Wages, then, it is necessary to inform the poor man, are governed in a great measure by the proportion between the demand for any particular article, and the rate at which he or others may be then supplying it. DEMAND and SUPPLY are the great ruling powers of the commercial world; and hardly any shift can take place in their relative position, but, like the sun and moon, they affect the tides of that ocean of workmen who lie between. If the public be requiring more of a particular article than the ordinary rate of manufacture, or the existing stores, can conveniently supply, the manufacturers take advantage of the circumstance to lay on an additional price, knowing very well that the public will rather stand that exaction than want the goods. The direct consequence of this is, that he [illegible] to increase the wages of the labouring producers of the article, to induce them to work, for it is not to be expected that they will suffer him to reap the whole benefit of the rise, when, by declining to work, they can bring him at once within their power. The same train of events takes place when there is even an *apprehension* that the public will want more of an article than what can be readily supplied. The dealers nearest to the public, called retailers, then press for anticipatory supplies upon the general merchant, who in his turn presses upon the manufacturer, who in his turn presses upon the workman.

A decline of prices, from over supply, produces a result exactly the reverse. The workmen, in that case, soon find that the master does not so highly appreciate their services, and has to pay off a few of them, besides offering the remainder a lower wage. At first, the workmen who remain in employment are reluctant to accept this; but they soon find that their discharged brethren, by offering to take it, leave them no other course. In all declines, as in all rises, the effect goes even beyond its proper natural bounds. A falling market, when once set agoing, gains from the imagination of the merchants, and the necessity for the last-bidden sum being under the preceding one; and it requires a time to come to its proper level.

It forms a great addition to the unhappy condition of the workman on this occasion, that he has no fort of vantage to set his back to, for the purpose of bearing up against the ebb tide. He cannot, like a master, stand upon his capital, and rather suffer a little than just immediately give way. His needs are urgent: he must *every week* have a wage, and to gain that in any shape, he is compelled to come down from what we may call his prices. It is obvious that, if he had a little store laid up from former gains, he would not be in nearly so defenceless a state, but would often keep up the market of his own labour.

But the grand protection of workmen from low wages is a shortcoming in their own number. Under ordinary circumstances, it is the superfluous unemployed man, who, by bating down his neighbour, reduces wages. And it must be clear to every capacity, that, if more are born than what there is employment for, the result must be a declension in that exact degree. It is always good times for a workman while a country is on the advance, as Britain has been, or *was*; for then the natural increase of the people does not press so much upon the sources of support. But when a country is stationary in resources, the natural increase of people, if not moderated by some means or other, is sure to reduce the wages and comforts of the working classes.

There is a general impression that wages have, of late years, suffered so great a depression, as to have materially lessened the workman's command over the necessaries of life. This, however, is hardly made out by statistical inquiries. Husbandmen of the year 1832, in receiving 12s. a-week, could purchase 60 pints of wheat, which is as much as the wages of husbandmen have been able to purchase at any time during the last two hundred years. Domestic artificers, such as carpenters and masons, whose average wages in 1832 are stated to have been 33s. a-week, could for that sum purchase 265 pints of wheat, being a considerably larger quantity than the wages of the same artificers could have purchased at any time during the last two centuries, except within the last ten years, when the quantity was on one or two occasions *slightly elevated*. It is, we suspect, in the comparative addition to articles differing in some degree from the character of necessaries, and almost all of which are heavily taxed, that the alleged disability of the operative to make himself as comfortable as formerly, lies. Out of 17s., calculated as generally spent weekly by working men, upon bread, bacon, butter, cheese, tea, sugar, beer, coals, &c., 5s. 5½d, or one-third, goes for tax and monopoly, being a much larger proportion than what we can suppose to have been enacted at any time before the late war.

The liability of wages to be affected by the number of hands competing for employment, brings us to the question of

POPULATION.

We have the ascertained fact that a population, where there is unlimited support, will *double itself in fifteen years*. This proves that, as one grain of any kind of seed produces many grains, so there is a principle in the human race tending to increase. Such a principle would appear to have been necessary from the first, in order that, from the original pair, all the earth to its uttermost corners might be peopled; and, conversely, it is important to observe, the principle is a *proof of all having proceeded from one pair.* Nothing can be more certain than that men, if unchecked, would very speedily outpeople the regions to which they are in the habit of confining themselves, unless they will or can obey the law which nature meant to impose upon them when she conferred this tendency, and move along over the surface of the earth till it is all brought under cultivation. Unfortunately, another law, which nature probably imposed for the moderation of the diffusive principle—namely, a disposition to become attached to particular scenes and persons—prevails very strongly among us, being greatly enforced by our insular situation, and our appreciation of generally good institutions. There is therefore a decided likelihood in population exceeding employment in this country, unless it be outstripped by our resources—which is not the case—or unless certain moral checks, imposed by immediate necessity, be also obeyed.

The moral check, in which of course lies the only hope, consists in the horror which a man of good feelings must entertain at the idea of bringing children into the world, to drag out a starveling existence, or be cut down in their early years by the effects of misery. He will not multiply competitors for his own and his neighbour's labour, or do that which will subdivide a morsel already too small, and make all, himself included, the more wretched. He will not do this, if he *have* good feelings and just views; but he will do it, if he want these great distinctive features of an estimable character. There is a proverbial expression, very generally used by the common people in reference to a too rapidly increasing family, to the effect that no more mouths are sent than what there is bread for. There could not be a greater fallacy; and if all men were to bring children into the world in the same spirit of heedlessness, an universal starvation would very soon take place—at least in such countries as Great Britain. No, no; it ought to be present to the mind of every man, that, without a reasonable prospect of maintaining his offspring decently, it is an offence against society—an act of unutterable meanness and cruelty—to marry.

It is obvious that much must here depend upon what different people may consider as the standard of a decent maintenance. The Englishman has erected the highest known standard, in requiring wheaten bread, animal food, and a malted liquor. The Scotsman is contented with oaten bread, very little animal food, and water for his drink. The labourer in China, where the population has been *completed*, and no moral check exists, feeds on garbage. Some individuals are easily induced to marry, compared with others: we once knew a poor author who married on the score of two pounds, which he had received from some unusually liberal publisher. And the poor Irishman, it is well known, marries almost without the hope of a potato. But it is certainly of importance on general views that men should keep up a high standard. Better, decidedly, that fourteen millions should now live in England on the excellent fare which they usually enjoy, than that eighteen millions should exist, and the wheaten loaf be exchanged for bannocks. Let them make a stand upon wheat and beef, and posterity will never blame them for not being called into existence. The working classes may depend upon it, there is no effectual way of keeping up wages but in restraining the population. If they make a strike at all it should be against matrimony: if they forbid any thing, it should be the banns.

[The writer is aware of the prejudice which exists in many cultivated as well as uncultivated minds, against what is called the Malthusian doctrine of population. To meet this, he begs leave to present the following extract from Mr M'Culloch's Principles of Political Economy:—

"It has been often said, that if the doctrines now laid down, with respect to population, were really well founded, they would go far to subvert all the best established opinions with respect to the goodness of the Deity, and would effectually paralyze all attempts at improvement, by showing it to be in a great degree **hopeless**. There is not, however, any real ground for these statements. Not only are industry and forethought natural to man, but his advancement in the scale of being has been made to depend on their cultivation and improvement. We should infallibly die of hunger and cold, did we not exert ourselves to provide food and clothes. But could any thing be more ludicrously absurd than to object to those who simply state a fact of this sort, that they are impeaching the order of Providence? The powers and capacities implanted in man, seem capable of an almost indefinite improvement; but instinct did not direct him in their use. The more remote the epoch to which we carry our researches, the more barbarous and uncomfortable do we find his condition. Pressed on the one side by the strong hand of necessity, and stimulated on the other by a desire to rise in the world, our powers have been gradually developed, according as observation or accident taught us the best method of effecting our ends. *Want* and *ambition* are the powerful springs that gave the first impulse to industry and invention, and which continually prompt to new undertakings. It is idle to suppose that men will be industrious without a motive; and though the desire of bettering our condition be a very powerful one, it is less so than the pressure of want, or the fear of falling to an inferior station. Were this not the case, invention and industry would be exhibited in the same degree by the heirs of ample fortunes, as by those who have been educated in humbler circumstances, and compelled to exert themselves. But every one knows that the fact is not so. The peerage cannot boast of having given birth to an Arkwright, a Watt, or a Wedgwood. Extraordinary exertions, whether of mind or body, are very rarely made by those who are enabled, without their assistance, to live comfortably. The principle of increase has, however, prevented this from ever becoming the condition of the great mass of mankind, and unceasingly applies the most powerful stimulus—the *duris urgens in rebus egestas*—to industry and invention. Much, indeed, of the effect usually ascribed to the desire of rising in the world, may be traced to the operation of this principle. It is not solely on the lower classes, nor by the actual pressure of necessity, that it exerts its beneficial influence. At that period of life when habits are formed, and man is best fitted for active pursuits, a prospect is presented to every one, whatever may be his rank or station, who is either married, or intends to marry, of an indefinite increase of his necessary expenses; and unless his fortune be very large indeed, he finds that economy and industry are virtues which he must not admire merely, but practise. With the lower classes the existence of present, and with the middle and upper classes the fear of future want, are the principal motives that stimulate intelligence and activity. The desire to maintain a family in respectability and comfort, or to advance their interests, makes the spring and summer of life be spent, even by the moderately wealthy, in laborious enterprises. And thus it is, that either for ourselves, or for those with whose welfare our own is inseparably connected, the principle of increase is perpetually urging individuals to new efforts of skill and economy. Had this principle either not existed at all, or been comparatively feeble, activity would have been superseded by indolence, and men from being enterprising and ambitious, would have sunk into a state of torpor; for in that case, every additional acquisition, whether of skill or wealth, would, by lessening the necessity for fresh acquisitions, have infallibly occasioned a decline in the spirit of improvement; so that, instead of proceeding, as it became older, with accelerated steps in the career of discovery, the fair inference is, that society would either have been entirely arrested in its progress, or its advance rendered next to imperceptible. But it has been so ordered, that whatever may at any time occasion a decline of the inventive powers, must be of an accidental and ephemeral character, and cannot originate in a diminution of the advantages resulting from their exercise. Even in the most improved societies, the principle of increase inspires by far the largest class—those who depend on their labour for the means of support—with all these powerful motives to contrive, produce, and accumulate, that actuates the whole community in more early ages. No people can rest satisfied with acquisitions already made. The constant pressure of population against the limits of subsistence renders the demand for fresh inventions and discoveries as great at one time as at another, and secures the forward progress of the species. A deficiency of subsistence at home leads to migrations to distant countries; and thus not only provides for the gradual occupation of the earth, but carries the languages, arts, and sciences of those who have made the farthest advances in civilisation, to those who are comparatively barbarous. It sometimes, no doubt, happens, that notwithstanding this resource, and the most strenuous efforts on the part of the industrious classes, population so far outruns production, that the condition of society is changed for the worse. But the evils thence arising, bring with them a provision for their cure. They make all classes better acquainted with the circumstances which determine their situation in life; and while they call forth fresh displays of invention and economy, they at the same time dignify and exalt the character, by teaching us to exercise the prudential virtues, and to subject the passions to the control of reason.

It does, therefore, seem reasonable to conclude, that the law of increase is in every respect consistent with the beneficent arrangements of Providence, and that instead of being subversive of human happiness, it has increased it in no ordinary degree."]

It is eminently satisfactory to know that marriages *are* progressively decreasing. In 1810, the number in England was one annually in 122 persons; in 1830, it was only one in 129. Of course, as the population is still on the advance, there can be no reason whatever for complaint, even among those philosophers who rejoice in the contemplation of matrimonial happiness. Nay, there is much reason for congratulation to a benevolent mind, for is it not thus proved, that, of the children born, fewer are cropped off by misery? It may be desirable that people were married rather than single—but not surely if the only result be to increase the number of deaths, without adding to the births. There is an amiable but pernicious weakness in society on this subject. No sooner does any one hear of an approaching marriage, than he pricks up his ears, and, though the parties be far beneath his notice on ordinary occasions, he dwells upon them *now* with a ludicrously profound sense of interest. Under the influence of this feeling, well-meaning people often encourage and contribute towards a marriage, when they should rather administer a solemn advice to the contrary.

There is a contingent advantage in keeping up a good standard of food. Supposing a great and sudden reduction of wages, or any other severe calamity, which would make provisions less easy of purchase, the workmen can resort to cheaper kinds of aliment, with which he may keep up existence till better times. The Englishman has always the reserve of potatoes; but if the Irishman should want that root, he has nothing to interpose between himself and starvation. It is desirable, however, that the standard should be as rarely departed from as possible, lest, becoming accustomed to the meaner fare, the population should lose relish in some degree for the better, and forego the prospect of returning to it.

EMIGRATION.

To press onward over the earth till it be all peopled, seems part of the general destiny of mankind; and indeed it is quite impossible for the principle of increase to act otherwise, without producing misery. Men should therefore look upon emigration as no strange or painful necessity, but as one which has been ordained by nature herself. It is obvious, that, for every active labourer who leaves the country, there is the more employment and food for those who remain, provided that the native principle of increase does not fully meet and overpower the benefit. It is also obvious that nothing can be more absurd than deliberately to submit to narrow supplies at the place of one's birth, when, by removing elsewhere, larger supplies are sure to be obtained. The hardships incurred in this way are clearly nothing more than the punishment ordained by nature for the resistance to one of her most imperative decrees.

A doubt may reasonably occur, however, as to the reality of this diffusive or dispersive principle in nature. Pursue the idea to its utmost extent, and you find the whole globe at length fully occupied, and population pressing, as it were, upon the very verge of creation. What is to occur then? Nature, it is to be supposed, could never have instituted a radical principle which was at length to expend the whole of its utility, and, beyond a certain and unavoidable point, become a source of distress. She could never have designed that her whole children were at length to fall into the present condition of the Chinese, whose misery arises from a reluctance to move into reserve lands which actually exist.

It *may be*, nevertheless, that the principle was intended to act beneficially for a certain length of time, and then to experience a check from another quarter, which would prevent it from acting detrimentally. It might be calculated, that, by the time the whole earth was peopled, the moral character of man would be so much improved, that the populative principle would be sufficiently weakened to keep all right. Or it might be ordained, that improved and extended means of maintenance were to be sufficient, when the land was entirely covered, to keep pace with the increase. It is evidently absurd to suffer any apprehension, even abstractly, on this score, after seeing so much done in our own country in a few years to extend the means of maintenance. After seeing such immense additions to human power—the steam-engine, for instance—recently conferred upon mankind, who were previously altogether unconscious of them, we are entitled to presume that there are still many latent bounties in nature, which are hereafter to be developed, for the yet farther aid of man in his endeavours to support himself. To doubt this were only to imitate the conduct of those gentlemen, who, on the first attempt of Fulton to impel a boat by steam, predicted its inevitable failure. The cotton-spinning machinery has enabled thousands to live where there were once only hundreds. The steam-engine has done, or is doing, something of the same kind. Nay, there is not a railway or a canal formed in the country, but a calculation might be made of the increase which it gives occasion for and justifies in the numbers of mankind. Why, then, this ludicrous despair of philosophers, as to a supposed overstocking of the globe!

It is at least clear to all, that in *the meantime* emigration ought to be encouraged. The rising of kindred and enlightened nations in the neighbourhood of such a country as Great Britain, holds out the most exalted hopes to the philanthropist, as it tends to strengthen that minority of liberalised beings, who constitute the only really estimable portion of the human race—to the merchant, as it tends to extend commercial relations—and, though last not least, to the poor labourer, since it promises him either a better home than what he now possesses, or increased means of enjoying himself where he is. There is little reason to fear an universal surplus of people in our own age—for the world, which at present contains about a thousand millions of inhabitants, is calculated as able to support fully ten times that number, even by the present modes of raising victual. And, indeed, calculating the one thing against the other, there is no reason to suppose that this surplus will occur before the period of equally universal moral improvement.*

COMPARATIVE REMUNERATIONS OF TRADES AND PROFESSIONS.

The great inequality in the condition and comforts of men is a thing obvious to every eye. It is often the source of discontent to those who feel themselves low in the scale; and it is hardly to be expected, perhaps, that the poor man can behold, without a sigh, the superior style of living in which the rich one can indulge. Few poor men, however, are so blind as not to perceive some of the causes which render this inequality unavoidable. We shall here explain these causes.

In the first place, it must be already plain that a great part of the advantages of the wealthy arise from the industry, talent, and economy of their forefathers. To be the descendant of a family which has acquired, in past time, either land, or goods, or the respect of the community, is a piece of natural good fortune, which such an individual must be permitted to enjoy, because it is evident that, though he did not create these advantages, he has still a right to them, through the will and pleasure of those who did create them—and further, because if he were deprived of them, or in the least disturbed in their enjoyment, existing men would want one of the greatest motives to exertion, and the commonwealth be injured accordingly. The contemplation of wealthy people, instead of inspiring poor men with envy, or any other malignant feeling, should make them cheerful and happy, in so far as it assures them that, whatever they can gain, they or their children will be permitted in the same way to enjoy.

It will be less plain, however, to common understandings, that the men engaged in certain trades and professions should realise large incomes, while others are kept at the merest pittance that will suffice to retain life. There are reasons, nevertheless, for all these inequalities—reasons quite sufficient to satisfy the sense of even those who enjoy the smallest denomination of incomes

The five following reasons are stated by Adam Smith, in his celebrated work on the Wealth of Nations, as those which chiefly tend to increase or decrease the recompense of employment:—

1. The agreeableness or disagreeableness of the employments themselves. Some employments are confessedly much more pleasant, much more healthy, and much more honourable to be engaged in, than others. The business of a gardener, for instance, is preferable in all these respects to many other occupations requiring the same degree of strength and ingenuity. Hence, it is more apt to be resorted to; and, consequently, its wages must be somewhat less than in trades otherwise corresponding. The business of an executioner is paid higher in proportion to the time, strength, and ingenuity engaged in it, than any other, in order to make up for its want of public respect. The trade of a tailor is also paid very high in these proportions, in consequence of the silly popular obloquy which attaches to it. Clergymen and officers of the army and navy are not, in general, paid so high as men exercising the same learning and talent, or encountering the same risks and disadvantages, in other employments—and this purely because a clergyman and an officer enjoy much public respect and eclat: their profession is styled that of a gentleman, and partly remunerates itself.

2. The comparative difficulty of learning a trade or profession, and the comparative time and money employed in so doing. It is evidently quite fair that, where a trade requires an apprenticeship of seven years, or a profession can only be exercised after a tedious and expensive education, the said trade and profession should afterwards bring greater remuneration than others more easily and more cheaply acquired.

3. The constancy or inconstancy of employment. Nothing can be more clear than that a trade which can only be exercised at a particular season, or which depends upon occasional chances to be called into exercise, should be paid higher than one which enjoys regular and permanent employment. Stone-masons, for instance, who are laid off work by bad weather, should be better paid when they do work, than a craft, equal in other respects, which can be exercised at all hours throughout the year. Street-porters, on the same principle, must be paid as high for their occasional jobs, as may enable them to live, upon the whole, as well as other persons who exercise the same degree of labour and ingenuity (such as it is) in a more steady way.

4. The comparative trust reposed in workmen. Character, be it observed, is just as good to a workman, in its proportion, as his skill or his possession of tools; for it is as likely to be called into service by employers, and as well entitled to remuneration. When a common labourer has afforded such grounds of confidence to his master as to justify his being entrusted with the least censorship over the rest, he naturally claims and receives a higher rate of wages; for in fact it is the utility of every thing that assigns its value—and character is here applicable to use. "We trust our health to the physician, our fortune, and sometimes our life and reputation, to the lawyer and attorney. Such confidence could not be safely reposed in people of a very mean or low condition. Their reward, therefore, must be such as may give them that rank in society which so important a trust requires. The long time and the great expense which must be laid out in their education, when combined with those circumstances, necessarily enhance still farther the price of their labour."—*Smith's Wealth of Nations.*

5. The chance of success in different employments. Where there is a risk of, say, one to three, that after all preparation employment will not be obtained, and where this is the result of incalculable circumstances, the remuneration of those who do gain employment ought to be so much higher as to make the loss of their competitors their own gain. In all ways of expending capital there is a risk, which is paid in proportion; and, accordingly, there should be payment in this case also. It is chiefly in *professions* that such risks occur—for in the most of trades and crafts, the skill required is such as the most of people are capable of acquiring.

In all ways of gaining a livelihood whatsoever, the remuneration will be governed by one or other of these circumstances, *balanced against the multitude of persons who compete for employment in the respective professions, trades, and arts.* We only recollect one exception from the general run of Mr Smith's remark—and that is in the monstrous over-payment of such persons as drivers and guards of stage-coaches, the exhibitors of public places, tavern-waiters, &c. It is notorious that waiters, though they lay out no capital, and boast but a very ordinary kind of skill and address, very frequently realise more profit than the master of the house, who has much property engaged and hazarded, and, by his superintending management, exercises a far higher and more useful kind of labour. In the palaces which are visited by public curiosity, a mere chambermaid is in the way of realising more money than an ingenious man who employs perhaps two thousand pounds of capital. And, in the shilling which one of every twelve persons, perhaps, gives to the guard of a stage-coach, after three hours of the most simple kind of service, there is perhaps ten times more remuneration than the said persons give every day to those who supply them with the necessaries of life. These are cases, however, in which no competition is admitted; and the abuse evidently lies so entirely with the simplicity of the public, that it cannot be held to enter into the consideration of the general question.

FLUCTUATIONS AND GLUTS.

The progress of production in manufactures is, unfortunately, not a regular flow; it is, like that of the blood in the pulses, of an intermittent nature. Demand asks only so much; but, let it be never so precise in its orders, supply is sure to give more. The state of hope into which a master is thrown by a little briskness in his trade, his consequent direction of all his force on that point, and the natural difficulty of drawing off in time, inevitably produce this result. The fear of a glut may with some be a check to a certain degree; but it is not all, nor nearly all, who will permit themselves, or are able, to foresee the tendency of their own over-activity. The only sure check is the glut which sooner or later takes place, and the consequent fall of prices beneath the level of competing articles, or beneath the expense of production.

Sometimes there is a glut in the market of goods, and sometimes in the market of labour. In the former case, there immediately takes place a glut of labour also; but the glut of labour may arise from distinct causes.

The glut of goods produces low prices, and this, after a time, generally attracts so much new custom as to occasion a revival of the trade—some new consumers being in this case generally added from a lower class, so that in the long-run a glut may be of some benefit. The trade, once more in active operation, is apt to proceed as formerly to the extreme of over-production, and then comes the glut once more. Thus things proceed, not only in particular trades, but in the entire business system of the empire.

Fluctuations arise from minor causes, as the seasons, the changes of fashion, the abbreviation of labour by machinery, and the shifting of manufactures from one district to another. It may be said that all variations in the rate of manufacture are of detriment to the labourer, as the periods of depression, which invariably produce real suffering, are not compensated by the rise, the results of which are seldom turned to their proper account. The workman, moreover, finding his wages fall, is apt to take a method for increasing them, which can only tend to increase his own distress or that of his neighbours. He works a longer time each day, and thus adds to that over-production which it would be his interest to diminish. Hence, in Manchester, there is always most work done in bad years.

Distinct and powerful causes of fluctuations are found in alterations of the currency, in erroneous legislation, and in political events. None of these, however, is it our present business to discuss. We conclude the subject by quoting and recommending the following excellent suggestions from Dr Wade's "History of the Middle and Working Classes;" a work that would be a treasure to the industrious part of the community, if any considerable portion of them could afford the treasure (eight shillings) necessary for purchasing it:—

"To provide for changes in employment occasioned by periodic alternations of prosperity and depression, two suggestions may be offered. First, the workman, by saving out of his high wages during years of brisk demand for labour, might lay by a fund for a period of stagnation of trade; or, secondly, he might enter into an agreement with his master to serve at an average rate of wages for such a term of years as would embrace the ordinary commercial cycle of depression and prosperity. Various other expedients might be suggested; but it appears superfluous, as they must be either generally obvious, or are already partly acted upon. The object sought is to make the *good* years cover the *bad ones*, and *vice versâ*. That this is partly possible, there does not appear any doubt; since it appears, from the inquiries made into the rate of wages in the principal trades and manufactures, that the earnings of workmen are sufficient, on an average of years (if the earnings could by any means be spread over the whole period), to maintain their families in comfort and independence.

In some of the trades of London (particularly the tailors) all the journeymen are in organised clubs for mutual support during want of work; and out of the general fund, to which they all contribute when in work, each man out of employment has a right to a weekly allowance. Such a society is, without doubt, highly beneficial, especially in a trade where the demand for labour is much greater at one period of the year than another. It has one drawback, in operating as a combination to regulate and keep up wages; and so far has this been successful, that no reduction in the wages of tailors appears to have taken place since 1815, notwithstanding the change in prices of almost every article of life. As respects a class of journeymen employed entirely on articles of home consumption, this may not be esteemed a disadvantage; but it is evident that if the same combination existed among workmen manufacturing articles of export which had to compete with the fabrics of other countries, such a system might be ruinous both to masters and men.

The journeymen brushmakers, amounting to not more than one thousand in number throughout the kingdom, support a union for mutual aid in scarcity of employment. The carpet-manufacturers, and other trades, are united for a similar purpose. Few of these, however, have any fund beforehand, but draw the support from increased contributions by the men who remain at work.

Some workmen of superior character make a provision for periods of temporary stagnation of trade, by accumulating a small fund in a savings-bank; but the great majority have no resource when out of work but to live much worse, to exhaust their credit, pawn their clothes and furniture, and finally apply to the parish, where their spirit is broken, and independent feeling lost.

The master manufacturers resort to two expedients of a very different character for meeting temporary stagnations of trade. In the one case, on the demand for goods becoming slack, the quantity made is diminished; a less amount of work being given out, and the workmen paid (by the piece) nearly as much as before. Having, however, but three or four days' work per week, they are obliged either to economize their expenses, or resort for support during the other days to whatever fund their forethought may have provided; thereby, the quantity of goods made being reduced nearly to the real demand, no glut is formed in the market, and on the revival of the trade the men again resume full work without great loss. This is the case with several trades having a fund to fall back upon, and is beneficial to all parties."

COMBINATIONS.

Combinations among workmen to keep up their wages, are, upon the whole, the characteristics of a period of decline—in other words, a period when either labourers are increasing too fast, or the means of employing them are diminishing.

The last few years have notoriously been a period of decline—not owing, apparently, to any failure of the natural resources of the empire, or to an imprudent increase of population, but to some unfortunate regulations respecting money, which have rendered the quantity of that article too small for its proper functions as a representative of capital in transition from one hand to another. One of the primary results of this state of things has been the embarrassment of men who would otherwise have had both the will and the power to give employment; another has been a large reduction of income to almost all men whatever, so as to render them unable to purchase

* In treating this department of our subject, we have not adverted to the different ways in which emigration is treated by different political thinkers. The Tories, we believe, in general, recommend emigration, as a means of relieving the distresses of the poor; while the Independent or Radical party assert, that it would not be necessary, if the landlords would give up their monopoly in the raising of bread. We trust it will be seen that we have argued in favour of emigration upon abstract views alone.

goods which they could formerly purchase. It is now found that no expensive kind of article will now be bought to nearly the same extent as formerly, but that cheapness has become a leading principle in every thing. Where formerly there were splendidly illustrated works, which amply remunerated their producers, there are now annuals at half a guinea; where formerly there were magazines at half a crown, there are now magazines at three-halfpence and a penny. It is not so much an extended appetite for literature which supports works, for instance, like our own—as it is an absolute inability in the public at large to purchase dearer ones. Hence the branches of bookselling which apply to more expensive kinds of literature, are experiencing a severe depression, from which there can be no rise, without a restoration of former circumstances in the public, if even then.

One of the notorious results of this state of things, is an almost universal combination of the labouring classes to keep up their wages. A general Trades Union has been formed for this object, and an alienation of the affections of masters and workmen from each other is rapidly advancing. If things were upon the rise, and if such a thing could be as a disposition on the part of masters to exclude workmen from a fair share of the advantage, such a combination would be decidedly necessary. But it would be a mere dishonest flattery of the working-classes, to tell them, that, under the contrary state of things, their efforts are either laudable or likely to be attended with any good effect. The misfortunes of the country, from whatever source arising, befall masters and men alike; for not more certainly does over-production, or failure of demand, or erroneous legislation, diminish the wages of the one, than they diminish the profits of the other; so that the relative circumstances of employer and employed must at all times be nearly alike. If the capitalist deserves a certain share of profit during good times, he deserves a proportionate share in bad times; and it would be equally unjust to ask workmen to labour for nothing, that masters might thrive, as to expect masters to lay out money for nothing, that workmen might thrive. Beyond this principle, there can be no claim from the workmen to the masters, further than what benevolence may sanction, or what the latter may be pleased to advance, in order to secure the services of estimable workmen against better times. Nor can the pressure of a general combination be of any permanent benefit, except perhaps to urge an alteration of parliamentary enactments, so far as these may be proved to have occasioned the decline.

