regard to the set of the current, up or down the river, that you may neither be horsed on the S. E. tail of the Ortiz Flats, nor on the western part of the Archimedes' Bank. The bottom above this is soft mud, or clay, in the channels, fit for safe anchorage. In latitude  $35^{\circ} 30'$  S., or thereabouts, and due south of the Archimedes' Bank, or some miles further to the eastward, I have been told by some persons they have had as little as 4 fathoms, hard ground.

"Ships leaving Monte Video, to proceed up to Buenos Ayres, must be very attentive to the lead; and the course steered across the river must be very carefully regulated by the set of current at the time. If the weather be sufficiently clear, the mount is the most sure guide, keeping it by an azimuth compass, on the magnetic bearing N. E. by N.; and when it sinks to an eye in the top, a more westerly course may be steered to raise the land about Point del Indio. This direction is intended to apply particularly to frigates, or any ships drawing more than 16 feet water; because it is not advisable for them to cross the tail of the Ortiz Flats much farther to the westward than a true S. W. course from the mount will take them; for, with a low river, I have had barely  $3\frac{1}{2}$  fathoms, in the Nereus, with the mount bearing N.  $35^{\circ}$  E. by compass, distant 10 leagues. At other times, I have sunk the mount on a N.  $53^{\circ}$  E. magnetic bearing, and had as much as  $3\frac{1}{2}$  fathoms water; but the river was then well filled.

"The Ortiz Bank extends from lat.  $34^{\circ} 25'$  S. to lat.  $35^{\circ} 15'$  S. Ships passing between the Ortiz and the south shore, have only to keep the land in sight, to clear the bank. On the Chico Bank, (the smallest of the Ortiz and the most southern,) there is the wreck of a vessel, the mast of which serves as a beacon, lying about 12 miles east from El Embudo, and 8 or 10 miles west from the S. E. buoy on the Ortiz, and may be

passed on either side, as there are 3 fathoms very near it all around, and also four buoys. There is a good passage between the Ortiz Bank and Chico, with nothing less than 4 fathoms; the Ortiz side is the deepest.

"Soundings, on approaching the south side of the Ortiz Bank, are regular, and shoalen gradually. When you get hard bottom, keep off a little and deepen into  $3\frac{1}{2}$ , 4 or 5 fathoms, soft mud. The approach to the Chico is not safe on the Ortiz side, as you get from 5 into 2 fathoms directly, in some places, which makes it safest to keep on the Ortiz side of the middle passage. The middle passage is soft mud until very near the banks; the passage between the Chico and the shore is for the most part soft mud, but in many places it will change suddenly, and appears to be formed of hard and soft ridges alternately. You will carry  $5\frac{1}{2}$ , 5, and 4 fathoms in the channel, and the passage is from 4 to 6 miles broad. Tide rises in the river about 5 feet in settled weather.

"For the distance of full 17 miles to the south-eastward of the Ortiz Beacon, there is generally no more, and often less, than  $3\frac{1}{2}$  fathoms: the bottom tough clay, nearest the bank; and in some places farther to the south-eastward, soft mud, not more than  $3\frac{1}{2}$  fathoms.

"After sinking the mount about N. E. by N. and having  $3\frac{1}{2}$  fathoms, a W. S. W. course will raise the land, (if the weather is clear,) about Point del Indio to the eye at the masthead; and probably you will not have more than  $3\frac{1}{2}$ , or at best,  $3\frac{1}{2}$  fathoms. The mount and land near Point del Indio are sometimes visible at the same time.

"Point del Indio is in latitude about  $35^{\circ} 16'$  S. and  $0^{\circ} 56'$  W. of the Mount Video, from which it bears S.  $63^{\circ}$  W. by the world, distant 50 miles. There is little more than 3 fathoms at the distance of 10 or 11 miles, when the river is in a mean state; farther to the southward, and off Point Piedras, there is only that depth 14 or 15 miles off shore. Very great caution, therefore, is required in approaching it; and a constant lookout should be kept for the land, as it is very low, and cannot be seen farther than 12 or 13 miles in any weather, from the deck of a frigate.

"When the land is barely raised to an eye 19 or 20 feet above the surface of the water, a W. N. W. magnetic course will lead along shore, between it and the south part of the Ortiz, which is distant about 14 miles from it; and between them there is no where more water than  $3\frac{1}{2}$ , but mostly  $3\frac{1}{2}$  fathoms. With a high river, I have had a quarter less 4 fathoms. The nearer the Ortiz, the deeper the water.

"In steering up W. N. W., with the land seen from the deck, (if clear weather,) you will have  $3\frac{1}{2}$  or  $3\frac{1}{2}$  fathoms, yet if the river is low, perhaps some casts of 3 fathoms, and raise a remarkable clump of trees, called Embudo, which are much taller than the rest, highest at the west end, and lie in lat.  $35^{\circ} 6'$  S., and in long.  $1^{\circ} 16' 30''$  W. of the Mount Video, or  $57^{\circ} 30''$  E. of the cathedral of Buenos Ayres. At some distance to the westward of the Embudo trees, there is another clump about the same height; but these being highest at the east end, are sufficiently distinguished not to be mistaken for the true Embudo.

"When in  $3\frac{1}{2}$  or  $3\frac{1}{2}$  fathoms, the Embudo trees bear by compass W. S. W., the S. E. end of the Chico Bank will bear W. N. W., or thereabouts, 10 or 11 miles from you, and you must now determine from the water that your ship draws, and the then direction of the wind and state of the weather, whether you will pass between the Chico and the shore, or between the Ortiz and the Chico. I have passed up and down several times between the Chico and the south shore in the Nerens, lightened in her draft to 18 feet; inches; but I would never attempt it again from choice, now I am better acquainted with the middle channel between the Chico and the Ortiz, and have every reason to believe that the middle ground some charts lay down in it, does not exist.

"A ship not drawing more than 15 feet may take either passage, and of the two, ought perhaps to prefer that to the southward of the Chico Bank, particularly if the wind should be well to the southward, as she might take her soundings from the weather shore, and keeping in somewhat more than her own draft, run up along it, and by not deepening above 3 fathoms, would ensure being to the southward of the Chico.

"The S. E. end of the Chico Bank bears from the Embudo trees, N.  $32^{\circ}$  E., true, distant 10 miles, and E.  $9^{\circ}$  N., 13 miles from Atalaya church. Its latitude there is  $34^{\circ} 56' 30''$  S., and longitude  $1^{\circ} 9'$  W. of the Mount Video. This bank runs in the direction of N.  $52^{\circ}$  W., true, or N.  $65^{\circ}$  W., by compass, about 13 miles to its N. W. end, which is in latitude  $34^{\circ} 48' 50''$  S., and  $17^{\circ}$  E. of Buenos Ayres Cathedral. From this N. W. end, in 14 feet water, Atalaya Church bears S.  $14^{\circ}$  W., distant 11 miles; and Point Santiago, forming the Ensenada de Barragan, bears W.  $4^{\circ}$  N., 14 miles from it. The breadth of the Chico does not exceed two miles, or perhaps a mile and a half, and its inner edge is about 9 miles from the shore. The water between it and the shore is no where more than  $3\frac{1}{2}$  fathoms, and the deepest water is along the inner edge of the shoal, at the distance of half a mile from it, or less in some places. About midway between it and the shore there is a quarter less three fathoms. On some parts of the Chico there

is very little. There was, on this shoal, excellent bearing very necessary centre and e.

ts of the Chico there

is very little water, and within the limits I have assigned to it no more than 14 feet. There was, for some years, the mast of a vessel called the Pandora, which was wrecked on this shoal, in lat. 34° 54' S., about 5 miles from its S. E. end, which proved an excellent beacon to guide ships passing it on either side; but it has disappeared. It is very necessary that three buoys should be placed on this dangerous shoal, to mark its centre and each end.

To ships drawing less than fifteen feet, it is only further necessary to recommend care and attention on approaching Point St. Iago, which forms bushy and distinct; and when it is brought to bear to the south-westward, haul out into the stream of 3½ fathoms, to round outside the spit, which runs about N. W. by compass from Point St. Iago at least ten or eleven miles; its extreme point, in two fathoms, being five miles from the shore. When two remarkable trees on Point Lara are brought to bear S. by E. ½ E. or S. S. E. by compass, you are past the Spit. This mark will also lead a ship of that draught of water clear to the westward of the Spit, in running in towards the Ensenada.

After passing the spit of Point St. Iago, in 3½ fathoms, a W. by N. northerly course by compass will lead up to the outer road of Buenos Ayres, where any ship may safely anchor in the water she draws, if the river is low.

Frigates, or any vessels drawing more than 16 feet water, should barely raise the land about Point del Indio to the eye on deck, and borrow nearest the Ortiz: more particularly when the Embudo trees are brought to bear as far as S. W. by W. (magnetic;) for, with the Embudo bearing from S. W. to S. S. W. the bottom is flat, off to 3 fathoms, full 7 miles from the shore, and chiefly hard clay. Therefore, when the Embudo trees bear W. S. W. by compass, and you are about 9 or 10 miles off shore, in 3½ fathoms, if you have a leading wind, haul to the N. W. by W. or more northerly; as may be required to clear the S. E. tail of the Chico, on which a red buoy is placed, and you will soon deepen your water to 4 fathoms, and more in the middle channel, between the Chico and the Ortiz Shoal. The fair course through, between them, is about N. W. by W. ½ W. (magnetic,) and in mid-channel the land can but just be distinguished from the quarter-deck of a frigate. When the Embudo trees bear S. 20° W. by compass, you will be abreast of the S. E. end of the Chico, and may either take your shoal soundings along its northern or outer edge, to about a quarter less four, if the wind is southerly, or if the wind be northerly, or easterly, borrow into a convenient depth along the southern edge of the Ortiz. I believe the breadth of this middle channel may be five or six miles, and the depth of water from 4 to 5½, and even 6 fathoms, in the fair-way, about the N. W. part of it, and abreast that end of the Chico. The quality of the ground all the way through this channel is generally soft mud, and fit for safe anchorage.

The N. W. pitch of the Chico Bank, on which is a red Buoy asbefore mentioned, being passed, and the depth of water 5 or 5½ fathoms, you may steer by compass W. by N. ½ N. or W. by N. for Buenos Ayres, taking care not to shoal under quarter-less four off Ensenada, till Point Lara trees bear S. S. E. A little more than half way from Point Lara to Buenos Ayres there are two other remarkable trees. When moored off Buenos Ayres, in the Nereus, in 19 feet water, and the bottom soft mud, these trees bore by compass, S. 17° E. the cathedral S. 67° W. and the spire of the Recoleta Convent S. 76° W. variation 12½ E.

P. HEYWOOD.\*

## THE RIVER PLATA TO CAPE HORN, FALKLAND ISLANDS, SOUTH SHETLAND, &c.

The coast of the Pampas, or plains of Buenos Ayres, extends from the River Plata to the Colorado or Red River, represented in lat. 39° 50' S. It is entirely flat, and destitute of harbors. The interior is one vast plain, mostly covered with grass and clover, the food of millions of horned cattle. The maritime part, next the sea, has been called by the Spaniards the Pays-del Diable, or Devil's Country, (no very attractive appellation,) yet the coast may be approached with safety, as the soundings are regular.

ARIEL ROCKS.—Coast of Buenos Ayres, lat. 40° 1' S., long. 57° 37' W. Rocks supposed to be above water.

Extract from the log book of the schooner Ariel, of Whitehaven, Thomas Dixon, master, on her passage from Liverpool to Valparaiso, Dec. 22, 1827:

\* There is a good harbor at this place.

"At 11 hours 45 minutes, A. M., moderate breezes from the N. E., steering S. S. W. by compass, saw something of a reddish appearance, a little above water, at about a quarter of a mile distant. Hauled in for it, sounded, and obtained bottom at 47 fathoms, fine grey sand. The object seen was about 6 feet above the water, and 20 or 30 feet in circumference, but more extensive underneath. When close to, we saw another head, at about 2 or 3 cables' length to the N. E. of the first, also of a reddish appearance. The sea was breaking over them, with a noise. There was some sea-weed, and a number of sea-birds about them. These rocks lie in the general track of vessels round Cape Horn, to the west coast of South America. The latitude was obtained by a good meridian altitude of the sun, and the longitude, by good lunar observations taken that day, and by chronometric observations.

THE DIXON, Master."

**RIO NEGRO.**—In coming from the eastward to Rio Negro, the navigator should endeavor to make the land, in about the parallel of  $49^{\circ} 52' S.$ , and longitude  $62^{\circ} 15' W.$ , when he will first see Point Raza, which will be readily known by three remarkable hummocks. After approaching to within one league of this point, he may steer south-west towards Rio Negro, taking care not to come into less than 6 or 8 fathoms water, with a sandy bottom. The shore is a continuation of low sand hills, interspersed with heath and brushwood, until you approach the river, where the hillocks become more elevated, and are composed of clean white sand, lying in ridges or undulations, like the waves of the ocean.

About 4 or 5 miles south of Point Raza, is a singular hillock of brushwood, having small shrubs towards the east end, which from the sea appears like a drove of cattle. Eight miles to the south and west of this, is a remarkable gap, about 2½ miles back of the beach. As you approach the entrance of Rio Negro, the range of white sand hills will terminate, and the mouth of the river bearing W. S. W. appears high and bluff on the eastern side. The western point of the river is low, but rises gradually to the South Baranca, which is high and bluff, terminating in a perpendicular point, and this point is a table land, for 4 or 5 miles to the westward.

To enter the harbor of Rio Negro, without a pilot, the south-east channel is to be preferred; and you must keep along in 4, 5, or 6 fathoms of water, until you bring Point de Maine to bear N. W. Then steer for the mouth of the river, observing to keep Point Welcome, which is a remarkable bluff promontory, about 10 yards open of a low point off the pilot's house. These marks are distinctly seen, when Point de Maine, the eastern point of the river, bears N. W. But beware of the flood tide, which sets strong over the north bank; and if your vessel draws more than 10 feet of water, you must not attempt to enter until three quarters of flood, when you will have from 2 to 2½ fathoms of water between the banks, which will deepen as you approach Point de Maine. The breakers on the bank are distinctly seen, and with a southerly wind it frequently breaks all round the channel. Having passed through between the north and south banks, you will find 4, 5, and 6 fathoms of water, but you must be careful and keep the eastern point on board until you are inside of the point of the borras; by which means you will clear the inner bank, which extends two thirds of its length outside the harbor's mouth. In this river, at the town, there are about two hours flood tide, and commonly about ten hours of ebb tide, frequently running at the rate of five or six miles an hour. But within the mouth of the river the flood tide runs four hours, and the ebb tide eight hours, at the rate of three and a half miles an hour. It is high water at the bar, on the days of new and full moon, at a quarter past 11; and the water rises there 11 feet on the spring tides, and 8 feet on the neap tides; but when the wind blows strongly from the S. E. the tide rises from 12 to 14 feet. There is a regular tide along the coast, 6 hours flood and 6 hours ebb, but the flood tide inclines rather towards the shore, about N. E. by N., at the rate of 2 or 3 miles an hour. Consequently in entering the Rio Negro, particular attention must be paid to the currents and tides which set strongly to the N. E. round the Point de Maine.

In this river, refreshments of all kinds can be procured.

**FAULKLAND ISLANDS,** the Malvinas of the Spaniards.—These islands have borne different names, successively imparted by the older navigators. Recently they have been taken possession of, in a formal manner, as belonging to the United Provinces of South America. And on account of some outrage committed by the settlers on American vessels, the settlement was broken up by the U. S. sloop of war Lexington, in the year 1831. Since then they have been taken possession of by order of the British government.

The islands and islets, in general, appear equally bleak and desolate, presenting barren shores and naked limestone mountains, with no other vegetation than heath and grass. In the low grounds a stratum of peat, 2 feet thick, covers a bed of stone or slate. The quadrupeds are wolves and foxes, which earth themselves alike. Seals and sea birds are innumerable. The advantages of the islands are their excellent harbors, a climate com-

monly temperate and abundant.

—These islands have ators. Recently they g to the United Pro- mitted by the settlers sloop of war Lexington of by order of the

plate, presenting barren than heath and grass, f stone or slate. The Seals and sea birds are harbors, a climate com-

monly temperate and healthy, but subject to great vicissitudes. The running waters are abundant. Though the islands have no wood, there is no want of fuel, the peat affording it in abundance. Large quantities are sometimes found, which appear to come from the south and west.

Our information with regard to the islands is yet imperfect. The positions in the table are, however, given as nearly as we could obtain them. We believe that they are very near the truth, especially in the western points.

Lieutenant Grant, commander of the *Lady Nelson*, in the relation of his voyage to New South Wales, has given some useful remarks on these islands. He states that, on the 21st January, 1802, having before intended to touch at these islands, they came safely to an anchor in Hope Bay, or Little West Point Harbor, in the N. W., and then proceeds as follows:

"Our intention had been first to touch at a cluster of islands to the westward, called New Islands by the Americans, who are the most constant visitors of Falkland's Islands. On New Islands are found plenty of goats and hogs. They lie about 30 miles S. S. W. by compass from West Bay, as a N. N. E. course carried us from them clear to the entrance of West Point. They are distinguished by a particular saddle island and a bluff, standing separately from each other. They are a little to the northward of Beaver Island, and may be easily found by the two remarkable islands just mentioned.

"As it is of the greatest consequence to mariners, when in want of water or refreshments, to obtain every possible information in order to secure a port amongst this foul-weather group of islands, which purpose may be defeated by the smallest oversight, I think that a few remarks made in the run may not be unacceptable.

"Having made New Islands, the westerly wind, which generally prevails, blowing very strong, and in squalls, would not permit us to anchor. We were therefore under the necessity either of making the harbor of West Point, or running in the night through a passage among the Jasons, well known to be full of rocks and shoals, many of them not laid down in any chart. I have before observed, that 30 miles N. N. E., by compass brought us to the entrance of West Point Harbor. In this run there are, on the right hand, a few small flat islands, called Pass Islands. These ought to be kept on board near enough to see the surf breaking on them; and soon after a remarkable island, with a steep side, will present itself, having the appearance of a split in the middle, which has given it the name of Split Island. Here we observed the latitude, at noon, to be 51° 14' south, when it bore E. N. E., by compass, distant three miles. The split must be brought to bear south by west in running in, and north by east in coming out. Observing this, a vessel will find itself in the fair-way; and right ahead coming in, or right astern going out, a sight will be had of West Point entrance, making at first like three hummocks, to the right of which is the mouth of the harbor. The small harbor on the left is preferable to the larger one on the right, though anchorage may be found in both, but fresh water may more readily be had in the little harbor. Both these together form nearly an oval, divided by the passage which runs directly through, where the tides of flood and ebb alternately enter. A vessel must therefore haul close round the rocks on the south side, to get into the little harbor for the ebb tide, with which she must go in, unless it blows very strong, so as to enable her to stem the flood, both tides running here with great rapidity, and when it blows hard raising a confused sea. There is a sandy beach at the top of the harbor, off which a vessel may choose her depth of water to anchor in. In going out of the harbor, the northern passage is most eligible; and a westerly wind, with a course N. by E., by compass, will carry a vessel out, provided she get under way at the first of the ebb.

"Five small perpendicular rocks, called the Needle Keys, appear when out, standing together, bearing N. E. by E., or thereabouts, from the harbor's mouth. It is best to leave them on the right; but should there be little wind, and the tide strong, as was the case when we passed them, a vessel may go close to the right of them. The tide must be attended to, as it runs strongly betwixt them. The water close to them is very deep, as we were carried by the tide near enough to throw any thing upon them. The bottom is very foul, so that if an anchor is let go, it is a chance if it is ever recovered; and should the wind continue light, the tide of flood making, a vessel may anchor at Sedge Island, if she can get as far down, where 10 fathoms water will be found, with a sandy bottom, within 2 or 3 miles of the shore. From Sedge Island, a N. by E. course will carry a vessel clear out to sea.

"It is proper to observe here, that if a vessel is obliged to leave the Needle Keys on her left hand, the nearer she keeps to them the better, and even to haul over on the larboard side after she is past, as she will have the more room to weather a ledge of rocks lying at a considerable distance out from Saunderson's Point. This passage is much preferable to running through the Jasons.

"Falkland's Islands have been described by many voyagers, whose stay there gave them better opportunity of observation. I shall just observe that they lie very convenient for being touched at on long voyages, when there happens such a necessity for a supply of sea stock as we experienced.

"The soil is light, producing a strong grass, known by the name of tussock, which, if set fire to, the turf will burn for a considerable time; and notwithstanding heavy rains, it is not to be extinguished. I saw but little timber, and even brushwood did not appear to be in plenty. Few birds are to be seen, but geese and penguins are in great numbers.

"We found the geese excellent eating, without the least taste of fish, as they live on grass and sea-weed. Celery was found growing plentifully. We used it freely, as its anti-scorbutic virtues are well known.

"We found an American ship lying here, called the *Washington*, of Nantucket. Her commander, Jedediah Fitz, informed me that the American sailors have discovered potatoes eaten raw to be a powerful anti-scorbutic, and that their whaling vessels constantly took a quantity with them to sea, to eat raw, as an antidote against the scurvy. He had planted a garden here, as was the custom with vessels visiting this place, and brought some potatoes fresh dug from it, which he recommended me to taste, after setting me an example. I complied, and must say that I have before taken a more palatable medicine. He made use of the young leaves of the common dock, boiling them as cabbage, to eat with his meat. He stripped the leaf from the rib or stem in the middle, which he said had a purgative quality. He made no use of the celery, as he thought the dock was preferable to it. I dined with him on board his ship, when a dish of the latter vegetable was served upon table, and upon eating, I thought its taste not unpleasant."

It is to be observed that the Eastern or Little Island has never yet been regularly surveyed, and its true figure is yet unknown. Many dangers not yet laid down in the charts may therefore exist in the vicinity. Of this there has lately been a signal example, in the sudden loss of the French sloop *Uranie*, which was wrecked on the 13<sup>th</sup> of February, 1820, by striking on a sunken rock near the mouth of French Bay. The vessel, commanded by M. Freycinet, was returning from her voyage around the world. She had been driven by a dreadful storm from Good Success Bay, in Tierra del Fuego. Happily her people and stores were saved, by an American, which happened to be near the spot. The account of this accident is so vague that we cannot gain from it the position of the rock, but it is clear that by French Bay is meant the Berkeley Sound of our charts.

Captain Barnard, who was inhumanly left in those islands, where he was a long time resident, by the master and crew of a British vessel, whom he took off a wreck, states that all the dangers with which he is acquainted (with the exception of the rock on which the *Uranie* was wrecked, are covered with kelp); and as a rule all the kelp is to be avoided. Captain King, of the R. N., has given some valuable remarks on kelp, in his survey of Tierra del Fuego, republished in this volume, to which we refer the reader.

Mr. Wm. Marsh, of the brig *Nancy*, 1813, has favored us with a rough sketch of the Maluinias, by which it appears that there is a group of isles at the S. W. end of Soledad, or the Little Maluina, which forms a convenient harbor, the track to which is denoted by the Chart, Kelp Bay, to the eastward of this group is full of weeds.

The late Capt. John McBride, of the Royal Navy, kept a regular journal of the winds and weather at the Falkland Islands, from 1<sup>st</sup> of February, 1766, to 19<sup>th</sup> January, 1775, which was published in 1775, by Mr. Dahymple. The journal concludes with the following general remarks:

"From looking over the foregoing journal of the winds, for the space of one year, there will be found to prevail in the western quarter, and generally blow a close-reeced topsail gale, with a cold air. In November the winds begin to be more frequent in the N. W. quarter, generally hazy weather, and for the most part blow about 16 or 20 hours, when it begins to rain. The wind then regularly shifts into the westward, and so on, till it gets to the S. W. by S. and S. S. W., when it blows fresh, and clears up. This S. S. W. wind continues for about 16 hours, then dies away, when the wind shifts again to the N. W. quarter. This continues during December, January, and February, and changes in the manner above mentioned, every three or four days. As March comes on, you have these changes but seldom, and as the winter advances, they are seldom in the N. W. quarter, but rather incline to the E. N. E., which is generally accompanied with sleet and snow. There is not the least proportion in the gales between winter and summer. In summer, (as I have before observed,) as the winds are in the westward, they blow in such heavy squalls off the tops of the mountains, that it is sometimes an hour before a cutter can row to the shore, although the water is smooth, and the distance but one cable and a half off. In winter the winds are pent up by a keen frosty air. The most lasting gales are those from S. by E. to S. by W., and are extremely cold."

The water th  
Weddel's plan  
to be obtained

In January and February, the thermometer several times rose to  $59^{\circ}$ , but no higher. In August, it once fell to  $20^{\circ}$ , but was seldom lower than  $32^{\circ}$ .

Of the isles, in general, Captain M'Bride said, "We found a mass of islands and broken lands, beaten by storms almost perpetual. Yet this is summer; and if the winds of winter hold their natural proportion, those who lie but 2 cables' length from the shore must pass weeks without having any communication with it."

**BERKELEY SOUND** is the Puerto de la Soledad of the Spaniards; and it would, perhaps, be more proper to give it that designation. It was at the N. W. part of this harbor that the French, under M. de Bougainville, had their settlement in 1764, as noticed above. A particular plan of it is given in the journal of the voyage, by which it appears to be more than a league wide at the entrance, extending east and west 3 leagues, to four islands which lie in the inner part of the harbor; three on the north, and one on the south side. The latter is the largest, and is called Penguin, or Burnt Island. The soundings to the space between these islands, decrease from 20 to 7 fathoms; and within the isles from 7 to 3 fathoms. Here, therefore, a convenient shelter may occasionally be found, and a day's sport, if desirable, among geese, bustards, ducks, seals, &c.

**L'AILLE SHOAL**.—This shoal was seen on the 1st of October, 1817. Mr. Poole places it in latitude  $51^{\circ} 51'$  S. and longitude  $64^{\circ} 50'$  W. It extends about north and south, breaking very high in an extent of 200 or 300 yards. The ship was then steering S. E. and about three quarters of a mile from it off and on. Steering south, about  $\frac{1}{2}$  mile, had soundings in 87 fathoms.

**L'AILLE ROCK**.—This rock is also reported by Captain Saloy, commander of the French brig of war L'Alert, who places it in lat.  $51^{\circ} 45'$  S. long.  $65^{\circ} 10'$  W. having soundings in a few feet water, rocky bottom. Also seen by several merchant vessels, one of which lowered a boat, and sounded on it. A depth of only a few feet water was found, and the surface of it, according to the lead, seemed to be very uneven. Capt. Saloy also reports that the sea always breaks on it. The position of this rock renders it exceedingly dangerous to vessels going round Cape Horn into the Pacific, as it lies nearly midway between the Falkland Islands and the South American Coast.

## EAST AND WEST PATAGONIA, STRAITS OF MAGALHAENS, AND THE SEA COAST OF TIERRA DEL FUEGO.

[From the Survey of Capt. P. P. King, R. N. F. R. S. &c.]

### COAST OF PATAGONIA FROM PORT ST. ELENA TO CAPE VIRGINS.

[In the following Directions all the bearings, which are not otherwise distinguished, are corrected for Variation. The latitudes being all south, and the longitudes west of Greenwich, and the variation easterly, the distinguishing letters S. W. and E. have been omitted.]

**PORT ST. ELENA**.—The plan in the Admiralty Chart, which is a copy of the excellent and correct survey by the officers of the Spanish ships *Atrevida* and *Descubierta*, is sufficient for the navigator; there is also a plan in Weddel's Voyage that is equally correct. The harbor may be easily known by some hummocky hills on the N. E. projecting point, on the eastern of which is a remarkable stone that appears to have been placed there as a monumental record, but which is a natural production. The best anchorage is at the N. W. corner of the bay, in 6 or 7 fathoms, but not too near to the shore, for when the sea is heavy the ground swell breaks for some distance off. In working into the bay the 2 fathom bank must be avoided, for which the low island is a good mark.

The projecting head at the north end of the bay is in

Latitude.....	$44^{\circ} 30' 45''$

Variation of the compass.....	$19^{\circ} 10'$
H. W. at full and change.....	4 o'clock.
rise at springs.....	17 feet.

The water that is contained in the wells, the situations of which are given from Mr. Weddel's plan, is too brackish to be worth consideration; nor is there any fresh water to be obtained from any part of the harbor. Of fuel, a temporary supply may be pro-

cured from the small shrubby tree that is described in the account of Port Desire, which is tolerably abundant here. Guanacoës, ostriches, armadillos, and the cavia, or Patagonian hare, are to be procured, as are also wild ducks, partridges, snipes, and rails; but fish seem to be scarce. The guanaco affords an excellent food, but it is difficult to approach them: one that was shot by us, when cleaned and skinned, weighed 168 pounds. The Indians sometimes visit this part of the coast, which is used by them principally for burying their dead.

In approaching Port St. Elena from the northward, there are several rocks near the shore which are very little above the water, and there is a considerable reef in the offing, situated  $4\frac{1}{2}$  miles S.  $78^{\circ}$  E. from Cape Raso, and N.  $51^{\circ}$  E. 8 miles from the N. E. trend of the north head of the port. It is a dry rock, and is near the extremity of a ridge which probably projects off from the latter point, for there are two dry docks in the same line of bearing, one  $1\frac{1}{2}$  mile and the other  $3\frac{1}{2}$  miles from the point, besides several patches which break. The tide sets rather strong along the shore, which is fringed by reefs for 2 or 3 miles off; great caution should therefore be used in approaching the coast, as the water is deep, and if becalmed, it may be necessary to anchor, which will be in at least 30 fathoms water.

Should the above reef be as continuous as it appears, there should be good riding in the bay between Cape Raso and Port St. Elena.

Between the south head of Port St. Elena and Cape Two Bays, are two bights in the coast, the southernmost of which is considerable and may probably afford a good anchorage. Cape Two Bays is a rounded point; the hill close to the sea on the most projecting part of the cape being in lat.  $44^{\circ} 58'$ : the small islet of Arce, to the south-east of the cape, is in lat.  $45^{\circ} 0' 50''$ , and lon.  $65^{\circ} 25' 25''$ ; and Rasa Island is in lat.  $45^{\circ} 6' 30''$ , lon.  $65^{\circ} 20' 11''$ .

The coast trends westerly round Cape Two Bays, and forms the northern part of St. George's Gulf.

The southern limit of St. George's Gulf, Cape Three Points, is very easily discovered at sea by its very level outline, being a long range of table land, higher than any part near it, visible from the deck for more than 20 miles; and to the south-east, detached, but near the range, there is a conical hill, which is easily discerned from the northward, but from the north-east is not seen, being concealed by the ranges of land behind it to the south-west. At  $6\frac{1}{2}$  miles to the south-east of Cape Three Points is Cape Blanco, a low rugged tongue of land, terminated by a rounded but very rugged hillock and two smaller ones; which, when first seen, appear to be islands detached from the coast. The neck of land which forms the communication with the coast is low and sandy, and probably offers, on its south side, shelter from southerly winds.

There are several shoals off this part of the coast, that at low water would doubtless be dangerous. His Majesty's Ship Adventure, passed over two, and had not less than 5 fathoms, but possibly at low water the depth may be considerably less; they are thrown up by the force of the tide, which sweeps round the cape, into and out of St. George's Gulf, with great strength.

The north and south ends of the northern shoal bear respectively from Cape Three Points and Cape Blanco east, distant from the former 7 miles, and from the latter 5 miles, consequently it extends in a N. by W. and S. by E. direction for  $5\frac{1}{2}$  miles: its scarcely a quarter of a mile wide.

The north end of the southern shoal bears S.  $75^{\circ}$  E. 7 miles from Cape Blanco, and extends in nearly a south direction for 2 miles. Between these shoals there is a passage 2 miles wide, and the depth gradually increases to more than 15 fathoms.

Within the outer shoals are 2 others seen by the Spaniards; they are laid down from the authority of a chart communicated to me by Don Felipe Bauza. The outer northern shoal is probably the one noticed by Commodore Byron\* who described it to bear from Cape Blanco W. S. W.  $\frac{1}{2}$  S. 2 leagues, the depth diminishing, as he approached it from the eastward, from 13 to 7 fathoms. There is, however, much shoal ground to the north-east; for in the year 1829, having approached the land, and being 14 miles from Cape Three Points, bearing S.  $38^{\circ}$  W. mag. the depth rather suddenly decreased from 40 to 14 fathoms, pebbly bottom, so that the foul ground extends for 14 or 15 miles to

\* Shoals off Cape Blanco.—Mr. Simpson's Journal says, "Found various soundings, the shallowest water 7 fathoms on a bank. Then Cape Blanco bore S. W. by W.  $\frac{1}{2}$  W. 2 leagues, and the southernmost land in sight south. This shoal shows itself by a great rippling; we had 12 fathoms without it, close to the rippling, and were soon over it and steered directly in for the land. The water soon after deepened very fast; at one league from the shore we had 42 fathoms."

The shoals, therefore, that the Adventure passed, are the same as the above. Hawkesworth has doubtless made an erroneous extract from the Commodore's Journal, in describing them to be four instead of two leagues off the shore.

e above. Hawkesworth  
in describing them to be

the north-east of the cape, the edge of the bank, (14 fathoms,) being about 8 or 10 miles within the soundings of 50 fathoms. On approaching it, the quality of the bottom becomes irregular, and changes from ooze to sand, and the shoal patches are pebbly; so that by attention to the soundings and nature of the bottom, these shoals may be easily avoided.

A good mark to avoid them is, not to approach so near to the cape as to see the rugged hillock of Cape Blanco, and to keep the high land of Cape Three Points, which is visible from the deck, about 20 miles, on the horizon.

The flood or northerly tide ceased in the offing at 4h. 15' after the moon's passage, which agrees very well with the establishment of the tide off Penguin Island; but in the neighborhood of the cape and among the shoals, the tides may be less regular; they produce strong rippings, and set with considerable strength.

There is reason to think that the two capes \* are laid down erroneously in latitude, and that the distance between them should be greater; for by a latitude observed at sea, compared with good bearings of the two capes, the error of the chart would be seven miles too southerly. We had no good opportunity of investigating this point, and the situation assigned to them is taken from the chart communicated to me by Don Felipe Bauza, above referred to.

The coast line between Cape Blanco and Port Desire has been imperfectly seen; within the distance of three to five miles from the shore, however, there are several small patches of rock, which uncover at half tide, but beyond that belt the coast is free from any known danger, and may be approached by sounding in not less than 14 or 15 fathoms; within that limit the ground is foul. To the northward of Port Desire the land is low, with a shingle beach, excepting for the first 3 miles, where it is high and cliffy. The north point of the entrance of the bay is a steep bluff, which is remarkable in being the only point of that description along the coast to the northward. At three miles N.  $28^{\circ}$  E. mag. from this bluff there is a ledge of rocks (Surrel's Ledge,) a quarter of a mile without which the depth is 13 fathoms. The Tower Rock becomes visible after passing this ledge: it opens out when the north bluff bears S.  $50^{\circ}$  W. mag. A ship bound to Port Desire, or merely wishing to anchor in the bay which fronts it, may procure a good berth in  $6\frac{1}{2}$  fathoms, at low water, well sheltered from N.  $\frac{3}{4}$  W. to S.  $50^{\circ}$  E. mag. with the

North bluff bearing.....	N. $48^{\circ}$ W.	} Magnetic.
Tower rock.....	N. $82\frac{1}{2}$ W.	
Penguin Island.....	S. $50\frac{1}{2}$ W.	

This situation being a little to the southward of the fair way of the port, and about one mile and a half from the nearest shore, is quite out of the strength of the tide; the bottom being strewed with rounded stones, is rather foul for hemp cables, but the holding ground, although of such suspicious quality, seemed to be good; at this place the tide rose from  $6\frac{1}{2}$  to  $9\frac{1}{2}$  fathoms, a difference of  $16\frac{1}{2}$  feet.

PORT DESIRE.—The river of Port Desire has rather a difficult entrance, from the strength of the tide and its narrow width, and it is rendered still more confined from several rocky reefs that extend off the north shore to nearly mid-channel. There is good anchorage off the mouth. By waiting, therefore, for low water, all the dangers that must be seen, and the vessel easily draught in with the tide, should the wind be, as it generally is, westerly. If it be fair, it is advisable for the ship to be in the entrance at slack water; or, if the breeze be strong enough, a little before: as the water is deep on the south shore, there seems to be no real danger that may not be avoided by a careful look out for kelp, which always grows upon, and therefore plainly indicates the existence of rocky ground. The course in is about S.  $76^{\circ}$  W. mag. and the distance from the entrance to the anchorage is one mile and a half. The anchorage is off the ruins  $\frac{1}{2}$  on the north shore, and the vessel should be moored: the tide sets in and out regularly.

The river was examined for 16 miles, but is probably navigable to a much greater distance.† Four miles above the ruins there is a small peninsula, connected by a narrow

\* *Cape Blanco*.—The Spanish chart, from which I have laid down the cape, places it in latitude  $47^{\circ} 15'$ . Mr. Simpson's Journal describes it to be in latitude  $47^{\circ} 10'$ , which is only 2 miles short of what our observations made it.

† Some years since, a Spanish colony was founded at Port Desire, but not answering the purpose it was soon afterwards given up. The ruins of the edifices, which are of stone, and the remains of a fruit garden, that at our visit produced quinces and cherries, distinctly point out the spot.

‡ *Port Desire*.—I have recommended the river to be entered at young flood, but Mr. Simpson thinks the last quarter flood to be the best time. If the latter be adopted, I would advise that the ship should be anchored off the entrance during the low water, in order to see the banks and rocks uncovered; since they will not be visible after half tide.

The Journal also mentions that the Commandore found a small run of good fresh water at about two miles S. W. of the Tower Rock. They filled five or six tuns of it. A pole was erected near it, to point the spot out to future visitors.

isthmus to the north shore; by sending a party up, and stationing men with guns on the isthmus, it is very likely that several guanacoës may be shot as they are driven across it; for the peninsula is their favorite place to feed upon. These animals are very abundant, but unless stratagem be used, they are very difficult, from their shyness, to be approached. There are some water holes near the ruins, which generally contain water, but of so brackish a quality as scarcely to be worth notice. The wood, although of very small size, burns well, and is much prized by sealers for that quality; it is a low shrubby tree, bearing a yellow flower, with a prickly at the extremity of every leaf. The sealers call it *piccolo*, from the small dimensions of the stem. The roots also are dug up and used for fuel.

The outer side of Penguin Island is bold, and may be passed very close without danger, for the tide rather sets off than towards the shore. The tide is very rapid, and forms, even in a calm, strong ripplings, which in a breeze must be very dangerous for boats to pass through, and, indeed, not agreeable for vessels of any size. The flood sets to the northward, and during its strength, at more than 3 knots; for we found the ebb to have set us 15 miles to the south in 5 hours. Off the island, the high water, or the termination of the northerly stream, takes place at about 4h. or 4h. 15m. after the moon's passage; which is  $3\frac{1}{2}$  or 4 hours at least after it is high water at the shore.

SEA BEAR BAY, is one of the best anchorages that I know of on the coast, but is difficult of access, without a leading and a fresh wind, on account of the strength of the tides, which set to the northward through the narrow channels separating the rocky islets that are strewn between Penguin Island and the main land. The bottom, besides, is not only deep, 23 to 30 fathoms, but is very foul and rocky; and although a ship may be prevented from drifting through by dropping an anchor, yet its loss, from the foulness of the ground, would be almost certain. In entering the bay, border pretty close to the low rocky point to the southward, to avoid a reef that lies about a quarter of a mile without it; but as the sea always breaks upon it, the eye and a due consideration of the tide are the best guides. This reef extends for some distance to the eastward of the breakers, and therefore the tides, when within it, set in or out of the bay, but with little strength. Should a ship not be able to enter the bay, there is anchorage off the point between it and the reef, on, I believe, tolerably clean ground. You will have 12 or 13 fathoms off the reef; then the depth shoals for one or two fathoms, to 7 fathoms, after which it deepens again: you may then haul across the bay, and anchor at about a quarter of a mile within the low rocky point, bearing E.  $\frac{1}{2}$  N. or E. by N. by compass, in 4 fathoms low water, avoiding the kelp which projects off from the low sandy beaches; this is, however, sufficiently distinct, and for further directions the plan will be the best guide. A small vessel may easily turn in, but I should hesitate taking such a step in one that I could not make quite certain of. When once in, the anchorage is good, and protected at all points, except between N.  $41^{\circ}$  and N.  $78\frac{1}{2}^{\circ}$  E.; but from the appearance of the beaches I do not think a heavy sea is ever thrown into it. There is no wood to be procured of any size, and the few gallons of water, that are collected in the wells at the point, so very precarious as to be scarcely worth attention. The passage to the watering holes is over a small rocky bar, which a boat may cross at three quarters flood; it is immediately within the eastern point of the bay: there is a small spring at the north end of the third sandy beach, which a herd of guanacoës was observed to visit every morning, but as the water only trickles down in a very small quantity, it cannot afford more than a temporary supply. Two of the three wells at the point we found to be full of sea water, which had breached over the rocks; the other contained about 40 gallons of rather a brackish taste. Besides a good and secure anchorage, this place affords no other advantages: it is convenient for sealing vessels to anchor in whilst employed in their occupation upon Penguin Island.

Sea Bear Bay is in latitude  $47^{\circ} 56' 49''$ , and longitude  $65^{\circ} 44'$ ; variation  $20^{\circ}$ ; high water at full and change 12h. 45', and the tide rises 20 feet.

Springs Bay is contained between the south head of Sea Bear Bay and the point within the Shag Rock; it forms a considerable bight, but is much exposed, being quite open to the south and east, and at the conclusion of the south-west gale, when the wind always veers to south and south by east, there is a considerable sea. The shore is skirted for some distance off with many rocks, and the bay altogether is quite unfit for anchorage. The land is of the same height as about Sea Bear Bay, but has more lumps or nodules of rocky hills visible on the outline of its summit.

Off this bay, in the old chart, is laid down a rock called the Eddystone. It would seem that this rock and the Bellaco Rock, discovered by Nodales, in 1619, is the same danger: but the whole coast between Cape Blanco and Port St. Julian is much strewn with shoals, which are the more dangerous from the strength of the tides which set between them. In navigating upon this part of the coast, the depth and quality of the soundings is a good guide, and, as a general rule, when the depth is more than 40 fathoms, there exists no known danger.

In directing the ship's course by night near this coast, regard should be paid to the tide, which sets with considerable strength, the current running parallel with the shore.

The Shag Rock is a whitish mass of rock, perfectly bare, lying about one mile and a half off shore; two miles to the south of it are four small dark colored rocks; and at three miles S. S. W. from it, there is rather a large rocky islet.

On the land, and at a short distance from the coast, are three hills, which appear, when a little to the southward of Sea Bear Bay, like three round-topped hills, but on reaching more to the southward they extend in length and form into two hills, and, at three leagues to the south of the Shag Rock, they appear to form one mass of table land. Watchman's Cape is very low, and may be distinguished by its bell-shaped mount: at two leagues from the point is a shoal with kelp upon it, on which the least water is 3 fathoms, but on approaching it the depth gradually decreases: there are also many other shoal patches, but are all buoyed with sea weed; the ship passed between several in 7 and 9 fathoms.

The ground is very foul and uneven for more than four miles from Watchman's Cape. Here the coast trends round to the westward and becomes higher. Being to the southward of the cape, there appears a mount about two miles from its extreme point resembling Monte Video, in the River Plate, both in shape and color, but not quite so high. It is called Monte Video, and in lat  $48^{\circ} 18' 55''$ , and long.  $66^{\circ} 18'$ .

The Bellaco Rock, or San Estevan's (Stephen's) Shoal, which was discovered by the Nodales, in 1619, was searched for in vain in the Descubierta and Atrevida's voyage; but Capt. Stokes, in the early part of 1828, on his passage down the coast, found it, and had an observation of the sun close to it for the latitude. It is in latitude  $48^{\circ} 30' 50''$ , and long.  $66^{\circ} 9' 25''$ . It bears S.  $13^{\circ}$  E.,  $10\frac{1}{2}$  miles from the extremity of Watchman's Cape, and S. E., mag., from Monte Video. The rock is a dark mass, about 9 or 10 feet above the water at high tide, and has the appearance of a boat turned bottom up. Within half a mile of its south side the Beagle sounded in 12 and 15 fathoms, rocky bottom, and on its east side, at the same distance, the depth is from 20 to 24 fathoms. The ground around it being foul and uneven, the coast in its neighborhood should be avoided. Between Watchman's Cape and Port St. Julian the land is of moderate height.\*

Wood's Mount is visible from the deck for at least 11 leagues, and is a good mark for Port St. Julian, being flat-topped and much more elevated than the land about it. The trend of the coast may also be a good mark; but as the land about Port St. Julian is higher than to the southward or northward, and Wood's Mount is so remarkable a feature, no mistake can be made. In a line with the south point of entrance the mount bears N.  $86^{\circ} \frac{1}{2}$  W. (W.  $16^{\circ} \frac{1}{2}$  S., mag.) The north head, Cape Curioso, is a low point jutting out to the northward, formed of cliffs horizontally stratified, of which the upper part is white brown, and the lower generally black, or with black streaks.

Keeping Wood's Mount bearing S.  $67^{\circ}$  W., by compass, will lead you to the south head, which will be easily distinguished when at the distance of 6 or 8 miles, or more, according to the state of the weather.

The land to the southward of Port St. Julian is uniform, flat, and low. It is covered by scrubby bushes, and fronted by a shingle beach. At 10 or 12 miles south of it, coming from the E. S. E., a small flat-topped hill is seen over the low coast hills.

In lat.  $49^{\circ} 27'$ , the character of the coast changes entirely to a range of steep white clay cliffs, the average height of which was calculated, by angular measurement, to be about 300 or 350 feet. They rise like a wall from the sea, which, at high water, nearly washes their base; but at low water they are fronted by a considerable extent of beach, partly of shingle and partly of mud. Some short rocky ledges, which break at half tide, lie off certain parts of this range, but none of the ledges extend for more than a mile from the shore. This cliffy range occasionally forms projections, but so slight as not to be perceived when passing abreast of them.

Anchorage along the coast may be taken up, with the wind off shore, at from a mile to two miles from the beach, in from 9 to 12 and 14 fathoms, oozy bottom. In latitude  $49^{\circ} 55'$  the range of steep white cliffs begins gradually to diminish in height, and terminates, at 9 miles farther to the southward, in a low point, forming the northern side of the entrance of Santa Cruz River. It is called in the chart North Point, and is in lat.  $50^{\circ} 5' 20''$ , and  $68^{\circ} 3'$ .

**SANTA CRUZ.**—The appearance of the coast about the entrance of the river of Santa Cruz is very remarkable, and easy to be known, from the manner in which it makes when seen from the northward, and is even more conspicuous when seen from

\* Eddystone.—Byron saw this rock, but from his position of it there seems to be little doubt that it is the Bellaco Rock of Nodales. Mr. Simpson's journal says, "it is 5 leagues from the shore, and is covered at high water. It bears from Penguin Island S. S. W., a little westerly, distant 14 or 15 leagues, and is in lat.  $48^{\circ} 30'$ . (The latitude of the Bellaco is  $48^{\circ} 30' 50''$ .)"

the southward. From the latter direction a coast line of cliffs and downs of considerable height is seen extending to the southward of the entrance as far as the eye can reach, and terminating abruptly to the northward in a high, steep, flat-topped cliff, Mount Entrance, of which the upper part descends vertically; the lower slopes off, and appears to be united with some very low land, which will be seen extending (according to the distance off) two or three points of the compass to the northward of it. Mount Entrance is at the south entrance of the river, and is, by angular measurement, 356 feet high. The low land is on the northern side of the entrance of the river.

The outer part of the bar, on which at low tide there are 14 feet water, is nearly four miles S.  $63^{\circ} \frac{1}{2}$  E. from Mount Entrance, and 9 miles from North Point, bearing N.  $54^{\circ}$  E.

Fourteen miles up the river, on the south bank, is Weddell's Bluff, a conspicuous headland; and 11 miles farther is another called Beagle Bluff. Weddell's Bluff, open of the south entrance, and in a line with the centre of Sea Lion Island, bearing N. W. by W.  $\frac{1}{2}$  W.,\* by compass, is the leading mark for the passage over the bar. With this mark on, and at high water, the Beagle crossed the bar in  $7\frac{1}{2}$  fathoms.† The Beagle Bluff, a little open of the low points of the north side of the river, is also a leading mark to cross the bar.

After passing the bar, which is about a mile broad, there is no impediment to a free course up the river, keeping midway between the narrow points of entrance, until reaching the shoals which project off the east point of Sea Lion Island. The best anchorage seems to be that occupied by the Beagle, on the south side of Sea Lion Island, where the water is shoaler and the tide not so strong.

At Weddell's Bluff the river divides into two arms. The northern one, which trends under the east fall of the Beagle Bluff, was examined by Captain Stokes for 12 miles above its commencement, where it ceased to be navigable, even at high water. Its bed was divided by banks of sand into several little fordable streams, preserving, as far as the inequalities of the land would permit the eye to follow their course, a mean N. W. by N. direction. The stream at this part was quite fresh, but still subject to the regular ebb and flow. On the boat's return she was left dry for six hours, in the middle of the channel, about two miles above Beagle Bluff. At half tide the boats took in their water at this place.

The shore on the S. W. side is a range of clay cliffs, of the average height of 350 feet, with grassy downs, and intersected with valleys and ravines. On the eastern side, the land for the most part is low and level, with a shingle beach. The aspect of the country is dreary, the soil gravelly, and the vegetation scanty, the largest production of that nature being bushes bearing berries, none of which exceed 7 or 8 feet in height. Many brant geese and ducks were seen, as well as the common sea fowl of these parts, such as penguins, cormorants, gulls, ducks, and divers. Several ostriches also made their appearance on the beach, and traces of guanaco were observed.

The south-western arm, which is the most considerable one of the two, was examined for 33 miles. It was supposed by Weddell to be of such considerable size and interesting appearance as to be likely to communicate with some branch from the Strait of Magalhaens. The first reach of the arm runs S. W. by W. 6 miles, with a mean breadth of  $2\frac{1}{2}$  miles. At  $1\frac{1}{2}$  league up, the boat, being anchored for the night in mid-channel at 12 feet, was left dry at low water. At the place of the first observation, on the north side, in lat.  $49^{\circ} 57'$ , and long.  $68^{\circ} 53'$  the influence of the tides had altogether ceased, and the water was quite fresh. The stream ran beautifully clear and pure, with the velocity of at least 5 miles an hour, over a bed of pebbles mixed with dark sand; its mean breadth being three quarters of a mile, and depth in mid-channel 8 feet. It runs between two nearly parallel ranges of hills, about 4 miles asunder. Beyond this the reaches are short, seldom more than 2 miles long, forming tortuous courses between S. S. E. and W. by S. The wind blew directly down, and the rapidity of the stream was so great that the boat was obliged to be tracked up the river.‡

The examination terminated in lat.  $50^{\circ} 9'$ , long.  $69^{\circ} 21'$ , which is 45 miles in a due west direction from its mouth, but by the course of the stream 53 miles.

At an anchorage outside the bar, Mount Entrance bearing N.  $82^{\circ}$  W., five miles off, and Weddell's Bluff N.  $65^{\circ}$  W., the Beagle rode out a gale from the S. S. W. and south with a heavy sea, without driving. The soundings that are marked in the chart, outside the bar, were taken at low water, whilst the ship occupied the above anchorage.

\* This is the bearing given by Weddell in his account of Santa Cruz.

† The rise of the tide is considerable. In going out, after crossing the bar, the Beagle anchored, and at low tide the water had fallen 26 feet.

‡ The above description of Santa Cruz and the river is taken from the late commander Stokes' MS. Journal.

ar, the Beagle anchored, late commander Stokes'

The tides in the offing were observed to flow very regularly six hours each way, but to turn two hours later than the time of high water in shore. The flood, as before, was observed to run to the northward.

The coast to the south of the river is bounded by a ledge of rocks, which are either dry at half tide, or are then shown by a line of breakers: they extend as far off as three miles. On one occasion the Beagle anchored among them, and had some difficulty, and not a little risk, in escaping.

Between Coy Inlet and Santa Cruz the coast trends lightly in, and is formed by a succession of cliffs and intervening low beaches. Coy inlet is conspicuous, as it is the only part of the coast that has the appearance of an inlet between Santa Cruz and Cape Fairweather.

When within seven miles of its latitude ( $50^{\circ} 57'$ ) as well to the northward as to the southward of it, a ship should keep at the distance of four or five miles off the coast. — There can be no inducement to go nearer, as it affords neither fuel nor water; and if incautiously approached much trouble and even danger may ensue, from the ledges of rocks which project at least three miles, and perhaps more from the coast.

COY INLET.—There is no account either of Coy Inlet or of the Gallegos River in Captain Stokes's Journal: what is here given is taken from the chart, and from what oral information I have received.

Coy Inlet is a shoal salt water inlet, terminating at 19 miles from the entrance, and fronted by a bar of rocks, leaving a passage only of six feet water on their south side; inside there seems to be little more than 3 feet water, and in most parts of the inlet, the banks, which are of mud and sand, are dry at low water; it is useless for any other purpose than to afford shelter to a small boat. The southern side of the inlet is cliffy, and at its termination receives the drains of an extensive flat country.

Thence to Cape Fairweather the coast is similar to the northern part, but more free from rocky ledges, and good anchorage may be had from 2 to 6 miles off shore, in from 7 to 12 and 14 fathoms, muddy bottom; the water shoaling gradually to the shore. The beach is of shingle to high water mark, and then of hard clay as far as one hundred feet beyond the low water limit, where a green muddy bottom commences, and the water gradually deepens. The outer edge of the clay is bounded by a ledge of rocks, on which the sea breaks; it extends for some distance parallel with the coast.

The flood sets to the N. W. by N. and the ebb S. E. by S. 6 hours each way; high water at full and change between 9 and 10 o'clock, and the tide rises 24 feet.

In lat.  $51^{\circ} 15'$ , about 17 miles north of the cape, there is a ravine containing abundance of fresh water, which may be obtained, when the wind is off shore, without any difficulty; it is standing water, and being much grown over with plants, may not keep, but for a temporary supply it seemed to be very good.

CAPE FAIRWEATHER, is the south extremity of the long range of clay cliffs that extends from Coy Inlet, almost, without a break. The cape resembles very much Cape St. Vincent, on the coast of Spain; it also bears a very great resemblance to Cape Virgins, for which it has frequently been taken, notwithstanding there is more than 45 miles difference in the latitude of the two headlands. This mistake was made in the Adventure as well as in the Beagle on our first visit, when, no observation for the latitude having been obtained, we were two days at anchor off it before our error was discovered. A similar error was also made by one of the ships belonging to the fleet under the command of Loyasa, in the year 1525 (see Burney's Collection of Voyages, vol. i. p. 131;) and the Nodales, in their description of the coast, warn the navigator from mistaking the one for the other, "y veniendo de mar en fuera a buscar la tierra, facilmente podian hacer de Rio de Gallegos el Cabo de las Virgines;" (and in making the land Cape Virgins may easily be mistaken for the River Gallegos.) Voyage of the Nodales, p. 53.

On the old charts of this part of the coast the shore is described to be formed of chalk hills "like the coast of Kent:" the resemblance, certainly, is very great, but instead of chalk they are of clay. They are from 3 to 4 hundred feet high, and are horizontally stratified, the strata running for many miles without interruption.

The interior is formed by open plains of undulating country covered with grass and plants, among which is abundance of wild thyme, but entirely destitute of trees: it abounds with guanacoes, which may be procured by laying in wait at the water holes.

Besides the pond above-mentioned, there is no want for fresh water; it may be seen trickling down the face of the cliffs at short intervals.

The entrance of the River Gallegos is formed on the north side by the cliffy land of Cape Fairweather, and on the south by a low shore that is not visible at sea for more than 4 or 5 leagues, excepting the hills in the interior, called the Friars, the Convents, and North Hill. It is fronted by extensive sand banks, most of which may be crossed at high water, but at half ebb they are almost dry. The entrance is round the south extremity of the shoals, which bear from the south trend of the cape S.  $43^{\circ} \frac{1}{2}$  E., distant 10 miles,

The passage in is parallel with the coast to the southward of the entrance, taking care not to open the land to the northward of Cape Fairweather's most eastern trend, which, when in the fair way, should bear N. 46° W. mag. The shore on the larboard hand must then be gradually approached, and, in the present state of the knowledge we possess, the ship should be anchored to await low water, in 10 fathoms, at a mile and a half from the shore, so soon as the south point begins to be observed to trend round to the westward; the anchorage there is good, and well sheltered from the prevailing winds.

By anchoring, the passage in will be easily detected, and may be passed before the shoals are again covered, which will be a good guide; 4 fathoms is the depth at low water in the narrowest part of the channel. Anchorage may be taken up on the south side, for to the northward the banks are extensive.

There is also a middle, and as it appears to be the widest, may be the the best channel, for crossing the bar. The outer part was not completely examined; but, no doubt, there is a sufficient depth of water at three quarters flood for any vessel to pass it. The southern channel, however, is preferable from having the land as a guide.

The river runs in to the westward for 30 miles, and then winds more southerly between two ranges of hills. Its banks are formed of downs, abounding with canoes and corals. The water is fresh at 25 miles from the mouth. In the entrance the time of high water at full and change is 8h 50m; the rise of tide, at the springs, is 46 feet, and the stream runs as much as five miles an hour.

From the south entrance of the Gallegos River, the coast, towards Cape Virgins, extends in a more easterly direction than it does to the northward of Cape Fairweather; and, for the first half of the distance, is formed by a low shelving coast, that at a few leagues from the shore is not visible, so that a stranger might readily suppose it to be the entrance of the Strait of Magallæns. There are, however, some marks by which it may be known, even should the latitude not have been ascertained. In clear weather the Friar and the other hills near them would be visible; and in thick weather the soundings of the cape will be an infallible guide; for at the distance of four miles off no more than 3 fathoms will be found, whereas, at that distance from Cape Virgins the depth is considerable; the bottom also to the north of Cape Fairweather is of mud, whilst that to the north of Cape Virgins is of gravel or coarse sand; and the latter cape has a long low point of shingle running off it for nearly five miles to the S. W. and, lastly, if the weather be clear, the distant land of Tierra del Fuego will be visible to the S. S. W.

At eighteen miles to the southward of Cape Fairweather the cliffs again commence, and continue to Cape Virgins, with only one or two breaks; in one of which, eight miles north of the latter cape, I think a boat may land if necessary. There is good anchorage along the whole coast between the Gallegos and Cape Virgins, at from two to five miles off shore; but the bottom is rather stony, and might injure hempen cables. As the cape is approached, the ground becomes more foul.

#### *Of the Winds and Weather, Tides, and Variation of the Compass, between CAPE BLANCO and CAPE VIRGINS.*

Our experience of the wind and weather upon this part of the coast was not sufficient to enable us to form any judgment of the changes that are liable to occur. The prevailing winds, particularly towards the southern portion, are from the south-west, from which quarter the gales are the strongest; but near the land, during the summer season, they veer about between south and W. N. W. and in the winter, when the sun has northern declination, they hang more commonly to the northward of west. Northerly winds are accompanied by misty or foggy weather, particularly on that portion of the coast between the Rio de la Plata and Port St. Elena.

The marine barometer here is of signal advantage. It is low with a northerly wind, but as soon as the column has fallen to 29 inches or lower, and ceases to fall, a change of wind from the S. W. may be expected: which commences with, or very soon follows, the ascent of the mercury; the wind then freshens and blows hard, and the weather clears up. The clouds are white, of large size, and of rounded form, and the air becomes elastic, dry, and cold. During the existence of, and for some days preceding, a northerly wind, there is generally a very copious deposition of dew; indeed, the appearance of it is an infallible presage of the change. With northerly winds the air is mild and excessively damp, but when they blow from the opposite quarter it is cold and dry. The wind rarely blows from east, but sometimes obliquely towards the coast from N. E. or S. S. E.

The flood tide sets to the northward, parallel with the coast. Near Cape Virgins, the northerly tide ceases at about four hours before the moon's passage; in the Gallegos River it is high water, at full and change, at 8h. 50m., and rises 46 feet: at Cape Fairweather, at 9 o'clock, and rises 28 feet; at Coy Inlet, at between nine and ten o'clock

at Santa Cruz Bear Bay, 1 St. Elena, and the tides are eddy tide sea.

a nine and ten o'clock;

at Santa Cruz, about 10h. 15m., rising 38 feet, but in the offing two hours later; at Sea Bear Bay, 12h. 45m., rising 20 feet; Port Desire, 12h. 10m., rise 18½ feet; and at Port St. Elena, at 4 o'clock in the afternoon, they rise 17 feet. In the offing of Port Desire, the tides are 3½ or 4 hours later than they are in-shore, which is probably owing to the eddy tide setting out of St. George's Gulf.

The variation of the compass gradually increases from the Rio de la Plata, where it is about 14°; in lat. 36°½, long. 55°½, it is about 14°½; in lat. 41°, and long. 60°, it is 16°; in lat. 41°½, and long. 60°½, it is 17°; at Port St. Elena, 19° 10'; at Port Desire, 19° 42'; at Sea Bear Bay, 20° 47'; at Port St. Julian, 22° 18'; at Santa Cruz, 20° 54'; at the River Gallegos, 21° 47'; and at Cape Virgins, it may be considered about 22°½. At the last place, according to Sir John Narborough,\* the variation in the year 1670 was 17° and Wallis and Carteret,† in the year 1767, found it 24° 39'; so that it has scarcely altered within the last hundred and sixty years.

#### *Strait of Magalhaens—Cape Virgins to Fort Famine.*

CAPE VIRGINS, a steep cliff, about 300 feet high, (in lat. 52° 18' 35", and lon. 68° 16' 55" E) is the southern extremity of the Patagonian coast, and the north entrance of the Strait of Magalhaens. There is an appearance of a reef that may extend off the point for half a mile, but not beyond that distance. The Adventure passed at 1½ mile from it, sounding in 8 fathoms, stones; and then standing to the south, crossed a bank of gravel, sounding regularly in 7 fathoms, until Dungeness Point bore S. W. by W. by compass, when the water deepened. This bank trends off more to the southward and eastward, but I believe its termination is at 5 miles S. 87° E. from the extremity of Dungeness.

I do not imagine that any part of it is shoal enough to endanger a ship, but near its extremity there are some overfalls, among which the least depth that we found was 5 fathoms at low water.‡

In rounding Cape Virgins, unless the wind be easterly or southerly, I should recommend a ship to pass within one mile and a half of the cape, and steer S. by E. by compass until Dungeness bears S. W. mag.; then to edge away around the latter point, and afterwards the coast is clear to Cape Possession. In moderate weather ships may anchor any where between Dungeness and Cape Possession. The bottom is of good holding ground, and quite clean. At from 3 to 5 miles from the coast, the depth will be from 15 to 20 fathoms.

We know nothing of the Fuegian shore, or south side of the entrance. The Beagle, in beating in, made a board for 8 miles to the southward of Dungeness, and had 40 fathoms; but I believe the coast to be of shoal approach, and to be lined by a bank that is connected to the extensive reefs which project from Cape Orange.

CAPE POSSESSION is a cliffy headland on the north shore, and will be seen opening round Dungeness, on the magnetic bearing of S. 86° 30' W.; the distance between them is 20 miles; at 10 or 12 miles to the west of Dungeness, Mount Aymond will make its appearance, bearing about N. 85° W. mag.

POSSESSION BAY, which extends from Cape Possession to the entrance of the First Narrow, curves in to the northward round the cape and is fronted by an extensive shoal, stretching off for more than 4 miles from the shore, many parts of which are dry at half tide; on its south side the depth diminishes gradually, and offers good anchorage for vessels entering the strait, to await the tide for passing the First Narrow.

On the western side of the bay, there are some remarkable hills of a darker green hue than others near them; I have called them the Direction Hills; because after passing Cape Possession, they afford a good mark for approaching the Narrows, which are not visible until well across the bay; by attention also to their bearings, the shoal that extends off Cape Orange may be avoided. To take up an anchorage on the bank, great attention must be paid to the soundings, which at the edge decrease suddenly; it would not be advisable to anchor in less than 10 or 12 fathoms at high water, for the tide falls 6 or 7 fathoms; but as the stream runs much weaker on approaching the edge of the bank, the nearer to it the better. A good berth for anchoring is to get the northern Direction Hill, (which is dark colored and very conspicuous,) to bear S. 56° W. Mount

\* Narborough's Voyage, p. 60.

† Hawkesworth, vol. i. p. 410.

‡ By chronometrical observation 68° 17' 46".

§ The shoal soundings of 5 fathoms off Cape Virgins bear from the cape, S. 35° E. There is anchorage under Dungeness with westerly winds. Wallis anchored in 10 fathoms, gravel; Cape Virgins bearing N. by W. ½ W., and Dungeness S. by W. but these bearings when laid down in the chart, do not appear to be correct. The Dolphin anchored at 4 miles off the cape, bearing N. ½ E. and at 2 or 3 miles from the extremity of the Ness, bearing S. S. W. ½ W.

23 WEST MAIN STREET  
WEBSTER, N.Y. 14580  
(716) 872-4503

Aymond N.  $45^{\circ}$  to  $50^{\circ}$  W., and the highest, (easternmost,) peaked hillock upon Cape Orange about S. S. E. (compass bearings.) When the hill above noticed bears S.  $56^{\circ}$  W. and Mount Aymond between N.  $50^{\circ}$  and  $60^{\circ}$  W.\* you are in 9 or 20 fathoms, just off the edge of the bank; about half to one mile more to the northward, or north-westward, good anchorage may be selected out of the strength of the tide.

There is, however, a more advanced situation about half a mile to the eastward of the end of the shoal, that may easily be taken up; namely, that where 14 fathoms is marked on the plan, for which the following are the bearings:—The

Northern Direction Hill,.....	S. $59^{\circ}$ W.	} Mag.
Mount Aymond,.....	N. $43^{\circ}$ W.	
Peak of Cape Orange,.....	S. $22^{\circ}$ E.	

One mile more in advance to the S. W. would still be a better berth, but great care must be taken not to ground on the tail of the shoal. At about half a mile more to the eastward, the situation would be more secure.

Should the distant land behind Cape Gregory be seen, which makes with a long level strip of land, terminating at its S. W. end with rather a bluff or precipitous fall, it is a good mark for the above anchorage. The fall, or extremity, should be visible in the space between the southernmost and central of the Direction Hills. There is also a conspicuous lump on the same land, which will be seen a little to the eastward of the northern Direction Hill; and the Asses Ears, nearly out of sight, should be seen a little to the eastward of that part of the shore of Possession Bay where the cliffy coast commences.

Another mark for the approach of the bank, which is very good when Mount Aymond bears more westerly than N.  $45^{\circ}$  W. mag. is, not to lose sight of the Asses Ears. At our anchorage in 6 fathoms, near the dry part of the bank, they were lost sight of by a rise in the land; half a mile to the southward, at the anchorage marked 11 fathoms, one of them re-appeared above the land; Mount Aymond at the same time bearing by compass N.  $41^{\circ}$  W. mag. But this rule fails to the westward, or nearer the Narrow, for the bank then trends more southerly, and the Asses Ears are visible at its edge; the west limit of this rule is, as before noticed, when Mount Aymond bears about N.  $45^{\circ}$  W. mag. There is, also, another remark worth attending to; which is, that, after passing Cape Possession, Mount Aymond assumes the appearance of a round obtusely-peaked hill, with a smaller elevation on each edge of its outline; which appearance is preserved until it bears N.  $50^{\circ}$  W. mag. and then the easternmost of the minor elevations gradually disappears, while the western one becomes more conspicuous.