While thus unavailing for good, it is certain that a general combination must produce harm, but in the first place to the workman only, in so far as it tends to embitter their employers against them, and, if temporary idleness should inter to injure their personal habits and value as workmen. It is also almost inseparable from the nature of a combination, that it must narrow the liberty, and interfere with the rights and profits, of men who are unwilling to join in it.

We would hope that the reasonable workman will not see, in these speculations, any disposition to take the part of capital, abstractly, against labour. There is hardly, we believe, a public writer in existence, who does not feel a deep and abiding sympathy with the prospects and interests of the labouring classes; but if there be any such, we are not of the number. Neither do we believe is there any indifference, generally speaking, among masters, towards the welfare of workmen. There has always appeared to us, on the contrary, to be a kind feeling, going far beyond the letter of the contract, and compensating in some measure for the unavoidable partiality of fortune. It is for the advantage of workmen that this feeling should not be impaired or banished.

To conclude, there is one advantage which *might* arise from trades associations, and prove of vast service to the labouring classes. This is the possible diffusion, by such means, of just and really profitable knowledge on the general interests of the manufactures and branches of business with which they are connected.

MONOPOLIES AND RESTRICTIONS.

While general combinations to prevent decline of wages are represented as unavailing, it would be the height of injustice to deny that the preservation of a free market here should be accompanied by a free market all over, so that no other class should gain at the expense of the labouring classes.

All kinds of restrictions whatever upon the free exercise of industry, and the range of commercial speculation, are radically evil—the characteristics of an ignorant people—and self-destructive in their effects. Great Britain, which at present struggles with the sloughs of all kinds of antiquated institutions, has, unfortunately, to deal with many of these legacies of former and less enlightened ages, by which her unexampled prosperity, so far from being favoured, has been only kept under what it must have otherwise been.

It is customary to trace these evils almost exclusively to interested legislation; but we are inclined to think that they have in a great measure arisen from the narrow prejudices with which the English nation in general has been heretofore replete, and from which it is only now awakening. The agricultural, and hitherto ruling class, have not solely instituted restrictions in their own favour; they have, at the same time, permitted almost every other trade and interest in the country to do the same thing. Their attentions to themselves were only to have been expected where all were attended to. The sin and blindness appear to us to have been quite general.

The first and leading prejudice is that of country. It is no doubt to be conceded that a high national feeling is sometimes of service in preserving national independence and honour; but the use has been carried into the abuse. An intense selfishness—a fear that any other nation should have the least benefit from the intercourse which we carry on with them for our own notorious profit—has prevailed among all the mercantile classes; and till a few years ago, it was accounted philosophy to suppose that certain neighbouring states were, in every relation of life, our "natural enemies." This and other causes led to bloody and expensive wars, the consequences of which were an enormous and apparently irreducible debt, entailed upon posterity. War is in every point of view an evil: it has not in itself a single redeeming feature. It may only be occasionally necessary, to protect a nation against unjust aggression or insult. We blush for our country, however, when we reflect on the heedlessness, and even eagerness, with which, not the government only, but the people, have hitherto entered into contests, where the utility of taking up arms was far from clear. For instance, the war of 1775–82, for reducing the American colonies, was at first far from unpopular, though certainly opposed in every respect to those principles which the nation had bled to defend in the preceding century. It is also a matter of historic certainty, that the people entered heartily into the last French war (the blame of which it now throws so absurdly upon a particular party of statesmen), and this from no clear or judicious perception of the causes assigned for it by the government (which might be good or evil, as men happened to think), but from a mere vulgar idea of national glory, and the fascination of empty military parade. It is pleasing to think that both the government, by which we mean the ruling class at large, and the people, have become, even in a few years, so much more enlightened than they were—so much more capable of perceiving the bearing and tendency of important national movements—that there is now little chance of any such infatuation again occurring. The best protection against such follies evidently lies in that intelligence which is now in the course of being implanted in the minds of the people, by which they will be placed above all risk of having their senses imposed upon by toys and sounds, and enabled, when necessary, to check the rashness of statesmen. Men are now beginning to overlook, in a great measure, the ideal bounds of particular countries, and to extend their sympathies over the whole family of man. It is a blessed change, and ought by all means to be encouraged. By such means, we have no doubt, different nations will soon look upon each other as friendly customers and reciprocal assistants, instead of rivals or aliens, and commerce will be permitted to go to a far greater extent amongst them than has ever heretofore been known. It will speedily be seen that the best way to cause other nations to buy from us, is to buy also from them. We must wean ourselves from a notion which has possessed us, that all the advantages of the commerce of this world are by a law of nature due to Great Britain, and that other nations must starve that we may enjoy. Like all unjust notions, it is eminently absurd.

Next comes the prejudice of district. When men live for a while in any place, interest and fancy conspire to give them a notion that there is an abstract advantage in favouring this place by all possible means, although it may be notorious that the same good could be done at less expense and more convenience elsewhere. "The garter trade of Stickleton ought by all means to be encouraged"—for—for—we live at Stickleton. It all resolves itself into a delusive prepossession. Under the influence of this feeling, a gentleman a few years ago laid out twelve thousand pounds in forming a small harbour at a rock-girdled part of the coast of Ayrshire, where the requisite space had to be cut from the solid granite, and nothing but a small village existed within many miles, to consume the articles proposed to be imported. Of course, the capital, instead of being turned to profit, which was perhaps the secondary object of the expender, was completely sunk. And every day we see instances of similar attempts to force trade and manufactures where nature presents no advantages for the purpose—though it seldom happens that the folly of the procedure is so very obvious as in this particular case. Men must clear their minds of this ridiculous propensity to think the interests of their own place of residence above all others, before they can *deserve* a free trade, even in the articles which it most concerns them to obtain without restriction.

The third grand prejudice is that in favour of particular trades or branches of commerce. Having expended time in learning an art, it is natural to cling to it very earnestly, and to desire to see it succeed beyond all others. Such a feeling, in so far as it produces competition, may do a general good. But it is iniquitous, and, like all iniquitous things, absurd, to hedge round these interests with corporate privileges and legislative restrictions. By such practices, the public is the first loser, neighbouring trades the second, and the privileged trader himself the third—for in the long-run his trade is limited by unnatural prices. No man, we hold, who belongs to a profession in the least favoured, or attempted to be favoured, by such restrictions, has any title to complain of either the corn monopoly or any other. Such, we are glad to see, is an incipient feeling among the trades themselves, for within the last year several corporations in Scotland have spontaneously resigned their privileges.

THE CORN MONOPOLY.

This is well known to consist in an exclusive right, with which the proprietors of British land are invested by Parliament, to supply the people with the chief article of human aliment, at prices higher (except under very particular circumstances) than the same article could be obtained from some of our supposed "enemies," the other countries of Europe.

The arguments generally presented in favour of this monopoly are chiefly grounded on an assumption similar to that expressed by an old Scotch proverb, that it is proper to keep the offal of our own fish for our own sea-mews. It is presumed to be of service to all classes within Britain, that the bread of the people should be purchased from British rather than from foreign growers, because the money is thus, as it is said, kept in the country, and speedily distributed again among the people for their own goods, whereas, if it were sent abroad, very little of it would ever again return.

Against this it is argued, that it is not money which is given for bread; it is, in either case, goods or manufactured articles. The true interest of Britain, it is alleged, does not consist in its agriculture, but in its manufactures. The country should be esteemed as only one vast factory, aiming at the supply of all other countries with goods, and taking the bread of its workmen from such producers as will give it cheapest, and take most goods in return. It is represented, that, if the people could get at the cheaper corn of the Continent, they would produce goods cheaper (which is self-evident), and would thus attract a wider range of customers all over the world, with or without regard to the people they bought their bread from; whereby, while the native landlord got no more than his due, all other persons would be greatly benefited.

In favour of these views, it is ascertained that the manufacturing classes of the empire are increasing at an infinitely more rapid rate than the agricultural, and are at this moment as two to one in comparative numbers.* If landholders are to be considered as only producers, like other people, which they really are, why, say the anti-monopolists, should the two be sacrificed for the one?

We believe it is now pretty generally conceded by candid thinkers, that the principle is wrong, and that the only valid objection to the abolition of the monopoly lies in the severe and sudden injury it would occasion to a class, who, though themselves instrumental as legislators in imposing the protective regulations, were so in a great measure under the influence of common error—who, as always necessarily happens, have laid out much capital on the faith of no speedy alteration—and whose distress would operate dispersively, for a certain time, over many departments of the working population. If a process could be instituted for returning, by imperceptible or slightly perceptible degrees, to a state of things more generally beneficial, little objection in any quarter would be raised. Agricultural capitalists, however, are entitled to expect that all kinds of monopolies should be given up at the same time, and by equal steps. It would be unjust that the manufacturer should get free bread, while the bread-grower could not get every thing *he* required as free. Nor can we see any moral or political difference between agriculturists making laws for their own behoof in Parliament, of which they happened in the course of things to have possession, and tradesmen making laws for theirs, within the circle, and under the protection of their own corporations, or by any other species of combination against competition. The whole system, in fact, is replete with reciprocal injustice, and ought to be subjected to an universal and impartial, but cautious reform.

FREE TRADE.

The practice of excluding this and that foreign article by heavy duties, in order that the producers in our own country or in our colonies may be advantaged by it, is liable to the same abstract objections as the monopolies in corn and certain kinds of goods. It favours or seems to favour a certain class of persons, at the expense of the community at large. As in the other cases, there remains little doubt any where, as to the expediency of abolishing such practices; the only objection is a fear to meet the distresses which their abolition would occasion, among those who are interested in them, and the various wide-spread connections of those parties. An abstract of the popular arguments on this subject may here be given:—

* "In Italy, the proportion of agriculturists to non-agriculturists is as one hundred to thirty one; in France, as one hundred to fifty; in England, as one hundred to two hundred. But the most remarkable fact, as respects this country, is the change that has taken place in the employment of the people since the commencement of the present century. In 1801, the number of persons engaged in trade and manufactures in England, as compared with those engaged in agricultural pursuits, was as six to five; in 1821, it had increased to eight to five; in 1830, to two to one. In Scotland, the change has been still greater, having risen from five to six in 1801, to nine to five in 1821, and is now estimated at nearly two to one, as in England. During the whole period of thirty years, the general population of the country has increased nearly fifty-one per cent., which exceeds the proportionate increase in the manufacturing districts. In four rural districts, the increase of population, during the last thirty years, has been only thirty per cent.; in London, fifty-eight per cent.; and, in three of the largest manufacturing towns, no less than one hundred per cent., or exactly double."—*Dr Wade.*

"Take the case which the opponents of free trade would put forward as most favourable to their cause. Assume, for instance, the case of the glove-maker. Gloves may be had, it shall be supposed, from a French maker for the value of two shillings a pair. An Englishman stands up and says, that he can make gloves of the same kind for three shillings; and therefore, for the sake of encouraging British commerce, it is expedient to pass a law to prohibit the introduction of French gloves at two shillings, in order that those who choose to wear gloves may be obliged to take them from the Englishman at three.

When you buy a pair of French gloves, it is clear that they have been paid for in something. You have the substantial evidence that *you* did not get them for nothing; and so has every body else. They must have been paid for either with goods of English produce, or with goods of some kind (gold and silver included) which have been bought from abroad with goods of English produce, or with bills, which are only an order for payment in one of the other ways a few days hence instead of to-day. Unless an Englishman has the art of getting any thing for nothing, in one or other of these ways must they infallibly have been paid for. Here, then, are, at all events, two shillings accounted for out of the three, which are as fairly expended for the benefit of British producers and manufacturers of some kind, as they would be if the gloves were bought from a British glove-maker at the same price. They are paid for to the Frenchman, it may be, in Sheffield goods. But if the glove-maker procures a law that gloves shall not be brought from France, it is plain that Sheffield goods must stop. The glove-maker may gain employment and trade by the alteration; but it is equally plain that the Sheffield man must lose.

So much for the part which consists of the *two* shillings—next for the part which consists of the other *one*. And this, says the glove-maker, is to be a clear gain to British commerce, and it is a horrible wrong if it is deprived of it. Now, mark the juggle—look sharply to the shuffling of the balls. If the wearer of gloves is to be forced to expend a shilling more upon the glove-maker, he must expend a shilling less upon [illegible]body else. It may be that he would not have [illegible]pended it at Sheffield, but at Birmingham; or that it would have been divided among fifty other places which it is impossible to assign by name. But still it is as clear as ever, that the shilling which it is proposed to make him expend *nolens volens* [willingly or unwillingly] upon the glove-maker, must be taken from the custom of some other British manufacturers somehow and somewhere. There is no deception arising from the payments being made in money; if, instead of shillings, they were made with pecks of wheat, it would be just as true that the third peck which the glove-maker demands a law to put into his own pot, must be taken from the pudding of some British manufacturer, to whom it would otherwise have gone. Sift this; turn it over; see if it be true or not. Do not allow yourself to be tamely taken in, because the men who try to do it wear good clothes. Either it is true or it is not. If it is not true, let somebody show where it is false. Till then, we account it correct.

Here, then, are the whole three shillings perfectly accounted for. It is shown to be a hocus-pocus and a fraud, that states that any gain arises to British commerce or production in the aggregate from the prohibition of the commerce in French gloves, or that any aggregate loss is induced by the permission. The whole amounts only to a plan for robbing a Sheffield man or a [illegible], who can make what people will volunt[illegible] for the benefit of the glover who cannot; [illegible] commerce of some individual who has [illegible] skill enough to command a market, to [illegible] who is without.

But [illegible] is another count in the Indictment. [illegible], the unfortunate who is in the habit of [illegible] gloves, is to be the gratuitous loser of a shilling [illegible] the shilling was to go to the benefit of commerce, he might wrap himself up in his patriotism, and be consoled. If it was really to cause any increase in the safety or strength of the community of which he is a member—if the thousandth part of a farthing of it was to appear in the shape of national wealth, security, or splendour—he might lay aside the feelings of an injured purchaser [illegible] mittees, and exult in his fractional portion of the [illegible] of those who have suffered for their country. [illegible] when it is to be taken from him with no object, [illegible] prospect, no hope, but that a clumsy and inefficient [illegible]man shall be enabled to appropriate the custom of [illegible] intelligent and effective one—his situation presents itself in all its nakedness, his courage sinks under the view, [illegible] feelings of humanity prevail, he drops a tear [illegible] wipes it on his three-shilling gloves, and sits down [illegible] melancholy monument of what it is to be 'the envy of [illegible] nations, and the wonder of the world.'

This is [illegible] exam[illegible]tion of one single act; the next is to multiply the cases, as is the fact in nature. Suppose that every individual in the community was a producer of some kind, and that every one had a 'protection' upon his particular trade. What would be the result, but that each would steal something out of his neighbour's box, with a general loss to be divided among themselves in their character of consumers, equal to what might have been saved by buying goods of all kinds where they were cheapest?

But it will be said that this is not an exact statement of the case;—that all men are not producers, but on the contrary there are large classes that produce nothing. And hereupon it will be attempted to infer, that the whole is a patriotic machine for drawing wealth from the unproductive, and giving it to the industrious. There might be some show of reason in this argument, *if the industrious classes were to gain by it.* But the industrious are in the aggregate to gain nothing—all that is to be given to one of them is to be taken from another; and the unproductive, as they are called, are to be robbed for love. A great proportion—a large and important share of the sum thus stupidly thrown away—must of necessity fall on the industrious; for though they do not consume all, they consume a great deal. And it is no remedy to *them*, that somebody else is to lose the rest. Besides this, the classes so unceremoniously voted unproductive, are in a very great measure composed of those who *have* produced. There is no reason in saying a man shall be protected while he is producing, but shall be robbed whenever he begins to enjoy. Men do not labour for the simple love of labour, but for the love of the enjoyment they may ultimately procure by it. No man in his senses would consent to an arrangement, by which he should be protected while he was a hard-working citizen, but should be exposed to all robberies whenever he had the impudence to think of retiring to live upon his savings. Yet this is the very theory of those who talk of robbing the unproductive with as much lightness of heart, as if men really produced and saved with no other view but that somebody else might take it from them.

It is clear, therefore, that what is really recommended, is to incur an assured loss in the aggregate; but men are exhorted to struggle and pull caps, for the chance of what they may individually get from others in the contest. That all the traders in a country, and all the inhabitants in general, whether they trade or not, must lose by such a principle, if the effects were evenly distributed, is as plain as in the case of a lottery; but they are to be cheered on by the probability that the distribution may not be even, and that they may be the lucky rogues who win. It is a political *little-go*, in which every body knows the concern to be ruinous in the main; but jolter-headed individuals are to be encouraged to throw again, by the vision of some paltry prize they are to catch at the expense of the remainder.

If a saving is to be made by the introduction of steam-coaches, no effectual opposition can be offered by the dealers in horses, because the public are sufficiently informed to know, that all they expend less upon coach-hire, will be expended upon something else instead, and therefore the loss of business to horse-dealers will be balanced by an increase of business of exactly the same amount to somebody and somewhere, and they (the public) will gain the difference besides. They are aware that such a piece of legislative dullness as this would amount to setting up the principle, that it was for the interest of every body that every thing should be done in the most bungling and round-about way possible. But let a single exchange intervene, and the question is too much for them. If the machine in which men are to ride for two shillings, instead of three, can only be bought with Sheffield cutlery from France, they are utterly unable to see, that the national profit by steam-riding—the ultimate advantage of employing an English cutler to effect the production of the cheap machine, instead of an English horse-dealer to supply the dear one—is the same as ever. In this case they are ready to join the horse-dealer in begging, first, that the employment may be taken from the Sheffield cutlers; secondly, that it may be taken from the persons at present employed by the expenditure of the shillings of which it is proposed to rob the coach-riding public; and, thirdly, that they (the public) may be robbed of a shilling in their coach-riding, without advantage in the aggregate to any body. They can see that it would be absurd to put down the *omnibus* on the ground that men rode cheaper in it; but they cannot see that if the omnibus could only be got from France in exchange for Sheffield goods, the case would be unaltered. Was it rightly said that John Bull is a man of one idea, or at most of two?"

"INTERESTS."

It is a result of the systems just described, that various branches of our national exertion and capital ha[illegible] [illegible]een resolved into large and powerful fraternities, all of which are favoured and protected by privileges or enactments, tending to their own apparent advantage, without regard to the general good. Thus we have the East India Interest, the West India Interest, the Bank Interest, and so forth. It is perhaps necessary, in the infancy of some departments of national enterprise, that, in order to obtain a certain ultimate and general good, some exclusive favour should be shown to them by the state. But after the first difficulties are got over, it is still more clear that a continuance of an exclusive system only confers an undeserved and unnatural force upon capital employed in these particular directions, and makes a limited number of people wealthy, while capital otherwise employed is just so much the less productive and useful, and other people of course so much the poorer. It could be shown that much of the evil arising from these causes was owing to a well-meaning and almost unavoidable, but nevertheless reprehensible compassion, which the state was called upon to show towards those interests, at various times when they were suffering under a natural depression. Whenever any branch of manufactures, or any of these larger systems called "Interests," happens to get the least deranged, or less prosperous than usual (even though this may be owing to an imprudent use of former advantages), up it comes to the government with a loud complaint, perhaps referring to opposite and jarring interests; and if the government be either weak enough or kind enough to lend a pitying ear, it is ten to one that it comes back with some additional restrictive privilege, which, though only designed for temporary relief, is never after resigned, but becomes a new and regular bead upon that string of millstones wherewith the public neck is adorned—the said public (and this is the most curious part of the affair) sympathising deeply with the event which confers upon it this new distress.

If it could be ascertained that all the various privileges and protective regulations enjoyed by different bodies throughout the empire, are so exactly balanced with each other that capital and industry are alike remunerated in all, in proportion to their deserts, there would lie little objection to the system, except that it was a ridiculous one. It is impossible, however, to prove that this is the state of the case; and hence, according to the principles of even-handed justice, it is desirable that a different plan should be instituted. As in other cases, the only valid objection lies in the difficulty of reforming so vast and intricate a system, without producing a greater degree of immediate misery than is to be coolly contemplated; and caution requires that, be it reformed when it may, the process should be one of slow and hardly perceptible degrees.

THE CURRENCY.

Coined money, it has been found, is only fully serviceable in a country where mercantile transactions are very limited; for the expense and risk of transporting large quantities of it would absorb great part of the profit of most transactions.* In a country where transactions are extensive, a lighter and more transportable representative medium is necessary. What is called paper-money presents its services for this purpose.

The advantage of this may be easily shown. Suppose a man in Kent owes [illegible] man in Yorkshire a thousand pounds, and another man in Yorkshire owes the Kent man an equal sum. It is evident, that, if the Kent debtor makes his Yorkshire debtor pay over the sum to his Yorkshire creditor, the transactions of all parties are managed without the use of an actual representative medium at all: a transference of credit, effected by a piece of paper, does all that is required. Such transactions, or modifications of them, melting into a general system, and employing agents called bankers, make up the paper currency.

As a piece of paper is in itself valueless, it is obvious, that, unless it be supposed to be backed by equivalent capital on the part of him who issues or gives it, no other man will have any thing to do with it. Paper-money, in fact, is only a credit asked and given, on the faith that there is something, which could be converted into its supposed value, standing behind, and liable to the demand of him who accepts such a visionary coin. If the Kent debtor was not supposed to have a thousand pounds worth of real stock, his little bit of paper would not carry that value, and the convenience and saving of the transaction above described would be lost. To have coin, it will be observed, a nation requires two capitals: it requires both the actual goods, and a thing for representing them which has an use and value in itself—for the metals from which coins are made, are wanted for making a certain kind of articles always more or less in request. If a nation was composed altogether of honest men, none of whom would issue a bit of paper without being certain that he could at any time give goods equivalent to the sum written on it, it might escape the expense of keeping up any part of this second and expensive capital. But just in so far as men are less honest and wise than they ought to be, this expense is unavoidable—an unhappy necessity, partaking in degree of what would be the case if no man would trust another so far as to give him a bullock, without getting a plough in return; for, after all, coin is only a less clumsy kind of barter. Coins, it is true, are of use in small retail transactions, but chiefly because among the poor there is no capital to enable them to give paper. The very tear and wear of gold and silver, occasioned by the use of coins, is an important consideration. It is calculated at a six-hundredth part every year for gold, and a two-hundredth part for silver.

The superior advantages of paper-money being thus established, it only remains to be considered what general forms and regulations shall be assumed for creating it.

The government, unquestionably, as the most creditworthy and extensive dealer in the country, ought to be the creator of paper-money. It draws and disburses fully as much annually as serves the whole country, and would thus promote circulation. The profit, moreover, on the creation of the national money, ought unquestionably to be a benefit to the nation.

The next best expedient is one which has been brought to the test of experience, and found bene-

* In what is called the Clearing-house at London—the grand centre of the mercantile transactions of England—five millions of money exchange hands every day. The interchange of this in coin, with all the corresponding transactions of carriage, &c., throughout the country, approaches to the character of a physical impossibility.

ficial. A number of individuals, possessed of a large aggregate capital, form a bank, and issue notes (or representations of fractions of their capital), on which they make a profit. As their whole issues are within the amount of what they can answer for by producing real goods, the public is completely safe in receiving their notes. These banks, moreover, give a certain interest on money deposited with them, and lend it again at a profit to persons of credit who want it (by discounting bills); and thus, becoming as it were centres of interchange, bring about the great general advantage that no part of the country's money is ever idle. This is the Scotch system of banking, and to it is to be attributed a great part of that prosperity, which, in less than a century, has raised our country from the poorest to one of the most comparatively productive and wealthy on earth.

England, with all her advantages in other respects, has wanted this great good fortune. A great privileged bank—the Bank of England, as it is called, but which should rather be termed the bank of a few Englishmen for the misery of the rest—has contrived, by obligations to the government, and other influences, to get into that old-constituted system of abuse, which there is hardly any altering. By forbidding the establishment of other banks (which is done by preventing a sufficient number of partners to render them credit-worthy), the whole of the *safe* business of the country centres here, producing illimitable inconvenience, obstructing trade to an inconceivable amount, and inducing the necessity of all the representations of capital in the country, in sums under five pounds, being in the expensive shape of coin.

It is of the last importance to all men in the country, from the wealthy capitalist to the poorest labourer who lives upon the using of capital, that money should at all times bear nearly the same value. The least increase or decrease in the full amount of existing money, has an immediate effect in diminishing or increasing the price of commodities; and if a man contracts a debt under the one set of circumstances, and has to pay it under another, or if he hires himself for a wage at the one thing, and live at the other, he is a loser. Now, owing to the decrease of gold and silver from the failure of mines, and the particular circumstances and modes of action of the Bank of England, there is not now nearly so much money in existence as there was twenty years ago, while, in the same time, the numbers of the people and the rate of their productive ingenuity have greatly increased. In 1797, in order to obtain money more easily for carrying on a war against France, the government granted to the Bank of England the tremendous boon of issuing as much paper money as it pleased, without the necessity of possessing equivalent goods to back its issues. Perhaps there was not the advantage taken of this privilege which there might have been; but the result, as is well known, produced an undue plenty of money, or apparent money, and as it thus became less valuable, all commodities rose in price. All seemed to be prosperity then; but, by and bye, in 1819, came the time for restoring things to their right footing, by compelling the bank to issue no more than it could account for by a show of real capital or goods—in other words, by paying gold for notes, on demand. Since that day, money has become every day scarcer and more valuable; and it is no unfounded calculation, that the debt contracted during the former period is now worth half as much again, and draws half as much more interest than it ought to do. Some political economists urge the propriety of an expansion of the value of money to its former amount, by which means it would become as abundant a commodity, and worth as little, as before. But, while this would equalise the obligations of the public, it would be unjust to all who have bought of the debt since its first contracting, and bring about a partial distress, and react against the public in some other way. It may also be represented with some force, that the debt contracted between 1797 and 1819, could not have been contracted, if the money had not been of reduced value, and thus rendered more than usually attainable by the lenders; that no provision was made in the contract for the consequences of a return to gold payments, which formed a contingency alike beyond the calculations of borrowers and lenders; and that, in fine, the larger sums we now pay and stand indebted for are just a natural penalty of our having contracted debt at all, under such circumstances. There is, however, no doubt that the extreme depression of prices and wages, and the consequent inutility of capital, and inadequacy of labour to support its votaries, arise in a great measure from this cause, and are evils of which we have not seen the end.

RENT.

Political economists are at issue respecting the bearing and nature of this well-known commodity.

According to Adam Smith, it is a surplus arising from the limited quantity of land, in comparison with the competitors for its produce.

A more intricate theory was suggested by Dr James Anderson, and has since been elaborated by Mr Ricardo and Mr Mill. According to these writers, as soon as the most fertile and easily cultivated land is brought fully into use, it is necessary to resort to the next best; and as soon as that is fully used, then the next best—and so on. It is not, say they, till the second comes into use, that the first pays any rent at all, and, till the third, that the second does so—and so forth. Rent is therefore the surplus yielded by land, above what is yielded by the worst kind which the necessities of a population have called into cultivation, or which is produced by a less than the maximum expenditure on the improvement and cultivation of land.

In the opinion of certain writers, characterised by an unsparing disposition to expose respectable fallacies, what is here stated as the cause of rent is only its consequence; for without the prospect of turning capital to account, land No. 2 would never have been cultivated—and so on as to the rest. For our part, we see no occasion to treat rent in any other light than we treat profits. Land, though originally perhaps appropriated by main force, is now to all intents and purposes mere capital—the same as a factory or a stock in trade. Money is every day invested in land, with the purpose of obtaining a return, which generally consists partly in money, and partly in privileges and honours attached by custom to land. True, it is almost always committed to the hands of an intermediate class of capitalists, called farmers, who take all the risk and trouble of cultivation for the sake of a certain share of the produce. But in what is this arrangement different from the demission of a factory, for instance, in full operation, into the hands of a person not possessed of enough to purchase one for himself, but enough to carry one on, and who, undertaking the risk and trouble, agrees to pay the proprietor a fair consideration, out of the profits, as a return for the capital sunk in the property? Landlords, it is true, are almost invariably deputers of their property, while manufacturers are as invariably the reverse; but this is a merely optional matter, depending on the respective convenience and taste of the parties. Landlords are, simply, manufacturers of food, disposed to purchase an exemption from the trouble and risk of additional capital [illegible]ary in carrying on their business, at the expe[illegible] to a deputy.

SUP[illegible] POOR.

It has been already [illegible]t the natural doom of all men is, that they [illegible]r for their own support. The wealthiest capi[illegible] in the country has either laboured himself, or received the benefit of the labours of his forefathers. There is no getting from him, by violent means, the least fraction of what he possesses, without taking away a great deal of the general inducement to labour, and thereby injuring the interests of the community. Even a legislative enactment for forcing away a shred of his gains, for the sake of others, is injurious in the same way, and irreconcileable with all the just notions of property.

The idea, then, of a natural right of the poor to relief, which some writers have advocated, must be abandoned. It may be expedient for the rich to support the poor, or they may do as much voluntarily towards that purpose as suits their inclinations and convenience. But there can be no enforcing a right of those who do not work upon part of the gains of those who do, without striking at the root of one of the most important and salutary points in the constitution of society.

The choice between a voluntary and irregular, and a compulsory and regular method of supporting the destitute (both resting upon the mere plea of expediency), is thus left as the only question liable to discussion. It is a point which has been very keenly debated, and, as usual, much may be said on both sides. The following are the chief arguments for and against:

1. Compulsory assessment for the poor breaks in upon the right of every man to enjoy his own gains.

Answer. Ordinary rights always sink, in the eye of the state, under general expediency.

2. It only tends to increase the evil.

Answer. From tables it is ascertained, that, ever since 1688, the number of paupers has kept steadily at about 9 in 100.

3. It encourages improvident marriages, as the parties always know they have the parish as a last resource.

Answer. It is ascertained by parliamentary evidence, that it *does not.* The idea of the poor-house rather acts as a beacon to warn the poor against rash marriages.

4. It encourages the increase of a mean-living population.

Answer. The reverse would appear to be the case. In England, where there has been a compulsory assessment for upwards of two centuries, the standard of living is higher than in any other country where there are no poor-laws. The knowledge that, if a pauper population increases, its support will come upon the rich, induces the rich to see to the keeping down of such population.

5. It chills the hearts of the rich against the poor, and prevents private charity.

Answer. Private charity is an evil, as it is always carried on by means of imposture, or something else on the part of the asker, which degrades his character more than the workhouse. It is also uncertain, and admits the hard-hearted to throw upon the benevolent the whole of a burden, in the discharge and benefit of which all are concerned.

Note. It is to be regretted, however, that, by totally repressing private charity, much surplus food in the kitchens of the wealthy, which would be a blessing to many poor persons, is left to waste.

6. It tends to take away the forethought of the poor.

Answer. In general, those persons who require parish assistance would have no forethought under any circumstances. Is it to be supposed that the forethought of the poor in Ireland, or of the Lazzaroni of continental countries, is improved by the want of poor-laws?

In short, it is argued by the friends of a compulsory assessment, that such is just the price paid by the rich, as a matter of police, for repressing the numbers, and diminishing the power of annoyance, of a set of people, who, under any circumstances, *will* exist in a certain proportion to the general population, and whose destitution would be incompatible with the enjoyment of life and property in the more opulent, prudent, and industrious.

In favour of this view, we must acknowledge that, before the institution of poor-laws in 1601, England abounded in vagrants, whose idleness and vice probably occasioned a greater proportionate loss to the rest of the community, than the amount since paid for keeping it in check. The complaint of vagabondage and mendicity rose steadily in proportion to the emancipation of the poor from slavery (under which condition, of course, all were supported by their proprietors); and hence poor-laws assume the complexion of a necessary result of the personal liberty, now and for a long time enjoyed by the working-classes.

"The legitimate purposes of a poor assessment," says Dr Wade, "I take to be the raising of a provisional fund for meeting, in the least objectionable way, a positive evil, inseparable from the existing knowledge and habits of society; that this fund ought to be so disbursed as to leave no one an excuse for being a beggar or a thief; and, at the same time, so sparingly disbursed, as to make it the interest of no person to be a pauper rather than live by honest labour. The object of the poor-laws is to relieve real and unavoidable distress, not distress wickedly and wantonly created; and if the poor-laws are perverted into the fostering of the idle and the dissolute, the fault is not in the laws, but in their administrators, who apply the poor when they ought to apply the vagrant laws."

This passage suggests some important considerations. In the first place, how far is it possible, by improving the knowledge and habits of society, to reduce the necessity for a poor assessment, or its amount? For the explication of this point, we are inclined to contrast the condition of Scotland with that of England. In the former country, begging is no more frequent than it is in England; the poor assessments are comparatively trifling (seldom producing to any single pauper above a shilling or eighteenpence a-week, while these paupers are very few in number); and a spirit exists very generally among the common people, as to the propriety of avoiding, by all possible means, a state of dependence upon parochial relief. If we contrast this with the state of England, where, in 1830, nearly seven millions were expended upon the poor, and where, although the character of the English labouring classes is remarkably independent and manly, still there prevails a far less disinclination to accept of the parish bounty, we might almost be tempted to conclude that the poor-laws of England had in a great measure produced the necessity of their own existence. But mark the real cause of the difference. Every Scottish peasant, however humbly born, learns to read and write. His mind is under the immediate and constant ministration of a clergyman, who takes a close and brotherly interest in his religious and moral condition, and exerts himself to see that he never for a moment forgets the decencies of life. The very penury of his country, though now in a great measure past, has conferred upon the people so much economical wisdom, that the relation of income and expenditure is in general preserved with singular exactness. It might be invidious to specify the particulars in which England differs from Scotland, as to the religious, moral, and economical culture of its lower inhabitants. But no one could assert that it approaches its poorer neighbour in any one of these respects. And hence, it appears to us, arises a great deal of that necessity for poor-laws in the southern state, which is escaped in the northern. The pressure of this tremendous assessment is just the penalty which the English landholders pay for their inattention to the moral interests of the working classes—the price of that security which they think they enjoy in the ignorance of their fellow-creatures.

In the second place, how far is it possible, by improved management, to reduce the assessment in England? We are decidedly of opinion that much might be done in this way. From Parliamentary evidence, it appears that in the poor-house of St Lawrence, Reading, from forty to fifty persons seldom consume less than one hundred and fifty pounds of meat weekly, or more than three pounds each per week. Now, there surely is no reason that paupers should live so well as this. Independent labourers in Scotland do not at an average, we are safe in saying, eat above a third of this quantity of butcher meat. Greater vigilance, moreover, on the part of the overseers, might perhaps preclude part of the imposture which is complained of in the applicants for relief. As it is proved that the rates have of late decreased, in consequence of improved management (being less in 1830 than ten years before, when the population was not so great by half a million), we are entitled to hope that much might be done in this way towards a lessening of the evil.

THE DOG.

The Shepherd's Dog.

The English Mastiff.

The Dog is an animal which seems to have been destined by the Creator to be the friend and assistant of man. Throughout the dangers and difficulties which beset the human being, particularly in an inartificial state of society, the dog has ever proved himself the kindly defender of his life and property, as well as a powerful and essential auxiliary in subduing other animals to his purpose. Without the assistance of the dog, man would not even yet have obtained a beneficial dominion over the various races of wild animals of the earth, or been able to watch with sufficient care those creatures formed for his food.

In entering upon the history and character of this valuable animal, nothing astonishes us so much as the extraordinary variety of its form. Whether sprung from one root or not, it is obvious that there now exist dogs fitted to perform purposes entirely peculiar to their peculiar varieties, in which respect this animal resembles no other in the list of animated nature, and therefore possesses distinguishing characteristics possessed by no other creature but man. In this respect, therefore, the dog in its numerous varieties answers every end that could have been gained by the creation and existence of many distinct races of animals. By it, we have an animal which watches our flocks; another which tracks and hunts down noxious wild beasts; another, which destroys and digs out vermin from the earth; another, which guards our houses and lives, while we are asleep; another, which seeks out for game in our field sports; another, which will plunge into the deepest waters, and save us from being drowned; besides many other varieties, all less or more distinct in character, yet all consorting together, and endowed with certain uniform peculiarities of character, which identify them as all of one species.

Widely different as are the varieties of dogs, it has been supposed by Buffon and other naturalists, who are certainly best entitled to judge, that all kinds of dogs whatsoever had their origin in the shepherd's dog, and that climate, food, domestication, and treatment, have been the prevailing causes of producing the departure from the primeval parent stock. It is nevertheless certain, that there is no variety of the dog now existing in an unreclaimed state which exactly agrees with our domesticated shepherd's dog; and it is likewise evident to our observation, that no description of treatment seems to have an effect in changing the apparently fixed character of a breed of dogs. If we trace the genealogy of a greyhound for centuries, we shall find that its forefather was just a greyhound like itself; or if we send a pair of mastiffs to the hills, it will similarly be remarked, that, at the end of a period of years, their progeny have not retrograded to the original shepherd's dog, although there is reason to believe that they may have somewhat degenerated from the true mastiff breed. M. F. Cuvier, a modern French naturalist, has devoted much attention to this curious subject, and has formed a new arrangement of dogs, founded on the shape of the head, and length of the jaws and muzzle. These he has separated into three great groups, as follow:—

I. Matins.—These have a head more or less elongated; the parietal bones insensibly approaching each other, and the condyles of the lower jaw placed in a horizontal line with the upper cheek-teeth.

II. Spaniels.—The head moderately elongated; the parietal bones do not approach each other above the temples, but diverge and swell out, so as to enlarge the forehead and cavity of the brain. In this group are included all the varieties of dogs which are of the greatest utility to man, and also the most intelligent.

III. Dogues.—The muzzle more or less shortened; the skull high; the frontal sinuses considerable; the condyle of the lower jaw extending above the line of the upper cheek-teeth. The cranium is smaller in this group than in the two previous, owing to the formation of the head.

Captain Thomas Brown, a Scottish naturalist, has formed an arrangement, in which he has followed M. F. Cuvier in the three great groups, but has divided these into distinct sections, agreeing in particular characters, for which the dogs which he has included in the several sections are remarkable. The table of his divisions and sections is as follows:—

Division I.—Head Elongated.

Section 1. Wild and half-reclaimed dogs, which hunt in packs.

Section 2. Domesticated dogs, which hunt in packs or singly, principally by the eye, although sometimes by the scent.

Section 3. Domesticated dogs, which hunt singly, and always by the eye.

Division II.—Head less elongated than former division.

Section 4. Pastoral dogs, or such as are employed in domestic purposes.

Section 5. Water-dogs, which delight in swimming, having their feet in general semi-webbed.

Section 6. Fowlers, or dogs whose natural inclination is to chase and point birds, and hunt singly by the scent.

Section 7. Hounds, which hunt in packs, by the scent.

Section 8. Mongrel hounds, which hunt singly, either by the scent or eye.

Division III.—Head much shortened.

Section 9. Watch-dogs, which have no propensity for hunting.

GENERAL CHARACTER OF DOGS.

The dog has six incisory or cutting teeth in both jaws; beyond which there are, on each side, both above and below, a canine tooth; and still farther into the mouth are six cheek-teeth, or molars, in each side of the upper jaw. The three first are sharp and cutting, which Cuvier calls false molars. The next tooth on each side is a carnivorous tooth, furnished with two cutting lobes, beyond which the other two teeth on each side are flat. There are seven cheek-teeth, on both sides, in the under jaw; four of these are false molars, a carnivorous tooth, with the posterior part flat, and behind it two tuberculous teeth. The muzzle is elongated, subject to great variety of length in different varieties. The tongue is smooth and soft; the ears erect in the wild varieties, and in some of the tame ones, but, in the latter kinds, for the most part pendulous. The fore-feet are provided with five toes, and the hind-feet with four toes, furnished with rather longish nails, obtuse at their points, and not retractile. The females are provided with both inguinal and ventral teats. The pupils of the eyes are circular.

The female goes with young sixty-three days, and generally produces from three to five at a birth, and sometimes even twelve, which are at first blind, in which state they continue for from nine days to a fortnight. About the end of two months, their faculties begin to develope themselves. They shed their first teeth at the end of six months, which are replaced by others that do not exfoliate. At twenty months, or two years, dogs arrive at their full vigour.

The males continue to propagate for nearly their whole lives, while the female discontinues having young ones at about the age of eight or nine years.

The average age to which dogs live is about fourteen years; they frequently, however, live to sixteen, and even have been known to attain the age of twenty years. In their latter days, dogs frequently suffer greatly from decay, and various diseases. They are extremely subject to rheumatism, from their liability to exposure to rain and damp beds.

Until dogs have attained seven or eight years, their teeth are white, smooth, and acutely-pointed; but after this age they become yellow spotted, and their points assume an uneven and jagged appearance. At this time, also, the hair of the muzzle and around the eyes assumes a hoary appearance, and becomes whiter as they increase in years.

The dog, independent of the beauty of his form, his vivacity, force, and swiftness, is possessed of all those internal qualifications that can conciliate the affections of man, and make a tyrant a protector. A natural share of courage, an angry and ferocious disposition, renders the dog, in a savage state, a formidable enemy to all other animals; but these readily give way to very different qualities, in a state of domestication, and his only ambition seems the desire to please; he is seen to come crouching along, to lay his force, his courage, and all his useful talents at the feet of his master: he waits his orders, to which he pays implicit obedience: he consults his looks, and a single glance is sufficient to put him in motion: he is more faithful than even the most boasted among men: he is constant in his affections, friendly without interest, and grateful for the slightest favours: much more mindful of benefits received than injuries offered, he is not driven off by unkindness; he still continues humble, submissive, and imploring; his only hope to be serviceable, his only terror to displease: he licks the hand that has just been lifted to strike him, and at last disarms resentment by submissive perseverance.

More docile than man, more obedient than any other animal, he is not only instructed in a short time, but he also conforms to the dispositions and manners of those who command him. He takes his tone from the house he inhabits: like the rest of the domestics, he is disdainful among the great, and churlish among clowns. He knows a beggar by his clothes, by his voice, or his gestures, and forbids his approach. When at night the protection of the house is committed to his care, he seems proud of the charge; he continues a watchful sentinel; he goes his rounds, scents strangers at a distance, and gives them a warning of his being upon duty. If they attempt to break in upon his territories, he becomes more fierce, flies at them, threatens, fights, and either conquers alone, or alarms those who have most interest in coming to his assistance; however, when he has conquered, he quietly reposes upon his spoil, and abstains from abusing—giving thus at once a lesson of courage, temperance, and fidelity.

Most animals have greater agility, greater swiftness, and more formidable arms, from nature, than man; their senses, and particularly that of smelling, are far more perfect; and having gained, therefore, a new assistant, particularly one whose scent is so exquisite as that of the dog, was the gaining a new sense, a new faculty, which was before wanting.

The dog, thus useful in himself, taken into a participation of empire, exerts a degree of superiority over all animals that require human protection. The flock and the herd obey his voice more readily even than that of the shepherd or the herdsman: he conducts them, guards them, keeps them from capriciously seeking danger, and their enemies he considers as his own. Nor is he less useful in the pursuit: when the sound of the horn or the voice of the huntsman call him to the field, he testifies his pleasure by every little art, and pursues with perseverance those animals, which, when taken, he must not expect to divide. The desire of hunting is indeed natural to him, as well as to man, since war and the chase are the only employment of savages. All animals that live upon flesh hunt by nature: the lion and the tiger, whose force is so great that they are sure to conquer, hunt alone and without art. The wolf, the fox, and the wild dog hunt in packs, and assist each other, and partake the spoil. But when education has perfected this talent in the domestic dog—when he has been taught by man to repress his ardour, to measure his motions, and not to exhaust his force by too sudden an exertion of it—he then hunts with method, and always with success.

As the dog is of the most complying disposition, so also is he the most susceptible of change in his forms. The varieties of this animal seem almost endless. Climate, food, and education, all make strong impressions upon the animal, and produce alterations in its shape, its hair, its size, and in every thing but its nature. The same dog taken from one climate to another, seems to become another animal, and different breeds are as much separated, to all appearance, as any two animals the most distinct in nature. Nothing appears to continue constant with them, but their internal conformation—different in the figure of the body, in the length of the nose, in the shape of the head, in the length and direction of the ears and tail, in the colour, the quality, and quantity of the hair; in short, different in every thing but that organization which serves to continue the species, and keep the animal distinct from all others. It is this peculiar conformation, this power of producing an animal that can reproduce another, that marks the species; for nature seems to have established a law, that one deviation from specific distinctions can be permitted, but no farther, as she has doomed that all mules shall be sterile.

The extremes of size are truly wonderful in this species, as dogs have been known to reach four feet in height; while there is one in the museum at Dresden, quite perfect in its form, and only five inches in length.

Dogs' flesh was lately an extensive article of food in the Sicilies, and we have the following interesting account of it, given by Swinburne in his travels in these countries:—"Casalnuova is a considerable town, containing about four thousand inhabitants, noted for nothing but their taste for dogs' flesh, in which they have no competitors that I know of, except their neighbours at Lecce, and the newly-discovered voluptuaries of Otaheite. We did not see one animal of the canine species in the streets, and wo to the poor cur that follows its master into this cannibal settlement! I could not prevail upon my conductor to own whether they had any flocks of puppies, as of sheep; or took any pains, by castration, or particular food, to fatten and sweeten the dainty before they brought it to the shambles. I have since procured some information upon the subject from impartial persons, and find that the people of this neighbourhood are looked upon by the rest of the kingdom as dog-eaters; and it is certain, that, both at Lecce and Casalnuova, many of the lower sort relish a slice of a well-fed cur."

This circumstance is further confirmed by the following extract of a letter from Sir William Hamilton:—"At Casalnuova we had a confirmation of what you mention concerning the inhabitants of that village eating dogs' flesh; for one of our guards had a dog with him, which was immediately stolen; and when I missed and inquired for the dog the next day, the guard told me that these cursed dog-eaters had got him. At Galipo I was assured that there was no doubt of the fact."

Lecce and Casalnuova are both celebrated for an imitation of Turkey leather, and the tanners of those places are known to kidnap dogs for this manufacture. The great demand for this article probably led to eating the carcases of the animals they had destroyed; and hunger and experience have at length taught them that dog's flesh is by no means so unpalatable as some imagine.

Captain Carver, in his travels through the interior of North America, in describing the ceremony attending the admission of an Indian of the Naudowessie nation into one of their societies, proceeds to give an account of the feast given in consequence, as follows:—

"The dishes being brought near me, I perceived that they consisted of dogs' flesh; and I was informed that at all their public grand feasts they never made use of any other kind of food. For this purpose, at the feast I am speaking of, the new candidate provides fat dogs, if they can be procured at any price. In this custom of eating dogs' flesh, they resemble the inhabitants of some of the countries that lie on the north-east borders of Asia."

On their declarations of war, they have also festive ceremonies, in which Captain Carver speaks of them as follows:—

"This ceremony is followed by dances, such as I have before described; and the whole concludes with a feast, which usually consists of dogs' flesh. This feast is held in the hut or tent of the chief warrior, to which all those who intend to accompany him in his expedition send their dishes to be filled."

This practice does not proceed from any want of food amongst these people, as they on ordinary occasions live upon the flesh of the buffalo, the elk, the wild boar, the red deer, bison and racoon, with which their country abounds.

We shall now proceed to give the characters of the different dogs, according to the arrangement of Captain Brown, and to intersperse these with a series of anecdotes.

DIVISION I.—DOGS WITH LENGTHENED HEADS.

Section I. Half-reclaimed dogs, which hunt in packs.

The *Dingo*, or *New Holland Dog*.—The head of this dog is not unlike that of a wolf, on which account Bewick calls it the New South Wales wolf. The muzzle is long and pointed, with short erect ears. He is two feet six inches in length, and about two feet in height. His fur is composed of a mixture of silky and woolly hairs, and is of a deep yellowish-brown colour. His tail is long and bushy, resembling that of a fox. This dog is of a ferocious disposition. Pennant mentions one which was brought to this country, and that leaped on the back of an ass, and had nearly destroyed it before a rescue could take place.

The *Dhole* is the native wild-dog of India, and bears a strong resemblance to the dingo, but without the bushy tail of that species; he is of a uniform bright red colour.

Differently from other dogs which hunt in packs, according to the account given by Captain Williamson, this species always hunts mute, and only utters a soft whispering sound when in high chase, and near his prey. The dhole is exceedingly swift of foot, and soon overtakes most animals which are the objects of his pursuit. It is said they are exceedingly fond of the flesh of the tiger, and that in consequence this animal is prevented from propagating to that extent which would soon overrun and lay waste all the countries which it inhabits. This predilection is confirmed by Bishop Heber, who states, upon the authority of the peasants of Khaysa, which borders the frontiers of China, that a tiger is often killed and torn to pieces by the wild dogs, which give tongue like foxhounds or harriers.

It is in the unfrequented wilds of the western frontiers of India that the dhole takes up his abode, lurking amongst the extensive jungles which cover mighty tracts of that territory.

The *Pariah* is the common village dog of India. He has a small sharp head, with short pricked ears, a slender body, and particularly drawn up about the abdominal region; his chest is deep, his limbs light, and his colour is of a reddish brown. The native Indians use these in hunting the tiger and wild boar. They are very fierce, and follow their game with much avidity.

The *Ekia* is the native dog of Africa, and in all likelihood sprung from the same stock as the dhole. They are said to be of various colours, as black, red, white, brown, and sandy yellow. They are eaten by the negroes. The African wild dogs, like those of India, hunt in packs.

The *South American Dog* is not unlike the dingo, and is about the size of the springer, with short and pricked ears like most other wild dogs. The hair on his tail is long and bristly; he is of a brownish-grey colour on the back, with sandy-coloured spots on the legs and flanks. In their general aspect, they greatly resemble the wolf, but are much smaller in size.

There is another South American dog called the Alco, of which there are two varieties. The head of the Alco is very small, and the ears pendulous; thus differing from almost all other wild dogs. The back is somewhat curved, and the tail rather short. It is said that the Spaniards found this dog among the natives on the first discovery of America. Herrera says, that Columbus found in America many dogs which did not bark.

The introduction of dogs into the continent and islands of South America, is thus described in the History of the Buccaneers:—"But here the curious reader may perhaps inquire, how so many wild dogs came here. The occasion was, the Spaniards having possessed these isles, found them peopled with Indians, a barbarous people, sensual and brutish, hating all labour, and only inclined to killing and making war against their neighbours, not out of ambition, but only because they agreed not with themselves in some common terms of language; and perceiving the dominion of the Spaniards laid great restrictions upon their lazy and brutish customs, they conceived an irreconcilable hatred against them, but especially because they saw them take possession of their kingdoms and dominions: hereupon, they made against them all the resistance they could, opposing every where their designs to the utmost; and the Spaniards, finding themselves cruelly hated by the Indians, and nowhere secure from their treacheries, resolved to extirpate and ruin them, since they could neither tame them by civility nor conquer them with the sword. But the Indians—it being their custom to make their woods their chief places of defence—made these their refuge whenever they fled from the Spaniards. Hereupon, these first conquerors of the New World made use of dogs, to range and search in intricate thickets of woods and forests for those their implacable and unconquerable enemies; thus they forced them to leave their old refuge, and submit to the sword, seeing no milder usage would do it; hereupon, they killed some of them, and quartering their bodies, placed them in the highways, that others might take warning from such a punishment. But this severity proved of ill consequence; for, instead of frightening them, and reducing them to civility, they conceived such horror of the Spaniards, that they resolved to detest and fly their sight for ever; hence the greater part died in caves and subterraneous places of woods, in which places I myself have often seen great numbers of human bones. The Spaniards, finding no more Indians to appear about the woods, turned away a great number of dogs they had in their houses; and they, finding no masters to keep them, betook themselves to the woods and fields to hunt for food to preserve their lives; thus by degrees they became unacquainted with houses, and grew wild. This is the truest account I can give of the multitudes of wild dogs in these parts."

The *North American Dog*.—We have no very distinct account of this variety, but it is said to resemble the dingo in its pricked ears and general conformation. It is remarkable for the acuteness of its scent, and very expert in the detection of its prey, or animals which it may be trained to pursue.

The following anecdote is highly illustrative of the exquisite sense of smelling possessed by this dog:—Le Fevre had a plantation in the neighbourhood of Warwaring, near the Blue Mountains, which stretch across part of the state of New York. His youngest son, only four years of age, disappeared one morning. He was missed, and partially sought for by his parents; who, not finding him, became alarmed for his safety, as these mountains abound in wild animals. As is the custom in these parts, they had recourse to the assistance of their neighbours. The united party separated, and bent their way through the forest in different directions; but no traces of the child could be had. They renewed their search next day, with no better success. The hearts of the parents were wrung with grief, and they were at a loss what steps to take for the recovery of their lost child, when one of the native Indians, named Tewenissa, happened to pass that way, accompanied by his dog, named Oniah. He called at Le Fevre's, to refresh and rest himself. He found him in deep grief; and being informed of the cause of his distress, he requested that the shoes and stockings which the lost child had last worn might be brought to him. He applied them to the nose of his dog, and desired him to smell them, and immediately afterwards departed for the woods, accompanied by the family; and describing a semicircle of a quarter of a mile, he urged the dog to discover the scent of the lost child. They had not proceeded far, when the dog began to bay; he followed up the scent, and his notes of triumph became louder as he proceeded, and at last he bolted off at full speed, and was soon out of sight. In half an hour after, they met him returning towards them, with a countenance full of animated expression; from which Tewenissa was sure he had discovered the child. But was he dead or alive? This was a moment of acute suspense, although happily of short duration. The Indian followed his sagacious dog, which soon conducted him to the spot where the lost child lay scaithless at the foot of a large tree. Tewenissa snatched him up in his arms, and with a joyful heart sped his way to where his distressed parents and friends were advancing with less speed than the son of the woods was able to do. He restored little Derick to his father and mother, when a scene of gratitude and tenderness ensued, which may be more easily imagined than described.

Section 2. Domesticated dogs, which hunt in packs or singly, principally by the eye, although sometimes by the scent.

The *Irish Greyhound* ranks among the noblest of the canine race; his mien is striking, full of dignity, and his conformation beautiful. In his general shape he bears a strong resemblance to the common greyhound, but is much taller, and more robust. He is not fitted for pursuing the more speedy animals of the chase. His use in early times was to free the country of wolves and wild boars, which abounded in England and Ireland. The hair is short and smooth, and the colour of these dogs is fawn or pale cinnamon. The Marquis of Sligo had some of this breed, which were of various colours; some were brown and white, and others black and white. The ordinary height of the Irish greyhound is about three feet, although they have been known to reach four feet. Goldsmith, who had seen several of this breed, says they were about four feet high, and as tall as a calf of a year old.

The *Albanian Dog.*—This variety is about the size of a full-sized mastiff. His hair is very fine and close set, and of a silky texture, variously clouded with brown; his tail is long and bushy, and carried like that of a Newfoundland dog; his muzzle is pointed, and rather long; his legs are strong and muscular, which fit him well for hunting the wild boar, in which sport he was much used in ancient times; he was also used in hunting wolves, and in protecting sheep-folds from thieves.

Lieutenant Shipp gives us the following anecdote of one of these dogs:—"I learnt," says he, "that this sagacious and faithful creature would regularly, when his master was on watch, stand his hour and walk his round; that in very dark nights he would even put his ear to the ground and listen; and that, during the period assigned to him as his turn to watch, he would never venture to lie down, but would steadily and slowly walk his round, which nothing could induce him to leave, such was his opinion of the nature of his post. The man added, that he once gave him to an officer of the Company's service, who took him from the station where he was (Meerut) to Loodianna, a distance of 400 miles, and that the moment the officer let him loose he returned to his old master, having performed this great journey in two days and a half. He was on the main-guard the night the dog returned, and was awoke by the animal licking his face. It appeared that he had been through the whole barracks, and visited every sleeping soldier on their separate bets, until he found his master. The man related several other anecdotes of the same brute. Among the rest, he said he was one day drinking toddy, some miles from camp, and, from the intoxicating effect and extreme heat of the liquor, he went to sleep. On waking, he found his clothes torn in several places, and observed that he had been dragged more than three yards from the bush under which he had lain down; but what was his astonishment on getting up, to find a large snake almost torn to pieces, no doubt by his faithful guard!"

The *French Matin* has an elongated head, and flat above; his ears are erect, and slightly pendulous towards the tips; the hair of a yellowish fawn-colour, with darker, oblique, and parallel indistinct rays traversing the whole of his fur. His height is about two feet, and his length three feet. He is strong, muscular, and active, and very courageous. He evinces great eagerness in hunting the wild boar and wolf, in which sport he is frequently employed. Pennant thinks this variety is a descendant of the Irish greyhound.