To avoid the north shoals, do not get the North Direction Hill to bear more southerly than S.  $56^{\circ}$  W. mag.; and the mark for avoiding the reefs that extend off Cape Orange, is not to get the same Direction Hill to bear more westerly than W. by S.  $\frac{1}{2}$  S. mag. (that W. by S.  $\frac{1}{2}$  S. will just pass without the edge,) until Mount Aymond bears N.  $45^{\circ}$  W. mag. or the peak of Cape Orange south, mag. when the fair way of the First Narrow will be open, bearing S. W. by S. mag. The north or north-western side of the First Narrow, is a cliff of moderate height, and makes like a flat table land. When abreast of Cape Orange, a S. S. W. mag. course must be steered. The tide sets right through; so that in drifting, which with the wind against the tide is the safest and best plan, there is no danger of being thrown upon the shoals.†

The First Narrow was called by Sarmiento, *Angostura de Nuestra Senora de Esperanza*. He describes it very correctly to be 3 leagues long, and less than half a league wide, with cliffy shores; the tide running strong; the depth more than 50 fathoms, sand and pebbles, (callao;) and on the north shore there is a beach of shingle. In this part, however, as discretion must be the best guide, it will be necessary merely to state the dangers that exist. To the north of Point Delgada, (meaning thin or slender,) the shore is fronted by extensive shoals that dry at half tide, and which, being dry when Sarmiento passed, was called by him Point Anegada, (drowned land;) these should not be approached. The south shore also, for nearly 5 miles to the west of Cape Orange, has a shoal off it, but it does not extend to a great distance from the beach; beyond this it is not safe to approach either shore within half a mile, for each is fronted by a bank that dries at low water. The western end of the Narrow on the north shore, Sarmiento's Point Barranca, (meaning a cliff,) has a considerable reef off it, upon which there is a

\* These bearings are by compass; the variation of the needle is  $22\frac{1}{2}^{\circ}$ .

† Reef off Cape Orange.—This reef extends off to the E. N. E. for a considerable distance. Byron struck upon it, as did also the *Santa Casilda*. The *Adeona*, a sealing vessel, in 1828, also struck upon it and was left dry; and the *Peagle*, in going to her assistance, crossed the tail of it at high water, occasionally striking the ground. Bougainville describes its position thus: "When the hillocks which I have named *Quatre fils Aymond*," (Asses Ears,) "only offer two to sight in form of a gate, you are opposite the said rocks."

very large quantity is 19 miles distant.

They also barter Paraguay tea,) tobacco, but are content with muskets, powder and men, who left an anchor and it is to be hoped.

THE SECOND runs five or six knots reach an anchorage

very large quantity of kelp. Point Barranca bears from Cape Gregory N.  $48\frac{1}{2}^{\circ}$  E. and is 19 miles distant.

After emerging from the Narrow, the ship should be allowed to drift with the tide, the course of which is S. S. W. for at least 3 miles, before hauling up for Cape Gregory, in order to avoid the rippings which rage furiously on each edge of the bank. I have passed twice through them for the sake of proving the depth, and once anchored within them, which gave me an opportunity of ascertaining the rise and fall of the tide; but it only altered 12 feet: the stream or current, however, set at 3 and 4 knots the whole tide, and there was scarcely five minutes slack water. It is an anchorage that ought not to be taken up without the greatest necessity, for the rippings break over the deck, and the security of the vessel is very doubtful.

POINT BARRANCA is a flat topped sand hill, the position of which being given in the chart, its bearing will indicate the situation of the ship: the point on the opposite side Sarmiento called Point Baxa, (low.)

After reaching thus far, steer W. S. W. by compass, until abreast of some remarkable peaked hillocks on the north shore; where, if necessary, anchorage may be had out of the tide, in from 6 to 10 fathoms; at any part of the northern side of the bay the anchorage is good, upon a clay bottom covered with broken shells: the lead brings up nothing but shells; underneath, however, it is of clay and good holding ground.

It is best to anchor near the shore on account of the tide, which ripples very much all over the centre of the bay.

The peaked hillock above mentioned is certainly Sarmiento's Point Nuestra Señora del Valle; to the eastward of it is St. Jago Bay; and to the westward his Bay of the Eleven Thousand Virgins. When abreast of the point, the land and bay to the north of Cape Gregory will be easily distinguished; the former will be seen first, and resembles an island; for the land of the bay is flat and low; but a very conspicuous hummock will also be seen half way between it and the flat table land, as soon as the land of the cape becomes visible. The hummock is marked on the chart.

The extremity of Cape Gregory bears from the western end of the First Narrow, S.  $73^{\circ}$  W. (S.  $50^{\circ}$   $\frac{1}{2}$  W. mag.) distant twenty-two miles. The anchorage is from two to two miles and a half to the N. N. E. of the cape, abreast of the north end of the sand hills that form the headland, and about one mile from the shore, in from 13 to 15 fathoms. The bottom is excellent, a soft, but tenacious mud, which, nearer the shore, is of a stiffer quality. At low water a sand spit extends off for one third or nearly half a mile from the shore; close to which there are 7 fathoms water. Care should be taken not to approach too near.

At the anchorage the tide turns to the south-westward, towards the cape, for two and a half or three hours before it begins to run to the westward in the Second Narrow; which should be attended to, for a ship will lose much ground by weighing before an hour or more after the tide has turned.

Upon the summit of the land of the cape, four fifths of a mile to the northward of the extreme point, is a remarkable bush; close to which the observations were made. The bush is in lat.  $52^{\circ}$   $38' 3''$  S., and long.  $70^{\circ}$   $9' 51''$  W. The variation of the compass  $23^{\circ}$   $34'$  E.

The country abounds with guanacoës and ostriches, and the valley, two miles to the westward of the cape, is frequently the abode of the Patagonian Indians; but their principal residence is upon the low land at the back of Peckett's Harbor and Quoin Hill, where guanacoës are more abundant, and the country more open. Ships coming from the southward also are seen by them at a great distance, so that by the time she reaches Cape Gregory they have already arrived to meet her. They do not, however, see ships coming from the eastward so easily, and we were, on two occasions, two or three days at the anchorage before it was known that we were present.

They are very friendly, and will supply guanaco meat at a small price. They are fond of beads and ornaments, but particularly of knives, and the larger they are the better. Swords are held in high estimation by them, as well as lead for the purpose of arming their *bolos*, an instrument used to entangle the legs of the guanacoës and ostriches.

They also barter their mantles and skins; and are fond of sugar, flour, matte, (the Paraguay tea,) tobacco, and horse gear, particularly bits. For spirits they are very eager, but are contented with it in a diluted state. At our last interview they asked for muskets, powder and ball, the use of which they have learned from two Portuguese seamen, who left an English sealing vessel to reside with them; but these were not given, and it is to be hoped that such weapons will not be put into their hands.

THE SECOND NARROW is about ten miles long; and, with a favorable tide, which runs five or six knots, is very quickly passed. With an adverse wind a ship will easily reach an anchorage to the north of Elizabeth Island.

The north side of the Second Narrow is very shoal, and ought not to be approached, for the ground is also very foul. There are two or three very inviting bights for a ship that is caught with the tide, but it is not advisable to anchor in them: she should rather return to the anchorage off Cape Gregory.

**SUSANNAH COVE** is where Sarmiento anchored in 8 fathoms, low water, half a league from the land, good bottom; but, as it was exposed to the strength of the tide, he shifted to another anchorage about half a league west of Cape Gregory, where the anchor was dropped in 8 fathoms, but the vessel tacking on the edge of the shoal in 3 fathoms, he was glad to make his escape.

The south shore of the Second Narrow, which Narborough called the Sweepstakes Foreland, is composed of cliffs, and is, I believe, of bold approach. The projecting head in the centre is Sarmiento's St. Simon's Head, and the western end he named Cape St. Vincent, from its resemblance to that of Spain. To the southward of the eastern point of this head, Point St. Isidro, which is a low sandy point, is Fish Cove, where Bulkely and Cummings anchored their boat: and Sarmiento says, "We anchored behind a point before noticed, called Santisidro, in a small bay, of low land and sandy beach, in 10 fathoms, at a quarter of a league from the shore, but upon veering cable the vessel was in 7 fathoms; so that fearing she would be left dry, from the great rise and fall of the tides hereabout, we shifted farther out to 15 fathoms, but the anchor dragged, and we subsequently came to in 9 fathoms, sandy bottom, where, at low water, the depth was 6 fathoms."<sup>\*</sup>

Three miles to the westward of Cape Gracia, the western end of the Second Narrow on the north side, is Oazy Harbor, so called by Narborough; it is a secure place for small vessels. The entrance is nearly two miles long, and too narrow for large ships, unless the weather be moderate, when they might drop in or out with the tide: the depth inside is from 3 to 10 fathoms. There is neither wood nor water to be got, and therefore no inducement to enter it; a plan of it was made. It is described by Sir J. Narborough,† and Cordova calls it Bird Bay (Ensenada de los Paxaros).‡

**NARBOROUGH'S PECKETT'S HARBOR**, or, as Sarmiento called it, St. Bartholomew's Bay, is 8 miles to the west of Cape Gracia, and, although very shoal, offers a good shelter, if required, for small vessels; but the space is very confined; the anchorage without is almost as safe, and much more convenient. The distance between the two points of entrance is nearly two miles, but from the north-east shore, to the small island of the south-west point, the whole space is a shoal, upon the greater part of which the sea breaks in a moderate breeze.

The entrance is between the south-west point and the island, and is rather more than one-fifth of a mile wide. Half a mile outside, the anchorage is good, in 7 fathoms: shoal ground extends for a quarter of a mile off the point.

The bay, which is formed by Peckett's Harbor and Elizabeth Island, is extensive and well sheltered, with an easy depth of water all over, between 5 and 7 fathoms; the nature of the bottom is clay, and offers excellent holding ground. In the centre is a patch of kelp; but it is not known whether the depth is shoaler in that part, or whether it proceeds from the bottom being rocky.

The tide is not strong to the westward of the north end of Elizabeth Island;§ but runs with considerable velocity in the deep channel between it and the Second Narrow. To the southward of the island the stream divides into two directions, and very soon loses its strength; one sets down the south side of the island, and the other between the islands of Santa Martha and Magdalena. This is the flood; the ebb sets to the northward. The ebb and flow are regular, high water at the full and change, being at about 12 o'clock.

There is good anchorage, out of the strength of tide, at a mile to the north of Point San Silvestre; it is convenient for a ship to leave with the intention of passing round Elizabeth Island. I conceive this to be the most difficult part of the entrance of the Strait of Magalhães, for the tide sets across the passage with some strength.

The passage to the west of the island is clear, and without danger, by keeping in the middle of the channel; but in passing down the south side of Elizabeth Island the shore should be kept close to, to avoid being thrown upon the islands of Santa Martha and Magdalena,|| although I believe there is plenty of water between them, for Sarmiento anchored there in 15 fathoms; as well as to clear the shoal that extends off the south-west end of the latter island, upon which we did not find less water than 5 fathoms upon

any part;\* but the ground being irregular, and much kelp strewed about it, it is not safe to trust too much to appearances. On all occasions, it is advisable to avoid passing through kelp; for although it frequently shoots up from 10, and even 20 fathoms, yet, wherever the bottom is rocky, there it is to be found. The presence of this vegetable renders the few dangers that exist in the navigation of the strait of little consequence, for it serves as a buoy to mark the existence of them, and it is only by a careless look-out that a ship can be placed in a dangerous situation. Another advantage in kelp is, that by its drift it shows both the direction and velocity of the tide.

LAREDO BAY offers good anchorage in the centre and towards the north side, and particularly in the north-west corner. Off the south point is a large patch of kelp, among which the ground is shoal and foul.

At Laredo Bay wood may be procured, and there is a fresh water lake of a mile in diameter at about half a mile behind the beach, much frequented by wild ducks.

For the purpose of anchorage only, the bay need not be entered; because a very good and secure berth may be found at from 1 to 2 miles off it, in 10 to 13 fathoms, having the south-west extremity of Elizabeth Island on with, or a little open off, the trend of Cape Negro, which is Byron's Porpesse Point.

We know scarcely any thing of the south side of St. Philip's Bay, or of the coast between Cape St. Vincent and Cape Monmouth. The latter is a lee shore, and should not be approached when the wind is northerly, for there seems to be no harbor or shelter, and the anchorage must be much exposed.

Two deep inlets were seen behind Sweepstakes Foreland, from the summit of the table land near Cape Gregory, one of which may probably insulate it, but this was not ascertained.

Between Cape Negro and Sandy Point, which is Sarmiento's Catalina Bay, good anchorage may be had, from one to two miles and a half from the shore. Here the country begins to be thickly wooded, and to assume a very picturesque appearance, particularly in the vicinity of Sandy Point.

SANDY POINT, Sarmiento's Cape de San Antonio de Padua, projects for more than a mile from the line of coast, and should not be passed within a mile. A shoal projects off it in an east direction (mag.) The mark for its south edge is a single tree, on a remarkably clear part of the country, (a park like meadow,) near the shore, on the south side of the point, in a line with a deep ravine in the mountain behind. One mile and a half from the point, we had no bottom with 18 fathoms.

To the southward of Sandy Point, as far as Point St. Mary, good anchorage may be had at three quarters of a mile from the shore, in 11 and 12 fathoms, sand and shells over clay. At the edge of the kelp, which fronts the shore, there are 5 and 6 fathoms; so that, with the wind off shore, a ship may anchor or sail along it very close to the coast, by keeping outside the kelp. The squalls off the land are very strong, sometimes so much so as to lay a ship on her broadside. It is not prudent, therefore, to carry much sail in coasting this part; and it is necessary to have the quarter boats secured with gripes, because the wind, for a moment, blows with the force of a hurricane. These land squalls are denominated by the sealers "williwaws."

POINT ST. MARY, in lat.  $53^{\circ} 21' 40''$ , is  $12\frac{1}{2}$  miles to the south of Sandy Point, and may be known by the land trending in to the southward of it, forming Fresh Water Bay. It has also a high bank close to the beach, with two patches bare of trees, excepting a few dead stumps. All the points to the northward are low and thickly wooded. As the bay opens, the bluff points at its south end become visible. There is also a remarkable round hill a short distance behind the centre of the bay, and a valley to the south of it, through which a river flows and falls into the bay.

It is convenient for wooding at, but from the river being blocked up by much drift timber, watering is difficult. The proximity, however, of Port Famine renders this of no material consequence.

When the wind is from the northward, a swell is thrown into the bay; but no danger need be apprehended from its being open to the eastward, for the wind seldom blows from that quarter, excepting in the winter, and then rarely with great strength. If it does, the holding ground is good, and with good gear there is no danger.

In standing into the bay from the northward, keep within three quarters to half a mile from the coast, in 10 or 11 fathoms; and passing Point St. Mary, steer on towards the bluff points at the south end of the bay, until the south pitch of the Centre Mount bears W. S. W., when you will be clear of the kelp that extends off the north side of the bay, among which I believe there is a sufficiency of water, but the ground is foul. Round its edge there are 6 and 7 fathoms. Having the mount bearing as above, steer

\* Shoal off Santa Magdalena. Simpson's Journal says there are 3 fathoms on it in many places; the least water found by us was 5 fathoms.

for it, or a little to the south of it, and anchor in 9 fathoms, sandy mud over clay, which will be with the following bearings :

Point St. Mary.....	N. 15° W.	} Mag.
Outer trend.....	N. 9° W.	
Centre Mount (south pitch).....	S. 74° <sup>1</sup> / <sub>2</sub> W.	
Entrance of River.....	S. 35° W.	
South Bluff.....	S. 21° E.	

A good berth may be had much nearer the shore in 6 fathoms, towards which the depth gradually decreases. If the anchorage is used merely as a stopping place, the first is best, for the wind near the shore is apt to flow and veer about.

Between Freshwater Bay and Point Santa Anna the coast is very bold, and so steep as to offer no anchorage, excepting in the bay that is formed by the reef off Rocky Point; but it is small and inconvenient to weigh from, should the wind be southerly.

Should the day be advanced, it is better to anchor in Freshwater Bay than run the risk of being under way all night, unless it be in the summer, with moonlight and the weather likely to be fine. In this climate, however, the latter is very doubtful, for weather changes so suddenly that no dependence can be placed upon appearances.

POINT SANTA ANNA will appear, on standing down near the coast, to be the termination of the land; it is a long point extending into the sea, having at the extremity a clump of trees. It bears from Cape Valenty S. 47½° W. mag. On approaching it, the distant point of Cape St. Isidro will be seen beyond it; but there can be no doubt or mistake in recognizing it.

Along the whole extent of the coast, between the Point Santa Anna and Elizabeth Island, the flood sets to the southward and the ebb to the northward, and it is high water about 12 o'clock at full and change. The variation is about 23° west. The strength of the tide is not great, but frequently after a southerly wind there is, in the offing, a current to the northward independent of the tide. In winter the tides occasionally rise very high, and on one occasion, in the month of June, nearly overflowed the whole of the low land on the west side.

PORT FAMINE.—Standing into Port Famine, pass round Point Santa Anna, if with a leading wind, at one fifth of a mile, in 17 fathoms; but if the wind is scanty, do not get too near, on account of the eddy tide, which sometimes sets towards the point. Steer in for the bottom of the bay, for the summit of Mount St. Philip, keeping it over the centre of the depth of the bay; that is, half way between the rivulet (which will be easily distinguished by a small break in the trees) and the N. W. end of the clear bank on the west side of the bay. This bank being clear of trees, and covered with grass, is very conspicuous. Keep on this course until the mouth of Sedger River is open, and upon shutting in the points of its entrance, shorten sail and anchor in 9, 8, or 7 fathoms, as convenient. The best berth, in the summer, is to anchor over towards the west side in 9 fathoms, with Cape Valenty in a line with Point Santa Anna; but in the winter season with N. E. winds, the best berth is more in the centre of the bay.

The strongest winds are from the south-west. It blows also hard sometimes from south, and occasionally a fresh gale out of the valley, to the south of Mount St. Philip. Unless a long stay be meditated, it would be sufficient to moor with a kedge to the N. E. The ground is excellent all over the port, being a stiff tenacious clay. Landing may be almost always effected, excepting in easterly gales, on one side or the other. There is fire wood in abundance on the beaches, and wells containing excellent fresh water, were dug by us at the N. W. extremity of the clear part of Point Santa Anna, on the bank above the third or westernmost small shingle bay. The water of the river, as well as of the ponds, of which there are many upon the flat shore of the western side of the port, is very good for present use, but will not keep, in consequence of its flowing through an immense mass of decomposed vegetable matter; but the water of the wells drains through the ground, and not only keeps well, but is remarkably clear and well tasted. Their situation is marked on the plan, and for some time our traces will not fail to show the road.

Our observatory, the situation of which is indicated by the stem of a tree 16 inches in diameter, placed upright about 8 feet under and 3 above the ground, banked up by a mound, is in lat. 53° 38' 12", and 70° 54'. High water at full and change at 12 o'clock; the ebb sets to the northward, and the flood to the southward; but the rise and fall is very irregular, depending entirely upon the prevalence of the winds, northerly and easterly winds causing high tides, and westerly and south-westerly low tides. The variation is about 23° 30'.

Of the tides in Possession Bay and the First Narrow, we have had too little experience to enable us to give a very clear account: I shall therefore here confine myself merely to such observations as may be of service to the navigator.

To the south-east of Cape Possession it is high water at 4h. 56m. before the moon's passage; but the stream of tide continues to run in until two hours after the water has ceased to rise. The easterly tide commences at 2h. 56m. before the culmination.

The same is the case as far as, and even in, the First Narrow, excepting in the times. At the centre of Possession Bay, near the bank, it was high water at 3h. 51m. before the moon's passage, and the tide turned to the eastward at noon, or 0h. 39m. after the passage. This observation was made on the day of full moon. The rise was 28 feet, but at an anchorage more to the westward, near the south-west end of the bank, it rose 35 feet, and ran at the rate of six knots and a quarter. In the First Narrow the eastern tide commences at noon (full and change.)

At the anchorage in Gregory Bay the easterly tide commenced 20 minutes earlier than in the First Narrow. In the Second Narrow the tides are two and a half or three hours later before they turn. To the westward of the Second Narrow high and low water take place regularly with the set of the tide, and the former occurs, at full and change, within a few minutes of noon. The rise and fall is inconsiderable; the greatest we experienced was eight feet.

*Strait of Magalhaens—Dawson Island—Admiralty Sound—the Gabiel, Cockburn, and Barbara Channels.*

USELESS BAY was examined in the hope of its communicating with the supposed St. Sebastian Channel, of the old charts; but it proved to be terminated by low land, reaching, perhaps, across the country, towards Cape St. Espirito Santo. It is more than 30 miles deep, and from 12 to 20 wide, and entirely exposed to the south-west. The north shore affords no shelter, but on the south there is an indentation of the coast line under the hill called Nose Peak, that may possibly afford a sheltered anchorage.

The termination of the flat table ridge, extending to the N. E. from Point Boqueron, a name of Sarmiento's, meaning an opening, is abrupt and very precipitous.

This country abounds with guanacoes, and the Indians are probably more dependent on hunting than fishing for their subsistence, for we observed their fires upon the hills, at a distance from the coast.

DAWSON ISLAND, which fronts Useless Bay, and the deep inlet called Admiralty Sound, is 46 miles long, and about 20 broad. Its northern extremity, Cape Valentyne, is low, but becomes visible in passing down the opposite shore, between Sandy Point and Freshwater Bay. Mount Graves, however, is seen from a much greater distance. On the western side of the island there are but two places in which vessels can anchor, viz., Lomas Bay and Port San Antonio, but both being on a lee shore, they are not to be recommended. Lomas Bay is a deep bight, sufficiently sheltered from S. W., but quite exposed to the north-west and westerly winds, which, during the winter, are the most prevalent.

Lieutenant Graves remarks that Lomas Bay, although only tolerably sheltered from the prevailing winds, would, from its extent (six miles deep) and nature of the bottom, a stiff blue clay, afford good shelter for vessels of any draft or burden. The appearance of the shores also seem to favor such an opinion, for scarcely any drift wood was found thrown up, even in those parts which were most exposed to the surf. Wood is sufficiently plentiful, and water very abundant. This bay appears at certain seasons to be much resorted to by the Indians, for upwards of twenty wigwams were seen near the beach.

Between Lomas Bay and Cape St. Valentyne, there is no landing, even for a boat, excepting at Preservation Cave, which affords only just room enough to beach one of small size.

PORT SAN ANTONIO, which is situated about the centre of the west coast, opposite to San Nicholas Bay, has the appearance of being well sheltered, but during a fortnight that we spent there we experienced so much inconvenience, and even risk, from the violence of the squalls, that we were obliged to secure the vessel with three anchors. We also found some difficulty in leaving it, on account of the baffling winds, as well as the narrow width of the passage, for we went out by the north entrance.

This place received the distinguishing epithet of Port from Cordova, and is described by him to be three quarters of a mile wide; instead of which, it is scarcely one third of that width, and deserves the name only of a cove. It is a very unfit place for a ship, or, indeed, for any vessel to enter, especially when there are so many much better places on the opposite or continental shore.

The anchorage is formed by a channel within the islands North Island and San Juan Island, in which, particularly at the north end, are several islets. The anchor may be dropped in from 10 to 15 fathoms, off a small beach in Humming-bird Cove, which is situated on the inner side, and about half a mile from the south end of San Juan Island.

From the west end of North Island a reef extends off for a quarter of a mile, and to the southward are two small islets, which may be passed on either side. North Island is separated from San Juan Island by a narrow and impassable strait.

The south entrance is, perhaps, the best, although with a northerly wind the north entrance should be preferred. There is no danger but what is evident: the ground, however, is not very clean until you reach Humming-bird Cove.

The south entrance is tolerably wide. In entering, haul round the south point of San Juan Island, for near the shore of the eastern side there is a rock under water. Opposite to Humming-bird Cove, in a small bight, there is a stream of fresh water.

PORT VALDEZ is a deep inlet, fronting W. N. W., and not at all inviting to enter. From the appearance of the hills, squalls must be very frequent, and blow with the greatest violence; for trees are seen torn up by the roots, in long lines, evidently caused by the destructive force of the winds.

The ebb tide sets to the north through the channel.

THE GABRIEL CHANNEL separates Dawson Island from the Tierra del Fuego. It is merely a ravine of the slate formation, into which the water has found its way and insulated the island. It extends precisely in the direction of the strata, with almost parallel shores. It is 25 miles long and from half a mile to one mile and a half wide, the narrowest part being in the centre. The north shore is a ridge of slate, rising abruptly to a sharp edge, and then as abruptly descending on the opposite side, where it forms a valley, which, had it been a little deeper, would have been filled by water and have become another channel like the Gabriel.

The south side of the Gabriel Channel is formed by a high mass of mountains, probably the most elevated land in the Tierra del Fuego. Among many of its high peaks are two more conspicuous than the rest, Mount Sarmiento and Mount Buckland. The first is 6,800 feet high, and, rising from a broad base, terminates in two peaked summits, bearing from each other N. E. and S. W., and are about a quarter of a mile asunder. From the northward it appears very much like the crater of a volcano; but when viewed from the westward, the two peaks are in a line, and its volcanic resemblance ceases. It is noticed by Sarmiento as well as by Cordova, in the journals of their respective voyages. Sarmiento calls it Volcan Nevado (the Snowy Volcano.)

It is the most remarkable mountain in the strait; but from the state of the climate and its being clothed with perpetual snows, it is almost always enveloped in condensed vapor. During a low temperature, however, particularly with a N. E. or S. E. wind, when the sky is often cloudless, it is exposed to view, and presents a magnificent appearance. From its great height and situation it served our purpose admirably to connect the points of the survey. It was seen, and bearings of it were taken, from the following distant stations, viz., Elizabeth Island, Port Famine, Cape Holland, Port Galant, and Mount Skyring, at the south entrance of the Barbara Channel.

MOUNT BUCKLAND is, by estimation, about 4,000 feet high. It is a pyramidal block of slate, with a sharp pointed apex, and entirely covered with perpetual snow.

Between these mountains the summit of the range is occupied by an extensive glacier, the constant dissolution of which feeds the innumerable cascades that pour large bodies of water down the rocky precipices overhanging the south shore of the Gabriel Channel.

At the extremity of the channel is Fitton Harbor; and on the opposite side of Cape Rawlett are Port Cooke and Brookes Harbor.

PORT COOKE is a very convenient and useful port. It is sheltered by a high wooded island. The anchorage is off the rivulet on the west side, in 9 fathoms.

BROOKES HARBOR, like Fitton Harbor, is spacious, but not good as a port, for the water is deep, and the anchorages, being in coves, are not easy of access without the labor of towing.

ADMIRALTY SOUND extends for 43 miles to the S. E. into the land of Tierra del Fuego. It is 7 miles wide at the entrance, and gradually diminishes to 3. On its north side the shore is very straight, but the south side has two deep inlets, Ainsworth and Parry Harbors. It terminates in a bay, affording anchorage in from 10 to 15 fathoms, but very much exposed to N. W. winds, which, I should think, from the funnel shape of the sound, would blow with furious strength. On the north side of the bay is Mount Hope, a lofty insulated mass of rock, but to the south of it lies a considerable tract of low land, over which the view was unobstructed for a considerable distance, and was bounded by a distant mountain, in the direction of the position of Captain Basil Hall's Volcano,\* in lat.  $54^{\circ} 48'$ , long.  $68^{\circ}$ . If the volcano exists, it is most probably the above mountain, but we saw nothing to indicate the appearance of its being in an eruptive state. It is placed on the chart from Captain Hall's authority.

\* A Loo Choo story, probably. See B. Hall's book.—E. & G. W. B.

In Ainsworth Harbours at the back of the sea.

PARRY HARBOR west side there are small vessels.

The eastern side of Parry Harbour is very low, with Lomas Bay, the large central bay.

The large central bay is remarkably sharp-pointed. NON-ENTRY Bay is a depth between the point of FOX BAY.—The kelp. A rapid stream is in from 3 to 5 fathoms within 20 yards of the shore.

HARRIS BAY is a small extent, affords tide rises and falls at the bottom of the bay.

CAPE ST. VALERIE has a small hummocky cape there is a slight rise from any wind on the beach, below high water and perfectly unsheltered.

The opening of Mount northward it appears Cape San Isidro that the reef for 20 miles, particularly on the west low narrow tongue of land called by Sarmiento on its summit.

Under this mountain bound through the rocky bed, on which basin, with good anchorage off the high land, which This little port is on the side, some of which is absent on a fishing boat.

To the south of the inlet. It is three miles but neither so good as three islets, (Rees Island).

MOUNT BOQUE is a capacious and lofty mountain but remarkably conspicuous a part of the western side of the bay, a south-west gale, are on occasion our decked ships than  $2\frac{1}{2}$  miles wide.

On the south-east for 2 miles. SHOLL BAY is a Point. There is a reef on the opposite shore and is between 4 and 6 miles.

In the centre of the bay at a short distance to the Labyrinth Islands, and

In Ainsworth Harbor there is anchorage at the bottom, on the west side. The mountains at the back of the harbor are capped by an enormous glacier that descends into the sea.

PARRY HARBOR is about five miles deep and three wide. At the entrance on the west side there are two coves, either of which offer a convenient stopping place for a small vessel.

The eastern side of Dawson Island is very much intersected by deep inlets, particularly Brenton Sound, and its termination, Port Owen, which very nearly communicates with Lomas Bay, the dividing land being low and marshy.

The large central island in Brenton Sound, Wickham Island, is high, and there is a remarkably sharp-peaked hill upon it, which is seen in clear weather from Port Famine.

NON-ENTRY BAY was not examined. It appeared to offer snug anchorage. The depth between the points of entrance was from 9 to 19 fathoms.

FOX BAY.—The bottom and south side are shoal, but the banks are indicated by kelp. A rapid stream of water empties itself into the bay. The anchorage in Fox Bay is in from 3 to 5 fathoms. The north head, Steep Tree Bluff, is of bold approach: within 20 yards of the shore the depth is 9 fathoms.

HARRIS BAY is an indentation of the coast, two miles deep.

WILLES BAY, off which is Offing Island, by which it may be known, although of small extent, affords excellent anchorage, upon a mud bottom, in 9 or 10 fathoms. The tide rises and falls about 6 feet. It is high water at full and change, about 12 o'clock. At the bottom of Willes Bay is Philip Gidley Cove, where a small vessel may lie in perfect security. There are not less than 3 fathoms in the entrance, and inside, in most parts, there is the same depth.

CAPE ST. VALENTYN is the northern extremity of Dawson Island. It is low, and has a small hummock near the point. Between the two points which form the cape there is a slight incurvation of the shore, which would afford shelter to small vessels from any wind to the southward of east or west; but the water is shoal, and the beach, below high water mark, is of large stones. The coast to the south-west is open, and perfectly unsheltered: it is backed by cliffs. The beach is of shingle.

The opening of Magdalen Sound was first noticed by Sarmiento. Coming from the northward it appears to be a continuation of the strait, and it is not until after passing Cape San Isidro that the true channel becomes evident. It extends in a southerly direction for 20 miles, and is bounded on either side by high and precipitous hills, particularly on the west shore. The eastern entrance of the sound, Anxious Point, is a low narrow tongue of land, with an island off it. Opposite to it is a steep mountain, called by Sarmiento the Vernal, (or summer house,) from a remarkable lump of rock on its summit.

Under this mountain is Hope Harbor, a convenient stopping place for small vessels bound through the sound. The entrance is narrow, with kelp across it, indicating a rocky bed, on which we had not less than 7 fathoms. Inside it opens into a spacious basin, with good anchorage in 4 fathoms, sheltered from all winds, excepting the squalls off the high land, which must blow with furious violence during a south-westerly gale. This little port is much frequented by Indians, for we found many wigwams on the south side, some of which were occupied by the women and children of a tribe, the men being absent on a fishing excursion.

To the south of Hope Harbor, between the Vernal and Mount Boqueron, is Stokes' Inlet. It is three miles long, with deep water all over: there is a cove on its north side, but neither so good nor so accessible as Hope Harbor. In the entrance of the inlet are three islets, (Rees Islets.)

MOUNT BOQUERON, the extremity of which is Squally Point, is a very precipitous and lofty mountain, about 3000 feet high, and having on its summit three small but remarkably conspicuous peaks. It is the eastern head of Stokes' Inlet, and forms a part of the western shore of Magdalen Sound. The squalls that blow off this during a south-west gale, are most furious, and dangerous unless little sail be carried. On one occasion our decked sailing boat was 7 hours in passing it. The sound here is not more than  $2\frac{1}{2}$  miles wide. On the opposite shore, within Anxious Point, is an islet extending to the south-east for 2 or 3 miles, but is narrow and unimportant.

SHOLL BAY is a small bight of the coast line, 5 miles to the south of Squally Point. There is a reef off it, the position of which is pointed out by kelp.

On the opposite shore is Keats' Sound. It extends to the south-east for 6 or 8 miles, and is between 4 and 5 miles wide.

In the centre of Magdalen Sound, abreast of the above opening, is a rocky islet; and at a short distance to the southward, on the western coast, is a bay and group, called Labyrinth Islands, among which small vessels may find good anchorage.

**TRANSITION BAY** is deep, and of little importance. Four miles farther, at Cape Turn, the shore trends suddenly round. Here Magdalen Sound terminates, and Cockburn Channel commences.

On the opposite shore, to the south of Kents' Sound, there are no objects worth noticing, excepting Mount Sarmiento, which has been already described, and Pyramid Hill, which was found to be 2500 feet high.

The bottom of Magdalen Sound is 6 miles wide, but at Cape Turn the channel narrows to 2 miles, and in one part is not more than  $1\frac{1}{2}$  mile wide. The south shore is broken, and there are many sounds penetrating deeply into the land, which, in this part, according to Captain Fitzroy's survey of Thieves Sound, is 7 miles wide. Eleven miles more to the westward, at Courtenay Sound, the width of the peninsula is not more than 3 miles.

**WARP BAY**, although exposed to southerly winds, is a convenient stopping place; a plan was made of it.

**STORMY BAY** is a very wild unsheltered place, unfit for any vessel to stop at. At the anchorage the water is deep, 15 to 20 fathoms, and the bottom rocky. The bay is strewn over with shoals, the existence of which is marked by kelp; these narrow the channel so much as to render the entrance and exit both intricate and difficult for any but a small and handy vessel.

**PARK BAY** is both very snug and secure, with good anchorage in 12 fathoms, sand and mud. It has the same disadvantage as Stormy Bay, in being on the lee side of the channel, and is, therefore, difficult to leave. There is, however, here, more room to beat out, and no dangers to encounter but what are visible. At the N. E. angle of the bay is a narrow isthmus, not more than 500 yards across, separating it from Mercury Sound, which was not examined. It is laid down from an eye sketch.

In working down the channel, the south side should be preferred, as it is a weather shore, and seems to be better provided with coves and harbors to anchor in.

**KING AND FITZROY ISLANDS** in mid-channel, are of bold approach; as are also Kirke's Rocks more to the westward.

The flood tide sets to the southward, or to seaward, but was not found to run with sufficient strength, to benefit or impede a vessel beating through. The rise and fall is also inconsiderable, not being more than 6, or at most, 8 feet at spring tides.

There are several anchorages among the Prowse Islands, which are very numerous, and skirt the coast for several miles. Behind them the land trends in and forms a deep sound. The Adelaide Schooner anchored in a bay on the north side of one of the islands opposite to Barrow Head, in 6 fathoms; but there are many places of a similar nature, equally convenient and secure. A vessel, in want of anchorage, should hoist a boat out and wait in the offing until one answering the purpose be found. Entering these deep-water bays, a boat should always be hoisted out, and a hawser kept ready to make fast to the shore. It will be frequently necessary to tow up to the head of the harbors; for, from the height of the land, the wind generally fails or becomes baffling.

The distance across the channel, between Prowse Islands and Barrow Head, is scarcely  $1\frac{1}{2}$  mile.

**DYNELEY SOUND** extends for more than 9 miles in a north-west direction into the interior of Clarence Island. On the west side of its entrance is a group of islands, affording several anchorages, which the chart will point out. One of them, Eliza Bay, offers shelter and security from all winds. The bottom of Dyneley Sound was not examined.

**MELVILLE SOUND**, which forms the embouchure of the Barbara and Cockburn Channels, is very extensive, and is completely filled with islands. Some of them are of large size, and all are of the most rugged and desolate character. The offing is strewn with clusters of rocks: of these the East and West Furies are the most remarkable, as well as the most important; for the passage into the Cockburn Channel lies between them. The former are very near the land of Cape Schomberg. The West Furies bear from the Tower Rock, off Cape Noir, N.  $84^{\circ}$  E. 25 miles; and S.  $30^{\circ}$  W. 11 miles from Mount Skyring. The Tussac Rocks, which are two in number, bear from the West Furies N.  $73^{\circ}$  E.  $4\frac{1}{2}$  miles; and in a line between the East and West Furies, 3 miles from the latter, and 2 from the former, is a rock standing alone. It bears from Mount Skyring S.  $12^{\circ}$  W.  $12\frac{1}{2}$  miles. To avoid it, in entering with a westerly wind, pass near the West Furies, and steer for the Tussac Rocks.

After passing these, there are no dangers that we know of, in the entrance of the Cockburn Channel. A reference to the plan will show every thing else that need be noted.

Mount Skyring is a very prominent object. It rises to a peak to the height of 3,000 feet; and, being visible for a considerable distance, was useful in connecting the trian-

gulation of the strait to the north end of the bearing of Mount Skyring. The variation is 2.

The southern cove, and rocks, that no the best guide for any vessel; there are many shoals, which would afford perfect shelter.

The land hereat coast of Tierra del Fuego, to its eastern extremity, and reference to the plan.

Among Magill's good and well sheltered anchorage, so frequent every vessel.

For sealing vessels they usually frequent North Cove was of the best.

**FITZROY HARBOR** is a very wild anchorage, and the Tussac Rocks, on the north side, are of great importance.

**BYNOE ISLAND** which a plan was made of it.

**BROWN'S BAY** the north entrance, and the north anchorage, is of great importance.

Between Hewett and shoals, some caution is therefore required.

The tide, to the north, is sufficient consequence as to impede vessels.

The country here, and cypress trees; or 18 feet. They are when seasoned, wood.

**BEDFORD BAY** narrow part of the channel, and perfectly sheltered, the eastern narrow channel; with a strait, will be of service.

Here, as well as at the (Lieutenant Graves).

**NUTLAND BAY** known by two small anchorages.

Between Bedford and the channel is open, and inlets not here described, were examined. They are the bottom is foul.

The western coast of the bay, FIELD'S BAY, place, unless the vessel is from with a view of the bay.

\* Views of parts of the vessel Beagle, 1829 and 1830.

† In the winter of 1829 and the crew saved by the vessel.

gulation of the strait with that of the outer coast. It was seen from Field Bay, at the north end of the Barbara Channel; and, from its summit, Capt. Fitzroy obtained a bearing of Mount Sarmiento. Its summit is in lat.  $54^{\circ} 24' 41''$ , and long.  $72^{\circ} 7' 40''$ . The variation is  $25^{\circ}$ .

The southern entrance of the Barbara Channel is so very much occupied by islands and rocks, that no direct channel can be perceived. The chart must be referred to as the best guide for its navigation. For small vessels there is neither danger nor difficulty; there are numerous anchorages that they might reach without trouble, and that would afford perfect security.

The land hereabout is also described in Captain Fitzroy's published Views of the sea coast of Tierra del Fuego, which contain excellent views of the land from Cape Pillar to its eastern extremity at Cape Diego. Section VII. contains the description of the coast, and references are therein made to the views of the land in Captain Fitzroy's work.\*

Among Magill's Islands there are several coves and anchorages. Tom's Harbor is good and well sheltered, excepting from the violent squalls off the high land, which are so frequent every where among the Coves of Tierra del Fuego.

For sealing vessels, however, it is more safe and secure than Fury Harbor, the place they usually frequent. Every thing that Fuegian Harbors afford is to be obtained in it. North Cove was occupied by Captain Fitzroy in the Beagle.

FURY HARBOR, on the south-east side of the central island of Magill's Group, is a very wild anchorage. From its contiguity to the East and West Furies, and the Tussac Rocks, on which seals are found, it is much frequented by sealing vessels.†

BYNOE ISLAND affords an anchorage on its north-east side; and Hewett Bay, of which a plan was made, is a good stopping place, either for entering or quitting the channel.

BROWN'S BAY is more extensive, but also affords good shelter in a small cove at the north entrance, in 8 fathoms, sand, among some kelp.

NORTH ANCHORAGE, for a small vessel, is tolerably secure, but not to be recommended.

Between Hewett Bay and North Anchorage, the channel is strewed with many rocks and shoals, some of which, although covered with kelp, only show at half-tide. Much caution is therefore necessary, and all patches of kelp should be carefully avoided.

The tide, to the northward of North Anchorage, which, to the southward, was not of sufficient consequence to interfere with the navigation of the channels, is so much felt as to impede vessels turning to windward against it.

The country here has a more agreeable appearance; being better wooded with beech and cypress trees; but the latter are stunted, and do not attain a greater height than 15 or 18 feet. They are very serviceable for boat-hook spars, boat's masts, &c. The wood, when seasoned, works up well.

BEDFORD BAY is a good anchorage. It is situated on the north-west side of the narrow part of the channel. Its depth is from 20 to 8 fathoms, good holding ground, and perfectly sheltered from the prevailing winds. At its entrance are several patches of kelp, the easternmost of which has 4 fathoms on it. A plan was made, including the narrow channel; which, as it is a place likely to be frequented by vessels navigating the strait, will be of service.

Here, as well as throughout the Barbara Channel, the flood tide sets to the southward. (Lieutenant Graves MS.)

NUTLAND BAY, having 8 and 15 fathoms over a sand and mud bottom, may be known by two small islands, Hill's Islands, which lie one mile N. N. E. from the anchorage.

Between Bedford and Nutland Bays, and, indeed, as far as the Shag Narrows, the channel is open, and may be navigated without impediment. There are many bays and inlets not here described or noticed, that may be occupied, but almost all require to be examined. They all trend far enough into the land to afford good shelter, but in many the bottom is foul and rocky, and the water too deep for anchorage.

The western coast, being the windward shore, should, of course, be preferred.

FIELD'S BAY is too exposed to southerly winds to be recommended as a stopping place, unless the wind be northerly. Nutland Bay is a more convenient place to start from with a view of passing the Narrows.

\* Views of parts of the sea coast of Tierra del Fuego, taken on board His Majesty's surveying vessel Beagle, 1829 and 1830.

† In the winter of 1826-7, the Prince of Saxe Coburg, sealer, was wrecked in Fury Harbor, and the crew saved by the Beagle's boats.

To the north of Nutland Bay is Broderip Bay; at the bottom, or northern part of it, are some good coves; but the most convenient of them is at the eastern extreme; it is called on the chart Dinner Cove. It extends to the north for about a furlong, and affords good anchorage in 10 fathoms, sufficiently well sheltered and distant from high land to be free from the mountain squalls, or willi-waws.

Round Dinner Cove is Icy Sound, a deep inlet with a glacier of considerable extent at the bottom, from which large masses of ice are constantly falling, and drifting out, occupy the waters of the inlet. The water is deep, and the anchorage not good, when there are so many better places. Dean Harbor is a considerable inlet trending in under the same glacier, which extends from the head of Smyth Harbor, to a considerable distance in the south-west. If of a favorable depth it might afford good anchorage. We did not enter it.

The only navigable communication that exists between the Barbara Channel and the Strait, is that called the Shag Narrows, on the western side of Cayetano Island. The width of the opening is at least one mile and three quarters, but the eastern portion is so filled with rocky islets and shoals, that the actual breadth of the only navigable part at the northern end, is about 100 yards; and the widest part at the south end, scarcely half a mile—the whole length of the passage being rather less than two miles. It is formed on the west side by a projecting point of high land, that gradually trends round to the westward; and on the opposite side by three islands, the northernmost of which is Wet Island; on the southernmost is Mount Woodcock, one of our stations for the triangulation.

Between Wet Island, where the Narrows on the north side commence, and the western shore, the width is not more than 100 to 150 yards, and perhaps 300 yards long.—Through this the tide sets as much as seven miles an hour; the sides of the rocks are steep to; so, that I apprehend no accident can happen to a ship in passing them, notwithstanding the want of room for manœuvring. At the south end of Wet Island, the stream of tide divides,—one sets to the eastward, round Wet Island, whilst the principal runs through the Shag Narrows. And in the same manner, a part of the southern tide, which is the flood, after passing Wet Island, runs to the south-east, round the eastern side of Mount Woodcock.

All the space to the eastward of Mount Woodcock is so strewed with islands and rocks, that the passage must be difficult if not dangerous.

To avoid the danger of being thrown out of the Narrows, it is only necessary to keep the western shore on board: where there are no indentations, the tide will carry a vessel along with safety. At the north end of the Narrows, on the west side, is a shelving point, on which there are 5 fathoms;—here is an eddy, but as soon as the vessel is once within the Narrows, (within Wet Island,) the mid-channel may be kept. In shooting this passage, it would be better to furl the sails and tow through, for if the wind be strong, the eddies and violent squalls would be very inconvenient, from their baffling, and laying the vessel upon her beam ends; which frequently happens, even though every sail be furled. It will be necessary to have a couple of boats out, ready, either to tow, the ship's head round, or to prevent her being thrown by the tide into the channel to the south of Wet Island.

If anchorage be desirable after passing the Narrows, there is none to be recommended, until the coves between Smyth Harbor and Cape Edgeworth be reached.

Of these Dighton Cove is preferable. The anchorage is off the sandy beach, in 20 fathoms.

Warrington Cove, the next to the north, also offers good shelter and anchorage; but both are exposed to easterly winds.

The tide in the Shag Narrows, at full and change, commences to set to the southward at 12 o'clock. In the Barbara Channel the flood tide was found by Lieutenants Skyring and Graves, to set to seaward, or to the southward; as was also the case in Cockburn Channel. Our experience of the tides hereabouts was not sufficient to justify our making any further observation upon them.

SMYTH HARBOR is about 4 miles deep, and a half to one mile wide, surrounded by high land, and trending in a westerly direction. The water is deep, excepting in Earle Cove, on the north side, where vessels might lie, if necessary; but I should think it a very wild place in bad weather.

The hills at the head are capped by glaciers that communicate with those at the head of Icy Sound. It seems possible that all the mountains between this and Whale Sound are entirely covered with a coating of ice.

Half a mile south-east from Cape Edgeworth is a shoal, so thickly covered with kelp as to be easily seen in passing or approaching it;—there are not more than two feet of water over its shoalest part.

## BLUNT'S AMERICAN COAST PILOT.

To pass through the Barbara Channel, from the north, it would be advisable to stay at Port Gallant until a favorable opportunity offers; for, with a south-west wind it would neither be safe nor practicable to pass the Shag Narrows.

The north-west wind prevails more than any other in the western portion of the strait, in consequence of the reaches trending in that bearing. It seems to be a general rule hereabouts that the wind either blows up or down them.

Between Cape Froward and the western entrance of the strait, the wind is generally from north-west, although at sea, or in the Cockburn or Barbara Channels, it may be in the south or south-western boards.

*Strait of Magalhães—From Port Famine to Cape Froward, the North Coast of Clarence Island, and from Cape Froward to the Jerome Channel.*

The Sedger River, which is fronted by a bar that dries at low water, can be entered by boats at half tide, and is navigable for 3 or 4 miles; after which its bed is so filled up by stumps of trees, that it is difficult to penetrate farther. The water is fresh at half a mile from the entrance, but to ensure its being perfectly good, it would be better to fill the casks at low tide. The low land near the mouth, as well as the beach of Port Famine, is covered with drift timber of large size, which we found very useful, and serviceable for repairing our boats.

The river was called by Sarmiento, Rio de San Juan. In Narborough's voyage it is called Segar's River, and his boat is described to have gone up it for 9 (!) miles; but was there stopped from going farther by "reason of the trunk-timber and shoalness of the water." Byron describes the river, which he calls the Sedger, in glowing terms, but gives rather a more flattering account of the timber growing on its banks than it deserves.

Voces Bay, or the Playa-de-las-Voces of Sarmiento, is to the southward of the south point of Port Famine, where the Sedger River falls into the sea. A ship may anchor in from 7 to 10 fathoms, off the Second River, but the shelter is not as good as in Port Famine. The Second River has a shoal entrance, but extends for some distance up the valley.

Between this bay and Cape San Isidro, (Point Shut-up of Byron,) the water is too deep for anchorage, even close to the beach. The cape is the termination of the ridge, whose summit is Mount Tarn, the most conspicuous mountain of this part of the strait. It is 2602 feet high by barometrical measurement. It is readily distinguished from abreast of Elizabeth Island, whence it appears to be the most projecting part of the continental shore. When viewed from the northward its shape is peaked, and during the summer it has generally some patches of snow a little below its summit; but in the winter months its sides are covered with snow for two thirds down. From abreast and to the southward of Port Famine, it has rather a saddle shaped appearance; its summit being a sharp ridge, extending very nearly for one mile, north-west and south-east, with a precipitous descent on the north-east, and a steep slope on the south-west sides. The highest peak near its north-east end, is in lat.  $53^{\circ} 45' 6''$ , and lon.  $70^{\circ} 58' 26''$ .

There is a low, but conspicuous rounded hillock covered with trees, at the extremity of Cape San Isidro; and a rocky patch extends off it for 2 cables' length, with a rock at its extremity that is a wash at high water. It is covered with kelp.

EAGLE BAY, (Valcareel Bay of Cordova,) is about three quarters of a mile deep; and its points one mile apart, bearing N. E. and S. W. The anchorage is at the head, in from 20 to 12 fathoms. There are two streams of water; but, being very much impregnated with decomposed vegetable matter, cannot be preserved long. The woods here abound with Winters Bark, of which there are many very large trees. A small reef extends for about a cable's length off the S. W. point of the bay, on which is an islet. Eagle Bay is not useful for any but a small vessel, that can be towed in, and then it will be necessary to steady her by warps, to the shore. The squalls, or willi-waws, at times, are very violent.

GUN BAY, the next to the westward, although small, affords anchorage for a single vessel near the shore, at its S. W. part, in from 8 to 9 fathoms. Its points bear S.  $57^{\circ}$  W. and N.  $67^{\circ}$  E. and are distant more than three-quarters of a mile. Two rivulets discharge themselves into it, from which water is easily procured. The bottom is a stiff clay, and good holding ground. A round hill of moderate elevation, and thickly wooded, separates it from Indian Bay, the points of which bear S.  $69^{\circ}$  W. and N.  $69^{\circ}$  E. and are distant more than  $1\frac{1}{2}$  mile. From the east point the shore runs due west, curving round at the bottom towards an islet covered with trees; between which and the shore there is only sufficient depth for a boat to pass. A rock about 12 feet high lies to the S. E., on either side of which is an anchorage, sufficiently sheltered from the prevailing winds, over a good bottom, in from 7 to 9 fathoms. The north side of the bay is shoal, caused, proba-

bly, by the alluvial deposit from a river nearly in the centre. A patch of kelp extends off the S. E. point for 2 cables' length, but has 9 fathoms over it at the centre.

Neither Guan nor Indian Bays are noticed in Cordova's description of the strait, although they are quite equal to any other in the neighborhood, for stopping places.

**BOUGHAGE BAY**, which is Cordova's Cantin Bay, is small, and the water very deep, except near the bottom, where anchorage may be obtained in 8 fathoms, clay. It is separated from Bournaud Bay, (Gul Bay of Cordova,) by Cape Remarquable, of Bougainville, which is a precipitous round-topped bluff projection, wooded to the summit. At two cables' length from the base no bottom was found with 20 fathoms of line, but at the distance of 50 yards the depth was 20 fathoms. Bournaud Bay is more snug and convenient than its northern neighbor, Boughage Bay, being sheltered from the southerly winds by Nassau Island. At the S. W. end of a stony beach at the bottom, is a rivulet of good water, off which there is good anchorage in 8 fathoms, stiff mud.

**BOUGAINVILLE BAY** (Cordova's Texada Bay) forms a basin, or wet dock, in which a vessel might careen with perfect security. It is from its small size, great depth of water, and the height of the land, rather difficult of access, which renders it almost always necessary to tow in. On entering, the anchor should be dropped in 12 fathoms, and the vessel steadied by warps to the trees, at the sides and bottom of the cove. It is completely sheltered from all winds, and an excellent place for a vessel to remain at, particularly if the object be to procure timber, which grows here to a great size, and is both readily cut down and easily embarked. A rivulet at the bottom affords a moderate supply of water; but if more be required, the neighboring bays will afford an abundance.

In the passage between Nassau Island and the main, the least water is 7 fathoms, over a stiff clay bottom, gradually deepening on each side. But the winds being baffling, and the tides irregular and rippling in many parts, a vessel should not attempt it but from necessity.

**NASSAU ISLAND'S** south extremity is Sarmiento's Point, Santa Brigida.

**ST. NICHOLAS BAY**, so named by the Nodales in 1618, (but previously, by Sarmiento, Bahia de Santa Brigida y Santa Agueda, and French Bay by De Gennes,) is not only of larger size than any of the bays to the south of Cape San Isidro, but is the best anchorage that exists between that cape and Cape Froward, as well from its being more easily entered and left, as from the moderate depth of water, and extent of the anchoring ground. Its points bear from each other S. 58° W. and N. 58° E., and are distant two miles. Nearly in the centre is a small islet covered with trees, between which and the shore is a passage with 9 fathoms water, stiff clay. The shore is, however, fronted for its whole length by a shoal bank, which very much reduces the apparent extent of the bay. This bank stretches off to the distance of a quarter of a mile from the shore, the edge of which is steep to, and is generally distinguished by the ripple, which, with a moderate breeze, breaks at half tide. The Beagle anchored in the bay, at 3 cables' length to the N. E. of the small central islet, in 12 fathoms, pebbly bottom; but the best berth is one quarter to one third of a mile to the S. W. of the islet, in 10 or 11 fathoms, muddy bottom. Captain Stokes recommends in his journal, in coming in, to keep sail upon the ship, in order to shoot into a good berth, on account of the high land of Nodales Peak becalming the sails; and to avoid the drift of the stream of the river setting the ship over to the eastern side of the bay. I do not, however, think that the stream of the river can affect a ship in any position between the islet and the peak. In taking up an anchorage, much care is necessary to avoid touching the bank. Less than 10 fathoms is not safe, but in that depth the security is perfect, and the berth very easy to leave. In passing through the strait this bay is very useful to stop at, as well from the facility of entering and leaving it, as for its proximity to Cape Froward. The islet is in latitude 53° 50' 33", and longitude 71° 3' 13".

In the middle of the bay is De Gennes River, (Rio del Valle Grande of Sarmiento,) which is of a larger size than Sedger River. It is 100 yards across, and apparently extends in a winding direction up the valley for some distance. From its entrance being fronted by a shoal or bank, the form of which must be constantly shifting, and its being strewn with trees that drift out of the river during the winter freshes, it is far from being an eligible place for procuring water.

From Glascott Point, the southern head of the bay, a mountainous and high range of hills runs back for some distance. On its summit are several sharp peaks, the most conspicuous of which is Nodales Peak.

From Glascott Point the coast extends in nearly a straight line to Cape Froward, a distance of 7 miles, the land at the back continuing mountainous and woody. A point formed by a beach of shingle, covered with trees to within 20 yards of the water's edge

\* It was here that M. de Bougainville cut timber for the French colony, at the Falkland Islands. To sailing vessels it is known by the name of Jack's Harbor.

\* Byron found the Midway between St. N.

and distant nearly 3 miles from Cape Froward, is the only projection. Between this and the entrance of a rivulet, which waters the only valley that exists in this space, an anchorage at a quarter of a mile from the shore, in 11 fathoms, might be occupied during a westerly wind; but with the wind more southerly it would be too much exposed to be safe. The Beagle anchored here at 2 cables' length off the sandy beach, in 11 fathoms.

CAPE FROWARD, the southern extremity of the continent of South America, rises abruptly from the sea. At its base is a small rock, on which Bougainville landed, as did Lient. Graves, for the purpose of obtaining a set of bearings. The hill that rises immediately above the cape, was called by Sarmiento the Morro of Santa Agueda. Cape Froward is in lat.  $53^{\circ} 53' 43''$ , long.  $71^{\circ} 14' 31''$ . The ebb tide sets to the northward, and the flood to the southward, but with very little strength. It is high water at full and change, at 1 P. M.\*

The north coast of Clarence Island extends from the entrance of Magdalen Sound to that of the Barbara Channel, the whole length of which is indented by sounds stretching deeply into the island.

BOUGAINVILLE'S PORT OF BEAUBASIN, (the Bahia Darsena of Cordova,) is sufficiently pointed out by the small rocky islet called Periagua, and the mountain of the Vernal, before described. The outer part of the port decreases in width gradually to the entrance of the harbor, which is formed by two projecting points, a very short distance apart, and is very shoal, the deepest water being only  $2\frac{1}{2}$  fathoms. Inside, in the basin, there are 5 fathoms. It is a very snug place when once in, but possesses no advantage, since it is on the wrong side of the strait for vessels bound through to the westward; for the northerly or easterly wind, which would be favorable to proceed, would prevent a vessel sailing out of it.

INMAN BAY, HAWKINS BAY, STAPLES INLET, AND SHOLL HARBOR, are all deep inlets, surrounded by high precipitous land.

To the westward of Greenough Peninsula, is Lyell Sound. It is 9 miles deep, and is separated at the bottom from Sholl Harbor by a ridge of hills about one mile and a half wide.

In the entrance of Lyell Sound, are two conspicuous islands, one of which is very small. They are called Dos Hermanas, and bear from Cape Froward S.  $48^{\circ}$  W., five miles and a half.

KEMPE HARBOR, one mile and a half within the entrance, on the west side of Lyell Sound, is rather difficult of access, but perfectly secure, and would hold six ships. Stokes Creek, on the same side, more to the southward, also offers good anchorage; but from its being out of the way, can be of no utility.

CASCADE HARBOR, AND MAZZAREDO BAY, are of less size, and therefore more attainable, but of the same character with Lyell Sound, viz., deep water, surrounded by high land. The former is known by the cascade which M. de Bougainville describes, from which it derives its name. On the headland that separates these harbors from Lyell Sound, is a sugar-loaf hill, the position of which is well determined, in lat.  $53^{\circ} 57' 32''$ , long.  $71^{\circ} 24' 13''$ .

HIDDEN HARBOR has a narrow entrance, but, if required, offers good shelter.

SAN PEDRO SOUND is the most extensive inlet that we know in Clarence Island. It extends, in a southerly direction, for nearly 13 miles, and has three other inlets branching off into the land, two to the westward and one to the eastward. There is a good, although a small, anchorage on its west side, one mile and a half within the entrance, called Murray Cove, and another close to it, which is even more sheltered.

FRESH WATER COVE, the Caleta de agua dulce of Sarmiento, is a confined and indifferent place for a ship.

BELL BAY, (the Bahia de la Campana of Sarmiento,) has a very convenient anchorage, Bradley Cove, on its west side, bearing S.  $79^{\circ}$  W. from Point Taylor, the eastern head of the bay. It will be readily distinguished by a small green round hill, which forms its north head. The anchorage is in 17 fathoms, and the vessel hauls in, by stern-hauls or a kedge, into 9 fathoms, in perfect security. Pond Bay, to the northward, has good shelter, but it is not of such easy access, for it would be necessary to tow both into and out of it.

MOUNT POND, a peaked hill over the harbor, is a conspicuous mountain, and is visible from the eastward as soon as it opens round Cape Froward. It has two summits, one of which only is visible from the eastward.

Between Cape Inglefield and Point Elvira, is St. Simon's Bay. It is studded with islands and rocks, and at the bottom has two communications with the Barbara Channel, separated from each other by Burgess Island, the easternmost of which, called Tom's

is both narrow and shoal, and not safe for a vessel drawing more than 6 feet. Inside the lagoon the depth is from 3 to 13 fathoms. With Fortescue Bay and Port Gallant so near, the probability is that it will never be much used; but in turning to the westward it would be better to anchor here than lose ground by returning to Woods' Bay. By entering the western channel and steering clear of the kelp, a safe and commodious anchorage may easily be reached.

FORTESCUE BAY is the first best anchorage to the westward of St. Nicholas Bay. It is spacious, well sheltered, easy of access, and of moderate depth. The best berth is to the south-east of the small islet, outside of Wigwam Point, in 7 or 8 fathoms. Having the entrance of Port Gallant open, small vessels may sail into the port, but the channel is rather narrow. The banks on the western side, off Wigwam Point, are distinguished by the kelp.

When within, the shelter is perfect; but Fortescue Bay is quite sufficiently sheltered, and much more convenient to leave. In this part of the strait, as the channel becomes narrowed by the islands, the tides are much felt. There are two good anchorages before reaching the entrance of the Gerome Channel, namely, Elizabeth Bay and York Roads, off Batchelor's River. They are, however, only fit for stopping places. There are no anchorages among the islands that can be recommended, excepting in the strait that separates the group of Charles' Islands, in which there is security and a convenient depth. When the wind blows fresh there is a hollow sea between Charles' Islands and the north shore, which very much impedes ships beating to the westward.

At a short distance to the E. S. E. of Passage Point, is a shoal, with 2 fathoms upon it. Elizabeth Bay has a sandy beach, and a rivulet emptying itself into it. Cordova recommends the best anchorage to be in 15 fathoms, Passage Point bearing E. S. E., distant half a mile, about 3 cables' length from the river, and to the N. W. of a bank on which there is much kelp.\*

Captain Fitz Roy describes the anchorage of York Roads, or Batchelor's Bay, to be good and convenient: "Half a mile off, a woody point, (just to the westward of the river,) bearing N. 6° E., and the mouth of the river N. E. three quarters of a mile, is a good berth, because there is plenty of room to weigh from and space to drive, should the anchor drag. The bottom is good in 10 or 12 fathoms, but not in a less depth. The shore is a flat shingle beach for two miles, the only one in this part of the strait." Cordova recommends the following as the best anchorage, at half a mile from the beach, the river bearing N. 5° E., and the west point of the bay N. 27° W.

The set and change of the tide here are very uncertain, on account of the meeting of the Jerome Channel tides with those of the strait, which occasions many rippings; and it would require a better experience than we possess, to give a correct explanation. Captain Fitz Roy says, that "the tide along shore, near Batchelor River, changed an hour later than in the offing. At Batchelor's Bay, by the beach, during the first half or one third of the tide that ran to the south-east, the water fell; and during the latter half or two thirds, it rose. In the offing it ran very strong." The establishment of the tide, at the entrance of the river, by an observation made by Captain Fitz Roy, with the moon eight days old, would be, at full and change, at 1h. 46m. By an observation made by Captain Stokes, two years previous, it was found to be 2h. 13m. The tide at the anchorage ran three knots.

BATCHELOR RIVER is accessible to boats only; and in going into or out of its entrance, they must be very careful to follow exactly the course of the stream, for a bar lies outside. Large boats cannot enter at half tide.†

To the following islands in the centre of the strait, that form the south limit of English Reach, I have restored the names that were originally given by Sir John Narborough.

SECRETARY WREN'S ISLAND is a small rocky islet, rising abruptly on all sides, and forming two summits. Near it are some rocks, and to the S. E. is a group of small rocks; and at a mile to the E. S. E. are two rocks above water, called Canoas. The islet has no name on Cordova's Chart.

CHARLES ISLANDS, besides some smaller islets, consist of three principal islands; and in the centre there is a very good port, having good anchorage within the

\* Mr. Simpson describes the Dolphin's anchorage here in 10 fathoms. Rupert's Island bore S. by E. 2 or 3 miles; Passage Point S. E. by S. three quarters of a mile; the west part of the bay W. by N. 2 miles, and a reef of rocks about a cable's length from the shore N. W. by W. a quarter of a mile. The reef is quite covered at high water. Here the flood set to the eastward, and flowed, at full and change, until 12 o'clock.

† "At three quarters of a mile to the eastward of Batchelor River, is a shoal which has not more than 6 feet upon it at low water, and 14 feet at high water. It is about half a mile from the shore, and shows itself by the weeds upon it."—[Simpson's Journal.]

islets, in 13 fathoms. It has an outlet to the N. W., and one to the S. W., also a narrow point communicates with the strait to the S. E.

Opposite to Cape Gallant, on the eastern island, near its N. W. end, is a conspicuous white rock, called Willis' Mark. Next to the westward, in succession, are Mounmouth and James Islands, (called by Cordova Isla de los Infantes,) then Cordova Islet, and Rupert's Island, and to the westward of these the island of Carlos III., so named by Cordova. The last is separated from Ulloa Peninsula by St. David's Sound, which is navigable throughout.

To the northward of Whale Point the eastern extremity of Carlos III. Island, is a cove with an anchorage, in 15 fathoms, close to the shore, on a steep bank, but bad ground. The Beagle and Adelaide both dragged off the bank, from the violence of the squalls off the high land. From the north point of the cove to Rupert's Island, is a rocky ledge, (Lucky Ledge,) over which the tide sets with considerable strength. The Beagle, having dragged her anchor in the cove, was brought up by its hooking a rock on the ledge, but it was found broken on being hove up. Whilst there, the tide set past her in a north and south direction, at the rate of three knots an hour.

To the westward of Cape Middleton, of Narborough, is Muscle Bay, having deep water, and of uninviting character. Cordova describes it to be a mile wide, with unequal soundings, from 12 to 40 fathoms, stones. This bay is not to be recommended, although it appears to be well sheltered. There is an anchorage in from 15 to 30 fathoms in Bonet Bay, of Cordova, close to Carlos III. Island. It lies under the S. E. side of some islands opposite to Batchelor River. At a short mile to the eastward of Cape Cross-side, the N. W. end of Carlos III. Island, is Tilly Bay, but it has nothing to recommend it, particularly when the much better anchorage off Batchelor River is so close at hand.

CHOISEUL BAY, AND NASH HARBOR, on the Fuegian Coast, are not in the least inviting; the former, Captain Fitz Roy describes to be a large, deceiving, harbor-like bay, full of islets and patches of kelp, under which, of course, there are rocks. Between the islets, the water is deep and unfit for anchorage.

NASH HARBOR is equally unserviceable.

WHALE SOUND, also on the Fuegian shore, at the back of Ulloa Peninsula, is a large inlet, trending eight miles into the land, and terminating in a valley bounded on each side by high mountains. There is anchorage only in one place, the west side of Last Harbor; and, although this harbor appears large, the anchorage is small, and close to the shore.

ST. DAVID'S SOUND separates Carlos III. Island from Ulloa Peninsula. At its north end the water is deep, but where it begins to narrow, there are soundings in it, on which anchorage might be found, if there was a necessity; but I cannot imagine such an occasion will ever happen:—should it, the chart will be a sufficient guide.

*Strait of Magalhaens—Jerome Channel—Otway and Skyring Waters, Crooked and Long Reaches*

THE JEROME CHANNEL was only slightly examined by Cordova's officers; for, their object being merely to confirm or disprove Sarmiento's statement of the insularity of the land between it and the Gulf of Xaultegua, now called Croker Peninsula, \* the Lago de la Botella was alone explored by them. The continuation of the Jerome, named in the old charts Indian Sound, having never been traced; and, therefore, being an object of great interest, it was investigated by Captain Fitz Roy as carefully as could be done in the middle of winter in an open boat. The period of his absence from the ship, however, 32 days, not being sufficient to complete the service, the western shores of the Skyring Water were not visited; and as a further examination of it will, probably, be one of the objects of the voyage he is now preparing for, a brief description will be sufficient.

THE JEROME CHANNEL is narrow, but throughout, free from danger. The western shore is high and steep, and covered with trees: the eastern shore is lower and less wooded. In mid-channel, near its western end, are two islets which have no place in the Spanish Chart; unless the Teran Isles be intended to represent them;—if so they are badly placed. The Spanish Chart makes the channel 6 miles too long.