The *Great Danish Dog.*—This variety is somewhat allied to the matin, but with a bluntee muzzle; he is also somewhat like the Dalmatian in appearance, but differs in his body being all covered with large black patches and spots, whereas the fur of the latter dog is universally spotted. His ears are pure white, while those of the Dalmatian are generally black. He is used as a dog of chase in his native country, and in England as an attendant upon carriages.

The *Scottish Highland Greyhound.*—This dog will either hunt in packs or singly. He is an animal of great size and strength, and at same time very swift of foot. In size he nearly equals the Irish greyhound. His head is long, and the nose sharp; his ears short, somewhat pendulous at the tips; his eyes are brilliant and very penetrating, and half concealed by the long crisped hairs which cover his face and whole body. He is remarkable for the depth of his chest, and tapers gradually towards the loins, which are of great strength, and very muscular; his back is slightly arched; his hind quarters are powerfully formed, and his limbs strong and straight. The possession of these combined qualities particularly fit him for long endurance in the chase. His usual colour is a reddish sand-colour, mixed with white; his tail is long and shaggy, which he carries high, like the staghound, although not quite so erect. It is this noble dog which was used by the Scottish Highland chieftains in their great hunting parties, and is supposed to have descended in regular succession from the dogs of Ossian.

Tradition states that the hunting dog of Fingal, called Branne, was the best dog in the world. In his hunting excursions, he is said to have taken *one hundred* dogs into the field with him at a time. Even the markings of Branne are celebrated in the Highland legends. He is said to have been of a sandy colour, with yellow legs, and his sides were black.

In Perthshire and Argyleshire are the remains of many old circular buildings which tradition assigns to the era of Ossian. On the estate of Garth, the property of our late distinguished and amiable countryman General Stewart, late governor of Trinidad, the walls of two of these buildings remain, which are constructed with such weighty stones that it is scarcely possible they could have been raised without the aid of machinery. These castles are called *Caistail nam Fiom*, or the castles of the Fingalians. In Glenlyon is shown the kennel for Fingal's dogs, and the house for the principal hunter.

Mr John Stewart (one of the higher class of farmers), at Baranamue, parish of Ardchattan, Argyleshire, about the year 1716, while shooting on the hills one afternoon, he was suddenly seized with inflammation in his side; he returned home, and died the same evening. His funeral took place some days afterwards, when his favourite greyhound, of the true Highland breed, followed the remains of his beloved master to the churchyard of Appin, betwixt nine and ten miles, and remained with a sorrowful countenance till the interment was completed; he then returned home with those who attended the funeral. Upon entering the house, he found his master's plaid hanging in the lobby; he pulled it down, and, in defiance of all attempts to take it from him, lay on it all night, and would not even allow any person to touch it. Every evening afterwards, about sunset, he left Baranamue, travelled to the churchyard, and reposed on the grave of his late master, and returned regularly in the morning, between nine and ten. And what was very remarkable, he never would touch any meat which was offered to him, and it was never known by what means he existed. While at home, he was ever dull and sorrowful, never moved about, but lay in a sleeping posture, frequently uttering long and mournful groans. Mr Stewart and family were in hopes that time would assuage his grief; but he continued his nightly wanderings and watching for a considerable time unremittingly, till the family, despairing of an end to his sorrow, and as it only kept alive their own grief for the departed worth of the head of their family, resolved to give it to a friend at some distance, where it still continued in a melancholy state. We have been favoured by the above from Mr Duncan Stewart, lately farmer at Dallens, Appin, Argyleshire, who is grandson to Mr J. Stewart's sister.

The *Russian Greyhound* is nearly as large as the Irish greyhound, resembling him in shape as nearly as possible, but covered with long bushy hair. His general colour is of dark reddish brown. He is sometimes hunted in small packs, and as frequently single, in which case he not unfrequently will kill a wolf, deer, or wild boar, without any aid whatever. When used in coursing, he is taken to the field in slips, in the same manner as is practised with greyhounds.

Section 3. Domesticated dogs, which hunt singly, and always by the eye.

The *Gazehound.*—This is a dog, the breed of which is now lost. It was hunted in the same manner as the greyhound, and took foxes and hares by running them down. It is said by Bewick that it was employed in stag-hunting, which we think is rather doubtful, as, although the stag is an animal of great speed, yet the contest between it and a dog possessing the swiftness of a greyhound would be but very unequal. No representation of this dog has been preserved, which is much to be regretted, as we are but imperfectly acquainted with its appearance.

The *Greyhound* is the fleetest of all dogs, which is in consequence of his peculiar conformation. His head is long, tapered, and shaped like that of a snake; his neck long and slender; his ears somewhat erect and pricked, slightly pendulous at their tips; the tail ought to be very fine, pointed, and the hair on it very short; the chest should be wide and deep; the belly drawn up, with strong loins, and with large and prominent hip-muscles. This dog is by no means so intelligent as many other varieties, and he is in consequence much less susceptible of education. He has, however, very fine feelings, and seems to be much alive to caresses, which excite him to such a degree, that it produces a quick pulsation of the heart. This may be felt beating against his side with much vigour. He is one of the most elegantly formed of all the canine species.

In November 1792, as Richardson, gamekeeper to the Earl of Egremont, was leading two greyhounds, coupled together, near Ulndale, a hare ran across the road; the dogs instantly broke from their conductor, and gave chase, fastened as they were to each other. The pursuit began at Ulndale Brow-top, and afforded a very entertaining sight to several spectators; the frequent windings of the hare embarrassing the dogs greatly, particularly in changing their direction. At one time puss was very near giving them the slip, but she was baffled in an attempt to escape through a gate; and, by the sudden turning of her pursuers, after a run of about four miles, she fell a sacrifice at Pikeless gate, being actually killed by the coupled greyhounds, whose eagerness for the chase could not be restrained by any efforts of the gamekeeper.

As a party of gentlemen were coursing at Wooley, the seat of G. W. Wentworth, Esq., on Monday, January the 21st, 1822, a brace of dogs, which had run together about half an hour before, being led by a boy at the top of a large stubble-field, by a handkerchief tied to the couples, a hare started within twenty yards of them; hereupon the dogs gave a sudden pull, and the boy lost his hold. Thus they run the hare, fastened together, nearly to the bottom of the field, when they gave her a turn, which was repeated about half way up the same field; here she got considerably the advantage, made for the hedge, and *smused*; the dogs following up, *fenced* in grand style, and turned her twice in the next field; whereupon, she took towards a lane, and ran through an opening betwixt a stone post and the end of the hedge, not more than fifteen inches wide: here it was expected that one or both of the dogs would be killed; but they, as if quite conscious of being fastened together, and knowing, instinctively, it would be impossible to pass *abreast*, darted through (as it were) *one over the other*, when, to the astonishment of all present, they killed the hare, after running about ten yards down the lane. During the whole course, the dogs kept as regularly together as soldiers marching to the attack; all the while the red handkerchief waving above their heads, as if they had been conscious of running under "flying colours."

The *Scotch Greyhound.*—This dog is formed exactly like the common greyhound, and differs from it merely by being of a larger size, and in the hair being longer and hairy. Its general colour is reddish brown, or of a sand colour.

The *Italian Greyhound.*—This dog is merely a miniature of the common greyhound, being only about half the size of that dog. It has a very fine skin of a silky texture.

The *Turkish Greyhound* is still smaller than the Italian greyhound, being little more than half its bulk, and is entirely divested of hair, except on the tail, where it is few and scattered. Its usual colour is blackish lead colour.

DIVISION II.—HEAD LESS ELONGATED THAN FORMER DIVISION.

Section 4. Pastoral dogs, or such as are employed in domestic purposes.

The *Shepherd's Dog.*—This dog is covered with long flowing, somewhat woolly, hair; his muzzle is long and pointed, and his ears erect, and slightly bent downwards at the tips; his tail is long and bushy, and the usual colour of his fur black and white, or varied with black and grey; the backs of his fore-legs have also long hairs.

The peculiar and highly useful qualities of this dog seem to be rather intuitive than acquired; indeed, nothing can hardly exceed the quickness with which he can be taught any lesson; and certainly no other dog has the same patient perseverance and courageous fidelity, and at the same time possessed of the greatest discrimination.

The labour of a shepherd, with the assistance of this faithful and intelligent animal, is comparatively an easy task; and it is hardly possible to fancy a more arduous employment than it would be, if divested of the services of the dog; for without him, how could he collect extensive flocks scattered over high and widely-spread mountain ranges? The shepherd's dog is possessed of great sagacity, gratitude, and self-denial. Mr Duncan Stewart informs us, that it is extremely common for the shepherds' dogs in the Highlands to point game, and that many of the young farmers in Argyleshire use them for that purpose. He has seen them as good finders as the pointer or setter, and as steady on their point.

Mr John Macintyre, farmer at Cuell, had a cross betwixt a pointer and shepherd's dog, which resembled the latter in every particular, and was of a black and brown colour—his body being black, and legs a brown tan colour—which was constantly used during the shooting season. One year, at the commencement of grouse-shooting, he was sporting, when he met with a party of gentlemen from the south, and accompanied them. It turned out, that, after a long day's shooting, the dog in question beat every dog in the field. The gentlemen were so highly delighted with the qualifications of this animal, that they offered a pretty large sum for him, which Mr Macintyre refused; and from that day he prized his dog more than ever, as he found, on competing with celebrated dogs, his qualifications were greater than he before was aware of. This dog was not only a good hunter, but also excellent as a sheep-dog, in which capacity or in driving cattle he was generally used the whole year. He was also an excellent watch-dog, and took the water very readily. He was up to every kind of sport, for he would find hares, roes, and all other kinds of game.

During a snow-storm, in February 1829, a remarkable incident of the brute-reasoning kind occurred at a farm house in the neighbourhood of Falkirk. A number of fowls were missing one evening at the hour when they usually retired to their roost, and all conjectures were lost in trying to account for their disappearance. While sitting around the kitchen ingle, cursing all the "gangrel bodies" who had been seen that day near the house the attention of the family was roused by the entrance of the house-dog, having in his mouth a hen apparently dead. Forcing his way to the fire, the cautious animal laid his charge down upon the warm hearth, and immediately set off. He soon entered again with another, which he deposited in the same place, and so continued till the whole of the poor birds were rescued. Wandering about the stack-yard, the fowls had become quite benumbed by the extreme cold, and had crowded together, when the dog observing them, effected their deliverance. They had not lain long before the glowing ribs, ere they started to their legs, and walked off to their *bawks*, cackling the *hen's march*, with many new variations, in thanks to their canine friend.

A shepherd, named John Lees, of Whitelaw, parish of Selkirk, had a young dog of little experience, but which evinced great judgment. One day a ram broke away to a neighbouring flock of ewes. The shepherd sent his dog after the ram to fetch him back; he had, however, got in amongst the ewes before the dog reached him. The dog, on getting up to the flock, darted amongst them after the ram, and cut him off, with about a score of ewes, from the flock, and drove them to some little distance; then stopt, and surveying them for a short time, he darted amongst them, separated the ram from the ewes, and brought him up the hill to his master. The distance where the ram joined the ewes was more than a mile from where the shepherd stood; therefore he could have no influence on the dog at that distance. The above anecdote was furnished to us by Mr Thomas Mackaill, an acute observer of the canine species.

On Saturday, the 5th January 1822, as Mr A. Byres, of Highstone Ridge, accompanied by Mr Johnston, of Chapel Hill, was travelling over Eskdale Muir, Dumfriesshire, a common sheep-dog, which had been trotting quietly along, commenced barking at some distant object, and, springing forward, was soon out of sight. At first they paid little attention to the circumstance, imagining the dog was attracted by some moorland hare, with which he was taking a gambol; but upon riding a little out of the way to partake of the sport, how greatly were they surprised at finding *colley* busily employed in turning and returning a full-grown fox athwart the face of a pretty steep hill. In point of speed, the parties were pretty well matched; but the strength and cunning of foxes being very well known, the gentlemen expected nothing less than that sly reynard would shortly "turn a corner juking," and earth him in some heathy retreat. But no; in this they were agreeably disappointed. In spite of every fox-like effort to get away, the new courageous cur kept close at the heels of his scented prey, or fought him in gallant style, until he at length succeeded in fairly killing him; and he was borne off in triumph, to attest in all time coming the mettle of the dog of Highstone Ridge.

In December 1830, A. W. Gardner, Esq. of Melrose, near Banff, hired a shepherd from Ross-shire, who, when he had entered his service, brought with him two sheep-dogs of the colley breed. In the beginning of August 1831, the shepherd had an errand to Macduff, about three miles distant from Melrose; and as there was a boat going round, he took the opportunity of going to it from the slate quarries below Melrose House. When the shepherd went into the boat, he left one of the dogs on the rock, refusing to allow him to follow: there the poor animal continued to remain for some days bewailing the loss of his master; at any rate, he was seen on the morning of the third day howling most piteously. The shepherd never imagined, when he left the dog, but that he would return to his house, not a rig distant; but finding that he did not, and after making search for him in vain for at least eight days, he at last bethought himself of writing to Ross-shire, to know if he had found his way there. He received an answer in course, stating that the dog had returned there quite exhausted and dispirited from the loss of his master, and even refused to be comforted because he was not there. He had occupied about two days in his journey; but how he crossed the ferries, or was supplied with food, will remain a mystery. The distance he had to travel was at least 180 miles, after a sojourn at Melrose for nine months.

The *Cur Dog* differs from the shepherd's dog in being nearly smooth; he is stronger in his make, and has half-pricked ears, and his tail is rather short, and slightly feathered beneath. He is a trusty and useful servant to the farmer and grazier, and is chiefly employed in driving cattle; and being larger and stronger than the shepherd's dog, from which he is sprung, he is better qualified for the grazier and farmer. He bites with great keenness, and always makes his attack at the heels. His sagacity is very great, and he soon knows his master's fields, and watches with great assiduity the cattle which are in them.

As a farmer of good circumstances, who resided in the neighbourhood of Bowbrink, in the county of Norfolk, was taking an excursion to a considerable distance from home, during the frosts in the month of March 1795, he at length was so benumbed by the intense cold, that he became stupified, and so sleepy that he found himself unable to proceed, and lay down, and would have perished on the spot, had not a faithful cur dog, which attended him (as if sensible of his dangerous situation), got on his breast, and, extending itself over him, preserved the circulation of his blood. The dog, so situated for many hours, kept up a continual barking, by which means, and the assistance of some passengers, the farmer was roused, and led to a house, where he soon recovered.

Section 5. Water-dogs, which delight in swimming, having their feet in general semi-webbed.

The *Pomeranian*, or *Wolf Dog*, has the hair on the head short, as is also that on the feet and ears; but it is long and silky on the body and tail, which last is curled up in a spiral form. His colour is white, black, gray, or sometimes yellowish; his head is long, and his muzzle pointed; his ears are short and pricked. He is possessed of intelligence nearly equal to that of the shepherd's dog.

The *Siberian Dog* has much the appearance of the Pomeranian dog, and is very nearly allied to him, except that he is covered with long hair even on the head and paws. In their native country, four of these dogs are attached by pairs to a sledge, and in front of them is placed a leader, on the proper training of which much of the useful services of the others depend. These sledges are just large enough to contain one person, who directs them with his voice, and in which he is partially assisted by a stick. The reins are fastened to the dogs' necks by a collar. These dogs, thus yoked, have been known to drag a sledge from seventy to eighty miles in a day, and so powerful is their scent, that they contrive to keep on the beaten track by that means alone, even although it be hid by showers of snow.

The *Greenland Dog* is of a large size, strong in the bone, and its fur consists of long, thick-set, woolly-like hair; his muzzle is sharp, and his ears short and pricked; his tail is thick, very bushy, and spirally twisted.

The *Iceland Dog* is shorter in the hair than the above variety; his ears are pricked, but slightly bent downwards on the tips. His general colour is white, with patches of black, differently disposed.

The *Esquimaux Dog.*—This highly useful variety is described by M. Desmarest as having the head shaped like that of the wolf dog; the tail is spreading and curved, and the ears erect. The hair is thinly scattered, and consists of two sorts, the one silky, the other thick and fine, and somewhat curled, and so detached from the other, that it may be pulled off in flakes from the animal.

The *Hare-Indian Dog* has a narrow, elongated, and pointed muzzle; his ears are broad at the base, and pointed towards the tips, and perfectly erect; his legs are long and slender, and his tail thick, bushy, and curved slightly upwards, but by no means so decidedly curved as that of the Esquimaux dog. His body is covered with long straight hairs, the ground colour of which is white, marked with large irregular patches of greyish black, intermingled with various shades of brown. Dr Richardson says it has neither courage nor strength for pulling down any of the larger animals.

The *Newfoundland Dog.*—This beautiful and intelligent dog is remarkable for the symmetry of his form and the acuteness of his understanding. He measures from the tip of the nose to the point of the tail, six feet and a half, the length of the tail itself being two feet: from the one fore-foot to the other, over the shoulders, five feet eight inches: the girth behind the shoulders three feet four inches: the length of his head is fourteen inches. He has webbed feet, in consequence of which he is a dexterous swimmer. His hair is long, flowing, and slightly curled, and his tail very bushy, particularly in the lower side, and he carries it in a very graceful manner. The docility of the Newfoundland dog is very great; there are innumerable most striking anecdotes of his sagacity and benevolence of disposition.

A gentleman who had for many years been commander of a ship in the West India trade, had a fine old Newfoundland dog, which accompanied him in all his voyages, and which was found to be very useful, for he would tell when land was near much better than any man on board. Some hours before land was made, the dog used to get to the side of the vessel, snuff the air, wag his tail, and seem much pleased, which was the signal for sending a man aloft, and in a short time the shore was discovered. The vessel no sooner came to anchor in ports which she had previously visited, than the dog would jump overboard, and swim to the shore; he there visited his friends, and after staying some time would return, and, on coming to the side of the ship, howl till he was taken on board. The captain retiring from the sea-service, took his dog with him, and went to reside at a village within a few miles of London, where he regularly attended church on Sundays, accompanied by his dog. On any particular occasion, when his master was prevented from going, the dog, on hearing the bell, would set off alone, walk slowly to the church, and lie down in the captain's pew till service was over, and then return quietly home.

During the gale on Thursday, June 11, 1829, a vessel was driven on the beach at Lydd; no boats could get off to the assistance of the crew, who were, however, all saved and brought ashore, through the activity of a fine Newfoundland dog. The surf was rolling furiously, and eight poor fellows were crying for aid, which the spectators could not afford them, when one man directed the attention of his dog to the vessel, and the intelligent animal at once swam towards it, and the crew joyfully made fast a rope to a piece of wood, which the dog seized and swam with to his master on shore; a line of communication was thus formed, and the eight mariners rescued from a watery grave.

Mr Smith, master of the William and Ann, whaler, has a very bold and docile Newfoundland dog, to which he is particularly attached. When at Greenland, during the summer, his son observed a large seal, which he fired at and wounded slightly; the dog instinctively leaped into the water, and pushed directly for the spot where the seal dived when it was hurt, and on reappearing, the dog seized it by the forefoot, and a desperate combat ensued. During the struggle, the combatants were frequently under water; but the dog resolutely kept his hold, till a boat was launched to his assistance, and, when seized by one of the sailors, he fairly pulled the seal aboard with him. On another occasion, when seven men were on an iceberg, it gave way; six of them got hold of the bow-ropes, but the seventh sunk, the waters closed over him, and his comrades concluded that he was lost. Mr Smith was in bed at the time, but hearing the noise, he promptly sprung on deck, and, in obedience to his signal, boats from the other vessels immediately came to his assistance. His faithful dog was at his foot, and while gazing intently, he observed the head of the sailor above the water. He pointed it out—gave the word—the dog leaped from the bow of the vessel, and, while swimming towards the man, he barked, either with anxiety, or with a view to cheer the perishing sailor with the prospect of assistance. When within a few feet, the man was picked up in a state of utter insensibility, by a boat from the Rambler of Kirkaldy. Observing the rescue of the man, the dog returned to his own ship, and when taken on board, his gambols, frisking and fawning on his master, indicated that though he had not saved the man, he was aware that he had done his duty.

On the occasion of opening the family vault of the Bosvilles, at Ravenfield, a short time ago, for the interment of Mrs Bosville, a large Newfoundland dog, belonging to the late Colonel Bosville, who was interred eleven weeks previous, found its way to its master's coffin, and placed itself upon it, and remained there until the funeral of Mrs Bosville took place, from whence it could only be removed by force. It is worthy of remark, that, though there were several coffins in the vault, the dog instantly proceeded to that of his old master.

The *Russian Dog* is somewhat larger and stronger than the Newfoundland dog: he is a cross between that variety and the Siberian dog, and has now become a distinct race. His head is large, with his ears pendulous and rather full sized; his tail is curled over his back; his hair is very long and shaggy, consisting of black and white patches.

The *Great Rough Water-Dog* is web-footed, swims with great ease, and dives with much dexterity; his hair is long and curly, and he is of various colours; his legs and feet are also thickly covered with thick and bushy hairs.

The *Large Water-Spaniel* is about the size of the English setter, but of a stronger make. His face is smooth, as also the front of his legs, while the rest of his body is covered with small crisped curls, usually of a dark liver-brown colour. This dog is very valuable in the sport of shooting wild-fowl.

The *Small Water-Spaniel or Poodle.*—This is a breed between the large water-dog and the springer; he is thickly covered with fine hair, all of which is in distinct small curls, more like an effort of art than of nature. It is one of the most active of dogs. Its general colour is white, and sometimes it has various black patches. It dives with much dexterity, and will leap from a very great height into the water; we have seen one leap over Tyne Bridge at Newcastle, a height of nearly fifty feet.

At the moment when the ranks of the Imperialists were broken, at the famous battle of Castiglione, and the heat of pursuit was in proportion to the obstinacy of the conquest, Bonaparte coming to the spot where the thickest of the combat had taken place, where French and Austrians lay strewed in horrible profusion, he perceived one living object amidst those piles of corpses, which was a small water-spaniel. The faithful creature stood with his two fore-feet fixed on the breast of an Austrian officer; his long ears hung over his eyes, which were rivetted on those of his dead master. The tumult seemed neither to distract the attention nor change the attitude of the mourner, absorbed by the object to which he clung. Bonaparte, struck with the spectacle, stopped his horse, called his attendants around him, and pointed out the subject of his speculations. "The dog," said Bonaparte, "as if he had known my voice, removed his eyes from his master, and throwing them on me for a moment, resumed his former posture; but in that momentary look there was a mute eloquence beyond the power of language: it was a reproach, with all the poignancy of bitterness." Bonaparte felt the appeal; he construed the upbraidings of the animal into a comprehensive demand of mercy. The sentiment was irresistible; it put to flight every harsh and hostile feeling—Bonaparte gave orders to stop the carnage instantly.

Mr Frazer, Minto Street, Newington, had a poodle dog, called Doon, which was possessed of great sagacity. Upon one occasion, Mrs Frazer, being accompanied by Doon, had gone a-shopping, and having purchased some small articles, which, after being rolled in paper, she put it into her muff. When nearly home, she missed the parcel, and immediately turned back to look for it, when she was agreeably surprised by seeing Doon travelling at her heels with the parcel in his mouth.

The *Shock Dog* is the smallest of the water-dog varieties, and is probably bred between the smaller spaniel or King Charles's dog and the poodle. Its hair is extremely long and flowing, so much so that its ears and eyes are nearly concealed from view by it. It is used as a lapdog.

Section 6. Fowlers, or dogs whose natural inclination is to chase and point birds, and hunt singly by the scent

The *Springer.*—This variety is shaped much like the English setter, but shorter in the body and legs in proportion to his size, being about two-fifths less than that dog; the hair is long and shaggy, and the ears very long and pendulous, and covered with long waved hairs. He is usually of a white colour, with patches of liver-colour or chestnut. He is, however, sometimes black, and at other times entirely of a liver-coloured brown.

The following circumstance occurred in 1793, at Uxbridge:—A fine springer, who, during the heat of the sun, was in the practice every day to enjoy the shade of a stately elm, the pride of that part of the country, one evening was observed to quit his favourite retreat rather suddenly, and plunge into an adjoining pond. The singularity of the circumstance induced the attention of the gentleman to whom the dog belonged, who, on approaching the pond, discovered the poor animal panting in the water, with the extremity of the mouth only above the surface; on dragging it on shore, it died in great apparent agony. The body was opened, when the throat appeared much inflamed and swelled. Various conjectures were formed on the occasion, but the cause remained undiscovered. Some weeks after, a hornet was discovered in the village, and, as is usual, a long thread was fastened round the body, and let fly, that, on returning home, its nest might be discovered. It was traced to the very tree under whose branches the poor animal was wont to repose, and who, it now appears, had most probably been stung in the throat by one of these poisonous insects. On examining the tree, a numerous nest was found; and in endeavouring to smother the latter, the former was consumed.

The following singular instance of animal adoption occurred in 1794, at Dyon's Hall, Essex, the seat of J. Sparling, Esq.:—A favourite spaniel bitch, remarkable as a hare-finder, having had her puppies drowned, went out one morning into the plantation, and soon after returned with a young leveret, about a week old, in her mouth, which she suckled.

About the year 1790, after a severe run, a fox was earthed; in digging for which, some cubs were found which were yet blind; two of them were killed by the terrier bitch which accompanied the pack: next morning she was shown the three remaining cubs, which she immediately adopted and suckled, and brought them up with as much care and fondness as if they had been her own whelps. What renders this circumstance the more remarkable, the terrier pups were upwards of a month old, and had been taken from her some days previously.

The *Cocker* is about a third less than the springer, and like it in all respects. It is used as well as that variety for raising woodcocks and snipes, in which exercise they are both very expert.

A lady had two dogs, Perdue and Vixen; the one a cocker, the other a terrier. These dogs were great favourites, and generally in the lady's sitting-room. Sometimes it happened that they were ordered out of it, and the humour shown on this occasion was whimsical. If Perdue was first ordered to quit the room, she rose reluctantly, but always went and seized hold of the ear of her companion Vixen, and so forced her out also; and if Vixen had the command given her first, she never failed to perform the same ceremony on Perdue, when they together contentedly sought another place of repose. It so happened that these favourites had puppies at the same time, all of which, except one, were drowned. About this single puppy the mothers were for the space of a week continually quarrelling, after which they were observed to agree perfectly well. On watching them, it was discovered that one mother nursed the puppy during the day, and then resigned her place to the other, who nursed it through the night.

A Mr Forbes of Glasgow was in possession of a little spaniel, who gave strong proofs of his having an ear for music. One day, when lying below his master's chair, in a room where a few friends had met, the conversation turned upon the sagacity of dogs, when Mr F. said his little dog never failed to show his displeasure, if he happened to make any discordant notes when playing on his flute. In order to try the animal, and to satisfy those in company, a flute was produced; and while he played a tune without introducing discords, the canine amateur raised his ears, and listened to the melody with evident signs of satisfaction; but in the middle of it, when he introduced some inharmonious notes, he got out from under the chair, and barked most furiously in the face of his master, till he changed the tones to others more consonant to the taste of the little musical quadruped, which at once allayed his rage.

On Wednesday, the 23d of July last, a child (says a letter from Paris, of 12th August 1783) thirty-five months old, belonging to a Swiss, a porter to Monsieur de Caumartin, provost de Marcha, or mayor of this city, disappeared between six and seven o'clock in the evening; at the same time, the father missed a favourite lapdog. The few hours that remained of the Wednesday, and the whole of the following day, were employed in search of the child; every place and corner was looked into, but to no purpose. At length, on the Friday, about eleven o'clock in the forenoon, the valet-de-chambre bethought himself of a reservoir of water, situate at one end of the dwelling-house. On a kind of terrace that leads to it, stands the door of a store-room, from whence the servant heard the howling of a small dog; he opened the door; the liberated animal, being tormented with thirst, went to the water, and returned in haste to the store-room. Word was brought to the Swiss that the dog was found; but how light and insignificant was such a comfort to the parents who were lamenting the loss of a child! But it soon appeared that the dog and child had been shut up in the store-room ever since the preceding Wednesday. The faithful animal, seeing that none of the signs he made were understood, returned to the room where the babe was, plunged in the deadly slumbers of inaction. The little dog gently dragged the child to the terrace, and thinking to have secured the child's life, he ran skipping to the porter's lodge, now and then turning his eyes and head towards the place he had just left. His mute language was at last understood; he led the way, and the joyful parents were so happy as to arrive soon enough to restore to life their long lost and almost expiring child.

When St Michael's bridge fell, a child was buried in the ruins, but luckily slipped in between two beams, which supported each other in such a manner as not to receive the least hurt. A small cocker dog happened to fall in the very same condition, and not being able to escape, barked incessantly. The noise attracted several people, one of whom released the animal with much difficulty; but the poor creature's joy was not of long duration, when it no longer beheld its infantine companion. It ran to the place, jumped into its former situation, and continued barking till they were both released.