On the west side of the Jerome are 2 coves, Wood Cove and Seal Cove, that may be used with advantage by small vessels. On the eastern shore, the bights, Three Island Bay (Cordova's Real Cove,) and Coronilla Cove, appeared to be commodious. Arauz Bay is open and exposed to the N. W.

Where the Lago de la Botella joins the Jerome, the latter winds round the north-east. On its eastern side, behind the False Corona Isles, is Cutter Cove, affording anchorage for a small vessel; a plan was made of it. Opposite is Nunez Creek, with deep water.

\* Sarmiento describes it to be an island by the Indian name of Cayrayxayiguá.

xayisigua.

Abreast of the Corona Isles, one of which, the Sugar Loaf, is about 200 feet high, is Sullivan Sound, penetrating for five miles into the land on the western side of the channel; and at a league to the northward of the Sugar Loaf, is another opening to the westward; on the north shore of which is Bending Cove; which, with Cutter Cove, are the only stopping places between Cape Forty-Five and Child's Bluff.

Between Child's Bluff and Point Stokes, the Otway water commences. On the west shore it affords several commodious anchorages. Off Point Villiers, lat.  $53^{\circ} 9'$ , at a quarter of a mile from the shore, there are from 10 to 30 fathoms; and the depth decreases in advancing more northerly. There is anchorage all across the north-east part of the water, in from 5 to 20 fathoms, the bottom of sandy mud.

Inglefield and Vivian Islands, at the west end of the water, are low, but thickly wooded. An isthmus, 6 to 10 miles across, separates the Otway Water from the Strait near Elizabeth Island. From an elevated station on the north side of Fitz Roy Channel, this narrow neck appeared to be low and much occupied by lagoons. The south shore of Otway Water is formed by high land, with three deep openings that were not examined. Brunswick Peninsula, a mass of high mountainous land, is the most southern extremity of the Continent.

In lat.  $52^{\circ} 40'$ , and long.  $71^{\circ} 10'$  W. is the east entrance of Fitz Roy Channel; it forms a communication between the Otway and the Skyring Waters, and takes a winding course to the N. W. for 11 miles, which is easily navigated. A strong tide running during the neaps at the rate of five or six miles an hour in the entrance, and two or three in other parts, sets through it, six hours each way. The rise and fall, however, were scarcely distinguishable.

SKYRING WATER, is 10 leagues long from east to west. Its shores are low. At the western extremity two openings were observed to wind under a high castellated-topped mountain, (Dynevov Castle,) which were supposed by Captain Fitz Roy to communicate with some of the sounds of the western coast. Through Euston Opening, the southern one, no land was visible in the distance; but, on a subsequent examination of the termination of the Ancon sin Salida of Sarmiento, by Captain Skyring, no communication was detected.

OF THE TIDES in the JEROME and INTERIOR WATERS.—The tide was found to set through the Jerome Channel with great regularity, six hours each way. The Spanish account, however, says, "The current is always in the direction of the channel, but rarely sets to the N. W., particularly in mid-channel and the western shore; on the opposite side, however, the tide sets six hours each way, to the N. W. and S. E."

The following observations were made by Captain Fitz Roy for the time of high water at full and change, at various parts of the Jerome and its interior waters, viz: in the entrance of the Jerome, near Arauz Bay, at 1 o'clock; near Bending Cove, at 3 o'clock; at Cutter Cove, at 4 o'clock; on the south shore of Fanny Bay, at Gidley Island, as also at Martin Point, at 5 o'clock; at Inglefield Island at 4 o'clock; and at the same hour at the eastern entrance of Fitz Roy Channel; but at the western end of it at 1h. 15m. The variation of the compass was found to be, at the

The mean of which will be  $23^{\circ} 49'$ .

The portion of the strait comprised between the western extremity of Ulloa Peninsula and the entrance of the Jerome is called Crooked Reach. In the navigation of this part Wallis and Carteret suffered extreme anxiety; and no one that has read their journals would willingly run the risk of anchoring in any port or bay on its southern shore. The chart will show several inlets deep enough to induce any navigator to trust to them; and, probably, for small vessels, many sheltered nooks might be found, but they have all very deep water, and when the wind blows strong down Crooked Long Reach, they are exposed to a heavy sea and furious wind. The anchorage of Lorja Bay, within the Ortiz Islands, (the Island Bay of Byron,) is so much preferable, that it alone is to be recommended. Both Captain Stokes and Captain Fitz Roy speak highly of it in their journals: it is snug and well sheltered, and tolerably easy of access, but in a gale, like its neighbors, the anchorage is much incommoded by the willi-waws, which "drive the ship from one side to the other, as if she were a light chip upon the water." Captain Fitz Roy says, "let me recommend Borja Bay as an excellent, although small, anchorage: wood and water are plentiful; under the coarse upper sand is a stiff clay, like pipe clay. Avoid the islet off its west side, as you go in or out."

As this is an anchorage that may be much used, Captain Stokes' account of it is also subjoined:

"BORJA BAY is situated on the northern shore of Crooked Reach, two miles to the eastward of Cape Quod. Its position is pointed out as well by the islet off its west point, as by its situation with respect to El Morrion, the helmet-shaped point previously called by the English, St. David's Head. The entrance to the bay is to the eastward of the largest islet, and presents no dangers; all the islets and shores of the bay may be approached to half a cable's length, even to the edge of the kelp. The only difficulty that impedes getting into the bay, arises from the baffling winds and violent gusts that occasionally come off the mountains and down the deep ravines which form the surrounding coast, and the utmost vigilance must be exercised in beating in under sail to guard against their effects. The anchorage is perfectly sheltered from the prevailing winds, the westerly and south-westerly gales, and is open only to south-easterly winds, which very rarely blow here, and still more rarely with violence; and as the holding ground is good (small stones and sand) and the depth of water moderate (14 to 16 fathoms) and any fetch of sea prevented by the narrowness of the strait in this part, the greatest breadth being only three miles, it may be pronounced a very good and secure harbor. The best plan is to anchor with the bow, and steadied to the shore by a hawser or a kedge. No surf or swell obstructs landing any where: good water and plenty of wood are easy to be embarked: the trees, a species of beech, are of a considerable size. The shores are rocky, and the beach plentifully stocked—as indeed are all parts of the strait to the eastward—with barberries and wild celery.

Byron anchored in Borja Bay, as did also Carteret, in the Swallow. The former gives a plan of it, and calls it Island Bay. He attempted to anchor in it, but was prevented by the strength of the tide.

Captain Stokes describes the Morrion, or St. David's Head, to be a lofty granitic rock, of which the outer face is perpendicular and bare, and of a light grey color, distinguishable from a considerable distance both from the east and the north-west, and forming an excellent leading mark to assure the navigator of his position.

Narborough thus describes Cape Quod: "It is a steep up cape, of a rocky greyish face, and of a good height before one comes to it: it shows like a great building of a castle: it points off with a race from the other mountains, so much into the channel of the strait, that it makes shutting in against the south land, and maketh an elbow in the strait."\*

Abreast of Cape Quod, captain Stokes tried and found the current setting to the eastward at  $1\frac{1}{2}$  knot an hour.

Between Borja Bay and Cape Quod are two coves, too small to be of any use when Borja Bay is so much superior.

Snowy Sound, a deep inlet, unimportant to the navigator, and not worth any person's while to enter, excepting for anchorage in a cove at about a mile, and in another at two miles, within its western head. It extends in for 10 miles and terminates in two inlets, surrounded by high, perpendicular, black rocks. Snowy Sound was formerly considered to be a channel communicating with Whale Sound, and insulating Ulloa Peninsula; but this is disproved by captain Fitz Roy's careful examination of it.

The following descriptions of the bays between Cape Quod and Cape Notch, are taken principally from the appendix to Cordova's Voyage to the Strait.

BARCELO BAY, the first to the west of Cape Quod, seems to be large and commodious, and strewed with small islets.

OSORNO BAY follows, and, according to Cordova, has very deep water all over; there being 40 fathoms within a cable's length of the beach, excepting on the west side, where there is a rocky ledge with from 10 to 20 fathoms.

Next, to the westward, is LANGARA BAY. It trends in for about a mile to the north-east, and has 10 to 12 fathoms, stony bottom. It is more sheltered than the two former bays.

POSADAS BAY is, most probably, Wallis' Lion Cove. Its western point is formed by a high, rounded, and precipitous headland, resembling, in captain Wallis' idea, a lion's head; and although Cordova could not discover the likeness, yet it is sufficiently descriptive to point out the bay, were the anchorage worth occupying, which it is not. Wallis describes it to have deep water close to the shore; his ship was anchored in 40 fathoms.

ARCE BAY.—Cordova describes it to have anchorage in from 6 to 17 fathoms, stones. It divides at the bottom into two arms, each being half a mile deep. The outer points bear from each other W. N. W. and E. S. E. half a mile across.

FLORES BAY is, probably, Wallis' Good Luck Bay, Cordova describes it to be

very small and exposed, with from 6 to 20 fathoms, stones and gravel. At the bottom is a rivulet of very good water.

VILLENA COVE has from 15 to 20 fathoms, and is very open and exposed.

Then follows GUIRIOR BAY.—It is large, and open to the south, and probably affords good anchorage in coves. Cordova describes it to extend for more than a league to the north, the mouth being 2 miles wide. Its west point is Cape Notch, which will serve to recognize it. Near the entrance is an island and several rocks; and within them, on the west side, are 2 coves, with from 15 to 30 fathoms, stones. Beyond them is the port, which has a narrow entrance. A river falls from a considerable height into it, and by the rapidity of the current has formed a channel of ooze in the direction of the entrance, in which there is good anchorage in from 20 to 26 fathoms: on either side of the channel the bottom is stony. The port is too difficult to reach to make it an object of any value. Should, however, a strong gale from south or south-west oblige a ship to run in, she should avoid passing too near the west side of the narrow; for a reef extends off it for nearly a cable's length. There is also a bank outside the narrow, but it is pointed out by kelp.

From the above description of the bays between Capes Quod and Notch, occupying a space of  $12\frac{1}{2}$  miles, and from the view we had of them in passing, none seem to be convenient, or very safe. The best port for shelter for a ship, is Swallow Harbor, on the opposite shore: but small vessels may find many places, that a ship dare not approach, where every convenience may be had; for if the water be too deep for anchorage, they may be secured to the shore at the bottom of the coves, where neither the swell nor the wind can reach them.

SWALLOW HARBOR is  $1\frac{1}{4}$  mile to the westward of Snowy Sound. It is a better anchorage for ships than any in the neighborhood. The plan of it is a sufficient guide, the dangers being well buoyed and pointed out by kelp. It was first used by captain Carteret in the Swallow; and Cordova gives a short description of it.

The anchorage is under the east side of the island which separates the harbor from Cordova's Condesa Bay, and which forms its westside. Wallis describes the harbor to be "sheltered from all winds, and excellent in every respect. There are two channels into it which are both narrow, but not dangerous, as the rocks are easily discovered by the weeds that grow upon them." Cordova's account of it runs thus—"To the westward of Snowy Sound are two bays formed in a bight by an island. The eastern, Swallow Harbor, has in its mouth three islands and a rock; besides strewn with kelp, which serves to point out the dangers in entering. Within, it is very well sheltered from all winds. The depth is from 40 to 16 fathoms, stones, and in some parts ooze. This bay is to the south of Cape Notch; and to recognize it, there is a cascade falling down the centre of a mountain at the bottom of the port, to the westward of which are 2 higher mountains; the summit of the eastern being peaked, and the western one rounded.

The bay, to the westward of the island, is Condesa Bay. It is full of islets and rocks, and the channel behind the island, communicating with Swallow Bay, is very narrow."

At about a cable's length off the west point of the entrance of Swallow Harbor, captain Fitz Roy saw a rock just awash. This danger should be carefully avoided.

STEWART'S BAY is less than a league from Swallow Bay. Of this place Capt. Stokes makes the following remarks:—"Stewart's Bay afforded us a quiet resting place for the night, but it is by no means to be recommended as an anchorage; for though it is sufficiently sheltered from wind and sea, yet the rocks, in different parts of it, render the passage in or out very hazardous: every danger in it is pointed out by rock weed, but it is so much straitened as to require the utmost vigilance. A plan of it was made and connected with the coast by bearings and angles to Cape Notch, and to other fixed points. The description of the place by Cordova cannot be improved."

The account in Cordova is as follows:—

"Stewart Bay, (La Bahia de Stuardo,) follows Condesa Bay. It has an island besides several patches of kelp, an indication of the many rocks that exist. Even the best channel is narrow and tortuous; the depth from 12 to 16 fathoms, stones. At the bottom is an islet, forming two narrow channels leading into a port or basin, 2 cables' length wide: the eastern channel is the deeper and has 15 to 20 fathoms. Inside the basin, and on the east side, the depth is 6 and 9 fathoms, mud. A reef extends for half a cable's length to the westward of the south end of the islet. It would be difficult and dangerous to enter this small basin."

Then follows a deep and extensive channel, of which we know only that it extends to the south for 5 or 6 miles, and perhaps, is very similar, in its termination, to Snowy Sound. It is Sarmiento's Snowy Channel. (Ensenada de Mucha Nieve.)

At this part of the strait, the breadth is about  $2\frac{1}{2}$  miles; but, at Cape Quod it scarcely exceeds  $1\frac{1}{4}$  mile. The shores are certainly much less verdant than to the eastward of Cape Quod; but not so dismal as Cordova's account would make them appear to be;

for, he says: "As soon as Cape Quod is passed, the strait assumes the most horrible appearance, (con el aspecto mas horrible,) having high mountains on both sides, separated by ravines entirely destitute of trees, from the mid-height upwards." To us it appeared that the hills were certainly much more bare of vegetation above, but below were not deficient; the trees and shrubs, however, are of small size. For the purposes of fuel abundance of wood is to be obtained. In the winter months the hills are covered with snow, from the summit to the base; but in the month of April, when the Adventure passed through, no snow was visible about them.

Captain Stokes remarks, that the mountains in this part, (Cape Notch,) spire up into peaks of great height, connected by singularly sharp saw-like ridges, and are of vegetation as if they had been rendered so by the hand of art. About their bases there are generally some green patches of jungle, but upon the whole nothing can be more sterile and repulsive than this portion of the strait. This account of Captain Stokes agrees with Cordova's; but upon examining the coves, we found them so thickly wooded with shrubs and jungle, and small trees, that it was difficult to penetrate beyond a few yards from the beach.

CAPE NOTCH is a projecting point of grey colored rock, about 650 feet high, having a deep cleft in its summit. It is a conspicuous headland, and cannot be mistaken.

The next place to the westward of Cape Notch, that can be recommended for an anchorage, is Playa Parda Cove, which is well sheltered, and, for chain cables, has a good bottom, being of sandy mud, strewed with stones; it is half a mile wide at the entrance, and about a quarter deep. Round the west side of Middle-point is a channel, a quarter of a mile long and 150 yards wide, with 6 and 7 fathoms water, communicating with a very excellent little harbor for a small vessel, of about a quarter of a mile in diameter.

Playa Parda Cove is easily known by Shelter Island, that fronts the inlet of Playa Parda. The inlet is  $1\frac{1}{2}$  mile long, and half a mile broad, but with very deep water all over. By luffing round the island, a ship will fetch the anchorage in the cove; and, although sail should not be reduced too soon, yet the squalls, if the weather be bad, blow down the inlet of Playa Parda with great violence. Anchor a little within, and half way between the points of entrance, at about  $1\frac{1}{2}$  cable from the middle point, in  $5\frac{1}{2}$  and 6 fathoms.

Of Glacier Bay, remarkable for a glacier at the bottom, and of another bay to the eastward of it, we know nothing: the former may possess good shelter and, perhaps, anchorage; but the latter is too full of islands to be recommended. Between Glacier Bay and Playa Parda, the shore is bold but straight, excepting a small cove about 2 miles from Playa Parda, which seemed likely to afford shelter for small vessels. Off the west inner point is a reef, but within it there seemed to be a basin half a mile deep. Eye sketches of these three indentations were made as we passed by.

To the westward of Snowy Channel are several inlets affording, apparently, good shelter, but those we examined were found to have very deep water.

Opposite to Playa Parda is a deep opening which has more the appearance of a channel leading through the Tierra del Fuego, than any opening to the west of the Barbara. It is evidently the inlet noticed by Sarmiento, and thus described by him:—"a great bay (Ensenada) which trends into the land in a W. S. W. direction for more than 2 leagues, and has an island at its mouth;—we called it the Abra (opening,) because we did not see its termination. On the opposite shore there is another port and grey beach (Puerto Playa Parda,) which has an island that shelters it. Within the Abra the land is low and hummocky;—half a league beyond (i. e. to the eastward of) the Abra is a cove; and on the opposite shore, a league across, is another cove which forms a port, which the Indians call Pelepelgua, and the cove they call Exequil." The cove Pelepelgua, may probably be Glacier Bay, and Exequil must of course be one of the coves to the eastward of the Abra.

To us, the opening or Abra seemed to be one mile and a half wide, with an island in the entrance. Within, it appeared to take, first, a south, then a S. W. course, and afterwards to trend round a projecting, low, hummocky point of the east shore, and wind under the base of a high precipitous ridge on the opposite or west shore, towards the S. E. beyond which its course could not be observed.

On the seaward coast there is a deep opening behind Otway Bay, which, probably, may communicate with it.

The weather here is generally so thick, that, although the distance across be only two to three miles, yet one shore is frequently concealed from the other, by the mist; on which account Captain Stokes found it impossible to form any plan of this part of the strait, on his passage through it. Captain Stokes, in leaving Stewart's Bay, says, "we continued our progress to the westward, having westerly and S. W. winds, with thick weather and drizzling rain. The coasts on both sides were very rarely visible to us, by reason of the thick mist by which they were capped. It is, however, a bold coast on

each side, otherwise the strait would be utterly unnavigable in such weather." MARIAN'S COVE, one mile and a half to the west of Playa Parda, is a convenient anchorage; at the entrance it is about one third of a mile wide, and more than half a mile deep; a plan was made of it, which will be a sufficient guide. Captain Stokes, observes, that it affords shelter from the prevailing winds; the anchorage is 22 fathoms, good holding ground; but less water may be obtained, if required, there being 8 fathoms within sixty yards of the beach, at the bottom of the bay. In entering, the west side should be kept aboard.

This cove is about midway between Cape l'Etoile and Playa Parda; and is a very advantageous place to stop at.

Opposite to Cape l'Etoile, is a bay with anchorage in 17 fathoms, in a well sheltered situation. From Cape l'Etoile to the entrance of the Gulf of Xaultegua, the shore is strait and precipitous, and the hills are barren and rocky. On the opposite shore there are a few inlets, but the most useful one for the navigator is Half Port Bay, rather more than a league to the east of Cape Monday. It is immediately round the south side of a deep inlet. It is merely a slight indentation of the coast.

The Beagle anchored here on two or three occasions, and found it to be an excellent stopping place; the anchorage is within two thirds of a cable's length of the west point, in 16 fathoms, muddy bottom. The situation of this cove was ascertained by observation to be in lat.  $53^{\circ} 11' 36''$ , and long.  $73^{\circ} 14' 57''$  W. (or  $2^{\circ} 20' 56''$  west of Port Famine.) There is a plan of this bay.

"The land on the S. W. side of the anchorage is high, and thickly wooded from its summit to the water's edge. On the eastern side it is lower, the vegetation more scanty and the trees crooked and stunted, and pressed down to the N. E. by the prevailing winds, S. W. by W. from the anchorage, is a remarkable cleft in the summit of the highland, from which a narrow stripe cleared of jungle descends to the water's edge, apparently formed by the descent of a torrent or of large masses of the rock.\* The anchorage is well sheltered from prevailing breezes, and the holding ground is good: water and fuel are abundant."—Stokes' MSS.

There is an anchorage under Cape Monday for small vessels, in which Byron anchored, and rode out a heavy gale of wind. With the exception of a shoal in midway of the entrance, on which there are 4 fathoms, it seems to offer good shelter from the prevailing winds. On the west side of Cape Monday is Cordova's Medal Bay (Puerto de la Medalla), of which a very full but florid description is given in the appendix of that voyage.

It has, according to the description, an island in the entrance which forms 2 channels, the easternmost of which is only deep enough for boats, but the western is 25 fathoms wide; it is strewed half way across with kelp; but between the kelp and the island is a good and clear passage with 6 fathoms, sandy bottom. In the kelp there is not less than 4 fathoms, and inside it the depth is 9, 8, and 7 fathoms, sandy bottom. To enter this port, there are no dangers that are not visible, and those are easily avoided; they consist only of the islet in its entrance, and some patches of kelp, over which, however, there is plenty of water.

The Gulf of Xaultegua, improperly called Bulkeley's Channel, is a deep opening, trending into the land in an easterly direction for 28 miles, and approaching within two miles of some of the inlets on the north-west side of Indian Sound. The entrance is about four miles across, but afterwards expands to a width of nearly 15 miles. At the entrance is St. Ann's Island, between which and the south point, is a navigable channel, half a mile wide. St. Ann's Island is about two miles long, and extends in a W. N. W. and E. S. E. direction; off its N. W. end is an islet, and there is another close to its S. W. extremity.

The land forming the north side of the strait, between the Gulf of Xaultegua and the Jerome Channel, is called Croker Peninsula.

The plan that was made of the gulf is little more than a sketch. Captain Fitz Roy, who passed through it in a boat, and examined it to its termination, says: "if ever an accurate survey be made of the gulf, it must be when all other gulfs in the world have been examined, for it is utterly useless; and from the appearance of its shores I do not think there is any anchorage in it. Therefore, should a ship be so unfortunate as to make a mistake and get into it, she must keep under weigh until she gets out again. There is no thoroughfare."—Fitz Roy's Journal.

Little has been said of the tides in this part of the strait, and, indeed, as to their rise and fall, they are really of no importance, being little more than 4 feet. It is high water

\* More probably by the effect of a gust of wind, which, to the eastward, particularly in the Gabriel Channel, is very common

† The name Xaultegua is from Sarmiento, who very correctly describes it.

at full and change in all parts within a few minutes of noon. The current sets constantly to the eastward with more or less strength.

Between Capes Notch and Quod, the current set us two miles to the eastward in 3½ hours; and from Cape Quod to Port Gallant, we found the current had favored us 6 miles in 3½ hours. The ebb tide sets to the eastward.

*Strait of Magalhaens—Sea Reach, including Capes Victory, and Pillar, and the Evangelists.*

Between Elizabeth Island and the western end of Long Reach, there is very little swell. In heavy gale, or, perhaps, even a strong breeze, a short sea may be experienced in the latter part of the strait, particularly near, and to the westward of Cape Froward; but nothing to be compared to the confused, breaking swell, that runs in the sea, or Western Reach. It was felt by the Beagle when beating to the westward, immediately on reaching Cape Providence. There seems to be no danger for vessels beating through the strait hereabouts, the shore being bold to. Byron passed a night, and a very tempestuous one, here; as did also the Beagle, the latter not being able to find anchorage before night. Captain Stokes upon this occasion, writes:—"We continued beating to windward, the wind squally and weather rainy. The coast on both sides is bold. Our boards were directed during the night, which was very dark, by the sight of Cape Upright when on one shore, and of Cape Providence when on the other. We commenced tacked at the distance of a mile from either shore."

A league to the westward of Cape Monday is an inlet, which we suppose to be Sarmiento's Puerto Angosto. Upon its west head is a conspicuous round mount, and to the north, between the mount and a projecting point, is a confined but very snug and commodious cove for a small vessel, in 17 fathoms, at a quarter of a mile within the head.

In consulting the appendix to Cordova's voyage, it would seem that this projection is an island, insulated by the inlet here, called Puerto Angosto. The description runs thus:—"A bay formed in the Tierra del Fuego, between Cape San Ildefonso, (Upright,) and an island in the eastern part of its mouth. The figure of the island is triangular, and its N. E. point lies in the line of bearing of Capes Lunes, (Monday,) and San Ildefonso, (Upright.) At the east end of the island is an inlet running to the south-west, 1½ mile wide, and a league long, to the bottom of the bay; the S. E. side of the island being 1½ mile long. To the westward, the distance between the shore and the island is much more, and the direction of the second channel is N. ¼ W. The bay, whose greatest breadth is two leagues, has at its bottom, and towards the S. E. part, the mouth of an inlet, the course of which disappears behind the mountains, in a S. ¼ E. direction. There appeared to be a good anchorage between the island and the eastern shore, but we had no bottom with 30 fathoms."

There seems to be no doubt that the island above described is the projecting point 4 miles to the west of Cape Monday, and that Sarmiento's Puerto Angosto insulates it; but the Spanish chart is so vague, and our own so imperfect in its part, that I prefer leaving it to future examination, rather than invent an island; although, from the Spanish account, there seems no reason to doubt its existence.

Of Upright Bay we know little. The Adelaide rode out a gale from the eastward with her stern in the surf of the beach, and the Beagle anchored under the east side of the cape, at about half a mile S. W. of the rocky islet, and for shelter from westerly winds, found it to be very good. Of this captain Stokes says:—"We anchored at cable's length off a small patch of light-colored shingle beach, situated at the west side of the bay, in 22 fathoms, sandy bottom. The anchorage, though affording excellent shelter from the prevailing winds, is bad with a southerly one; for the steepness of the bottom requiring a vessel to anchor close to the shore, sufficient scope is not left for veering cable. There is a plan of the bay in Hawkesworth from Byron's account, who anchored in the southern part of the bay, perhaps under the lee of the islands to the S. E. of the cape."

CAPE UPRIGHT bears due south 5 miles from Cape Providence. It has a rocky islet a quarter of a mile off its east extremity, surrounded by kelp, which also extends for some distance from the cape towards the islet, at the end of which there are 7 fathoms.\*

CAPE PROVIDENCE is a rugged rocky mountain, higher than the adjacent coast; it is deeply cleft at the top, and, when bearing about north, the western portion of its summit appears arched, the eastern lower and peaked. When the cape bears E. by S.

mag. distant about  $1\frac{1}{2}$  league, a little round rocky islet will be seen open of it, about one quarter of a point of the compass more southerly."—Stokes' MSS.

There are some anchorages on the right, to the N. E. of Cape Providence, according to a plan given in Hawkesworth's Collection of Voyages, but they are too much out of the way, as well as very open and exposed to southerly winds, to be of use, or to offer any security to vessels bound through the strait.

The distance from Cape Providence to Cape Tamar, is  $9\frac{1}{2}$  miles; in this space the land arches inwards, and forms a bay about a league and a half deep. Captain Stokes describes the coast to the east of Cape Tamar to be formed into two large bights by the land of Cape Providence. On the western side of the latter are several islands, of which two are conspicuous; they are round and of a good height, and well wooded; at a distance their form is conical, the eastern being the lowest. Between them is a passage to two good anchorages, which Lieutenant Skyring, who examined them, considered even more sheltered than Tamar Harbor.

Four miles to the eastward of Cape Tamar is Round Island, to the N. W. of which is a well sheltered anchorage, but with deep water. In standing in, pass midway between Round Island and an island to the westward, which lies close to the shore, and haul round the latter to the mouth of a cove, in the entrance of which, near the south shore, there are 23 fathoms, sand. The shore to the N. and N. E. of Round Island, is very rocky. On the east side of the promontory of Cape Tamar, is the useful and excellent anchorage of Tamar Harbor. It is scarcely 2 miles wide, and rather more than half a mile deep. Its entrance is not exactly free from danger, but with attention to the following directions, none need be apprehended. There is a sunken rock between a group of rocky islets, one third over on the western side, and a patch of kelp, one third towards the eastern side of the bay. With a westerly wind it would be advisable to give the outer rock a berth of 2 cables' length to avoid this danger, on which there are only 9 feet of water, and upon which the Beagle struck.

"An excellent leading-mark for this shoal, is a whitened portion of bare rock, looking like a tombstone, about one third of the way up the green side of the mountainous land that forms the coast of the bay. This stone bears N.  $76^{\circ}$  W., (by compass,) from the rocks to be rounded on entering the anchorage."

The least water found among the kelp on the east side of the channel was  $4\frac{1}{2}$  fathoms, and near and within the edge towards the rocky islets, there are 7 fathoms; so that with the lead in hand, and a look out for kelp, which should not unnecessarily be entered, there is no real danger to be apprehended. The Beagle anchored at about one third of a mile from the back of the bay. The plan will show what is further necessary to be known of the anchorage.

High water at full and change takes place in Tamar Harbor at 3h. 5m, and the perpendicular rise and fall is 5 feet.

The flood tide on this part of the northern shore of the strait sets to the eastward, and rarely exceeds half a mile an hour. At this part the strait is 7 miles wide: at Cape Phillip, to the westward the breadth increases to 5 leagues; but at Cape Parker it narrows again 4 leagues, which breadth it keeps to the end.

To the westward of Cape Tamar is Tamar Island. It is high, and is separated from the land of the cape by a deep channel from half to one mile wide. Half a mile off its S. W. end is a rock.

Between Capes Tamar and Phillip, a space of 4 leagues, there is a deep bight, with two openings; the easternmost, in which are Glacier and Icy Sounds, extends to the N. E. for 10 miles from the mouth, and the westernmost is the commencement of Smyth's Channel. The rocks, called the Stragglers, extend to a considerable distance to the S. W. as far as 3 miles within the line of bearing between Cape Phillip and Tamar Island.

Under the lee, (the N. E.) of Cape Phillip is Sholl's Bay, in which the Beagle anchored in 1827. Of this place Captain Stokes writes:—"We found there an excellent anchorage in 15 fathoms. It is valuable for vessels working through the strait to the westward, inasmuch as, from the discontinuous nature of the northern shore, (which here is formed into deep bays,) this place will be much more easily recognized than the anchorages on the opposite coast; besides the winds hang here, in general, somewhat to the northward of west, hence a better starting-place for the westward is obtained. Here, as in every anchorage on the strait, water and fuel are easily procured; but nothing more, unless we except the wild berries, (Berberis, sp.) celery, mussels, and limpets; the wild goose abounds here, but its nauseous, filthy taste renders it uneatable. No inhabitants, no quadrupeds."

Of the coast of the strait on the south side, between Cape Upright and Valentine Bay, we know very little; there are several deep bights and spacious harbors, which may contain anchorage, but, in general, they are not found in the large harbors, which are mostly deep, precipitous chasms or ravines in the rock. The smaller coves, or where the land shelves down to the sea, are more likely to afford anchorages.

In the appendix to Cordova's work are descriptions of some anchorages, which it may be useful to mention here: it says, "In rounding Cape (Hdefonso.) Upright we found ourselves in a bay, not very deep, 2 miles across, divided in its centre by many islets and rocks extending to the north; the outer or northernmost of which bears W. from the extremity of the cape. One mile N. W.  $\frac{1}{2}$  N. from the northernmost islet is a round rock, which is of dangerous approach."

To the westward of this bay is another, 3 miles wide, and about as deep; the whole of it, particularly towards the eastern part, is full of islets, and at the bottom is a narrow canal trending to the S. S. E. At the western end of this bay, called by Walla the Bay of Islands, from the number it contained, commences a third, which, with the two preceding, make the great bay, called by the Indians, according to Sarmiento, Aiquilqua. It is contained between Cape Upright and a bold projecting point, 10 miles to the W. N. W., called Point Echenique. The country is there described to be poor, and the vegetation scanty.

The eastern point of the Third Bay has a string of islets extending a mile to the north, and to the south-west are several others. And on its east side is a bay called Cuaquilqua; and a little beyond it, at the bottom of the bay, is Port Uriarte, the mouth of which is 2 cables' length across.

PORT URIARTE was carefully sounded, but the bottom is generally bad and stony, with 5, 8, 14, to 18 fathoms. The harbor is surrounded by high mountains, rising vertically, and with only a few stunted trees on the shores. Its greatest extent, which is from north to south, is half a mile; the mouth is not visible until close to it: its bearing from Cape Providence is S. 42° 30' W. There is no danger in entering it but what is visible; but it is not recommended as a good harbor, from the foul ground all over it. A little to the eastward also, of Point Echenique, is Cape Santa Casilda—a low point.

To the west of Point Echenique is a harbor  $2\frac{1}{2}$  miles wide, the points of entrance being N. W. and S. E. There is an island in the centre forming two channels, but with very deep water, no ground being found with 55 fathoms. At the bottom is a canal trending to the S. S. W. and disappearing between the mountains. On the eastern side of the island the channel is at first a mile wide, but afterwards narrows gradually; the western channel is scarcely two cables' length across. The shores are high precipitous mountains. The Indians, according to Sarmiento, call the place Puciacalagua.

THE CANAL DE LA TEMPESTAD, (or Stormy Channel,) from the description is not to be recommended. The water is very deep all over, and the place affords no security for vessels of any description. To the westward is a better harbor, which the Spanish officers thought to be Sarmiento's Port Santa Monica. It bears S. S. W. from Cape Tamar, and it is 14 miles to the westward of Cape Upright, but not more than 3 leagues according to Sarmiento's account.

Two thirds of a mile to the westward, is a point with two islets off it, round which is Port Churruca, a deep and spacious bay, two miles wide, the points bearing E. S. E. and W. N. W. containing two ports and some coves, but with very deep water, and therefore useless, for it would be necessary to make fast to the rocks to secure a vessel.

To the westward of this we have laid down a useful cove, Darby Cove, in which small vessels may obtain good shelter.

From Darby Cove the coast extends to the N. 65° W. for 7 miles, having in the interval several indentations, but all with deep water; at Point Felix the land trends deeply in to the south-west, and forms a bay 5 miles wide and  $2\frac{1}{2}$  deep. At its western side is Valentine Harbor, in which the Beagle anchored, of which there is no written description in captain Stokes' Journal: the plan, however, will show the nature of the anchorage, which seems to be commodious and secure, and of easy approach. On hauling round the island, there are some islets half a mile off, which must be avoided, but otherwise there seems to be no dangers.

The anchorage, as a stopping place, is in from 20 to 26 fathoms, sand, at nearly a quarter of a mile from either shore. A more sheltered situation may be obtained to the south-west.

The latitude of the mount (marked in the plan) is 52° 55' 5", and long. 74° 15'. Variation of the compass 24° 10'.

CAPE CUEVAS, the extremity of an island that is close to the shore, is in latitude 52° 53' 19", and long. 74° 17' 30". Between it and Cape Valentine the coast forms a bay with islands in it. To the westward, also, of the cape, the coast is broken, and forms some sinuosities. A league N. W.  $\frac{1}{2}$  W. from Cape Cuevas, is the east part of Truxillo Bay, which was not examined.

The Spanish account describes it to be  $1\frac{3}{4}$  mile wide, in the direction of N. W. and S. E., and half a mile deep. At the bottom there is a port with an entrance half a mile across, bearing nearly N. and S. It is a well sheltered port, trending W. S. W. for  $1\frac{1}{2}$  mile, with two small basins at the bottom. The depth is very great, but close to the

west shore there are is great, and generally none was there less.

There is plenty of reference to Tuesday situated three quarters of a fathom. Tuesday ship perhaps might.

On the north side a remarkable projection over it. To the eastern head of which several islands in the ing to the north.

On the west side approach is not clear, seems to afford with two rocky islets.

The land of Cape it commences a range never be approached island is Westminster spicuous points, such The Beagle ran in a of ascertaining its position.

SIR JOHN NAR and perhaps, hundred amongst them are seen on the south coast to access.

It is a dangerous sea breaches very high frequently in amongst.

A league to the west is one mile and a quarter W. for one mile and S. E., with 10 fathoms gained in 27 fathoms.

At  $3\frac{1}{2}$  miles from the OF MERCY, (Pue and Carteret,) one only 4 miles within await a favorable opportunity there is no danger holding ground except one off the first light convenient for many purposes.

The observations of Islets, the summit of The variation is 23°.

Three miles to the which Capt. Stokes had difficulty, owing to the he observed the latitude 1829, with his instrument was so great that The extremity of the Victory in 52° 16' 10' the strait.

"THE EVANGEL the Isles of Direction western mouth of the and some detached rocks invited only to afford a landing on one of the and highest may be seen.

west shore there are 8, 10, to 13 fathoms, on sand and coral. Near the mouth the depth is great, and generally of stones. There are several banks buoyed by sea weed, but in none was there less than 7 fathoms water.

There is plenty of wood and water in Truxillo Bay, but nobody will visit it in preference to Tuesday Bay, or, rather, the more convenient anchorage of Tuesday Cove, situated three quarters of a mile south of Cape Cortado. The anchorage is in 12 to 14 fathoms. Tuesday Bay is larger, and therefore more exposed to the squalls, but for a ship perhaps might be more convenient.

On the north shore of the strait, opposite to Cape Cortado, is Cape Parker, a remarkable projection, with three hummocks on the summit of the high land which rises over it. To the eastward the coast trends deeply in to the north, forming a bay, the eastern head of which, Cape Phillip, bears S. 97° E. 9 miles. There appeared to be several islands in the bay, and at the bottom a narrow opening, perhaps a channel, leading to the north.

On the west side of the bay the coast is indented and affords some anchorages, but the approach is not clear. The first bay, however, to the eastward of the S. E. trend of the cape seems to afford a good stopping place; but it is fronted by a considerable shoal, with two rocky islets. The depth is from 7 to 22 fathoms.

The land of Cape Parker will probably turn out to be an island. To the westward of it commences a range of islands, rocks and shoals, fronting a broken coast that should never be approached but for the purpose of discovery or seal fishery. The easternmost island is Westminster Hall, a high rocky island, and there are two or three other conspicuous points, such as the Cupola and Observation Mount, that might be noticed. The Beagle ran in amongst the breakers, and anchored near the latter, for the purpose of ascertaining its position, and obtaining bearings for the survey.

SIR JOHN NARBOROUGH'S ISLANDS consist of 8 or 10 principal islands, and perhaps, hundreds of smaller ones. Behind them there seemed to be a channel, and amongst them are several anchorages, but none to be recommended, especially when on the south coast there are two or three much better, much safer, and of much easier access.

It is a dangerous coast, as well from the immense number of rocks upon which the sea breaches very high, as from the tides, which near the edge of the line of shoals set frequently in amongst them.

A league to the westward of Cape Cortado, is SKYRING HARBOR. Its entrance is one mile and a quarter wide, and afterwards half a mile, and trends to the S. W. by W. for one mile and a half, and then terminates in a cove extending half a mile to the S. E., with 10 fathoms in it. There are some islands in it, and anchorage might be obtained in 27 fathoms.

At 3½ miles from the west point of Skyring Harbor is the east head of the HARBOR OF MERCY, (Puerto de la Misericordia of Sarmiento, Separation Harbor of Wallis and Carteret) one of the best anchorages of the western part of the strait, and being only 4 miles within Cape Pillar, is very conveniently placed for a ship to anchor at to await a favorable opportunity for leaving the strait. The plan will be a sufficient guide; for there is no danger in entering. The depth is moderate, 12 to 14 fathoms, and the holding ground excellent, being a black clay. A ship may select her position; but the one off the first bight round the point being equally well sheltered, and much more convenient for many purposes, is the best berth.

The observations for latitude and longitude were made upon the largest of Observation Islets, the summit of which was found to be in lat. 52° 44' 57", and long. 74° 35' 31". The variation is 23° 48'.

Three miles to the westward of the largest Observation Islet, is Cape Pillar, upon which Capt. Stokes landed, on the 25th of February, 1827, but not without considerable difficulty, owing to the great swell that then, and indeed always, prevails near it. Here he observed the latitude. Captain Fitz Roy also landed in a cove under the cape in 1829, with his instruments, to obtain bearings from its summit; but the difficulty of the ascent was so great that he did not risk the destruction of them.

The extremity of Cape Pillar is in lat. 52° 42' 53", and long. 74° 39' 31", and Cape Victory in 52° 16' 10", and 74° 50' 55". These points form the western entrance of the strait.

THE EVANGELISTS, as they were named by the early Spanish navigators, but the Isles of Direction by Narborough, from their forming a capital leading mark for the western mouth of the strait, are a group of rocky islets, consisting of four principal ones, and some detached rocks and breakers. The islands are very rugged and barren, and suited only to afford a resting place or breeding haunt of seals and oceanic birds. There is landing on one of the islands, and anchorage round them, if necessary. The largest and highest may be seen in tolerably clear weather, from a brig's deck, at the distance of

7 or 8 leagues.\* The southernmost, from its shape called the Sugar Loaf, is in lat.  $52^{\circ} 24' 18''$ , and long.  $75^{\circ} 02' 56''$ . From the Sugar Loaf the extremity of Cape Pillar bears N.  $33^{\circ}$  W., 23 $\frac{1}{2}$  miles, and from Cape Victory, according to Capt. Stokes' survey, S.  $42^{\circ}$  W. 11 miles.—[Stokes' MSS.]

The tides here are very variable, and sometimes set to the E. N. E. towards the rocks that front Cape Victory and Sir John Narborough's Islands.

*Of the Sea, or outer Coast of Tierra del Fuego, from Cape Pillar to Cape Diego, in Strait Le Maire, by Captain Robert Fitz Roy, R. N.*

[In this section, references (printed in Italics) are made to a work published by Captain Fitz Roy, entitled "Views of the Coast, taken on board his Majesty's surveying vessel, Beagle, 1829 and 1830."]

The western entrance to the Strait of Magalhaens is easily known by the wide opening between Sir John Narborough's Islands and Cape Pillar. The Evangelists show themselves distinctly at 6 miles distance. They are four barren rocks, about 100 feet above the sea.

On the north side of the strait, near Cape Victory, is a remarkable height, called Diana's Peak.

WESTMINSTER HALL is remarkable, but the land about Cape Pillar cannot be mistaken, after a glance at the chart.

In making the land and approaching the strait, a ship should keep well to the northward of Cape Pillar, and should, indeed, close the Evangelists, unless the wind has southing, because there is a strong current which sets across the entrance of the strait directly towards the dangerous cluster of rocks called the Apostles and Judges. It follows the trend of the coast, and would set a ship many miles to the southward of Cape Pillar if she stood in for it without making proper allowance. It runs from 1 to 2 miles an hour, according to the winds that are or have been prevalent.

When fairly within the strait, a ship should close the southern shore. If intending to anchor, the first anchorage is the Harbor of Mercy, 4 miles from Cape Pillar. Its place is shown by five small islands, round which you pass and haul in to the anchorage.

Close to Cape Pillar are two small rocks, called the Launches. They are not more than 3 cables' length from the shore.

The cape and the shore on each side are steep to. Off the cape, at 2 miles distance, are 60 and 70 fathoms, fine sand.

Proceeding along the outer, or south-west coast, the Apostle and Judge Rocks show themselves. They are some feet, from 5 to 50, above the water, but many breakers show near them, and indicate an extensive reef. The outer rock is four miles from the land. Eleven miles from Cape Pillar is Dislocation Harbor, a place of refuge for an embayed or distressed ship, but unfit for any other purpose. Its entrance is rendered difficult, to the eye, by rocks, on which the sea breaks violently, and by two rocks under water, on which the sea does not always break, but whose place is accurately shown in the plan of the harbor. The place of Dislocation Harbor is pointed out by the heights, called Lion and Shoulder Peaks. They are the most remarkable on that part of the coast, and immediately over the harbor.

To find the entrance, steer for the peaks; look out for the weather and lee rocks, both several feet above water, the sea breaking violently on them, and when within 4 miles of the shore you will distinctly see the opening from the mast-head. In going in, avoid the two rocks at the entrance, and anchor in the innermost part. Only a small ship can get out again without a fair wind. The prevailing winds send in a swell, but the place is quite secure. Water may be obtained very easily. The boats can lie in a stream which runs from the mountains, and fill alongside. Wood is plentiful. Four small vessels may lie in security. The bottom is very even, from 15 to 25 fathoms, fine white sand.

The entrance is narrow, exposed to the prevailing wind and swell, which might, for days together, prevent a vessel from getting out to sea. Two miles from Dislocation Harbor, is Cape Deseado, the highest land hereabout, and remarkable. A rocky islet lies one mile off shore.

From Cape Deseado the coast runs high and unbroken for about two miles, then there is an opening, not examined.

Several islands succeed for a space of two miles, after which you open Barrister Bay, an exposed place, full of islets, rocks, and breakers, and unfit for any vessel.

CAPE SUNDAY is the next headland. It is high and prominent. (See No. 7.) Two islets and two dangerous rocks lie off it; they are shown in the chart.

strait, opposite Playa F

stead, with good holding in 18 or 20 fathoms, coarse gravel and sand, with patches of rock. It is exposed to southerly winds and to those from the west; therefore I should not advise a vessel to anchor there. Between the islands is a snug berth for a small vessel, quite secure, but difficult of access. The Beagle lay at anchor there one week, in 24 fathoms, good holding ground.

The eye must be the chief guide in entering most of these places. They are of one description—inlets between high land, having, generally, deep water, with kelp buoying the rocky places. Flaws of wind and violent gusts off the high land render the approach to them difficult, and, to a large ship, impracticable.

There are, however, anchorages on this coast fit for a fleet, which will be mentioned in their order.

Six miles south of the Week Islands are the Landfall Islands, (Nos. 9, 10 and 11,) so named by Capt. Cook, from seeing them first when he visited this coast.

CAPE INMAN is a very remarkable head-land at their western extremity. (See Nos. 7, 8 and 9.)

Behind the island, of which it forms the most conspicuous part, is LATITUDE BAY, an anchorage decidedly good, though somewhat exposed to a swell thrown in by heavy north-west winds.

The Beagle rode out a heavy gale from that quarter, though having anchored too far in, she was exposed to rollers. The plan shows the best anchorage, (and the sketch annexed how to find it: see No. 11.)

Between the islands is a snug berth for a vessel not drawing more than 12 feet, in perfect security, smooth water; and a vessel should not moor in less than ten fathoms, as close to the west shore as possible, with an anchor to the eastward, in the event of a wind blowing from that quarter. Water and wood are plentiful, as is the case in every Fuegian harbor.

Behind, or to the eastward of the Landfall Islands, is OTWAY BAY, an extensive space of water, surrounded by broken land, islets and rocks. Many of the latter are scattered about, and render it unfit for any vessel. It is probable that passages lead hence to the Straits of Magalhaens, as deep inlets run in that direction as far as the eye can reach, from the Landfall Islands. They were not explored for want of time.\*

Off CAPE INMAN are several detached rocks, on which the sea breaks violently, and gives them a formidable appearance. The outermost one is not two miles from the shore, and shows itself plainly.

CAPE SCHETKY is a remarkable double-peaked height, at the south extremity of the Landfall Islands. Some rocks just awash lie off it, distant one mile. The true course along shore, after giving the Apostles a proper berth, is S. 29° E. as far as the latitude of Cape Tate, (No. 12,) the southern limit of Otway Bay.

Off CAPE TATE, which is rather high, and rounded at the summit, are several clusters of rocks, called the College Rocks. They are only seen when near the land.

THE FINCHAM ISLANDS next are noticed in passing along shore. There are many islets and rocks near, and very many scattered between the islands and Cape Tate. As a reference to the chart will show, there is no good anchorage hereabout. The coast is very dangerous and unfit to be approached. The Beagle tried to anchor in Deep-water Sound, but failing to find a proper depth of water, was obliged to drop her anchor upon the shelving end of a small island, being too far up the sound to get out again before dark.

Between the Fincham Islands and Cape Gloucester, is BREAKER BAY, a large wild place, full of rocks and breakers, and exposed to all the strength of the west winds. I had neither time nor inclination to examine it, for I never saw a place more unfit for the approach of a vessel. The surrounding coast is broken into islands, islets, and rocks, almost innumerable.

CAPE GLOUCESTER is a very remarkable promontory, and cannot be mistaken. (See Nos. 13, 14, 15, 16 and 17.) At a distance it appears to be a high, detached island; but, on a nearer approach, a low neck of land is seen, which connects it with the largest of the Grafton Islands. (No. 18.) A rock (on which the sea breaks) lies nearly one mile to the north-west. There is no other danger. The cape may be passed quite close, being steep to.

Cape Gloucester is a guide to EUSTON BAY, (Nos. 19, 20 and 21,) one of the best anchorages on this coast, one which can be approached and left with any wind, without risk, and in which a fleet may lie in perfect security from all but the S. E. winds, the least prevalent of any on this coast.

\* It seems probable that a communication may exist between this inlet and the Abra, in the strait, opposite Playa Parda.

THE GRAFTON ISLANDS extend about 20 miles in a S. E. direction from Cape Gloucester. Between them are several anchorages, but the best and easiest of access is Euston Bay.

Passing Cape Gloucester, you see a high island to the S. E., distant 7 miles. This is Ipswich Island. (Nos. 19 and 20.) Between it and Cape Gloucester is a Bay, in which are many rocks and breakers.

Rounding IPSWICH ISLAND, you must give a good berth to the rocks under water, which lie one mile from its S. E. extremity. The sea does not always break upon them, but it does generally. Their place in the chart may be depended upon. There is no other hidden danger. After clearing these rocks, pass close to Leading Island. (Nos. 19 and 20,) and steer for the opening of Laura Basin, which you will see under a high-peaked mountain. (Nos. 19, 20 and 21.) Choose your berth by the eye, if intending to anchor in the bay, or work as far up the passage to the basin as you think proper, then anchor and warp to the berth marked in the plan.

The Beagle worked up all the way against a fresh wind blowing directly out. There is water for a frigate in the basin, but it is better suited to a small vessel. Large ships should anchor in the bay; and as the bottom is even and good, and the bay capacious, exposed only to S. E. winds, which come on gradually and seldom blow hard, it may be considered a fit place for ships of any size, or for a squadron. Wood and water are plentiful, and easy to be obtained. The depth of water in the bay varies from 5 to 20 fathoms; the bottom generally fine speckled sand.

A large patch of kelp lies across the entrance of the harbor, but there is no danger beneath it, except for a line-of-battle ship, as in one spot there are four fathoms only. This kelp was very closely examined, and its safety satisfactorily proved.

There are other anchorages among these islands, but none fit or desirable for a ship while so near Euston Bay.

HOPE HARBOR is one of those formerly used by sealing vessels.

Under ISABELLA ISLAND is an anchorage fit for a sealing vessel, but no other. Rocks lie in the way to it, as the chart shows. The Beagle passed a night there, but not by choice.

THE GRAFTON ISLANDS are high, and the remarks on the general character of the coast are applicable to them. (See No. 21.) Behind them lies a passage, through which a sealing vessel has passed. To the N. E. of it is a mass of land, broken into islets and rocks.

Having passed Cape Gloucester, your attention is drawn to NOIR ISLAND, of moderate height, about 600 feet above the sea, and having a remarkable neck of land to the S. W., ended by a rock like a steeple, or tower. (See Nos. 22, 23 and 24.) One mile south of this point is a sunken rock, over which the sea occasionally breaks. Two other breakers are in the light close to the point.

There is an excellent roadstead under the east side of Noir Island. Several ships may lie there, secure from all winds between north and south by the west, over a clear sandy bottom. Wood and water plentiful, and easily obtained. There is a cove at the south part of the island, where boats would be perfectly safe in any weather, but the entrance is too narrow for vessels of any kind.

The large space between Noir Island and the Agnes Islands is extremely dangerous for shipping, being scattered with rocks, some just awash, many showing themselves several feet above, others under water. Still there is abundant room to go round the island in perfect security; therefore no ship need fear being hampered by an east wind, in the event of anchoring in Noir Roads. A rock lies in the roads, and another, a very dangerous one, four miles to the eastward. They are exactly laid down in the chart.

Seven miles south of Noir Island are the Tower Rocks. (No. 23.) They are high, quite steep to, and exactly laid down in the chart. A ship may pass close to either side of them.

Between Noir Island and Cape Schomberg, on London Island, lie many reefs, and a great number of detached out-lying rocks, which render this part of the coast extremely dangerous and unfit for vessels. No chart could guide them. They must trust to daylight and clear weather, with a good lookout, if necessary to enter or leave the Barbara Channel, which opens into this bay.

The Agnes Islands, and those in their neighborhood, do not require any description. They are so fortified by outlying rocks as not to be fit places for the approach of any vessel.

Northward of them is Stokes Bay, and to the eastward a number of islands, between which is the Barbara Channel.

No vessel ought to entangle herself in these labyrinths: if she does, she must sail by eye. Neither chart, directions, nor soundings, would be of much assistance, and in thick weather, her situation would be most precarious.

Between Noir every part of which them the sea could not pass. The Beagle passed; but I should not have been so sure of its ever being so.

This part of the coast is at the south of the Saxe Coburter, and very bad for sealing vessels.

Between Fury Peaks. (No. 26 b.) East and West by sealing vessels.

Four remarkable peaks, (No. 26 a, and 27,) is high, near Fury Island.

The situation of the cove, unless you hold your temporary Tom's Harbor, fit for a sealing vessel, anchored.

There are soundings exceeding 60 fathoms.

London Island is a safe anchorage point out its situation, and near the As there are no soundings into the passage, your harbor. The holding off the high land may here moored, and raised outside by moving an anchor.

The lee side of the island lies to the windward, because the leeward of them is Levanter.

Between and to the west of the islands, in which is BRECKNOCK.

ing or leaving the CAPE DESO.

land; (No. 27,) it is a large space of water and Whale-boat S.

Rocks and breakers small vessels might ways be with much an object does not.

Under Cape Cas large, but for small wind, having three

Between Noir and Kempe Islands, (No. 25,) is the Milky Way, a space of sea, in every part of which rocks are seen just awash with, or a few feet above the water. On them the sea continually breaks.

The Beagle passed in shore of them all, close to the Agnes, Kempe, and Fury Islands; but I should not advise any vessel to follow her track, nor is there any probability of its ever being attempted.

This part of the coast only requires to be known to be the more avoided.

At the south side of Fury Island is Fury Harbor, a bad place, unfit for any vessel. The Saxe Coburg sealing schooner was lost in it in the year 1827. There is little shelter, and very bad ground.

Between Fury and London Islands is the entrance of the Barbara and Cockburn Channels. (No. 26 b.) Rocks show themselves in every direction,—the two clusters called East and West Furies being the most remarkable. They have been much frequented by sealing vessels' boats, fur seal being numerous upon them at times.

Four remarkable mountains point out the entrance to the Barbara Channel very distinctly. The Kempe Peaks, (No. 25,) are high and show three points. The Fury Peaks, (No. 26 a, No. and 27,) are high and divided. Mount Skyring, (No. 26 a, 26 b, and 27,) is high, and has a single peak. St. Paul's is similar to, and in one view, from near Fury Island, appears very like the dome of the cathedral whose name it bears.

The situation of the rocks off the channel's entrance, as laid down in the chart, is accurate; but no vessel should attempt to pass them without daylight and clear weather, so that she may sail more by a good eye at the mast-head, than by any chart.

At the north side of Fury Island, is a snug and perfectly safe anchorage, called North Cove. It is, however, only fit for small vessels. When there, they are in security; but it must be remembered that there is no anchorage in the channel, nor until you get into the cove, unless you close the weather shore, and find a creek, in which the anchor will hold you temporarily. At the north side of Mount Skyring is another anchorage, Tom's Harbor, fit for small vessels. The Adelaide, tender to His Majesty's sloop Adventure, anchored in it when exploring these parts.

There are soundings over all the tract of sea between Noir and London Islands, seldom exceeding 60 fathoms, and near the rocks diminishing to 20, 15, and 10.

London Island is one of a large group called the Camden Islands. At its east end is a safe anchorage called Townshend Harbor. (No. 27.) The Horace Peaks, (No. 27,) point out its situation. Some rocks on which the sea breaks violently, lie off the islands, and near the entrance of Pratt Passage. They are exactly laid down in the chart. As there are no soundings in less than 50 fathoms after passing these rocks, and getting into the passage, you must depend upon the wind lasting to carry you into or out of the harbor. The holding ground in it is excellent, and though you have tremendous squalls off the high land to the westward, there is no fear of an anchor starting. The Beagle lay here moored, during the worst weather she had on the coast. A very high sea was raised outside by a violent southerly gale, but she remained in perfect security without moving an anchor.

The lee side of high land, as I have elsewhere remarked, is not the best for anchorage in this country. When good holding can be found to windward of a height, and low land lies to the windward of you, sufficient to break the sea, the anchorage is much preferable, because the wind is steady and does not blow home to the heights. Being to leeward of them is like being on the west side of Gibraltar Rock when it blows a strong Levanter.

Between and to the northward of these islands, are passages with deep water, numbers of islets and rocks, and anchorages opposite to most of the valleys, or between the islands, in which small vessels could lie securely, if necessary.

BRECKNOCK PASSAGE is wide and clear of all danger. I should prefer entering or leaving the Barbara Channel by this way, rather than by passing the Fury Rocks.

CAPE DESOLATION, the south point of Basket Island, is a very remarkable headland; (No. 27,) it is rugged with many peaks.

The next promontory which is approached in passing along the coast, is Cape Castle-reagh; (No. 27,) it is high and remarkable. Between this and Cape Desolation, is a large space of water, called Desolate Bay, leading to Courtenay Sound, Thieves Sound, and Whale-boat Sound.

Rocks and breakers abound, and make these sounds quite unfit for shipping; no doubt small vessels might, in clear weather, traverse any of these passages, but it would always be with much risk, and should not be attempted without an adequate object. Such an object does not now, nor is it likely to exist.

Under Cape Castlereagh is an excellent anchorage, called Stewart Harbor. It is not large, but for small vessels is an exceedingly good place, being easy of access with any wind, having three openings. A vessel may anchor in the entrance and warp in; there

is no where more than 16 fathoms, generally from 6 to 12. Wood and water, as in every Fuegian harbor, are plentiful, and easily obtained.

Two rocks lie nearly in the middle, just awash at high water. The plan shows their place exactly.

A rock, on which the sea breaks, lies one mile west of the middle opening to the harbor. There is no other danger.

Farther to the south-east are the Gilbert Islands, off which, 8 miles S. 30° E. from Cape Castlereagh, are the Nicholson Rocks.

Between the Stewart and Gilbert Islands, is Adventure Passage, an open space, with deep water, clear of danger.

At the north-eastern side of the eastern Gilbert Isle, is Doris Cove, a safe anchorage for a small vessel. The Beagle lay there moored one week. There are no hidden dangers hereabouts; the eye and the chart will guide a vessel safely.

I say nothing of the large sounds and numerous passages lying to the northward of these and the Stewart Islands, because they are not likely to be again visited.

The Londonderry Islands are the next, they extend nearly to Christmas Sound.

TREBLE ISLAND is a remarkable height, having three peaks; it is visible from a considerable distance; near it are some straggling rocks, shown in the chart.

Nine miles S. 22° E. from Treble Island, are the Phillips' Rocks. They are dangerous, though above water, because so far from the shore, and so low.

COOK BAY is a large space between Cape Ahikhaolip and Waterman Island. Broken land, islets and breakers, surround and make it unfit for the approach of vessels. Its shores were explored by the Beagle's boats.

At the north-east is the entrance of the Beagle Channel, and a passage to Whale-boat Sound, both unfit for sailing vessels, excepting with a fair wind.

WATERMAN ISLAND (No. 28,) is soon known by the remarkable heights at its south part. The southernmost was named by Capt. Cook, "York Minster," from its fancied resemblance to that building. He well describes it as a "wild looking rock." (No. 28.)

Eight miles west of "York Minster," and 5 from Point May, are the Capstan Rocks, above water about 20 feet. There are no other dangers to seaward of a line from York Minster to the Phillips' Rocks.

Hauling round York Minster, you may enter Christmas Sound. There is no hidden danger; the chart and plan are exact. Adventure Cove, (in which captain Cook anchored,) is the easiest of access, but it will only hold one vessel.

MARCH HARBOR is large, with good holding ground, but there are many rocky places; and one rock, under water, (see the plan,) having on it only one fathom; its place is marked by very thick kelp. The Beagle worked through the narrow passage, round Shag Island, from Adventure Cove, and worked into the innermost corner of the harbor without using a warp; larger vessels would of course find themselves more confined.

I do not think a vessel of more than five hundred tons should attempt to enter Christmas Sound.

The Beagle lay moored in this harbor all the month of March, in perfect safety; but her chain cables became entangled with the rocks, and were not hove in without much difficulty and delay.

PORT CLERKE is a bad place for any vessel, though quite secure when in it; access is difficult, and from its situation, it is exposed to very violent squalls.

PICKERSGILL COVE, (named by Cook,) as well as Port Clerke, is unworthy of notice as an anchorage.

Cook's description of Christmas Sound, is as accurate as his accounts of other places. His "Great Black Rock" and "Little Black Rock," show themselves as you enter. Near York Minster are several rocks and islets, close to the eastward; one rock, on which the sea breaks violently, lies 2 miles E. 20° S. from the south extreme of the Minster. You may pass it quite close. Off the "Great Black Rock," there are two or three breakers, caused by rocks under water.

But little current sets among these islands. To seaward of them, and near the headland, it sets as I before described.

The tides between Cape Pillar and Cape Horn, are regular, as regards their rise and fall, and time of high water, but not so with respect to their velocity and direction. It appeared to me that while the water was rising upon the shore, the tide, (or rather current,) set along shore from the north-west towards the south-east, at the rate of one mile an hour, or more, according to the wind.

During the six hours of falling water, or ebb tide, there was little or no current setting along shore.

At Cape Pillar it is high water at one o'clock, on the days of full and change. At York Minster it is high water at 2 in the afternoon.

At the intermediate places the time gradually changes from 1 to 3, as you go to the south-east.

Further eastward high water is still later. At Cape Horn it is at half past 3.

The rise of tide varies from 4 to 8 feet. It is noted in each plan.

Eastward of Christmas Sound lie the Wood Islands. There is no good anchorage among them. Passages and broken land lie behind them to the northward.

Off Point Nativity are two islands and an outlying rock. Hope Island is six miles to the south-east of this point.

The Hdefonsos, a large group of rocks and islets, next claim attention. They are thirty-five miles distant from York Minster, and bear from that spot S. 41° E. They extend five miles in a north-west and south-east direction, are very narrow, and about one hundred feet above the sea. (See No. 29.) They appear to be the remains of the ridge of a mountain, broken through in many places by the sea. You may pass close by them in a vessel, for there is no danger. Sealers have much frequented them for fur seals.

Neither Trefusis Bay nor Rong's Sound afford anchorage.

LEADING HILL, (of Mr. Weddell,) is a very remarkable double peaked height; beyond it are Duff's Bay, Morton and Henderson Islands, and the entrance of Indian Sound (of Mr. Weddell).

There may be good anchorage between these islands. There was not time to examine some coves on the east side of Morton Island, whose appearance promised shelter and holding ground.

CLEARBOTTOM BAY is at the north end of Morton Island, and a good anchorage. It is described in Mr. Weddell's useful and interesting Journal.

INDIAN COVE, in which also he anchored, and remained some time, is not a place to be recommended to vessels. They must go far among the islands to reach it, and when there, have a bad rocky bottom, with deep water, excepting one corner, where the Jane lay at anchor with the Beaufoy. Many better anchorages may be attained on this coast with less trouble.

INDIAN SOUND is a large tract of water, extending to the north-west. It is full of islands.

Between Cape Weddell, at the east side of Indian Sound, and False Cape Horn, (No. 33) is a tract of broken land, which has not been properly examined. It is, however, a lee shore during south-west and southerly winds, and therefore unfit for anchorage.

On Henderson Island is a high sharp-pointed hill, which is visible at a great distance. From its summit the Diego Ramirez Islands (Nos. 30, 31, and 32,) were seen, though fifty miles distant. The highest point of these islands is about 150 feet above the sea. There is no hidden danger near them. They lie nearly north and south, and extend over a space of five miles.

A ship may pass between the northern cluster and that to the southward. Detached rocks lie off the southern island: all the outer ones are above water. The southern or Boat Island has a cove at its north-east corner, in which boats may land; there is water on the point lose to the eastward of this landing-place.

Their place on the chart may be depended upon, because they were seen from, and connected by triangulation to, Henderson and Hermite Islands (Kater's Peak.) There are soundings on each side, but too deep for anchorage, excepting to the south-east, where Mr. Weddell lays down some soundings (in his chart,) which were not found.

Between the Diego Ramirez and the Hermite Islands there is no danger of any kind.

FALSE CAPE HORN is a very remarkable headland. (No. 33.) From the east or west it looks like a large horn. It is a leading mark to the best anchorage on this coast.

"ORANGE BAY."—To anchor in this bay you must pass to the eastward of the False Cape, as close as you please. Steering N. E. (*true*) for four miles will bring you abreast of Point Lort; a bay two miles wide is then opened, in which you may anchor, if necessary, in 8 or 10 fathoms, over a fine sandy bottom. Some rocks, above water, lie at the north side. Beyond the point which forms the north side of this bay, is a small cove, with 18 fathoms water in the middle; beyond it is another cove, rather larger, after which you open Schapenham Bay (so called by the Nassau Fleet). A north course (*true*) from Point Lort will take you abreast of Orange Bay.

SCHAPENHAM BAY is one mile and a half wide; there is a small black rock, above water, rather to the northward of its middle. A great deal of kelp, lying over a rocky bottom, is seen at the head of the bay, and a large waterfall marks the place distinctly. There is anchorage in from 10 to 15 fathoms, near the south point; but I should not recommend a vessel to use it, when by going further she may get into an unexceptionable harbor, or anchor off its entrance in perfect security.

The land behind these coves that have been mentioned is high and rugged: two singular peaks show themselves, which resemble sentry-boxes. Near the shore the land is low, compared with other parts of the coast, and has not the iron-bound forbidding appearance of the more westerly shores.

From the heights sudden and very strong squalls blow during westerly winds. Being generally a weather shore, and regular soundings extending along it, there is no difficulty in choosing or approaching an anchorage.

Off Orange Bay anchor soundings extend to two miles from the land. The opening of the bay is three miles wide, and in that part are eighteen or twenty fathoms, over a fine speckled sand. Two islands, the larger having a smooth down-like appearance, lie in the middle; behind them is the harbor, a square mile of excellent anchorage, without a single rock or shoal. In the two creeks at the south side is good anchorage for small vessels: the depth of the water varies gradually from 5 to 20 fathoms. The bottom every where is a fine speckled sand. The land hereabouts is low, comparatively speaking, and you are not annoyed by the violent squalls which come from the heights in other places.

You may go close to the shore in every part, therefore no directions are necessary to point out the way to the best berth which is marked in the plan. Wood and water are plentiful; the best watering place is in a small cove at the north side, called Water Cove. This harbor is fit for a fleet of line-of-battle ships, and could supply them with any quantity of wood and water.

Off the north point are several small islets, which must not be approached too closely; they are, however, out of the way.

Six miles N. N. W. of the outer anchorage is a curious island, like a castle, or a pack-saddle.

Orange Bay is somewhat open to east winds, but they seldom blow strong, and would be fair for ships bound westward. No sea can be thrown in, because of the Hermite Islands.

There is no current here worthy of notice. The tide rises six feet: high water at half-past three.

Opposite to the land lying between New-Years and Tekeinika Sounds, called Hardy Peninsula, on the east side of which is Orange Bay, are the Hermite Islands. (Nos. 34, 35, and 36.) Their northern shores have not yet been examined. The southern are accurately laid down in the chart.

NASSAU BAY extends to the north and north-west into the Beagle Channel.—There is nothing to lead a vessel into these openings, therefore a description of them is not necessary. They may prove useful for boats, and a glance at the chart will be of more service, for their purpose, than any directions.

Nassau Bay is very accessible, and free from dangers. Anchorage may be found on each coast, and the only dangers are some rocks (or islets,) above water, shown in the chart, and visible at a distance by daylight. The northern shore is low, particularly towards Guanaco Point, where the coast first begins to show signs of approaching Eastern Patagonia, changing its rocky heights for level land and low earthy cliffs.

On the southernmost of the Hermite Islands is Cape Horn. There is nothing very striking in the appearance of this promontory, as seen from a distance; but, in passing near, it is more remarkable, showing high black cliffs towards the south: it is about five hundred feet above the sea. (*The Sketches Nos. 34, 35, and 36, are faithfully drawn.*)

No dangers exist to the southward, in approaching these islands—they may be closed without hesitation.