The *King Charles's Dog* is still less than the cocker, and distinguished by the very great length of his ears.

The *Comforter* is another diminutive variety of this race, chiefly used as a lapdog. It is supposed to be a cross between the Maltese and King Charles's dog.

The *Maltese* and *Lion Dogs* are descendants from nearly the same stock.

The *Alpine Spaniel.*—This dog exceeds all other varieties of the spaniel for size and beauty. Its usual height is two feet at the shoulders, and he is six feet in length from the nose to the tip of the tail. Two of these dogs are sent out from the monasteries of the Alps of Switzerland, to scour the mountains during snow-storms, in search of lost or wearied travellers—the one with a warm cloak fastened to his back, and the other with a basket tied round his neck, containing a bottle with some cordial, and bread. In this employment they manifest great judgment, and seem to understand perfectly the import of their mission. They are frequently of the greatest use in meeting the travellers who in those stormy and dangerous regions often fall victims to the inclemency of the weather. It is said that if they meet with a traveller who has sunk under the fatigue and inclemency of the blast, that they will lie close to him, until by their warmth they restore heat and energy to the animation which is nearly suspended, and thus frequently will save the life of the sufferer. Should they discover a traveller to have fallen into some deep pit or fissure, from whence he is unable to ascend, and if they are unable to render him any assistence, they will return to the convent, and give the alarm to the monks, and then conduct them to the place where the unfortunate traveller is immured.

The *Old English Setter.*—It is supposed that this breed was produced between the large water-spaniel and the Spanish pointer: they were much more curled than the present breed of setters, and were very steady in the field, but not so rapid in their movements.

The following may be relied on as a fact:—In 1795, a clergyman in London was possessed of an old English setter dog, which had a strange custom of going every morning, during the summer season, to the New River, and plunging into the water, after which immersion he trotted home again in a very orderly manner. This peculiarity attracted the attention of another clergyman, who in his morning walks had more than once been a witness of the fact, to his no small entertainment. Nor did he escape the notice of the dog; for honest Rover, finding he had crept into some little favour with the parson, resolved, as will appear, to cultivate a farther acquaintance. Upon one of these occasions, instead of making the best of his way homewards, he made bold to arrest the clergyman, by seizing the skirt of his coat, rather sportively, indeed, than with any vicious or sanguinary intention. But yet he seemed unwilling to let go his hold. The oddity of the circumstance, as may be imagined, awakened the curiosity of his prisoner, who, wisely thinking it would be to no purpose to remonstrate, put himself under the conduct of his canine companion, and walked on, musing on the whimsicality of the adventure, at the same time what would be the issue.

> "Around from all the neighb'ring streets
> The wond'ring people ran,
> And said the dog had lost his wits
> To follow thus the man."

Through many byways and windings did they travel, till at length Rover released his captive, and made a *set*, which was saying as plain as a dog could say, that their journey was at an end. So in fact it was. And now the last act of civility remained to be performed on the part of the dog, which he acquitted himself of (to his credit be it spoken) very handsomely, never losing sight of his charge until he had introduced him to his master. The *denouement* was not inconsistent with the whole tenor of the dog's deportment, the clergymen having contracted an intimacy, and lived on habits of the greatest friendship ever afterwards.

The *English Setter* is a mixed breed between the water-spaniel, Spanish pointer, and the springer, which has attained a very high degree of perfection as a sporting dog. He is one of the most beautiful, lively, and active of dogs.

The *Spanish Pointer* is the stock from whence the English pointer has sprung. He is one of the most staunch of all dogs used in the sports of the field, although he is considered too heavy for the present improved mode of sporting, and has now nearly become extinct in Great Britain.

A pointer dog, which was brought from South Carolina in an English merchant vessel, was a remarkable prognosticator of bad weather. Whenever he was observed to prick up his ears in a listening posture, scratching the deck, and rearing himself up to look to windward, where he would eagerly snuff up the wind—if it was then the finest weather imaginable—the crew were sure of a succeeding tempest; and the dog became so useful, that whenever they perceived the fit upon him, they immediately reefed the sails, and took in their spare canvass, to prepare for the worst.

The *English Pointer* was obtained by a cross of the Spanish pointer and fox-hound, and is unrivalled for the rapidity of his movements in the field, and the beauty and symmetry of his form. Since his first production, he has been improved by being re-crossed with the harrier. He is subject to considerable variety in point of size.

Pointers have not unfrequently been known to point otters. In the beginning of February 1792, as two gentlemen were sporting in the fields, in the parish of Pilton, in Devonshire, their pointer stood at a brake in a hedge-row. When they came to the spot, suspecting it to be a hare, the pointer rushed in, and out burst a large dog-otter. The pointer seized him, though he was soon obliged to quit his hold, having been sorely bit; but after driving him about for some time in a turnip-field, they struck him several violent blows on the head, and killed him. What is rather singular, it was at a distance of at least five miles from any river where this animal was found.

"I have frequently endeavoured," says a sportsman, in the third volume of the Sporting Magazine, after stating that he has a pointer bitch, the equal of which he had never met with, although hunted with numberless first-rate dogs, "to learn of my sporting friends what were the most valuable qualifications of a pointer. Their different replies were, to find the most game, steady when found, to back the find, come into charge, bring the game, &c. &c.—(this last quality is now exploded). I will add, in my opinion, the greatest of all qualifications in this list, and that is, when, having several times found a straggling bird, or birds of a scattered covey, at a remote part of the field or heath (for she ranges wide), but sufficiently within rake, in making the point more frequently trod upon one or more birds (perchance I killed), the game has often dropt in her sight, and several times within a few yards of her; and provided the game at her nose withstood the first report, I never yet lost the advantage of her find. At two years old she first acquired this habit, being out with a friend the season before last (1791). In beating the first snipe-ground we came to, she being soon found in making up, within about thirty paces of the point, I sprung a snipe; it fell close before her; she turned her head towards me, as if to rebuke me for trying her patience so long; then to the point as before. I rather delayed reloading, as I was foremost, and wished my companion the shot; but he declining, I walked on, and trod up the jack-snipe, which she highly enjoyed to see drop to him. That same day, at the request of my friend, I made a mark in my pocket-book of every point she had, and at the close of that day's sport, her performances of finding amounted to thirty-two brace and a half of snipes, two coveys, and a single bird, of partridges, notwithstanding I hunted her with another brace, her half brothers, one year older than she was, and allowed, by the first judges, to be as excellent dogs as any in the kingdom. In the course of December 1792, and three following months, I killed to her nearly two hundred brace of snipes, and, upon a fair calculation, her *finds* were five to her constant companion's one."

A gentleman who lived in Stockport, and who was a keen sportsman, had a pointer, which evinced on many occasions great sagacity, but it did so in an especial manner in 1793. Having one day been led farther than he intended, by the wildness and continued evolutions of the covey he was in pursuit of, at length he only began to think of returning when the curtain of night had been drawn around him; being unwilling to return through the many windings by which he had advanced, and thought of shortening the distance by returning through an almost trackless path. He had travelled this way, but not for many years; he therefore kept the route he had formerly known, by the side of the river Mersey, whose stream had in one place undermined its banks, and left only the turf remaining above, twenty yards from the surface of the water. When he reached this place, it sunk with his pressure, and he must have inevitably perished, had not his gun, which he carried under his arm, caught two trees that had inclined, but not totally uprooted. Here he must have remained while his strength enabled him, or have fallen into the muddy depths of the river, had not one of his faithful dogs rescued him from his perilous situation. Had he himself attempted to move, his gun would have lost its hold; and he felt quite at a loss what to do, when his faithful dog, seeming to be aware of his danger, ran about in despair, whining, and at length gazing at him with an expression indicative of his strong desire to release him; then seized him by the collar of the coat, and absolutely drew him from his pendant situation. The gentleman, when delivered, lay for some time on the ground, thunderstruck and motionless, hardly able to fancy himself safe. His faithful dog watched him with apparent solicitude; but when he perceived him rise, he bounded round the field, in an ecstacy of transport, leapt up as high as his head, again bounded about, and used every other conceivable gesticulation to manifest his joy.

The *Small Pointer*.—This is a diminutive breed, being only about two feet from the point of the nose to the tip of the tail, and scarcely a foot in height, and is a complete and beautiful miniature of the large pointer. They have proved themselves excellent sporting dogs, but their small size renders them unfit for use in rough land.

The *Russian Pointer* is much like the Spanish pointer in shape, but his hair is long and hairy.

The *Dalmatian* is that well-known dog which is used as an attendant upon carriages. He is a handsome dog, and the spotting on his skin gives him a beautiful appearance. He is a native of Dalmatia, in European Turkey, where he is used as a pointer.

Section 7. Hounds, which hunt in packs by the scent.

The *English Terrier*.—This beautiful dog is too well known to require any description. He is possessed of great courage, and is famous for killing all kinds of varmin, and is a useful attendant upon a pack of fox-hounds, for getting into the earth when the fox has taken to his hole, and driving him out. His hair is smooth. His general colour is black, with tanned cheeks, and the insides of his legs are of the same colour. They are now to be met with of a brown, and even white colour, but these have unquestionably an admixture of some other breed in them.

The *Scotch Terrier*.—This breed has short wiry hair, and is much shorter in the legs than the English terrier. His usual colour is sandy, but he is also to be found black, and also grey. He bites with great keenness, and is a bold and determined dog. He will attack dogs of any size; and when he fixes on an animal, he maintains his hold with great pertinacity. He is much used as an attendant upon packs of foxhounds.

In 1822, an engagement took place on the banks of the Monkland Canal, Scotland, between a terrier pup and a weasel. After varied success on the part of the combatants, they went into the canal, where the pup was gaining a decided advantage, when the weasel seized him by the snout. To get free from such a perilous hold, appeared impracticable; and the terrier, as if aware of the only way to terminate the struggle, thrust his head under water, and drowned his adversary.

Mr Webster, of Leven, had a dog of the terrier kind, but in appearance resembling a Dutch pug, with which Mr W. Keith, portrait-painter, amused himself lately by taking a likeness. On the picture being shown to the animal, he ran off, and has not since been heard of; he had been ten years about the house. This reminds us of the story of Northcote, the celebrated pupil of Sir Joshua Reynolds, who made a portrait of one of Sir Joshua's servants so like, that it was mistaken by a tame macaw for the man himself; and the bird having a grudge at him, flew on the picture with beak and claws, considering his quietness there only as a good opportunity for getting revenge.

The *Talbot* is one of the primitive breeds of British dogs, and is the same which was used by the ancient Britons in the chase of the deer, and other wild animals. Several gentlemen in the town of Presteign, in Radnorshire, were concerned in a pack of hounds of the Talbot or southern kind. The gentleman who had the principal care and management of them, one day met with a badger, in November 1793, which he determined to turn out before his hounds. This he did the next day, and the badger had ten minutes' *law* given to him; they took him alive, and bagged him in reserve for another day's sport. They ran him three miles only, this first day.

On the second day, they had a very numerous field of horsemen; they turned the badger out, to give him half an hour's *law*; and being determined to have a better day of this, the manager, who was mounted on a very fleet bloodhorse, rode after him, to flog him on, that he might be as far as he possibly could, before the hounds were put on; and he assured us, that it was with the greatest difficulty he now and then got a cut at him, with a very long hunting whip, for the badger ran so fast. At the end of the half hour, the time allowed him, the hounds were put on, and they ran him *twenty-five miles*, in full cry all the way, when he was again taken alive, and bagged; for which purpose, the huntsman carried a bag under his saddle. He was again put by in reserve, for another day's sport, when a Counsellor Jenkins, of that town, begged, if they should kill him the next run, that they would give him the hams, as he would have them cured; it being a very common practice of that country to cure the hind-quarters of badgers, and eat them for hams.

The next day they turned him out, giving three quarters of an hour's *law*, resolving, if he could get away, they would not prevent him. They flogged him in the same manner as they had done before, but notwithstanding the extra time they gave him *law*, they only ran him eighteen miles, before they took him alive, and bagged him. This was the third time he had escaped death. He was again conveyed back to his habitation, to be preserved for some future sport; and all the sportsmen returned, hoping to have the pleasure of spending another day at the expense of this extraordinary animal; but in this they were much disappointed, owing to the neglect of the huntsman, whose omission of providing him with food caused the poor animal to die of hunger.

Bloodhound.—It was this dog which was so much used in former times for tracing criminals who had committed murder, as also the remains of murdered persons. He is a large and bold-looking animal, and possessed of great strength. He can discover the scent of a man or animal hours after they have passed over the ground.

On the night of Tuesday, January the 22d, 1822, a labouring man, named Tipper, of Forestside, Stenstead, had a fat hog, of twenty stone, stolen from his stye. He made application to the park-keeper of Lewis Way, Esq., to assist him in its recovery. A couple of sleuth-hounds were laid on, which ran on trail six miles and a half, to the door of a cottage in Westbourne, where James Goble was taken into custody, he having killed the hog and cleaned it.

In the island of Cuba, a certain species of bloodhound is trained to hunt and destroy the negroes who escape from slavery, just as in England the dogs are instructed to pursue hares and foxes. In that island, and in other islands to which these bloodhounds are transported, such is the ferocity of their nature, that, unless they were chained up, or kept in confinement, no negro would be safe. In the island of Hispaniola, during the late revolution which gave independence to the black population, many families were torn in pieces in the woods by these ferocious animals, stimulated to these deeds of barbarity by the inhuman white men. To go a negro-hunting with bloodhounds, was, in the last-mentioned island, a sportive employment, which existed before the French revolution began; and frequently, as soon as the fugitive negro was overtaken, his head was severed from his body. The latter was then given to the dogs for their repast, while the former was carried in triumph to the appointed office, to procure the offered premium, with which the hunting vagabonds of Hispaniola thought themselves honourably rewarded. It is obvious, from hence, that a similar training under the blacks would call forth the canine appetite against the whites; and that against persons of either colour, the ravenous disposition may at times break from all artificial restraints, through the influence of exciting causes with which mankind are but imperfectly acquainted.

The *Staghound* is the largest of all the British dogs of the chase; he has a noble and dignified aspect, and possesses great sagacity and endurance in the chase; this dog is also supposed to be a direct descendant of one of our original British dogs.

The *Foxhound* has a much larger muzzle than the staghound, and his head is small in proportion to the size of his body; his ears are very long and pendulous, although less so than those of the staghound and bloodhound.

A foxhound bitch, belonging to the Kirlington Hunt, near Bolton, on Thursday the 8th November 1792, during the chase, pupped four whelps, which she carefully covered in a rush aisle, and immediately afterwards joined the pack. In a short time after, she pupped another, which she carried in her mouth during the remainder of a hard chase of many miles, to the great astonishment of a number of spectators, after which she returned to the place where she had dropped the four.

On the 20th November 1792, Mr Willoughby's foxhounds had one of the longest and most severe runs ever known in England. They unkennelled a fox at Skusely-wood, near Hull, which was killed seven miles beyond Black, after a run of four hours and ten minutes, with only one short check. The ground they went is calculated at fifty-one miles, over a very deep and strong country. The only persons in at the death were the two whippers-in, Lord Carlisle's stud-groom, and a gentleman of the name of Leatham. Thirty couple of hounds went into the field, nineteen of which were in at the death.

A female fox, with her litter of cubs, were taken to Blackmore Park, the residence of T. C. Hornybold, Esq., and an outbuilding on the premises appropriated to the crafty family as a nursery. Impatient, however, of restraint, and having become convalescent, Madame Reynard escaped the first opportunity to her native haunts, abandoning her progeny to chance. It happened that about this period a favourite hound of Mr Hornybold's had destroyed her whelps; and although she had for six years distinguished herself as a determined and relentless pursuer of the species, it was resolved to place the cubs within her kennel; the anticipated result was their instant destruction; but the generous animal, on the deserted little ones being given to her, instantly softened down the sterner qualities of her nature, and adopted them as her own, suffering them immediately to suckle, and continued to foster and nurse them with every appearance of maternal attention and anxiety.

Mr Hazland's Kentish foxhounds had a famous chase of nearly five hours, in January 1822; in the course of which, the fox crossed the orchards and leaped the garden-wall at Shieldwich, and secreted himself under a water-butt; but finding he was discovered, he again mounted the wall, and, repassing the gardens, darted through the kitchen window of a lady of the name of Beck, and thence into the parlour, and there seated himself. Being quite spent with fatigue, he here suffered himself to be quietly taken alive.

The following circumstance proves that the dog will in some instances devour human flesh, and we believe it is not uncommon for wild dogs to do so:—On Friday, the 5th January 1793, as the hounds of Mr Gordon were hunting at Whitley Shrubs, near Seven Oaks, in Kent, a hound was perceived with a head in his mouth, which, on examination, proved to be a human one; and, in searching the wood, the remaining part of the body was found, with the flesh all eaten from the bones, and supposed to have been there from October 1792, at which time a boy was lost from the workhouse at Heresford, and who was then advertised, but not since heard of.

On Monday, November 25, 1793, a bag-fox was turned off in the parish of Paglesham, in Roachford Hundred, Essex, which afforded much diversion in that neighbourhood, and, after a long chase of hard running, took across the water to Creeksea, in Dengie Hundred, where he was pursued by four of the best hounds, Drummer, Blueman, Tyser, and Trueman. The three young hounds took the lead after crossing the water; but being rather eager, quite lavish, and no way to be depended upon, overshot the fox, leaving only poor Trueman in the chase. Trueman, however, came up with reynard, fastened upon him, and a strong contest ensued; but poor Trueman being rather lame, and otherwise much disabled, reynard broke from him, and ran off in full view of the three young hounds, without their stirring one step to pursue him.

Mr Newman, in Essex, had a pack of foxhounds, which were remarkable for their staunchness. On Monday, December the 2d, 1793, they found a fox at Broomfield Hall-wood, near Chelmsford, and, after a chase of more than twenty-six miles, without the least check, ran into him, as he was attempting to get into Lord Maynard's garden, at Dunmow, and killed him. It is worth remarking, that the hounds pursued the fox through several herds of deer, and amazing quantities of hares, in Lord Maynard's park, with a steadiness not customary to some crack packs which sometimes hunted that country.

A little after nine o'clock on Saturday morning, the 7th December 1793, Mr Curwen's hounds started a fox upon Moutray, which they pursued through the line of woods from Isell to within a very short distance of Whitefield, when he took up the side of Skiddaw, and went clear over to Threlkeld; then skirting the mountains towards Ormthwaite (the seat of Dr Brownrigg), he ascended Skiddaw a second time, passing over the highest parts of it, and crossing in his route a considerable drift of snow. Night coming on, the foot-hunters durst pursue him no longer, and most of the dogs were with difficulty taken off. The whipper-in followed the greater part of this very remarkable chase on Miss Frances, the mare which had won the hunter's whip at Carlisle, on the Thursday previous. They who know the country will be astonished at this relation; every circumstance of which is, however, matter of fact. For extent and difficulty of ground, this chase has probably never been exceeded; and perhaps it is not easy to instance one in which it has been equalled.

In 1794, a singular accident happened to Mr Roche's foxhounds, in Pembrokeshire. In a thick foggy day, four of the best hounds were lost in the Hook Wood; and, notwithstanding the strictest search was made by the colliers in the coal-mines, and a considerable reward offered, no account whatever could be had of them. About three weeks afterwards, a collier fancied he heard a noise in a pit near the road-side; he procured a rope, and let himself down, where he found one bitch alive, and in excellent condition, the skulls of the others, and a small one, like that of a fox, quite picked to the bone, and the hind-quarters of one of the dogs whole.

The *Harrier*.—This dog is used in hare-hunting, and was originally obtained by a double cross between the small beagle, and southern hound. He is very eager in the pursuit of the hare. There are few instances of any of the deer tribe being hunted with success by dogs of so small a description as harriers, therefore the following deserves to be recorded, being rather an uncommon feat:—

On Friday, the 4th January 1822, Mr Best and some of his friends enjoyed a great treat in hunting a very fine doe, which had been known to be resorting in the woods near Rochester eight or ten days before, and having been seen by a woodman, Mr

Best was informed where she might be found. That gentleman took out ten couple of his harriers, and soon discovered her. The doe came out into a large lay field between the woods; and as if to display herself, and bid defiance to her pursuers, bounded about the field, full of pride and fire, in the finest style, exhibiting to the spectators one of the most beautiful sights imaginable. She crossed the turnpike road, from wood to wood, several times, seeming determined not to leave her haunts; but after being hunted about for half an hour, and closely pressed, she broke cover to the eastward for Chatham, where, being turned on the road, she made off behind the town of Streetend and Luton, and from thence along the Suttonton vallies, for Lord's Wood, which she made; but on the hounds coming up, she headed back again into the open fields, and then took a direction for Shartstead and Hemstead, and through the greater covers belonging to the crown, once the estates of the Earls of Aylesford and Thanet, in the neighbourhood of Bainham, through Mr Stacy's preserves at Stockbury, and was at last killed between Stockbury and Binbury, after a run of exactly three hours, in which the harriers scarcely came to a check. This chase excited the astonishment of all who witnessed it, as it was supposed impossible that a few low-scented harriers could overtake an animal possessing such strength and speed. Five of the horsemen only were in at the death.

On Tuesday, the 20th November 1822, the harriers belonging to Mr Hill of Press, and Mr Roberts of Wem, had one of the longest and severest runs ever perhaps known to have been performed by a pack of harriers in this kingdom. They started a fox on Twamlows Moor, and he was killed under Beeston Castle, in Cheshire, after a run of at least sixty miles! Of thirty horsemen that started with the hounds, only six were in at the death.

In February 1793, an extraordinary circumstance occurred with Mr Palmer's harriers. Finding a hare at Sonning, she made a circle to the turnpike road near Twyford, where, with an excellent chasing scent, the hounds pressed her closely; she swam the deepest part of the river Loddon, followed by the hounds with the rapidity of a fox-chase, leaving a numerous field of horsemen to explore their way through the only passable part of the river, which, with the waters being out, was up to the skirts of the saddles for half a quarter of a mile, before the opposite shore could be gained: this they had no sooner accomplished, than the hare, making a semicircle on that side, recrossed the river near Hurst Lodge, in so rapid a part that many of the hounds were unable to recover the land, but were extricated by the hunting whips of the company; though it was much to be regretted that neither her fortitude nor her sagacity could resist the severity of her fate, the leading part of the hounds having run into, killed, and consumed her, before a single horseman could get in to save her—a matter that had been previously determined on, could it have been luckily effected.

On Monday, December the 16th, 1793, the hounds of Mr Snep, of Haremare, immediately after killing a hare, struck off on a fresh scent, which was supposed to be from the foot of another hare; but after following it a while, the game appeared in view, and proved to be a marten-cat, which produced most excellent sport. The little animal was treed and dislodged six times before it was killed. But the most extraordinary circumstance that attended this hunt, was that of a man's flushing, and catching a woodcock as he was preparing to climb a tree after the marten.

The *Beagle* is the smallest of the dogs of the chase. He is possessed of a very acute sense of smelling, and pursues the hare with unwearied steadiness, and what he wants in speed and strength he makes up for by his perseverance.

The *Otter-Hound* is a cross between the large southern hound and the large rough terrier. He has a large head with pendulous ears, and his whole fur is of a wiry texture and rather long; his colour is either sandy or black. Otter-hunting was a favourite sport in ancient times, but is now nearly lost in this country.

The *Bull-Terrier* is a cross between the bull-dog and the terrier, as its name implies, and has now assumed the character of a distinct breed. It is much used by the gentlemen of the fancy as a fighting dog.

Section 8. Mongrel hounds, which hunt singly, either by the scent or eye.

The *Lurcher* is a cross between the greyhound and harrier, and re-crossed with the terrier. His limbs are strong; his head less sharp than that of a greyhound; his ears are short, erect, and half-pricked; and his hair coarse and wiry. He is much used by poachers, and is famous for killing rabbits, as he has a fine scent, and runs his game without giving tongue.

The *Leymmer* and the *Tumbler* are imperfectly known dogs, which are now nearly, if not entirely, extinct. They hunted both by the scent and eye.

The *Turnspit* is a small dog with a long body and short crooked limbs, and was much used in turning the spit before the invention of jacks.

Division III.—With short heads.

Section 9.—Watch-dogs, which have no propensity for hunting.

The *Mastiff* has a large flat head, and a short and blunted muzzle; his lips are full, and hanging considerably over the lower jaw; his ears, although rather small, are pendulous. He has a sullen and grave aspect, and is excellent as a watch-dog; his voice is loud and deep-toned. He is a dog of large size, and is supposed to have been produced betwixt the Irish greyhound and bull-dog.

The following anecdote of the ferocity of a mastiff is recorded by Colonel Thornton in his Sporting Tour:—"After breakfast, having advanced the carriage and horses a mile, as we walked smartly on, an accident occurred which had like to have proved serious. A favourite pointer that attended us happened to be playfully rambling about, when on a sudden he was attacked by a very large and furious mastiff, which rushed forward, and apparently with an intention to destroy him. We immediately interfered, and the attack in an instant was changed from the pointer to us. Mr P—— had no other offensive weapons than stones, which he threw at the creature, who, contrary to the general custom with these animals, valued them not, and was in the act of flying at my friend, when I gave him the severest crack I could with my gig-whip. This changed the attack to me. I had no defence but parrying as skilfully as I could with my whip and my hat; the latter I took off, to allow him to seize it when he had broken the whip, which he soon did, and intended, as soon as he had firmly seized the hat, by some violent kicks on the tender parts of his belly, to defend myself, or rather to defeat my antagonist—a way, when at college, and priding myself on this *métier*, I have often effected on my very superior master in this mode of fighting, Mr C—n. But courage is all custom; and had not the owner fortunately come to our assistance, roused by Mr Gerard, who had no offensive weapon but his delicate *gollette* and more delicate brush, I rather fear I should only have been second in the contest; for a more ferocious or much larger mastiff I never saw."

A mastiff bitch, belonging to a butcher in Greenock, had a practice of hiding part of her provisions in a neighbouring wood. On one occasion her store was plundered, and it appears she had discovered, by the smell round the place, that the theft had been committed by pointers, as she has ever since had a strong antipathy to pointers, and attacks them on every opportunity. A gentleman wished to have some pointers nursed by her, and for this purpose her own pups were drowned, and the young pointers put in their place. On the following morning, when the gentleman went to see his pups, he discovered, to his astonishment, that they had been devoured by the mastiff bitch, and nothing remained of them but the claws of their feet.

A mastiff bitch, belonging to Mr William Fyfe, in Rutherglen, in June 1823, littered nine pups, one of which was dead. To this dead carcase, however, she was more attached than all the rest of her family, and resisted with great bitterness any attempt to deprive her of it. She kept it in this manner ten days, after which she took the putrid remains in her mouth to the garden, where she dug a hole, in which she deposited her defunct offspring, and with mournful howling carefully covered up the grave.

A gentleman, some years since, who resided in Macclesfield, possessed a large mastiff dog, remarkable for his great sagacity. One day a maid-servant belonging to the house, being particularly busy, desired a poor woman, who occasionally paid them a visit, to go into the market and purchase some vegetables, which were wanted for dinner. The poor woman excused herself by saying that she had no shoes fit to wear in such a public place. The servant, in reply, said that she should put on an old pair belonging to her master, which were then in the kitchen. The woman, thus equipped, set off to the market, where she was unfortunately met by the dog that had been out on his rambles. The dog, on coming near, began to examine her feet; when, discovering his master's shoes, he attacked her, threw her on the ground, pulled off the shoes, and with them marched home in triumph, leaving the poor woman to return barefooted to tell her mournful tale.

The *Bull-Dog*.—This dog is remarkable for the depth of his chest and the strength of the whole muscles of his body. His head is large, flattened above, and his muzzle much blunted, with the under jaw projecting considerably beyond the upper one; his eyes are set far apart, and project considerably from his head; his power of smelling is less acute than any other of the canine race, on which account he is a dangerous dog, for he frequently has been known to lay hold of his master without discriminating the difference between him and a stranger. He is the boldest and most obstinate of all dogs, and has been known to hold his adversary so determinedly, that his legs have been cut off without making him desist.