WEST CAPE is low. The land about St. Martin's Cove is high and rugged.—Wollaston and Herschel Islands have also ridges of mountains. Kater's Peak, the highest land (excepting Mount Hyde) on the islands, is seventeen hundred feet above the sea.\*

In the channel between False Cape Horn and the Hermite Islands, a current is found setting into Nassau Bay, and rather towards the Hermite Islands, at the rate of two knots an hour with the flood tide, and about half a knot with the ebb. As this current sets rather towards West Cape, a good berth must be given to it in passing.

FRANKLIN SOUND is clear of obstruction, and has no other danger than those which are shown in the chart.

In Nassau Bay the compasses are much affected; they become very sluggish, and might cause a serious error if not carefully attended to.†

\*By barometrical measurement, 1742 feet above high water mark.—[P. P. K.]

†The magnetic needle was very remarkably affected in many parts of the islands of the group, although I did not observe any great difference, when at a distance from the rock of which they are

A strong current sets, at times, along the outer coast of the Hermite Islands, and through the Bay of St. Francis. It varies from half a knot to two knots an hour, according to the wind and the time of tide; and, in the bay, changes its direction with the change of tide.

With the sketch or chart, no one would require a direction to point out St. Martin's Cove. Temporary anchorage may be had in the small bay leading to St. Joachim's Cove, or under the south head of St. Martin's Cove, where you find from 20 to 25 fathoms, over a clear sandy bottom. As you approach the western end of St. Martin's Cove the water shoals to 15 and 10 fathoms. It is perfectly secure, but visited by very violent squalls during a westerly wind.

PORT MAXWELL is a perfectly secure anchorage, and untroubled by mountain squalls, (or willi-waws,) but it is rather out of the way. Though it has four openings, only two are fit for vessels—those to the north and east. The best berth in it has 16 fathoms water, over a clear sandy bottom. This harbor is decidedly good, though it requires a little more time and trouble in the approach.

The passages between these islands have deep water, and are free from dangers. What few rocks there are, show themselves above water, or are thickly covered with kelp. Some rocks lie off the south end of Chanticleer Island, too close to be of much consideration.

One mile to the westward of Cape Horn there are three rocks, generally above water. The sea always breaks on them.

Off the east point of Horn Island, are some small rocks and breakers. Off Cape Deceit are several rocks, all above water; and two miles to the S. E. is a cluster rising 30 or 40 feet above the sea.

Off Cape Horn the current is as strong as in any part of the coast. Between it and Cape Pillar, it is by no means regular; sometimes with a strong wind and flowing tide it runs two knots an hour—at others it is hardly worth notice.\* I never found it set to the westward at any time of tide, or with any wind.

The Barnevelt Islands (No. 28) lie 11 miles N. E. by E. from Cape Deceit. The chart and sketch are a sufficient description. For the Evouts Isles, (No. 38,) I should refer also to the chart and the accompanying view; and for the appearance of this part of the coast, from Cape Horn to Cape Good Success, to the sketch. (No. 37.)

The space between Cape Deceit and New Island, is free from hidden dangers, as far as I am aware, but it has not yet been sufficiently examined.

In Goeree Road there is very good anchorage in 6 or 7 fathoms water, over a sandy bottom.

LENNOX ISLAND, as well as New Island, and indeed any part of the coast hereabouts, may be approached with confidence, using the lead and looking out for kelp.

There are no shoals, but the water is not so deep as to the west of Cape Horn, neither is the land near so high.

At the east side of Lennox Island is excellent anchorage. Small vessels may go into a cove in which the Beagle lay moored, but large ships must anchor in the road, which is quite secure, and sheltered from all but south-east winds, with which of course a vessel would not wish to remain at anchor. To the north of Lennox Island is the eastern opening of the Beagle Channel. It is easy of access, but useless to a ship. Boats may profit by its straight course and smooth water. It runs 120 miles in nearly a direct line between ranges of high mountains covered always with snow. The highest are between 3 and 4,000 feet above the sea. This channel averages  $1\frac{1}{2}$  mile in width, and in general has deep water; but there are in it many islets, and rocks near them.

A range of high mountains runs uninterruptedly from the Barbara Channel to Strait le Maire. Mount Sarmiento, more than 5,000 feet above the sea, is in this range.

formed, or on board the ship. On one occasion, on ascending the summit of Maxwell Island, in Port Maxwell, the compass was placed for convenience upon the rock, when the needle was found to be so much influenced by the ferruginous nature of the rock, composed of Quartz with large and numerous crystals of Hornblende, that its poles became exactly reversed. An experiment was afterwards made by taking a set of bearings of a distant object, (to prevent an error of parallax,) at several stations around, at fifty yards from the above magnetic rock; when the extreme difference amounted to  $127^{\circ}$ . The block upon which the compass was placed in the first instance is now in the museum of the Geological Society.

No sensible difference, however, was found in the valley at the bottom of St. Martin's Cove, where the variation of the compass was observed by several different instruments, and compared with astronomical bearings, when the deviation did not amount to more than the usual amount of the variation in that neighborhood.—[P. P. K.]

\* In beating up to the anchorage in St. Martin's Cove, at from 20 to 60 miles to the eastward of Cape Horn, I found the current setting constantly at from half to one mile per hour, the wind throughout being south-westerly.—[P. P. K.]

† 6,800 feet.

Southward of these mountains is a succession of broken land, intersected by passages or large sounds. A boat can go from the Week Islands to the eastern entrance of the Beagle Channel, without being once exposed to the outside coast, or to the sea which is there found.

Some heights on New Island were noticed by Cook; they were not, however, so visible from the west as from the east side.

Good temporary anchorage during westerly winds may be obtained under New Island, or near the shore to the northward; but I know of no good harbor between Richmond Road and Good Success Bay, in Strait le Maire.

Regular soundings are found hereabouts, in all directions, and the shore is steep to. Neither Aquirre Bay, Spaniard's Harbor, nor Valenty's Bay, are fit for more than temporary anchorage during northerly or westerly winds. They are much exposed to the south. For that purpose the chart is a sufficient guide.

The tide is felt strongly on this part of the coast, causing races and eddies near the projecting points. In the offing, the current (or tide) sets towards Strait le Maire, from 1 to 3 knots an hour, when the water is rising on the shore, and the wind westerly. While the water is falling, it runs with less strength, and with an easterly wind is not felt at all.

The Bell Mountain is remarkable: it is seen far at sea, from the north as well as from the south. It is high, and in shape resembles a large bell.

CAPE GOOD SUCCESS is high and bluff. (No. 40.) Some rocks lie close to it, above water.

The land from the Bell Mountain to Good Success Bay is higher than that near Lennox and New Islands. It more resembles the south-west coast.

Between Cape Horn and Staten Island, regular soundings are found, between 30 and 70 fathoms, over a sandy bottom.

The soundings in Strait le Maire are similar near their southern entrance. Towards the north the soundings diminish; and 2 miles from Cape San Diego there are not more than 30 fathoms water, over a rocky bottom. The strait is clear of all obstacles, the tide excepted. The land, from Cape Good Success to Maurice Cove, is high and bold, with water for a ship as near to it as she ought to go.

Rather more than two miles north-east of Cape Good Success is a projecting headland, which, at first, appears to be the cape. Two rocky islets show themselves close to it, and from a distance appear like a ship under sail.

Six miles from these rocks, N. E. by N., is the Bay of Good Success. (No. 40.) It is a good anchorage, perfectly safe, provided that a vessel does not anchor too far in towards the sandy beach at its head; for, during south-east gales, a heavy swell with dangerous rollers sets right into the bay. The best berth is shown in the plan. Heights of about 1,200 feet above the sea, surround the bay; therefore, with strong winds, it is subject to squalls, which, during westerly gales, are very violent.

GOOD SUCCESS BAY is an excellent anchorage for vessels of any size to stop in to get wood or water, but it would not answer if a vessel required to lie steady for repairs, as a swell frequently sets in. It is quite safe; but in the winter season, when easterly winds are common, no vessel should anchor so near the head of the bay as she might in summer.

The "Broad Road," mentioned by Cook, is a good mark for the bay, if the inbend of the land does not sufficiently point out its situation. It is a barren strip of land on the height at the south side of the harbor. Maurice Cove has no good anchorage; it is merely a rocky bight.

Hence to Cape San Diego, the land is much lower, and the water near it less deep.

CAPE SAN DIEGO is low. A ship may go close to it. There are shoaler soundings towards the east, for about two miles, than in other parts near here; for a rocky ledge under water seems to project from the cape. On this ledge there are overfalls, strong eddies, and a violent race of tide when the wind is opposed to it.

Beyond Cape San Diego the land suddenly trends away westward.

CAPE ST. VINCENT is a rocky point, with low bluffs above it.

Between this point and Cape San Diego, is "Thetis Bay," a tolerable anchorage during west or southerly winds, though the bottom is rocky in many places. Between the heads the tides run with great strength; therefore a ship should anchor off a green bluff at the west side, and within the line of the heads she will have from 6 to 12 fathoms of water, over a coarse sandy bottom, mixed with patches of rock.

Beyond Cape St. Vincent the land trends to the W. and N. W. It is rather low near the sea, but in shore are many hills partially covered with wood.

Regular soundings extend to seaward for many leagues; and good anchorage may be found near the land, on any part of this coast, during westerly winds.

The tides in Strait le Maire are as regular as in any part of the world. They will assist a vessel materially in her passage, if taken at the right time.

As the strait is regular, with Good Success Bay, vessels may pass to the southward.

When the tide is running, it is dangerous, race of tide, and the tide runs, but let it be remembered that full moon, we are in the morning.

Though the tide is seen in every direction, it is high water in the afternoon, at 10 in the morning.

At Cape Pillar and S. E. coasts, from one knot to one to three in the wind. The ebb is at times, when off Cape San Diego, the strait is clear of all obstacles, the tide excepted.

CAPE ST. VINCENT, are high, and give notice of the strait.

As the strait is very wide, perfectly free from obstacles of any kind, the soundings regular, with Good Success Bay close at hand, in case the wind or tide should change, vessels may pass through without difficulty or risk.

When the tide opposes the wind and swell, there is a heavy, and, for small vessels, a dangerous, race of tide off Cape San Diego, where, as I said before, there is a shoal ledge, and the tide runs very strongly. We found it so in the Beagle at even a neap flood tide; but let it be remarked, that on another day, at the top of the springs, being the day after full moon, we passed the same spot at half flood, with perfectly smooth water.

Though the tide was running three or four knots an hour round the cape, and eddies were seen in every direction, the vessel's steerage was but little affected by them.

It is high water on the shore in Good Success Bay, and slack water in the strait, at 4 in the afternoon on the full and change days, and low water with slack tide in the offing, at 10 in the morning. The tide rises perpendicularly from 6 to 8 feet, according to the wind.

At Cape Pillar, as I before said, the turn of tide is about 1 o'clock. Along the S. W. and S. E. coasts, the time gradually increases to 4 in the afternoon at this place.

From Cape San Diego to the northward, the tide sets north and west along the shore, from one knot to three. The ebb sets in a contrary direction, but not so strongly.

In Strait le Maire the flood tide runs from two to four knots near the cape, and from one to three in mid-channel, more or less, according to the strength and direction of the wind. The ebb sets to the southward, about one knot an hour.\*

At times, when a strong flood tide is opposed by a northerly wind, there is an overfall off Cape San Diego, like the "Bores" on our own coast and elsewhere.

STATEN ISLAND is high, and its mountains are generally covered with snow. Its shores lying towards the strait are very bold and rugged. No danger is near them, excepting strong eddies and races, caused by the tide near the headlands.

CAPE ST. ANTONY, MIDDLE CAPE, AND CAPE SAN BARTHOLOMEW, are high, bluff promontories. The soundings to the northward are very regular, and give notice of your approach to Staten Island, or the Strait le Maire.

*General Observations upon the appearance and character of the Sea Coast of Tierra del Fuego; Description of the Anchorages; and Remarks upon the Seasons, Wind and Weather.*

From Cape Pillar to Cape Horn, the coast of Tierra del Fuego is very irregular, and much broken; being, in fact, composed of an immense number of islands. It is generally high, bold, and free from shoals or banks; but there are many rocks nearly level with the surface of the water, distant 2, and even 3 miles from the nearest shore, which make it very unsafe for a vessel to approach nearer than 5 miles, excepting in daylight and clear weather. The coast varies in height from 3 to 1500 feet above the sea. Further in shore are ranges of mountains always covered with snow, whose height is from 2 to 4000 feet, and in one instance, (Sarmiento,) 5009.

With daylight and clear weather, a vessel may close the shore without risk, because the water is invariably deep; and no rock is found which is not so marked by sea-weed, (or kelp, as it is generally called,) that by a good look out at the mast-head, its situation is as clearly seen as if it were buoyed. By avoiding kelp you are sure of having sufficient water for the largest ships, on any part of this coast. At the same time it must be remembered that kelp grows in some places from a depth of 30 fathoms, and that on many parts of this coast you may pass through thick beds of sea-weed without having less than 6 fathoms water; still it is always a sign of danger, and until the spot where it grows has been carefully sounded, it is not safe to pass over it with a ship. As an instance:—after sounding a large bed of this weed in one of the Beagle's boats, and thinking it might be passed safely, a rock was found, not more than 4 feet in diameter, having only one fathom water over it.

Viewing the coast at a distance, it appears high, rugged, covered with snow, and continued—as if there were no islands. When near, you see many inlets which intersect the land in every direction, and open into large gulfs or sounds behind the seaward islands.

You now lose sight of the higher land, which is covered with snow throughout the year, and find the heights close to the sea thickly wooded towards the east, though bar-

\* The flood tide sets through Strait le Maire from the southward, and along the north and south sides of Staten Island from east to west. It is high water, at full and change, at the anchorage within the New Year's Isles, as well as on the east side of Strait le Maire, at 5 o'clock. The current is very strong, running from 4 to 6 knots. Off Cape St. John there is a tide race, which extends for some distance off the point.—[P. P. K.]

ren on their western sides, owing to the prevailing winds. These heights are seldom covered with snow, because the sea winds and the rain melt it soon after it falls. Opposite to the eastern valleys, where the land is covered with wood, and water is seen falling down the ravines, good anchorage is generally found. But these valleys are exposed to tremendous squalls, which come from the heights. The best of all anchorages on this coast, is where you find good ground on the western side of high land, and are protected from the sea by low islands. It never blows near so hard against high land as from it, but the sea on the weather side, is of course too formidable, unless stopped, as I mentioned, by islets.

Where the land is chiefly composed of sandstone or slate, anchorages abound; where of granite, it is difficult to strike soundings.

The difference between the granite and slate, or sandstone hills, can be distinguished by the former being very barren and rugged, and of a grey or white appearance; whereas the latter are generally covered with vegetation, are dark colored, and have smoother outlines. These slate or sandstone hills show few peaks, and the only rugged places are those exposed to wind or sea.

Soundings extend to 30 miles from the coast. Between 10 and 20 miles from the land, the depth of water varies from 60 to 200 fathoms, the bottom almost everywhere a fine white or speckled sand. From 10 to 5 miles distant the average depth is 50 fathoms; it varies from 30 to 100, and in some places no ground with 200 fathoms of line. Less than 5 miles from the shore the soundings are very irregular indeed, generally less than 40 fathoms, but in some places deepening suddenly to 100 or more: in others a rock rises nearly to, or above, the surface of the water.

After carrying 50, 40, 30, or 20 fathoms, towards an inlet which you are desirous of entering, you will probably find the water deepen to 60 or 100 fathoms as soon as you enter the opening: and in the large sounds, behind the seaward islands, the water is considerably deeper than on the outside.

There is a bank of soundings along the whole coast, extending from 20 to 30 miles from it, which appears to have been formed by the continued action of the sea upon the shore, wearing it away and forming a bank with its sand.

Between the islands where there is no swell or surf worth notice, the water is deep, and the bottom very irregular.

A small ship may run among the islands in many places, and find good anchorage; but she runs into a labyrinth, from which her escape may be difficult, and, in thick weather, extremely dangerous.

Fogs are extremely rare on this coast, but thick rainy weather and strong winds prevail. The sun shows himself but little; the sky, even in fine weather, being generally overcast and cloudy. A clear day is a very rare occurrence.

Gales of wind succeed each other at short intervals and last several days. At times the weather is fine and settled for a fortnight, but those times are few.

Westerly winds prevail during the greater part of the year. The east wind blows chiefly in the winter months, and at times very hard, but it seldom blows in summer.

Winds from the eastern quarter invariably rise light, with fine weather;—they increase gradually—the weather changes—and at times end in a determined heavy gale. More frequently they rise to the strength of a treble-reefed topsail breeze, then die away gradually, or shift to another quarter.

From the north the wind always begins to blow moderately, but with thick weather and more clouds than from the eastward, and it is generally accompanied by small rain. Increasing in strength, it draws to the westward gradually, and blows hardest between north and north-west, with heavy clouds, thick weather, and much rain.

When the fury of the north-wester is expended, which varies from 12 to 50 hours, or even while it is blowing hard, the wind sometimes shifts suddenly into the south-west quarter, blowing harder than before. This wind soon drives away the clouds, and in a few hours you have clear weather, but with heavy squalls passing occasionally.

In the south-west quarter the wind hangs several days, (generally speaking,) blowing strong, but moderating towards its end, and granting two or three days of fine weather.

Northerly winds then begin again, generally, during the summer months; but all manner of shifts and changes are experienced from north to south by the west, during that season, which would hardly deserve the name of summer, were not the days so much longer, and the weather a little warmer. Rain and wind prevail much more during the long than the short days.

It should be remembered that bad weather never comes on suddenly, from the eastward, neither does a south-west or southerly gale shift suddenly to the northward. S. W. and southerly winds rise suddenly and violently, and must be well considered in choosing anchorages, and preparing for shifts of wind at sea.

The most usual weather in these latitudes, is a fresh wind between a north-west and south-west, with a cloudy overcast sky.

Much difference of opinion has prevailed as to the utility of a barometer in these latitudes. I can only say, that during 12 months constant trial of a barometer and symphonometer (Adie's,) I found their indications of the utmost value. Their variations do not, of course, correspond to those of middle latitudes, but they correspond to those of high northern latitudes in a remarkable manner, changing south for north, (east and west remaining the same.)

There is a continual current setting along the south-west coast of Tierra del Fuego, from the north-west towards the south-east, as far as the Diego Ramirez Islands. From their vicinity the current takes a more easterly direction, setting round Cape Horn towards Staten Island, and off to seaward to the E. S. E.

Much has been said of the strength of this current, some persons supposing that it is a serious obstacle in passing to the westward of Cape Horn, while others almost deny its existence.

I found it run at the average rate of a mile an hour. Its strength is greater during west,—less, or insensible, during easterly winds. It is strongest near the land, particularly near the projecting capes or detached islands.

This current sets rather from the land, which diminishes the danger of approaching this part of the coast.

There is, in fact, much less risk in approaching this coast than is generally supposed. Being high and bold, without sand-banks or shoals, its position accurately determined, and a bank of soundings extending 20 or 30 miles from the shore, it cannot be much feared. Rocks, it is true, are abundant near the land, but they are very near to the shore, and out of a ship's way.

A line from headland to headland, (beginning from the outermost Apostle,) along the coast, will clear all danger, excepting the Tower Rocks, which are high above water, and steep to.

Gales of wind from the southward, and squalls from the south-west, are preceded and foretold by heavy banks of large white clouds rising in those quarters, having hard edges, and appearing very rounded and solid. (*Cumuloni.*)

Winds from the northward and north-westward, are preceded and accompanied by low flying clouds, with a thickly overcast sky, in which the clouds appear to be at a great height. The sun shows dimly through them, and has a reddish appearance. For some hours, or a day, before a gale from the north or west, it is not possible to take an altitude of the sun, although he is visible: the haziness of the atmosphere in the upper regions, causing his limbs to be quite indistinct. Sometimes, but very rarely, with the wind light between N. N. W. and N. N. E., you have a few days of beautiful weather. They are succeeded by gales from the southward, with much rain.

It may be as well to say a few words respecting the seasons in the neighborhood of Cape Horn, as much question has arisen respecting the propriety of making the passage round the cape in winter or in summer.

The equinoctial months are the worst in the year, generally speaking, as in most parts of the world. Heavy gales prevail at those times, though not, perhaps, exactly at the equinoxes. In August, September, October and November, you have the worst months in the year. Westerly winds, rain, snow, hail, and cold weather, then prevail.

December, January and February are the warmest months: the days are long, and you have some fine weather; but westerly winds, very strong gales at times, with much rain, prevail throughout this season, which carries with it less of summer than in almost any part of the globe.

March, as I said, is stormy, and perhaps the worst month in the year with respect to violent winds, though not so rainy as the summer months.

In April, May and June, the finest weather is experienced; and though the days shorten, it is more like summer than any other time of the year. Bad weather is found during these months, but not so much as at other times. Easterly winds are frequent, with fine clear settled weather. During this period there is some chance of obtaining a few successive and corresponding observations. To try to rate chronometers by equal altitudes, would be a fruitless waste of time at other seasons. June and July are much alike, but easterly gales blow more during July.

The days being so short, and the weather cold, make these months very unpleasant, though they are, perhaps, the best for a ship making a passage to the westward, as the wind is much in the eastern quarter.

I should say that the summer months, December and January, are the best for making a passage from the Pacific to the Atlantic Ocean, though that passage is so short and easy that it hardly requires a choice of time. For going to the westward I should prefer April, May and June.

Lightning and thunder are seldom known. Violent squalls come from the south and south-west, giving warning of their approach by masses of clouds. They are rendered more formidable by snow, and hail of large size.

*South-west Coast, or Western Patagonia, from the Strait of Magalhaens to Cape Tres Montes.*

Very small portions of the sea coast of this interval were seen by us. The following descriptions are principally abstracted from the manuscript journals of the late Captain Stokes, Lieutenant (now Captain) Skyring, and Mr. Kirke, mate of his Majesty's sloop *Beagle*.

BETWEEN CAPE VICTORY AND LORD NELSON STRAIT, the coast is very much broken, and intersected by channels leading between the islands of Queen Adelaide Archipelago, on the sea coast of which, to the N. N. E. of Cape Victory, is a remarkable pyramidal hill called Diana Peak, which, in clear weather, is visible to ships entering the strait. Cape Isabel is a steep rocky promontory of great height, with a peaked summit, and a sharply serrated ridge, having two detached columnar masses of rock. *Beagle* Island, lying off it, is well sided; but although tolerably high, is much lower than the land of the cape.

CAPE SANTA LUCIA, the westernmost point of Cambridge Island, is high and precipitous. Cape George, at the south end, is lower, and forms a bluff point.

THE SAN BLAS CHANNEL, DUCK AND DUNCAN HARBORS, THE DUCK CAN ROCK, and other rocks off them, are inserted from the oral information of the master of an American schooner, and, probably, are very incorrectly laid down. *Augusta* Island and the White Horse were seen by Lieutenant Skyring.

CAPE SANTIAGO, the south end of Madre de Dios Archipelago, is correctly placed, as are also the general direction of the coast to the northward, and the summit of the land that are particularized, viz., the opening of West Channel, April Peak, Tower Rock, and the bay to the north of it, and Cape Three Points, which is the south entrance of the Gulf of Trinidad. Opposite to the latter cape is Cape Primero, the south point of the mountainous island of Mount Corso, the land of which may be seen in clear weather, from the southward, at the distance of ten leagues. It forms the visible northern termination of the coast line. Viewed when bearing north, or any point to the westward of north, its summit makes like a round mount rising conspicuously above the contiguous land, from which a small portion of low coast extends for two degrees beyond it to the westward. The land of the northern shore of the gulf makes in mountainous ridges and peaks, the average height of which Captain Stokes estimated to be about 3,000 feet.

CAPE THREE POINTS rises to a lofty rocky mountain, nearly 2,000 feet high, the summit being of peaks and sharp serrated ridges, with a detached mass of rock of pyramidal form at the base, which shuts in with the land on the bearing of N. 51° E. The variation here is 20° 58'.

PORT HENRY is 3 miles to the N. E. of Cape Three Points. The shore between them is lined for nearly a league off with rocks and islets, of which several scores might be counted in the space of a square mile; but they seem to be of bold approach, and no dangers probably exist that are not above water, or are not shown by kelp.

Bound to Port Henry, a vessel should keep on the south side of the gulf, for the northern part is strewn with many rocks, and seemed to be exceedingly dangerous. The soundings, also, are very irregular, and the bottom is foul and rocky.

The entrance of Port Henry will be easily distinguished by its sandy beach, since it is the first that is observed on the south shore on entering the gulf. It is a small, light colored beach, with a lowish sandy cliff at the back, and a round, rocky and wooded mount at its western end. The Seal Rocks, also in the offing, are a good mark. They bear N. 12° E., 5 miles from the west point of the entrance, which is about a mile wide. The channel is bounded on each side by low rocks, lying off highish round rocky islets, that may be approached within one and a half cable's length. The soundings are from 20 to 25 fathoms, on a sandy bottom. Afterwards they decrease pretty gradually to the anchorage, which is in 9 and 10 fathoms.

When the sandy beach bears S. 19° E., *mag.*, the fair way of the entrance will be quite open; and a vessel may stand in, keeping the round mount at the western end of the sandy beach on the larboard bow, until nearly abreast of it. She may then proceed up the harbor as high as convenient, and select her berth; for the ground is quite clear of danger to the line of rock weed, which skirts the shores and islets. The depth of water is between 12 and 8 fathoms, and the bottom generally of sand and mud.

In turning in there are some patches of kelp on each side, growing upon rocks that wash at high water, which must be avoided. Their positions are given in the plan.

As the squalls off ship to anchor as soon as possible of the water, in the plan will show. Wood and water at the anchorage.

It is high water at the stream of the tide, at 11 o'clock. The observatory is on the western side of the island. Variation of 11°.

THE GULF OF TRINIDAD. It is nearly 10 leagues long. Madre de Dios, in the middle of them were visited. The island is Port de la Trinidad, from Sarmiento's anchorage.

On the northern shore, the mountain communicates with the North Arm, appears like a Cathedral mount. It is said to resemble the Cathedral of Seville. Between the two openings is a anchorage in 11 fathoms.

The gulf meets the channel in contracted spaces and rocks in the channel, mentioned, the Van der Meer, and extending for 11 miles. On the south side, the reef off its S. W. end.

The island of Montserrat is more than a league off the west coast of the shore. There is a deepens immediately off the shore.

PICTON OPENING. The island of Montserrat, of which Captain Blunt was 10 miles off the coast to the westward, are more numerous, and other islands are awash, and other islands are awash, and other islands are awash.

CAPE DYER is a rocky islet, called after the similarity to that of the southernmost point of the island.

This rock is a good mark. S. 64° W., (S. W.).

At one mile to the south of the approaching Port Henry, by compass, you will find a good anchorage. Abreast of the channel here is one of the Breaksea Islands, about one eighth of a league from 6 to 8 fathoms deep, the case of being becalmed.

BREAKSEA ISLANDS. There are three quays, which are three quays, 4 fathoms, and grow to 6 and 8 fathoms, with 6 and 8 fathoms of anchoring your vessel out by its vicinity.

\* There must be a...

As the squalls off the high land are sometimes very strong, it will be advisable for a ship to anchor as soon as possible, and warp up to her berth, which, from the smoothness of the water, may be easily effected. Any security may be obtained in this harbor. The plan will show that the basin at the bottom of the harbor is a complete wet dock. Wood and water at the sandy beach are in abundance.

It is high water at full and change within a few minutes of noon, and rises 5 feet. The stream of the tide, however, is very inconsiderable, and never exceeded half a mile an hour. The observations for latitude and longitude, &c., were made on a rock at the western side of the port, marked A, in the plan. The lat. is  $50^{\circ} 00' 18''$ , long.  $75^{\circ} 15' 11''$ . Variation of the compass,  $20^{\circ} 50'$ .

THE GULF OF TRINIDAD separates Wellington Island from Madre de Dios. It is nearly 10 leagues long, and from 4 to 8 miles wide. Its south shore, or north coast of Madre de Dios, is very much broken, and, probably, contains many ports. None of them were visited excepting for night anchorages. Under the east side of Division Island is Port de la Morro, which, with Point Candelaria and Port Rosario, are inserted from Sarmiento's account.

On the northern shore are two opening-like channels. The westernmost probably communicates with the Fallos Channel; the other, Sarmiento's *Banco de Norte*, or North Arm, appeared to trend under the base of the range of mountains, among which Cathedral mount is a conspicuous object. From the entrance of the strait this mountain resembles the spire and roof of a church, and is visible for more than 20 leagues. Between the two openings is Neesham Bay, in which the *Adelaide* found a secure anchorage in 11 fathoms. There is also good anchorage for a small vessel in Windward Bay.

The gulf meets the Wide Channel at its junction with Conception Strait, where the channel is contracted by an island to the width of one mile and a half. There are several isles and rocks in the gulf, of which the most remarkable are the Seal Rocks, before mentioned, the Van Isles, opposite the western channel, and a group of numerous islands extending for a league to the southward of the land to the westward of Neesham Bay. On the south shore are also several isles, but they are near the coast, and are particularized in the chart. The most remarkable is Middle Island, which, with the reef off its S. W. end, is well described by Sarmiento.

The island of Mount Corso is separated from Cape Brenton by Spartan Passage. For more than a league off Cape Primero are some extensive reefs; indeed the whole line of the west coast of Madre de Dios is fronted by rocks, some of which are 2 leagues from the shore. There are regular soundings in the entrance of the gulf, but the water deepens immediately after passing to the eastward of Port Henry.

PICTON OPENING and Dynely Bay very probably insulate the land that separates them, of which Cape Montague is the S. W. extreme. There are some rocks 8 or 10 miles off the coast to the southward; but between Cape Montague and Cape Dyer they are more numerous. Several are from 8 to 10 miles off the shore. Many are dry, some are awash, and others show only by the breaking of the sea. The coast to the north of Dynely Bay is very broken.

CAPE DYER is in lat.  $48^{\circ} 5' 55''$ , long.  $75^{\circ} 34' 35''$ . At 5 miles S.  $86^{\circ}$  W. from it is a rocky islet, called by Bulkely and Cummings "The Rock of Dundee," from its similarity to that island in the West Indies, but not so large. It lieth about 4 leagues\* from the southernmost point of land out at sea."

This rock is a good mark for Port Santa Barbara, from the entrance of which it bears S.  $64^{\circ}$  W., (S. W. mag.) distant nine miles.

At one mile to the north of the rock, the depth is 23 fathoms, and gradually decreases on approaching Port Santa Barbara; in steering for which, as soon as Cape Dyer bears S. by compass, you will be close to some rocks, which you should keep on your larboard hand. Abreast of this rock, one eighth of a mile off, the depth will be 11 fathoms. The channel here is one mile wide, but gradually narrows on approaching the south-west end of Breaksea Island: and at Wreck Point, the west head of the port, the width is about one eighth of a mile. There are several rocks in this passage, but as the depth is from 6 to 8 fathoms, the anchor may be dropped, and the ship warped clear of them, in case of being becalmed: calms, however, are of rare occurrence here.

BREAKSEA ISLAND, more than two miles long, fronts the port, the heads of which are three quarters of a mile apart. In the entrance of the port the depth is  $3\frac{1}{2}$  and 4 fathoms, and gradually decreases to  $2\frac{1}{2}$  fathoms, but at the bottom there is a basin with 6 and 8 fathoms in it. This is a very good harbor, and from the rare opportunity of anchoring your ship in a moderate depth, is of easy access. It is also readily made out by its vicinity to the Dundee Rock, which serves to point out its position.

\* There must be a mistake here: it should probably have been four miles.

The west head of the port is in latitude  $48^{\circ} 2' 15''$ , and longitude  $75^{\circ} 29' 45''$ ; variation  $19^{\circ} 10'$ . High water takes place at full and change, at 0h. 28m. and rises three to four feet (neaps).

To the N. E. of Breaksea Island are many straggling rocks. The Beagle having entered the port by the western entrance, left it by threading the rocks to the eastward, in doing which, she had not less than 9 fathoms.

Between the island and the mouth of the port, the depth is from 6 to 7 fathoms, good ground, which renders the entrance and exit very easy.

FLINN SOUND is a deep opening to the eastward of the port; that was not examined.

POINT BYNOE, with the group of islands—Bynoe Islands, extending for two miles off it, is the west head of the Fallos Channel, which was explored for 30 miles without offering any interesting feature. Mr. Kirke, who examined it, describes it to be perfectly clear of rocks, and abounding in anchorages for small vessels, although the water is deep. The bottom is sandy. Its general width is one and a half to two miles. The western side of the mouth is a ridge of mountains; the eastern side is much lower, and very broken, and formed by many small islands. At five miles within it, on the west side is our Lady's Bay, of the old charts. Fallos Channel probably communicates with the sea by Dynely Bay and Picton Opening; and, beyond the latter, was supposed to communicate with the Gulf of Trinidad by the channel to the west of Neesham Bay.

THE GUAIANECO ISLANDS, twenty miles in extent, are composed of two principal islands, and many smaller islets—the westernmost is called Byron Island, and the easternmost Wager Island. They are separated by Rundle Pass, called in Bulkely's Narrative, The Lagoon; on the west side, and at the north end of it, is Speedwell Bay.

RUNDLE PASS is only a  $\frac{1}{4}$  of a mile wide, but perfectly clear in the whole extent of its channel, excepting the northern entrance; where it is guarded by many detached rocks, which render the entrance to Speedwell Bay rather difficult.\* According to Byron's and Bulkely's Narratives, the situation of the wreck of the Wager is near the west end of the north side of Wager Island. Harvey Bay and Good Harbor are mentioned by Bulkely. Off the western end of Byron Island are some rocky islets; and its north coast is also very much strewed with them, even to a considerable distance from the shore.

The Guaianeco Islands are separated from the land of Wellington Island by a clear, but, in some parts, narrow passage. At its S. W. end it is contracted by rocks to a mile and a half, and at the south end of Byron Island is scarcely a mile broad; afterwards, however, it widens to two and a half and three miles.

The north point of Wellington Island is Cape San Roman. It is the west head of the Mesier Channel.

TARN BAY is about five leagues wide. The Ayautau Islands are four miles from the coast, but the interval is occupied by several rocky reefs, between which Lieutenant Skyring thought there seemed to be a sufficiently clear passage. The pilot Machado, however, thought differently. The latter describes a small boat-haven on the larger island, but it is among rocks. Opposite to Ayautau is a port, called by the missionary voyagers, San Policarpo; which, from its exposure to the westward, I should not think very inviting. The ports of Tianitau and Asaurituan are also mentioned by the missionary priests, in their journals. The former is described to have many islands in its entrance, and to be to the northward of San Policarpo; and the latter to be to the south of Tianitau, and opposite to Ayautau.

The Channel's Mouth of the old chart is laid down, as well as all this part of the coast, from Machado's account, who describes the opening, and gives it lat.  $47^{\circ} 23'$ , which is only 3 miles in error. We found it to extend in a S. E. direction for eleven miles, and then to divide into two arms, one trending 15 miles to the eastward, and the other eleven miles south, where they terminate. They are merely deep and narrow arms of the sea, running between steep-sided ranges of mountains. The shores are rocky, and afford neither coves nor bights, nor even shelter for a boat, and are perfectly unproductive; for no seals or birds were seen, and the shores were destitute even of shell-fish.

CAPE MACHADO, in lat.  $47^{\circ} 27' 35''$ , long.  $74^{\circ} 26' 10''$ , is the north head of this opening. Two miles off it are two rocks, which the pilot carefully and correctly de-

\* Machado, the pilot who explored this coast in the year 1769, by order of the Governor of Chile, Don Carlos de Beranger, describes these islands at some length, but with a little confusion of bearings. The north end of Rundle Pass, he calls the west end, and the south outlet, the eastern. Byron's Island, he describes as being the southern island. I think his Port Ballenas must be on the south side of Wager Island, for he describes it to be opposite to Cape Roman; therefore, Port Eustaquio should be on the north coast, probably in the strait within San Pedro Island.

scribes, as he also does the rocks and breakers which extend off the south head for nearly a league. The Beagle twice occupied an anchorage under the Hazard Isles, in the entrance, and on both occasions was detained many days from bad weather, with three anchors down.

Excepting this very bad and exposed anchorage, there exists none in the channel.— Captain Stokes describes it to be an extremely perilous anchorage. "The anchors," he says, "were in 23 fathoms, on a bad bottom, sand and coral. The squalls were terrifically violent. Astern, at the distance of half a cable's length, were rocks, and low rocky islets, upon which a furious surf raged, and on which the ship must have been inevitably driven, if the anchors, of which three were down, had started."

Between Channels Mouth and Jesuit Sound, the coast is more unbroken and low than usual. In lat.  $47^{\circ} 17'$  are some reefs which project two miles to sea; behind them there was an appearance of a bight, which may afford anchorage.

JESUIT SOUND, like Channels Mouth, is quite unfit to be entered by any ship. It terminates in two inlets, Benito and Julian. The former is bounded on either side by high mountains, and terminates in low land, with a rivulet that originates in a large glacier. The latter ends in high mountainous land, with streams of water between the hills: one part of it is clifty; and it has, on the S. W. side, a long sandy beach. In its entrance is a large island, making the passages on each side very narrow, and they are rendered still more so by rocks and islets.

Separated by Cheap Channel from the main is Xavier Island, the Montrose Island of Byron's Narrative. It is eleven miles and a half long, and four wide, and is very high and thickly wooded with lofty trees. The only two anchorages which the island affords are noticed and named by Machado, the northern one, Port Xavier, the southern Ignacio Bay.

The former is by much the better place, being secure from prevailing winds, with 17 fathoms at eight hundred yards from the shore. The south end of the bay is a sandy beach, backed by tall beach trees. The shore to the south of Xavier Bay, for the first four or five miles, consists of a high, steep clay cliff, with a narrow stony beach at its base, backed by mountains of twelve or fourteen hundred feet high, and covered by large and straight-stemmed trees. The remainder of the coast, to Ignacio Bay, is low, and slightly wooded with stunted trees; and its whole extent is lashed with a furious surf, that totally prevents boats from landing.

IGNACIO BAY affords anchorage in 9 fathoms. The western coast of the Island is lined by reefs extending two miles off, upon which the sea breaks high.

KELLY HARBOR is situated at the bottom of the north-east corner of the Gulf of Penas, in the bay formed between the land of St. Estevan Gulf and Xavier Island. It trends inwards in an easterly direction for eight miles. The land about the harbor is high, rugged and rocky, but by no means destitute of verdure. In the interior are lofty-peaked and craggy ranges of snow covered mountains. The points of the entrances are two miles asunder, and are thickly wooded, and low, compared with the adjacent land; their magnetic bearing is N.  $48^{\circ}$  E. and S.  $48^{\circ}$  W. Between them is a channel of from 35 to 40 fathoms deep, over a mud bottom, without danger, to a cable's length of the rocky islets that fringe the shore for a quarter of a mile off. On approaching the harbor the remarkable muddled appearance of the water is rather startling; but the discoloration proceeds only from the freshes of the river, and the streams produced from a very extensive glacier that occupies many miles of the country to the north. The plan will show the depth of water. The course is E. S. E. by compass, until in a line between the inner north point, and an inlet on the south shore that is fronted by five or six wooded islets. Then haul up along the larboard side of the harbor, as close to the shore and as far as you please to an anchorage. The best berth is when the two points of entrance are locked in with each other, and within a cable and a half of the sandy spit that extends off the western end of a high and thickly wooded island. The ground is excellent, and so tenacious, that it was with difficulty that the Beagle lifted her anchors. Shelter, wood and water, however, are the only advantages offered by the harbor. Environed by lofty mountains, some fourteen and eighteen hundred feet high, and ice-filled valleys and ravines—it is chill, damp and dreary. A few birds, and a small number of hair seals, were the only living animals seen by us. Not a trace of human beings was observed.

For knowing Kelly Harbor the glacier is a capital leading-mark. It is a large field of ice, lying on the low part of the coast, about 2 miles to the northward of the harbor. The water at the anchorage, at half tide, was perfectly fresh, but was too muddled to be fit for immediate use. When in the fair way of the harbor, the Sugar-loaf in Hollow Sound, will be seen just on with the end of the land, to the north of Purcell Island, bearing W.  $1^{\circ}$  N. by compass. The latitude of the north point of the harbor is  $46^{\circ} 59'$ , and the lon.  $74^{\circ} 5' 30''$ ; the variation about  $20^{\circ}$ . The mountain on the south shore,  $3\frac{1}{2}$  miles east southerly from the north point, is 1,540 feet high.

**ST. ESTEVAN GULF.**—The entrance of this gulf, which is situated 9 miles north of the N. E. end of Xavier Island, is 4 miles wide. The land on the western side, Forelius Peninsula, is a narrow tongue of land nearly 5 leagues long. The eastern side of the gulf is a long sandy beach, curving round to the N. W. towards the entrance of the River San Tadeo, between which and Cirujano Island, forming the south, (or rather the west,) point of entrance, the width is less than 5 miles; and at a league farther to the westward, it is not more than  $3\frac{1}{2}$  miles across. Here, in the centre, there is a small islet, called Dead Tree Island.

Beyond this is St. Quentin Sound, 10 miles deep; and, at its N. W. corner, Aldunate Inlet extends in for about 8 miles. St. Quentin's Sound terminates in continuous low land, with patches of sandy beach, over which, among other lofty mountains, the Dome of St. Paul's is seen. The shores are thickly wooded with shapely and well-grown trees; the land near the beach, for the most part, is low, rising into mountainous peaks; a little distance in the interior of which, some are 1,500 feet high, but they are not craggy.

**ST. ESTEVAN GULF** is one of the best harbors of the coast, being easy of access, and with moderate depth of water all over; with good holding ground, and a clean bottom. The best anchorage is at about 2 miles above Dead Tree Island, in from 4 to 6 fathoms, sandy bottom. This will be at 2 miles from either shore, but the berth is perfectly land-locked; and, if necessary, anchorage may be taken up much nearer to it.

**CIRUJANO ISLAND**, above mentioned, is that on which the surgeon of the Wager was buried.\* The missionary priests describe a port on the island, called San Tomas. The island is separated from the extremity of Forelius Peninsula by a strait, one mile to three quarters of a mile wide.

The mouth of the **RIVER SAN TADEO**, is easily distinguished on entering the gulf, by the sand hills on each side of its entrance, and the bearing of the east trend of Cirujano Island, S. W.  $\frac{1}{2}$  S. (by compass, S. by W.  $\frac{3}{4}$  W.) A sandy beach extends to the east and west of it for many miles; the land is low and marshy, and covered with stumps of dead trees. It has a bar entrance, much of which must be nearly dry at spring tides. A heavy swell breaks upon it for its whole length, so that no opening or swatch-way is left, and excepting in very fine weather, it is very hazardous to cross. At the mouth the breadth is not more than a quarter of a mile: but, within the entrance it opens to a basin of some extent; and at 3 miles up it is 300 yards wide, after which it gradually narrows. Nine miles from the entrance, the stream is divided into two arms; the Northern or Black River, takes a northerly, and the other an easterly direction. The former is a strong and rapid stream, quite uninfluenced by tide, which, however, extends for a short distance up the eastern arm; after which, the current down becomes gradually as strong as in the Black River. The banks of the latter are comparatively barren to those of the Black River, where the wood is very thick. The courses of both arms are very tortuous, and the bed of the river so choked with trunks and branches of trees, as to prevent its complete exploration, as well as the detection of the Desecho, the place where the Indians carry their canoes across the Isthmus of Osqui.

**PURCELL ISLAND** is separated from the land of Forelius Peninsula, by a good channel 2 miles wide; it is moderately high and thickly wooded, and about 6 miles in circuit. About mid-channel, and nearly abreast of the east end of the island, is a rock only a few feet above the water. The channel to the south of the rock, is from 18 to 22 fathoms deep, and the bottom sandy.

Upon the peninsula, opposite to the west end of Purcell Island, is an isthmus of low, sandy land, scarcely a mile wide; the one over which, I think it may be inferred from the narrative, that the canoes in which Byron and his companions were embarked, were carried. One day's journey by land to the west of this isthmus, Byron describes a river, up which the Indian guides attempted to take the Wager's barge. This river, if it exists, probably falls into Bad Bay.

The Beagle anchored in **BAD BAY** after dark, in 8 fathoms, sandy bottom, and left it at 9 o'clock the following morning. Of this place, captain Stokes remarks:—"At daylight we found that we had anchored in a small bay about half a mile off a shingle beach, on which, as well as on every part of the shore, a furious surf raged that effectually prevented our landing to get chronometer sights. The mouth of this bay is N.  $50^{\circ}$  E., mag., 9 leagues from Cape Tres Montes, which, in clear weather, may be seen from its mouth. Like all this shore of the gulf, it is completely open to the S. W. and

a heavy rolling sea south-east."

\* Of this circumstance I was informed by Pedro Osorio, an old soldier, whom I saw at Chiloe, who formed one of the party of the missionary voyages. I asked him why it was called El Cirujano, to which he replied: "Porque alli murio el cirujano del Wager." (Because the Surgeon of the Wager died there.) Pedro Osorio knew Byron's party well although it was 88 years since they visited the island.—See also Byron's Narrative, p. 147.

\* It was here that voyage, after the wre

a heavy rolling sea. About 9 A. M. we left it, and proceeded to trace the coast to the south-east.

To the westward, between Bad Bay and the land of Cape Tres Montes, is an extensive bight, 16 miles wide and about 12 deep. The centre is occupied by a group of islands, called Marine Islands,\* upon which the Sugar-loaf, a mountain 1,840 feet high, is very conspicuous; it was seen from the Wager the day before her wreck. Upon the main,  $5\frac{1}{2}$  miles N.  $15^{\circ}$  E. from the Sugar-loaf, is another equally remarkable mountain, called the Dome of St. Paul's, 2,284 feet high.

NEUMAN INLET, at the N. E. corner of this gulf, extends for 17 miles into the land, where it terminates; but it is of no use, as the water is too deep for anchorage. It is the resort of large numbers of hair seal. At the north-west corner is Hoppner Sound, about 5 miles in extent. At its south-west end is a deep inlet, extending 7 miles to the S. W. and reaching to within 2 miles of the sea coast, from which it is separated by an isthmus of low and thickly-wooded land. Captain Stokes walked across it to the sea-beach, from whence he saw Cape Raper. The Beagle anchored at the bottom of Hoppner Sound, off the mouth of the inlet. The mouth of the sound is very much blocked up by the Marine Islands; but the southern channel, although narrow, has plenty of water. On the south-west side of the Marine Islands is Holloway Sound, in which is Port Otway, an inlet extending for 5 miles into the land, in a S. W. direction.

The entrance of PORT OTWAY is on the west side of Holloway Sound, about 14 or 15 miles distant from Cape Tres Montes, and may be readily known by its being the first opening after passing the cape. Off the mouth are the Entrance Isles, among which is the Logan Rock, having a strong resemblance to the celebrated rock whose name it bears. It is broad and flat at the top, and decreases to its base, which is very small, and connected to the rock on which it seems to rest. Immediately within the entrance on the west shore is a sandy beach, over which a rivulet discharges itself into the bay. Here anchorage may be had in 9 or 10 fathoms. It is by far the most convenient one the port affords. The plan will show the particulars of the inlet, which contains anchorage all over it, but the depth is generally inconveniently great, from 20 to 30 fathoms.

CAPE TRES MONTES is a bold and remarkable headland, rising from the sea to the height of 2,000 feet. It lies in lat.  $46^{\circ} 58' 57''$ , and lon.  $75^{\circ} 27' 30''$ , and is the south extremity of the Peninsula of Tres Montes.

To the northward of it is Cape Raper, in lat.  $46^{\circ} 48' 25''$ . Rocks and breakers extend off it for half a league to seaward.

POINT MITFORD REES, the northernmost land seen by the Beagle, is in lat.  $46^{\circ} 43'$ .

Of the WIND AND WEATHER.—The climate of the coast of Western Patagonia, described in this section, is cold, damp, and tempestuous. The reigning wind is N. W.; but if it blows hard from that quarter, the wind is very liable to shift suddenly round to the westward and blow a heavy gale, which raises a mountainous cross sea. These westerly gales do not generally last long, but veer round to the southward, when the weather, if the barometer rises, will probably clear up. Should they, however, back round to the N. W. again, and the barometer keep low, or oscillate, the weather will, doubtless, be worse. Easterly winds are of rare occurrence; they are accompanied with fine clear weather; but westerly winds bring with them a constant fall of rain, and a quick succession of hard squalls of wind and hail.

Should a vessel be near the coast during one of these northerly gales, it would be advisable for her to make an offing as quickly as possible, to guard against the sudden shift to the westward that is almost certain to ensue. The discovery, however, of the anchorages of Port Henry, Port Santa Barbara, Port Otway, and St. Quentin's Sound, has very much reduced the dangers of the lee shore; and a refuge in either of them will always be preferable to passing a night on this coast in a gale of wind.

The barometer falls with northerly and westerly winds, but rises with southerly. It is at its minimum height with N. W. winds, and at its maximum when the wind is S. E. The temperature is rarely so low as 40 degrees, excepting in the winter months. At Port Otway, in the Gulf of Penas, the maximum and minimum for 19 days, in the month of June, were  $51^{\circ}$  and  $27\frac{1}{2}^{\circ}$ .

Of the TIDES.—High water, at most parts of this coast, takes place within half an hour on either side of noon. The stream is inconsiderable, and the rise and fall rarely more than 6 feet.

The variation of the compass, at the western entrance of the strait, is  $23\frac{1}{2}^{\circ}$ ; at Port Henry,  $21^{\circ}$ ; at Port Santa Barbara,  $19^{\circ}$ ; Xavier Island,  $20^{\circ}$ ; and at Port Otway,  $20\frac{1}{2}^{\circ}$ .

\* It was here that four Marines voluntarily remained on shore during Byron's perilous boat voyage, after the wreck of the Wager. Byron's Narrative, p. 85.

*Of the Interior Sounds and Channels between the Strait of Magalhaens and the Gulf of Penas.*

The western coast, between the Strait of Magalhaens and the Gulf of Penas, is formed by a succession of islands of considerable extent, the largest of which, Wellington Isl. and, occupies a length of coast of 138 miles. It is separated from the main by the Mesier and Wide Channels; and from Madre de Dios by the Gulf of Trinidad. Madre de Dios, which is probably composed of several islands, has for its inner or eastern boundary the Conception Strait.

HANOVER ISLAND has the Sarmiento and Esteven Channels on its eastern side, and on the south is separated from Queen Adelaide Archipelago by Lord Nelson Strait, which communicates by Smyth Channel with the Strait of Magalhaens.

SMYTH CHANNEL commences in the strait at Beaufort Bay, on the eastern side of Cape Phillip, N.  $78^{\circ}$  E.  $5\frac{1}{2}$  miles from which are the Fairway Isles; and at a little more than 6 miles from the cape, on the west shore, is the anchorage of Deep Harbor, the entrance of which is a quarter of a mile wide. The anchorage is about half a mile within the head, off the entrance of a lagoon, in from 30 to 35 fathoms. North and south of the port are inlets, each one mile deep. In entering, there is a patch of kelp on the starboard hand, and the shore is fronted for a short distance off by rocks.

GOOD'S BAY, the next anchorage, is better than the last, the depth being from 20 to 25 fathoms. It is convenient for vessels going to the northward, but when bound in the opposite direction North Anchorage will be better, from the depth being less; but it is small, and the entrance is more fronted by rocks than Good's Bay. It is not intended to anchor in either of the above places. The widest and best channel is to the eastward of Middle Island. There is a plan of these anchorages.

Off the N. E. point of Shoal Island is a rocky patch, upon which the Adelaide struck. The channel for the next four miles is rather intricate; but all the dangers are pointed out.

Opposite to Cape Colworth is Clapperton Inlet, beyond which is a considerable tract of low country, a rare sight in these regions. Two miles further, on the eastern side, is Hose Harbor, suitable for a small vessel; and on the opposite shore is Retreat Bay, fronted by low rocky islets. The depth within is 24 fathoms.

Onwards the channel is clear, as far as Oake Bay, where the depth is 9 fathoms; but the anchorage is better among the Otter Islands, the depth being 6 and 7 fathoms, and the ground clean.

The channel, for the next 8 miles, becomes more strewed with islands and rocks, and has much shoal water off every low point. The coast, also, is very low on the eastern shore, as far as the base of Mount Burney, which is 5,800 feet high, and covered with perpetual snow.

The best channel is on the east side of the Otter Islands, and between the Summer Isles and Long Island, for which the chart and a good lookout for kelp will be sufficient guides.

FORTUNE BAY is at the south-east extremity of, apparently, an island in the entrance of a deep channel, which is, probably, one that Mr. Cutler, the master of an American sealing vessel, passed through.\* Upon the supposition of its leading through the land, and insulating the western shore of Smyth Channel, to the north of Point Palmer. The latter is distinguished by the name of Rennel Island. Fortune Bay is a very convenient and good anchorage, the depth being moderate, and bottom good. The best berth is within Low Island, in from 8 to 12 fathoms. At the bottom of the bay is a thickly wooded valley, with a fresh water stream.

A league to the north of Point Palmer, on the opposite shore, is Isthmus Bay, affording excellent anchorage, but open to S. W. which here is not of much moment, for the channel is only two miles wide. The bottom of Isthmus Bay is formed by a very narrow strip of land separating it from what I have no doubt is Sarmiento's Oracion Bay. Five miles north of Point Palmer is Welcome Bay, also affording an excellent place to anchor in, with moderate depth and good bottom. A plan was made of it.

In SANDY BAY, on the east side of the channel, and off Inlet Bay, on the opposite shore, there are good anchorages. Both have a moderate depth, and are sheltered from the prevailing winds, which generally are north-westerly.

In lat.  $52^{\circ} 1'$  is Victory Passage, separating Zach Peninsula from Hunter Island, and communicating with Union Sound, which leads to the Ancon Sin Salida of Sarmiento.

\* We met this intelligent person two or three different times whilst employed upon the survey, and received much valuable, and what afterwards proved to be correct information from him, which I am here much gratified to have an opportunity of acknowledging.—[P. P. K.]

DISAPPOINTA vered with stunted a flat stony beach, within a quarter of

\* These islets were with birds.

On the west side of Hunter Island is Island Bay, with good anchorage both to the north and south of the islets. The Adelaide anchored in the latter in 17 fathoms.

At the south extremity of Piazzzi Island is Hauser Bay, with anchorage in from 7 to 15 fathoms. Here the channel widens to three miles and a half; but at two leagues farther on, near Ceres Island, under the S. E. end of which the Adelaide anchored in 10 fathoms, it narrows to two miles. Rocky Cove is not to be recommended, and Narrow Creek seems confined.

Hence to the mouth of the channel, which again widens here to 5 miles, and in which, during strong north-west winds, the sea runs heavy, we know of no anchorage; but a small vessel in want will doubtless find many, by sending her boat in search. The Adelaide anchored among the Diana Islands, and in Montague Bay, having passed through Heywood Passage. The northern point of Piazzzi Island is Saraiunto's West Point, (Punta del Oeste,) and a league to the south is his Punta de Mas-al-Oeste, or Pointmore-West. Lieutenant Skyring concludes the journal of his survey of Smyth Channel with the following remarks:

"So generally, indeed, do the northerly winds prevail, that it would be troublesome even for working vessels to make a passage to the northward; but it is a safe channel for small craft at any time. The tides are regular: the rise and fall at the southern entrance is 8 and 9 feet, but at the northern only 5 and 6. The flood tide always sets to the northward, and the strength of the stream is from half to one mile and a half an hour; so that a vessel is not so likely to be detained here for any length of time, as she would be in the Strait of Magalhaens, where there is little or no assistance felt from westerly tides. The channel besides is comparatively free from sea, and the winds are not so tempestuous."—[Skyring's MS.]

As the sounds within Smyth Channel will never be used for any purpose of navigation, little need be said in a work destined solely for the use of shipping frequenting the coast. The chart will be sufficient to refer to for every purpose of curiosity or information. They possess many anchorages for small vessels, affording both shelter and security.

Sarmiento, on his third boat voyage to discover a passage through the land into the Strait of Magalhaens, gives a detailed and very interesting account of his proceedings. All his descriptions are so good, that we had no hesitation in assigning positions to those places he mentions, to all of which his names have been appended. Cape Ano-nuevo cannot be mistaken, and the description of his Ancon Sin Salida is perfect. He says "the Morro of Ano-nuevo trends round to the S. E. and S. S. E. for a league, to the first water ravine that descends from the summit. In an east direction from this, appears a large mouth of a channel, about two leagues off. We went to it, and found it to be a bay without a thoroughfare, forming a cove to the north, about a league deep; so that, finding ourselves embayed, we returned to the entrance, which we had previously reached with great labor and fatigue. This bight has four islets. The bay, from the islets to the westward, has a sandy beach, backed by a low country for more than a league and a half to the Morro of Ano-nuevo."

The anchorages that were used by the Adelaide upon the examination of the interior sounds, were as follows:

**LEEWARD BAY**, exposed, and being upon the leeward shore, is not to be recommended.

**WHALE BOAT BAY**, about one mile to the east of Grey Cape.

A small cove on the north shore of Kirke Narrows, about a mile to the east of Cape Retford.

**FOG BAY**, two miles and a half to the north of the east end of Kirke Narrows.

**EASTER BAY**, a convenient anchorage within White Narrows.

The Canal of the Mountains, nearly 40 miles long, is bounded on each side by the high snow-capped Cordillera, the western side being by very much the higher land, and having a glacier of 20 miles in extent, running parallel with the canal. Eighteen miles from Cape Earnest, where the canal commences, the channel is contracted to the width of about half a mile; otherwise its width is from one to two miles.

**WORSLEY BAY AND SOUND** extend 15 miles into the land.

**LAST HOPE INLET** is 40 miles in length. Its mouth is  $3\frac{1}{2}$  miles wide, but at 8 miles the breadth is contracted by islands\* to less than a mile, the channel being 5 to 14 fathoms deep. Beyond this narrow the sound trends to the W. N. W.

**DISAPPOINTMENT BAY**.—The land at the bottom is very low, and thickly covered with stunted wood. Mr. Kirke traced its shores, and found them to be formed by a flat stony beach, and the water so shallow that the boat could seldom approach it within a quarter of a mile. A considerable body of water was noticed by him over the

\* These islets were covered with black-necked swans, and the sound generally is well stocked with birds.

low land, probably a larger lagoon, for it communicates with the bay by a rapid stream 50 yards wide. No high land was seen in an easterly direction; so that the country between Disappointment Bay and the eastern coast may probably be a continued pampa, or plain, like the coast of Eastern Patagonia.

**OBSTRUCTION SOUND** extends for thirty miles in a south by east direction, and then for fifteen more to the W. W. where it terminates. It is separated from the bottom of Skyring Water by a ridge of hills, perhaps twelve miles across. Some water was seen from a height, about six miles off, in the intervening space, but the shores were so carefully traced that Lieutenant Skyring, who examined it, feels satisfied that no communication exists. This question, however, will probably be set at rest by Captain Fitzroy, during his intended voyage.

A large plan was made of these sounds, to which a reference will give every desired information.

**SARMIENTO CHANNEL**, communicating between the east side of Piazzini Island and Staines Peninsula, continues to the northward of the mouth of Peel Inlet, where it joins the San Estevan Channel, from which it is separated by the islands of Vancouver and Esperanza. Between these is a passage nearly a league wide, but strewn with islands.

**RELIEF HARBOR**, at the south end of Vancouver Island, is a convenient anchorage; but the best hereabouts is Puerto Bueno, first noticed by Sarmiento. It affords excellent anchorage and a moderate depth of water, the latter of very unusual occurrence. A small cove, round the north point, called Schooner Cove, is well adapted for a small vessel, and may be used in preference even to Puerto Bueno.

In **SAN ESTEVAN CHANNEL**, Escape Bay, although small, is convenient and well sheltered. Opposite the south end of Esperanza Island is the deep opening of Ellen Bay, which may probably be a channel passing through and dividing Hanover Island. To the north the anchorages of Rejoice Harbor and Anchor Bay are commodious and useful.

**PEEL INLET** extends in for 7 leagues, communicating with Pitt Channel, and including Chatham Island, which is separated from the N. end of Hanover Island by a continuation of the Sarmiento and San Estevan Channels, of which the principal feature is the Guila Narrows.\* These narrows are 6 miles long, and, excepting the north end, where it is only one fifth of a mile wide, is from half to one mile broad. The tides here are not very rapid. High water at full and change takes place at 2h. 8m., the flood running to the southward. At the south entrance of San Estevan Channel, the reverse is the case, of which, for vessels passing through, some advantage may be taken.

The north-west coast of Chatham Island has many bights and coves fronted by islands, among which is Guard Bay, where the Adelaide anchored; but the coast is too exposed to the sea and prevailing winds, to offer much convenient or even secure shelter.

The north-west points of Hanover and Chatham Islands are more than ten miles apart, and midway between them is situated Sarmiento's Innocent's Island (Isla de los Inocentes.)

**CONCEPTION STRAIT** separates Madre de Dios and its island to the southward from the Main land. It commences at Cape Santiago, in lat.  $50^{\circ} 30'$ , and joins the Wide Channel, or Brazo Ancho of Sarmiento in  $50^{\circ} 5'$ . On the west side (the eastern coast of Madre de Dios) are several convenient anchorages, particularly Walker Bay, a bay to the north of Point Michael, and Tom Bay, all of which, being on the weather shore, afford secure anchorage; but the squalls off the high land are not less felt than in other parts.

**ST. ANDREW SOUND** is four leagues wide; but the mouth is much occupied by the Canning Isles, upon the northernmost of which, at the south-west end, is Portland Bay, a good anchorage for a small vessel, in 9 fathoms. The principal entrance of St. Andrew Sound is to the north of Chatham Island. It is 5 miles wide, and at 6 leagues within, divides into two arms: the northern one is 5 or 6 leagues long, and terminates; but the southern channel, which is Pitt Channel, trending behind Chatham Island, and communicates, as before mentioned, with Peel Inlet.

The anchorage of Expectation Bay, 5 leagues within the Sound, at the east extremity of the Kentish Isles, was used by the Adelaide in her examination of these inlets.

At **POINT BRAZO ANCHO** the Gulf of Trinidad commences, and the Conception Strait terminates; for its continuation to the north-east bears the name of Wide Channel, which is 40 miles long, and from  $1\frac{3}{4}$  to  $3\frac{1}{2}$  miles broad.

At **SAUMAREZ ISLAND** it joins the Mesier Channel, and to the N. E. communicates with Sir George Eyre Sound, which is 40 miles long, and with an average

\* So called after Sarmiento's Boat. It was by this route he passed down to the examination of his Ancon Sin Salida. He describes it as a narrow, 300 paces wide.

breadth of 4 miles, seals, and another.

keep close in with

breadth of 4 miles. Near the entrance on the east side was found a large rookery of seals, and another, 13 miles farther up, on the same side, in lat.  $48^{\circ} 21'$ .

The southern end of the Mesier Channel, for nearly 10 leagues, is named Indian Reach. It is narrow, and has many islets, but the water is deep. Then follows English Narrows, 12 miles long, and from half to one mile and a quarter wide; but many parts are contracted by islands to 400 yards. The passage lies on the west side of the channel, to the westward of all the islands.

From the north end of the narrows to the outlet of the Mesier, at Tarn Bay, in the Gulf of Penas, a distance of 75 miles, the channel is quite open and free from all impediment.

THE ANCHORAGES in the Wide and Mesier Channels, are more numerous than we have any account of. Those occupied by the Adelaide in her course through, are as follows, viz.:

FATAL BAY, in lat.  $47^{\circ} 55'$ , on the western shore, at the north entrance of the channel, insulating Millar Island. This bay is open and exposed.

ISLAND HARBOR, on the east shore, in lat.  $48^{\circ} 6' 30''$ , is a small but excellent land-locked anchorage, with good holding ground. Wood and water close at hand, and abundance of fish.

WATERFALL BAY, in lat.  $48^{\circ} 17'$ ; at the entrance of an inlet on the east side of the channel.

At this part of the Mesier Channel the tides are regular, and run 6 hours each way, the flood setting N. by W.

WHITE KELP COVE, on the north side of Lion Bay, about one mile within the head, is confined, and only fit for a small vessel.

HALT BAY, on the east shore, at the north end of the English Narrows, in lat.  $48^{\circ} 54'$ . Here the flood sets to the S. S. E., and the tide being confined by the narrow width of the channel, runs with considerable strength.

LEVEL BAY, on the eastern side of the channel, at the south end of the narrows, is in lat.  $49^{\circ} 7' 30''$ .

ROCKY BIGHT, opposite the north-east point of Saumarez Island, in from 17 to 12 fathoms.

FURY COVE, near Red Cape, the extremity of Exmouth Promontory. It is very confined, there not being room for more than two small vessels; but the ground is good, and although open to the S. W., it is a secure haven.

SANDY BAY, on the west shore of Wide Channel, in lat.  $49^{\circ} 45' 30''$ .

SMALL CRAFT BIGHT, also on the west shore, near the south end of the Wide Channel, is of small size, but answers every purpose of a stopping place for the night.

OPEN BAY, on the east shore, opposite the Gulf of Trinidad. The anchorage is sheltered by two islands; but it is too exposed to trust a vessel in, and therefore not to be recommended.

Besides the above anchorages, there are many equally convenient, and, perhaps, much better, that may be occupied by vessels navigating these channels. Every bight offers an anchorage, and almost any may be entered with safety. On all occasions the weather shore should be preferred, and a shelving coast is generally fronted by shoaler soundings, and more likely to afford moderate depth of water than the steep-sided coasts; for in the great depth of water alone consists the difficulty of navigating these channels.

Throughout the whole space between the Strait of Magalhães and the Gulf of Penas, there is abundance of wood and water, fish, shell-fish, celery, and birds.

*Remarks upon the Passage round Cape Horn, and to and from the Atlantic and Pacific Oceans, through the Strait of Magalhães.*

Ships bound from the Atlantic to any of the ports in the Pacific, will find it advantageous to keep within 100 miles of the coast of Eastern Patagonia, as well as to avoid the heavy sea that is raised by the westerly gales which prevail to the eastward, and increase in strength according to the distance from the land, as to profit by the variableness of the wind when fixed in the western board. Near the coast, from April to September, when the sun has north declination, the winds prevail more from the W. N. W. to N. N. W. than from any other quarter. Easterly gales are of very rare occurrence, but even when they do blow, the direction being obliquely upon the coast, I do not consider it at all hazardous to keep the land on board. In the opposite season, when the sun has south declination, the winds will incline from the southward of west, and frequently blow hard; but as the coast is a weather shore, the sea goes down immediately after the gale. In this season, although the winds are generally against a ship's making quick progress, yet as they seldom remain fixed in one point, and frequently shift backward and forward 6 or 8 points in as many hours, advantage may be taken of the change so as to keep close in with the coast.

Having once made the land, which should be done to the southward of Cape Blanco, it will be beneficial to keep it topping on the horizon, until the entrance of the Strait of Magalhaens be passed.

With respect to this part of the voyage, whether to pass through the *Strait le Maire*, or round Staten Island, much difference of opinion exists. Prudence, I think, suggests the latter; yet I should very reluctantly give up the opportunity that might offer of clearing the strait, and therefore of being so much more to windward. With a southerly wind, it would not be advisable to attempt the strait; for, with a weather tide, the sea runs very cross and deep, and might severely injure and endanger the safety of a small vessel, and to a large one do much damage. In calm weather it would be still more imprudent, (unless the western side of the strait can be reached, where a ship might anchor,) on account of the tide setting over to the Staten Island side, where, if it becomes necessary to anchor, it would necessarily be in very deep water, and close to the land. With a northerly wind the route seems not only practicable, but very advantageous, and it would require some resolution to give up the opportunity so invitingly offered. I doubt whether northerly winds, unless they are very strong, blow through the strait; if not, a ship is drifted over to the eastern shores, where, from the force of the tide, she must be quite unmanagable.