Many instances have been recorded of the invincible courage of the English bull-dog, but we scarcely recollect one in which so much unconquerable spirit and tenacity of life have ever been displayed, as on the following occasion:—A short time since, a large dog of this species, from some cause that was not observed, suddenly flew at a fine cart-horse that was standing at the end of the salt-house dock, Liverpool, and, fixing his lacerating teeth in his shoulder, defied every effort to get him off. At first he was beaten with cartwhips and sticks with such fury as seemed to break his bones; but this being unavailing, a carpenter with an adze in his hand came up and beat him with the blunt iron head of the instrument, till it was thought he had pounded him to a jelly; but the dog never moved a tooth. A man then took out a large pointed clasp-knife, with which he stabbed him repeatedly in the back, loins, and ribs, but with no better success. At length, one of the spectators, who appeared to have more strength of sinew and arm than the rest, squeezed the ferocious beast so tightly about the throat, that at length he turned up the white of his eyes and relaxed his jaws. The man threw him off to a distance, but the dog immediately went round the crowd, got behind the horse, and again seized him by the under part of the thigh. As no terms could now be kept with this untameable brute, he was again loosened, and thrown into the dock to drown. He instantly, however, rose to the surface, when a sailor struck him a supposed deadly blow on the head with a handspike, which again sent him to the bottom. He arose once more, and was again sent down in the same manner, and this process was repeated five or six times. At length one of the bystanders, who either possessed or assumed some right of property in the dog, overcome by his amazing tenacity of life, and weary of persecution, got him out, and walked off with this prodigy of English courage, to all appearance very little worse for the horrible punishment he had undergone.

On Monday, February 18, 1822, a large brindled bull-dog flew at a gentleman's cabriolet horse, in Mount Street, Grosvenor Square, and, horrible to relate, fastened on the poor animal's shoulder, where he held on with the most surprising tenacity. The gentleman leaped out, and providentially escaped with his life, as, in a second after, the horse set off at full speed, the dog hanging to his shoulder, when, turning into an adjoining mews, the cabriolet upset, and the owner of the dog with difficulty got him off, no other person daring to approach him. The horse then fell from exhaustion, when the traces were cut, and the poor animal was extricated.

The *Pug Dog* is descended from the bull-dog, by a cross with the small Danish dog, and resembles the former so much in appearance, that he may be considered as a miniature of that variety. He is a useless dog, without a single quality but his ugliness to recommend him.

MISCELLANEOUS DOGS,

Whose varieties are not known.

THE ISLE OF DOGS.

The servants of a gentleman who had a house near the river's side, opposite to the little island in the river Thames called the Isle of Dogs, observed that a dog came constantly every day to them to be fed, and as soon as his wants were satisfied, took to the water and swam away. On relating this to the master, the gentleman desired them to take a boat and follow the dog the next time he came. They did so; and the dog, on their landing, expressed, by his emotions, great pleasure, and made use of all the gestures in his power to invite them to follow him, which they continued to do till he stopped, and began scratching with his foot on the ground, and from that spot he would not move. Either that day or the next, they dug up the earth in the place, and found the body of a man, but it was impossible to discover who it was; and after every requisite step had been ineffectually taken to find out the murderer, the corpse was buried, and the dog discontinued to visit the island. The gentleman, pleased with a creature which had shown such uncommon sagacity, and that faithful attachment to his former master, caressed him greatly, and succeeded in gaining his attachment; he became an inmate of his domicile, and made him the frequent companion of his walks. When he had possessed the faithful animal for some time, he was going to take a boat at one of the stairs in London, when the dog, which had never before been known to do such a thing, seized one of the watermen. The gentleman immediately thought that this fellow was the murderer of the dog's former master, and taxed him with it; and he directly confessed it, on which he was taken into custody, and soon afterwards suffered for the crime.

WILDBRAT.

The fidelity of the dog is immortalised in the noble order of the elephant, instituted by Christian the First, king of Denmark, so far back as the year 1463. The origin was, his being deserted at a most critical period by all his friends and courtiers, at the time he stood in great need of their assistance; and having a favourite dog, called Wildbrat, who loved and constantly attended him, the contrast between this grateful animal, and the infidelity of the vipers he had formerly cherished, struck him so forcibly, that he commemorates the fact by having the following initials placed under the elephant's feet, which hangs at the bottom of the order:—

T.I.W.B.—*Trew* is Wildbrat.

THE REBEL'S DOG.

At the battle of Ballynahinch, Ireland, one of the insurgents who fell in the engagement was followed by a dog. The faithful creature for three days lay across his master's bosom, until he was buried, and then for some time afterwards constantly attended his master's grave, except at intervals when hunger forced him into town in quest of food. His remarkable attachment and fidelity being observed, a person took him under his charge, who, by caressing him, and kind attention, so gained his affections that he seemed at last to forget his grief for the loss of his unhappy master.

DUMB ELOQUENCE.

In the severe winter of 1783, a hairdresser at Hanover went out of the city gate, in the dusk of the evening, with one of his friends, who had business at a neighbouring village, in order to show him the road. As the ground was then covered with snow, they were but a short way in the country, when they met a dog, who came running from a track which lay out of their way, and by his whining and piteous gestures seemed desirous to gain their attention. On their noticing him, he ran back a little part of the way, then returned to them, and, by his actions, indicated his desire that they should follow him. Struck by the expressive countenance of the dog, they agreed to follow him, and therefore turned towards the way from whence he came. They had not gone many yards, when the dog, by his frisking about, appeared to express great joy at this circumstance. He then continued running a little way before them, and at times returned to point out to them the road from whence he came. After following him for some time, the dog suddenly stopped, when, on examining the place, they discovered the body of a man, apparently frozen to death, around whom the dog went moaning in a piteous manner. They conveyed the body to a neighbouring village, where, by proper care, suspended animation was restored; and the dog was thus the providential preserver of his master's life.

MUTUAL ATTACHMENT BETWEEN A DOG AND A HORSE.

The late Mr Thomas Walker, of Manchester, had a dog, which was accustomed to be in the stable with two of his carriage horses, and to lay in a stall with one of them, to which he was particularly attached. The servant who took care of the horses was ordered to go to Stockport (a distance of six miles), upon one of the horses, and took the one to which the dog was attached with him, and left the other with the dog in the stable, being afraid he might lose him. After the man had been gone about an hour, some person coming accidentally into the stable, the dog took the opportunity of quitting his confinement, and immediately set off in quest of his companion. The man, who had finished the business he was sent upon, was just leaving Stockport, when he was surprised to meet the dog he had left in the stable coming with great speed down the hill into the town, and seemed greatly rejoiced to meet his friendly companion, whom he had followed so far by scent. The friendship between these two animals was reciprocal; for the servant going one day to water the carraige horses at a large stone trough, which was then at one end of the Exchange, the dog, as usual, accompanying them, was attacked by a large mastiff, and in danger of being much worried, when his friend, the horse, which was led by the servant with a halter, suddenly broke loose from him, and went to the place where the dogs were fighting, and, with a kick of one of his heels, struck the mastiff such a severe blow, that he drove him into a cooper's cellar opposite; and having thus rescued his companion, returned quietly with him to drink at the conduit.

LODBROG'S DOG.

There is a trait of English history, which seems to be well authenticated, proves that the first landing of the Danes in this country was occasioned by the sagacity and affection of a dog. Lodbrog, of the blood-royal of Denmark, and father to Hinguar and Hubba, being in a boat with his hawks and his dogs, was driven by an unexpected storm on the coast of Norfolk, where, being discovered, and suspected as a spy, he was brought to Edmund, at that time king of the East Angles. Having made himself known, he was treated with great hospitality by the king, and in particular cherished on account of his dexterity and activity in hawking and hunting. Berick, the king's falconer, grew jealous of his attention; and lest it should lessen his merit in his royal master's opinion, and so deprive him of his place, had the treachery to waylay Lodbrog, and murder him; which done, he threw his body into a bush. He was presently missed at court, and the king grew impatient as to what was become of him; when the dog, who had staid in the wood by the corpse of his master till famine forced him thence, came and fawned on the king, and enticed him to follow him. The body was found; and, by a train of evidence, Berick was proved to be the murderer. As a just punishment, he was placed alone in Lodbrog's boat, and committed to the mercy of the sea, which bore him to the very shore the prince had quitted. The boat was known, and Berick, to avoid the torture, falsely confessed that Lodbrog had been murdered by the order of Edmund, which account so exasperated the Danes, that, to revenge his death, they invaded England.

THE PEDLAR'S DOG.

In Lambeth church there is a painting of a man with a dog on one of the windows. Tradition informs us that a piece of ground, near Westminster Bridge, containing one acre and nineteen roods (named Pedlar's Acre), was left to that parish by a pedlar, upon condition that his picture and that of his dog should be perpetually preserved on painted glass on one of the windows of the church, which the parishioners have carefully performed. This gift was made in 1504, at which time the ground was let at two shillings and eightpence per annum; but in the year 1752 it was let on lease at L.100 per year, and a fine of L.800, and is now estimated to be worth L.350 yearly. The reason alleged for the pedlar's request, is, that, being very poor, and passing the afore-mentioned piece of ground, he could by no means get his dog away, who kept scratching a particular spot of earth until he attracted his master's notice, who, going back to examine the cause, and pressing with his stick, found something hard, which he dug up, and on inspection is turned out to be a pot of gold. With part of this money he purchased the land, and settled in the parish, to which he bequeathed it on the conditions above narrated.

THE WATERMAN'S DOG.

In the year 1760, whilst a man of the name of Richardson, a waterman, near Hammersmith, was sleeping in his boat, the vessel broke from her moorings, and was carried down by the side of a west-country barge. Fortunately for the man, his dog happened to be with him, and the sagacious animal awaked him, by pawing his face, and pulling the collar of his coat, at the instant the boat was filling with water; he seized the opportunity, and thus saved himself from otherwise inevitable death.

A DOG RECOGNISES HIS MISTRESS'S PORTRAIT.

A dog, which had been the favourite of an elderly lady, some time after her death, discovered the strongest emotions on the sight of her picture, when taken down from the wall, and laid on the floor to be cleaned. He had never been observed to notice the picture previous to this incident. Here was evidently a case of passive remembrance, or of the involuntary renewal of former impressions.

EXTRAORDINARY INSTINCT.

A dog, the property of a gentleman who died, was given to a friend in Yorkshire. Several years afterwards, a brother of the deceased, from the West Indies, paid a short visit at the house where the dog was then kept. He was instantly recognised, though an entire stranger, in consequence, probably, of a strong personal likeness. The dog fawned upon him, and followed him, with great affection, to every place he went.

MARVELLOUS INCIDENT.

On the 13th of November 1803, as Mr Pettye, a baker, belonging to Briston, in Yorkshire, and his wife, were returning home in their bread-cart, on turning into the yard the cart was overturned, when Mrs Pettye fell with her neck directly under the wheel, and her husband was placed between the wall and the cart. While in this perilous situation, his dog rushed forward, and seized the horse by the nose, which effectually prevented him from stirring, until Mr Pettye, with great difficulty, extricated himself, and came to his wife's assistance.

THE DOG OF THE PRINCE OF ORANGE.

Sir Roger Williams, in his account of the actions of the Low Countries, says, the Prince of Orange one evening having retired into the camp, Julian Romero, with earnest persuasions, prevailed on the Duke D'Alva to hazard a *comisado*, or night attack upon the prince. At midnight, Julian sallied out of the trenches with a thousand armed men, mostly armed with pikes, who forced all the guards that they found in their way into the encampment of the prince, and succeeded in getting even to the front of his tent, and killed two of his secretaries; the prince himself very narrowly escaped, through the wisdom of his dog, which awoke him, by scratching, barking, and crying, while the enemy were approaching; and but for his timely interposition, he would have been taken and slain. The attack was made with such promptitude and determined resolution, that the guards took no alarm, until their fellows were running to the place of arms, with their enemies at their heels. The Prince of Orange always lay on his arms, and had a servant constantly holding one of his horses, ready bridled, yet, in going out of his tent, he could hardly reach his horse before the enemy arrived. One of his equerries was slain in the act of mounting his horse, close behind the prince, as were also several of his servants. The prince, to show his gratitude to his deliverer, not only kindly preserved the faithful animal that had thus been instrumental in saving his life, but also kept one of his race until the day of his death, which example was followed by many of his friends and adherents.

MR LACKINGTON'S DOG.

Mr Lackington, speaking of the portrait annexed to the volume of Memoirs of his Life, says, that, before the original painting was finished, Mrs Lackington called on the artist to examine it. Being introduced into a room filled with portraits, her little dog being with her, immediately ran to that particular portrait, paying it the same attention as he was always accustomed to do the original; which made it necessary to remove it from him, lest he should damage it, though this was not accomplished without expressions of dissatisfaction on the part of the dog.

AN ORDERLY CUSTOMER.

A gentleman at Ramsgate, in the year 1798, had a dog with which he used to amuse his friends and others, by frequently standing on a cliff which looked into the inner basin of Ramsgate pier, and calling his favourite dog, showed him a halfpenny, and then threw it down the cliff among the shingles. The dog immediately took a circuit to the bottom of the cliff, and searched till he found the halfpenny, which he carried directly into the town to a baker's shop, where he obtained a roll for his money. The baker declared he was better pleased with the orderly behaviour of this four-footed customer than with one-half of the bipeds who frequented his shop.

A DOG PROTECTS AN IDIOT.

A poor idiot who lived with his father, and was inhumanly treated by him on account of his infirmity, was one day severely beaten for some trifling cause. The father kept a dog, who was then standing by during his brutal behaviour. The idiot was remarkably fond of the animal, and used to caress him. While his father was beating him, he burst into tears, and exclaimed, as he eyed the dog with compassion, "As there is no one to take my part, I am sure the dog will;" upon which the animal instantly seized the father, and would not let go his hold until he left off beating his son.

A CONSIDERATE MONARCH.

We are told by Plutarch, that there was a certain Roman slain in the civil wars, whose head nobody durst cut off, for fear of the dog that guarded his body, and fought in his defence. It happened that King Pyrrhus, travelling that way, observed the dog watching over the body of the person slain; and hearing that the dog had been there three days without meat or drink, yet would not forsake his dead master, ordered the body to be buried, and the dog preserved, and brought to him. A few days after, there was a muster of the soldiers, so that every man was forced to march past in order before the king. The dog lay quietly by him for some time, and among them happened to be the murderers of his late master; he instantly flew upon them, with more than ordinary fury, seized them by the throats, and frequently turned round and looked at the king. This led him to suspect that they were the murderers, as it did also all that were about him. The men were apprehended, and though the circumstances were very slight which otherwise appeared against them, yet they confessed the fact, and were executed for it.

DOG DETECTS A TRAP-DOOR.

In the Duke of Hamilton's rooms, in Holyrood-house, is a dog's collar, with armorial bearings, which is said to have belonged to a dog who saved the life of a marquis or duke of that family, when on his travels abroad. At an inn this nobleman was put into a bed, made to sink by a trap-door, a method contrived by the host to murder his guests with impunity. But the dog made such a scratching under the bed, and disturbed his master so much, by pulling him by the clothes, &c., that the door was discovered, and by this means his master's life was saved.

UNACCOUNTABLE INSTINCT.

A gentleman, who had been in Ireland for some years, returned to Scotland, and is now residing at Gateside, in the vicinity of Neilston. Two months after his arrival, a favourite dog, which he had left at Belfast with his son, made his appearance *solus* at Gateside. This appeared the more extraordinary, as the animal had never before been in Scotland. In a few days, however, information was received that the dog had been put on board the Rapid steam-boat, under the charge of some person; but it is supposed that after coming on shore at the Broomielaw, he had got the scent of his master's foot, who had been there the day before, and had succeeded in tracing him to his residence, a distance of eight miles.

TRUST NOT STRANGERS.

A serious accident happened on Friday morning, the 30th September, about one o'clock, near Langtown. While Mr Jackson's carts were proceeding on the road to Edinburgh, it is supposed that the carter had fallen off his cart, and the Edinburgh night mail coming forward some time after, the coach ran over the body of the man. The coachman perceiving something wrong, pulled up; and on the guard attempting to lift the body, the man's faithful dog, which had been watching its master, seized the guard, and tore his coat; nor was it till the dog recognised some people who came up, that it allowed the body to be lifted. The unfortunate man was conveyed to his own house in a very dangerous state.

FRIENDLY TRAVELLERS.

An innkeeper, at Astley Chapel, once sent as a present by the carrier, to a friend at Warrington, a dog and a cat tied up in a bag, who had been companions more than ten months. A short time after, the dog and cat took their departure from Warrington together, and returned to their old habitation, a distance of thirteen miles. They jogged along the road, side by side, and on one occasion the dog gallantly defended his fellow-traveller from the attack of a dog they met.

EDINBURGH: Published by W. and R. CHAMBERS, 19, Waterloo Place; also by ORR and SMITH, Paternoster Row, London; and W. CURRY, Jun. and Co. Sackville Street, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight.
Stereotyped by A. Kirkwood, and printed by Ballantyne & Co. Paul's Work.

No. 17. PRICE 1½d.

DOMESTIC ECONOMY AND COOKERY.

OUR object in the present publication is to be simply useful. We are anxious to put into the hands of young women, especially those entering into the management of a family, such a series of practical rules in DOMESTIC ECONOMY and the art of COOKERY, as may lead them to execute with facility and credit the important and respectable duties of the housewife. We are aware that many excellent works already exist, illustrative of these branches of female education; but we also know that there are many thousands of persons who have neither leisure to study such treatises, nor the means of purchasing them. On this account we now place within the reach of *all*, a summary of short, though sufficiently explicit rules, calculated principally for those in the middle and lower ranks of life. The directions given for the preparation of dishes are the *original* composition of an individual well acquainted by experience with both the principles and practice of cookery, and may therefore be depended on as genuine, and every way suitable to govern housewives in the affairs of the kitchen. We take the liberty of commencing with a few familiar observations on the conduct of families generally, as regards their

DOMESTIC MANAGEMENT.

No folly is perhaps so common in the present day as that of families living beyond their incomes. This arises, of course, from a want of reflection on what the consequences must infallibly be of such conduct. It is the duty of all—no matter in what rank of life they move—to regulate their expenditure to their incomes, as nearly as such can be calculated, and, if possible, to live at a somewhat lower rate. If a family have three hundred pounds a-year, it should live upon two hundred and fifty; if it have only one hundred, it should do with at most ninety. A little experience in housekeeping will show the propriety of this regulation; for unforeseen outlays are continually occurring, and must be provided against; besides, there are urgent reasons for making some provision against the day of sickness and death, calamities from which no family is exempted. We are willing to believe that most persons are disposed to live within their means, but their intentions are never so strong as to enable them to withstand the temptation to fall into extravagant habits. They are generally borne away by the bad example offered by acquaintances, some of whom may have better incomes than themselves, or may be reckless of how much debt they contract. Carried away into the commission of excesses by example, and dreading to be ridiculed for "not doing as others do," numberless families bring themselves into a series of distressing pecuniary difficulties, humiliating to good principle, and not unfrequently productive of ruin in their worldly prospects.

We confess it is sometimes no easy matter to resist the stream of dissipation, particularly since the style of living is now so often made the standard of respectability; yet it is worthy of a trial. A great deal may be done to secure comfort, and even luxury, without injury, provided the husband and wife consult coolly on the subject by themselves. Let them ascertain by this species of investigation what it is that constitutes their mutual happiness, and what line of life it is that holds out the promise of being longest pursued without mischief both to themselves and others. The exact length to which they may go in a mode of comfortable living, in a great measure independent of acquaintances, or what they call "the world," is likewise exceedingly worthy of being established in their minds. For want of these inquiries, many families indulge in an extravagant style of living, thinking all the time that they are gaining friends by so doing, and deluding themselves into the notion that they are securing happiness. While making every allowance for families "seeing their friends" occasionally, we cannot shut out the knowledge, that it is by means of "parties" that most of those families who sink into a state of poverty are first indebted for their ruin. An insatiable desire to give and to be at entertainments is a prevailing cause of family distress, and should on all accounts be restrained. We are aware that a wife must in many instances be governed in her conduct in this respect by her husband; but if she be really a good housewife, and prefer the quiet enjoyments of home to the racket of miscellaneous assemblages of people, she will do much to preserve the family from indulging in those expensive modes of living which cannot be safely afforded. One thing is worthy of remark: if she be more fond of gadding than of staying at home, more delighted with "showing off" abroad than pursuing her household duties, she will not be surprised if she find that her husband has grown careless of coming home direct from his daily occupations to his own fireside. Almost in any way it can be viewed, it appears that the propensity to spend money on company is among the most fatal that can well be imagined; for it leads to disasters which years of economy and repentance will fail to obviate, and is absolutely destructive of the principles of moral rectitude.

On this subject, Mrs Child has these observations:—"To associate with influential and genteel people with an appearance of equality, unquestionably has its advantages; particularly where there is a family of sons and daughters just coming upon the theatre of life; but, like all other external advantages, these have their proper price, and may be bought too dearly. They who never reserve a farthing of their income, with which to meet any unforeseen calamity, 'pay too dear for the whistle,' whatever temporary benefits they may derive from society. Self-denial, in proportion to the narrowness of your income, will eventually be the happiest and most respectable course for you and yours. If you are prosperous, perseverance and industry will not fail to place you in such a situation as your ambition covets; and if you are not prosperous, it will be well for your children that they have not been educated to higher hopes than they will ever realise.

If you are about to furnish a house, do not spend all your money, be it much or little. Do not let the beauty of this thing, and the cheapness of that, tempt you to buy unnecessary articles. Doctor Franklin's maxim was a wise one, 'Nothing is cheap that we do not want.' Buy merely enough to get along with at first. It is only by experience that you can tell what will be the wants of your family. If you spend all your money, you will find you have purchased many things you do not want, and have no means left to get many things which you do want. If you have enough, and more than enough, to get every thing suitable to your situation, do not think you must spend it all, merely because you happen to have it. Begin humbly. As riches increase, it is easy and pleasant to increase in hospitality and splendour; but it is always painful and inconvenient to decrease. After all, these things are viewed in their proper light by the truly judicious and respectable. Neatness, tastefulness, and good sense, may be shown in the management of a small household, and the arrangement of a little furniture, as well as upon a larger scale; and these qualities are always praised, and always treated with respect and attention. The consideration which many purchase by living beyond their income, and of course living upon others, is not worth the trouble it costs. The glare there is about this false and wicked parade is deceptive; it does not in fact procure a man valuable friends, or extensive influence. More than that, it is wrong—morally wrong, so far as the individual is concerned; and injurious beyond calculation to the interests of our country. To what are the increasing beggary and discouraged exertions of the present period owing? A multitude of causes have no doubt tended to increase the evil; but the root of the whole matter is the extravagance of all classes of people. We never shall be prosperous till we make pride and vanity yield to the dictates of honesty and prudence. We never shall be free from embarrassment until we cease to be ashamed of industry and economy. Let women do their share towards reformation. Let their fathers and husbands see them happy without finery; and if their husbands and fathers have (as is often the case) a foolish pride in seeing them decorated, let them gently and gradually check this feeling, by showing that they have better and surer means of commanding respect. Let them prove, by the exertion of ingenuity and economy, that neatness, good taste, and gentility, are attainable without very great expense."

"How great is the change (says another respectable female writer*) which is effected in the situation of a woman by the few solemn words pronounced at her marriage! She who the moment before was perhaps a careless member of one family, finds herself, as if by magic, at the head of another, and involved in duties of the highest importance. If she possess good sense, her earnest wish will be to act with propriety in her new sphere. The married and single state equally demand the exercise and improvement of the best qualities of the heart and the mind. Sincerity, discretion, a well-governed temper, forgetfulness of self, charitable allowance for the frailty of human nature, are all requisite in both conditions. But the single woman being in general responsible for her own conduct solely, is chiefly required to cultivate passive qualities. To fall easily into the domestic current of regulations and habits—to guard with care against those attacks of caprice and ill-humour which disturb its course—to assist rather than to take the lead in all family arrangements, are among her duties; while the married woman, in whose hands are the happiness and welfare of others, is called upon to lead, to regulate, and command. She has to examine every point in the new situation into which she is transplanted; to cultivate in herself, and to encourage in her husband, rational and domestic tastes, which may prove sources of amusement in every stage of their lives, and particularly at the latter period, when other resources shall have lost their power to charm. She has to proportion, not, as in the single state, her own personal expenses merely, but the whole expenditure of her household, to the income which she has now to command; and in this part of her duty there is often exercise for self-denial as well as for judgment. The condition of her husband may require her to abandon not only habits of expense, but even those of generosity. It may demand from her a rigid adherence to economy neither easy nor pleasant, when contrary habits and tastes, under more liberal circumstances, have been fixed and cultivated. Such alterations in habit may at first be regarded as sacrifices, but, in the end, they will meet their compensation. Sometimes, however, the means of indulging liberal and generous propensities are extended by marriage. Where this is the case, that extreme attention to economy, which circumscribes the expenditure very much within the boundaries of the income, would betray a narrow and mean spirit, and would have the effect to abridge the blessings which by affluence may be dispensed around.

No woman should place herself at the head of a family without feeling the importance of the character which she has to sustain. Her example alone may afford better instruction than either precepts or admonition, both to her children and servants. By a 'daily beauty' in her life, she may present a model by which all around her will insensibly mould themselves. 'Knowledge is power' only when it fits us for

* Mrs Parkes on Domestic Duties. Longman, London.

the station in which we find ourselves placed. Of all the social domestic and personal obligations of the young wife, her husband is the centre: when they are properly discharged, his welfare and happiness are certainly promoted, and his esteem, affection, and confidence established on a permanent basis. In neglecting them, he is neglected, his respectability diminished, and his domestic peace and comfort destroyed. One who, selfishly regardless of family duties, leads a life of dissipation and amusement, whose heart and soul are in the world, and never at home, is worthless as a wife and mother. She neglects the chief and positive duties of life, without fulfilling those of a minor character with any good effect. At home her example is injurious, and if abroad she possess any influence, it is merely of a temporary nature, resting, probably, on no securer ground than that of fashion. In pourtraying the *beau-ideal* of a married woman, I should describe one not absorbed in any single part, but attentive to the whole of life's obligations—one who neglects nothing—who regulates and superintends her household concerns; attends to, watches over, and guides her children, and yet is ever ready to consider, in moderation, the demands upon her time, which the numerous and various claims of society may make. Such appears to me to be a right sketch of the character of the married woman."

The house being the appropriate kingdom of the wife, it is necessary that she should be thoroughly mistress of all its details, and in no instance be left at the mercy of strangers or servants, who, even if anxious to please, seldom possess an education which renders them competent to carry on a household in its different parts. By a close, yet tempered supervision on the part of the mistress of the establishment, a corresponding degree of comfort, peace, and saving of expense, is produced, and by her laxity or carelessness, exactly the opposite results take place. Without proper discipline and firmness, all the cares of the young wife may be frustrated. We think it is Miss Edgeworth who says, in one of her excellent novels, that the greater proportion of the miseries of life *proceed from taking things for granted*. The good wife takes nothing for granted. She gives forth her orders distinctly, and, if requisite, *sees* them executed. Let those things be impressed on the minds of our fair young countrywomen. William Cobbett, who has written a good deal on the value of industry in household affairs, has well said "that the lover is blind; but that the husband has eyes to see with. He soon discovers that there is something [illegible] beside dimples and cherry cheeks; and I would [illegible] (says he) have fathers seriously reflect, and to be well assured, that the way to make their daughters to be long admired, beloved, and respected by their husbands, is to make them skilful, able, and active in the most necessary concerns of a family. Eating and drinking (continues he) come three times every day; the preparations for these, and all the ministry necessary to them, belong to the wife; and I hold it to be impossible, that, at the end of two years, a really ignorant sluttish wife should possess any thing worthy of the name of love from her husband. A woman who understands all things above mentioned is really a skilful person—a person worthy of respect, and that will be treated as such."

Besides being acquainted with the art of cookery, every woman who aspires to the character of a good housewife, and mother of a family, should be qualified by previous habits and education to act as a good sempstress. The wife of a man in the lower and middle ranks of life who cannot sew plain work, is a being to be pitied, but much more are her husband and family to be commiserated for their unhappy fate. If she have a disinclination to put her hand to this kind of labour, the misery is not the less, while her error is more heinous. Young women are in general but too apt to neglect this useful branch of education, and to address themselves almost exclusively to the acquisition of fashionable accomplishments calculated to make a show in company. But as soon as they are married, and have a family—that is, if not wedded to a man of wealth—they find their deficiencies. They discover that the amount of sewing to be given out is incalculable. Instead of doing so, they ought to be able to cut out and make all their own gowns, bonnets, and other articles of apparel; to mend all kinds of small holes or rents in garments, whether for the male or female members of the family; to darn stockings; and at least be able to sew loose buttons on the clothes of their husband or children. A woman who can do all this will save her husband many pounds in the year, and herself a great deal of trouble and vexation.

DIET.