Captain Fitz Roy, whose authority, from his experience, must be very good, seems to think there is neither difficulty nor risk in passing the strait. The only danger that does exist, and that may be an imaginary one, is the failure of the wind. Ships passing through it from the south, are not so liable to the failure of the south-westerly wind, unless it be light, and then it will probably be from the N. W. at the northern end of the strait. The anchorage in Good Success Bay, however, is admirably situated, should the wind or tide fail.

In passing to leeward of Staten Island, the tide race, which extends for some distance off Cape St. John, at the N. E. end of the island, must be avoided, otherwise there exist no dangers.

The anchorage under New-Year's Islands, although it is a wild one and the bottom bad, and the tide very strong, yet offers good shelter from south-west winds, and might be occupied with advantage during the existence of a gale from that quarter, since it is unfavorable for ships bound round the Horn.

After passing Staten Island, if the wind be westerly, the ship should be kept upon the starboard tack, unless it veers to the southward of S. S. W. until she reaches the latitude of 60° south, and then upon that tack upon which most westing may be made. In this parallel, however, the wind is thought to prevail more from the eastward than from any other quarter. Never having passed round Cape Horn in the summer season, I may not perhaps be justified in opposing my opinion to that of others; who, having tried both seasons, give the preference to the summer months. The advantage of long days is certainly very great, but from my experience of the winds and weather during these opposite seasons at Port Famine, I preferred the winter passage; and in our subsequent experience of it, found no reason to alter my opinion. Easterly and northerly winds prevail in the winter off the cape, whilst southerly and westerly winds are constant during the summer months; and not only are the winds more favorable in the winter, but they are moderate in comparison to the fury of the summer gales.

Having passed the meridian of Cape Pillar, it will yet be advisable to take every opportunity of making westing in preference to nothing, until reaching the meridian of 82° or 84°, which will enable a ship to steer through the north-westerly winds that prevail between the parallels of 50° and 54°. (See Hall's South America, Appendix.)

With respect to the utility of the barometer as an indicator of the weather that is experienced off Cape Horn, I do not think it can be considered so unfailing a guide as it is in the lower or middle latitudes. Captain Fitz Roy, however, has a better opinion of the indications shown by this valuable instrument: my opinion is, that although the rise or fall precedes the change, yet it more frequently accompanies it. The following sketch of the movement of the barometer, and of the weather that we experienced, may not be without its use.

Being to the north of Staten Island for 3 days preceding full moon, which occurred on the 3d of April, 1829, we had very foggy weather, with light winds from the eastward and northward, causing a fall of the mercury from 29.90 to 29.56. On the day of full moon the column rose, and we had a beautiful morning, during which the high mountains of Staten Island were quite unclouded, as were also those of *Tierra del Fuego*. At noon, however, a fresh gale from the S. W. set in, and enveloped the land with a dense mist. No sooner had the wind changed, than the mercury rose to 29.95, but fell again the next morning; and with the descent the wind veered round to, and blew strong from N. W., with thick cloudy weather and rain, which continued until the following noon, when the wind veered to S. W., the barometer at 29.54, having slightly

risen; but after this when we had a fresh wind and continued to sail until it reached a change of wind, east, with squally weather.

The column now fell and showed a dull and showery day from the southward.

After this to the north and W. S. W., the wind more westerly; but the mean height of the mercury still rose.

With the wind at 28-80, a S. W. gale ceased to descend. In the month of January it usually rose to 30.5, at 12°.

The following is the position of the Observatory at Port Famine.

#### *Of the Passage to*

The difficulties well from adverse great, that the Strait they may be avoided; but by and weather, has and plans of the descriptions of the him with advice moved, but there large, or even any unless detention be.

In the eastern of the Strait of Magalhaens, where, in the side of the channel, and of reaching the Strait of passing the Strait, which place the difficulties are

risen; but after the change it fell and continued to descend gradually until midnight, when we had a fresh gale from W. S. W. When this wind set in, the mercury rose, and continued to rise, as the wind veered, without decreasing in strength, to S. S. W. until it reached 29.95, when it fell again and the weather moderated, but without any change of wind. During the descent of the mercury, the sky with us was dull and overcast, with squalls of wind and rain, but on shore it seemed to be very fine sunny weather.

The column now fell to 29.23, and during its descent the weather remained the same, dull and showery; but as soon as the mercury became stationary, a fresh breeze set in from the southward, with fine weather.

After this to new moon, the weather was very unsettled, the wind veering between S. and W. S. W., the barometer rising as it veered to the former, and falling as it became more westerly; but on no occasion did it precede the change.

The mean height of the barometer is about 29.5.

The mercury stands lowest with N. W. winds, and highest with S. E.

With the wind at N. W. or northerly, the mercury is low; if it falls to 29 inches or 28.80, a S. W. gale may be expected, but does not commence until the column has ceased to descend. It frequently, however, falls without being followed by this change. In the month of June, at Port Famine, the barometer fell to 28.17, and afterwards gradually rose to 30.5, which was followed by cold weather, in which the thermometer stood at 12°.

The following table shows the mean temperature and pressure as registered at the Observatory at Port Famine, in the Strait.

1829.	Temperature.	Pressure.
February,...	51.1	29.40

August, ....	33.2	29.28

*Of the Passage to and from the Atlantic and Pacific Oceans, by the Strait of Magalhães.*

The difficulties that present themselves to navigators, in passing round Cape Horn, as well from adverse winds as the severe gale and heavy sea that they are exposed to, are so great, that the Strait of Magalhães has naturally been looked to as a route by which they may be avoided. Hitherto no chart has existed in which much confidence could be placed; but by the present survey, the navigation through it, independent of wind and weather, has been rendered much easier; since a correct delineation of its shores, and plans of the anchorages, have been made; and in the preceding pages sufficient descriptions of them have been given to assure the navigator of his place, and furnish him with advice as to his proceedings. The local difficulties, therefore, have been removed, but there remain much more serious ones, which I should not recommend a large, or even any but a very active and fast-sailing square-rigged vessel, to encounter, unless detention be not an object of importance.

For a square-rigged vessel bound through the strait, the following directions will be useful:—

In the eastern entrance, the winds will frequently favor a ship's arrival off the First Narrows; where, if she selects a good anchorage on the bank which bounds the northern side of the channel, she may wait an opportunity of passing through the First Narrows, and of reaching Gregory Bay; where also a delay may safely be made, for the purpose of passing the Second Narrows and arriving at the neighborhood of Cape Negro; at which place the difficulties and dangers of the eastern entrance cease.

The dangers being carefully placed on the chart, and sufficiently described in the preceding part of this memoir, nothing need be repeated here; and indeed much must be left to the judgment and discretion of the navigator.

The passage of the First Narrow, the anchorage to the eastward of, and in, Gregory Bay, the passage of the Second Narrow, the anchorage to the north of Elizabeth Island, and the passage round its south side, have already been described.

The tides answer best for vessels entering the Strait at the period of full and change of the moon, since there are two westerly tides in the day. In the winter season, if the morning tide be not sufficient to carry a vessel through the First Narrow, she may return to Possession Bay, select an anchorage, and be secured again before night; or, in the summer, if she has passed the Narrow, and enabled to anchor for the tide, there will be sufficient daylight for her to proceed with the following tide to Gregory Bay, or at least to a safe anchorage off the peaked hillocks, on the north shore.

I have twice attempted to pass the First Narrow, and been obliged to return to the anchorage in Possession Bay; and twice I have passed through it against a strong breeze blowing directly through, by aid of the tide; which runs, in the narrower parts, at the rate of 10 or 12 miles an hour. When the tide and wind are opposed to each other, the sea is very deep and heavy, and breaks high over the decks; it is, therefore, advisable to close reef, or lower the topsails on the cap, and drift through; for the tide, if at the springs, will generally be sufficient to carry a ship to an anchorage, although not always to one that it would be safe to pass the night at. On this account, it would be prudent to return; for, although the holding ground is exceedingly good, yet, to part in the night, or drift towards, or through the Narrow, could scarcely happen without accident.

In leaving the anchorage in Gregory Bay, attention must be paid to the tide, which continues to run to the eastward in the Second Narrow, 3 hours after it has commenced to set to the S. W. at the anchorage.

With a leading wind through the Second Narrow, a ship will easily reach an anchorage off Laredo Bay; but if the tide fails upon emerging from it, she should seek for a berth in the bay to the north of Elizabeth Island, as near to the island as possible, but to the westward of its N. E. end, to be out of the influence of the tide. The depth of water, however, will be the best guide.

Directions to pass round the south side of Elizabeth Island have already been given; and as this part offers some dangers, the chart and the description should be carefully referred to.

The only advice that seems wanting to improve the directions of the coast from this to Port Famine, is, with a south-westerly wind, to keep close to the weather shore, in order to benefit by the flaws down the valleys; but this must be done with caution, in consequence of the squalls off the high land, the violence of which, to a person unaccustomed to them, cannot be well imagined.

The fourth section gives an account of the anchorages between Port Famine and Cape Froward, of which the only convenient one for a ship is St. Nicholas Bay, and to which, if defeated in passing round the cape, a ship had better return; for it is easy to reach as well as to leave, and extremely convenient to stop at, to await an opportunity of proceeding.

From Cape Froward to the westward, unless favored by a fair wind, it is necessary to persevere and take advantage of every opportunity of advancing step by step. There are several anchorages that a ship may take up, such as Snug Bay, off Wood's Bay, near Cape Coventry, in Fortescue Bay, Elizabeth Bay, and York Roads. These are before described. To the westward, in Crooked Reach, the anchorages are not so good, and, excepting Borja Bay, none seem to offer much convenience. Borja Bay, however, is well calculated to supply the deficiency, although for a square-rigged vessel there must be some difficulty in reaching it.

LONG REACH is both long and narrow, and ill supplied with anchorages for a ship. Such as they are, Swallow Harbor, Playa Parda, Marian's Cove, and Half Port Bay, seem to be the best. In thick weather, although the channel is very narrow, yet one side is scarcely visible from the other, and the only advantage it has over other parts of the strait is the smoothness of the water. In Sea Reach there is a heavy rolling swell, with a short and deep sea, which renders it very difficult to beat to windward.

TAMAR HARBOR, Valentine Harbor, Tuesday Cove, and the Harbor of Mercy, are the best anchorages; and the latter is particularly convenient to occupy, to await an opportunity of sailing out of the strait.

In the entrance the sea runs very heavy and irregularly during and after a gale; so that a ship should not leave her anchorage in the harbor of Mercy, without a fair or a leading wind to get her quickly through it.

For small vessels, particularly if they be fore-and-aft rigged, many, if not all of the local difficulties vanish; and inlets which a ship dare not or cannot approach, may be

entered with safety, be better off in entering a heavy sea; but for advantage. She has the wind be north-west the Pacific.

One very great opportunity of obtaining difficulty. Another months, from January Famine, at the first fish are also caught morning or late in place where there is On the outer coast

entered with safety, and anchorage easily obtained by them. A large ship will perhaps be better off in entering and leaving the strait where there is open space, and frequently a heavy sea; but for the navigation of the strait, a small vessel has considerably the advantage. She has also the opportunity of passing through the Cockburn Channel, should the wind be north-westerly, which will very much reduce the length of the passage into the Pacific.

One very great advantage to be derived from the passage through the strait is, the opportunity of obtaining as much wood and water as can be required, without the least difficulty. Another great advantage is, that by hauling the seine during the summer months, from January to May, at the mouth of the river or along the beaches in Port Famine, at the first quarter flood, a plentiful supply of fish may be obtained. Excellent fish are also caught at the anchorage with the hook and line, at all seasons, early in the morning or late in the evening. Fish may also be obtained with the seine at any other place where there are rivers. Freshwater Bay and Port Gallant are equally productive. On the outer coast of Tierra del Fuego an excellent fish may be caught in the kelp.

*Directions for passing through the Strait of Magalhães, from the Pacific to the Atlantic.*

The advantage which a ship will derive from passing through the strait, from the Pacific to the Atlantic—for there must be some great one to induce the seaman to entangle his ship with the land when fair winds and an open sea are before him—is very great. After passing through the strait, the prevailing winds being westerly, and more frequently from the northward than from the southward of west, they are fair for his running up the coast; or if not, the ship is not liable to receive much injury from the sea, which is comparatively smooth; whereas, to a ship passing round the Horn, if the wind be north-west she must go to the eastward of the Falkland Islands, and be exposed to strong gales, and a heavy beam sea, and hug the wind to make her northing. To a small vessel the advantage is incalculable; for, besides filling her hold with wood and water, she is enabled to escape the severe weather that so constantly reigns in the higher latitudes of the South Atlantic Ocean.

Coming from the northward it will be advisable to keep an offing until the western entrance of the strait is well under the lee, to avoid being thrown upon the coast to the northward of Cape Victory, which is rugged and inhospitable, and, forming as it were a breakwater to the deep rolling swell of the ocean, is for some miles off fringed by a cross hollow sea almost amounting to a rippling.

The land of Cape Victory is high and rugged, and much broken; and if the weather be not very thick, will be seen long before the Evangelists, which are not visible above the horizon from a ship's deck, for more than four or five leagues.\* Pass to the southward of them, and steer for Cape Pillar, which makes like a high island. In calm weather do not pass too near to the cape, for the current sometimes sets out, and round the Cape to the southward; but with a strong wind get under the lee of it as soon as you please, and steer along the shore. In the night it will be advisable to keep close to the land of the south shore; and if a patent log be used, which no ship should be without, your distance will be correctly known. The course along shore, by compass, is E.  $\frac{1}{2}$  S. and if the weather be thick, by keeping sight of the south shore, there will be no difficulty in proceeding with safety.

The Adventure entered the strait on the 1st of April, 1830, at sunset; and after passing within half a mile of the islets off the Harbor of Mercy, steered E.  $\frac{1}{2}$  S., mag., under close reefed topsails, braced by, the weather being so squally and thick that the land was frequently concealed from us; but, it being occasionally seen, the water being quite smooth, and the course steadily steered, with the patent log to mark the distance run, we proceeded without the least anxiety, although the night was dark and the squalls of wind and rain frequent and violent. When abreast of Cape Tamar, that projection was clearly distinguished, as was also the land of Cape Providence, which served to check the distance shown by the patent log, but both giving the same results proved that we had not been subjected to any current; whereas the account by the ship's log was very much in error, in consequence of the violence of the squalls and the long intervals of light winds, which rendered it impossible to keep a correct account of the distance. At daybreak we were between Cape Monday and the Gulf of Xanitegua; and at 8 o'clock we were abreast of Playa Parda, in which, after a calm day, the ship was anchored.

In the summer season there is no occasion to anchor any where, unless the weather be very tempestuous, for the nights are short and hardly dark enough to require it, unless as a precautionary measure, or for the purpose of procuring wood and water, the

\* From the Adventure's deck, the eye being thirteen feet above the water, they were seen on the horizon at the distance of fourteen miles.

best place for which is Port Famine, where the beaches are strewed with abundance of logs of well seasoned wood, which is very superior to the green wood that must otherwise be used.

Notwithstanding the Adventure experienced no current in the western part of the strait, there is generally a set to the eastward, which is more or less felt according to circumstances. The direction and strength of the currents are caused by the duration of the gales.

The chart will be a sufficient guide for vessels bound through from the westward as far as Laredo Bay, after which a few directions will be necessary. The land here should be kept close on board, to avoid the reef off the south-west end of Santa Magdalena. Being abreast of it, bear away, keeping the north-east extremity of Elizabeth Island on the starboard bow, until you see Santa Martha in one with, or a little to the southward of, the south trend of the Second Narrow, (Cape St. Vincent,) which is the leading mark for the fair channel until you pass the spit of shoal soundings, which extends across to St. Magdalena. There are also shoal soundings towards the south-west end of Elizabeth Island. At half a mile off we had 5 fathoms, Cape St. Vincent being then the breadth of Santa Martha open to the northward of that island. Keeping the cape just in sight to the northward of Santa Martha, steer on and pass round the low N. E. extremity of Elizabeth Island, off which are several tide eddies. The tide here sets across the channel.

Now steer for the Second Narrow, keeping Cape Gregory, which will be just discernible as the low projecting extreme of the north side of the Second Narrow, on the starboard bow, until you are three miles past Santa Martha. The course may then be directed for the cape, opening it gradually on the larboard bow as you approach it, to avoid the shoal that extends off it.

If you anchor in Gregory Bay, which is advisable, in order to have the whole of the tide for running through the First Narrow, haul up and keep at a mile and a half from the shore. When the north extremity of the sandy land of the Cape is in a line with the west extreme of the high table land, you will be near the anchorage; then shorten sail, and when the green slope begins to open, you will have 14 fathoms: you may then anchor or keep away to the N. E. and choose a convenient depth, taking care not to approach the shore, so as to bring Cape Gregory to the southward of S. by W.  $\frac{1}{4}$  W. (by compass.) The best berth is with the Cape bearing S. S. W.

Hence, to the First Narrow the course by compass is due N. E. by E.\* The land at the entrance, being low, will not at first be perceived, but on steering on you will first see some hummocky land, making like islands. These are hills on the eastern or Fuegian side of the Narrow. Soon afterwards a flat low sand hill will be seen to the northward, and this is at the S. W. extremity of Point Barranca. On approaching the Narrow at 4 miles off, keep a cliffy head, 4 or 5 miles within the east side of the Narrow, open of the trend of Point Barranca, by which you will avoid the shoal that extends off the latter point. You should not go into less depth than 6 fathoms. At most times of the tide there are long lines and patches of strong ripplings through which you must pass. The shoal is easily distinguished by the kelp.

When the channel through the narrow bears by compass N. by E.  $\frac{3}{4}$  E., steer through it; and that, or a N. N. E. course will carry you through. On each side, the bank extends off for some distance; but by keeping in mid-channel, there is no danger until the cliffy coast be passed, when reefs extend off either shore for some distance, particularly off Cape Orange. The N. N. E. course must be kept until the Peak of Cape Orange bears S., and the northern Direction Hill W. S. W. or W. by S.  $\frac{1}{4}$  S. by compass. Then steer E. N. E. for Cape Possession, taking care not to approach too near to the bank off Cape Orange, or the one on the north side of Possession Bay, for which the chart must be consulted.

For a small vessel, the passage through the strait from west to east is not only easy, but to be strongly recommended as the best and safest route. Indeed, I think the passage would be quite as expeditions, and, perhaps, much safer to enter the Gulf of Trinidad, and pass down the Conception Strait, the Sarmiento or St. Estevan Channels, and Smyth's Channel, and enter the strait at Cape Tamar. In these channels northerly winds prevail, and there is no want of convenient and well-sheltered anchorages for the night, many of which have already been mentioned, and multitudes of others, and perhaps much better ones, might be found.

\* If from the Second Narrow, N. E.  $\frac{1}{4}$  E. will be the compass course; but I should recommend a ship hauling up to the northward until abreast of Cape Gregory, and then to steer as above.

## GULF STREAM, AND STRAIT OF FLORIDA.

That immense current which continually sets from the Gulfs of Mexico and Florida, to the northward and north-eastward, should be well understood, as all who navigate the coast of North America, experience more or less of its influence.

Three degrees to the N. N. E. of Vera Cruz, the current has been found setting to the N. E. one mile an hour. Then N. N. E. and N. by E., and again N. E., nearly to the parallel of  $25\frac{1}{2}^{\circ}$ , long.  $91\frac{1}{2}^{\circ}$ . Here it changes more to the east, and becomes, in lat.  $26^{\circ}$  E. by S., changing southward to S. E. by S. In the direction of the River Mississippi, and lat.  $25^{\circ} 30'$  N., the current sets variously to the south-eastward. Its extent and exact direction are here unknown, but it is certain, that setting towards the N. W. part of Cuba, and striking on the banks of Isabella and Colorados, a portion of it winds round Cape Antonio to the south-eastward, while the great body of it sets eastward, to the northward of Cuba, winding to E. N. E., N. E., and N., through the Strait of Florida, into the Atlantic Ocean.

The Derrotero de las Antillas says, "By the Strait of Florida, we understand the space included between the meridian of the Dry Tortugas, and the parallel of Cape Canaveral. The simple inspection of the chart will show this to be a bed or course, which, like a river, conducts the water to the northward. This river, or general current, flows first to the E. N. E. as far as the meridian of the western part of the Double Shot Keys, by which keys the stream is diverted from E. N. E. to N. by E., the direction which it pursues on the parallel of Cape Florida; thence to Cape Canaveral it runs north, inclining a little to the east.

"On the meridian of the Havana; stripes of current are at times found setting to the E. S. E. and S. E. from the Tortugas soundings. Care should be taken not to confuse the southern differences, caused by this branch of the current, with those caused by the eddy current near the Colorados—the one giving eastern departure, the other west. The distinction is very clear, and can admit of no doubt, because the eddy current is met only from the meridians of Cavanas and Bay Honda to Cape Antonio, and not farther out from the coast than the parallel of 23 degrees.

"As the velocity of the current varies, it is requisite for every navigator to ascertain its strength as frequently as possible, while within the stream. Every one who enters this channel, having marked well either the lands of Cuba or the Florida Reef, so as accurately to establish this point of departure, ought to determine in his first day's work, the velocity of the current by the difference of latitude, by account and observation. We say during the first day's work, because the generality of common navigators make use of meridian altitudes of the sun alone, to find the latitude; but it is very clear, that altitudes of the planets and fixed stars ought not to be neglected; not only because by this you cannot be in doubt of your real latitude, but also because they may be more exact than latitudes deduced from meridian altitudes of the sun, when that luminary passes in the proximity of the zenith, and because these repeated observations during the night assume, as much as possible, the situation of the ship. Thus you may go on, with a clear idea of the operation of the current, and the way that the ship is making. Having ascertained the velocity of the current, use can be made of it to find the ship's departure, and this knowledge will be most important when you fail in obtaining observations for latitude; because, in such a case, wanting a knowledge of the difference of latitude given by the current, you will be in want of every thing; but if you know the velocity of the current, and with it the course which it follows, you may find the difference of latitude and departure which the current gives, and which, though it will not give the position of the ship with that precision with which it might be obtained by latitude observed, will still approximate sufficiently to the truth to enable one to avoid danger, if prudence and seaman-like conduct are combined."

For those who have little experience in the art of navigation, we add—

1. That it is most convenient to direct your course in mid-channel, not only because it is the farthest from danger, but because you will there have the strongest current, which is desirable. (See Remarks of Mr. Romans on the Gulf Stream.)

2. That, as you cannot ascertain with all necessary certainty the position of the ship, notwithstanding the rules given to diminish the errors occasioned by the currents, you ought, with the utmost care, to shun the eastern coast of Florida, as being very danger-

ous, the trade wind blowing upon it, while there is not the least risk in running along the Salt Key Bank, and the edge of the Great Bank of Bahama. Upon the latter, also, you meet with good anchorages, very fit to lie in during the hard northerly gales experienced between November and March, and which do not fail to cause much damage, and sometimes even force vessels to bear away, which is always dangerous, for the weather is generally thick, with such winds, and the greatest danger will be to run, in one of them, ashore upon the coast of Cuba, when hoping to have made Havana or Matanzas. Therefore, so soon as there is an appearance of a northerly gale, the best way is, if near the Salt Key Bank, to anchor on it; and if near the Great Bank, to approach the edge of it, in order to be able to anchor when it may be necessary; for, although you may have a hard norther, so long as you can lie to in it, you ought to pursue your voyage, as the current will certainly carry the ship through the strait.

3. It is very necessary to sight the keys on the bank, even though you have no fear of a norther, and there may be occasions in which every exertion should be made to see them, especially if, from want of observations, the situation of the ship is not well known.

4. When, owing to calms or light winds, a vessel not bound to the northward is in danger of being carried through the strait by the current, she ought immediately to approach the edge of the Salt Key Bank, or of the Great Bahama Bank, and return from thence by the Santaren Channel to the coast of Cuba, without trying to beat back the lost ground; for by doing this, she would only render the chance of being carried through more certain.

5. Should you involuntarily approach the coast of Florida, you should take extraordinary care to examine whether you have advanced out of the general current, and into the eddy. That you may know this, observe the eddy forms a remarkable and visible line between it and the general current, which line of division is, in many places, out of sight of land; that in general you have no soundings on it, and that it shows, not only by the change in the color of the water, but that also in it, during the greatest calms, there is a kind of boiling or overfalling of the water. From this line of division the water gradually changes color, so that near the Florida Keys it is a beautiful sea green, and at last it becomes almost as white as milk.

6. When in the eddy, you have to make the correction of currents on courses entirely different from those in the stream. This is the more necessary to be attended to, because, from ignorance of this circumstance, many have been shipwrecked.

7. When you enter the channel, or strait, from the Tortugas Bank, with the intention of passing through, take care to become certain of the land of Cuba, or some part of the Reef of Florida, in order to have a good departure; for although the latitudes and soundings on the Tortugas Bank are more than sufficient to ascertain the place of the ship, yet the variable set of the current toward the Havana may produce a serious error, if not properly attended to. The meridian of the Havana is, in a word, the best point of departure for ships bound to the north-eastward.

At about  $3\frac{1}{2}$  degrees north of Cape Antonio, the current has at times been found setting to the S. W., winding towards the northern edge of the Yucatan Bank; but at a degree thence eastward, setting nearly S. E. Off the west end of Cuba, at 10 leagues N. W. from Cape St. Antonio, it has been found setting S. W. by W. one mile an hour. But these cannot be considered as its "general directions."

The stream in mid-channel, on the meridian of Havana, acquires the direction of E. N. E., and velocity of about  $2\frac{1}{2}$  miles an hour. On the meridian of the southernmost point of Florida its velocity, at about one third over from the Florida Reefs, is commonly 4 miles. Between the Bemini Isles and Cape Florida, its direction is about N. by E., and velocity more than 4 miles.\*

On the Cuba side the stream is weak, and it sets to the eastward. On the opposite side, along the Florida Reefs and Keys, there is a re-flow or counter current, setting to the S. W. and W. By the assistance of the latter, many small vessels have navigated through the strait from the northward; but this navigation is too dangerous to be attempted by strangers. The tides set strong among these reefs, and are more particularly described in this work.

The winds are found to affect the position of the stream considerably. Between Cuba and Florida northerly winds press it southward towards the shore of the former; southerly winds have a contrary effect. When turned to the north, easterly winds press it to the Florida side, and westerly winds nearer to the Bahamas. Southerly winds cause it to spread, and so may those from the north.

\* "The calculations of the velocity of the Gulf Stream are not to be depended upon. I have found it setting at the rate of 5 knots, and even upwards. This was on the 16th and 17th of August, 1817. On the 19th and 20th February, 1819, it seemed to be imperceptible. In September, 1819, it set at much about the rate described in the chart."

In the Strait of Florida, within the Bahamas, when a northerly gale increases to a storm, it opposes the stream in its course, though adverse power causes it to fill all the channels and openings among the Martyr Isles and Reefs, and to overflow all the low coast. Shipping have even been carried over the low keys, and left dry on shore.\* The water is supposed at times to have arisen to the height of 30 feet, and to have been running against the fury of the winds at the rate of 7 miles an hour. During these times the Strait of Florida exhibits a scene terrific beyond description.

*Remarks on the Stream, &c. by Captain J. Steele Park.*

"Sailed from Jamaica for London, on the 20th May, 1824. At noon, on the 27th, was off the S. W. side of Cuba, in latitude  $21^{\circ} 26'$ , longitude by chronometers and lunars  $84^{\circ} 47' W$ . Here was discovered a current setting to the N. W. at the rate of two miles an hour. At 7h. 30m. Cape Antonio bore N. W. 5 or 6 miles. The current to the N. W." says Capt. Park, "swept us into the Gulf of Mexico; and there we were beating about three or four days, making nothing and westing in spite of our teeth. All this time the wind was easterly, and we might have cruised about there till Christmas, had the wind not got a little to the southward of east, which enabled us to get over to the N. E. side, where we found the current running directly opposite to the former, being now in the Florida Stream.

"After rounding Cape Antonio, the land of Cuba was not seen. At this time, (the latter days of May, 1824) the Stream along the Florida side, and even in the Strait, was by no means so strong as it is generally found. In the narrowest part, where, of course, we had a right to expect the greatest velocity, it was running at the rate of only  $2\frac{1}{2}$  miles in the hour. This was correctly ascertained by meridian altitudes of sun and moon, and an excellent chronometer.

"When we cleared the Gulf," (Strait) Capt. Park adds, "I was anxious to keep in the influence of the Stream, and pass near the Tail of the Bank of Newfoundland, but it came on to blow hard from the northward, in latitude  $34^{\circ} 35'$ , and longitude  $72^{\circ} 20'$  (E. by S. from Cape Hatteras.†) This, of course, drove us away to the eastward, out of the favorite track, and we passed about 300 miles to the northward of the Bermudas. During this gale, for several days a current was found to proceed from the eastward to the W. S. W. but in latitude  $38^{\circ}$  and longitude about  $59^{\circ}$ , the ship was in the Gulf Stream setting finely to the N. E.

"On June 23d, at noon, lat.  $37^{\circ} 51'$ , long.  $61^{\circ} 54'$ ; June 24th, lat.  $39^{\circ} 56'$ , long.  $57^{\circ} 26'$  (by altitudes and chronometer.) Here the ship really made  $4^{\circ} 28'$  of easting in the 24 hours run, and the log gave only  $3^{\circ} 16'$ . In the same time nothing was made. The true difference of latitude was 125 minutes, but the log gave about 80 only. The vessel had been running all the time E. by N. by compass, and went through the water 173 miles. Allowing half a point of variation, gives the true course N. E. by E.  $\frac{1}{2}$  E. Subsequently, on making Scilly, there was not an error in the watch of a single mile.

"After the gale from the northward subsided, the winds became variable between N. W. and S. W. The ship passed near the Tail of the Great Bank, and continued to carry a fine north-easterly current at the rate of 30, 25, and 20 miles a day, until she reached lat.  $43^{\circ} 35'$  and lon.  $36^{\circ} 50'$ , where it ceased."

\* In the month of September, 1769, there happened an inundation, which covered the tops of the highest trees on the Cayo Larga, &c., and during which the Ledbury Snow, John Lorain, master, was carried over the reef by the N. W. current of the stream, caused by a gale from N. E. The vessel bilged in shallow water, but an anchor was thrown out, and the next day the vessel was found to have grounded on Elliot's Key, with its anchor among the trees.—[De Braham's Atlantic Pilot.]

† A scientific navigator says, "When in the Gulf, eastward of Hatteras, I generally endeavor to get out of it as early as possible, especially with a strong N. E. wind, for I think the advantage of the current will not compensate for the effects of the destructive sea and squally weather, which generally attend that part of the ocean."

From the S. W. corner of the Tortugas Bank, the current has, at times, been found to set S. S. W. directly over to the Colorados. But between the Tortugas and Bay Hunda, or Port Cavanas, it takes its regular set to the eastward.

The boisterous east, N. E. and N. winds, which affect the Gulf Stream, generally begin in September, and continue until March.

On the southern edge of the Tortugas Soundings, lat. 24° 30', long. 83° 30', the current sets about E. by S. 20 miles in the 24 hours; and in lat. 24°, long. 82° 20', it sets about E. by N. 42 miles.

*Remarks on the Stream, by Captain W. J. Monteath.*

Between latitude 25° 40', and 28° 20', Captain Monteath found the current in the Strait had set 80 miles in the 24 hours of June 27, 1820. On the southern border of the stream, (northward of the parallel of Cape Hatteras,) 6th July, 1820, lat. 35° 20' to 36° 30', long. 72° 30' to 71° 3', Captain M. found the current setting N. E. 75 miles in the 24 hours. Next day, July 7, to lat. 37° 40', long. 69°, he found it N. 53° E. 86 miles in 24 hours. On the following day, July 8, to lat. 38° 38', long. 67°, it ran N. 58° E. 30 miles. July 9, to lat. 39° 10', long. 66° 10' westward, only 10 miles. The observations were continued each day by Chronometer, which agreed within a few miles.

The Stream, from lat. 26° to 28°, generally sets north, rather easterly; from 25° to about 31°, it appears to run north, inclining a little in the direction of the coast, rather westerly; it thence suddenly turns to N. E. by E. or a little more easterly, to latitude 35°, or about the parallel of Cape Hatteras, where it runs within about 18 miles of the Cape.

The Stream, in the neighborhood of the coast at Cape Hatteras, inclines more to the eastward, at the rate of about 2½ knots; then the shoals of Nantucket appear to front it, and to throw it off to the E. N. E. and E. by N. northerly. In about the parallel of 39½°, longitude 63½°, it has been found to run at the rate of two knots between E. by N. and E. N. E.

Col. Williams, in his "Thermometrical Navigation," states that the whirlpools on the northern edge of the Stream, have been seen in lat. 41° 57', long. 65° 1'. He also observed great quantities of weed, supposed to be on the northern edge of the Stream in latitude 41° 53', long. 65° 33'. It has subsequently been ascertained by Lieut. Charles Hare, R. N. that on the meridian of 57° W. in the summer season, the northern edge of the Stream ranges up to 42½° N. and even in the winter months to above 42° N. This has been confirmed by twenty-five voyages across the Atlantic, assisted by chronometer, thermometer, &c., the last of which was made in the fall of the year 1824.

It is, however, to be considered, that a north, N. E. or east wind forces the Stream towards the coast, contracts its breadth, and thus increases its rapidity. On the contrary, S. W. west and N. W. winds, &c. &c. the stream farther into the ocean, and diminishes its strength.\* It is clear, then, that the Stream fluctuates in its direction and

\* An experienced navigator, before quoted, says "It is always found that the strongest current is in the warmest water. I have observed the greatest degree of heat of the Gulf, between the meridian of Cape Hatteras, and that of Nantucket, to vary at different times from 75° to 67° of Fah-

force, according to circumstances, and no absolute rule can be given for ascertaining its more ordinary boundaries; it therefore follows, that a description of the indications by which it may be known, is of more importance. These are, the appearance and temperature of the water; the Stream in its lower latitudes, and usual course in fair weather, where it flows uninterruptedly, may be known by its smooth and clear surface, and blue color. The margin of the Stream is marked by a ripple on its edge; the water in some places appears like boiling water; and in other places, it foams like the waters of a cataract, even in dead calms, and in places which are fathomless; and during strong N. E. winds, that part from Cape Roman to the north and east breaks violently, so much so that it has been mistaken for shoals during the night.

On the outer edge of the Stream, especially in fair weather, there are great ripplings, which are very perceptible; and it has been observed, by many navigators, that in the Gulf the water does not sparkle in the night, but with south-easterly winds it does as much as in other parts of the ocean. The appearance of the weed called Gulf-weed is also an indication of being in or near the Stream, as it is never seen far north of it.

By the advantage of knowing how near to the coast a ship may venture, and how to distinguish the Gulf Stream from the water between it and the coast, we can be sure of a favorable current either way; and a small vessel might make a short voyage from Halifax to Georgia, which is thought by some a longer one than to Europe. Suppose you had the wind a-head all the way: take your departure and stand for the Stream: so soon as you find the water to increase in heat about half as much as you know it would when in the stream, heave about and stand for the coast; you will infallibly discover the edge of soundings by the cooling of the water; then stand off again, and so on to the end of the voyage; when it is almost certain, that the distance would be run in a shorter time than if there were no Stream, for you would have a favorable inside current. On the return passage, take your departure, and run off till you get into the warmest water, which will be the middle of the stream, and take the advantage of its currents.

The following fact may serve to illustrate the propriety of these directions. In June, 1798, the Mail-Packet for Charleston, had 25 days' passage in going, but returned in 7. The captain accounted for this by having calms, or very light airs and a northerly current. This was the true cause. He was in the middle of the stream, where there generally are calms or light winds; the edges only, which come in contact with colder regions, being tempestuous. After being in the latitude of Cape Hatteras, he found himself in that of Cape Henry, (37 leagues to the northward.) The vessel, however, arrived at last; and on the return voyage, the captain steered the same course back again; and, with the same light airs, he performed the voyage in 7 days. Had this captain known the use of the thermometer, need he to have been much longer in going than in coming?

The thermometer is not only useful for ascertaining when in the Gulf Stream, but it is likewise advantageous in discovering the approach to soundings on the Coast of North America between Cape Canaveral and the island of Newfoundland.

In June, 1791, captain W. Billings, of Philadelphia, in latitude  $39^{\circ}$  long.  $56^{\circ}$ , abreast of the Bank of Newfoundland, found that the mercury in the thermometer fell 10 degrees. It was near the same place that a similar observation was made by Dr. Franklin, in November, 1776, and another by Mr. Williams, in November, 1789, who has observed that, "by the coincidence of these three journals, at so great a distance of time, and without any connexion with each other, this important fact seems to be established; A navigator may discover his approach towards objects of danger, when he is at such a distance as to be able easily to avoid them, by attentively examining the temperature of the sea, the water over banks and shoals being colder than that of the deep ocean."

Others, also entitled to credit, believe the thermometer only indicates the difference of temperature caused by going into or leaving the Gulf Stream, on the principle that its temperature is influenced and governed entirely by the fact that it comes from the Tropical regions, where the mean temperature is  $82^{\circ}$ , and it requires a long time before so large a body of water loses or changes its temperature in a very great degree.

At the edge of the grand Bank of Newfoundland, the water has been found 5 degrees colder than the deep ocean to the eastward. The highest part of the bank is 10 deg. colder still, or 15 deg. colder than the ocean eastward.

renheit, and the strongest current to differ from 3 to  $1\frac{1}{2}$  miles per hour; that the breadth of the Stream current is much less than is generally supposed, and that the winds cause a great effect on the Gulf: for instance, a wind that would produce a current of one knot, would retard one of 3 knots to 2 knots if opposed to it; and would accelerate the same to 4 knots, if in the same direction; and that a wind crossing a current obliquely, would affect it as the sine of the angle at which it is opposed. The direction of a current cannot, however, be materially changed, when forced against an opposing barrier."

On the coast of New-England, near Cape Cod,\* the water out of soundings is 8 or 10 deg. warmer than in soundings; and in the stream it is about 8 degrees warmer still, so that, in coming from the eastward, a fall of 8 deg. will indicate your leaving the stream, and a farther fall of 8 deg. will indicate your being on soundings.

On the coast from Cape Henlopen to Cape Henry, the water, out of soundings, is 5 deg. warmer than in soundings; and in the Stream, about 5 degrees warmer still; so that, in coming from the eastward, a fall of 5 deg. will indicate your leaving the stream, and a farther fall of 5 deg. will give notice of soundings.

Mr. Williams recommends to seamen to take three thermometers. "Let them," he says, "be kept in one place some days previous to sailing, in order to try their uniformity. The plate should be made of ivory or metal, for wood will swell at sea; and as the glass tube will not yield, it is from this reason very liable to break: bell-metal is the best. Let the instrument be fixed in a square metal box, the bottom of which, as high as the mark 30°, should be water tight; so that, in examining the degree of heat, the ball may be kept in the water; the remainder of the length should be open in the front, with only two or three cross-bars to ward off any accidental blow, like the thermometer used by brewers. Fix one instrument in some part of the ship, in the shade, and in open air, but as much out of the wind, and in as dry a place as possible. The after part of one of the after stanchions, under the quarter rail, may answer, if no better place can be found.

Let the second instrument be neatly slung, with a sufficiency of line to allow it to tow in the dead water of the wake.

Put the other away safely, to be ready to supply the place of either of the others in case of accident.

About the edges of the stream there is generally a current running in a contrary direction, which is accelerated by the wind, in proportion to its strength, blowing contrary to the stream, and retarded, or perhaps altogether obstructed, by the wind blowing in the direction of the stream. In the latter case, the limits of the stream will be extended.

In the winter, when the cold upon the land is most intense, which is generally between December and March, heavy and continued gales very frequently prevail, which commonly proceed from between the north and west, across the course of the Gulf Stream, from Cape Hatteras until past George's Bank, and bend its direction more to the eastward; being aided at the same time by the discharge of the great bays and rivers, increased by the force of the wind blowing down upon them, and the constant supply of stream that passes along the coast of the Carolinas, the whole produces so strong a current to the eastward as to render it impossible for a ship to approach the coast until there is a change of wind.

During the prevalence of a southerly or easterly wind, which is not so common here, it has been found that the current is forced close to, and in some parts upon the soundings. From a scientific nautical gentleman we received the following, viz. while off Cape Lookout, in 11 fathoms water, he had a strong current from the southward, owing entirely to the Gulf current. This also proves the Gulf influenced by winds. Being thus pent in between the wind and the shoal grounds near the shore, the breadth is greatly diminished, and the velocity proportionably increased. This circumstance has been, in particular, observed from about the longitude of Block Island, along the edges of Nantucket Shoals, thence beyond George's Bank; it has the same effect along the coast of Georgia and part of South Carolina. In the first place, the southerly winds forced the current to the edge of the soundings, where it then ran from  $1\frac{1}{2}$  to 2 knots; and, in the latter place, that the easterly wind forced the current upon soundings.

With west and N. W. winds, the Stream would be removed some leagues farther off. These remarks are sufficient to show the uncertainty of the boundaries or edges of the Stream. These eddies on the inner edge are inconsiderable; but on the outer one, in fine weather, they are strong, and of considerable extent.

By an ingenious work, entitled "Thermometrical Navigation," written by Mr. John Williams, and published at Philadelphia, in 1799, we are informed that Commodore Truxton has often ascertained the velocity of the Gulf Stream, to the northward of Cape Hatteras, and found it to be seldom less than one knot, and never more than two knots, an hour. The temperature of the air and water without the Stream, was generally the same; that is, the difference seldom exceeded 2 or 3 degrees; the air being sometimes the warmest, at other times the water.

\* The bank, from Cape Cod, extends almost as far as Cape Sable, where it joins the banks of Nova Scotia, deepening gradually from 20 to 50 or 55 fathoms, which depth there is in lat. 43°. In crossing the bank between lat. 40° 41' and lat. 43°, the bottom is very remarkable. On the outside it is fine sand, shoaling gradually for several leagues. On the middle of the bank, it is coarse sand or shingle, with pebble stones. On the inside it is muddy, with pieces of shells, and deepens suddenly from 45 or 48 to 150 or 160 fathoms.

Capt. Livingston says, "it set me, off Cape Hatteras, one degree and eight miles, by sidereal and solar observations, to the northward, in 16 hours by dead reckoning; and Capt. Joreal Coltast, of Philadelphia, informed me that it set occasionally with greater velocity."

Mr. Williams observes, "In the Stream the water is much warmer than the air; indeed, I have known it 10 degrees warmer; but so soon as you get within the Stream, (that is, between it and the coast,) the water becomes colder than the air; and the more as you get on soundings and approach the shore.\* If mariners who have not the opportunity of determining their longitude by celestial observations, will only *carry with them a good thermometer*, and try the temperature of the water, and compare it with that of the air, every two hours, they may always know when they come into, or go out of, the Gulf Stream. Indeed, I have always made a practice, when at sea, of comparing the temperature of the air and water daily, and often, very frequently during the day throughout my voyage; whereby I immediately discovered any thing of a current that way going; and afterwards found its strength and direction by observations for the latitude and longitude. It is of the utmost consequence, in making a passage to and from Europe, to be acquainted with this Gulf Stream; as, by keeping in it when bound eastward, you shorten your voyage, and by avoiding it when returning to the westward, you facilitate it inconceivably; so much so, that I have frequently, when bound from Europe to America, spoken European ships, unacquainted with the strength and extent of it, off the banks of Newfoundland, and been in port a very considerable time before them, by keeping out of the Stream, whereas they lengthened their passage by keeping in it. The general course of the Gulf Stream is marked on the chart published by E. & G. W. Blunt, in 1832; and I would advise those who make the northern passage from Europe, never to come nearer the inner line of it, by choice, than 10 or 15 leagues; and then the probability will be, that their passage will be assisted by the help of a counter current which often runs within it. In coming off a voyage from the southward, be sure to steer N. W. when approaching the Stream, if the wind will permit you; and continue that course till you are within it, which may be easily known by the temperature of the water, as before mentioned. I have always considered it of the utmost consequence, when bound in, to cross the Stream as speedily as possible, lest I should be visited by calms or adverse winds, and by these means drove far out of my way, which would prolong the voyage considerably, especially in the winter season.

The course of ships bound from Europe, to the ports of the United States, is controlled, in a great degree, by the operation of the Florida Stream. Little, therefore, requires to be added to the subject here. Those bound to the northern and middle ports, when passing the shoal grounds on George's Bank, should take care to pass between these shoals and the Stream. Also, when passing the Nantucket Shoals, to keep between them and the Stream. The south part of the most dangerous shoal on George's Bank, is in latitude  $41^{\circ} 34' N.$  and the shoals extend to latitude  $41^{\circ} 53' 30'' N.$  and that of Nantucket South Shoal in latitude  $41^{\circ} 4' N.$

Ships crossing the Stream, when bound to the westward, must get over as quickly as possible; or, it is clear that they will be carried far out of their course.†

\* By the journals of Capt. W. Billings, of Philadelphia, it appears that in June, 1791, the water on the coast of America was at the temperature of  $61^{\circ}$ , and in the Gulf Stream at  $77^{\circ}$ . By those of Mr. J. Williams it appears, that in November, 1789, the water on the coast was  $47^{\circ}$ , and in the Gulf Stream at  $70^{\circ}$ , viz.:

1791, June, Coast	$61^{\circ}$	1789, Nov., Coast	$47^{\circ}$	Difference between	Coast	$14^{\circ}$

Stream warmer 16      Stream warmer 23

The difference of heat is therefore greater in winter than in summer. See the concluding observation hereafter, and also the pamphlet published with "Blunt's Chart of the Western Ocean," which contains all the remarks of Mr. Williams on the subject.

Captain A. Livingston says, "On my voyage from Philadelphia to Kingston, Jamaica, October, 1817, I particularly attended to the thermometer. Close off the mouth of the Delaware, in about 16 fathoms, it stood at  $60^{\circ}$ ; on the inner edge of the Gulf Stream it rose pretty rapidly to  $66^{\circ}$ , and in the course of an hour to  $76^{\circ}$ ; next morning  $78^{\circ}$ , which heat continued till we were to the southward of Bermuda, whence it gradually increased until between Cuba and St. Domingo, and at Jamaica it was  $82^{\circ}$ , which appears to me to be the mean temperature of the sea water about Jamaica.

† The following notice relative to several short passages across the Atlantic, was given in a Liverpool paper, January, 1824, and affords a pleasing demonstration of improved knowledge in the navigation of this ocean:

"The packet ship New-York, Capt. Thomas Bennet, arrived here on Thursday last, after one of the shortest passages we believe yet made between New-York and this port. She sailed on the

It has been remarked that, "ships from sea, approaching any part of the American coast between Long Island and Cape Hatteras, if in doubt about their reckoning, should take notice of what is commonly called the Gulf-weed, which is in greater plenty, and in larger clusters, to the eastward of the Gulf Stream than in it, where the sprigs are but small and few. Within the Stream there is no weed, unless in rare instances, and there the color of the water changes to a still darker and muddy color.

The outer edge of the bank off this part of the coast appears to be very steep; for it has been frequently found that, while the lead has been kept going, there have been found 45 fathoms, soon after, 35, and a mile nearer shore only 25 or 20 fathoms; from these depths the shoaling to the shore varies in different directions.

Sir Charles Blagden, M. D. and F. R. S. in the transactions of the Philosophical Society says, "during a voyage to America, in the spring of the year 1776, I used frequently to examine the heat of sea water newly drawn, in order to compare it with that of the air. We made our passage far to the southward. In this situation, the greatest heat of the water, which I observed, was such as raised the quicksilver in Fahrenheit's thermometer to  $77\frac{1}{2}^{\circ}$ . This happened twice; the first time, on the 10th of April in latitude  $21^{\circ} 10' N.$  and longitude, by our reckoning,  $52^{\circ} W.$ , and the second time, three days afterwards, in lat.  $22^{\circ} 7'$ , and long.  $55^{\circ}$ ; but in general, the heat of the sea, near the tropic of Cancer about the middle of April, was from  $76^{\circ}$  to  $77^{\circ}$ .

"The rendezvous appointed for the fleet being off Cape Fear, our course, on approaching the American coast, became north-westward. On the 23d of April, the heat of the sea was  $74^{\circ}$ , our latitude, at noon,  $28^{\circ} 7' N.$  Next day the heat was only  $71^{\circ}$ ; we were then in latitude  $29^{\circ} 12'$ ; the heat of the water, therefore, was now lessening very fast, in proportion to the change of latitude. The 25th, our latitude was  $31^{\circ} 3'$ ; but though we had thus gone almost  $2^{\circ}$  farther to the northward, the heat of the sea was this day increased, it being  $72^{\circ}$  in the morning, and  $72\frac{1}{2}^{\circ}$  in the evening. Next day, 26th of April, at half past eight in the morning, I again plunged the thermometer into sea-water, and was greatly surprised to see the quicksilver rise to  $78^{\circ}$ , higher than I had ever observed it even within the tropic. As the difference was too great to be imputed to any accidental variation, I immediately conceived that we must have come into the Gulf Stream, the water of which still retained great part of the heat that it had acquired in the torrid zone. This idea was confirmed by the subsequent regular and quick diminution of the heat; the ship's run for a quarter of an hour had lessened it  $2^{\circ}$ , the thermometer, at three quarters after eight, being raised by sea-water, fresh drawn, only to  $76^{\circ}$ ; by nine, the heat was reduced to  $73^{\circ}$ ; and in a quarter of an hour more, to  $71^{\circ}$  nearly; all this time the wind blew fresh, and we were going seven knots an hour on a north-western course. The water now began to lose the fine transparent blue color of the ocean, and to assume something of a greenish olive tinge, a well known indication of soundings. Accordingly, between four and five in the afternoon, ground was struck with the lead, at the depth of eighty fathoms, the heat of the sea being then reduced to  $69^{\circ}$ . In the course of the following night and next day, as we came into shallower water and nearer the land, the temperature of the sea gradually fell to  $65^{\circ}$ , which was nearly that of the air at the time.

Unfortunately, bad weather on the 26th, prevented us from taking an observation of the sun; but, on the 27th, though it was then cloudy at noon, we calculated the latitude from two altitudes, and found it to be  $33^{\circ} 26' N.$  The difference of this latitude from that which we had observed on the 25th, being  $2^{\circ} 23'$ , was so much greater than could be deduced from the ship's run, marked in the log book, as to convince the seamen that we had been set many miles to the northward by the current.

On the 25th, at noon, the longitude by our reckoning was  $74^{\circ} W.$ , and I believe the computation to have been pretty just; but the soundings, together with the latitude, will determine the spot where these observations were made, better than any reckoning from the eastward. The ship's run on the 26th, from 9 in the forenoon to 4 in the afternoon, was about 10 leagues on a N. W. by N. course: soon afterwards we hove to in order to sound, and finding bottom, we went very slowly all night, till noon the next day."

From these observations, I think it may be concluded that the Gulf Stream, about the 33d degree of north latitude, and the 76th degree of longitude west of Greenwich, is, in the month of April, at least 6 degrees hotter than the water of the sea through which it runs. As the heat of the sea water evidently began to increase in the evening of the 25th, and as the observations show that we were getting out of the current when I first tried the heat in the morning of the 26th, it is most probable that the ship's run during the night is nearly the breadth of the Stream, measured obliquely across; that

16th of December, and arrived here in the morning of the 1st of January, being little more than 15 days. The Mary Catherine, which left Charleston on the 16th of December, made her voyage from port to port in 19 days. The Marmion arrived in the evening of the 7th January, in 18 days from Charleston, and two more from that town."

as it blew a fresh breeze, could not be less than 25 leagues in 15 hours, the distance of time between the two observations of the heat, and hence the breadth of the Stream may be estimated at 20 leagues. The breadth of the Gulf of Florida, which evidently bounds the stream of its origin, appears by the charts to be 2 or 3 miles less than this, excluding the rocks and sand banks which surround the Bahama Islands, and the shallow water that extends to a considerable distance from the coast of Florida; and the correspondence of these measures is very remarkable, since the stream, from well known principles of hydraulics, must gradually become wider as it gets to a greater distance from the channel by which it issues.

"If the heat of the Gulf of Mexico were known, many curious calculations might be formed by comparing it with that of the current. The mean heat of Spanish town and Kingston, in Jamaica, seems not to exceed  $81^{\circ}$ ;\* that of St. Domingo, on the sea coast, may be estimated at the same, from Mons. Godin's observations;† but as the coast of the continent, which bounds the Gulf to the westward and southward, is probably warmer, perhaps a degree or two may be allowed for the mean temperature of the climate over the whole bay; let it be stated at  $82$  or  $83$  degrees. Now there seems to be great probability in the supposition that the sea, at a certain comparatively small distance below its surface, agrees in heat pretty nearly with the average temperature of the air, during the whole year, in that part; and hence it may be conjectured that the greatest heat of the water, as it issues out of the bay to form the stream, is about  $82$  degrees,‡ the small variation of temperature on the surface not being sufficient to affect materially that of the general mass. At the tropic of Cancer, I found the heat to be  $77^{\circ}$ ; the stream, therefore, in its whole course from the Gulf of Florida, may be supposed to have been constantly running through water from  $4$  to  $6$  degrees colder than itself, and yet it had lost only  $4^{\circ}$  of heat, though the surrounding water, where I observed it, was  $10^{\circ}$  below the supposed original temperature of the water which forms the current. From this small diminution of the heat, in a distance of probably 500 miles, some idea may be acquired of the vast body of fluid which sets out from the Gulf of Mexico, and of the great velocity of its motion. Numerous observations of the temperature of this stream, in every part of it, and at different seasons of the year, compared with the heat of the water in the surrounding seas, both within and without the tropic, would, I apprehend, be the best means of ascertaining its nature, and determining every material circumstance of its movement, especially if the effect of the current, in pushing ships to the northward, is carefully attended to, at the same time with the observations upon its heat."

On the 25th September, 1777, as the ships which had transported Sir William Howe's army up Chesapeake Bay were returning towards the Delaware, with the sick and stores, they were overtaken, between Cape Charles and Cape Henlopen, by a violent gale of wind, which, after some variation, fixed ultimately at N. N. E. and continued 5 days without intermission. It blew so hard that they were constantly losing ground, and driven to the southward. We also purposely made some casting, to keep clear of the dangerous shoals which lie off Cape Hatteras.

On the 28th, at noon, our latitude was  $36^{\circ} 40'$  N., and the heat of the sea, all day, about  $65^{\circ}$ . On the 29th our latitude was  $36^{\circ} 2'$ . We had, therefore, in the course of these 24 hours, been driven by the wind 38 nautical miles to the southward. The temperature of the sea continued nearly at  $65^{\circ}$ . Next day, the 30th, our latitude, at noon, was  $35^{\circ} 44'$ , only 18 miles farther to the southward, though in the opinion of the seamen aboard, as well as my own, it had blown at least as hard on this as on any of the preceding days, and we had not been able to carry more sail; consequently it may be concluded that some current had set the ship 20 miles to the northward. To know whether this was the Gulf Stream, let us consult the thermometer. At half past nine

\* History of Jamaica, London, 1774, vol. iii. page 652, 653. The different observations of the heat recorded in that work, do not agree together, but those adopted here are taken from that series which appear to me most correct.

† Monsier Godin's experiments upon the pendulum were made at the petit grove. They continued from the 24th of August to the 4th September, and the average heat during that time was such as is indicated by  $25^{\circ}$  of M. de Reaumur's thermometer, (see Mem. Acad. Science, 1735, p. 5. 7.) According to M. de Luc's calculation, (see Modifications de l'Atmosphere, vol. i. p. 378,) the 25th degree of Reaumur's true thermometer answers to about the 85th of Fahrenheit's; but the average heat in Jamaica, during the months of August and September, is also  $85^{\circ}$ ; hence we may conclude that the mean heat for the whole year is nearly the same on the sea coasts of both islands.

‡ The lowest calculation of the mean temperature of the Gulf is preferred on this occasion, because of the constant influx of new water from the Atlantic ocean, produced by the trade winds, which water, not having been near any land, must, I think, be sensibly colder than that which has remained some time enclosed in the bay. On this subject, the observations made by Alexander Dalrymple, Esq. relative to the heat of the sea, near the coast of Guinea, ought to be consulted.—(See Phil. Trans. vol. lxxviii. p. 394, &c.)

in the forenoon of this day, the heat of the water was  $76^{\circ}$ , no less than  $11^{\circ}$  above the temperature of the sea, before we came into the current.

Towards evening the wind fell, and we stood N. W. by N. close hauled. As the sea still ran very high, and the ship scarcely went above two knots an hour, we did not make less than three points of leeway on this tack. The course we made good, therefore, was W. N. W., which on the distance run by noon next day, gave us about 16 miles of nothing; but that day, the 1st of October, our latitude was  $36^{\circ} 22'$ , 38 miles farther to the north than we had been the day before; the difference, 22 miles, must be attributed to the Gulf Stream. This, however, is only part of the effect which the current would have produced upon the ship, if we had continued in it the whole 24 hours; for though we were still in the stream at five in the afternoon of the 30th, as appeared by the heat of the water, being then above  $75^{\circ}$ , and at eight in the evening the heat being still  $74^{\circ}$ ; yet by seven the next morning we had certainly got clear of it, the heat of the sea being then reduced to its former standard of  $65^{\circ}$ . On this occasion, therefore, we did not cross the stream, but, having fallen in with it obliquely on the western side, we pushed out again on the same side, as soon as the gale abated.

These observations having been made  $3^{\circ}$  to the northward of my former ones, it is curious to observe that the heat of the Gulf Stream was  $2^{\circ}$  less. The seasons of the year, indeed, were very different; but, perhaps under such circumstances, that their effects were nearly balanced. In the latter observations, the meridian altitude of the sun was less, but then a hot summer preceded them; whereas in the former, though the sun's power was become very great, yet the winter had been passed but a short time. Calculating upon this proportion, we may be led to suspect, that about the 27th degree of latitude, which is as soon as the stream has got clear of the Gulf of Florida, it begins sensibly to lose its heat from  $82^{\circ}$ , the supposed temperature of the Gulf of Mexico, and continues to lose it at the rate of about  $2^{\circ}$  of Fahrenheit's scale to every  $3^{\circ}$  of latitude, with some variation, probably, as the surrounding sea and the air are warmer or colder at different seasons of the year.

The preceding facts had made me very desirous of observing the heat of the Gulf Stream on my passage homeward, but a violent gale of wind, which came on two days after we had sailed from Sandy Hook, disabled every person on board, who knew how to handle a thermometer, from keeping the deck. The master of the ship, however, an intelligent man, to whom I had communicated my views, assured me, that on the second day of the gale, the water felt to him remarkably warm: we were then near the 70th degree of west longitude. This agrees very well with the common remark of seamen, who allege that they are frequently sensible of the Gulf Stream off Nantucket Shoals, a distance of more than 1000 miles from the Gulf of Florida! According to the calculation I have before adopted, of a loss of  $2^{\circ}$  of heat for every  $3^{\circ}$  of latitude, the temperature of the Gulf Stream here would be nearly  $73^{\circ}$ , the difference of which from  $59^{\circ}$ , the heat that I observed in the sea water, both before and after the gale, might easily be perceived by the master of the vessel. This was in the winter season, at the end of December.

An opinion prevails among seamen, that there is something peculiar in the weather about the Gulf Stream. As far as I could judge, the heat of the air was considerably increased by it, as might be expected, but whether to a degree or extent sufficient for producing any material changes in the atmosphere, must be determined by future observations.

Perhaps other currents may be found, which, issuing from places warmer or colder than the surrounding sea, differ from it in their temperature so much as to be discovered by the thermometer. Should there be many such, this instrument will come to be ranked amongst the most valuable at sea, as the difficulty of ascertaining currents is well known to be one of the greatest defects in the present art of navigation.

In the mean time, I hope the observations which have been here related are sufficient to prove that in crossing the Gulf Stream, very essential advantages may be derived from the use of the thermometer; for if a master of a ship, bound to any of the southern provinces of North America, will be careful to try the heat of the sea frequently, he must discover very accurately his entrance into the Gulf Stream by the sudden increase of the heat, and a continuance of the same experiments will show him, with equal exactness, how long he remains in it. Hence he will always be able to make a proper allowance for the number of miles a ship is set to the northward, by multiplying the time into the velocity of the current. Though this velocity is hitherto very imperfectly known from want of some method of determining how long the current acted upon the ship, yet all uncertainty arising from thence must soon cease, as a few experiments upon the heat of the stream, compared with the ship's run, checked by observations of the latitude, will ascertain its motion with sufficient precision. From differences in the wind, and perhaps other circumstances, it is probable that there may be some variations in the

velocity of the current frequently he present moves the less be. In this observation partly because it is water in the Gulf of be greater or less, warmer or colder, rather less than in would be much greater had lost very little the same temperature meter when a ship

velocity of the current; and it will be curious to observe whether these variations may not frequently be pointed out by a difference in its temperature, as the quicker the current moves the less heat is likely to be lost, and consequently the hotter will the water be. In this observation, however, the season of the year must always be considered, partly because it may perhaps in some degree affect the original temperature of the water in the Gulf of Mexico, but principally because the actual heat of the stream must be greater or less, in proportion as the tract of the sea through which it has flown, was warmer or colder. In winter I shall suppose that the heat of the stream itself would be rather less than in summer, but that the difference between it and the surrounding sea would be much greater; and I conceive that in the middle of summer, though the stream had lost very little of its original heat, yet the sea might, in some parts, acquire nearly the same temperature, so as to render it scarcely possible to distinguish by the thermometer when a ship entered into the current.

Vessels may with safety avoid the eddy of the gulf, or make allowance for it in their calculations; that is, if they cannot help falling into them, after they have taken all the precautions by soundings in blue water, and when they had bottom, stood off, they will naturally subtract what longitude they make in the eddy, from what they had made in the stream, and begin a new departure, being at the same time very precise in their morning and meridian observations. Many ships bound through the Strait of Florida, unacquainted with the stream's eddy, and ignorant also of the soundings being under blue water, have been lost in fair weather. They were swept insensibly by the eddy to the westward, and when they found by their calculations that they had a sufficient offing east of Cape Florida, they stood north, and instead of entering the strait ran directly upon a reef.

If, with adverse northerly, easterly, or N. E. winds, vessels happen to be in the mouth of the Gulf of Mexico, that is, between the Havana and Cape Florida, they had best endeavor to make the Bahama Islands, or at least the soundings of them, and proceed under the lee side; but when they are to the north of them, it is best to keep in the eastern extent of the stream, or else they will not be able to clear their way through the strait, nor along the coast of East Florida, and may get on shore upon the reefs either of Cape Florida or Cape Canaveral, if not upon the beach between the two capes, which is the least of the two; for thus the crew and cargo may be saved; and some vessels may also be brought off, provided the storm ceases before the vessel is made a wreck of. But if at any time of the south sun, or at any other time, the winds are westwardly, then the Atlantic coast affords the most eligible lee for navigators who do not choose to take the stream; but if the current in the gulf is well understood, it will greatly facilitate the progress, when bound to the northward, as fully illustrated in the following remarks:

"We took our departure from the westward of Cat Key, and steered S. S. W. 24 leagues; then S. S. W.  $\frac{1}{2}$  S.  $5\frac{1}{2}$  leagues, when we altered our course to S. S. W.  $\frac{1}{2}$  W. 6 leagues, with the wind squally at N. W., going at the rate of 8 knots. While in the act of reefing top-sails, judging ourselves near the Double-headed Shot Keys, we struck on Carysfort Reef." [The course steered by compass was S. S. W., whereas the drift made her course W. S. W.]

"I left," says an experienced navigator, "the Bahama Bank in lat.  $24^{\circ} 33' N.$ , and steered S. W. by S., by compass, and in the morning discovered myself within 6 miles of the Double-headed Shot Keys, which bear from the latitude I took my departure from, S. W. by W."

"August 29, 1816.—At midnight left the bank with the wind south and south-westerly; ran 28 miles W. S. W.; 22 miles W. by S., close hauled upon our larboard tack, and found, by meridian altitude of the sun, our latitude to be  $24^{\circ} 50' N.$ "

"Aug. 30.—Winds westerly and light, still on the wind on our larboard tack; ran 25 miles west to midnight, sounded, no ground; continued W. and W. by N. 4 miles, to 3 A. M. the ship Three Sisters, captain Armington, being then on our weather bow, distant one mile, made a signal she was ashore; hove the lead and had but 5 fathoms, tacked ship and stood off ten minutes, sounded, quarter less 3, tacked again and stood in, sounded with  $4\frac{1}{2}$  fathoms, when we let go our anchor and brought up at 4 A. M. Manned the boat and ran out east three quarters of a mile, when the boat struck on a reef, the ship Three Sisters then bearing W. S. W. one mile. Went off in the boat again in a N. E. by E. direction, and found a narrow channel of 12 feet; tried again in a S. S. E. direction, where we found a passage of 15 feet, one mile wide, current setting N. N. E. This must have been the channel which we fortunately got in at, there being but two channels to be found; the wide channel was the only one which would admit us both in the same direction we then were. Gut under way the captain of the ship being on board, the wind veering from S. S. W. to N. W. and stood out, but on approaching the passage, found the current to set strong on the S. end of the N. reef, which set us into

11 feet water, in about the length of the vessel, when it deepened to 3, 4, 6, 7, 16, 25 fathoms, and off soundings, the lead being hove as quick as possible.

"The place we got in at, appears to be, by the chart, Buller's inlet and outlet, lying between Biscayne's and Leducburg's reef, in latitude  $25^{\circ} 24' N.$ "

"During my several cruises within the Martyrs or Florida Reef," says Mr. Romans, "I have seen a great number of vessels borrow so close on the reef, that they appeared to be within it; and sometimes I could even see the people with the help of a glass; the people, I suppose, were well acquainted or very bold; but let the man who does this ever so experienced, he must be very careful to keep a strict look-out; for my part I would not come nearer than just to raise the land, especially as tides may have their influence farther off than we are aware of."

"Besides this reason for standing longer off than in, there is one still greater. Every experienced mariner knows that a vessel will run towards shore in less time than she can run the same distance from it; and that the higher the land she works under, the quicker she runs in, consequently the slower she runs off. Hence almost every one in bearing upon a lee shore will stand out a longer time than in; but few, even among the most experienced, know the philosophy of this phenomenon against which they guard so carefully. It is that great law of nature, whereby all light bodies must fall on the heavier ones—I mean attraction. To explain this by an experiment; take any vessel, fill it almost with water, put a cork or chip in it; while that remains in the centre, it is attracted from every side alike, and therefore stands fixed; but no sooner is it thrown out of the centre than it will begin to approach the side; and, as it draws near, attraction is increased, till at last the velocity of the chip becomes so great as to run with considerable violence against the vessel, where it remains fixed; and, if it is an oblong piece in shape of a vessel, the same will happen as when a ship runs ashore stern-on, viz. it will wind broadside to. The explanation of this phenomenon we owe to John Collins, Esq. of Newport, in Rhode-Island, formerly first counsellor of the state, and a very experienced commander."

Speaking of the GULF STREAM, Mr. Romans,\* whose surveys of the Coast of Florida reflected great credit on him, says: "The All-gracious Ruler of the Universe has so disposed the several shores of this mazy labyrinth, as to cause this current to run in a direction N. E. and at the rate of 3, and  $3\frac{1}{2}$  miles in an hour; by which means we are enabled better to avoid the imminent dangers of the reef, where it becomes a lee shore; for the violence of the easterly gales beats the Gulf-water over the reefs, so as to destroy the effect of flood-tides, by causing a constant reverberating current from the shore over the reef, inasmuch that a vessel riding under the reef will lay with her stem to windward."

"I once came out from Matacumbe, and was scarcely clear of the reef, before I was overtaken by a gale from the eastward, which was very violent. It was 5 o'clock in the evening, and it being dark, to attempt a re-entrance of the reef, I was forced to leave the vessel to, which I did under the balanced mainsail; she was a heavy schooner of about 70 tons, and a dull sailer. The succeeding night I passed in the deepest distress of mind, seeing the burning of the breakers in constant succession on the reef, till past one o'clock; the storm continued till ten next morning, when I made sail to the northward, and at noon, to my utter astonishment, I had an observation of the sun's altitude, which proved me to be in  $26^{\circ} 50'$  latitude, by which I had made a difference of latitude of 118 miles, in the short space of 19 hours, 17 of which I lay to."

"I am an utter enemy (continues Mr. Romans,) to all theoretic and systematic positions, which has caused in me an indefatigable thirst for finding, in my experience,

\* Mr. Romans observes, "If by keeping to the northward, the current of the Mexican Gulf has set you on soundings on Tortugas Shoal, these soundings, in foggy weather, may be a guide, being properly laid down in the chart. You do not change the color of your water till you get well in with the shoal, but there is generally an eddy current so soon as you are on soundings; therefore, if you stand over to the Florida shore, so soon as you are up to the latitude of  $23^{\circ} 25'$ , keep as much to the eastward as N. N. E. or N. E. by N. till you get soundings. And, whatever terrible idea people may have of that shore, if the wind will allow you, keep it on board, especially in the autumn and winter seasons, when the N. and N. W. winds are frequent, and the current often runs to leeward. In those seasons, you may take an advantage of the tides on soundings, by carefully observing their time; and this conduct will tend to shorten your passage. When, however, you are got as far windward as the south end of Matacumbe Reef, endeavor to get all the easting you can possibly acquire, in order to get the Bahama shore on board, which is the most eligible in going northward. The proximity of the Reef of Florida will manifest itself clearly in day-light by the white color of the water, and thus there may be no danger in approaching it; but this is far from being the case at night, when it ought to be carefully avoided, and the lead kept constantly going; because, having soundings to the distance of two miles without the steep part of it, they will show the proximity of danger."

causes for all extra position of the ear that blow contrary by the swelling of 1769, when the 12

causes for all extraordinary appearances, be they what they may. And my experimental position of the cause of the increase of the velocity of this current, during the gales, that blow contrary to its direction, is no other than the reverberating current occasioned by the swelling of the water within the reef, which in the memorable gale of October, 1769, when the *Ledbury* was lost, was no less than 30 feet above its ordinary level."

Besides the convenience of correcting a ship's course, by knowing how to make a proper allowance for the distance she is set to the northward by the current, a method of determining with certainty when she enters into the Gulf Stream, is attended with the farther inestimable advantage of showing her place upon the ocean in the most critical situation; for, as the current sets along the coast of America, at places on soundings, the mariner when he finds this sudden increase of heat in the sea, will be warned of his approach to the coast, and will thus have timely notice to take the necessary precautions for the safety of his vessel. As the course of the Gulf Stream comes to be more accurately known, from repeated observations of the heat and latitudes, this method of determining the ship's place will be proportionably more applicable to use. And it derives additional importance from the peculiar circumstances of the American coast, which from the mouth of the Delaware to the southernmost point of Florida, is every where low, and beset with frequent shoals, running out so far into the sea, that a vessel may be aground in many places where the shore is not to be distinguished, even from the mast-head. The Gulf Stream, therefore, which has hitherto served only to increase the perplexities of seamen, will now, if these observations are found to be just in practice, become one of the chief means of their preservation upon this dangerous coast.

*Extract of a Letter from Francis D. Mason, Esq., to Col. John Williams, Commandant of the Corps of Engineers, and Author of "Thermometrical Navigation," at New York; dated CLIFTON, (Eng.) 20th June, 1810.*

"My voyage from New York to Halifax, in the British packet *Eliza*, was so very tempestuous and unfortunate, (having carried away our foremast,) that I did not make any thermometrical observations; but when we sailed from Halifax, on the 27th April, I began them, and continued until I unfortunately broke both my thermometers. However short the time was, you will perceive that my observations have been very important, and I herewith send the result of them. You will perceive with what fidelity the thermometer indicated the banks, and the approximation towards islands of ice. The captain was so convinced of the usefulness of the thermometer, that he made regular remarks, and inserted them in his journal. I gave him one of your books, thinking it would be pleasing to you that I should extend the knowledge of a discovery so useful as yours, and I wish it were more generally known. After having miraculously escaped the islands of ice, and several severe gales, we arrived at Fulmouth on the 22d of May, 1810."

*Extract from the Eliza's Journal.*

*Remarks on the foregoing Journal.*

The important point of comparison is the difference in the heat of the water in different places, in or near the stream, in the ocean, out of the stream, on the coast, and near islands of ice—not the difference between the heat of the water and the air, as some have imagined. The latter is merely a concurrent observation: it serves to account for ordinary changes, and thereby to guide the judgment.

From April 28, at 10 A. M., to April 29, at 8 A. M., we see the temperature of the sea in the shoals of Sable, from 40° to 43°. At 5 P. M. we see the warm influence of the Gulf Stream from 62° to 64°. At 10 P. M. we see the temperature between the influence of the stream in deep water and the coast at 54°, which is about a mean between the two; then standing off shore, at 9 the next morning, 30th, we see the warm influence of the stream again.

If these stripes of water had been distinguished by the colors of white, red, and blue, could they be more distinctly discoverable than they are by the constant use of the thermometer?

About 23 hours afterwards, May 1, at 8 A. M., we find the water cooling, and in 3 hours more the mercury falls 14° (46°). Here no bottom could be found by the lead; and there was probably an island of ice, obscured by fog. [Let it be remembered, that the coldness of ice condenses the atmosphere, and of course the consequence must be fog.] Passing this at 2 P. M., the thermometer rose to 54°, but in one hour more it fell to 46° again; and an island of ice appeared at the distance of 7 miles. Let navigators reflect on this, and say that a sudden fall of 6° in this part of the ocean, ought to induce them to haul to the southward, and keep a good lookout. From May 1, at 11 A. M., to the next morning at 1 A. M., we see the gradual changes as the ship passes the ice and comes again into ocean water (50°); but in 2 hours more the ship is in the warm influence of the stream again, and the mercury rises 10° (60°). She proceeds in a nearly regular degree of heat during 17 hours, till at 6 P. M. the water begins again to cool, falling to 56° at midnight. There was no bottom in 80 fathoms. May 3d, at 4 A. M., the water was at 43°, still no bottom in 80 fathoms. Now, from past experience, we must say, here is an island of ice in a less distance than 7 miles, because at that distance the water was 46°. When day appears, behold an enormous island of ice abreast, 100 yards, and the heat of the water reduced to 39°! A question now occurs: Had not the thermometer been thus used, had it not been continued during the night, what would have been the fate of the ship? Let the recollection of the miserable fate of the ship \*Jupiter, be an impressive answer; and let it be laid down as a maritime axiom, that want of caution, or ignorance, can alone cause such accidents in future.

JONA. WILLIAMS.

† West of the Bank.			‡ On the Bank.		§ East of the Bank.	

\* Captain Law's protest, containing the particulars of the distressing circumstance of this ship, states, "April 6, in lat. 44° 20', long. 49°, at 8 A. M., saw several pieces of broken ice, from which

*Off-Set from the Gulf Stream.*

From the superior elevation of the Gulf Stream, its water, about the Bahamas, appears to have a declivity or tendency to the eastward; and there is reason to believe that an off-set of the Stream, from without the Maternillo Bank, sets, if not generally, very frequently, to the eastward and S. E. With the usual set of the currents, along the eastern range of the Bahama Islands, we are not accurately acquainted; but, with a N. W. wind, we have no doubt that it is in a S. E. direction. The *Europa*, a ship of war, returning to Jamaica, by this passage, from a cruise off Havana, in 1787, steered east on the parallel of  $30^{\circ}$  N. with a westerly wind, until the run was supposed to have brought her on the meridian of Turk's Islands, by which it was intended to pass southward, but an easterly current had swept her along as high as that of the Mona Passage. Captain Manderson, of the Royal Navy, who first noticed this event, observes, "if it were once ascertained that a current was common in that part of the ocean, might it not be favorable for vessels bound from Jamaica to the Caribbee Islands, especially in the summer months, during the prevalence of the sea breezes?"

"The ship *Fame*, Captain J. W. Monteath, a good lunarian, assures me," says Captain Livingston, "that he had been carried three degrees and upwards to the eastward, between the time of his departure from the American coast and making the Windward Passages; but this may have been partly occasioned by the Gulf Stream, which he may have crossed too obliquely in proceeding from Norfolk." The *Fame* above mentioned was bound from Norfolk, in Virginia, to Kingston, Jamaica, in May, 1816; and in a run of thirteen days, until in the latitude of  $29^{\circ}$ , and longitude  $61^{\circ}$ , it was found that the current had set the vessel  $3^{\circ} 10'$  E.

"Captain Hall, in the Brig *Lowland Lass*, passed to windward of Porto Rico, when he thought that he had run through the Mona Passage. Captain Paterson, of the brig *Clyde*, as I am informed, passed down the Anegada Passage, when he intended to have made the Mona.

Capt. Romans, before quoted, says, "within the edge of the Stream is a smooth eddy, gradually changing, as it approaches Hawke Channel and its Islands, from the Stream's deep blue to a beautiful sea green, and at last into a milk-white. The soundings, under the blue colored water, are generally on a fine white marl; under the sea green, on the said marl, you meet with sponge, white coral, sea-feathers, turtle-grass, and sometimes banks of rocks; and under the white colored water, the soundings are on white marl, with banks or rocks, or white sand. The eddy takes its current in an opposite direction from that of the contiguous stream, viz. south-westwardly."

The soundings of the eddy, provided no reef be in the way between the Stream and the Hawke Channel, run from 20 fathoms to  $2\frac{1}{2}$ ; and when the reef divides the Stream and the Hawke Channel, the soundings, in some places, are from bottomless at once to 12 or 11 fathoms. Hawke Channel is the channel between Florida Reef and Keys.

"In addition to the above notices, I have been assured, by an intelligent Spanish navigator, that, about thirty years since, vessels bound from Havana to Europe, used generally to cut off three degrees of longitude from their reckoning, on account of this set, which he said, was considered then as certainly existing. At that time the charts were about a degree wrong, which would reduce the Spaniard's allowance to two degrees, or thereabout.

at 11 the same day, we supposed ourselves entirely clear, and steering W. by N., W., E. N. E., and foggy weather. At 2 P. M. began to discover islands of ice again, and at 3 o'clock saw a large field ahead, which appeared to have no opening. We then wore ship, and kept off to the southward and eastward, continually passing small islands of ice, until five P. M., when we found ice extending so far to north and south that we could not clear it. We then hove about and stretched to the northward among the broken ice, till night came on, and no prospect of getting clear. We hove to under three topsails double reefed, in hopes to have sufficient drift to keep clear of the field of ice to leeward, until daylight, but found at about 11 we were drifting fast upon a large field, and were obliged to wear ship and haul to the southward under easy sail, huddling and bearing away from the broken ice as occasion required, until half past 12, when we struck a small piece, which we found had gone through the starboard bow.

"Captain Law would recommend to any vessel bound to Europe, not to go to the north of lat.  $30^{\circ}$ , as the information of Captain Guiner in the schooner that relieved him, had been as far to the southward as  $41^{\circ} 30'$ , and could see no southern termination."

By a reference to the journal of Capt. Carlton, who ranks with the first navigators of the age, and an ornament of the U. S. Navy, the importance of the marine thermometer is fully illustrated. On the 16th the ship crossed the bank, at which time the temperature of the water was  $15^{\circ} 45'$  colder than the previous and following days. A particular use of this instrument, as you approach the coast, will unquestionably point out the soundings, and render useful services to the navigator.

"These notices the northward of the ship from the Ha follow my own plan the aid of this off-set in the southern part and I know that"

It has been found N. W. 160 leagues 12 miles per day, the current was which continued toward and westward land. This current more probably a according to the

It has also been sets in high latitude at the rate of a league

An experienced I made, during five ward and westward it generally prevailed to that of  $69^{\circ}$ . A longitude, found a Europe, bound to of latitude  $37^{\circ}$ , or westward of the B against the wind

*Upon soundings:* New York, the current influenced by the wind a slow current of prevail, the current the pilots of this current happen, yet they frequent. It is present near the entrance N. E. In the morning in the latitude of gins to color of a current from the

\* Captain Thomas ward 104 miles, in 79° 50' W. To the 25°, the current was

On the 16th February Maternillo Bank, an 23° 7' N., and 76° 5' W. fore, evidently in the

In proceeding on the northward of the meridian of  $57^{\circ}$ , until  $3^{\circ} 34'$  E.

Capt. Hamlin, in the current westerly, from gale, from the 28th to which, to the eastward. The ship passed apparently the Gulf still finding a strong Bank of Sable Island

The brig afterward 62° W. found a slight ridian of  $64^{\circ}$ , had a current to the westward

"These notices tend to prove that an easterly off-set, from the Gulf Stream, sets to the northward of the Bahamas; of this I am so firmly convinced, that if, in charge of a ship from the Havana, or even New-Orleans, bound to Jamaica, I should, if allowed to follow my own plan, run out the Strait of Florida, and attempt making my passage with the aid of this off-set. This is to be understood in case I should not have westerly winds in the southern parallels; for such winds are, I am told, more frequent than formerly; and I know that they are by no means of rare occurrence on the S. W. of Cuba."\*

It has been found that when Cape Henry, (the south point of the Chesapeake,) bore N. W. 160 leagues distant, a current was setting to the southward, at the rate of 10 or 12 miles per day, which so continued until Cape Henry bore W. N. W. 89 or 90 leagues; the current was then found setting to the N. E. at the rate of 33 or 34 miles per day, which continued until within 32 or 30 leagues of the land; then a current set to the southward and westward, at the rate of 10 or 15 miles per day, to within 12 or 15 miles of the land. This current, which is considered as the eddy of the Gulf Stream, (but which is more probably a continuation of the Labrador current,) sets, more or less, to the S. W. according to the figure of the coast.

It has also been observed by others, that a southern and western current constantly sets in high latitudes between the Gulf Stream and coast, more particularly in soundings, at the rate of a half mile an hour, or more, according to the wind.

An experienced officer of the navy, before quoted, has said, that "In all the observations I made, during five years cruising on the American coast, I never found this eastern current to the southward of latitude  $36^{\circ}$ , and only once, (the above-mentioned time,) so far; it generally prevailing between the latitudes of  $37^{\circ}$  and  $40^{\circ}$ , from the longitude of  $60^{\circ}$  to that of  $69^{\circ}$ . And I have often, about the latitude of  $36^{\circ}$  or  $37^{\circ}$ , and about the above longitude, found a strong current to the south, and south-west. Therefore ships from Europe, bound to America, should endeavor to make the passage either to the southward of latitude  $37^{\circ}$ , or to the northward of latitude  $40^{\circ}$ ; that is to say, when as far, or to the westward of the Banks of Newfoundland, they should, as much as possible, avoid beating against the wind to the westward, between the latitudes of  $37^{\circ}$  and  $40^{\circ}$ .

Upon soundings, along the coasts of Georgia, Carolina, Virginia, New Jersey, and New York, the current runs, in general, parallel to the shore; and is, in general, influenced by the wind, which mostly prevails from between the south and west, producing a slow current of about one or a half knot to the N. E.; but when the N. and E. winds prevail, the current along shore to the south-west will frequently run two knots; on which, the pilots of this coast remark, that the south and S. W. currents, though they but seldom happen, yet they are always stronger than those to the northward, which are more frequent. It is probable the tides may have some influence on these currents, particularly near the entrance of the great bays and inlets. The flood on this coast comes from the N. E. In the months of April and May I have observed, on crossing the Gulf Stream, in the latitude of Cape Henry, that, when near the inside of the Stream, the water begins to color of a deeper green; and thence to the edge of soundings there is a strong current from the eastward. The color of the water from green, turns to muddy when

\* Captain Thomas Hamlin, in the brig Recovery, then in the Gulf Stream, was set to the northward 104 miles, in the 24 hours of the 29th March, 1820. The ship's place, at noon,  $28^{\circ} 4' N.$ ,  $79^{\circ} 50' W.$  To the north-eastward, on the next day, without the Stream in lat.  $29^{\circ} 35'$ , long.  $77^{\circ} 25'$ , the current was found to have set only 11 miles north, but considerably more to the eastward.

On the 16th February, 1818, the ship Mars, under the same commander, was at the back of the Maternillo Bank, and no northerly current was found; and nearly two degrees farther eastward, in  $23^{\circ} 7' N.$ , and  $76^{\circ} 58' W.$  the current, in 24 hours, had set  $3^{\circ} S.$  and  $14^{\circ} E.$  The ship was, therefore, evidently in the off-set from the Gulf Stream.

In proceeding onward, towards Ireland, in March, Capt. Hamlin passed about four degrees to the northward of the Azores, and was favored by an easterly current from the parallel of  $35\frac{1}{2}^{\circ}$ , and meridian of  $57^{\circ}$ , until he reached the Salters, on the S. E. coast, where his differences amounted to  $3^{\circ} 38' E.$

Capt. Hamlin, in the Recovery, on his passage outward to Halifax, September, 1819, found the current westerly, from  $45^{\circ}$  to  $30^{\circ}$  per day, between the parallels of  $51^{\circ}$  and  $46^{\circ}$ , long.  $29^{\circ}$  to  $37^{\circ}$ . A gale, from the 28th to the 30th Sept. disturbed the ship's course in about  $43^{\circ} N.$  and  $41^{\circ} W.$  after which, to the eastward of the Newfoundland Bank, the current was found to set strongly to the eastward. The ship passed over the bank in the parallel of  $43^{\circ}$ ; the current still strong to the eastward; apparently the Gulf Stream. The Recovery thence proceeded to the southern edge of Banquereau, still finding a strong easterly current, but with diminished strength, which continued thence to the Bank of Sable Island.

The brig afterwards proceeded from Halifax to Jamnia; and on the 22d of Nov. 1819, in  $40^{\circ} N.$ ,  $62^{\circ} W.$  found a slight current to the southward; which, in the parallel of  $26^{\circ}$  to  $23^{\circ}$ , near the meridian of  $64^{\circ}$ , had changed to the eastward; but, on approaching the Silver Key Passage, a slight current to the westward appeared to prevail.

on soundings, the current still continuing until within the influence of the tide; this eastern current is, no doubt, occasioned by the discharge of water out of the Chesapeake, by the floods from the snow melting in the country; and it prevails, in some degree, throughout the year, but its effect is greater at this time. It is probable that a similar current prevails off the mouth of the Delaware.

Round the east end of Long Island, and thence to the eastward round Nantucket Shoals, across George's Bank, to Cape Sable, a strong tide runs; the flood setting to the north and west, in order to fill up the bays, rivers, and inlets, and the ebb the contrary. The tides that set across George's Bank into the Bay of Fundy, are very much influenced by the winds, particularly if after a strong S. or S. E. wind, it should suddenly change to W. or N. W. (circumstances that often happen,) ships will then find themselves drifted by the outset 50 or 60 miles in the 24 hours, or more, to the S. E. The indraught is also great with S. or S. E. winds, which ought to be paid particular attention to.

Upon the Nova Scotia coast the currents run parallel to the shore, but more frequent from the eastward than from the westward, particularly in the spring: the southerly winds force them upon the shore by the water running in, to fill up the bays and inlets; and the N. and N. W. winds have the same effect in forcing them off shore. A regular tide here runs along shore; the flood from E. N. E.

---

*Remarks on the foregoing, and on the General Character of the North Atlantic Current, by W. C. Redfield.*

It appears from the foregoing observations, that immediately contiguous to the borders of the Gulf Stream, on the coast of the United States, a moderate current is generally found setting to the southward and westward, or in the direction which is opposite to the Stream, and parallel to the American coast. By a familiar association, this is styled, by all the fore-mentioned observers, as an *eddy current*; but we shall probably find, on more particular inquiry, that it has little or no claim to this character. An eddy, as is well known, is usually caused by some fixed obstacle opposed to a stream, and is nearly circular in its action. Moreover, it derives its waters directly from the parent stream, and necessarily partakes of the same temperature. I must, therefore, dissent from the views of those persons who refer this current to the eddying action of the Gulf Stream, for these reasons:

1st. Because this current, in open sea, nowhere assumes the *form* of an eddy; but, when unobstructed by violent winds, pursues its course towards the south-west, on a line which is parallel to the general direction of the coast.

2d. Because, on the outward edge of the Gulf Stream at least, there are no obstacles presented which could divert the progress of that portion of the Stream, and circumscribe the same in eddies.

3d. Because, if this current was derived from the Gulf Stream, it must necessarily partake of its temperature; but the sudden reduction of temperature on leaving the margin of the Gulf Stream is most remarkable, and is almost unparalleled, except in the immediate vicinity of ice.

We shall in vain attempt to explain this extraordinary change of temperature by the proximity of shallows or soundings, for this cannot avail if the water itself be derived from the Gulf current, to say nothing here of the general unsoundness of this explanation.

I have long since become satisfied that the current in question is neither more nor less than a direct continuation of the polar or Labrador current, which bears southward the great stream of drift ice from Davis' Strait, and which, in its progress to the lower latitudes, is kept in constant proximity to the American coast by the same dynamical law or influence, which, in the northern hemisphere, causes all currents which pass in a southerly direction to incline to the westward, in consequence of the increasing rotational velocity of the earth's surface in the opposite direction, as in the case of the trade winds in the lower latitudes.

In collating the observations of various navigators, we find reason to conclude that, in ordinary states of weather, this current may be traced from the coast of Newfoundland to Cape Hatteras, and, perhaps, to Florida, the reflux influence which follows a violent gale being of short duration.

According to this view of the case, the Gulf Stream, in its course from Florida to the Bank of Newfoundland, is for the most part imbedded or stratified upon a current which is setting in the opposite direction in its progress from the polar regions. The impulses by which these diverse currents are maintained, being as permanent and unchanging as the diurnal rotation of our planet, their opposite courses on this coast, while in contact with each other, are no more surprising or inexplicable than those of two op-

posite currents of sea for a long period.

From the fact that other in the polar monometer; and with terminated with ground between Nantucket contribute somewhat indications are required. It is desirable, therefore, to record his observations.

The drift ice from North Atlantic Current writer in the London after bearing the ice becomes exhausted is undoubtedly the Grand Bank itself process during a later in no other manner bosom, the order of temperature. The ice after the latter has by the rapid water obstructions which These two streams but like other currents, the Gulf Stream acquired in latitude along the shoals depths, by the tides.

The writer above Davis' Strait, to be to the effect of the drifts which are borne spite of the power, however, like bottom yield greatly to the the Gulf Stream in Europe, where a large the coast of Norway. The south-easterly gravitation, by the merges in the Florida subordinate gyration system of oceanic wholly unfelt upon tained, in all its elements combined with an

From the temperature in some other position of the sea is satisfactorily for such deed been ascribed that such radiation the colder particles how the supposed temperature of a current source; for on no Were it otherwise in winter, and an in tropical latitudes. work, who has kept

\* Nautical Magazine 43<sup>d</sup> west, is the farthest

posite currents of atmosphere, and the latter are often known to maintain opposite courses for a long period and at high velocities, while thus superimposed one upon the other.

From the fact that these great currents have their origin, one in the tropical and the other in the polar seas, their presence can be unfailingly identified by means of the thermometer; and with the aid of good chronometers their position and extent may be determined with greater certainty than has yet been done, particularly in the latitudes between Nantucket and Florida. In this department of hydrology every navigator may contribute something of value to his profession, and to science, for which no other qualifications are required than frequent observations and proper attention to the ship's place. It is desirable, therefore, that every ship master who traverses this region, should make and record his observations hourly upon these currents.

The drift ice from the polar basin is all found in the western portion of the Arctic and North Atlantic Oceans, notwithstanding the influence of violent westerly winds. A writer in the *London Nautical Magazine*\* supposes that a portion of the polar current, after bearing the ice along the eastern edge of the Grand Bank into the Atlantic, there becomes exhausted, or joins the Florida Stream. By its action the great stream of ice is undoubtedly thus brought within the dissolving influence of the Gulf Stream, and the Grand Bank itself, perhaps, owes its origin to the deposits which have resulted from this process during a long course of ages. But the former current probably "joins" the latter in no other manner than by passing under the same, or yielding it a passage upon its bosom, the order of super-position being mainly determined by the great diversity of temperature. The icebergs being thus carried southward by the deeper polar current, even after the latter has lost its influence at the surface, their rapid destruction is here effected by the tepid water of the Gulf Stream, and we are thus relieved from the dangerous obstructions which would otherwise be found in the lower latitudes of the Atlantic. These two streams of current, therefore, neither meet nor coalesce in any proper sense, but like other currents, both atmospheric and aqueous, pursue each its determinate course, the Gulf Stream being thrown eastward by the greater rotative velocity which it acquired in latitudes nearer the equator, and the polar current being thrown westward along the shoals and soundings of the American continent, and its contiguous ocean depths, by the tardy rotation which it derived in higher latitudes.

The writer above alluded to, supposes the natural course of the polar current from Davis' Strait, to be towards the coast of Morocco, in North Africa; but a little attention to the effect of the earth's rotation on this current, will show that both it and the ice drifts which are borne on its surface must be turned westward as here described, in despite of the powerful westerly gales which prevail in these latitudes. Light articles, however, like bottles, which are set afloat to determine the drift of currents, will not only yield greatly to the influence of these winds, but on falling into the surface current of the Gulf Stream will, of course, accompany that current in its progress to the coast of Europe, where a leading branch of this stream is found penetrating the polar sea along the coast of Norway, and appears to be ultimately resolved into the Labrador current. The south-easterly branch of the Stream assumes the shorter and more direct circuit of gravitation, by the coast of North Africa to the tropical latitudes, from whence it again merges in the Florida Stream. It is by this system of compensation, aided by various subordinate gyrations, such for instance as Rennel's current, that the great mechanical system of oceanic circulation is apparently maintained; and were the influence of winds wholly unfelt upon the ocean, it is probable that the same system would still be maintained, in all its essential features, by the mechanical influences of the earth's rotation, combined with an unstable state of equilibrium.

From the temperature of the sea upon the North American banks and soundings, and in some other positions which are analogous, it has been assumed that the mean temperature of the sea is lower on shoals than in deep water, but it seems difficult to account satisfactorily for such a result, unless upon the ground already mentioned. It has indeed been ascribed to increased radiation from the bottom, and again it has been denied that such radiation can be carried on through water from a non-luminous body; and, as the colder particles can have no tendency to rise towards the surface, it does not appear how the supposed reduction in the temperature of the bottom can materially affect the temperature of a current of fifty or sixty fathoms in depth, which is derived from a foreign source; for on none of these shoals or soundings is the water permanently quiescent. Were it otherwise, we might reasonably expect a diminution of temperature on shoals in winter, and an increase of temperature in summer, with a permanent increase if in tropical latitudes. I am informed by Mr. Geo. W. Blunt, one of the proprietors of this work, who has kept a thermometrical journal while crossing the Atlantic, that on enter-

\* *Nautical Magazine* for March, 1837, p. 139. In this article it is stated that between 42° and 43° west, is the farthest easterly position in which floating masses of ice have been found.

ing upon soundings in the English Channel, he has found an increase of temperature in the water of  $2^{\circ}$ , Fahrenheit. Those who differ from our views in regard to these currents, ought therefore to propose some rational hypothesis to account for the great reduction of temperature in the waters which lave the Atlantic coast of the United States. Were these waters derived as an eddy current from the Gulf Stream, it is probable that they would no longer serve for the myriads of codfish which now frequent our shores, and which are known to inhabit the coldest waters.

Many experiments upon the drift of currents have been made with bottles containing memorandums of the date and locality in which they were committed to the sea. These experiments are not without their value, although it is obvious that a circuitous course is liable to be construed into a direct one, and that violent winds may greatly affect the course of such objects upon the surface of the ocean, while an important diversion may result from a mere superficial cross current, as we have noticed in the case of the Gulf Stream. Perhaps the suspension of a light weight to these floats, with a line from five to twenty fathoms in length, would afford results of a more satisfactory character, although the duration of such pendulous fixtures can hardly be relied on. If fitted in this manner the fact should be noted upon the memorandum inclosed, which should specify also the length of line which may be attached.

## TIDES.

**TIDE** is a periodical motion of the water of the sea, by which it ebbs and flows twice a day. The flow continues about 6 hours, during which the water gradually rises till it arrives to its greatest height; then it begins to ebb or decrease, and continues to do so for about 6 more, till it has fallen to nearly its former level; then the flow begins anew. When the water has attained its greatest height, it is said to be high water, and when it has done falling, it is called low water.

The cause of the tides is supposed to be the unequal attraction of the sun and moon upon different parts of the earth. For they attract the parts of the earth's surface nearest to them, with a greater force than they do its centre, and attract the centre more than they do the opposite surface. To restore this equilibrium the waters take a spiral figure, whose longer axis is directed towards the attracting luminary. If the moon only acted upon the water, the time of high water would be when the moon was upon the meridian, above or below the horizon, or rather at an hour or two after, (because the moon continues to act with considerable force for some time after passing the meridian.) But the moon passes the meridian about 49m. later every day: of course, if she only acted on the tides, they would be retarded every day 49m, and it would be high water at the same distance from her passing the meridian, and it is upon this principle that the time of high water is calculated in most books of navigation, although the time thus calculated will sometimes differ an hour from the truth, owing to the neglect of the disturbing force of the sun. The effect of the moon upon the tides is greater than that of the sun, notwithstanding the quantity of matter in the latter is vastly greater than in the former; but the sun being at a much greater distance from the earth than the moon, attracts the different parts of the earth with nearly the same force: whereas the moon being at a much less distance, attracts the different parts of the earth with very different forces. According to the latest observations, the mean force of the sun for raising the tides, is to the mean force of the moon as 1 to  $2\frac{1}{2}$ . By the combined effect of these two forces, the tides come on sooner when the moon is in her first and third quarters, and later in the second and fourth quarters, than they would do if caused only by the moon's attraction. The mean quantity of this acceleration and retardation is given in the Table B, subjoined, the use of which will be explained hereafter.

The tides are greater than common about three days after the new and full moon: these are called spring tides. And the tides are lower than common about three days after the first and last quarters: these are called the neap tides. In the former case the sun and the moon conspire to raise the tide in the same place, but in the latter the sun raises the water where the moon depresses it. When the moon is in her perigee, or nearest approach to the earth, the tides rise higher than they do, under the same circumstances, at other times, and are lowest when she is in her apogee, or farthest distance from the earth. The spring tides are greatest about the time of the equinoxes, in March and September, and the neap tides are less. All these things would obtain exactly, were the whole surface of the earth covered with sea; but the interruptions

caused by the continents. A small one because the action of such seas. In view

By the Nautical minutes. The land is 9m., which 8h. 58m. nearly. is to be added to 8. To the sum 9h. 2 45m., and the sum of May 23, that is 20h. 6m. we have of May 23, 1820.

In this manner degree of accuracy that the calculated.

Many pilots rec upon at that time it is high water at 15m. they say a 5

caused by the continents, islands, shoals, &c., entirely alter the state of the tides in many cases. A small inland sea, such as the Mediterranean or Baltic, is little subject to tides, because the action of the sun and moon is always nearly equal at the extremities of such seas. In very high latitudes the tides are inconsiderable.

From the observations of many persons, the times of high water on the days of new and full moon at the principal places in North and South America, have been collected. These times are put in a table against the names of the places, arranged in alphabetical order in the table. The most common rule prescribed for finding high water is that depending on the golden number and epoch, the tide being supposed to be uniformly retarded every day. This method will sometimes differ two hours from the truth, for which reason I shall not insert it, but shall proceed to explain the calculation by the adjoined tables A and B, and the Nautical Almanac, by means of which the time of high water may be obtained to a greater degree of exactness than from our common almanacs.

#### RULE.

Find the time of the moon's coming to the meridian at Greenwich on the given day, in page 6th of the Nautical Almanac. Enter the Table A, and find the longitude of the given place, in the left hand column, corresponding to which is a number of minutes to be applied to the time of passing the meridian at Greenwich, by adding when in west longitude, but subtracting when in east longitude. The sum or difference will be nearly the time that the moon passes the meridian of the given place. With this time enter Table B, and take out the corresponding correction, which is to be applied to the time of passing the meridian of the place of observation, by adding or subtracting, according to the direction of the table.

To this corrected time add the time of full sea on the full and change days. The sum will be the time of high water at the given place, reckoning from the noon of the given day. If this sum be greater than 12h. 24m. you must subtract 12h. 24m. from it, and the remainder will be the time of high water nearly, reckoning from the same noon; or if it exceed 24h. 48m. you must subtract 24h. 48m. from that sum, and the remainder will be the time of high water, reckoning from the same noon nearly.

#### EXAMPLE I.

Required the time of high water at Charleston, (S. C.) March 17, 1820, in the afternoon, civil account.

By the Nautical Almanac I find that the moon passed the meridian of Greenwich at 2h. 31m.; to this I add 11m., taken from Table A, corresponding to the longitude of Charleston. With the sum 2h. 42m. I enter the Table B, and find (by taking proportional parts) that the correction is 45m., which is to be subtracted from 2h. 42m. (because immediately over it in the table it is marked Sub. ;) to the remainder, 1h. 57m., I add the time of high water on the full and change days, 7h. 15m. (which is found in the tide table following ;) the sum 9h. 12m. is the time of high water on the afternoon of March 17, 1820, civil account.

#### EXAMPLE II.

Required the time of high water at Portland, Maine, May 23, 1820, in the afternoon, civil account.

By the Nautical Almanac the moon will pass the meridian of Greenwich at 8 hours 49 minutes. The correction from Table A, corresponding to 70°, the longitude of Portland is 9m., which added to 8h. 49m. gives the time of the moon's southing at Portland 8h. 58m. nearly. The number in Table B corresponding to 8h. 58m. is 23m., which is to be added to 8h. 58m. (because immediately over it, in the table, is marked Add.) To the sum 9h. 21m. I add the time of high water, on the full and change days, 10h. 45m., and the sum is 20h. 6m.; consequently the high water is at 20h. 6m. past noon of May 23, that is, at 8h. 6m. A. M. of May 24. And by subtracting 12h. 24m. from 20h. 6m. we have 7h. 42m. which will be nearly the time of high water on the afternoon of May 23, 1820.

In this manner we may obtain the time of high water at any place, to a considerable degree of accuracy. But the tides are so much influenced by the winds, freshets, &c. that the calculated times will sometimes differ a little from the truth.

Many pilots reckon the time of high water by the point of the compass the moon is upon at that time, allowing 45m. for each point. Thus on the full and change days, if it is high water at noon they say a north and south moon makes full sea; and if at 11h. 15m. they say a S. by E. or N. by W. moon makes full sea; and in like manner for

any other time. But it is a very inaccurate way of finding the time of full sea by the bearing of the moon, except in places where it is high water about noon on the full and change days.

When you have not a Nautical Almanac, you may find the time of high water by means of the following tables C and D; and although the former method is the most accurate, yet the latter may be useful in many cases. To calculate the time of full sea by this method, observe the following

### RULE.

Enter Table C, and take out the number which stands opposite to the year, and under the month for which the tide is to be calculated; this number added to the day of the month, will give the moon's age, rejecting 30 when the sum exceeds that number. Against her age, found in the left hand column of Table D, is a number of hours and minutes in the adjoined column, which being added to the time of high water at the given place on the full and change days, will give the time of high water required, observing to reject 12h. 24m. or 24h. 48m. when the sum exceeds either of those times.

By this rule I shall work the two succeeding examples.

### EXAMPLE III.

Required the time of high water at Charleston, (S. C.,) March 17, 1820, in the afternoon, civil account.

In the Table C, opposite 1820, and under March, stands 16, which added to the day of the month 17, gives 33, and by subtracting 30 leaves 3, the moon's age. Opposite 3 in Table D, is 1h. 46m., which added to 7h. 15m., the time of high water on the full and change days, gives 9h. 1m. for the time of high water—differing 11m. from the former method.

### EXAMPLE IV.

Required the time of high water at Portland, (Maine,) May 23, 1820, in the afternoon, civil account.

In the Table C, opposite 1820, and under May, stands 18, which added to the day of the month 23, gives (by neglecting 30) the moon's age 11. Opposite to this, in Table D, is 9h. 19m., which added to 10h. 45m., the time of high water on the full and change days, gives 20h. 4m., from which subtracting 12h. 24m., there remains 7h. 40m. for the time of full sea, May 23, 1820. This differs 2m. from the former method.

In the third column of Table D, is given the time of the moon's coming to the meridian, for every day of her age: thus, opposite 11 days stands 8h. 57m., which is the time of her coming to the meridian on that day. This table may be of some use when a Nautical Almanac cannot be procured; but being calculated upon the supposition that the moon moves uniformly in the equator, the table cannot be very accurate. The numbers in this table are reckoned from noon to noon: thus, 1h. A. M. is denoted by 13h., 2h. A. M. by 14h., &c.

The time of new moon is easily found, by subtracting the number taken from Table C from 30. Ex.: Suppose it was required to find the time of new moon for May, 1820. By examining the table we find the number corresponding to that time is 18: this subtracted from 30 leaves 12; therefore it will be new moon the 12th May, 1820.

When the time of high water is known for any day of the moon's age, we may from thence find the time of high water on the full and change days, by the following

### RULE.

Find the time of the moon's coming to the meridian of Greenwich, in the 6th page of the Nautical Almanac; to this time apply the corrections taken from the tables A and B, (in the same manner as directed in the preceding rule for finding the time of high water,) subtract this corrected time from the observed time of high water, and the remainder will be the time of high water on the full and change days.

NOTE.—If the time to be subtracted be greater than the observed time of full sea, you must increase the latter by 12h. 24m. or by 24h. 48m. nearly.

### EXAMPLE.

Suppose that on the 17th of March, 1820, the time of high water at Charleston (S. C.) was found to be at 9h. 12m. P. M., required the time of high water on the full and change days.

I find, as in example taking this from 9 and change days.

When you have full and change by Table C, that of Table D, is 1h. high water on the

TABLE A.			T

160	22		2
170	23		2
180	24		2

In all the preceding arising from the various declinations of time of high water, t

I find, as in example 1st, preceding, that the number to be subtracted is 1h. 57m.; taking this from 9h. 12m. leaves 7h. 15m., which is the time of high water on the full and change days.

When you have not a Nautical Almanac, you may find the time of high water on the full and change by means of the tables C and D. For in the present example, I find by Table C, that the moon's age was 3, corresponding to which, in the second column of Table D, is 1h. 46m.; this subtracted from 9h. 7m., leaves 7h. 21m. for the time of high water on the full and change days.

In all the preceding calculations of the Time of High Water, we have neglected the correction arising from the variation of the distances of the sun and moon from the earth, and from the different declinations of those objects. These causes might produce a correction of 10' or 12' in the time of high water, but in general will be much less, and may, therefore, be neglected.

## CURRENTS.

A CURRENT is at present to be understood as a stream on, or a particular set in the direction of, the surface of the sea, occasioned by winds and other impulses, exclusive of (but which may be influenced by) the causes of the tides. It is an observation of Bannier that currents are scarcely ever felt but at sea, and tides but upon the coasts; and it is certainly an established fact that currents prevail mostly in those parts where the tides are weak, and scarcely perceptible, or where the sea, apparently little influenced by the causes of the tide, is disposed to a quiescent state. This will be obvious by attentive consideration of the following descriptions. The necessity of attention to the silent, imperceptible, and therefore dangerous, operation of currents, will be equally apparent.

The currents of the Atlantic are often of a local and temporary nature; yet experience has shown where and how they predominate, and reason will inform the mariner where he is to expect and allow for their operation.

With the greatest velocity of the equinoctial current we cannot pretend to be accurately acquainted. Its central direction, when in full force, is W. N. W., and generally, it is imagined, about one mile and a half in the hour, but increasing to the westward; so that off the coast of Guyana it commonly sets at the rate of two or three miles.

At any considerable distance from the coast of America, the easterly current, caused by the action of violent W. or N. W. winds, is seldom felt to the southward of lat. 36°; consequently the sea about the Bermudas, and thence southward, is free from the influence of this current. The currents here, though slow, are produced in the direction of the wind, particularly when it is of long continuance. These currents are found stronger near the islands and rocks of Bermudas than at a distance. In a brisk gale, the current here has been experienced from 12 to 18 miles in 24 hours, in the direction of the wind; at other times, when the wind was not settled, no current has been found.

To continued westerly winds are to be attributed the common occurrence of a passage from Halifax to the English Channel in 16 or 18 days, with such currents as those which carried the bowsprit of the *Little Belt*, sloop of war, lost near Halifax, in 18 months, to the entrance of Basque Roads. The currents of the Atlantic have sent to the shores of the Hebrides the products of Jamaica and Cuba, and of the southern parts of North America.

The easterly and south-easterly currents are blended in their southern regions, with the Florida or Gulf Stream, already described, and they do not seem to prevail to the S. W. of the Azores. On the contrary, to the W. S. W. and S. W. of those islands, the currents appear to follow the course of the trade winds towards the Caribbean Sea; and to the southward of the tropic they blend with the equatorial current, which sets from E. S. E. to W. N. W. and W. Towards the west, they occasionally extend to the northward of the Bermudas, and even unite with the southern edge or reflow of the Gulf Stream. The existence of these currents has long been known, but a farther examination, and more precise information are still desiderata. The recent examples of them which we have to adduce are not numerous, but they are satisfactory; they also accord with natural facts, and are in unison with that theory which derives its currents from the rotary movement of the earth, and the operation of the trade winds.

"The currents of the Caribbean Sea are probably varied by the influence of the moon, and combine in some degree, with the tides, especially about Cuba, Jamaica, and St. Domingo."

The Derrotero adds, "This idea is confirmed by what Don Torquato Pedrola, the captain of a frigate, has communicated to the Hydrographic Board. 'Although, generally,' says this officer, 'the currents between the Spanish main and the West India Islands set towards the fourth quadrant, (that is, north-westerly,) yet it, sometimes, though seldom, happens that they are found setting to the first quadrant.' N. E. in proof of which he states that he perfectly remembers, though he cannot give the elements, in consequence of having lost his journals, that in July, 1795 or 1796, when sailing with a fresh breeze from Santa Martha to Jamaica, in a schooner, he steered for Morant Point; but considering that by keeping as close hauled as that course required, he must be unable to make it before the day was spent, he preferred keeping away, to make the land to leeward of it, and did so at 8 A. M., thus augmenting the rate of the vessel's sailing. At noon he observed the latitude, in conjunction with the pilot, Don Miguel

Patina, and found keeping away W. tion and velocity, they were three o

Patina, and found that they were some minutes to the northward of Morant Point; and keeping away W. by S., they saw it at 2 P. M. Although they calculated the direction and velocity of the current, he remembers only that it was to the N. E., and that they were three days crossing from Santa Martha to Jamaica.

"On leaving the parallel of the Bago del Comboy ( $15^{\circ} 30'$ ) the first time that the Spanish surveying vessels went in search of it, and being to leeward of the meridian under which the charts placed it, by 12 leagues, they made sail so that, at the rate of sailing they expected to join the brig *Alerta* next evening, as they knew she was waiting for them at her anchorage at the southernmost of the Pedro Keys. At 8 A. M. next day, a vessel was seen ahead, which at first they mistook for a rock, but soon made out that it was a vessel at anchor; and by 9 A. M. they saw not only the *Alerta* at anchor, but also the Pedro Key, towards which the current carried them with much strength; and in spite of having to make several tacks, in order to fetch the proper channel, they were anchored beside the *Alerta* by mid-day. The commander does not recollect the longitude he observed that morning, but remembers that the current had carried them to the northward. In the next year, when surveying the west end of the Pedro Shoals, they found the current nearly the same; and this ought to be a warning to navigators not to make too free with the southern edge of the Pedro Shoals during the night.

"Much current has also been found near the Baxo Nuevo, lat.  $15^{\circ} 50'$  and long.  $78^{\circ} 40'$ , as was remarked by the brig *Alerta*, when near its northern extremity. The same is the case on its southern side; for in prior years, the schooner *St. Gregorio*, bound from Carthagena to Trinidad, saw the south end of the shoal at 4 P. M. At 5 she was three miles from it; but, noticing that the current set strongly towards the shoal, they set all sail and ran to the south until they considered the vessel 9 miles from the southern point; and the following morning tacked to sight it, which she did not effect, having doubtless passed to leeward of it.

"In more than thirty voyages made by Captain Pedrola, from the Spanish main to Porto Rico, St. Domingo, and Cuba, sometimes with chronometers, and others without them, he remarked that between the last two islands and the coast of the main, sixteen miles daily might be counted on for a westerly current, but not so much for the former."

In the Memoir, 3d edition, pp. 68-9, was this passage—"The trade wind blows with strong and continued vigor, at certain seasons, particularly in the winter months, and rolls the waves over a great extent of sea, into the great bay westward of Carthagena, which we have called the Bay of Guatemala. This may cause, at times, an onset, but no constant current is to be found." To this is added, in the *Derrotero*, "Among the original papers possessed by the Deposito Hydrografica, the following observations, by different officers, have been found, which may tend to throw some light upon the matter:

"In the examination of the coast between Porto Velo (Porto Bello) and the Bocas del Toro, made in 1787, by Don Fabian Abances, he found on that coast, in the month of April, strong currents setting to the E. N. E. at the rate of two miles an hour; so that, heaving to at night, off Cocle Point, he found himself in the morning up at Chagre. The winds at the time were either calm or squally from the south-westward. Don Fabian proceeded to the northward, to the parallel of  $10^{\circ}$ , and then met with winds from N. and N. N. E., with which he steered W. and W. N. W. until he considered himself 10 leagues to the west of the Bocas del Toro; but the current had carried him to the E. S. E., so that, when he expected to make the Bocas, he found himself at the point of Miguel de Borda, about 5 leagues to the westward of Chagre. During the whole time, from leaving Porto Velo, he never gained an observation, the weather being adverse. On the 11th May he noticed that the waters of the Lagoon of Chiriqui ran out through the Bocas with violence, and formed, at a short distance from the coast, an angle bending to the E. S. E."

Again, "The captain of the ship of the line Don Pedro de Obregon, in the month of July, was bound from the Rio Tinto, (Black River,) to the Havana, and he experienced currents to the north-westward, with winds from the N. E., E. N. E., squalls and calms, and in such a manner that he made the Tortugas Bank of Florida, without having been able to sight Cape Antonio or west end of Cuba."

"Don Joaquin de Asunsola and la Azuela, in July, found strong currents to the S. W. of Cape Gracias a Dios, after having strong winds from the E. N. E. and E. S. E., with squalls; and from the said cape to the westward he found, also, that the current took the same course; and he concludes that, after he had made Providence Island, and until he arrived at Black River, the currents were strong to the W. and S. W."

"The captain of a frigate, Don Gonzalo Vallejo, when at anchor on the Mosquito coast, near Barancas, or Bragman's Bluff, observed that the current set to the north, at the rate of rather more than half a mile in the hour."

Finally, "Don Ignacio Sanjust, commanding the frigate *Flora*, on a voyage from Havana to the Gulf of Honduras, and being off Caballos Point, noticed that the current

ran with much force to the N. E. in the month of December; and he adds that, in this gulf, the currents followed no known rule; that near the keys they run with violence, and into the channels between them; so that by them a vessel, during a calm, may soon be carried on the reefs. In the channel between the keys and coast of Honduras, to the south, the water was found setting to the N. E., and, near the coast, to the east."

Near the parallel of 10° N. the currents produced by the N. E. and S. E. trade winds may be imagined to unite; and this united stream, being divided by the island of Trinidad and the Southern Antillas, thence passes into the Caribbean Sea.

From the mouths of the Amazon, Orinoco, and other rivers, a vast efflux of water falls into the Equatorial Sea, more particularly in the wet season: what effect this water may have on the current is at present unknown. But we learn, from the *Derrotero de las Antillas*, that, "Off the coasts of Guyana there are two currents: 1st. The general or equinoctial current and another caused by the tides; the boundary of the first is 12 leagues from shore, or in the depth of 9 fathoms of water, from which towards the shore, that of the tide is experienced. The ebb sets to the N. E. and the flood towards shore. In the Gulf of Paria, also, the tide influences the currents.

"In the southern straits, or channels of the Antillas, the velocity of the current inward is seldom under a mile an hour; but its changes are so great, that it is impossible to point out its exact direction, or to establish any general rule for its velocity."

"On the Colombian coast, from Trinidad to Cape la Vela, the current sweeps the frontier islands, inclining something to the south, according to the straits which it comes from, and running about 1½ mile an hour with little difference. Between the islands and the coast, and particularly in the proximity of the latter, it has been remarked that the current, at times, runs to the west, and at others, to the east. From Cape la Vela, the principal part of the current runs W. N. W.; and, as it spreads, its velocity diminishes; there is, however, a branch, which runs with the velocity of about a mile an hour, directing itself towards the coast about Carthagena; from this point, and in the space of sea comprehended between 14 degrees of latitude and the coast, it has, however, been observed, that, in a dry season, the current runs to the westward, and in the season of the rains, to the eastward.

"On the Mosquito Shore, and in the Bay of Honduras, no rule can be given for the alterations of the current. All that can be said is, at a good distance from land, it has generally been found setting towards the N. W.

"In crossing from the coast, or from Carthagena, to the islands, it has been observed that, from La Guayra to the eastern part of St. Domingo, on a voyage made in December, a difference of 106 miles to the westward, was found during the seven days the voyage lasted."—*Derrotero de las Antillas*.

Mr. Town, in his *Directions for the Colombian Coast*, has said, "Although, between the island of Jamaica and the Spanish main, westerly currents are most frequent, yet they do not always prevail; for ships have been known to be driven by the current from 50 to 60 miles to the eastward, in 4 or 5 days. From the beginning of May till November, (the rainy season,) the sea-breeze seldom or never blows home to the main; and ships going there should never go to the southward of the latitude of 11°, until they are, at least, 40 or 50 miles to the westward of their intended port; after which they may make a south course, as the land-breeze, which is generally from the S. W., and the strong easterly current, will set you to the eastward of your intended port, if great care be not taken. When to the eastward, if light winds prevail, you must stand to the northward until you meet the sea-breeze, which will be between the latitudes of 10 and 11 degrees, and then run to the westward.

"Being off Porto Bello, in His Majesty's ship *Salisbury*, on or about the 12th of August, 1816, and being a little to the eastward of that port, with light variable winds for several days, the ship was set to the eastward, at the rate of 50 miles per day; and, having been afterwards placed in the same situation, I found it necessary to make the land well to the westward, and to keep close to it. From November until May, (the dry season,) you should endeavor to make the land well to the eastward, and run along shore; as the sea-breezes generally blow very strongly, and the current sets to the westward at the rate of about 2 or 3 miles an hour.

"Between Chagre and Porto-Bello, during the rainy season, there is generally a northerly current, at the rate of from 1½ to 2½ miles an hour. After the end of the rainy season the current sets to the southward and westward, and strong southerly and easterly winds prevail here. From November until May, (the dry season,) the southerly and westerly are very light winds, except in squalls, which end with heavy rain. In sudden squalls, you will often have the winds from all points of the compass.

"If at Chagre, at any time during the rainy season, (May till November,) and bound to the eastward, endeavor to get 4 or 5 leagues from the land, so soon as you can; for the winds are, in general, very light, and the current very strong. The latter sets from

Chagre directly on the rocks of Porto Bello, and thence along the land from E. by N., E. N. E., E. S. E., and according as the land lies: its general rate being from  $1\frac{1}{2}$  to  $2\frac{1}{2}$  miles in an hour. Great care should be taken when near the land, if a heavy squall and rain appear to be coming on. During this you will have the wind from all points of the compass, and often so strong that all sail must be taken in.

"In crossing the Gulf of Darien, little or no current will be found; whenever there is any, it sets about south, S. by W., or S. by E. up the Gulf.

"Near Carthagena the current generally goes by the wind; but off the islands of Rosario it sets to the N. W. and N. N. W., from one to two miles an hour.

"Between Carthagena and the Magdalena, in the rainy season, you cannot put any dependence on the winds or currents; but, from November to May, the trade wind blows home.

"I should recommend, if turning to windward, with strong trade winds, to keep the shore close to; whereas, by going off from the land, you will not only have a heavy sea, but also a strong N. W. current. If you have light variable winds, approach no nearer to the land than 4 or 5 leagues, as you may be certain of an easterly current."

Captain Livingston says, "During 5 weeks in which I remained at Carthagena, in June and July, 1817, the current in-shore set constantly and strongly to the northward, at a rate, I am convinced, of not less than  $1\frac{1}{2}$  mile an hour, or nearly as strong as the Mississippi at New Orleans. I have seen the *Esk*, sloop of war, current-ride against a very fresh sea-breeze, when at anchor, nearly west from the city, distant about a mile."

Upon the Current between the Grand Cayman and Cape Antonio, Captain Monteath has said, "In the months of May, 1814 and 1815, (two voyages in which I was chief-mate of the ship *Prince Regent*, from Kingston,) in June, 1817, in the ship *Fame*; and in April and December, 1820, in the ship *Mary*, between Grand Cayman Island and Cape Antonio, I invariably found the current setting strong to the eastward, or E. S. E.; and I have heard it generally remarked that, vessels shipping a course from the Caymans for Cape Antonio, have found themselves off, or even to the eastward of Cape Corrientes; this has, in the above cases, invariably happened to myself."

Farther on, "In my passage from Kingston, towards Campeche, in the ship *Fame*, June, 1817, between Cape Antonio and Cape Catoche, I found the current to set due north 27 miles in a run of 18 hours."

We have already given, in the preceding page, the remark of the Spanish navigators on the currents of the Mosquito Shore and Bay of Honduras. We now add those of Captains W. J. Capes, of London, and John Burnett, of Port Glasgow.

Captain Capes says, "Between Jamaica and Bonacca the current generally sets to the northward and westward. Here, in May, 1816, I was set 60 miles to the westward by the current, and found that it set rather northerly, from one quarter to half a mile an hour. Between Jamaica and Bonacca are the islands called the Swan Islands, in latitude  $17^{\circ} 22'$ , longitude  $83^{\circ} 36'$ . I would not advise any one bound to the Bay to make these islands, for it cannot be of service, and the current is so very irregular about them, that the attempt serves only to bewilder the navigator; and by falling in with them in a dark night, a ship would be in danger of running on shore, as the land is very low.

"About the southern Four Keys the currents are very uncertain. I have known three ships to be lost on these Keys by lying to for the night, after they have made them; for, at all times, the current sets strongly on them; and, in two of the cases, the ships wore every two hours, with an intention to keep their station. In one voyage I took my departure from Bonacca at four P. M. with a strong breeze from the east, which continued till midnight; it then died away, (no uncommon circumstance in this part,) so that I did not lift the southern Four Keys before four P. M. the next day, from the fore-yard. I then made all snug, and plied to windward, under single-reefed topsails and top-gallant sails over them; tacked ship every three hours during night, and, to my surprise, in the morning, we were not more than one or two miles to windward of them; so, if I had have the ship to, I have no doubt but she would have been driven on shore by the current.

"If a ship be lying-to, under Rattan, it will not be amiss to try the current. It is my opinion that the current about Bonacca takes two different directions; one part setting to the N. W. and the other part branching to the S. S. W. I have found it so on several trials, which is the reason that I prefer taking a departure (for the bay) from the middle or east end of Rattan; for, if a ship take her departure from the west end, her course will be N. N. W.; but it very frequently happens that ships get down on those reefs when they take their departure from the west end. The reason is this: a ship steering N. W. from the west end has more of the current on her beam, which sweeps round the west end of Rattan very strong at times; consequently ships that take their departure from the east or middle part do not feel so much of the current."

Captain Burnett, in his directions for sailing from the Bay of Honduras, says, "when the trade wind prevails, a current, often very strong, sets down between Mauger Key and

the Northern Triangle; there, dividing itself, it sets to the southward, between Turneff and the Main Reef; and to the northward between the Triangle Reef and Ambergris Key. It is most advisable, with the wind from the east to E. S. E. to sail to leeward of the Triangle, as you will have a strong current in your favor so soon as you bring it to the eastward of you.

In the channel, between the island Cozumel and the shore, the current along shore runs at the rate of nearly  $2\frac{1}{2}$  miles an hour, till lost in the Mexican Sea.\*

MEXICAN STREAM, &c.—It is, we believe, a well-established, although a controverted fact, that there is a constant indraught on the western side of the Channel of Yucatan, into the Mexican Sea: and that there is commonly a redow on the eastern side of the same channel around Cape Antonio, &c.

With the former in its favor, his Majesty's ship *Resistance*, Captain Adam, off the Bank of Yucatan, made a course W. N. W.  $\frac{1}{2}$  W. nearly 80 leagues in the 24 hours, December 16 and 17, 1806;† and we have no doubt that many instances may be found to prove the same effect: on the Cuba side only, it appears that vessels have been set to the southward; and Captain Manderson has stated that, when a strong easterly wind has been blowing between Cuba and Florida, vessels heaving to off the south side of Cape Antonio, at about two leagues from shore, have, in the course of one night, been carried against a strong sea-breeze, nearly as high as Cape Corrientes, being a distance of 10 leagues‡.

From Cape Antonio the current sets, at times, to the E. S. E. past the Isle of Pines. Captain Livingston has informed us that, in March 1818, he found the current between the Great Cayman and Isle of Pines to set in that direction, at the rate of full 2 miles and a half an hour, or 66 miles in the 24 hours. In August, 1817, he found the set nearly the same, but the current not half so strong. The Spanish Directory says, "From Cape de Cruz, on the south side of Cuba, it is noticed that there is a constant current to the westward, with some inclination to the southward or northward, and which has been known sometimes to set 20 miles in a single day." In opposition to this, the exact words of Captain Livingston are, "I have twice experienced a strong current setting about E. S. E. between the Caymans and Isle of Pines; and on the latter of these occasions, both my mate and myself separately calculated it to set about 60 miles per day or  $2\frac{1}{2}$  per hour. This, however, I incline to think a very particular case, such as may but seldom occur. The winds at this time were light and westerly. On the other occasion, so far as I recollect, it set about 12 or 14 miles per day only. All my papers on these subjects have been lost; but the first instance was too remarkable to be forgotten."

On the northern coast of St. Domingo, and in the windward passages, there does not appear to be any general current. On the north side of Cuba the case is nearly the same; but in the channel here is a regular tide throughout the year, subject, however, to certain variations.

The currents of the Caribbean Sea are probably varied by the influence of the moon and change of seasons, and combine, in some degree, with the tides; especially about Cuba, Jamaica and St. Domingo.‡

In an old book, (Kelly's Navigation, vol. i. 1733,) is an abstract from a journal, which contains the following passage:—"Between the west end of Hispaniola and the Island of Jamaica, if I took my departure upon a full or change of the moon, I found that I made many leagues more than I did at the quarters of the moon. At the full and change, I was looking out for the land long before I saw it; and, at the quarters, I was down upon it long before I looked for it. The reasons, as I found afterwards, were, that the full and change made a strong windward current, and the contrary on the quarters. This has been exemplified in many instances."

On this subject Captain Livingston says, "It is a prevailing opinion with many, that the moon governs entirely the currents among the West India Islands. No doubt the moon has some effect on them, but I am of opinion that the winds have a still more powerful influence.

"It is rarely, indeed, on the north side of the Island of Jamaica that there is a westerly current when the north and N. W. winds prevail; the current then always, or almost always, setting to the eastward.

"On the south side of Cuba, when the wind is westerly, which it often is, you are al-

ways certain of a re-flowing current round Cape Antonio. This is easily accounted for: as, when the fresh trade wind ceases, and the westerly winds set in, the barrier is, in some degree, removed, which confined the waters in the Gulf of Mexico, and they seek to regain their level as well by the Channel of Yucatan as by the Strait of Florida."

In the windward Channel of Jamaica the current generally sets with the wind to leeward or S. W., yet, both here and at Jamaica, it is variable. Some have affirmed that, when a current runs to leeward, on the south side of Jamaica, there is frequently one setting eastward on the north side; and, at other times, no current is to be perceived; also that, when a lee current runs on the north shore, the same circumstances may be perceived on the south shore as were before observed on the north.

But between the Mona Passage and the Caymans, south of the islands, the tendency of the currents towards shore is most commonly found to the north-westward.

In the Bahama Passages the currents are devious; both weather and lee currents having been found. These also appear to be influenced by the tidal causes; for the tides are operative on the banks, and sometimes set strongly.

The following is an additional detail of the best information we have been able to collect, of the currents in the Caribbean and Mexican Seas, from the Derrotero de las Antillas, &c.

In the channel between Trinidad and Grenada the current has been found to set nearly west; on the south side half a point southerly, and on the north side half a point northerly. Its velocity from a mile to a mile and a half per hour.

Between Grenada and St. Vincent's, among the Grenadines, the currents are devious; but the general inset appears to be W. by N.

Between St. Vincent's and St. Lucia, the current, from the eastward, sets in more northerly; and within, on the west, it has been found setting to the N. W. Between these islands it seems to be as strong as in any other part of the range.

Between St. Lucia and Martinique it has been found nearly north. Very variable on the western side of the latter.

The current sets nearly in the same manner between Martinique and Dominica; but to the north-westward of the latter, it has been found nearly S. W. three-fourths of a mile hourly. Northward of Guadaloupe it sets W.  $\frac{1}{2}$  S. and between Montserrat and Antigua N. W.

Between Redonda and Nevis it has been found W. S. W. half a mile hourly.

Without Barbuda and the northern isles, it has set about W. by N. and to the northward of the Virgin Isles and Porto Rico about W. S. W.

At the distance of about one degree, within the range of the Caribbee Islands, and to the Virgin Islands, the current has been found setting, in general, to the W. N. W. from one mile to one mile and a half an hour.

In the Mona Passage, between Porto Rico and Hayti, the current has been marked as frequently setting to the N. W. and we have instances of a set through to the S. W.; but Captain Monteath, in February, 1816, when proceeding southward towards Porto Rico, in from latitude  $23\frac{1}{2}^{\circ}$  to  $22^{\circ}$ , and longitude  $64^{\circ}$  to  $65^{\circ}$ , found the current setting N. N. E. at the rate of 20 miles in the 24 hours; and he says that, off the N. W. end of Porto Rico, it invariably set from the Caribbean Sea to the north and N. N. E. On the western side of the passage it set north, two miles an hour.

From Trinidad, westward, and off the north side of the Spanish Leeward Isles, the current has been found setting west and S. W. to the Gulf of Maracaybo; thence S. W. also to Cartagena: but it varies, as has been already noticed.

From Cartagena towards the channel of Yucatan, it has been found N. N. W., N. W., W. N. W., and N. W. by N., from 1 to nearly 2 miles, and then decreasing to  $1\frac{1}{2}$  mile per hour. It has also been found setting to the eastward, as shown in the preceding pages.

At about 40 miles northward of Cape Catoche, the current has been found N. W. by W.; changing thence to S. S. W. off the N. W. point of Yucatan, nearly at the same distance from the coast. Rate something less than half a mile an hour. Between this and Vera Cruz the current ceases.

The action of the S. E. trade wind, in the equatorial regions, and the apparent disposition of the waters in these regions to retire westward, which has been attributed to the rotary motion of the earth, are considered as the causes of a current which is known to flow, during a great part of the year, from the Ethiopic Ocean to the Caribbean Sea, and which has frequently carried ships considerably to the west and W. N. W. of their reckonings, when off the N. W. part of Brazil.

On the east coast of Brazil the currents generally partake of the direction of the monsoons, as before explained, but vary in velocity according to the advance and decline of them, as well as the part of the coast.

Lieutenant Hewett says, during the southerly monsoon, the currents to the southward of Cape St. Augustin are not so powerful as to the northward, where they increase in strength until the months of June and July, and then gradually decline. On the contrary, in the northerly monsoon, they are generally very strong to the southward of Cape St. Augustin, when they are weak to the northward, as they have some difficulty in detaching themselves from the stream, which runs from the S. E. trade around Cape St. Roque.

Mr. Lindley also notices that "A strong current runs southward from Cape St. Augustin, commencing about the middle of October, and continuing until January, after which there is no particular current till the middle of April, when a powerful one sets in northerly till July, and then subsides in like manner."

The currents of the River Plata, and other local currents near the shores, have been before noticed, in the Descriptions and Sailing Directions.

The following facts establish the existence of the combined current; and they show, in some degree, its force and direction towards the Brazilian coast:

1. In June and July, 1795, the *Bombay Castle*, East Indiaman, between the Isle of Palma (of the Canaries) and the coast of Brazil, experienced a westerly current, amounting to  $6\frac{1}{2}^{\circ}$ .

2. On May 20, 1802, the *Cuffnells*, East Indiaman, lost the N. E. trade in  $8\frac{1}{2}^{\circ}$  north, long.  $22^{\circ}$ . Gained the S. E. trade June 4, in  $5^{\circ}$  N., long.  $21^{\circ}$ . From the equator the current was found to set W. and W. by N., from 30 to 52 miles daily, till the coast of Brazil was in sight on the 14th, in  $8^{\circ}$  S.

3. May 23, 1802, the *Sir Edward Hughes* lost the N. E. trade in  $6^{\circ}$  N., long.  $23^{\circ}$ , and the wind was from S. S. E. on the 25th, in  $5^{\circ}$  N., and  $23^{\circ} 30'$  W. The trade kept far at southward, and the current set strongly to the west.

4. October 16, 1805, the European fleet lost the N. E. trade in  $11^{\circ}$  N., long.  $28^{\circ}$ , and gained the S. E. trade on the 26th, in  $4^{\circ}$  N., long.  $29^{\circ}$ . On the 4th of November, the land of Brazil was seen in lat.  $6^{\circ}$  S.; the wind near the land was at E. by S. and E. S. E. By proceeding too far to the westward, two ships of the fleet were wrecked in the morning of the 1st of November, on the Roccos, or Low Keys, in lat.  $3^{\circ} 52'$  S., and  $33\frac{1}{2}^{\circ}$  W., and several others had nearly shared the same fate. This catastrophe had probably been avoided by a due knowledge of, and attention to, the effects of the current, which was subsequently ascertained to set  $2\frac{1}{2}$  miles per hour to the westward, near the Roccos.

5. On the 1st of June, 1793, the *King George*, East Indiaman, crossed the line in  $30^{\circ}$  W., and from the 2d to the 5th experienced a westerly current of  $1^{\circ} 33'$ . On the 5th, Cape St. Roque was in sight, and the ship was kept working until the 10th, endeavoring ineffectually to weather it. She then stood to the north-eastward, closely hauled, to lat.  $1^{\circ}$  N., in order to regain the variable winds in north latitude, and then proceeded to cross the equator, which was at length effected.

6. In May and June, 1807, the transports, laden with ordnance stores, for the army at Monte Video, by crossing the equator too far to the westward, were carried so far in this direction by the current, that they could not get to the southward of Cape Augustin, (lat.  $8^{\circ} 23'$  S.), and were twice obliged to stand to the northward, into variable winds, to regain easting, after having attempted ineffectually to gain the regular south-east trade wind.

7. It is a well known fact, that several ships have made the isle of Fernando Noronha, on their outward bound passage to India, by the currents having set them to the westward, after the failure of the N. E. trade wind. The current runs strongly about this island.

## WINDS.

WIND is a sensible current or movement of the atmosphere over the earth's surface. The Winds are divided into Perennial, Periodical, and Variable. They are also divided into General and Particular. Perennial, or Constant Winds, are those which always blow the same way; such is that easterly wind, between the tropics, commonly called the Trade Wind. Periodical Winds are those which constantly return at certain times: such are land and sea-breezes, blowing alternately from land to sea, and from sea to land. Variable, or Erratic Winds, are such as blow now this way, now that, and are now up, now hushed, without regularity either as to time or place: such are the winds prevalent to the northward of  $30^{\circ}$  N. latitude.