Experience, and the advice of the best physicians, inform us that plain simple food does not only agree best with our stomachs and constitutions, but keeps us longest in a healthful condition. By adhering to the practice of dining on one substantial dish, and abstaining alike from pickles and stimulating liquors, we have the best chance of escaping epidemical and other diseases, and of enjoying a good state of bodily action and a pleasing serenity of mind. A liberal indulgence in made dishes, as well as in spirituous liquors, whether mixed or otherwise, may not *immediately* cause disease; and on that account little care is often taken as to what is either eaten or drunk. But the mischief lies in the predisposition to disease which such indulgences create. A person, for instance, is always more liable to take colds and sore throats after being intemperate than before. The human being, in short requires no pampering; and the more simple and elementary our food and drink are, we are the more likely to enjoy good health and long life. We are told by those best informed on the subject of diet, that in taking our daily food, we ought to draw our meals to a point; that is, beginning with a sufficient and nutritious breakfast—in the middle of the day taking a good dinner—and from that time till bed-time conveying as little as possible into the stomach, and by all means abstaining from heavy suppers.

A good housewife should endeavour to impress these rules on the minds of those about her, and, by her ingenuity, prepare such meals as will be both gratifying to the palate and good for the health, and of such variety as will not pall by repetition.

Some housewives, under the idea of being great savers, have a practice of making and storing up large quantities of currant jellies, jams, preserves, and pickles. But experience will soon convince the young housewife that there is little economy in laying out money in this way. Currant jellies and jams are certainly useful to form drinks in cases of colds, but the quantity used for this purpose is small in comparison to that which is needlessly devoured by children, or perhaps wasted. The economical should therefore make but a small quantity of such confections, and they will probably find it cheaper to buy from the shops of confectioners, as required, than lay in an expensive store. Pickles are far from being salutary to most constitutions, and the same degree of care should be taken in making such preparations. Scotch marmalade is a confection which, from its agreeable bitter quality, is allowed to be beneficial to the stomach, and may be safely administered.

COOKERY.

It is of great consequence to housewives that they should possess a proper cooking apparatus, for on this depends much of the comfort of their establishment, and the saving of a deal of money. It would be needless to give here any recommendation with respect to the number and variety of utensils, for common judgment directs on this point. But it may be of use to state, that the utmost attention should be bestowed in having a proper kitchen range or grate. In Scotland, in particular, the grates are all too large for small families, and are calculated to consume too much coal. By want of care on this point, a family in Edinburgh, where coal is 10s. per ton, is put to as much expense for fuel as a family in London, where coal is three times the price. One of the chief points in housekeeping, is to cook victuals with the smallest possible quantity of fuel; this may be attained by one of the smallest-sized ranges, having a narrow fire-place in the centre, only large enough for one vessel, with an oven upon the one side and boiler on the other; the boiler also going round the back of the fire-place. Both oven and boiler should thus be heated without disturbing the fire in the grate, or making additional fires on purpose. A range of this description, which will cost in London about L.4, 10s., will at once roast meat in front, boil water, bake a dish in the oven, and keep boiling and simmering at least three vessels on the fire and top of the boiler and oven. Roasting is always best performed with a hook and a twirling bottle-jack; a spit spoils a small piece of meat.

ROASTING.

TO ROAST BEEF.

The best piece of beef for roasting is the sirloin. It should be kept for some time, but the time must be regulated by the state of the weather. It should be wiped, to free it as much as possible from the mustiness that gathers upon all meat when kept for many days. When preparing to be roasted, if too fat, cut out part of the suet, which does admirably for puddings, dumplings, &c.; wash the beef in salt and water; wipe it quite dry, and put it on the spit, balancing it nicely without much handling; place it at a good distance from the fire, to allow it to get warmed to the heart before the outside is scorched. The fire must be quite clear and brisk. Allow a quarter of an hour to every pound of meat, and baste it very frequently. For gravy, use only its own juice and boiling water, of which pour a little over the browned part of the meat.

TO ROAST MUTTON.

The best parts of mutton for roasting are the leg (called in Scotland the gigot), the shoulder, and the loin. The piece may be kept longer than would be desirable for mutton for boiling. It should have a quick fire. A leg will take two hours to roast; but this, as well as the time required for roasting the other parts, must be regulated by the fire and the weight of the meat, and can only be learned by attention. The best sauce for roast mutton is its own gravy, drawn by a little salt and boiling water, poured over the part which is the most browned.

TO ROAST VEAL, PORK, AND LAMB.

The best parts of veal for roasting are the fillet, the breast, the shoulder, and the loin. Directions are given in another place for stuffing the fillet, and the breast should have the stuffing of the same ingredients. Both veal and pork should have a slow fire at first, and finished with a brisk quick fire; they require more time than beef or mutton. Pork should be scored in neat regular slices, to enable the carver to get through the skin. Lamb requires a fire similar to veal and pork. The best sauce for either is their own gravy, drawn by salt and water. Apple sauce is by many considered an improvement, as taking away from the insipid and sickly taste of pork. Lamb should have mint sauce served along with it in a sauce tureen.

TO ROAST PIGEONS.

Pick and wash them well, keeping on the feet; make a stuffing of the liver chopped, crumbs of bread, minced parsley, pepper, salt, and a bit of butter; put this inside; make a slit in one of the legs, and slip the other leg through the slit; skewer them, and roast them for half an hour, basting them well with butter. Serve with brown gravy; the gravy of roast beef does very well for birds of this description.

TO ROAST DUCKS.

Pick and singe them well; dip the feet in boiling water to take off the outer yellow skin; truss them neatly, turning the feet flat upon the back; wash them well inside, and make a stuffing of chopped sage, onions, bread-crumbs, pepper, salt, and a bit of butter; fill the inside with this, skewer them nicely, and roast them before a clear fire.

TO ROAST FOWLS.

Pick and singe the fowls; wash them well inside; break the legs by the middle of the first joint, drawing out the sinews; put a piece of butter and a little white pepper inside; tie the legs down with a small string; spit them, basting well with butter for some time after they are put to the fire. Twenty minutes to half an hour will roast a chicken; from three quarters to an hour will roast a good-sized fowl.

TO ROAST A TURKEY.

Pick and singe your turkey; draw and wash it well inside; break the legs in the middle of the first joint, and draw out the sinews; stuff the breast with minced suet, bread-crumbs, parsley, salt, a little Cayenne, and a scrape of nutmeg; thin it with milk, and stuff the breast. A turkey will take from an hour and a half to two hours; dust with flour, and baste frequently with fresh butter.

TO ROAST A GOOSE.

Pick and singe the goose very carefully; wash and dry it; mince half a dozen onions, a few sprigs of sage, a good piece of butter, a slice of bread grated, black pepper, and salt; stuff the goose with this; spit it, and put it down before a clear brisk fire. It will take two hours and a half to roast.

TO ROAST PARTRIDGES AND PHEASANTS.

Clean the birds well by drawing them as fowls, but leave the head and feet on; make a slit in the neck, and draw out the gizzard by it; make a hole between the sinews of one of the legs, and put the other leg through it; twist the neck round the left wing, and skewer down the pinions; put them down before a clear fire, and baste them with butter; when about half done, dust a little flour over them. A partridge will take from twenty minutes to half an hour, and a pheasant three quarters of an hour. They must be laid on toasted bread, soaked in the dripping-pan, and a little brown gravy poured over them. Melted butter or bread-sauce must be served in a sauce-tureen. Grouse and blackcock should be dressed and served in the same manner.

A BEEF STEAK.

Cut slices of three quarters of an inch or an inch thick, from the rump; beat them, and put them on a gridiron, on a clear slow fire; turn them constantly, to preserve the juice as much as possible; when done, put on a hot plate, and sprinkle a little salt on each side; the juice is much better preserved when the steak is done in a small Dutch oven, with hooks inside, upon which the steak is hung, with a plate underneath to catch the gravy. This method is much superior to the common way of dressing a steak, as it also does it without scorching.

A SUCKING PIG.

Procure a young pig, not exceeding three weeks old; scrape off the hair, by scalding it in boiling water; take out the entrails, and soak it well in cold water; cut the feet off by the first joint, and draw down the skin of the legs over the joint. For stuffing, take a handful of sage, eight or ten onions, a large cupful of grated bread-crumbs, a good piece of butter, and plenty of pepper and salt; sew up the opening, and spit it with the head next the point of the spit; baste frequently with fresh butter, and, when warmed and moistened, keep wiping with a damp cloth, to make the skin clear and crisp. A pig will take two hours and a half or three hours to roast. A little veal or beef gravy poured over the pig, and mixed with the stuffing when the pig is cut up, does very well, and apple-sauce served in a sauce tureen.

A FILLET OF VEAL.

Cut out the knuckle neatly, without disfiguring the veal; make a stuffing of grated bread, minced suet, chopped parsley, a little grated nutmeg, a little grated lemon peel, and pepper and salt. (Eggs may be used in this stuffing, but we do not approve of them, either for this or any stuffing, as they only serve to harden it.) Stuff the flap of the fillet with this; roll it up neatly and firmly; bind it with tape, and roast it before a clear fire; cover the ends with buttered paper, and baste frequently with butter; take off the paper a short time before the meat is done; a little salt laid on the brownest part of the roast, and a little boiling water poured over it, will extract a rich enough sauce. Garnish with sliced lemon.

BOILING.

TO BOIL A TURKEY.

Pick and singe it carefully; cut the legs at the first joint, and pull out the sinews; clean the turkey well inside; pull down the skin, and draw the legs inside; put pepper inside, and make a stuffing of half a pound of suet, a cupful of bread-crumbs, a few sprigs of chopped parsley, some white pepper, salt, and a little mace or grated nutmeg; stuff the breast with this; skewer it down, and boil it in a cloth, and boil according to the age and size of the turkey; if young, an hour will be enough; if old and tough, it will require two hours or two hours and a half. Serve with parsley, celery, or oyster-sauce poured over it.

TO BOIL A ROUND OF BEEF.

Wash the meat well; if large, cut out the bone; roll it up firmly, and bind it with tape; it must be put in with as much cold water as will entirely cover the meat; scum it frequently; keep the pot closely covered, and boil slowly and equally, allowing a quarter of an hour to every pound of beef. The vegetables should be boiled separately, as they are apt to have a greasy flavour when boiled along with the meat. The beef should be carefully wiped, or have boiling water thrown over it before dishing. Garnish with carrot, and either greens or cabbage. When cold, cover it with a cloth to keep it moist. If the beef is not to be used at all when hot, it will improve it very much to let it cool amongst the liquor in which it was boiled.

TO BOIL A LEG OF MUTTON.

A leg of mutton will be tough and hard if newly killed; it should be kept for four or five days, to make it tender; press down the shank, and cut a small piece off it; put it on with cold water; when it boils, scum it carefully and frequently; two hours of slow equal boiling will be sufficient for a good-sized leg of mutton. The vegetables may be boiled along with the meat, carrot, and turnip, and laid round it when dished. Melted butter, with capers, is the most appropriate sauce for boiled mutton. Excellent broth may be made next day of the liquor, with sliced carrots and turnip, a grated carrot, a few onions, a cupful of barley, and a little shred cabbage.

TO BOIL LAMB.

Lamb, when slowly and nicely boiled, is a very delicate and excellent dish; a leg of lamb will take an hour and a half to boil; it may be garnished with the loin cut into steaks, fried, and laid round it; pour parsley sauce, or melted butter, and a spoonful of vinegar over it.

TO BOIL HAM.

Put on the ham with plenty of cold water, and when it boils, scum it frequently, to remove the grease which is constantly rising to the top; half an hour before dishing, take it off and skin it; strew fine bread-crumbs over the ham, and set it before the fire to brown slightly. Garnish with greens or cabbage.

TO BOIL A TONGUE.

Soak the tongue in water all night before using, if hard; put it on with cold water, and boil it from two hours and a half to three hours; scum it before dishing, and glaze it, if convenient. Garnish with greens or cabbage.

TO BOIL FOWLS.

Choose white young fowls; pick them carefully, and singe with white burning paper; wash them well; cut the legs off by the first joint; draw down the skin of the body over the legs; tie a piece of tape round them; boil them in plenty of water slightly warmed. For chickens, twenty minutes to half an hour will be enough; from that to an hour and a half for older fowls. For particular parties, fowls ought to be boiled in a cloth to keep them perfectly white; if not, a little broth may be made, by adding a little rice well washed, a few sliced onions, a little shred parsley, and a blade of mace. Serve with parsley, celery, or egg-sauce.

TO BOIL VEGETABLES.

All vegetables, with the exception of potatoes, ought to be put upon the fire in boiling water and salt. They should be soaked amongst cold water and salt until they are to be boiled. A small bit of soda, the size of a nut, will preserve their colour, and will also make them more tender. Green peas should have a small bit of white sugar boiled along with them, and some salt. A few leaves of mint may be boiled along with green peas, if the flavour be liked. All vegetables ought to be boiled in an open pot, so that the colour may be preserved; and they ought also to be boiled very quickly. We do not mean to give full directions for every different vegetable; but by attending to the above rules, the young cook cannot go far wrong; only, we may remark, nothing looks worse at a table than ill-cooked vegetables. Give them plenty of time to boil thoroughly, but they should not be allowed to stand for any length of time after they are ready, as they lose both flavour and colour by it. Allow them to stand for a few minutes in a drainer, to drip all the water from them before going to table.

TO BOIL RABBITS WHOLE.

Wash them well in warm water; make a stuffing of suet, bread-crumbs, parsley, onions, pepper, and salt, minced altogether; sew this into the belly of the rabbits; truss them nicely, as for roasting; put them in a cloth, and boil slowly for an hour in as much water as covers them; make a sauce of melted butter and flour thinned with milk, a good many onions parboiled, white pepper and salt, pour this over the rabbits when to be served.

PIG'S CHEEK.

Take the half of a pig's head; clean and wash it well; put it on to boil with rather more cold water than will cover it; boil it till all the bones will pull out from the meat; cut it down, while it is hot, into handsome pieces of an inch square; season it with black and Jamaica pepper and salt; put it into a stew-pan, cover it with a plate on the top, and press it down with weights; when it has stood in this manner in a cool place for a day, turn it out, and garnish with parsley. The head will be the better of lying amongst salt for a day or two previous to being boiled.

SOUPS.

BROWN SOUP.

Take an ordinary sized hough of beef; have it broken in several places; cut the beef from the bones; take out part of the marrow, and lay on the bottom of your stock-pot; lay the meat above, and then the bones, and place it on the fire to brown; let it brown for nearly an hour; add a pint of water, to draw the juice from the meat; let it stand a little longer, then fill up the pot with cold water; put in two carrots and turnips, a dozen onions, whole black and Jamaica pepper, a stalk or two of celery, and a bunch of sweet herbs; let it boil slowly for six hours, then put it gently through a hair sieve; you may fill up your pot with more water and vegetables as above, and boil for six hours more. This forms a stock for mock-turtle or any other soup. It is advisable to make brown soup on the day before being used, as the fat can be better taken off when the soup is cold. Vermicelli or vegetable soups may be made by boiling or preparing them separately, and adding them to brown soup.

MOCK-TURTLE SOUP.

Take a calf's head, and wash it well; put it on to scald for a few minutes; take it off, and put it amongst cold water, and scrape off the hair. When it is perfectly clean, put it on to parboil; when the bones are loosened, take it off; and when cold enough, cut it into handsome pieces of an inch square; scrape and cut the tongue in the same manner; take the stock which has been made from brown soup, or the liquor in which the head was parboiled, and four pounds of shin of beef, and a knuckle of veal well broken; add to this a dozen onions, a carrot and turnip, a bunch of sweet herbs, and black and Jamaica pepper, whole; let it boil slowly for four or five hours; strain this, and, when cold, take off the fat; put half a pound of butter into a stew-pan, and, when melted, put in two handfuls of flour, and let it brown nicely, stirring it all the time; add a little of the stock, a few onions, a sprig or two of sweet basil, and a few bunches of parsley; let all this boil slowly for nearly an hour; then strain it through a sieve into your pot, where you have previously the stock and hash; add the juice of one lemon, a wine-glassful of ketchup, a little Cayenne pepper and salt to taste, four glasses sherry or cape wine, and let the whole boil for an hour. When to be served, add two dozen egg-balls. This soup will keep for a fortnight.

OX-TAIL SOUP.

Take two or three well-sized ox-tails; divide them at the joints; soak or wash them in salt and water, and dry them; take two or three pounds of a shin of beef, a carrot and turnip, a bunch of sweet herbs, a head of celery, and some black and Jamaica pepper-corns; add to this three quarts of cold water; let it boil for two hours; strain it, and put in the tails to stew amongst it till tender; cut carrots in straws and scooped turnips; stew them amongst butter, and when soft, drain them, and add them to the soup. This soup may be thickened by browning a little flour and butter, but it is generally preferred clear.

HARE SOUP.

Take a fresh hare, and, when skinned, wipe it well with a cloth; cut off the belly, and take out the entrails, taking great care not to lose any of the blood; cut the hare into small pieces, and wash them well, and put the washings and the blood through a fine sieve into your pot, along with the meat, and two or three pounds of beef cut into pieces, or the stock of beef previously made, two carrots, and two turnips, six onions, a few sprigs of thyme, some black and Jamaica pepper-corns, and four table-spoonfuls of flour mixed with cold water; keep stirring this until it boils; let it boil for an hour and a half; pick out the best pieces of the hare, and beat the rest of the meat and soup through a sieve; put it again on the fire, with a few fresh onions, a stalk or two of celery cut down, the best pieces of the hare, and a glass of mushroom ketchup; boil this for half an hour, and serve the pieces of hare in the tureen along with the soup. Two glasses of port wine to the tureen of soup will be sufficient to give it a mild flavour, which is all that is desired, by putting wine in the soup.

MULLIGATAWNY SOUP.

Make a stock of beef or veal, with vegetables and herbs; take then a good large fowl, parboiled, skinned, and cut into handsome pieces, or veal sliced and fried; take a dozen good large onions cut down, half a pound of sweet butter, two handfuls of flour, and two dessert-spoonfuls of curry powder; brown them well in a stew-pan, stirring all the time; add a little of the stock, and rub this through a sieve into your stock; put in the meat or fowl, and boil for half an hour; add the juice of a lemon, and two glasses of sherry wine. Before serving, put in two table-spoonfuls of rich cream. A dish of rice should be served with mulligatawny soup.

KIDNEY SOUP.

Make a stock of three or four pounds of a shin of beef; brown it, as directed for brown soup, and add two carrots, two turnips, a few onions, a stalk of celery, and some whole black and Jamaica pepper; let all this boil slowly for five or six hours, and, when ready, put it through a sieve; cut down two beef kidneys, and stew them amongst some of the stock for an hour; when ready, put them amongst the stock, and strain the soup in which they were stewed into the soup.

PIGEON SOUP.

Take three or four pounds of the leg or neck of beef, two carrots, two turnips, four onions, some whole black and Jamaica pepper, a head of celery; boil this slowly for two or three hours; brown a good piece of butter in a stew-pan, and put in a handful of flour; brown them together for a few minutes, and add the strained stock to this; stew or fry the birds, and put them amongst the stock; season with white pepper and salt. Chopped lettuce may be added to this soup if approved, and a glass of port wine is by some considered a great improvement.

PEAS SOUP.

Take a good marrow-bone, or the bones of cold roast beef, which make better soup than any other kind of meat whatever; a shank or slice of ham may be added, if the flavour be liked; break the bones in several places; put in as much water as you think will make a sufficient quantity of soup, allowing a little for boiling down; take two pounds of the best split peas; wash them, and put them on with the cold water and the bones; add to this two carrots and two turnips, a stalk of celery, half a dozen onions, a bunch of thyme, and some whole black and Jamaica pepper. Let all this boil for two hours, stirring often, as it is very apt to stick to the bottom of the pot. When the peas are quite soft and broken down, take it off, and put it through a sieve into another pot; rub it well through until all the pulp be mixed with the soup; add salt melted in a little water, and boil for a few minutes; and serve with toasted bread, cut into little square pieces, and put into the soup.

LEEK SOUP.

Take three or four pounds of a coarse piece of beef—the shin is considered the best; put it on with as much water as you think will make a sufficient quantity of soup; let this boil for two hours, and take one or two bunches of leeks, in proportion to the quantity of water; cut them into pieces of an inch long, and wash them well. (They must be particularly well washed, as the sand is apt to lurk about the folds of the leeks more than any other vegetable.) Put them into the soup, and let them boil for an hour. The beef, if not too quickly boiled, will eat very well. A fowl is considered a great improvement to leek soup, to be boiled along with the beef. It is then called in Scotland cockaleekle.

HOTCH-POTCH.—(A SCOTCH DISH.)

Put on as much water as you think will make a sufficient quantity of soup; when it boils, put in three or four pounds of the back ribs of mutton, six young turnips cut into squares, six carrots cut down and two grated, a stock of cauliflower and a stock of lettuce cut down, a few young onions, and a peck of green peas, the one half along with the other vegetables, and the other half about half an hour before the soup is ready for dishing. When the meat has boiled for an hour and a half, take it out, and cut it into chops, and add it to the soup before dishing. This is considered a very excellent soup.

MUTTON BROTH.

Take of the back ribs or breast of mutton three or four pounds; to this add water in proportion; and when the water boils, put in a breakfast-cupful of barley; scum this, and let it boil for an hour; add to it one carrot grated and one cut small, two small turnips, and six onions sliced; boil for an hour more, and serve the meat, with boiled carrot and turnip laid round it, and a little melted butter over it, or in a tureen. Beef broth is made in the same manner, only substituting beef for mutton, and greens and leeks for carrot and turnip.

CHEAP BROTH, WITHOUT MEAT.

Put a table-spoonful of butter amongst a small potful of cold water, a tea-cupful of rice washed, or half a cupful of barley, a carrot and turnip grated, and a few sliced onions; boil this for an hour and a half. Do not put in the rice until the broth be nearly ready.

POTATO SOUP.

This soup may be made of any bones or trimmings of meat; the bones of cold salt meat or roast beef bones are preferable; boil them for an hour and a half amongst as much water as you think will be sufficient for the quantity of soup you want; put this through a sieve to keep back all the pieces of fat or loose meat; add then as many parboiled potatoes as you think will make it thick enough, and half a dozen sliced onions, a small carrot grated, and a few bits of celery; season this with white pepper and salt, and boil for half an hour more. This soup may be made very well from dripping, and seasoned with a few onions and pepper and salt.

STEWING.

TO STEW BEEF.

Take six, eight, or ten pounds of a brisket of beef; let it brown for ten minutes in the bottom of your stew-pot; when sufficiently browned, lift it out, and lay two or three skewers in the bottom of the pot; put in [illegible], along with as much water as will half cover [illegible] stew it slowly for two hours, and, when ready, strain off the gravy, and thicken it with a little browned butter and flour; cut down into handsome shapes a boiled carrot and turnip, and add them to the gravy; season highly with pepper, salt, Cayenne, and a glass of ketchup; boil all together for a few minutes, and pour over the beef. The meat will be improved by lying in salt for two days before being used.

TO STEW A SHOULDER OF MUTTON.

Take a pretty large shoulder of mutton. When to be used, cut out the shoulder or blade-bone without destroying the meat; make a stuffing of bread-crumbs, minced parsley, a few sprigs of green or dried sweet herbs, a quarter of a pound of minced suet, a shred onion or two, and pepper and salt; lay this inside the shoulder, and roll it up, and skewer or bind it firmly with tape; rub the bottom of a stew-pan with suet or butter, and brown the mutton. When sufficiently brown, lay two skewers in the bottom of the pan; add some stock or boiling water, and let it stew for an hour and a half; the gravy drawn from itself will be sufficiently rich for sauce, seasoned with pepper and salt, and scummed before being poured over the meat.

STEWED VEAL.

The best parts of veal for stewing are the fillet, the breast, and the shoulders; the shoulder must be stuffed when the knuckle is cut out, which must be done neatly, without disfiguring the meat; the stuffing should consist of bread-crumbs, minced meat, chopped parsley, grated lemon peel, white pepper and salt; fill the shoulder and sew it up; rub the bottom of a large stew-pan with butter; lay in the veal, and brown it on both sides; when sufficiently brown, put in a pint of cold water, and stew it slowly for two hours, or, if large, two hours and a half. Before it is to be dished, draw off the gravy, and if not thick enough, brown a little butter and dust in a little flour; put it amongst the gravy, and season with Cayenne, salt, and the squeeze of a lemon (a glass of sherry will be an improvement); scum the sauce, and pour it over the meat before dishing.

TO WARM A COLD GIGOT OF BOILED MUTTON.

When there is any left of a cold leg or gigot of mutton, it is not good to be eaten when cold; it can, however, be warmed up the second day, so as to taste as well as when newly cooked; take the mutton and lay it upon an inverted pie-dish in an oval pot, with as much water as will steam it without touching the meat; let it lie in this for an hour, and when to be dished, pour some melted butter, with a spoonful of vinegar, over it.

TO STEW KIDNEYS.

Cut the kidneys into slices, wash them, and dry them with a clean cloth; dust them with flour, and fry them with butter until they are brown; pour some hot water or beef stock into the pan, a few minced onions, pepper, and salt, to taste; let them stew slowly for an hour, and add a spoonful or two of mushroom ketchup before dishing.

MINCED COLLOPS.—(A SCOTCH DISH.)

Take two pounds of beef, and having cut out the skins and gristles, mince it very fine, with a proportion of suet; either mince a few onions with the collops, or fry them in butter before putting the collops into the pan; beat them, and stir in a little flour, some water or stock, and season with pepper and salt to taste; add a little ketchup before they are dished.

TO STEW PIGEONS.

Pick and wash the pigeons well, trussing them as fowls for boiling; put a piece of butter and pepper inside; dust them with flour, and brown them in a covered stew-pan with a good piece of butter; put in a little more flour; add some stock or water; season them highly, and let them stew slowly for twenty minutes or half an hour. Before dishing, add half a glass of port wine, if the flavour be approved.

TO STEW RABBITS.

Wash the rabbits well, cut them into pieces, and put them on to scald for a few minutes; melt a good piece of butter; fry the rabbits in this for a few minutes; when slightly browned, dust in some flour; then add as much stock or water as will make sufficient sauce; put in half a dozen large onions, or more in proportion if small, two spoonfuls of mushroom ketchup, some white pepper and salt to taste; stew for an hour slowly.

TO MAKE POTATO-STEW.

Take any cold fat meat you may have, salt or fresh, or a good bit of fresh dripping; pare some potatoes, and cut them in pieces; lay a few slices of your meat, or pieces of dripping, and then the potatoes, two or three sliced onions, some black pepper and salt, and a little water; cover it up, and let it stew for an hour, taking care not to let it stick to the bottom of the pan. This is a very savoury and cheap dish.

AN IRISH STEW.

Take two or three pounds of back ribs or loin of mutton; cut it into chops; put it in a stew-pan with pared potatoes, sliced onions, pepper, salt, and a little water; put this on to stew slowly for an hour, shaking it occasionally to prevent it sticking to the bottom of the pan. Cold mutton or lamb is almost as good made up in this manner as fresh meat.

PIES AND DUMPLINGS.

VEAL PIE.

Cut chops from the back ribs or loin; trim off the bones and flatten them; shake minced parsley, flour, white pepper and salt, over each layer of the meat; add a little gravy drawn from the trimmings, and cover the pie. Some add slices of bacon.

PIGEON PIE.

Pick and clean the birds well, cutting off the wings, and trussing them in the same manner as boiled fowls; put a little bit of butter, flour, shred parsley, pepper and salt, in the inside of each bird; lay slices of beef or veal in the bottom of the dish; lay in the birds, and the wings and gizzards round them, and, if approved, a few sliced hard-boiled eggs; add water or gravy; cover the pie, and bake for an hour.

GIBLET PIE.

Clean and scald the giblets; cut them into neat pieces; lay slices of beef, mutton, or veal, in the bottom of the dish; put in the giblets, and strew in a small shred onion and parsley, pepper, salt, and a little flour, to thicken the gravy; cover the pie with a common or puff paste.

RABBIT PIE.

Soak and wash the rabbits well, and cut them into pieces; lay some thin slices of bacon in the bottom of your pie-dish, or, if the bacon flavour be not liked, some slices of beef may be substituted, or the pie may be made without either, only this serves to enrich it; lay in the rabbits; season it well with pepper and salt, and a dust of flour; add some stock or water; cover with paste, and bake for an hour. The oven should not be too hot.

BEEFSTEAK PIE.

Take some slices of beef from the rump, or hock-bone, tender and well mixed; flatten them, and season with pepper and salt; roll them up, or lay them in the dish; put in some stock, gravy, or water, and a little flour to thicken it; cover it with paste, and bake for an hour.

LAMB PIE.