PERENNIAL latitudes, or to follow the course the African shore from the north comes more east either to the north.

The Perennial times, to  $30$  deg on the African which is here from Brazil than on the motion of the earth.

HEAT' increased greater quantity one continued with imbibe more moisture in winds and land and sea-breezes of wind \*

Small islands. Trade Wind. It is he occasioned, by the tops of the hills, an effect peculiar to it is sufficiently explained according to its nature. Upon a mountain a pleasant breeze is (being condensed) flying clouds; but any mountainous.

The clouds, in contrary to the wind above it; and west. It is found blows from the fresh Trade Wind.

There are several those which appear in the atmosphere before the appearance of a glim (as the sailors call it) a N. E. storm of  $30^{\circ}$ , whether toward, along the current of the region tended with a N. flying clouds which.

Ship Masters as these higher

\*The causes of the delphinia:—The air, heat, and it does not earth, will give place elevation, one stratum altitude, as denser much denser by the warmer. Hence, each other. Yet, exceed that in the preponderate and with increasing velocity increases as it falls it rises, and hence daily varying current, No. 12.

**PERENNIAL or TRADE WIND.**—Over extensive tracts of ocean, in the lower latitudes, or toward the equator, Perennial or Trade Winds are found to prevail, which follow the course of the sun: thus, on the Atlantic Ocean, at about 100 leagues from the African shore, between the latitudes of 10 and 26 degrees, a constant breeze prevails from the north-eastward. Upon approaching the American side, this N. E. wind becomes more easterly, or seldom blows more than one point of the compass from the east, either to the northward or southward.

The Perennial or Trade Wind, on the American side of the Atlantic, extends, at times, to 30 degrees of latitude, which is about 4 degrees farther to the northward than on the African side. Likewise on the south of the equator, the Perennial Wind, which is here from the south-east, extends 3 or 4 degrees farther towards the Coast of Brazil than on the opposite side of the ocean. The general cause of this wind is the motion of the earth, in its diurnal rotation, connected with its orbital movements.

HEAT increases evaporation, and renders the atmosphere capable of supporting a greater quantity of moisture than it would do in a cooler state:—were the atmosphere of one continued warmth, and its motion uniform, there would be no rain; for it would not imbibe more moisture in exhalation than it could support. Heat often produces diversity in winds and weather, for near the land, when the sun has great influence, it occasions land and sea-breezes near the shore; and, in particular situations, heavy gusts and squalls of wind.\*

Small islands, lying at a great distance from the main land, operate very little upon the Trade Wind. If elevated, these islands are more subject to rain than if low: this may be occasioned, principally, by the ascent given to the wind, or atmosphere, in rising over the tops of the hills; when, being cooled, it condenses into small drizzly rain. This is an effect peculiar to all mountains, even in the middle of continents, when the atmosphere is sufficiently charged with moisture. For the sun's rays, by heating the atmosphere, according to its density, renders it much warmer at the bottom than at the top of hills. Upon a mountain sloping from the sea towards the top, and about 700 yards in height, a pleasant breeze has been observed in shore, and fine clear weather; the air in ascending, (being condensed by cold,) at about half way up, had the appearance of fog, or thin light flying clouds; but at the top was a misting rain; and this may frequently be seen in any mountainous country.†

The clouds, in the higher regions of the air, are frequently seen to move in a direction contrary to the wind below. The north-east Trade Wind has frequently a south-westerly wind above it; and a south-east wind often prevails beneath one whose direction is north-west. It is found that, just without the limits of the Trade Wind, the wind generally blows from the opposite quarter. The counter-current of air, above, is often seen in a fresh Trade Wind.

There are several heights of clouds on the coast of North America; the highest and those which appear of the finest texture, (if I may be allowed the expression) float highest in the atmosphere. Clouds of this description always come from the westward; just before the appearance of an easterly storm, they gather in the S. W. and S. S. W., and if a glim (as the sailors call it) in the N. E. and N. N. E. their appearance in the sky indicates a N. E. storm of snow or rain. All great storms which are met with above the lat. of 30°, whether snow or rain, begin to the westward and advance gradually to the eastward, along the coast of North America, in conformity with the general atmospheric current of the region. When a S. W. wind, in the upper regions of the atmosphere, is attended with a N. E. or opposite wind below, the latter is commonly accompanied with low flying clouds which drive before the wind, while the higher clouds go in a contrary direction.

Ship Masters and Pilots, on leaving the coast, outward bound, may notice that so long as these higher clouds do not gather and thicken in the W. or S. W. so long a heavy or

\*The causes of Tornadoes, Hurricanes, and Squalls, have been thus assigned by Dr. Hare, of Philadelphia:—The air, being a perfectly elastic fluid, its density is dependant on pressure, as well as on heat, and it does not follow that air, which may be heated in consequence of its proximity to the earth, will give place to colder air from above. The pressure of the atmosphere varying with the elevation, one stratum of air may be as much rarer by the diminution of pressure consequent to its altitude, as denser by the cold consequent to its remoteness from the earth, and another may be as much denser by the increased pressure arising from its proximity to the earth, as rarer by being warmer. Hence, when unequally heated, different strata of the atmosphere do not always disturb each other. Yet, after a time, the rarefaction in the lower stratum, by greater heat, may so far exceed that in the upper stratum, attendant on an inferior degree of pressure, that this stratum may preponderate and begin to descend. Whenever such a movement commences, it must proceed with increasing velocity; for the pressure on the upper stratum, and, of course, its density and weight, increases as it falls; whilst, on the contrary, the density and weight of the lower must lessen it as it rises, and hence the change is, at times, so much accelerated as to occasion the furious and suddenly varying currents of air which attend tornadoes, hurricanes, and squalls.—*Silliman's Journal*, No. 12.

† Oriental Navigator, or East India Directory.

long storm of snow or rain will not occur. Any rain or foul weather, that proceeds from winds, which rise from the eastward, and drive before the wind to the westward, without a fall of the barometer, is not attended with violent wind.

The space from latitude  $25^{\circ}$  to  $28^{\circ}$  or  $29^{\circ}$  between the Variable and Trade Winds, is remarkable for a continual change of winds, with sudden gusts and calms, rain, thunder, and lightning. This space has been called the Horse Latitudes, because it has often been found necessary here to throw overboard the horses which were to be transported to the W. Indies, &c. To the northward of these latitudes, upon the American coast, and more than one third over the Atlantic, westerly winds prevail nearly nine months in the year.

In the latitude above the Trade Winds, the wind from the W. S. westward being replete with moisture, from the great exhalation between the tropics, as it approaches the cold and higher latitudes, becomes condensed into showers of hail, rain, or snow.

There is often an interval of calm between the Trade Winds and the opposite winds in high latitudes. This is not, however, always the case; for, if the Trade Wind in its borders be much to the eastward, it frequently changes gradually round without an interval of calm. There is generally also a calm in a certain space between the two prevailing winds blowing in opposite directions, as between the Trade Wind and the westerly wind on the African coast. In the limits of the Trade Wind, a dead calm is generally the prelude to a storm, and it ought always to be considered as a prognostic thereof, though a storm often appears without this warning.

When the sun is at its greatest declination, north of the equator, the S. E. wind, particularly between Brazil and Africa, varying towards the course of the sun, changes a quarter or half a point more to the southward, and the N. E. Trade Wind veers more to the eastward. The contrary happens when the sun is near the southern tropic: for then the S. E. wind, south of the line, gets more to the east, and the N. E. wind, on the Atlantic, veers more to the north.

On the African side of the S. Atlantic, the winds are nearest to the south, and on the American side nearest to the east. In these seas, Doct. Halley observed, that when the wind was eastward, the weather was gloomy, dark, and rainy, with hard gales of wind; but, when the wind veered to the southward, the weather generally becomes serene, with gentle breezes, next to a calm.

The EQUATORIAL LIMITS of the N. E. Perennial or Trade Wind between the meridians of  $18^{\circ}$  and  $26^{\circ}$  degrees west, have been found, upon the comparison of nearly 400 journals, English and French, to vary considerable even in the same months of the year. We have shown, by the annexed table, where the N. E. Trade, according to the probable mean, may be expected to cease in the different months: and it will be found to answer the purpose with sufficient precision.

In this table the columns of Extremes show the uncertain termination of the trade winds, as experienced in different ships. The annexed columns show the Probable mean; and the last column exhibits the mean breadth of the interval between the N. E. and S. E. winds.

Thus the table shows, that, in the month of January, the N. E. Trade has been found sometimes to cease in the parallel of  $10^{\circ}$ , and sometimes in that of  $3^{\circ}$  N. That the probable mean of its limit is about  $5^{\circ}$  N.—That the S. E. Trade at the same time, has been found to cease sometimes at only half a degree north of the line, and sometimes at 4 degrees. That the probable mean of its limit is, therefore, two degrees and a quarter. And that the interval between the assumed means of the N. E. and S. E. Trade Winds is equal to  $2\frac{1}{4}$  degrees: and so of the rest.

Table showing the Equinoctial Limits of the N. E. and S. E. Trade Winds, between the Meridians of  $18^{\circ}$  and  $26^{\circ}$  Degrees West.

"The annual of the sun, which dry seasons. loud thunder east, but interrupts the atmosphere.

"When the then the trade

In the space of variable winds between the trades, exhibited in the last column, it has been found, that southerly winds prevail more than any other; more particularly when the sun has great northern declination. Homeward bound East India ships are therefore enabled, at this season, to cross the space more quickly than those outward bound; which they do, in some degree, at all other times. Yet calms and variable winds are experienced in every month in the year, within this space; but the former, which are more generally in the vicinity of the N. E. trade, seldom continue long. These calms are frequently succeeded by sudden squalls, against which every precaution should be taken, as many ships have lost their topmasts, and have been otherwise damaged by them. Whirlwinds have sometimes accompanied these squalls.

On the eastern coast of North America, and among its islands, the course of the general easterly or trade wind is uninterrupted, though subject to some modifications in direction and force. At a short distance from the land the sea-breeze calms at night and is replaced by the land-breeze. This variation happens every day, unless a strong wind prevails from the northward or southward; the first of these being experienced from October to May, and the second in July, August, and September.

To the southward of Newfoundland, shifts of wind are very common, and it frequently happens that, after blowing a gale upon one point of the compass, the wind suddenly shifts to the opposite point, and blows equally strong. It has been known that, while one vessel has been lying to, in a heavy gale of wind, another, not more than 30 leagues distant, has, at the very same time, been in another gale equally heavy, and lying to, with the wind in quite an opposite direction. This fact shows the whirlwind character of these gales, the opposite winds being on opposite sides of the circuit of the gale.

In the year 1782, at the time the *Ville de Paris*, Centaur, *Ramillies*, and several other ships of war, either foundered, or were rendered unserviceable, on or near the Banks, together with a whole fleet of West Indian men, excepting five or six, they were all lying to with a hurricane from E. S. E. the wind shifted in an instant to N. W. and blew equally heavy, and every ship lying to, under a square course, foundered.

The winds within the Gulf are not so liable to sudden shifts as on the outside, or to the eastward of Breton Island. The weather to the southward of Magdalen Islands, between them and Prince Edward Island, is generally much clearer than on the north.

**BERMUDAS' ISLES.**—Near these islands, hurricanes and tempests are very frequent; but the prevailing winds, with fine weather, are from between the south and west. Hakluyt, in his voyages, 1598, calls the sea about the Bermudas a "hellish place for thunder, lightning, and storms;" and another writer, in 1615, describing the arrival of the English at these islands in 1609, has said, "Sir George Somers, sitting at the sterne, seeing the ship desperate of relief, looking every minute when it would sinke, he espied land, which, according to his and Capt. Newport's opinion, should be that dreadful coast of the Bermodes, which islands were, of all nations, said and supposed to be enchanted, and inhabited with witches and devils; which grew by reason of accustomed monstrous thunder, storms, and tempests, neere unto those islands; also for that the whole coast is so wondrous dangerous of rocks that few can approach them but with unspeakable hazard of shipwreck." We now laugh at this; knowing that the mild and regular climate of these islands is preferable even to that of Madeira, and to be preferred for the purity of its air, together with the abundance and quality of fruits and vegetables.

The general easterly wind, of the tropical regions, is felt on the coast of Guyana and on the coasts of the Caribbean and Mexican Seas, but with variations which may be denominated diurnal and annual. The diurnal period is that which the sea-breeze causes, and which strikes the coast usually at an angle of two points, less or more, according to the locality and other circumstances; and then the land wind, which, coming from the interior, always blows off shore. The sea-breeze comes on at about nine or ten in the forenoon, and continues while the sun is above the horizon, increasing its force as that luminary augments its altitude, and diminishing, in a similar proportion, as the sun's altitude decreases. Thus, when the sun is on the meridian, the sea-breeze is at the maximum of its strength; and at the time that the sun reaches the horizon, this breeze has perceptibly ceased. The land-breeze commences before midnight, and continues until the rising of the sun; sometimes longer. A space of some hours intervenes between the land-breezes ceasing and the sea-breezes coming on, during which there is a perfect calm.

The annual period of the trade wind here is produced by the proximity or distance of the sun, which occasions the only two seasons known in the tropic; the rainy and the dry seasons. The first is when the sun is in the tropic of Cancer, and heavy rains with loud thunder are prevalent. In this season the wind is generally to the southward of east, but interrupted by frequent calms, yet it occasionally blows with force and obscures the atmosphere.

When the sun removes to the tropic of Capricorn, the dry season commences, and then the trade wind, which is steady at N. E. is cool and agreeable. At this season, N.

and N. W. winds are sometimes found blowing with much force, and, indeed, in some degree, they regularly alternate with the general wind, as they are more frequent in November and December, than in February and March.

"In the change of the seasons there is a remarkable difference; for, in April and May, no change is experienced in the atmosphere, and the weather is, in general, beautifully fine; but in August, September, and October, there are usually calms, or very light winds; and dreadful hurricanes, in these months, sometimes render the navigation perilous. From these perils, however, are exempted the island of Trinidad, the coast of Colombia, (late Terra Firma,) the Gulfs or Bays of Darien and Honduras, and the Bight of Vera Cruz, to which the hurricanes do not reach.\* In the space of sea between the Great Antillas and the coast of Colombia, the general N. E. or Trade Wind regularly prevails; but, near the shore, the following peculiarities are found:

"At the Greater Antillas, the sea-breeze constantly prevails by day, and the land-breezes by night. These land-breezes are the freshest which are known, and assist vessels much in getting to the eastward or remounting to windward, which, without them, would be almost impossible. At the Lesser Antillas, as Dominica, Martinique, and St. Lucia, &c. there are no land breezes.

"On the Coasts of Guyana there are no land-breezes, nor more wind than is generally experienced between the tropics. In January, February, and March, the winds here blow from N. to E. N. E. and the weather is clear. In April, May, and June, the winds are from E. to S. E. In July, August, and September, there are calms, with tornadoes from S. and S. W.; and, in October, November, and December, there are continual rains, while the sky is, in general, obscured by clouds. In the dry season, which is from January to June, the heat is very great; and, in the wet season, rains and thunder are constant and violent.

"On the Coasts of Cumana and Caraccas, to Cape la Vela, the breeze follows the regular course; but from that cape to Cape San Blas the general wind alters its direction; for it blows from N. E. or N. N. E., excepting in the months of March, April, May, and June, when it comes to E. N. E. and is then so uncommonly strong as to render it necessary for vessels to lie to. These gales, which are well known to mariners, extend from about mid-channel to within two or three leagues of the coast, where they become weak, especially at night. On this coast, about the Gulf of Nicaragua, are westerly winds, which the pilots of that country call *Vendeales*, (rainy winds,) in the months from July to December; but these winds never pass the parallel of 13° N., nor do they blow constantly, but alternate with the sea-breeze.

"Upon the Mosquito Shore, Honduras, and Eastern Coast of Yucatan, the general winds or breezes prevail in February, March, April, and May; but, during the first two of these months, they are occasionally interrupted by norths. In June, July, and August, the winds here are from the eastward and westward of south, with tornadoes and calms. In September, October, November, December, and January, they are from the northward or southward of west, with frequent gales from W. S. W., W., N. W. and north.

"On the Northern and Western Coast of Yucatan, between Cape Catoche and Point Piedras, or Desconida and thence to Campeche, there is no other than the N. E. or general wind, interrupted by hard norths in the season of them; and about the end of April, tornadoes commence from N. E. to S. E. These tornadoes generally form in the afternoon, continue about an hour; and, by nightfall, the serenity of the atmosphere is re-established. The season of the tornadoes continues until September, and in all the time there are sea-breezes upon the coast, which blow from N. N. W. to N. E. It has been remarked that, as the sea-breeze is the more fresh, the more fierce is the tornado, especially from June to September. The sea-breezes come on at about 11 of the day: and at night the wind gets round to East, E. S. E. or S. E., so that it may be in some degree considered as a land-breeze.

"On the Coast of the Mexican Sea, from Vera Cruz to Tampico, the breeze from E. S. E. and E. prevails in April, May, June, and July; and, at night, the land-breeze comes off from S. to S. W.; but, if the land breeze is from the N. W. with rain, the wind, on the day following, will be from North, N. N. E. or N. E., particularly in August and September: these winds are denominated, in the country, *Vientos de Cabo* or *Vendeales*, (head-winds or rainy winds;) they are not strong, nor do they raise the sea; with them, therefore, a vessel may take an anchorage as well as with the general breeze; but they impede getting out, for which the land breeze is required. The *Vientos de Cabeza*, or head-winds, reach to about 20 or 30 leagues from the coast, at which distance are found those at E. and E. S. E.

\* Hurricanes have sometimes occurred in these regions.—W. C. R.

"From the middle of September until the month of March, caution is necessary in making Vera Cruz, for the norths are then very heavy. The narrowness of this harbor, the obstruction formed by the shoals at its entrance, and the slender shelter it affords from the norths, render an attempt to make it during one of them, extremely dangerous, for it will be impossible to take the anchorage. The following description of the winds here, has been written by Don Bernardo de Orta, a captain in the Spanish navy, who has been captain of the Port, and who surveyed it.

Although in the Gulf of Mexico we cannot say that there is any other constant wind than the general breeze of this region, notwithstanding that, from September to March, the north winds interrupt the general course, and, in some degree, divide the year into two seasons, wet and dry, or of the Breezes and Norths: the first, in which the breezes are settled, is from March to September; and the second, in which the norths blow, is from September to March. For greater clearness we shall explain each, separately.

\*The first of the norths is regularly felt in the month of September; but, in this month and the following one, October, the norths do not blow with much force. Sometimes it happens that they do not appear, but, in that case, the breeze is interrupted by heavy rains and tornadoes. In November the norths are established, blow with much strength, and continue a length of time during December, January, and February. In these months, after they begin, they increase fast; and in four hours or a little more, attain their utmost strength, with which they continue blowing for 48 hours; but afterwards, though they do not cease for some days, they are moderate. In these months the norths are obscure and north-westerly, and they come on so frequently, that there is, in general, not more than 4 or 6 days between them. In March and April they are neither so frequent, nor last so long, and are clearer; but yet they are more fierce for the first 24 hours, and have less north-westing. In the interval before November, in which, as we have said, the norths are established, the weather is beautiful, and the general breeze blows with great regularity by day: the land breeze as regular by night.

“There are various signs by which the coming on of a north may be foreseen; such are, the wind steady at south; the moisture of the walls, and of the pavements of the houses and streets; seeing clearly the Peak of Orizaba and the Mountains of Perote and Villa-Rica, with the cloud on those of St. Martin, having folds like a white sheet; the increase of heat and of dew; and a thick fog or a low sand, flying with velocity to the southward; but the most certain of all is the barometer; for this instrument, in the time of the norths at Vera Cruz, does not vary more, between its highest and lowest range, than eight tenths; that is to say, it does not rise higher than  $30\frac{3}{16}$  inches, nor fall lower than  $29\frac{3}{16}$  inches. The descent of the mercury predicts the norths; but they do not begin to blow the moment it sinks, which it always does a short time before the north comes on: at these times lightnings appear on the horizon, especially from N.W. to N. E.; the sea sparkles, cobwebs are seen on the rigging, if by day: with such warnings trust not to the weather, for a north will infallibly come on.

This wind generally moderates at the setting of the sun; that is, it does not retain the same strength which it had from 9 in the morning to three in the afternoon, unless it commences in the evening or at night, for then it may increase otherwise. Sometimes it happens that, after dark, or a little before midnight, it is found to be the land-wind, from the northward and westward; in which case, should it get round to the southward of west, the north will be at an end, and the general breeze will, to a certainty, come on at its regular hour: but if that does not happen at the rising of the sun, or afterwards, and at the turn of the tide, it will return to blow from the north, with the same violence as on the day before, and then it is called a North de Marea or Tide-North.

"The Norths also, sometimes, conclude by taking to the northward and eastward, which is more certain; for, if the wind in the evening gets to N. E., although the sky remained covered the day following, but by night the land breeze has been from the northward and westward, the regular breeze will surely ensue in the evening, good weather succeeding and continuing for 4 or 6 days; the latter period being the longest that it will last to, in the season of the norths: but, if the wind retrograde from N. E. to N. N. E. or N., the weather will be still unsettled.

\* Examples are not wanting of norths happening in May, June, July, and August, at which times they are most furious, and are called Nortes del Museo Colorado; the more moderate are called Chocolateros, but these are rather uncommon.

The wet season, or the season of the breezes, is from March to September: the breezes, at the end of March, and through the whole month of April, as already explained, are from time to time, interrupted by norths, and are from E. S. E. very fresh; the sky sometimes clear, at other times obscure. At times these touch from S. E. and continue all night, without giving place to the land-breeze, which prevails, in general, every night, excepting when the north wind is on. The land-breeze is freshest when the rains have begun.

"After the sun passes the zenith of Vera Cruz, and until he returns to it, that is, from the 16th of May to the 27th of July, the breezes, are of the lightest description; almost calms, with much mist or haze, and slight tornadoes. After that time, the pleasant breezes from N. W. to N. E. sometimes remain fixed.

"From the 27th of July to the middle of October, when the norths become established, the tornadoes are fierce, with heavy rains, thunder, and lightning: those which bring the heaviest winds are from the east, but they are also of the shortest duration.

"In the season of Breezes, the total variation of the barometer is four-tenths; the greatest ascent of the mercury is to 30 inches thirty-five one-hundredths, and its greatest descent to 29 inches ninety-six one-hundredths. The thermometer in July rises to  $87^{\circ}$ , and does not fall to  $83\frac{1}{2}^{\circ}$ ; in December it rises to  $80\frac{1}{2}^{\circ}$ , but never falls below  $66\frac{1}{2}^{\circ}$ . This, it must be understood, was ascertained in the shade, the instrument being placed in one of the coolest and best ventilated halls in the castle.

"In the months of August, and September, rarely a year passes without hurricanes near Florida and the northern Antillas; but to Vera Cruz, or any part of the coast thence to Campeche, they never arise; all that is felt being the heavy sea, which has arisen in the higher latitudes. Hurricanes begin blowing from the northward and eastward; and although they do not always go round the same way, yet in general they next go to the southward and eastward, with thick squally weather and rain."

From Tampico to Bay of St. Bernard, the winds are continually from E. to S., and light from the month of April to August; the contrary is experienced in the other months. This coast is exposed on account of the hardness of gales from E. and E. S. E., which blow without intermission for two or three days before hauling to the northward.

In latitude  $26^{\circ} 30'$  N. there are land breezes at night, which blow from midnight to nine A. M.

From Bay St. Bernard to the Mississippi, there are land-breezes at daylight, and on the day's entering, the winds haul to S. E. and E. S. E. and in the afternoon it generally hauls S. W. In winter the southerly winds are very tempestuous, and blow for the space of two or three days. The months most to be feared to navigate this sea, are August, September, October, and November, in which there are hurricanes and winds on shore so heavy that no canvass can stand them; upon the Mississippi, and all its mouths, there are very thick fogs very frequently, especially in February, March and April, and in June and July.

From the Mississippi to lat.  $28^{\circ}$  N., in the month of April to July, the reigning winds are generally from N. to E. and from E. to S. in the morning, and in the afternoon they haul S. W. These S. W. winds are tempestuous in August, September, and October, an epoch in which are also experienced heavy southerly and hurricanes. From November to March the winds blow from the northward, beginning first from S. E. and S., with heavy rain, when it hauls to S. W. and W., and blows very heavy, till it hauls to N. W. and N., when it clears the weather, and then to N. E., and is mild.

From lat.  $28^{\circ}$  N. to the southernmost of the Florida Keys, the trade wind reigns in the morning, and at mid-day it hauls in from the sea. This happens in summer, but in winter, especially from November to March, the winds blow from S. to W. and raise a very heavy sea.

In the new channel of Bahama, the reigning wind is the trade, interrupted in winter by norths, and in summer by calms. Although the northern limits of this channel is in  $28^{\circ} 30'$  N., and consequently within the limits of the trades, yet it is necessary to keep in mind that in winter, that is, from November to April, you will meet with the variables at or before you arrive to lat.  $27^{\circ}$ , which variables are from E. to S. and from S. to W., and in summer you have calms and light airs from S. to W. and from W. to N.

ON THE EASTERN COAST OF BRAZIL, between the months of September and March, the winds generally prevail from N. by E. to N. E. by E. Between March and September the prevailing winds are from E. by N. to E. S. E.

The former of these is generally termed the northerly monsoon, and the latter, the southerly one; although there appears, in fact, to be no direct and opposite change is them on or about the equinoxes, as is generally the case with the winds so called.

These winds are simply a continuation of the S. E. trade, which changes its direction as above described, and is influenced by the land on its approach thereto. When the sun is to the northward, no particular difference is observed in the S. E. trade, but it may be carried within sight of the coast, with scarcely any deviation; nevertheless, about both equinoxes, but more especially when the sun is advancing to the northward, calms and very light winds, with apparently no settled quarter, will prevail near the coast; and this may be said to be more particularly the case on that part of it between the Abrolhos and Cape Frio. As the sun advances to the southward, the trade wind will generally come round to the north-eastward, and will have its retrograde movement with the return of the sun to the equinox. At this latter season, ships, on approaching the coast, will begin to observe this northerly inclination of the S. E. trade, when

within four or five days incline to the westward.

Within a few days generally blows a generally superabundant breeze. About Rio de Janeiro, and while at Pernambuco.

The preceding month, M. D'Apres, has had, and March, are those of the southward, may therefore be that those near Cape.

Mr. Lindley, on shore, at Bahia Augustine, (southward) the morning, and then the wind is generally changing a regular land breeze. During the month of May, the wind is south-west.

Lieutenant Lindley, the southward of N. E. Cape, to obviate the same effect.

The same effect from ten hours of seven a.m. the N. W., namely, breeze, lasting for

Captain Peter, zil station, and then the winds in page.

The late Captain, winds and weather, 1767, which was the following general.

"From forenoon they will be found topsail gale, with N. W. quarter, when it begins to get to the S. S. W. wind comes the N. W. quarter changes in the afternoon, you have then in the N. W. quarter, with sleet and summer. When they blow an hour before a trace of but one frosty air. The tremely cold."

Observe

"The trade wind according to the Windward more to the north and August. I Nevis, &c., the about north, or

within four or five degrees of it, and which they will find gradually to increase as they incline to the westward.

Within a few miles of the coast, and in the different roadsteads and harbors, the wind generally blows directly upon it; and, in the deep harbors, and upon the shore, this is generally superseded by a land breeze which sometimes lasts a greater part of the night. About Rio de Janeiro this land breeze sometimes extends as far seaward as Round Island, while at Pernambuco it rarely reaches the roadstead.

The preceding remarks are those of Lieutenant Hewett. Pimentel, and, after him, M. D'Apres, has said that the winds of the northerly monsoons, between September and March, are from N. E. and E. N. E., or less northerly than as above; and that those of the southerly monsoon are from E. S. E. to S. S. E., or more southerly. It may therefore be admitted, that they do sometimes prevail more from the south, and that those near the north but seldom occur.

Mr. Lindley, in his narrative of a voyage to Brazil, having resided a considerable time on shore, at Bahia, &c., has described the in-shore wind as follows:—"From Cape St. Augustine, (southward,) the wind blows, 9 months in the year, chiefly north-easterly in the morning, and north-westerly during the evening and night. This continues gradually changing along the coast, till, at Rio de Janeiro and the Rio Plata, it becomes a regular land breeze from evening till morning, and throughout the day the reverse. During the three stormy months, that is, from the latter end of February to that of May, the wind is generally southerly, blowing very fresh and squally, at times, from the south-west."

Lieutenant Hewett has observed, that the winds off Cape Frio are seldom found to the southward of east; and in the northern monsoon they are generally to the northward of N. E. Heavy and violent squalls are occasionally met with in rounding the Cape, to obviate the effects of which every precaution is required.

The same officer adds, that at Rio de Janeiro, the sea breeze varies in its commencement from ten to one o'clock in the forenoon, and ceases in the evening between the hours of seven and eleven. At the full and change of the moon, violent squalls from the N. W., named by the Portuguese "Terc Altos," immediately supersede the sea breeze, lasting from four to six hours.

Captain Peter Heywood, in the British frigate *Nereus*, was for three years on the Brazil station, and the greater part of that time in the River Plata. This gentleman describes the winds in page 576 of this work.

The late Captain John M'Bride, of the Royal Navy, kept a regular journal of the winds and weather at the Falkland Islands, from 1st of February, 1766, to 19th January, 1767, which was published in 1775, by Mr. Dalrymple. The journal concludes with the following general remarks:

"From foregoing over the following journal of the winds, for the space of one year, they will be found to prevail in the western quarter, and generally blow a close reefed topsail gale, with a cool air. In November the winds begin to be more frequent in the N. W. quarter, generally hazy weather, and for the most part blow about 16 or 20 hours, when it begins to rain; the wind then regularly shifts into the westward, and so on, till it gets to the S. W. by S. and S. S. W., when it blows fresh, and clears up. This S. S. W. wind continues for about 16 hours, then dies away, when the wind shifts again to the N. W. quarter: this continues during December, January, and February, and changes in the manner above mentioned every three or four days. As March comes on, you have these changes but seldom; and as the winter advances, they are seldom in the N. W. quarter, but rather incline to the E. N. E., which is generally accompanied with sleet and snow. There is not the least proportion in the gales between winter and summer. In summer, (as I have before observed,) as the winds are in the westward, they blow in such heavy squalls off the tops of the mountains, that it is sometimes an hour before a cutter can row to the shore, although the water is smooth, and the distance of but one cable and a half off. In the winter, the winds are pent up by a keen frosty air. The most lasting gales are those from S. by E. to S. by W., and are extremely cold."

*Observations on the Winds, by Captain Frederick Chamier, R. N.*

"The trade winds, in the West Indies, generally blow from N. E. to S. E., varying according to circumstances, which will be hereafter expressed. About Barbadoes and the Windward Islands, that is, from Tobago to Barbuda, the wind will be found to veer more to the northward in the early part of the year, than in the months of June, July, and August. In the more northern islands, such as Dominica, Montserrat, Antigua, Nevis, &c., the wind, in the evenings of January, February, and March, veers round to about north, or N. N. E., blows very fresh in squalls; and from the extensive space of

ocean over which it travels, becomes cool and very refreshing. The thermometer, even in English Harbor, in the above months, at 8 o'clock, P. M., I never saw above 76°. In this season of the year, the sickness of the hot months is no longer experienced; the general lassitude of the mornings and noons of July and August seems forgotten; and no man who visited these islands during the first three months of the year, would believe that the change of seventy or eighty days could make such an amazing difference in the look, as well as in the energy, of the inhabitants of the Windward Islands. In the change of seasons (from wet to dry) a great difference is experienced in the winds. In April and May, the atmosphere is in general clear, and fine weather prevails; but in August, September, and October, calms or very light winds are not uncommon. Strong hurricanes blow in these months.

"In speaking of hurricanes, they are well known to have been very rarely experienced in Trinidad. The main land of Colombia, the Gulf of Darien and Honduras, and likewise Vera Cruz, are almost exempt from this scourge. In the "Derrotero de las Antillas," however, mention is made of a hurricane having been experienced on the morning of the 18th of August, 1810.

"In the greater Antilles, such as Jamaica, Cuba, St. Domingo (or Hayti,) and Port Rico, the sea-breeze blows by day, and the land wind by night; but in the lesser Antilles, such as Martinico, Dominica, St. Lucia, Antigua, &c. land winds are very uncommon, and certainly, in all my cruising in these seas, about these islands, I never experienced the land wind.

From the Coast of Cumana to Punta Aguja, the common trade wind constantly blows at E. S. E. to E. N. E., the land wind being uncommon, but still not unknown. At Port of Spain, in La Guayra Road, in February, 1827, a very light cool land wind, from the S. W. occasionally reached the ship, but I doubt its ever extending more than five miles to sea. On the evening of the 20th October, 1816, a heavy squall came from the S. W. off Cape la Vela, and blew for some time with violence. I have merely mentioned the two above facts, because in the Derrotero it is asserted that land winds are rarely known on this coast.

"The Coast between Cape la Vela and Santa Martha seems more accustomed to changes of wind than any other part of the West Indies. Although the remarks of some celebrated Spanish navigators would lead us to believe that the winds blow so fiercely from the E. N. E. that ships are obliged to lie to; yet I have, in the month of August, by keeping close in shore between Punta Aguja and Cape la Vela, had the wind at west for two or three days together; and until we had passed Rio de la Hacha, and opened Cape la Vela, we neither had easterly winds nor westerly currents.

"In that part of the Coast of Yucatan, between Cape Catoche and Punta Piedras, or Deconocida, and that coast which trends to the southward to Campeche, the trade winds have generally been at E. N. E. In the evening, towards September, the wind occasionally veers to the E. S. E., and this has been called a "land wind" by many authors.

"At all seasons of the year, I have experienced land winds on the coast of Cuba; that is, from Cape Corrientes to St. Jago de Cuba. If the sea breeze, which in Cuba as well as Jamaica and St. Domingo (or Hayti,) generally begins about nine o'clock in the morning, and freshens until noon, should in the evening about sun-set dwindle to nearly a calm, you may be certain of a light air off the land:—a mark to judge by, and which I never knew to fail, was the clouds hanging heavily over the blue mountains of Jamaica, or Copper Hills of Cuba.

"The winds operate very little upon the Thermometer. From May to October in Jamaica, at day-dawn, 82° will be the average; it will be 88° at noon, and again, 82° in the evening. To find the Thermometer at 78° during the night, even in a place where the wind circulates freely, cooled also by the dew, is a luxury so rarely likely to occur, that in looking over my private Journal for two years, I cannot discover one instance of it in the above months; yet still, the land winds, to those who have been long residents in the country, is a luxury most eagerly expected, and most welcome received. It is so different a kind from the sea breeze, that respiration becomes easy; whereas, with the Thermometer at 90° at Port Royal, and the sea breeze blowing nearly a gale, I have found inhaling the hot wind very oppressive and very relaxing.

"It would very far exceed the limits I propose for these remarks, to dwell upon the different changes and different winds in these seas, although I have kept a most accurate private Journal, from which I have extracted the foregoing remarks. It is merely requisite to mention, in conclusion, the season of the 'norths' in the Gulf of Mexico.

"Don Bernardo de Orta has given one of the best and truest accounts of these winds that I have seen: comparing this with the accounts of Humboldt and Don Cosme Churrua, it will be seen that the norths are so well marked, that nobody could mistake the approach of one. For instance, lying in Sacrificios, near Vera Cruz, if the peak of Orizaba is very clear in the morning, a light thin cloud here and there, and the streets

of Vera Cruz, the gale of wind. It

"These winds and sometimes to the N. E., flying wind begins to veer. In the night time of the gale; and reduce sail, and t

of Vera Cruz, the walls of the houses, &c. damp,—before night you will have a hard gale of wind. Its duration is very uncertain.

"These winds, which commence about the end of July, and continue to February, and sometimes to March, blow occasionally with great violence, beginning generally at the N. E., flying round the compass, and ultimately settling at N. N. W. When the wind begins to veer again towards either the east or the west, the gale will soon be over. In the night time, the highly phosphorescent appearance of the sea, marks the approach of the gale; and the squall being visible long before it approaches, gives ample time to reduce sail, and to have every thing prepared.

"Between Jamaica and Maracaybo, and in the space between the latter and St. Domingo, I have always observed, that should the trade wind at day-light be at E. N. E. at noon it will generally be about E. by S. if the day is clear. The knowledge of this gives a great advantage in a windward beat; and by this means, watching the variation of the wind, you will be able to head the current for some hours,—an advantage which every one must perceive."

## CURSORY REMARKS AND SUGGESTIONS ON VARIOUS TOPICS IN METEOROLOGY.

BY AN AMATEUR OBSERVER.

The science of Meteorology is not only interesting to the philosophic observer, but the natural phenomena of which it takes cognizance are such as daily affect the interest and comfort of every member of the human family. But to no class of persons are these phenomena, as exhibited in various parts of the world, of so much practical importance as to the members of the nautical profession. A competent knowledge of these exhibitions, or of geographical meteorology, is therefore an important element of that varied knowledge which is acquired by the skilful navigator.

In the preceding pages of the American Coast Pilot, will be found a valuable collection of observations on the winds which have been found to prevail in the Atlantic Ocean, and on different portions of the American coast. We now proceed to exhibit a more general and cursory view of the atmosphere and winds, and of various atmospheric phenomena which occur in these regions.

### *General View of the Atmosphere.*

The transparent aerial fluid which surrounds our globe, and which we denominate the atmosphere, forms a comparatively thin stratum or envelope, which in the immediate vicinity of the earth, is greatly compressed by its own weight, and which in its most expanded and tenuous state is supposed to extend itself to the height of only forty-five or fifty miles from the earth's surface. Its superincumbent pressure or weight is ascertained by means of the barometer, and is equal to a column of mercury about thirty inches in height. By means of this instrument we learn that one half its weight or actual quantity is within three miles and a half of the surface of the ocean; and it is within this limit that nearly all the visible or important phenomena of the atmosphere are apparently developed. The lower surface of the atmosphere is equal to about 200,000,000 square miles; and as a compression of the whole mass to the common density which it exhibits at the sea level, would reduce its entire height to about five miles, it follows that by this standard of comparison the height or thickness of the atmosphere is to its superficial extent in the proportion of only 1 to 40,000,000.

These several facts are too important to be lost sight of in our general reasonings upon the phenomena of the atmosphere; and the more so, as we are prone to give too much altitude to our conceptions on these subjects. If we even consider the proper height or thickness of the atmosphere as equal to fifty miles, still, as compared with its entire surface, this is only equal to one five hundredth of the proportion which the thickness of a common sheet of paper, of the foolscap size, bears to its surface dimensions; and if we view the atmosphere either as condensed to the mean of the surface pressure, or in relation to the actual limit of all its tangible phenomena, it will only be equal to one five-thousandth part of the proportional thickness above mentioned. We may hence perceive the inapplicability of analogical reasonings that are founded on the movements

WEBSTER, N.Y. 14580  
(716) 872-4503**

which occur in a chimney, or in an inclosed apartment, as attempted to be applied in explanation of the general movements of the atmosphere.

Two instruments of modern invention, the *barometer* and *thermometer*, are truly invaluable as testing the condition of the atmosphere, and their use should be familiar to every navigator. By the first, as we have seen, the amount or weight of the superincumbent atmosphere, at any place, may always be accurately known, and by the indications of the other, the temperature of the air, as well as of the ocean, may be ascertained with equal precision.

Among the most striking peculiarities of the atmosphere, are its rapid and almost constant movements of progression or circulation, which, with some unimportant exceptions, appear to prevail throughout the globe. These movements evidently show the continued operation of some powerful impulse, which, to the writer at least, does not appear to have been satisfactorily explained. It is estimated from the average rate of sailing of ships during long voyages through different seas, and from other data, that the average velocity of the wind near the surface of the ocean is equal to eighteen miles an hour throughout the year, and in the common region of the clouds the velocity must be much greater.

#### *Temperature of Elevation.*

Elevation above the level of the sea, or the general level of a country, causes a regular variation in temperature. The first 300 feet usually causes a difference of about one degree of Fahrenheit's thermometer. After ascending 300 feet, it is estimated that the thermometer falls a degree in 295 feet, then at 277, 252, 223, and 192 feet; but 300 feet to a degree is a common rule. On these principles the limit of perpetual frost has been calculated. It is made a little more than 15,000 feet at the equator, and from that to 13,000 between the tropics, and from 9,000 to 4,000 feet between latitudes 40° and 50°.

It has been found, however, that the above rule is subject to great variations, owing, probably, to the course, temperature, and super-position of the atmospheric currents which prevail in different regions at different altitudes. Colder currents are often found resting upon, or interposed between, those of a higher temperature, and *vice versa*. On the Himalaya Mountains, in Asia, between the latitudes of 28° and 34° north, the region of vegetation has been found to extend several thousand feet above the supposed line of congelation in those latitudes. It is also remarkable that the line of perpetual snow is found at a much greater altitude on the northern side of these mountains than on the southern side, in a lower latitude. From this it may be inferred that the temperature in high regions, as well as in lower situations, is greatly affected by the geographical course and physical condition of the currents of atmosphere which prevail in these regions.

#### *Stratification and Elevation of the Currents of the Atmosphere.*

It is obvious, from the courses of the clouds and other light bodies which sometimes float in the atmosphere, that the movements of the latter are mainly horizontal, or parallel to the earth's surface. Notwithstanding this, the common theory of winds supposes a constant rising of the atmosphere in the equatorial regions, connected with a flow in the higher atmosphere towards the polar regions, and a counter flow at the surface towards the equator, to supply the ascending current. This ascending movement, however, has never yet been discovered, and it is easy to perceive that if it existed in the manner supposed, its magnitude and velocity must be altogether too great to have eluded observation.

It is apparent, however, that different currents often prevail at different altitudes, superimposed one upon another, and moving at the same time in different directions. These currents are often of different temperatures and hygrometrical conditions, and are found moving with different degrees of velocity. It is by the influence of these currents that volcanic ashes, and other light substances, which are elevated by means of whirlwinds to the higher regions of the atmosphere, are conveyed to great distances, and in directions which are often contrary to the prevailing wind at the surface. On the eruption in St. Vincent, in 1812, ashes were thus deposited at Barbadoes, which is 60 or 70 miles to the windward, and also on the decks of vessels still farther eastward, while the trade wind was blowing in its usual direction. On the great eruption of the volcano of Cosiguina, on the shores of the Pacific, in Guatemala, in January, 1835, the volcanic ashes fell upon the island of Jamaica, at the distance of 800 miles in a direct line from the volcano. Facts like these ought to put at rest the common theory of the trade winds, according to which these ashes would sooner have fallen upon the northern shores of the Gulf of Mexico, or the peninsula of Florida. On the same occasion the

volcanic ashes were also carried westward in the direction contrary to the trade wind on that coast, and fell upon H. M. ship Conway, in the Pacific, in lat.  $7^{\circ}$  N., long.  $105^{\circ}$  W., more than 1,200 miles distant from the volcano, in the direction which is nearly opposite from Jamaica. These phenomena were doubtless the effect of two different currents prevailing at different elevations; but we shall seek in vain, in these developments, for proof of the commonly received but imaginary system of the trade winds.

The occasional interposition of a warmer current of atmosphere between the lower current and the higher regions, has been proved by the observations of aeronauts. In countries situated like the United States, where the surface is often occupied in winter, for long periods, by an intensely cold stratum of air from the interior elevations, the warm currents from lower latitudes appear to find their way at a superior elevation; and their presence in this position is often demonstrated by the phenomena which they induce.

### Clouds, Fogs and Rain.

The atmosphere is always pervaded by water in the form of transparent or invisible vapor, and the process of evaporation is continually carried on, except in cases where the thermometer is below what is called the dew point, or when the vapor is being condensed in the form of clouds, fogs, or rain. "Clouds and fogs are the same thing, being an assemblage of small vesicles of water floating in the atmosphere. At a distance in the atmosphere we see the whole as a cloud, but when the vapor sinks to the earth, or will not rise, and we are immersed in it, we call it a fog. Dew-fogs which hang over fields, are *stratus* clouds; and fogs which involve elevated objects, are *cumulous* clouds." It is to circumstances of distribution, light, shade, distance, and perspective, that the great variety in the appearance of the clouds is owing; and on this variety of appearance the following classification has been founded, by which the clouds have been considered as pertaining to seven classes:

1. Like a lock of hair, or a feather, called *cirrus*.
2. A cloud in conical or rounded heaps, called *cumulus*.
3. A horizontal sheet, called *stratus*.
4. A system of small fleecy or rounded clouds, called *cirro-cumulus*.
5. The wavy or undulating stratus, called *cirro-stratus*.
6. The cumulus and cirro-stratus mixed, called *cumulo-stratus*.
7. A cumulus spreading out in cirrus, and raining beneath, called *nimbus*.

The cirrus is usually the most elevated—sometimes as a gauze veil, or parallel threads. Its height is apparently from one to four miles.

Dew is the condensation of aqueous vapor upon the surface of a condensing body or substance. Clouds and fogs are watery particles condensed from aqueous vapor while floating in the atmosphere, where they continue to float till precipitated, or again dissolved. If by the concentration of these particles, or by any additional condensation, their weight be increased beyond that which the extent of their surface can sustain, they then descend in the form of rain; and as the condensation ordinarily increases as the drops increase in magnitude, it is common to have more rain fall on the surface of the ground than on an equal space upon the top of a house or church. Clouds, fogs, and rain are therefore essentially the same, the latter being the continuation or extension of the same process which produced the former.

Owing to the evaporating qualities of the atmosphere in the higher regions, as well as to the intensity of cold which there uniformly prevails, distinct clouds are seldom, if ever, found at a greater elevation than the summits of the highest mountains, which is about five miles. At an intermediate region, however, the clouds are often at a temperature above freezing, while the air at the surface is much below the freezing point, and the earth covered with snow. This condition of the clouds seems not unfrequently evident by their appearance to the eye of an observer. Snowy or frozen clouds are usually dim and undefined in their aspect or appearance; and a fall of snow may not unaptly be termed the fall of a frozen cloud.

### Of Hail.

Hail of small size, as it falls in wintry storms, appears as frozen rain-drops. From the occurrence of this phenomenon in a freezing state of weather, we find evidence that a stratum of air in the region of clouds is at a temperature above the freezing point, or warmer than that which is found at the surface at the same time. A heavy fall of snow affords, perhaps, the same indication.

Summer hail of large size, which is deposited in a definite path or vein, or in a locality of limited extent, is usually accompanied by heavy thunder and vivid or continued lightnings, or a heavy rumbling sound or rapid concussions, high winds, &c., and is believed

to be the production of a vortex or whirlwind in the atmosphere, which is connected at its upper extremity with an overlying stratum of unusually cold air. A portion of this cold stratum probably descends on the exterior of the vortex, and reaching the earth's surface, is pressed into the vortex and there entwined or laminated with the layer of warm and humid air of the surface, which is drawn in at the same time. A rapid condensation, as is known, thus commences at the lower extremity of the whirling mass or column, and the condensed drops, alternately in a freezing and unfrozen layer of air, are carried upward by the powerful whirling and ascending action of the vortex, till, with the successive coatings of condensation received, they are finally discharged into the cold stratum at the upward extremity of the vortex, owing to the reduced temperature of which, they are prepared to receive a renewed accession during their fall to the earth; or perhaps by their accumulated weight they are sometimes thrown through the sides of the vortex before reaching its higher extremity. By this violent gyrotory and elevating action, some of the hail-stones are thrown against each other and broken: and each successive layer of congelation may often be seen in the fractured sections of the hail. In all vorticular condensations of this character, when the cold is not sufficiently intense to produce hail, drops of rain are produced of a much greater size than are ever found in a common and direct fall of rain.

Hail storms of this character are less frequent in the tropical regions than in the temperate latitudes, for the reason, probably, that a stratum of sufficient cold to produce the hail, is seldom found so near the inferior stratum that a vorticular communication can be established with the former, by means of an ordinary gust, spout, or whirlwind. Nor does this ordinarily happen in the temperate latitudes; but only when the lower warm stratum becomes overlaid, in close proximity, by a stratum from a colder region; an event which is not unfrequent in most countries within the temperate latitudes. It commonly happens, therefore, that several hail storms of greater or less magnitude and violence, occur on the same day, or about the same period.

#### *Of Thunder Storms and Gusts.*

When a cold stratum or current of the upper atmosphere moves or rests upon a warm one which is next the earth, neither stratum, as such, can penetrate or displace the other. Nor can a sudden interchange or commingling take place between the masses or particles of which these strata are composed, except by the slow and tedious process of the successive action and convolution of single particles, or small groups of particles, upon or around each other; but if a communication or interchange between the two strata becomes established by means of the action of a gradually excited whirlwind or water-spout, or if, owing to any inequality of surface or other accident, a depression is made upon the lower stratum, so as to enable the colder air to descend at this point, then an immediate gyration or convolution will take place in the two masses at this point, the warm air rising as it becomes displaced, and a copious condensation will immediately follow. It is movements of this character which produce the dense and convoluted appearance known as a thunder cloud, and the thunder and lightning, rain, and perhaps hail, follow as necessary results.

The precipitation of the colder stratum thus commenced, is regularly continued and enlarged till an equilibrium is produced, and the thunder storm thus engendered, assumes, of course, the direction of the upper current to which it is appended, and which, in the temperate latitudes, is commonly from the western quarter. The warm surface air which is thus displaced at the commencement of the process, rises immediately in front of the colder intruding mass, and by the gyrotory action thus commenced, becomes convoluted in detached masses or layers with the colder surrounding air, and by the reduction of temperature thus produced, furnishes the large supply of aqueous vapor which is first condensed in the heavy thunder cloud, and then precipitated in a heavy fall of rain; and the electric phenomena which are induced by this sudden contact or intermingling of masses of air of different temperatures and hygrometric conditions, become highly vivid, and too often destructive. The active gyration which is commonly produced within the body of the thunder storm or gust, is in the direction of the advance of the storm and of the rising warm air which is forced upward, or in the direction of forward and upward at the lower front of the storm.

In consequence of this gyrotory action, a storm which advances at the rate of fifteen or twenty miles an hour, is often known to exhibit a velocity of wind during the period of its greatest violence, of sixty or eighty miles an hour. If the axis of this gyration in a thunder storm assumes, from any cause, a vertical position, we then have a perfect whirlwind or tornado, which, if it be so situated as not to reach the earth by its direct action, will exhibit to us the phenomena of a heavy thunder storm accompanied by rumbling sounds and concussions, and a fall of hail in or near some portion of its path.

But if the regularity, great density of winds is general.

From the occurrence of a current on the surface marked in the often found the different parts son to believe occurred on the atmosphere at change in the after.

But if the regular action of the whirlwind should reach the earth, and continue for some time, great destruction may be expected to follow. The path of these destructive whirlwinds is generally narrow, and often but a few hundred yards in width.

From the nature of the causes which we have set forth as being favorable to the occurrence of a thunder storm, it follows that many of these storms will be likely to occur on the same day, in different parts of the same country, as has been already remarked in the case of hail storms, with which they are often identical; and the writer has often found this to be true to a remarkable extent. The fatal accidents by lightning, in different parts of the country, have often happened on the same days, and we have reason to believe that scores of tornadoes, hail storms, and thunder storms, have sometimes occurred on the same afternoon. It usually happens that the precipitation of colder atmosphere at these numerous points of disturbance, is sufficient to produce a marked change in the temperature of the surface stratum within a period of twelve hours thereafter.

Atmospheric disturbances of this kind, which do not produce violent thunder or hail, are usually denominated *squalls*; and it appears highly probable that the presence of air of a temperature considerably above the freezing point, is necessary to the production of thunder and lightning. In the Strait of Magalhaens, in Patagonia, where the air at the surface is neither warm nor yet very cold, the squalls, called by the sailors *wil-liaws*, are very frequent, and tremendously severe; but, according to the observations of Capt. P. P. King, lightning and thunder are seldom known.

The heavy condensation presented in a thunder cloud, is often spoken of in a manner which implies that the cloud possesses some mechanical or other energy, by means of which the violent wind is sent forth; but nothing can be more unreal than such a supposition. The cloud may indeed be the means of electric development, and furnishes also the watery deposition for the hail or rain, but all the particles of the cloud are passively inert, like those of a common fog or mist, and the violent winds and disturbing forces which may be present, operate to produce the cloud, but do not, in any important sense, result from its action.

#### *Water-spouts and Whirlwinds.*

The character of these meteors has already been described in a measure, in our account of hail and thunder-storms. The identity of whirlwinds and water-spouts, was maintained by Franklin, and although at a later period this has been called in question, it appears to have been done without sufficient reason.

From the equal distribution of the atmosphere as the oceanic envelope of our earth, it results, that no movement of great violence can take place in any of its parts, except by means of a direct circuit of rotation in the form of a vortex or active whirlwind.

A vortex will not be regularly formed, nor continue itself in action, without the aid of an external propelling force and a constant spiral discharge from that extremity of its axis towards which is the tendency of motion. Both these conditions, it is believed, are fulfilled to the letter in the case of a common whirlwind or water-spout. The air at the upper extremity of the whirling column, owing to its elevation, is rarer than at the base, and the column itself, particularly in its central portions, is mechanically rarefied by the centrifugal effect of its own whirling motion. We have thus a sort of rarefied chimney into which the denser air at the base of the column is continually forced, by the pressure of the surrounding atmosphere; not to ascend in a separate current as in the common chimney, but entering into the organization of the whirling vortex, to supply the place of the preceding portions of air which are winding inwards and upwards to be again discharged at the upper extremity. The condition of force by which the propulsion is maintained, is found in the pressure of the surrounding atmosphere upon all sides of the mechanically rarefied column, and if the expansive whirling motion be sufficiently active to produce nearly a vacuum at the centre, the external propelling force will be nearly fifteen pounds to the square inch; and as the whirling column turns within its own compass like a top or any other rotative body, this force is quite sufficient to account for all the violence that is ever produced.

Were there no vorticular or whirling action already excited, and no discharge from the upper extremity of the vortex, the external pressure, it is true, could not produce rotation; but this movement and upward discharge having once commenced, from any cause, the particles near the exterior of the column, like those of water in a funnel, yield at a little more than a right angle, to the external pressure, in their spirally approximating course towards the rarified centre. By the slowness of this central approximation as compared with the whirling action, the intensity or magnitude of the external pressure becomes merged in the velocity of the rotative action. As the area of the spiral circuit decreases rapidly as we approach the centre, it follows that the velocity of

the whirling movement must be proportionably increased, as we perceive it to be in the funnel and in all regular formed vortices. Thus, if the rotative velocity near the exterior of a column be at the rate of but ten miles an hour, at one third nearer the centre the velocity must be more than doubled, and at two thirds of the distance from the first named point to the centre, the absolute whirling velocity must be increased nine fold, which in this case is equal to ninety miles an hour; and in consequence of the reduced diameter of the circuit of gyration at the last point, the number of revolutions must here be as four hundred, to one at the point first mentioned. The increased ascending velocity, however, is not here taken into account, which may perhaps reduce the number of comparative revolutions in the central portions of the column. The condensing and electric effects which often attend or follow these active whirlwinds, have been cursorily noticed under the head of thunder-storms.

It is not intended to dwell here upon the causes by which whirlwinds and spouts are excited or first set in motion, but the local disturbance of heat is probably the chief exciting cause as in thunder-storms. The agency of heat may also be effective in continuing the upward discharge and vorticular organization, in cases where there is great disparity in the temperatures of the air at the upper and lower extremities of the whirling mass or column, but it is to the mechanical expansion of the centrifugal action and the powerful impulse of the atmospheric pressure, that the increased and powerful activity of the whirlwind is chiefly to be referred.

The term *water-spout* is undoubtedly a misnomer, as there is no effect produced of which this term is properly descriptive, although the term *air-spout* would not be greatly inappropriate. The visible column of condensed vapor which often appears in the rarified centre of the vortex when the latter is not enveloped in cloud, has probably given name to this meteor. But the water of the sea is not taken up by the spout or whirlwind, except in a slight degree and in the form of fine spray, like other light matter which is swept from the surface. This cloudy stem or column frequently appears and disappears, while the action of the whirlwind continues without any important change. Owing to this fact, observers sometimes believe that they witness the commencement of a water-spout, or tornado, when the same has previously been in action for one or more hours, and when the cloudy pipe or pillar happens to disappear the spout is supposed to have 'burst,' while, often, it has undergone no important change, except, perhaps, a slight decrease in its activity. The active and violent portion of the whirlwind surrounds the spout invisibly, and is probably of much greater diameter at a distance from the surface of the earth than at the base of the spout. Thus, when a spout or whirlwind has passed near a ship, the upper spars have been converted into wreck while no violence of wind was felt on the deck.

Water-spouts follow the course either of the surface wind or of the higher current with which they may communicate, or their course may be modified by both these influences without being absolutely determined by either. They abound most, however, in those calm regions which are found at the external limits of the trade winds, and in the regions near the equator.

It has been common to ascribe whirlwinds and water-spouts, as well as larger whirlwind storms, to an impulse produced by the meeting of contrary currents, but the laws of distribution and of motion in an oceanic body, are such as do not permit the movements of its different currents and gyrations to meet in conflict with each other, besides any conflicting movement in the air would necessarily produce a rise in the barometer, whereas it is generally known to fall at the commencement of a storm, either of large or small extent. We may observe, also, that whirlwinds and spouts appear to commence gradually, and to acquire their full activity without the aid of foreign causes; besides, it is well known that they are most frequent in those calm regions where, apparently, there are no active currents to meet each other, and they are least frequent where currents are in full activity.

#### *Of Trade Winds and the circuitous Character of the Atmospheric Currents.*

It is found that in almost every country, and in every sea, the wind is more or less predominant in a particular direction. In open sea, between the equator and the 30th parallel of north and south latitudes, the wind, for the most part, blows from the eastward; but near the eastern borders of any ocean, below these latitudes, the wind blows in a direction more towards the equator than in its central or western portions.

In the higher latitudes north of 30°. the westerly winds are found greatly to predominate, although the eddying or rotative action which is acquired by large portions of the lower stratum of air in these latitudes, causes much diversity and frequent changes in the initial direction of the wind. But in the common region of clouds where this eddying movement is less frequent, the main atmospheric current, at least in the United

States, is fully any tropical region.

At New-York the easterly, at the same period, at the same elevation to be the prevailing by the observation the easterly, in the prevalence of ships, from Europe to America to Europe.

The first monsoon occasioned an easterly trade winds; in the elements, across which or thrown off the sphere in the hemisphere it the rotative slower rotative westerly winds.

An entire circle, the most easterly trade winds; and our atmosphere by the winds in temperature and chiefly to be peculiar to certain regions.

The Monsoon circulation; the here deflected westerly monsoon have, indeed, by westerly monsoon of the great Pacific.

The rotative the trade wind necessarily subject in warm regions.

States, is fully as constant from the westward as is the trade wind from the eastward in any tropical region.

At New-York, in four successive years, the westerly winds have been found to be to the easterly, as nearly two to one. Observations on the courses of the clouds for the same period, show the prevalence of an atmospheric current from the westward at that elevation to be, as compared with those from the eastward, nearly as fourteen to one; the prevailing wind being south-westerly. At Montreal, in Lower Canada, as appears by the observations of J. M'Cord, Esq., the westerly surface winds also appear to exceed the easterly, in the proportion of more than four to one. In consequence of the general prevalence of westerly winds and currents in these latitudes, the passages of the fastest ships, from Europe to America, are found to occupy a much longer period than from America to Europe.

The first movement of the trade winds towards the equator and westward, necessarily occasions an equal movement from the higher latitude to supply their place; and as the trade winds in their progress westward are opposed by the American and Asiatic continents, across which these winds do not pass, it follows that these winds become deflected or thrown off towards the poles in order to support an equal distribution of the atmosphere in the higher latitudes; but the air thus transferred to these latitudes carries with it the rotative impulse which it acquired in the tropical latitudes, and by reason of the slower rotative motion which here prevails, is thrown to the eastward in the form of westerly winds.

An entire circuit of atmospheric currents is thus maintained on both sides of the equator, the most equable and determinate portion of which is to be found in the region of the trade winds; and this appears to be the general outline of the great system of circulation in our atmosphere, as well as in the ocean itself. It is to the geographical course pursued by the winds in different portions of these great circuits, that the peculiarities of temperature and climate pertaining to different countries lying in the same latitudes, are chiefly to be referred, as also the remarkable absence or predominance of rain which is peculiar to certain regions.

The Monsoons of the Indian Seas are but a modification of the same system of circulation; the regular trade wind instead of turning towards the higher latitudes, being here deflected across the equator, where it returns to the eastward in the form of the westerly monsoons; the easterly monsoons being the regular trade wind. The monsoons have, indeed, been ascribed to local rarefaction in Asia and New-Holland, but the north-westerly monsoon, regardless of this hypothesis, sometimes sweeps over half the breadth of the great Pacific in its eastwardly progress.

The foregoing generalization may also be expressed in the following form:

- I. Between the two parallels of  $30^{\circ}$  N. and S. the atmosphere at the earth's surface, for the most part, revolves around the axis of the earth with a slower motion than the earth's crust, or is constantly being left behind in the movement of rotation.
- II. The space previously occupied by the atmosphere so left behind, is by the centrifugal action of the earth's rotation, constantly supplied from the higher latitudes.
- III. That portion of the atmosphere which is left behind in the tropical latitudes, and passes westward by the earth's rotation, as above described, is, by the force of direct gravitation, constantly transferred to the higher latitudes; thus preserving the equilibrium of distribution, so far as the same is ever maintained in these latitudes.
- IV. That portion of the atmosphere which is so transferred to the higher latitudes after having acquired the high rotative velocity of the equatorial regions, is, by this previously acquired impulse, thrown rapidly eastward in the form of westerly winds, thus completing the great circuit of perpetual gravitation, which is developed in each of the oceanic basins on both sides of the equator.

It is by the currents of these natural circuits of gravitation, that hurricanes and storms are found to be transported from one region or locality to another; and the track of these storms affords demonstrative evidence of the predominating course which these currents pursue. The currents themselves often become modified in their apparent courses from various causes, and being often stratified, or as it were *shingled* upon each other, they exhibit in their crossings, initial movements in different directions, and frequent changes at the surface, while still performing with no little regularity the systematic courses which have been summarily pointed out. One obvious cause of the irregularity and superposition of these currents is found in the retardation to which the lowest portions are subject, owing to the resistance of the earth's surface.

The rotative motion of the atmosphere and the earth's surface in the latitudes between the trade winds and the returning westerly winds being nearly equal, this region is necessarily subject to calms, and to those sudden gusts and squalls which are usually excited in warm regions in the absence of a prevailing wind. This region, in the North Atlantic,

is known to navigators as the *horse latitudes*, because the traders between New England and the West Indies, in consequence of the lack of sustenance occasioned by these calms, were sometimes under the necessity of throwing overboard the whole or a part of their deck loads of horses. The great circuits of winds intersect and cross these latitudes in both directions on almost every meridian, but with little sensible effect at the surface, except towards the eastern margin of the Atlantic, where the northerly winds decidedly prevail; and towards the western margin of the Atlantic and in the Gulf of Mexico, where the southerly winds are usually prevalent.

Similar results are found in nearly all the regions which separate the great natural circuit of winds from each other, and these tracts of ocean are known by the designation of the *calms*, and sometimes are called the *rains* or the *variables*. Such is the region about the equator, which separates the northern from the southern trade winds, and the easterly from the westerly monsoons. The easterly monsoons, in approaching the equator, where they run into the westerly monsoons, necessarily acquire the same velocity of rotation as the earth's crust, which of course produces calms; the northerly or southerly tendency of the monsoons being here too small to produce a leading breeze at the surface.

#### *Land and Sea Breezes.*

Near the shores of an island or country it is often found that the wind, during different hours of the day and night, blows alternately to and from the land. Or in the case of a general or trade wind which is parallel to the coast, its course becomes alternately modified by an approximation to the above result. This effect has properly been ascribed to the influence of diurnal heat and cold. Not that any vacuum is created by the heat into which the surrounding air rushes, as has sometimes been supposed; for, aside from the general error of this notion, a flat, low, and strongly heated island or coast, has less effect in producing these breezes than a high sloping country of more even temperature.

The truth appears to be, that when the stratum which lies upon the inclined surface of a coast becomes warmed and rarified by the daily heat, it is forced by the increment of pressure at its lowest margin to move along the inclined surface in the direction of greatest elevation, or as near that direction as the prevailing tendency of the lower current will allow. Owing to the cooling process which goes on during the night, the specific gravity of the inclined stratum becomes predominant, and the reverse movement then commences and continues into the following morning. We find, too, that on the slopes of certain coasts and islands where there is sufficient elevation, the higher margin of this stratum, at certain seasons, will daily reach an altitude at which it is brought in contact with a higher stratum sufficiently cold to set in operation a squall or thunder storm, at a certain hour; after which the equilibrium is restored, and the usual counter movement again follows in its turn.

Some diurnal effect of this kind upon the wind is observed at times in almost every region; and, taken altogether, it is probably the most extensive agency which is exercised by heat in the production of winds.

## OBSERVATIONS

ON THE

HURRICANES AND STORMS OF THE WEST INDIES AND THE  
COAST OF THE UNITED STATES,

BY W. C. REDFIELD.

From a careful attention to the progress and phenomena of some of the more violent storms which have visited the Western Atlantic, I have found that they exhibit certain characteristics of great uniformity. This appears, not only in the determinate course which these storms are found to pursue, but in the direction of wind, and succession of changes which they exhibit while they continue in action. The same general characteristics appear also to pertain, in some degree, to many of the more common variations and vicissitudes of winds and weather, at least in the temperate latitudes. The following points I consider as established:

1. The storms of greatest severity often originate in the tropical latitudes, and, not unfrequently, to the eastward of the West India Islands; in the tropical regions they are distinguished by the name of *hurricanes*.

2. These storms cover, at the same moment of time, an extent of contiguous surface; the diameter of which may vary in different storms, from one hundred to five hundred miles, and in some cases they have been much more extensive. They act with diminished violence towards the exterior, and with increased energy towards the interior, of the space which they occupy.

3. While in the tropical latitudes, or south of the parallel of  $30^{\circ}$ , these storms pursue their course or are *drifted* by the natural atmospheric current of the region towards the west, on a track which inclines gradually to the northward, till it approaches the latitude of  $30^{\circ}$ . In the vicinity of this parallel, their course is changed somewhat abruptly to the northward and eastward, and the track continues to incline gradually to the east, towards which point, after leaving the lower latitudes, they are found to progress with an accelerated velocity.

4. The rate at which these storms are found thus to advance in their course, varies in different cases, but may be estimated at from 12 to 30 miles an hour. The extent to which their course is finally pursued, remains unknown; but it is probable that as they proceed, they become gradually extended in their dimensions, and weakened in their action, till they cease to command any peculiar notice. One of the hurricanes of August, 1830, has been traced in its daily progress, from near the Caribbee Islands to the coast of Florida and the Carolinas, and from thence to the banks of Newfoundland, a distance of more than three thousand miles, which was passed over by the storm in about six days. The duration of the most violent portion of this gale, at the different points over which it passed, was about 12 hours, but its entire duration was in many places more than twice that period. Another hurricane which occurred in the same month, passed from near the Windward Islands, on a more eastern but similar route, and has also been traced in its daily stages by means of the journals and reports of voyagers, near two thousand five hundred miles. It was in this storm that the Russian Corvette, *Kensington*, Captain Ramsey, suffered so severely. The hurricane of August, 1831, which desolated the island of Barbadoes on the 10th of that month, the daily progress of which has also been ascertained, passed in nearly a direct course to the northern shores of the Gulf of Mexico and New Orleans, where it arrived on the 16th of the same month, having passed over a distance of twenty-three hundred statute miles in 6 days after leaving Barbadoes.\* Many cases of like character might be adduced.

4. The duration of the storm, at any place within its track, depends upon its extent and the rate of its progressive velocity, as these circumstances are found to determine the time which is required for the storm to pass over any given locality falling within its route. Storms of smaller extent, or dimensions, are usually found to move from one place to another with greater rapidity than larger storms.

5. The course thus pursued by the storm, is found to be entirely independent of the direction of wind which it may exhibit at the different points over which it passes—the wind in all such storms being found to blow after the manner of a whirlwind, around a common centre or vortex, during their entire progress, and in a determinate direction of

\* The tracks of these and other hurricanes appear on the annexed chart.

course of rotation, which is from *right* to *left* (or in the direction from west to south) horizontally. The direction of the wind, therefore, for the most part, does not coincide with the course of the storm.

6. In the lower latitudes while drifting to the westward, the direction of the wind at the commencement, or under the most advanced portion of these storms, is from a *north-eastern* quarter, usually at some point from north-east to north-west, and during the latter part of the gale, it blows from a southern quarter of the horizon, at all places where the whole effect of the gale is experienced.

7. After reaching the more northern latitudes, and while pursuing their course to the northward and eastward, these storms commence with the wind from an eastern or southern quarter, and terminate with the wind from a western quarter, as will appear more distinctly under the three following heads, the latter portion of the storm being usually attended with broken or clear weather.

8. On the outer portion of the track, north of the parallel of  $30^{\circ}$ , or within that portion of it which lies *farthest* from the American coast, these storms exhibit at their commencement a *southerly* wind, which, as the storm comes over, *veers gradually* to the *westward*, in which quarter it is found to terminate.

9. In the same latitudes, but along the *central portions* of the track, the first force of the wind is from a point near to *south-east*, but after blowing for a certain period, it *changes suddenly*, and usually after a short intermission, to a point nearly or directly opposite to that from which it has previously been blowing, from which opposite quarter it blows with equal violence till the storm has passed over, or has abated. This sudden change of a south-easterly wind to an opposite direction, *does not occur towards either margin of the storm's track*, but only on its more central portion, and takes effect in regular progression along this central part of the route, from the *south-west* towards the *north-east*, in an order of time, which is exactly coincident with the progress of the storm in the same direction. It is under this portion of the storm that we notice the greatest fall of the barometer, and the mercury usually begins to rise a short time previous to the change of wind. In this part of the track, the storm is known as a *south-easter*, and is usually attended with rain previous to the change of wind, and perhaps for a short time after.

10. On that portion of the track which is *nearest* the American coast, or which is *farthest* inland if the storm reaches the continent, the wind commences from a more eastern or north-eastern point of the horizon, and afterwards veers more or less gradually, by north, to a north-western or westerly quarter, where it finally terminates. Here also the first part of the storm is usually, but not always attended with rain, and its latter or western portion with fair weather. The first or foul weather portion of the storm, is on this part of its track, recognized as a *north-easter*.

It should be noted, however, that near the latitude of  $30^{\circ}$ , and on the shores of Carolina, where the storm enters obliquely upon the coast, while its track is rapidly changing from a northwardly to an eastwardly direction, the wind on the central track of the storm, will commence from an eastern or north-eastern point of the compass, and will gradually become south-easterly as the storm approaches its height.

11. A full and just consideration of the facts which have been stated, will show conclusively that the portion of the atmosphere which composes for the time being the great body of the storm, whirls or blows as above stated, in a horizontal circuit, around a vertical or somewhat inclined axis of rotation which is carried onward with the storm; that the course or direction of this circuit of rotation is from *right* to *left*; and that the storm operates nearly in the same manner as a tornado or whirlwind of smaller dimensions; the chief difference being in the more disk-like form of the whirling body and the magnitude of the scale of operation.\* This view of the subject, when fully comprehended, affords a satisfactory solution of the otherwise inexplicable phenomena of storms, and will also be found to accord entirely with the fact which appears in the above statement, that in the phases or changes which pertain to a storm, the wind, on one margin of its track, veers *with the sun*, or from *left* to *right*, while under the opposite margin of the same storm it veers *against the sun*, or from *right* to *left*; for this peculiarity necessarily attends the progressive action of any whirlwind which operates horizontally.

12. Owing to the centrifugal action of these rotative storms, the barometer, whether in the higher or lower latitudes, always sinks while under the first portion or moiety of the storm on every part of its track, excepting, perhaps, its extreme outward margin,

\* It is to be understood that the diameter of the whirlwind which constitutes the storm is commensurate with the width of the track over which the storm passes. The main body of the storm is supposed to move in the form of an extensive disk, whirling around its own centre as it advances in its regular track—with this difference, that the rotative movement is far more rapid in the interior portions of the whirling body, than towards its exterior limits.

and commonly affords us the earliest and surest indication of the approaching tempest. The mercury in the barometer always rises again during the passage of the last portion of the gale, and commonly attains the maximum of its elevations on the entire departure of the storm.

The great value of the barometer to navigators is becoming well understood, and its practical utility might be greatly increased by hourly entries of the precise height of the mercurial column, in a table prepared for the purpose. Its movements, unless carefully recorded, often escape notice or recollection; which may easily happen at those times when a distinct knowledge of its latest variations might prove to be of the greatest importance.

In the foregoing statements our design has been to designate in a summary manner the principal movements which, in these regions at least, constitute a storm; and we do not attempt to notice the various irregularities, and subordinate or incidental movements and phenomena of the atmosphere with which a storm may chance to be connected, or which may necessarily result from such violent movements in a fluid which is so tenuous and elastic in its character. It may be remarked in general, that the most active or violent storms are usually the most regular and uniform in the development of those characteristic movements which we have already described. It is also probable, that the vortex or rotative axis of a violent gale or hurricane, oscillates in its course with considerable rapidity, in a moving circuit of moderate extent, near the centre of the hurricane; and such an eccentric movement of the vortex may, for aught we know, be essential to the continued activity or force of the hurricane. Such a movement will fully account for the violent *flashes* or *gusts* of wind, and the intervening *lulls* or remissions, which are so often experienced towards the heart of a storm or hurricane, when in open sea; but of its existence we have no positive evidence.

In Purdy's Memoir of the Atlantic Ocean, it is stated "That while one vessel has been lying to in a heavy gale of wind, another, not more than 30 leagues distant, has at the very same time been in another gale equally heavy, and lying to with the wind in quite an opposite direction."

This statement is obviously to be understood as applicable to two vessels falling under the two opposite sides or portions of the same storm, where the wind in its regular circuit of rotation must, of course, blow from the opposite quarters of the horizon. We will suppose one of the vessels to be at A and the other at B, in the annexed figure.

The storm in pursuing its course from W towards N, will strike the first mentioned vessel in the direction which is shown by the wind-arrows at the point c, which, if the position be in the temperate latitudes, north of 30°, will be from eastward. Now, it is obvious, that as the storm advances in its course north-eastward, this vessel, if nearly stationary, will intersect the body of the gale on the line c A d. As the storm advances, the wind must also veer to the northward, as shown by the arrows, being at N. E. when the vessel is brought under the point A, and near the close or departure of the storm by its further progress eastward, the wind will have further veered to the direction shown at d, which,

with due allowance for the progressive motion of the storm, we will set down at N. N. W. The other vessel, as is equally obvious, will first take the wind from the southward, as shown at e, in which quarter it will blow, with no great variation, till, by the advance of the storm, the ship is brought under the point B. The barometer, which had previously been falling, will now commence rising, and the wind, veering more westerly, will, at the departure of the storm, be found in the direction shown at f, which, after the allowance already referred to, may be stated at W. N. W. Such, substantially, are the facts commonly reported by vessels which fall under the lateral portions of the Atlantic storms, and it is readily seen, that the opposite winds which are exhibited on the two different intersections of the storm, as above described, will very naturally be mistaken for two separate and distinct gales.

The phases of the wind in these gales are, however, in all cases modified more or less by the course or changing position of the vessel exposed to its action. For example; a ship on taking the gale, say at E. S. E. at the point h, on the figure, and lying to with

her head to the northward, may by that means be brought to intersect the storm on the line *h i*, and, at the point *i*, would suddenly be taken aback, with the wind, say at N. N. W., as in the case of the Jamaica homeward-bound fleet in 1782, and the barometer, which reaches its lowest depression under the central portion of the storm, would about this period be found to have commenced rising with some degree of rapidity.

A further reference to the figure will show that a ship, which may be at the point *G* during the passage of the gale, would be exposed to a heavy swell from the southward and westward; but, being beyond the organized limits of the storm, may remain entirely unaffected by the violence of the wind, which at the same time may be raging with destructive fury at the distance of a few leagues. The writer has knowledge of many such examples.

It has been suggested that "the larboard tack is the proper one to lie to on, as the wind will then be found to draw aft;" but this will frequently prove erroneous, as the wind may draw either way, on either tack, according to the position and course of the ship, in the storm, and the extent and rate of progress of the latter. In the case of the fleet which encountered the gale of 1782 it was probably the best course to carry sail to the northward at the very commencement of the gale, and as far and as long as possible. By this means the fleet might, perhaps, have been drawn as far northward as the point *A* on the figure, and the change of wind to the northward and westward would have been rendered more gradual. The chief difficulty and danger, is when the direction of the wind at the first setting in of the gale, is found to be nearly at right angles with the known courses of the storms in the region where the gale is encountered, and it is then desirable to pursue such a course as to avoid, if possible, falling into the heart of the storm.

It frequently happens that a storm, during the first part of its progress over a given point, fails to take effect upon the surface, while it exhibits its full activity at a greater altitude. This commonly happens when this portion of the storm arrives from, or has recently blown over a more elevated country, or is passing or blowing from the land to the sea. On land, the most violent effects are usually felt from those storms which enter and blow from the open ocean upon the shores of an island or continent. Upon the latter, under such circumstances, the *first* part of the gale is usually the most severe, and that coast of an island upon which a storm first enters, or blows, also suffers most from the early part of the gale, but its later, or receding part, often acts with the greatest fury upon the opposite side of the island, which had previously derived some degree of shelter from the intermediate elevations and other obstacles opposed to the force of the wind, the benefit of which is now lost by its counter direction from the open ocean. Owing to similar causes, the force of the storm is sometimes very unequal at different places, situated in nearly the same part of its track, and such inequality, as we have before intimated, necessarily pertains to two places, one of which is near the centre and the other towards the margin of the route.

Of the multitude of facts by which these views might be illustrated, we will only state, that in the late hurricane at Barbadoes, (that of August, 1831,) the trees near the northern coast of that island, lay from N. N. W. to S. S. E., having been prostrated by a northerly wind in the earlier part of the storm, while in the interior and some other parts of the island, they were found to lay from south to north, having fallen in the later period of the gale. That after the same hurricane, advices that were received from the islands of St. Croix and Porto Rico, (which lay near the northern margin of its track,) stated that no hurricane had been experienced at these islands; but it afterwards appeared that some portions of these islands had suffered damage from this hurricane in the night of the 12th to 13th of August, two days after it passed over the island of Barbadoes.—That the sea-islands which border the coast of Georgia and the Carolinas, are known to suffer greatly from these tempests, while little or no injury is sustained in the interior at the distance of a few miles from the coast. One of the most striking characteristics of these storms, is the *heavy swell* which in open sea is often known to extend itself on both sides of the track, entirely beyond the range of the gale by which it was produced. The last hurricane to which we have alluded, threw its swell with tremendous force upon the northern shores of Jamaica, having passed to the northward of the island.

So strong is the influence of our established modes of thinking on this subject, that it seems to be difficult, even for those who admit the rotative character of these hurricanes, to understand correctly the true bearing and relations of the different phases of the wind, which are presented at two or more points or places visited by the same storm, unless the subject has been thoroughly and carefully studied. Speculative opinions, also, upon the course of a storm, are, usually, if not always, founded upon the erroneous notion of a rectilinear course in the wind. In the accounts received of the hurricane at Barbadoes on the 3d of September, 1835, which raged for a few hours from E. N. E. fears

were expressed for the safety of the islands to the northward; but subsequent intelligence from Guadeloupe and Martinico, shewed that the gale had not extended to these islands. Had the direction and changes of the wind in this storm been viewed in their true relations, it would have been perceived that the heart of the gale must have passed to the southward of Barbadoes; and, as a general rule in the West India latitudes, where the onset of the storm is found to be in the general direction of the trade wind, or more eastward, the observer may consider himself as under the northern verge of the gale; but if the onset of the gale be from the north-westward, veering afterwards by west to the southern quarter, the heart of the storm will be found to have passed to the northward of the point of observation, the latter being under the southern margin of the gale.

In order to illustrate the foregoing statements, I annex a chart of the Western Atlantic, on which is delineated the route of several hurricanes and storms, as derived from numerous accounts which are in my possession, by which their progress is specifically identified from day to day, during that part of their route which appears on the chart.

The route designated as No. I, is that of the hurricane which visited the islands of Trinidad, Tobago, and Grenada, on the 23d of June, 1831. Pursuing its course through the Caribbean Sea, it was subsequently encountered by H. M. Schooner Minx, and other vessels, and its swell was thrown with great force upon the south-eastern shores of Jamaica on the 25th, while passing that island, where the wind, at this time, was light from the northward. After sweeping the through Caribbean Sea, this hurricane entered upon the coast Yucatan, on the night of June 27th, having moved over the entire route from Trinidad to the western shore of the Bay of Honduras in a little more than one hundred hours, a distance of about seventeen hundred nautical miles, which is equal to nearly seventeen miles an hour. I have no account of this storm after it crossed the peninsula of Yucatan, and it is probable that it did not again act with violence upon the ocean level. Its course or track to Honduras was N. 74° W.

Track No. II, is that of the memorable hurricane which desolated Barbadoes on the night of August 10th, 1831, and which passed Porto-Rico on the 12th, Aux-Cayes, and St. Jago de Cuba on the 13th, Matanzas on the 14th, was encountered off the Tortugas on the 15th; in the Gulf of Mexico on the 16th, and was at Mobile, Pensacola, and New Orleans on the 17th; a distance of 2,000 nautical miles in about 150 hours, equal to something more than 13½ miles an hour.\* Its course, until it crossed the tropic of Cancer, was N. 64° W., or W. N. W. nearly. In pursuing its northern course, after leaving the ocean level, it must have encountered the mountain region of the Alleghenies, and was perhaps disorganized by the resistance opposed by these elevations. It appears, however, to have caused heavy rains in a large extent of country lying north-eastward of the gulf of Mexico.

Track No. III, is that of the destructive hurricane which swept over the Windward Islands on the 17th of August, 1827; visited St. Martin's and St. Thomas on the 18th; passed the north-east coast of Hayti on the 19th; Turks' Island on the 20th; the Bahamas on the 21st and 22d; was encountered off the coast of Florida and South Carolina on the 23d and 24th; off Cape Hatteras on the 25th; off the Delaware on the 26th; off Nantucket on the 27th; and off Sable Island, and the Porpoise Bank, on the 28th. Its ascertained course and progress is nearly 3,000 miles, † in about eleven days; or, at the average rate of about eleven miles an hour. The direction of its route before crossing the tropic, may be set down at N. 61° W., and in lat. 40° while moving eastward, at N. 58° E.

Track No. IV, is that of the extensive hurricane of September, 1804. It swept over the Windward Islands on the 3d of that month; the Virgin Islands and Porto-Rico on the 4th; Turks' Island on the 5th; the Bahamas and gulf of Florida on the 6th; the coast of Georgia and the Carolinas on the 7th; the great bays of Chesapeake and Delaware, and the contiguous portions of Virginia, Maryland, and New Jersey, on the 8th; and the states of Massachusetts, New Hampshire and Maine on the 9th; being on the highlands of New Hampshire, a violent snow-storm. The destructive action of this storm was widely extended on both sides of the track indicated upon the chart, and the same fact pertains, in a greater or less degree, to the other storms herein mentioned. It appears to have passed from Martinico, and the other Windward Islands, to Boston in Massachusetts, by the usual curvilinear route, in about six days; a distance of more than 2,200 miles, at an average progress of about 15½ miles per hour.

Track No. V, represents the route of the hurricane which ravaged the islands of Antigua, Nevis, and St. Kitt's, on the afternoon and night of August 12th, 1835; Saint Thomas, St. Croix, and Porto-Rico on the 13th; Hayti and Turks' Island on the 14th; the vicinity of Matanzas and Havana on the 15th; was encountered off the Tortugas in

\* Mr. Purdy states that this gale was felt at Natches, 300 miles up the Mississippi.

† All the distances are expressed in nautical miles.

the gulf of Mexico on the 16th; in lat.  $27^{\circ} 21'$ , lon.  $94^{\circ}$ , and other points on the 17th and 18th; and also at Metamora on the coast of Mexico (lat.  $26^{\circ} 04'$ ) on the 18th, where it was most violent during the succeeding night.\* This storm is remarkable, as moving more directly, and farther to the west, than is usual for storms which pass near the West India Islands, it having reached the shores of Mexico before commencing its sweep to the northward. Its course, so far as known, is  $N. 73^{\circ} W.$  Its progress, more than 2,200 miles in 6 days, which is nearly equal to  $15\frac{1}{2}$  miles per hour.

Track No. VI, is that of the memorable gale of August, 1830, which, passing close by the Windward Islands, visited St. Thomas' on the 12th; was near Turks' Island on the 13th; at the Bahamas on the 14th; on the gulf and coast of Florida on the 15th; along the coast of Georgia and the Carolinas on the 16th; off Virginia, Maryland, New Jersey, and New York on the 17th; off George's Bank and Cape Sable on the 18th; and over the Porpoise and Newfoundland Banks on the 19th of the same month: having occupied about seven days in its ascertained course from near the Windward Islands, a distance of more than 3000 miles—the rate of its progress being equal to 18 miles an hour.† If we suppose the actual velocity of the wind, in its rotary movement, to be five times greater than this rate of progress, which is not beyond the known velocity of such winds, it will be found equal, in this period, to a rectilinear course of 15,000 miles. The same remark applies, in substance, to all the storms which are passing under our review. What stronger evidence of the rotative action can be required, than is afforded by this single consideration?

Route No. VII is that of an extensive gale, or hurricane, which swept over the western Atlantic in 1830, and which was encountered to the northward of the West India Islands on the 29th of September. It passed on a more eastern route than any which we have occasion to describe, to the vicinity of the grand Bank of Newfoundland, where it was found on the 2d of October, having caused great damage and destruction on its widely extended track, to the many vessels which fell on its way. Its course is quite analogous to that which we have considered as having been probably pursued by the hurricane of October 3d, 1780. The ascertained route may be estimated at 1800 miles, and the average progress of the storm at 25 miles an hour.

Route, No. VIII, is that of a much smaller but extremely violent hurricane, which was encountered off Turks' Island on the 1st of September 1821; to the northward of the Bahamas and near the lat. of  $30^{\circ}$  on the 2d; and on the coast of the Carolinas early in the morning of the 3d; and from thence, in the course of that day, along the sea coast to New-York and Long Island; and which, on the night following, continued its course across the states of Connecticut, Massachusetts, New Hampshire, and Maine. We are not in possession of accounts by which its farther progress can be successfully traced.‡ The diameter of this storm appears not to have greatly exceeded 100 miles; its ascertained route and progress, is about 1800 miles in 60 hours; equal to 30 miles an hour.

The last mentioned route may also be considered to be nearly the same as that of a similar, but less violent storm, which swept along the same portion of the coast of the United States on the 28th of April, 1835.

No. IX, represents the route of a violent and extensive hurricane, which was encountered to the northward of Turks' Island on the 22d of August, 1830; northward of the Bahamas on the 23d; and off the coast of the United States on the 24th, 25th, and 26th of the same month.

Much damage was done on the ocean by this storm; but it scarcely reached the American shores. Its duration off this coast, was about 40 hours, and its progress appears to have been more tardy than that of some other storms.

No. X, represents the track of a violent hurricane and snow-storm, which swept along the American coast from the lat. of  $30^{\circ} N.$  on the 5th and 6th of December, 1830.

\* Since the above was written, it is ascertained that this storm also passed over Galveston Bay on the coast of Texas, where the hurricane blew with violence from the north-east, while at the mouth of the Mississippi and along the northern shores of the gulf, the gale was not felt. Such facts appear quite sufficient to overthrow the hypothesis of Franklin relating to north-east storms, and are equally fatal to the more common theories. At Galveston this storm, in passing over, veered by east to the south-east; the rationale of which may be made evident by drawing a line through the northern side of the figure on the chart, parallel to the track of the storm. A little further attention to the figure will also illustrate the general character of the northers, which are so common on the coast of Mexico during a considerable portion of the year.

† For a more extended notice of this storm, see American Journal of Science, vol. xx, pp. 34-38.

‡ The phenomena and progress of this storm have been more fully noticed in Silliman's Journal, vol. xx, pp. 24-27.

The last men which swept along violent winter storms, as those which

A variety of der some of which, the might be out of place any bondage to exist

The last mentioned track also corresponds to that of another storm, of like character, which swept along the sea-coast on the 13th, 14th, and 15th of January, 1831. These violent winter storms exhibit nearly the same phases of wind and general characteristics, as those which appear in the summer and autumn.

Track No. XI, represents a portion of the general route of the violent inland storm which swept over the lakes Erie and Ontario on the 11th of November, 1835. This storm was very extensive, spreading from the sea-coast of Virginia into the Canadas, to a limit at present unknown. The anterior portion of this gale was but moderately felt, and its access was noted, chiefly, by the direction of the wind, and the great fall of the barometer: the violence of the storm being chiefly exhibited by the posterior and colder portion of the gale, as is common with extensive overland storms. The regular progression of this storm in an easterly direction is clearly established, by facts, collected by the writer, from the borders of Lake Michigan to the Gulf of St. Lawrence and the sea-coasts of New-England and Nova Scotia.

We have thus given a summary description of the route of twelve storms, or hurricanes, which have visited the American coasts and seas, at various periods, and at different seasons of the year. The lines on the chart, which represent the routes, are but approximations to the centre of the track, or course, of the several storms; and the gales are to be considered as extending their rotative circuit from 50 to 300 miles, or more, on each side of the delineations; the superficial extent of the storm being estimated both by actual information and by its duration at any point near the central portion of its route, as compared with its average rate of progress. The figure which appears upon the chart, on tracks No. I, V, and VII, will serve, in some degree, to illustrate the course of the wind in the various portions of the superficies covered by the storm, and, also, to explain the changes in the direction of the wind which occur successively at various points, during the regular progress of the gale. The dimensions of the several storms appear also to have gradually expanded during their course.

Storms of this character do not often act with great violence on any considerable extent of interior country to which they may arrive. Even upon the coasts on which they enter, such violence is not often experienced under the posterior limb of the gale which sweeps back from its circuit over the land, the usual woodlands and elevations being a sufficient protection. Often, indeed, the interior elevations afford such shelter as entirely to neutralize the effect of the wind at and near the surface, and the presence and passage of the hurricane is, in such cases, to be noted chiefly by the unusual depression, which the great whirling movement of the incumbent stratum of air produces in the mercury of the barometer, which thus indicates the presence or passage of the hurricane, in positions where the force of the wind is not felt at all, or only with a moderate degree of violence. The action of these storms appears, indeed, to be at first confined to the stratum or current of air moving next the earth's surface, and they seldom, while in this position, appear to exceed a mile or so in altitude; and the course of the next highest or overlaying stratum does not, in these cases, seem to be at all affected by the action of the storm below. During the progress, however, by the influence of high land and other causes, the storms often become transferred, in whole or in part, to the next higher stratum of current. Thus we sometimes see a stratum of clouds moving with the full velocity of a violent storm, while the stratum of surface wind is nearly at rest, or moves with its ordinary velocity; and thus, also, it happens that balloons, ascending under such circumstances, are carried forward with a velocity of from 60 to 100 miles an hour. The foregoing remarks are by no means hypothetical, but are the result of long continued observation and inquiry.

It will hardly escape notice that the track of most of the hurricanes, as presented on the chart, appears to form part of an elliptical or parabolic circuit, and this will be more obvious if we make correction, in each case, for the slight distortion of the apparent course in the higher latitudes, which is produced by the plane projection. We are also struck with the fact that the vertex of the curve is uniformly found on or near the 30th degree of latitude. In connection with this fact it may also be noted, that the latitude of 30° marks the external limit of the trade winds, on both sides of the equator; and perhaps it may not prove irrelevant to notice, even further, that by the parallel of 30° the surface area, as well as the atmosphere, of each hemisphere, is equally divided; the area between this latitude and the equator being about equal to that of the entire surface between the same latitude and the pole. It is not intended, however, to make these facts the basis of any theoretical inductions on the present occasion.

A variety of deductions may be drawn from the general facts which we have stated, some of which, though deeply interesting to the philosopher and votary of science, might be out of place in a nautical work of this description. For ourselves, we disclaim any bondage to existing theories in meteorology; and shall on the present occasion, only

illman's Journal,

proceed to notice a few of the more practical inferences which, to navigators and others may, perhaps, be of no doubtful utility.

1. A vessel bound to the eastward between the latitudes of  $32^{\circ}$  and  $45^{\circ}$  in the western part of the Atlantic, on being overtaken by a gale which commences blowing from any point to the eastward of S. E. or E. S. E. may avoid some portion of its violence, by putting her head to the northward, and when the gale has veered sufficiently in the same direction, may safely resume her course. But by standing to the southward under like circumstances, she will probably fall into the heart of the storm.

2. In the same region, vessels, on taking a gale from S. E. or points near thereto, will probably soon find themselves in the heart of the storm, and after its first fury is spent, may expect its recurrence from the opposite quarter. The most promising mode of mitigating its violence, and at the same time shortening its duration, is to stand to the southward upon the wind, as long as may be necessary or possible; and if the movement succeeds, the wind will gradually head you off in the same direction. If it becomes necessary to heave too, and the wind does not veer, be prepared for a blast from the north-west.

3. In the same latitudes a vessel scudding in a gale, with the wind at east or north-east, shortens its duration. On the contrary, a vessel scudding before a south-westerly or westerly gale, will thereby increase its duration.

4. A vessel which is pursuing her course to the westward or south-westward, in this part of the Atlantic, meets the storms in their course, and thereby shortens the periods of their occurrence; and will encounter more gales in an equal number of days, than if stationary, or sailing in a different direction.

5. On the other hand, vessels while sailing to the eastward or north-eastward, or in the course of the storms, will lengthen the periods between their occurrence, and consequently experience them less frequently than vessels sailing on a different course. The difference of exposure which results from these opposite courses, on the American coast, may in most cases be estimated as nearly two to one.

6. The hazard from casualties, and of consequence the value of insurance, is enhanced or diminished by the direction of the passage, as shown under the two last heads.

7. As the ordinary routine of the winds and weather in these latitudes, often corresponds to the phases which are exhibited by the storms as before described, a correct opinion, founded upon this resemblance, can often be formed of the approaching changes of wind and weather, which may be highly useful to the observing navigator.

8. It will be perceived from the foregoing facts, that the occurrence of a storm at a particular locality, has no immediate connection with astronomical periods, such as the changes of the moon, or the time of the equinoxes.

9. A due consideration of the facts which have been stated, particularly those under our twelfth head, will inspire additional confidence in the indications of the barometer; and these ought not to be neglected, even should the fall of the mercury be unattended by any appearances of violence in the weather, as the other side of the gale will be pretty sure to take effect, and often in a manner so sudden and violent as to more than compensate for its previous forbearance. Not the least reliance, however, should be placed upon the prognostics, which are usually attached to the scale of the barometer, such as Set-Fair, Fair, Change, Rain, &c. as in this region at least, they serve no other purpose than to bring this valuable instrument into discredit. It is the mere rising and falling of the mercury, which chiefly deserves attention, and not its conformity to a particular point in the scale of elevation.

10. These practical inferences apply in terms, chiefly to storms which have passed to the northward of the 30th degree of latitude on the American coast, but with the necessary modification as to the point of the compass, which results from the westerly course pursued by the storm while in the lower latitudes, are, for the most part, equally applicable to the storms and hurricanes which occur in the West Indies, and south of the parallel of  $30^{\circ}$ . As the marked occurrence of tempestuous weather is here less frequent, it may be sufficient to notice that the direction of the winds of the West Indian seas, is from 8 to 11 points of the compass *more to the left* than on the coast of the United States in the latitude of New-York.

Vicissitudes of winds and weather on this coast which do not conform to the foregoing specifications, are more frequent in April, May, and June, than in other months. At this season it is not uncommon to find a regular current of easterly wind prevailing for many days, producing sometimes heavy rains, and always an elevated state of the barometer. Easterly or southerly winds under which the barometer rises, or maintains its elevation, are not of a gyratory or stormy character; but such winds frequently terminate in the falling of the barometer and the usual phenomena of an easterly storm.

The typhoons and storms of the China sea and eastern coast of Asia, appear to be

similar in character to those which prevail in the great ocean north of the equator, and winds in the same direction.

From the foregoing facts, the relative importance of the different ports relative to the trade and commerce of the world.

similar in character to the hurricanes of the West Indies and the storms of this coast, when prevailing in the same latitudes. There is reason to believe that the great circuits of wind, of which the trade winds form an integral part, are nearly uniform in all the great oceanic basins; and that the *course* of these circuits and of the stormy gyrations which they may contain, is, in the southern hemisphere, in a *counter direction* to those north of the equator, producing a corresponding difference in the general phases of storms and winds in the two hemispheres.

From the foregoing results we infer the value and importance of correct marine reports relating to violent gales. Those reports should always comprise the *date*, the *latitude and longitude*, and the *principal direction and changes of the wind*.

[This Table contains the LATITUDES and LONGITUDES of the most remarkable Harbors, Islands, Shoals, Capes, &c. in this work, founded on the latest and most accurate Astronomical Observations, Surveys, and Charts.]

The Latitudes and Longitudes in the preceding Table have been selected from the most recent and best authorities.

Those of the Coast of Newfoundland and Gulf of St. Lawrence have been altered to correspond with the recent observations, as far as received, of the officers under the direction of Sir Charles Ogle, and those made by Capt. Bayfield, R. N., who is now surveying the St. Lawrence.

The positions of the principal points of the Coast of the United States are altered to agree with the observations made of the Eclipse of the Sun of February 12th, 1831.

The West Indies are adapted to the most recent observations; among others, to those of Com. R. Owen, R. N.

The Coast of South America, from St. Luis, Maranham, to St. Catharines, from the observations of Baron Roussin; from St. Catharine's to the River Plate, by M. Barral; and from Port St. Elena to Cape Horn, by P. P. King, R. N., and his associates.

It may be remarked that the recent English and French surveys of the Coast of South America, differ from 5 to 10 miles in longitude\* by their chronometers, in every place where both have observed, we therefore have taken the French observations from St. Luis to the River Plate, as there is a regularly connected chain of observations, and the English from thence to Cape Horn, for the same reason.

\*The English make all their points of observation so much to the eastward of the French.

## APPENDIX.

### SABLE ISLAND.

*Copy of a Letter from Capt. Joseph Darby, Superintendent of Sable Island, to the Editors.*

GENTLEMEN—

SABLE ISLAND, October, 1836.

I have known the island for the last twenty-eight years, in which time the west end has decreased in length about seven miles, although the outer breakers of the N. W. bar have the same bearing from the west end of the island that they then had, about N. W. by compass, distant about 8 miles, which clearly shows that the whole of the bank and the bar travels to the eastward. The ground is high and the water shoal outside of the breakers. Seven or eight miles more, in a N. W. direction, the variation is increasing to the westward, and is now nearly  $1\frac{1}{2}$  point west. The flood tide sets across the bar to the northward and eastward very strong, and the ebb tide to the opposite point, changing alternately at half flood and half ebb. The ground to the southward and westward of the bar is very regular, deepening very slowly to a considerable distance, but to the northward and eastward the ground is very steep, and from the breakers, or from very shoal ground outside of the breakers, you fall into deep water all at once. The bank to the N. W. is very uneven, and curves round to the northward in a steep ridge, and at the distance of about 35 miles from the island, in a N. W. direction, are 10 fathoms water, and W. N. W. and E. S. E. from that the ground falls very suddenly into deep water. This ridge joins the middle ground, and extends in an easterly and a N. E. direction to a considerable distance, with shoal water; the bottom in small ridges, with 11, 12, 11, 13 fathoms of water, and so on, over it; and between this bank and the bar, or the island, the water is very deep, 80 or 90 fathoms. The bank extends to the eastward abreast of the island, the southernmost edge of the bank, from 20 to 25 miles to the northward of the island.

The east end has altered very little since my knowledge of it, except in height, which is much greater than it was, and the whole island seems to increase in height every year, but grows narrower. There is a low bar of dry sand running from the high land of the east end, in a N. E. direction, about three miles, from whence shoal water, that always breaks, extends about two miles farther in an E. N. E. direction, outside of which, for a distance of about six miles, is a passage across the bar, with from  $2\frac{1}{2}$  to 3 fathoms of water in it. Outside of that, again, is a piece of high ground that always breaks, and is sometimes dry, and extends in an E. N. E. direction between 2 and 3 miles, from which the shoal ground continues in the same direction some miles farther. The flood tide across this bar sets very strong to the northward, and the ebb tide in the opposite direction, but not so strong. The soundings to the southward and eastward of the bar are flat and regular for a considerable distance, but to the northward and westward the ground is very steep—close to the breakers 10 fathoms, and goes down suddenly into 70 or 80 fathoms to 100 or upwards. I believe, in general, there is a very strong current setting to the W. S. W., between the Sable Bank and the Gulf of Mexico Stream; and there is a strong current sets down the western side of the Gulf of St. Lawrence Stream, in a S. S. W. direction; and I have some reasons for thinking that the Banquereau is laid down a little too far to the eastward in all charts that I have seen. The current along the south side of the island is very shoal water, runs both east and west, and is principally influenced by the winds. The most of the wrecks that happen here are in error in their longitude; for instance, vessels bound to the eastward think themselves past the island when they get on shore upon it, and vessels bound to the westward (say from Europe) do not think themselves so far to the westward when they get on shore upon it. I have known several cases of vessels from Europe that have not made an error in their longitude exceeding half a degree, until they came to the Banks of Newfoundland, and from that here, in moderate weather and light winds, have made errors of from sixty to a hundred miles, which, I think, goes so far to prove the existence of a westerly and southerly current between the Grand Banks and here, and also of the existence of a westerly current between the Sable Bank and Gulf of Mexico Stream, which will be stronger or weaker according to the distance between the stream and the banks.

When a casualty has occurred, and you find that you are on the body of the Island, I would recommend that nothing of masts or rigging be cutaway without the vessel should be very tender, and then you may do it to ease her a little; but a vessel of ordinary strength will bear her spars until she heaves up on the beach, or settles in the sand and lays quiet, as lives and property have often been saved by a vessel having her spars standing, as from the heads of which you may often send a line on shore when it is not possible to work a boat; and by sending a good hawser after it and securing it well on shore, a chair or other more efficient article may be rigged for conveying passengers, or others, or valuable property, over the breakers in safety; as from the nature of the soft sandy bottom a vessel will not go to pieces as soon as if she was on rocks, and by the rigging being left standing it may afterwards be saved, whereas if the masts are cut away the whole of the rigging goes with them, and all get tangled and buried in the sand, and are generally totally lost. But if you are on either of the bars, the first consideration should be to secure the boats and lighten the ship, and leave her as soon as ever you have to abandon the hope of getting her off; endeavor to get to the leeward of the breakers, and land on the island according to circumstances, endeavoring to land on the north side if possible, as vessels that get on the bars very soon disappear altogether, either by going to pieces in the irregular sea and strong currents, or by rolling over the steep bank to the northward and sinking in deep water. When property can be saved on the island, it is proper for the master and his crew to do the utmost in their power to save it; they can get the assistance of the people of the island with a boat and teams of horses, not for hire, for they are employed by government, and the island draws a salvage of whatever may be saved on it, which is apportioned by the magistrates at Halifax: the more there is saved by the master and crew the less salvage will be taken; but it is very often the case that the crews will not assist to save property, and whatever is saved is done exclusively by the establishment, in which case the salvage is pretty high. There are buildings on the island for the shelter of persons cast away on it, with provisions for those who save none; also some buildings for the reception of perishable goods. These buildings, and whatever is put into them, are under the charge of the superintendent. All property saved must be sent to Halifax by the first opportunity: the master can keep inventories and continue with the goods if he likes, but has no control over their destination; but I believe, by petitioning the governor at Halifax, he might get permission to take them where he pleases, on paying the duty and salvage. When any property is saved on the island it is sent to Halifax, where it is advertised and sold by order of the Commissioners, and the proceeds paid into their hands, out of which they pay the king's dues, the salvage apportioned by the magistrates, the expenses of freight, and other small charges, and the residue is paid over to the master, or other authorised agent, for the benefit of the underwriters and all concerned. The superintendent is under the control of the governor and the commissioners, and can take no new step without orders from them. The above and before mentioned custom is an old and long established rule, and supported by many acts of the Provincial Legislature, and more particularly by an act passed the 4th day of April, 1836, and in the sixth year of his Majesty's reign, which does more fully explain and set forth the rules for the guidance of the establishment.

The north side is very safe, as a vessel may approach any part of it within a mile, and vessels in distress might, by standing in on the north side and near the west end where the principal establishment is, get a supply of fresh water or fuel, or a partial supply of provisions and fresh meat, except in cases of a strong breeze and in heavy sea on shore. There is no difficulty in working boats on this side of the island. The south side is also very safe to approach in clear weather, but from the heavy sea that constantly breaks on it, the communication with a vessel by boats, is extremely difficult, except after a spell of northwardly winds for three or four days, when the sea becomes smooth, and boats may work.

Should you deem further information necessary respecting the laws governing the island, I beg leave to refer you to the commissioner for the affairs of Sable Island, at Halifax, for an abstract of the Province Laws, passed at the last session of the House of Assembly. I regret much that this information has been withheld from you so long, the unavoidable consequence of a very rare and uncertain communication.

## LIGHTHOUSES, BEACONS, &amp;c.

Appropriations were made at the second session of the twenty-fourth Congress, (January, 1837,) for building Lighthouses, Beacons, &c., as follows, subject, however, to the decision of the Board of Navy Commissioners, "whether the safety of navigation requires any additional facilities, and if so, what is most suitable for each place needing such additional facilities."

## STATE OF MAINE.

Lighthouse on Mark Island, Harpswell Sound.  
 Lighthouse on Mount Desert Island, at the entrance of Frenchman's Bay.  
 Fog-bell on Seguin Island, at the entrance of Kennebec River.  
 Buoys in West Quoddy Bay, and for substituting for the present fog-bell, at the entrance of said passage, a cast steel triangular bell, or a bell of the usual form, but increased weight.  
 Lighthouse on a proper site at Spoon Isle, Penobscot Bay.  
 Lighthouse on Saddleback Ledge, in Penobscot Bay.  
 Lighthouse on Eagle Island Point, in Penobscot Bay.  
 Lighthouse at the mouth of Pleasant River.  
 Monuments on Fort Point Ledge, Adam's Ledge, and Buck's Ledge, in Penobscot River.  
 Beacon-light on Half-tide Ledge, and two buoys about a mile and a half from the town of Sullivan, in the county of Hancock.

Lighthouse on York Nubble, in the county of York.

## STATE OF NEW HAMPSHIRE.

Buoys at or near a rock at the mouth of Spruce Creek, in Piscataqua River.

## STATE OF MASSACHUSETTS.

Two small lighthouses, should two be necessary, on proper sites, at or near Ipswich Harbor.

Lighthouse at or near Ned's Point, contiguous to the village of Mattapoisett.

Three small lighthouses on Nauset Beach, Cape Cod.

Buoys upon the rocks and ledges at the entrance of the harbors of Lynn, Salem, Beverly, Marblehead, and Manchester.

Buoys on Aldridge Ledge, False Spit, Hunt's Ledge, Hospital Island Ledge, Sculpion Ledge, Governor's Island Point, and Little Farm Bar, in Boston Harbor.

Beacon at the mouth of New Bedford Harbor.

Spindle in the harbor of Edgarton, and buoys.

Lighthouse at Wing's Neck.

Buoys in the harbor of Mattapoisett.

Buoys on Bay Rock, the ledge on the shoal on the west side of Taunton River, opposite Fall River.

Buoys at a place called Egypt, in Taunton River.

Beacon on Muscle Bed, and a beacon on Oyster Bed, in Mount Hope Bay.

Lighthouse on Mayo Beach, in Wellfleet Bay.

## STATE OF CONNECTICUT.

Buoys on Black Boy Reef, Barney's Reef, Stony Point Reef, and Wheeler's Rock, in the harbor of Killingworth.

Beacon at Round Island, on Saybrook Bar.

Buoys on the rocks in the harbor of Greenwich.

## STATE OF RHODE ISLAND.

Lighthouse on Papoose Squaw Point, near the port of Bristol.

Buoy and beacon on South White Rock, and a buoy on Charles Rock, near the harbor of Wickford.

Rebuilding and changing the location of the light on Block Island.

## STATE OF NEW YORK.

A revolving or double light upon the south side of Execution Rocks, opposite Sand's Point, in Long Island Sound.

Buoys out Gedney's Channel, New York Harbor.

Two light-boats, one at Flynn's Knoll, and another south of Sandy Hook, New York Harbor.

Buoy in the newly discovered channel over Sandy Hook Bar, and a beacon light on Romer's Shoal, New York Harbor.

Lighthouse on Cedar Island, Sag Harbor.

Buoys in Sag Harbor.

Floating light on or near the Middle Ground, so called, in Long Island Sound.

Lighthouse on Robin's Reef, in the harbor of New York.

## STATE OF NEW JERSEY.

- Lighthouse at the mouth of Cohansey Creek.
- Lighthouse at or near Egg Island, near the entrance of Maurice River.
- Lighthouse near Absecuin Inlet, on the sea coast of New Jersey.

## STATE OF DELAWARE.

- Lighthouse on the lower or southern end of Reedy Island, Delaware Bay.
- Lighthouse on the Brandywine Shoal, Delaware Bay.
- Buoys in the harbor of the Delaware Breakwater.

## STATE OF MARYLAND.

- Lighthouse on Sharp's Island, Chesapeake Bay.
- Buoys on the rivers Nanticoke, Manokin, Annemessex, Pocamoke, and Wicomico, Hooper's and Cajey's Straits, and Tangier and Pocamoke Sounds.
- Lighthouse at Love Point.

## STATE OF VIRGINIA.

- Lighthouse on the south end of Hog Island, on the Atlantic coast.
- Light-boat on York River Spit, or a lighthouse.
- Removing the lighthouse at Old Point Comfort, Fortress Monroe.
- Lighthouse in the Chesapeake.
- Lighthouse at Day's Point, on James River.
- Light-boat in the Chesapeake Bay.

## STATE OF NORTH CAROLINA.

- Lighthouse off Powell's Point, Albemarle Sound.
- Lighthouse on Pea Island, near New Inlet.

## STATE OF SOUTH CAROLINA.

- Lighthouses or light-boats in the inlets of Saint Helena and Port Royal.
- Five beacon-lights in Charleston Harbor.

## STATE OF LOUISIANA.

- Beacon-light at or near the south-west part of Vermilion Bay.
- Lighthouse at the pass between Lake Pontchartrain and Lake Maurepas.
- Lighthouse on St. Joseph's Island, in Lake Borgne.
- Two buoys at Dolphin Island Pass, two buoys at Pass Marianne, two buoys at Pass Christian, and two buoys at Heron Pass.
- Beacons and lighthouses at the entrance of the harbor recently constructed on Lake Pontchartrain.
- Lighthouse on Lake Pontchartrain, at the mouth of the Bayou St. John.

## TERRITORY OF FLORIDA.

- Lighthouse on the most suitable site at or near the east entrance from the Gulf of Mexico into Apalachicola Bay.
- Lighthouse at the entrance of St. Joseph's Bay.
- Three buoys at the mouth of St. John's River.
- Buoys to mark the channel from the eastern pass into Apalachicola Bay to the town of Apalachicola.
- Light-boat to be stationed at the north-west passage, twelve miles from Key West.
- Buoys at the north-west passage and harbor of Key West.
- Rebuilding and changing the location of the lighthouse at Mosquito Inlet.
- Buoys on a rock in the outer harbor of Key West.

## ADDITIONAL APPENDIX.

JANUARY 1, 1838.

Page 124.

**WEST QUODDY HEAD LIGHT** may be seen at sea, in clear weather, six leagues.

It is situated on the S. E. side of Quoddy Head, and contains a fixed light, elevated ninety feet above the level of the sea. It bears from the Southern Head of Grand Manan N.  $\frac{1}{2}$  E., distant about 16 miles, and from the northern head of said island, W. N. W. distant about nine miles.

Sail Rock bears from the light S. S. E. about  $\frac{3}{4}$  of a mile: it is not covered at high water, and at some distance has the appearance of a sail, from which it derives its name. There is a passage between it and the main shore, at low water, but which had better not be attempted, unless forced by the currents, and light winds. Near the above mentioned lighthouse is an alarm bell, weighing 28 cwt. 2 qrs. (twenty-eight hundred weight, and two quarters,) which is, at present, rung by hand, and may be heard at sea, from 3 to 6 miles, in thick weather.

Liberty Point bears from the light, E. N. E. about one and a half mile, this being the southernmost point of Campo-Bello Island, and forming the eastern side of West Quoddy Bay.

West from said Point, about  $\frac{3}{4}$  of a mile distant, lies a rock called Black Rock, which is not covered at high water, and is bold all around.

The middle ground is a shoal, near the middle of West Quoddy Bay, about  $\frac{1}{4}$  of a mile in circumference, with a good channel on either side of it. The shoalest part is often dry. On the western part of the shoal is a Spar Buoy, moored in five feet at low water, and which bears from West Quoddy Head, N. N. W. distant about one mile.

From the above mentioned Buoy, N. W. by N.  $\frac{1}{4}$  N. about  $1\frac{1}{2}$  mile distant, is a Nun Buoy, painted red, and moored in two fathoms at low water. To the southward of this Buoy is a rocky Bar, extending from Campo-Bello Island to the main shore of West Quoddy Bay, and which is nearly dry at low water. N. N. E. distant  $\frac{1}{2}$  a mile from the above Red Nun Buoy, is a similar Buoy, painted black, moored in four feet at low water, on the eastern part of the Muscle Bank, so called, which is bare at half tide.

From the Black Buoy to Delesdernier's Point, it is N.  $\frac{1}{4}$  W. distant about  $\frac{3}{4}$  of a mile. This point is very bold, and may be known by a number of fish houses upon it, which may be seen on the larboard hand, in running through the Narrows.

The entrance of West Quoddy Bay is wide, and the shores are bold, and may be neared, until up with the Spar Buoy. If in want of a pilot, by displaying a signal, one can be obtained at the lighthouse.

### *Sailing Directions for West Quoddy Bay and through the Narrows.*

Vessels bound to West Quoddy Bay, and being to the westward of the lighthouse, should give the shore a berth of  $\frac{3}{4}$  of a mile, and steer N. E. by E., which will carry you clear of Sail Rock; and when the light, or sound of the bell bears W. N. W. you may steer N. W.  $1\frac{1}{2}$  mile, which course and distance will bring you up with the Spar Buoy on the Middle Ground, and if low water, here you may anchor and wait for the tide to go over the Bar, which you cannot cross until  $2\frac{1}{2}$  hours flood; but if high water, and you wish to continue through the Narrows—

Bring the Red Buoy to bear N. by W.  $\frac{1}{2}$  W., and steer direct for it. You may go on either side, by keeping it close on board, and after passing it one cable's length, steer N. E. by N. for the Black Buoy, which you leave on your larboard hand, and after passing it half a cable's length, steer N. by W. for Delesdernier's Point, which you must keep close on board.

After passing this point you must keep in the middle of the Narrows, due regard being had to the tide, as it runs upon the flood and ebb from 3 to 5 knots.

Page 143.

**PENOBSCOT RIVER.**—From Seguin to Manheigan, the course is east; but you must not bring Seguin to bear west, until you have passed Bantam Ledge, as it bears east, about 4 miles from Seguin. Manheigan is good land to run for, being bold. There are several high rocks on the N. W. side, but they are also bold. From thence to Whitehead, the course is N. E.; leaving George's and Mosquito Island on the larboard, and Matinic on your starboard hand. The latter is foul. There are two rocks off George's Islands, called the Old Man and Old Woman, with a passage between them. The first lies more than a mile off. When you can see Mosquito Island to

the eastward of George's, you are clear of them. There is a ledge between George's Island and Mosquito Island, called Scilly; and also another about one-third of the way from Matinic to Manheigan, called the Roaring Bull, which latter bears about N. E.  $\frac{1}{2}$  E. from Manheigan; but you have a clear bay until you come near Whitehead. There is a ledge south by east  $\frac{1}{2}$  mile from the Head, and several near the land to the westward. The Head is very bold. When a little inside the Head, haul up nearly for the N. E. point of a large White Island, with trees on it, on the larboard hand, to avoid a ledge called the Gangway Ledge. It lies directly off the mouth of Seal Harbour, and about N. E. from the light. The course from Whitehead to the point of Ash Island is N. E. The point of Ash Island is bold at low water, but at high water some of the rocks are covered. There is a sunken ledge off this point, the kelps on which are seen at low water, called also Gangway Ledge, which you leave on the starboard hand. Thence to Owl's Head, about N. N. E. The course from Owl's Head to Castine, is N. E. by N.; passing close to Mark Island, which is the first you come to, and leaving several small islands and ledges on the starboard hand, Mark Island on the larboard. The passage is here rather narrow, but with a fair wind there is no danger. The Bay, however, is not so clear to the eastward as to the westward of Long Island. From Owl's Head to Camden the course is N. by E. 10 miles, leaving a high rock called the Graves on your starboard, and Negro Island, on which there is a lighthouse, on your larboard hand. There are some sunken rocks between the Graves and the northern point of the harbour, nearest the latter, which are on the starboard hand. From Owl's Head up the Bay the course is N. N. E. easterly, to Spruce Head, in Northport, 7 leagues. You pass a good harbour on Long Island side, called Gilkey Harbour. It is easy of access, but is bad to find in the night, the land back being higher than that in front of the Harbour. Here a lighthouse is much needed, as it is the best harbour in the whole Bay. It lies directly opposite Ducktrap. From Spruce Head to Old Fort Point, the course is N. E. 5 leagues, leaving Belfast and Cape Jellison Harbours on the larboard hand. If you wish to harbour in Cape Jellison, you enter with Brigadier Island on the larboard hand, keeping it nearest aboard, as there is a long ledge makes off from Squaw Point on the starboard hand, which is covered at high water. There is a ledge off Fort Point in a southerly direction, called Fort Point Ledge, a half a mile or more. It lies S. S. E. and N. N. W., and is bare at half tide. There are two Buoys, one off each end of it. There is a lighthouse on the Point, near which it is so bold, that there is a good channel between that and the ledge for beating. The extreme point, however, to the eastward of the light, is shoal, and you must give it a good berth. When you have turned this point, you have an excellent harbour on the larboard hand, called Fort Point Cove. There is one small rock near Sandy Point, on which there are about 7 feet at low water, near which there is a log buoy placed. From Fort Point to Bucksport Narrows, the course is north, 5 miles. Above Sandy Point lies Odum's Ledge, which is nearly covered at high water. You may go either side of it, but the eastern is the best channel. When you open Bucksport village, your course is N. E.  $\frac{2}{3}$  of a mile, when you will open Marsh Bay, N. W., at the head of which is Frankfort village, 5 miles. Run up midway till you come near Marsh River, on the larboard hand. The point on the opposite side of the Bay is called Drachin Point, from which a flat extends  $\frac{2}{3}$  the distance across to Marsh River, on the end of which a buoy is placed. Should you not see the buoy, shut Pickard's Point on McKenzie's Point a handspike's length, and run until you fairly open the reach to Oak Point; Pickard's Point is the land on the S. E. side of Marsh River, and McKenzie's Point is the first point on the starboard hand above Bucksport village. From Marsh River to Oak Point the course is N. E. 5 miles; good anchorage all the way. Thence to Hinkley's E. by N.  $\frac{1}{2}$  of a mile. Thence to Mill Creek N. by E. 1 mile, leaving Buck's Ledge, on which there is a spire and ball, on the starboard hand. Thence to Bald Hill, N. W. by W.  $1\frac{1}{2}$  mile. Thence to Higgins', N. N. E.  $\frac{1}{2}$  mile. Thence to Bragdor's Castle, N. E.  $\frac{2}{3}$  of a mile. Thence to Crosby's, N. N. E. 2 miles. Thence through Crosby's Narrows N. E.  $\frac{1}{2}$  mile. Thence to Crosby's Old Wharf N. N. E.  $\frac{1}{2}$  mile. Thence to Brewer Village, E. N. E. 2 miles. Thence to Mitchel's Steam Mill N. E. by N.  $\frac{1}{2}$  mile. Thence to Highhead, N. E.  $\frac{3}{4}$  mile. Thence to Bangor, N. E. by N.  $\frac{3}{4}$  of a mile.

Pages 157—161.

**PORTSMOUTH HARBOUR.**—A black spar buoy has been placed on Cod Rock, near Fort Point, at the entrance of Portsmouth harbour, in thirteen feet of water. Vessels passing into the harbour, by leaving this buoy on the larboard hand thirty feet distant, will have six fathoms of water.

A black spar buoy has also been placed on the ledge at the N. E. point of Amazeen's Island, in ten feet of water. Vessels passing up the harbour, by leaving this buoy on the larboard hand, thirty feet distant, will have nine fathoms of water.

A black spar buoy has also been placed at the eastern edge of Sanken Rocks, in ten feet of water, bearing about East, from the monument on said rocks. Vessels passing up the harbour, by leaving this buoy on the larboard hand, forty feet distant, will have seven fathoms of water.

Two spar buoys have also been placed as guides, in entering Spruce Creek harbour, to wit: a White Buoy on the S. W. point of Hicks' Rocks, in fourteen feet of water, and a Black Buoy on Jamaica Point, in ten feet of water. Vessels entering Spruce Creek harbour, by leaving the White Buoy on the starboard hand, thirty feet distant, will have five fathoms of water; and by leaving the Black Buoy on the larboard hand, fifty feet distant, will have six fathoms of water.

After passing the two last mentioned buoys, about one hundred feet, vessels may anchor in seven fathoms of water, in good muddy bottom, and by keeping in mid-channel, and running about N., may anchor in the creek, in six or seven fathoms.

N. B. Hicks' Rocks are under water at about two-thirds tide; and the depths of water named in the preceding directions, were taken at low water.

*Page 159.*

**NEWBURYPORT.**—The directions given for entering this harbour, we are informed, are not at present correct, in consequence of the shifting of the Bar. The directions state that "You must keep the lights in a range, and run for them, until within a cable's length of the Eastern Light." We have not been as yet informed of the correct directions for entering this dangerous harbour; and it is advised in all cases to take a pilot.

*Page 162.*

**IPSWICH BAY.**—Two lighthouses have been erected on Ipswich Beach, which will be lighted on the first of December next. The lights bear from each other W. one quarter N., and E. one quarter S. Keeping the two lights in one, will lead over the Bar in the best water, a little to the S. of the buoy. Run in close to the beach, and follow it up close to, to avoid the Northern Spit on the starboard hand; run up round the first high bluff head, where will be found safe anchorage. There are eight feet of water on the bar, at low water.

*Pages 191-197.*

**WAREHAM HARBOUR, Buzzard's Bay.**—This harbour can only be attempted in the day time; and the only safety is to keep in between the buoys, of which there are nine in number, leaving, in going in, the Black Buoys on the starboard hand, and the White on the larboard. Lieut. Sturges, of the revenue cutter McLane, has furnished us with a particular description of the buoys, which, however, it is not necessary to insert.

*Page 198. Note.*

**BLOCK ISLAND Lights.**—Two new lights have been recently erected in place of the old ones. They are built one-third of a mile nearly due south of the old ones; are a few feet higher, and the distance between them is 40 feet.

*Page 201.*

**FISHER'S ISLAND.**—The following remarks and directions, by Capt. Andrew Mather, of U. S. revenue cutter Wolcott, are for sailing through the Race:

Vessels bound eastward through the Race, in the night, when abreast of Gull Island Light, with the tide of flood and a leading wind, should steer E. by S., or E. S. E., until Gull Island Light bears W. by S.; preserve that bearing until they see Stonington Light over the low land of Fisher's Island; they are then clear of Race Point and Race Rock. The spring tides in the Race run about five knots per hour; neap tides about four knots. High water, full and change, at 11 o'clock. The first half flood sets N. W., the last half about W. N. W.; consequently, when steering E., or E. by N., which is the "Sound Course," they have a strong tide on the starboard bow, which cuts them over to the northward, and instead of making, as they suppose, an East, or East by North course, which often carries them on Race Point, from which runs off far out a reef of rocks, under water. From conversations with the masters and pilots of shipwrecked vessels, I have been led to believe that the cause of most of the losses that have taken place, may be attributed to their mistaking the tides.

*Pages 214-219.*

**NEW YORK HARBOUR.**—The buoys to mark out Gedney's Channel to the northward and eastward of Romer, are ten in number, and with the following distinguishing marks. Those on the larboard hand coming in, are black and white, in horizontal stripes; those on the starboard hand, red and black.

The first buoy on the larboard hand coming in, is in 25 feet water.

The second buoy	"	"	"	"	"	19	"	"
" third	"	"	"	"	"	24	"	"
" fourth	"	"	"	"	"	24	"	"
" fifth	"	"	"	"	"	24	"	"

The first buoy on the starboard hand coming in, is in 19 feet water.

The second buoy	"	"	"	"	"	19	"	"
" third	"	"	"	"	"	24	"	"
" fourth	"	"	"	"	"	24	"	"
" fifth	"	"	"	"	"	24	"	"

The above named buoys are placed in the shoalest water in the channel, and on the edge of the banks which form the channel; and in no one case must a vessel stretch beyond the buoys on either side.

There is a true tide setting through the channel, the time of high water the same as at the Hook, viz. full and change 7h. 35 min.

The course in, after entering the channel, is W. N. W. by compass, until the Hook and Highland Lights are in range. Keep these in range, and run up for the Narrows, which will carry you clear of every thing.

To the northward of the black buoy off the Bar, the following spar buoys have been placed. Those on the larboard hand coming in, are black, with white tops; and those on the starboard hand, white, with black tops.

The 1st buoy on the larboard hand is in 31 feet water.

2d	"	"	"	"	"	24	"	"
1st	"	"	starboard	"	"	30	"	"
2d	"	"	"	"	"	24	"	"

The flood tide sets, first half, N. W., last half S. W. All the above depths are at low water.

The spar buoys at the entrance will be changed in the spring, and can-buoys, with the same marks will be put down.

Page 223.

POTOMAC RIVER.—A Floating Light is anchored on the end of the Bar that runs off Upper Cedar Point, on the Maryland shore, and her light was exhibited for the first time, on or about the 11th October, 1837.

Page 245.

ST. AUGUSTINE.—Two miles distant from the Island of Anastasia, and nine miles from St. Augustine Light, S. E. by S. from the light by compass, there has been recently discovered a fresh water fountain, about 100 feet diameter, appearing like breakers.

Page 277. Note.

# ADDITIONAL APPENDIX.

JULY 1, 1838.

## GEORGE'S SHOAL—Page 165.

A survey of this Shoal has been made by Lieut. Wilkes and others, in the U. S. brig Porpoise. We annex, from his report to Congress—

"The shoalest water found on any part of the Bank was  $2\frac{1}{2}$  fathoms, or 15 feet, reduced to low water; and this is only to be found in two small places, viz.

Lat.  $41^{\circ} 40' 13''$  Long.  $67^{\circ} 44' 10''$

Lat.  $41^{\circ} 40' 33''$  Long.  $67^{\circ} 44' 30''$

"The whole of the Shoal is composed of hard sand-spits—fine sand on the shoalest places, and coarser as the water deepens, until it becomes large pebbles without sand."

"The rise and fall of tides is 7 feet, extremely regular, the first part of the flood setting N.N.W., the latter part N. by E., and ebb S.S.E. and S. by W. The flood runs  $4\frac{1}{2}$  hours, ebb  $5\frac{1}{2}$  hours; greatest velocity two and six tenths of a mile, from half an hour to two hours in changing, going round with the sun on from North by way of East. The wind has but little effect on the velocity. High water, at full and change, at 10 o'clock 30 minutes. Variation of the compass  $8^{\circ} 15''$ ."

## RACE POINT—Page 177.

An accurate and very detailed survey of this point has been made under the direction of Major J. D. Graham, U. S. engineer. From his observations on the tides, which are very full, we extract—

"High water, at full and change, from 10 40 to 11 30 A.M. Spring tides rise 14 feet, neap tides 11 feet.

"Between Long Point and Race Point the tide runs from 3 to 4 knots, generally parallel to the direction of the shore."

## PROVINCETOWN HARBOR—Page 178.

High water, at full and change, from 10 20 to 11 20 A.M. Spring tides 14 feet, neap tides 9 feet.

Page 211.—A light vessel has been moored on the N.E. point of Stratford Shoal, (the Middle Ground.)

Page 216.—A light ship with two lights, the forward one 30 feet above deck, and the after one 40 feet, has been moored in 13 fathoms water, Sandy Hook Lighthouse bearing W.N.W., distant 13 miles.

## ST. AUGUSTINE—Page 245.

The bar at the entrance of this harbor has opened in a new place. In crossing the bar, with the Lighthouse bearing W. by S., steer W.S.W., which secures 14 feet at high water.

*The following Table of the Times of High Water and Rise of the Tide, is from actual observation, made by request of the British Admiralty.*

# NAUTICAL WORKS,

PUBLISHED AND SOLD, WHOLESALE AND RETAIL, BY

**EDMUND & GEORGE W. BLUNT,**

**No. 154 Water street, corner of Maiden Lane, New York.**

## BOOKS.

**BOWDITCH'S NAVIGATOR**, stereotype edition.

**BLUNT'S AMERICAN COAST PILOT**, 13th edition.

**MERCHANT AND SHIPMASTER'S ASSISTANT.**

**THE EXPEDITIOUS MEASURER**, stereotyped, to show the solid contents of packages and casks.

**SEAMANSHIP AND NAVAL TACTICS**, second edition, with PLATES.

**NAUTICAL ALMANACS**, from 1811 to 1838, inclusive.

**WARD'S LUNAR TABLES**, second edition.

## CHARTS.

**A CHART** of Magnetic Curves of equal variations, between the lat.  $60^{\circ}$  N. and  $55^{\circ}$  S. from the most recent observations, by *Peter Barlow, F. R. S.*

Do. extending from Montauk Point to Cape Antonio, improved by the Government surveys, with Plans of the principal Harbors.

Do. of the Mississippi River, with plan of Mobile, &c.

Do. from New New York to Nova Scotia, including George's Bank.

Do. of the Atlantic or Western Ocean, with plans of George's and Nantucket Shoals, and the Virgin Rocks, on large scales, from actual surveys up to 1832.

Do. of the South Atlantic Ocean, containing more authentic information than any extant.

Do. of the Coast of Brazil, from the Line to the River Plate, on a large scale, with plans of Harbors.

**A NEW CHART** of the West Indies, on six sheets, to be had separate, from the Spanish, French, Danish, and English surveys; with plans of St. John's Harbor, Porto Rico, St. Thomas, Port au Prince, Vera Cruz, Havana, Matanzas, &c. &c., on large scales, together with views of land, including Commander R. Owen's recent surveys of the Windward Passages, the Coast of Honduras, &c. &c.

Do. of the River Plate, on a large scale, from the late surveys, with sailing directions.

Do. of the Coast of Guayana.—Do. of the Island of Bermudas, with sailing directions.

Do. of the Coast of Labrador.—Do. of Newfoundland.—Do. of New London Harbor.

**A NEW CHART** of Long Island Sound, surveyed by Edmund Blunt, in the years 1828, '29, and '30.

**NEW CHART** of New York Harbor, from Barnegat to Fire Island Inlet, on a scale of 35 inches to a degree, from actual surveys made in the years 1821, '22, '23, and '24, by Edmund Blunt. The surveys of Long Island Sound and of New York Harbor, are the only surveys ever taken of the entrances of the Port of New York.

Do. of Bahama Banks and Florida Coast, on a square and large scale; the Bahama Banks, from the surveys made in the sloop Orbit, and by the British Government by De Maine; the Coast of Florida, from U. S. Government Surveys, to the present date, (1834,) intended with the Bahama Banks, to complete the whole Florida Coast of the United States.

Do. from New York to Nova Scotia, on a square and large scale, in which all the surveys recently made are introduced.

Do. of the Southern Coast, on a square scale, from Fire Island Inlet to St. Augustine, containing more information than any other chart extant, with plans of New York, St. Augustine, St. John's, E. F., and Charleston, S. C. Harbors, and Capes Hatteras, Fear, and Lookout, on large scales.

—ooo—

**FOR SALE AS ABOVE**, a complete assortment of the most improved Charts and Nautical Books of all parts of the world. Nautical Instruments of all kinds. Nautical Instruments repaired with care and despatch.

N. B. This establishment being exclusively Nautical, gentlemen may depend on finding the most recent and useful Nautical intelligence.

June, 1837.

## CHRONOMETERS.

The increased use of Chronometers by Nautical men, and their great importance, has induced the subscribers to make arrangements to supply these valuable instruments to their friends.

In order to be enabled to ascertain and verify the rate of Chronometers, the subscribers have erected an Observatory at Brooklyn, and furnished it with a Transit Instrument, two Astronomical Clocks with Mercurial Pendulums, Circle, and other necessary instruments.

The subscribers have now on hand Chronometers made by *Arnold & Dent*, and others. None will be offered for sale except those which have been subject to a sufficient trial, and which can be warranted to perform well, from a critical examination of their previous rates, compared with the rates given by the manufacturer, and the rates while in our possession.

The above named makers have received premiums from the Board of Longitude in England, for the excellence of the performance of their instruments. We subjoin an account of the performance of two made by *Arnold & Dent*, which were placed in the Royal Observatory, with ten others of their make, for the purpose of determining some experiments on Chronometers, with a view to their improvement.

Extreme variation, . .	1 <sup>h</sup> 1	1 <sup>h</sup> 1	1 <sup>h</sup> 2	1 <sup>h</sup> 2	1 <sup>h</sup> 0	1 <sup>h</sup> 0

#### ARNOLD & DENT.—No. 114.

Actual extreme variation in 12 months, . . . . . 0<sup>h</sup> 54.

This Chronometer took the first premium in 1829, at the Royal Observatory, it having the least variation of any Chronometer yet recorded.

These instruments, though very superior, have been equalled by many others by the same manufacturers. Out of eight Chronometers on board *H. M. Surveying Ship Blossom*, *Arnold & Dent's* proved the best; and of twenty-two Chronometers embarked in *H. M. Surveying Ship Beagle*, Capt. Fitzroy, No. 663, made by *Arnold & Dent*, was the most accurate, and gave the longitude of Rio within one minute in space of the mean resulting from the whole number. So close an approximation is convincing proof of the accuracy of their instruments. And it need not be feared that this accuracy will not continue. It is the result of a division of labor, a profound chemical knowledge of the qualities of metals, with a series of numerous and singular experiments, fostered by the care of the British Government, and rewarded by annual premiums.

These valuable but delicate instruments, besides requiring great care in their use, are frequently in want of repairs; to make their business complete in relation to Chronometers, they sent for, and now have in their employ, a workman brought up to the business, and highly recommended by one of the first Chronometer makers in London. In many cases an old Chronometer requires but few repairs or alterations to make it perform well, and these repairs, made under the direction of the subscribers, will be as faithfully done as they could be done in London.

The subscribers will determine the rates of Chronometers, and all Chronometers let with them will be carefully attended to.