Cut chops from the back ribs, loins, or from the thick of the leg; lay the meat in your dish, and season with white pepper and salt; add some gravy or water; cover, and bake for three quarters of an hour.

ROOK PIE.

Skin the birds, cut out the backbones, and steep them in water for twenty-four hours, to extract the bitter flavour; season them with pepper and salt; lay a beefsteak in the bottom of the dish; add a little good gravy, and cover with a common crust. They will require three quarters or an hour's baking.

MINCE PIE.

Mince a pound of rich beef-suet, a pound of grated bread, a pound of apples pared and cored, minced separately from the suet, a pound of currants washed and picked, a pound of stoned and chopped raisins, an ounce of ground cinnamon, an ounce of ground ginger, an ounce of orange and an ounce of lemon peel candied, a tea-spoonful of Jamaica pepper and a little salt, half a pound of raw sugar, one nutmeg grated, two glasses of brandy and two of sherry; mix all together, and lay the bottom of your pan or dish with rich paste; fill in the mince, and cover the top with barred paste. A marrow pasty is made in the same way, with marrow instead of suet. This will make a great many mince pies; but a proportion of the ingredients may be taken, or it may be put into a can, and it will keep for a long time. Add a little more spirits before using.

AN APPLE PIE.

Pare and core ten or a dozen large apples; cut them down, and lay them neatly in a baking-dish; season with cinnamon, sugar, and a few cloves; add a little water, and cover with a puff paste, iced on the top, and bake in an oven.

A BEEF DUMPLING.

Take a pound of suet; mince it very fine; mix it up with a pound of flour and a little salt; pour in as much cold water as will allow it to mix up to a paste; roll it out, and lay in slices of beef as for steaks, pepper, and salt; dip a cloth in water, and shake a little flour over it, and boil the dumpling in it, or in a basin tied in a cloth; boil it for an hour and a half or two hours; a few sliced onions put in along with the beef will be an improvement. A pound of suet will make a very large dumpling; for a small family, half a pound will be sufficient, and the same proportion of flour.

AN APPLE DUMPLING.

Take a pound of fresh suet; mince it very fine; mix it with a pound of flour and a little salt; pour in some cold water, and work it up to a proper paste, but do not handle it much, as that makes it heavy; roll it out, and have your apples pared and cored; lay them on the paste, with plenty of brown sugar, cinnamon, and a few cloves; gather it up, and boil it either in a buttered basin tied in a cloth, or in a cloth dipped in water, and a little flour sprinkled over it without the basin; boil it for three hours. Serve with cream in a sauce-tureen. If for a small family, half a pound of suet will be enough, as a pound will make a very large dumpling.

A GOOSEBERRY DUMPLING.

Make the paste as directed for apple dumpling, and have the gooseberries picked; lay them in the paste along with a good handful of brown sugar; gather it up, and boil as above. Serve with cream.

PUDDINGS.

PLUM-PUDDING.

Take a pound of the best muscatel raisins stoned and minced, a pound of currants washed and picked, a pound of rich beef-suet minced, and a pound of stale bread-crumbs, six eggs well beaten, an ounce of cinnamon and an ounce of ginger in powder, half a pound of sugar, one nutmeg grated, the grate of a lemon, a tea-spoonful of Jamaica pepper, and a little salt; mix this all together with as much milk or cream as will make it sufficiently thin, and add a glass of rum or brandy; butter a pudding-pan well, or if to be boiled in a cloth, wet it and dust it with flour; boil it slowly and regularly for four or five hours; turn it carefully out, and serve with pudding sauce. This will make a very large pudding; but the proportion of the ingredients may be taken, as three quarters of a pound of each, or half a pound, if sufficient.

PLAIN PUDDING.

Take half a pound of suet minced, a good slice of stale bread broken down, a quarter of a pound of currants cleaned, a little cinnamon and ginger, some brown sugar, and a scrape of nutmeg, a little spirits of any kind, two eggs, and milk to make it up to the proper consistency wanted; boil for two or three hours in a pudding-pan or cloth, and serve with a little melted butter, sugar, and a scrape of nutmeg.

AN APPLE PUDDING.

Pare, core, and cut down, as for a pie, six or eight apples; butter a pudding-pan well; butter also a few slices of bread with sweet butter, and line the pudding-pan with the bread and butter; lay in the apples; season with ground cinnamon, sugar, and a few cloves; cover the top with a slice of bread and butter, and bake before the fire in a Dutch oven. When done, turn it out, and serve with cream in a sauce tureen.

A BREAD AND BUTTER PUDDING.

Beat four eggs well, with a little ginger, a little cinnamon, and a scrape of nutmeg; butter two or three slices of bread, and also a pudding-pan or shape; lay a slice of bread in the bottom of the pan; shake a few currants over it, then another slice of bread and butter, then a few currants, and so on till all the bread is in; mix up the eggs with milk, and pour it over the bread; either bake it before the fire in a Dutch oven, or steam it, and serve with pudding sauce.

PUDDINGS IN HASTE.

Take half a pound of suet minced, the same of grated bread, a quarter pound of currants, the grate of a lemon, a scrape of nutmeg, some sugar, and a little salt; mix this up with three or four eggs, into little balls; put them in a pan of boiling water, and boil them for half an hour; when ready, they will float on the top of the water; pour over them a sauce made of a little melted butter, a little sugar, a small quantity of spirits or wine, and a scrape of nutmeg.

A BREAD PUDDING.

Boil as much milk as you think will be sufficient for the size of the pudding you want; break down a thick slice of stale bread, and a small piece of butter, into a basin; when the milk is just rising in the pan, take it off and pour over the bread, and cover it up for a few minutes; beat three or four eggs, with a tea-spoonful of ground cinnamon, and the same of ginger, the grate of a lemon, and sugar to taste; stir this amongst the bread and milk; a little rum may be added, stirring all the time. This pudding may be baked before the fire, or boiled in a pudding-pan well buttered, and turned out. Serve with pudding sauce.

A BATTER PUDDING.

Take four eggs and beat them well, with as many table-spoonfuls of flour, a little cinnamon and ground ginger, the grate of a lemon and the grate of a nutmeg; mix this with milk, until it is rather thicker than the consistency of a pancake, and boil it in a buttered pudding-pan for an hour.

A CUSTARD PUDDING.

Take four eggs and beat them well, with two spoonfuls of flour; season with sugar, cinnamon, and lemon grate; pour on [illegible] boiling milk, and either boil it in a buttered pudding-shape, or bake for half an hour before the fire in a Dutch oven.

A RICE PUDDING.

Take a cupful of rice well washed, and boil it amongst water; when ready, drain the water off, and put it on again with a good piece of butter, or a little suet minced very fine, and as much milk as you think enough for the size of the pudding; when cool, mix this with four beat eggs, cinnamon, ginger, nutmeg, and the grate of a lemon; sweeten with sugar to taste, and bake for half an hour before the fire in a Dutch oven.

A RICE PUDDING WITHOUT EGGS.

Take a quarter pound of rice, washed well, and two or three table-spoonfuls of brown sugar, a little ground cinnamon or nutmeg, and a good quantity of milk; a few currants may be added, and bake in an oven.

POTATO-PUDDING WITH EGGS.

Pare and boil a few potatoes; when ready, pour and mash them with a good bit of butter; beat them with a fork, to make them light; beat three eggs, and add a little cinnamon, ginger, nutmeg, the grate of a lemon, and a little brown sugar; mix the potatoes with milk, till the consistency of a batter pudding; pour in the eggs, and bake it in a Dutch oven before the fire.

MISCELLANEOUS DISHES.

A SCOTCH HAGGIS.

Procure the tripes and pluck of a sheep, and clean the tripes very carefully; parboil the heart and lights, half of the liver, and a small part of the tripe, for an hour and a half; let them cool, and then mince them very fine; mince also a pound of fresh suet, and grate the parboiled liver; mix this along with two handfuls of oatmeal (previously browned before the fire), a few onions, black and Jamaica pepper, and salt; take the large bag, and wash it first with cold water, then with boiling water; when quite clean, fill in the mince, but do not let it be more than half full, else the bag will burst in the boiling; add a little of the liquor in which the meat was parboiled, and sew up the bag; put it on the fire in boiling water, and prick it frequently with a large needle, to let the air escape; boil it for three hours, with a plate in the bottom of the pot.

POACHED EGGS.

Put a pan upon the fire half filled with boiling water, and put in some salt; when it has boiled through, take it off, and break the eggs gently into it, and let it stand upon the table for three or four minutes; in the meanwhile, toast some slices of bread on both sides; pare off the crust, and butter it; lift the eggs out with a fish-slice or flat spoon, and let them drip for half a minute, and lay them upon the toast. This is by far the best way of poaching eggs, as the boiling breaks them. A spoonful of vinegar dropped into the water serves to firm them.

POTTED HEAD.

Take the half of an ox head and wash it well, taking out all the blood and slimy parts from the nose, and the black part of the eyes; put it on the fire in as much cold water as will more than cover it; boil it until the bones shake out of the meat; strain the soup through a sieve, and let the meat be quite cool before cutting it down; scum all the fat from the stock, and preserve it for other purposes; cut down the meat into neat pieces of half an inch square; put them to the soup, and season with black and Jamaica pepper and salt to taste; allow it to boil altogether for half an hour; dish it into small shapes, and, when cold, turn it out. This is a cheap and excellent dish, and will keep for a fortnight. If it be observed to be getting soft and old tasted, put it on to boil for a few minutes; dish it again, and it will keep for a few days longer.

WHITE ROUX.

Take half a pound of butter; put it into a small stew-pan, and, when melted, shake into it two handfuls of flour; keep stirring constantly for ten or fifteen minutes, but do not let it get brown; dish it up in an earthen pot, and it will keep for weeks. This will be found very useful for sauces or gravies, as, by adding a spoonful of it, it will thicken them, without the trouble of making it every time. Brown roux is made in the same way, only allowing it to brown, and is used for brown sauces, where the other is for white sauces—as for veal and other white meats. We have said, in our directions, where a sauce of this kind was requisite to brown or melt the butter; but if this be made previously, it will do equally well just put amongst the gravy and allowed to boil through.

BROILED CHICKEN.

Pick and singe the chicken; wash and truss it, and cut it down the back; season it with white pepper and salt in the inside; lay it on a gridiron, at a good distance from the fire, to allow it to be done through, before being scorched outside; keep the skin side uppermost, and rub it with butter while broiling; if wanted very light, the skin may be taken off. Serve with parsley-sauce, or plain melted butter.

FRICASSEED CHICKEN.

Cut down the chicken, and stew it slowly in veal stock, or a little gravy made from any trimmings of meat you may have; cover it up, and allow it to stew for half an hour, with two or three onions and a blade or two of mace. The sauce must be strained, and thickened with a little white roux, if you have any, or a little butter and flour. When to be served, put in a glassful of cream, and the beat yolk of an egg; it must not boil after the cream is added, as it will break and curdle. The grate of a lemon and the grate of a nutmeg will improve the flavour.

POTATO-BALLS.

Wash, pare, and boil some dry mealy potatoes; pour the water from them, and beat them with a bit of butter; season them with an onion shred very fine, white pepper, and salt; roll them up into balls the size of an egg, and either fry them in fresh dripping, or brown them below a roast.

POTATO-FRITTERS.

Boil and mash some potatoes; add a bit of butter, white pepper, and salt; thin them with milk, till they are of the consistency of thick pancake batter; drop them into a frying pan of boiling dripping. Brown them, and serve very hot.

TO FRY TRIPE.

The tripe must be washed well, and boiled for three hours; take the thickest parts, and dry them well with a cloth; make a batter of three eggs, three table-spoonfuls of flour, a little salt, and a little sweet milk on small beer; dip the tripe in this, and fry it in a pan, with as much fresh dripping as will almost cover it; when nicely browned, take it out, and lay it before the fire for a few minutes before serving, to absorb the dripping. Garnish with fried parsley.

SCOTCH COLLOPS.

Cut the meat into slices, and beat them well; put a good piece of butter in a frying-pan, and, when hot, lay in the meat; strew sliced onions and pepper and salt over it; fry slowly, having the pan covered; when ready, draw aside the collops, and put in a little flour, some stock or boiling water, and a little ketchup. Serve hot.

TO FRY SAUSAGES.

Cut the sausages into links, and fry them in butter; when ready, lay them on toasted bread, cut into small pieces. Poached eggs may be laid round the dish if approved.

TO FRY LIVER.

Cut down and wash a fresh sheep or calf liver; dry it, and dust it with flour; fry it with a good piece of butter; when put in the pan, strew some finely minced onions and pepper and salt over it; fry it slowly, and when sufficiently done, lift it out, and pour a little water or gravy into the pan; toss it round for a minute or two, and pour it over the liver.

TO DRESS TRIPE.

Choose the thickest and fattest parts of the tripe; soak and wash it well in cold water; put it on to boil with as much water as will cover it; let it boil slowly for four hours; when to be used, cut down half a dozen onions, or boil them whole amongst a little of the liquor in which the tripe was boiled; melt a table-spoonful of butter, the same of flour, and a little sweet milk; add the onions to this, and a little salt, and pour it over the tripe before dishing. The onions should never be added, unless to be used immediately, as they are very apt to sour the tripe.

TO DRESS A VEAL PLUCK.

Parboil the heart and lights for an hour; take them out, and when sufficiently cold, mince them down; put them in a pan, with minced onions and parsley, a little flour, salt, pepper, and one or two table-spoonfuls of mushroom ketchup; thin this with a little gravy, or some of the liquor in which the pluck was boiled; let it [illegible] for half an hour; cut down the liver, and [illegible]ngst butter, and lay round the mince.

ANOTHER WAY.

The heart may be stuffed with bread-crumbs, onions, and parsley minced, pepper, salt, a little suet, and then roasted; the lights may be dressed as above, and the liver fried, and the hash and liver laid round the heart.

A HARRICO OF MUTTON.

Take two or three pounds of the back ribs or loin of mutton; cut it down into chops; skin and flatten them; season them with pepper and salt; rub them with flour, and fry them in butter or fresh dripping, and put them on to stew with their own gravy. A little stock may be made of the trimmings of the chops, an onion or two, and a piece of carrot and turnip; or, put a little water to them, and let them stew for a short time very slowly; parboil a carrot and turnip; cut them down into neat shapes, along with a few onions, and add them to the chops; season it well, and let it all stew for a quarter of an hour. Dish the chops neatly, and pour the sauce and vegetables over them.

DRESSED MUTTON CHOPS.

Cut the chops from the back ribs or loin; trim and flatten them neatly, cutting off the skin; dust them with flour, and dip them in beat egg; strew bread-crumbs, chopped parsley, onions, white pepper and salt, over them; fry them in butter. They will keep for several days.

VEAL CUTLETS.

Slice the cutlets from the back ribs, loin, or fillet; trim and flatten them; dust them with flour; rub them with beat egg; and strew bread-crumbs, parsley and onions shred fine, lemon grated, and white pepper and salt, over them; fry them in butter; when nicely browned, lay on a dish before the fire; dust a little flour amongst the butter, a little stock or water, the juice of a lemon, a little Cayenne pepper, a spoonful of ketchup, and half a glass of sherry wine; put this through a sieve, and lay the cutlets neatly round a dish; pour the sauce in the middle, and serve hot.

TO MASH POTATOES.

Wash and pare your potatoes; boil them with a handful of salt; when ready, pour them, and put in a piece of butter and a little milk; an onion, chopped very small, gives them a fine relish.

A POTATO-PUDDING WITH MEAT.

Mash some potatoes, and add a good large cupful of milk, an onion shred very fine, pepper and salt; take some beef, mutton, or pork, and cut it into slices; season them with pepper, salt, and a finely-shred onion; put a layer of this in a baking dish, and a layer of potatoes, above them a layer of meat; finish with potatoes, and stick bits of butter over the top, and bake in an oven.

TO DRESS A LAMB'S HEAD.

Cut the neck from the head; split up the forehead, and take out the brains; wash the head carefully, taking out the slime from the nose and the black part of the eyes; put it on with the neck, heart, and lungs, to boil; by adding a tea-cupful of rice, a little parsley, a few sliced onions, and a blade of mace, you may have some good broth; let the head, &c., boil for an hour and a quarter; take them out and dry the head and neck; rub it over with an egg well beaten; strew crumbs of bread, pepper, and salt over it; stick pieces of butter over the head and neck, laying the head flat upon a dish before a clear fire, and brown them nicely; mince the lungs and heart with two onions, a little parsley, pepper, salt, and a little flour; add some of the liquor in which the head was boiled, a grate of nutmeg, and a table-spoonful of ketchup; let it stand at the side of the fire for half an hour; take the brains, and beat them well with two eggs, two table-spoonfuls of flour, an onion, and a sprig of parsley shred small, a little white pepper and salt, and two or three table-spoonfuls of milk; have a frying-pan with a little butter, and drop the batter into it in spoonfuls; brown and turn them; take the liver, wash and dry it, and dust it with flour; fry it with butter; lay the head and neck flat upon your dish; lay the hash round it, and then a slice of liver and a braincake alternately around the hash. This is a very cheap and handsome dish.

TO DRESS A SHEEP'S HEAD.

Split, scrape, and wash the head very clean; score it across, and lay it flat upon a dish; strew bread-crumbs, minced parsley, pepper and salt, over it; stick pieces of butter over that, and bake it before the fire in a Dutch oven. A sauce may be made of the brains by parboiling and mincing them down, and stirring them among melted butter, seasoned with a little Cayenne.

A HASH OF COLD MEAT.

Cut the meat into small pieces; brown some butter in a stew-pan, and put in the meat; dust in a little flour, some sliced onions, pepper, and salt; put in as much water, or stock, or the gravy of roast meat, as will bring it to a proper thickness, and stew it for half an hour. A little mushroom ketchup is a great improvement.

LIGHT DISHES AND CONFECTIONS.

ARROW-ROOT.

Make some arrow-root, by breaking it with a very little cold water; pour boiling milk into it until it becomes quite thick; sweeten it with pounded loaf sugar, and season with a little nutmeg or ground cinnamon; put it into a shape, and set it in a cool place to fasten; when to be turned out, run a knife round the edge of the shape, and turn it out. It looks very nice garnished with spoonfuls of red currant jelly laid round it.

RICE.

Wash and pick two or three ounces of rice; boil it in sweet milk till quite soft; sweeten and season it with cinnamon or nutmeg; put it in a shape, and set it in a cool place to fasten; turn it out, and garnish with jelly, which must be eaten along with the rice.

GOOSEBERRY JAM.

Pick and clean your gooseberries, and to every pound of fruit take a pound of brown sugar; boil them in a preserving pan; keep stirring till they boil; boil them for twenty minutes or half an hour; after they come to the boiling point, scum it before dishing. Put into earthen pots, and paper when cold.

RASPBERRY AND STRAWBERRY JAM.

Take equal weight of fruit and lump sugar; pick the fruit, and put it on with the sugar in a preserving pan; put a spoonful or two of water in the bottom of the pan, and stir it frequently till it boils; allow it to boil for half an hour; scum it, and fill it into earthen pots; when cold, cover the tops with paper.

RED CURRANT JELLY.

Take some fresh red or white currants; pick the stalks from them, and put them on the fire in a preserving pan; when warmed, take them off, and squeeze them through a cloth. For every Scotch mutchkin or English pint of juice, take a pound of lump sugar, and boil for twenty minutes, or, if the fruit was wet before being gathered, allow it half an hour; scum it before dishing it, and, when cold, cover the tops of the pots with paper.

ORANGE MARMALADE.

Take six or eight pounds of bitter oranges, and the same weight of loaf sugar; pare off the yellow skin, taking off as little of the white interior part as possible; cut the parings down into small stripes, or cut them again across, which will make them still smaller; put them on in a brass preserving pan, with as much water as will cover them; boil them for an hour, to take out the bitter, and strain them through a sieve; quarter the oranges, and scrape out the pulp, keeping out the seeds. When the pulp is all scraped off, steep the white skin in a basin of cold water; when they have soaked a little, scrape them again, and you will by this means use almost every part of the orange; put the pulp and the parboiled chips on to boil, with the sugar and half of the water in which the skins were soaked; keep stirring till they boil, and allow it to boil for half an hour; scum it, and [illegible] it into earthen pots, and, when cold, cover the tops with paper. If the flavour of lemon be liked, four lemons will be sufficient for this quantity of marmalade. The outer yellow rind should be grated, and the pulp scraped down amongst the oranges.

CUSTARDS.

Boil a quart of sweet milk, with a stalk of cinnamon, a little of the rind of a lemon, a bay leaf, or two or three bitter almonds, with sugar to taste; beat the yolks of six eggs, with a spoonful of flour, and a little milk; pour the boiled milk through a piece of muslin into a basin, and stir the eggs into it; set it on the fire, stirring constantly; let it come to the boiling point, but not more; stir it till cold, and fill the cups, strewing a little cinnamon or grated nutmeg over the top.

CHEESE-CAKES.

It is often inconvenient to procure curd for making cheese-cakes, but there is an excellent substitute in potatoes, and, at the same time, more economical. Pare and boil a few potatoes; beat them very finely, with two ounces of melted butter, two of sugar, the grate of two lemons, a little cinnamon, the yolks of four or six eggs, and a glass of brandy (currants may be added, to make them richer); mix all the ingredients well together; line patty-pans with puff paste, and fill them up; bake for fifteen or twenty minutes in a quick oven.

PANCAKES.

For every pancake that is wanted, allow one egg, and a proportion of one table-spoonful of flour to each egg, a little sugar, a little ginger, and a little cinnamon or nutmeg; put in as much milk as will make a thick batter; put a small piece of sweet butter in a frying-pan, and when hot, pour in the batter; brown it equally, and turn it, or brown the upper side before the fire, which makes them lighter; roll them up, and strew white sugar over them.

APPLE FRITTERS.

Make a thick batter, as for pancakes, only substituting beer for milk; mix minced apples amongst it; melt a piece of butter in the frying-pan, and drop the fritters into it; brown them nicely on both sides, and strew sifted sugar over them.

ANOTHER WAY.

Make a batter the same as above, only a good deal thicker; pare and slice two or three large apples; dip them in the batter, and fry them in plenty of butter or fresh dripping.

BLANCMANGE.

To a quart of sweet milk or cream, take an ounce and a half or two ounces of isinglass—(but the quantity of isinglass required must depend greatly upon the shape or mould; if it be a plain oval or round shape, it does not require so much isinglass as if it were a branched shape, where it depends upon the strength of the isinglass alone)—boiled for a quarter of an hour, with the rind of a lemon, a blade of mace, and white sugar to taste; blanch and pound to a paste six or eight bitter almonds, and four times that number of sweet ones, with a little water; put this gradually to the hot milk, and strain it through a muslin sieve; let it settle for a little; then pour it into the mould, keeping back the sediment; when to be turned out, lay a cloth dipped in hot water round it for a few moments; run a knife round the edges, and turn it out.

CALF'S-FEET JELLY.

Take two cow's feet, well cleaned; take off the hoofs, and break the feet in several places; put them on with two Scotch pints of cold water; boil them slowly until the bones loosen from the meat; strain it, and let it stand till cold: it should now be quite firm, and if not, put it on again to boil down for an hour; when cold, take off the fat carefully from the top; put the jelly into a preserving pan (keeping back the sediment) with the peel of three lemons and the juice, two stalks of cinnamon, half a bottle of sherry or Madeira wine, eight eggs, well whisked, and white sugar to taste; stir it all together, and put it on to boil for a quarter of an hour or twenty minutes; take it off, and let it settle, with a cloth over it, for a few minutes; then pour it through a clean jelly bag until it be quite clear; keep the bag covered, and let it stand near the fire. Plain, and almost as good jelly, may be made with ale instead of wine, and vinegar instead of lemons. Many persons keep back the yolks of the eggs, but it is equally clear, and a great deal more firm, when they are added to the jelly.

ITALIAN CREAM.

Whisk up a pint of rich cream with the rind of two lemons rubbed off with sugar, the juice of the lemons, and pounded sugar to taste; when well whisked, add half an ounce of isinglass, melted with a little boiling water, and a glass of brandy; whisk it up till it is quite stiff; fill the shape, and set it in a cool place to freeze. Salt is a very good substitute for ice, to place the shape amongst damp salt in a cool cellar. This cream will have a delightful flavour, and also a beautiful colour, by rubbing a little raspberry preserve through a fine sieve amongst the cream.

PUFF PASTE.

To one pound of butter take a pound and a half of flour; mix the third part of the butter amongst the flour, by rubbing it through the hands; if the butter be sweet, add a little salt; put in as much water as will make it into dough; work it up quickly, and roll it out; take the other two-thirds of the butter which remains, and divide it into four or five parts, and stick one of the parts in small bits over the paste; strew a little flour over it; fold it together, and roll it out again, and so on till all the butter is used. If it has to stand for any time before being baked, cover it with a damp cloth.

COMMON PASTE.

Take three quarters of a pound of butter to two pounds of flour; rub the butter amongst the flour, and add as much water as will make it into a paste; if the butter be fresh, add a little salt; knead it up quickly, roll it out, and cover your pies. This quantity of flour and butter will make as much paste as will cover two or three pies; when only one is to be made, a proportion of the ingredients must be taken; but this is left to the judgment of the cook.

SWEET PASTE.

Take a pound of fine flour, and half a pound of fresh butter, the beat yolks of two eggs, two ounces of pounded white sugar; make it into a paste with hot milk, and knead it until it is quite smooth. Fruit pies, and all sweet pies, should have the white of an egg well beaten with fine pounded sugar, laid on the top with a feather brush.

SHORTBREAD.

To two pounds of flour, add six ounces of fine sugar pounded, an ounce of lemon, and an ounce of orange-peel, candied, cut into small pieces, and mixed amongst the flour; melt a pound and a half of butter, and pour it amongst the flour, and knead it up quickly; roll it out into cakes of an inch and a half thick; pinch them neatly round the edges, and prick them on the top with a fork. This will be equally good, although not so rich, by leaving out the peel, and it may be made richer by adding chopped almonds.

TO MAKE EGG-BALLS FOR MOCK-TURTLE SOUP.

Boil four or five eggs till they are quite hard; take out the yolks, and beat them in a mortar with salt and Cayenne pepper; make them into a paste with the white of one or two raw eggs; roll them into small balls of the size of a marble; roll them in flour; fry them in butter, and put them amongst the soup.

SAUCES.

[*General Directions.*—Care must be taken, in preparing the following sauces, to remove them from the fire on their reaching the boiling point, as they become thin by boiling.]

MELTED BUTTER.

Take two ounces of butter, and two table-spoonfuls of flour; add to this a small cupful of cold water; toss it round well, and do not allow the flour to get into lumps, which it will do if the water be not put in by degrees; keep stirring or tossing it round till it boil. In stirring melted butter, it should be always stirred one way, as there is a danger of its oiling; if it should oil, it may be recovered by putting a little cold water into it.

CAPER SAUCE.

Melt a piece of butter, and, when to be used, stir in two table-spoonfuls of capers; the one-half of them may be minced, to give the flavour more freely to the sauce; add a little vinegar or lemon-juice.

MINT SAUCE.

Take a few leaves of fresh green mint; wash them, and chop them very fine, and mix them with vinegar and brown sugar.

APPLE SAUCE.

Pare and cut down two or three baking apples; put them on with a little water to stew very slowly, until quite soft; beat them up with sugar and a small bit of butter, and serve in a sauce tureen.

BREAD SAUCE FOR GAME.

Crumble down a thick slice of bread; put it on in a sauce-pan, with as much sweet milk as will make it a thick sauce; beat it well with a spoon, till quite smooth: season with white pepper, and serve in a sauce tureen.

CAUDLE SAUCE FOR PLUM-PUDDING.

Melt some butter, and stir into it a glass of sherry, half a glass of brandy or rum, the grate of a lemon, the grate of a nutmeg, and sugar, to taste; do not allow the sauce to boil after the spirits are added to it.

OYSTER SAUCE.

Take a hundred fresh oysters, and scald them for a few minutes; take a good piece of butter; melt it in a pan; shake in some flour; stir it constantly until it be of a nice light brown; pour in some stock, or the liquor of the oysters, to thin it; season it highly with Cayenne pepper and salt to taste, and some mushroom ketchup, but do not add the salt until you have put in the ketchup; pick and beard the oysters, and put them amongst the sauce. Half a glass of sherry will be a great improvement.

PLAIN OYSTER SAUCE.

Melt a good piece of butter, and add to it half a hundred oysters, scalded and picked, and season with Cayenne. A spoonful of ketchup will make this a very nice sauce.

LOBSTER AND CRAB SAUCE.

Melt the butter as directed above; pick out the red meat of a boiled lobster, or the meat from the claws of a boiled crab; chop it down very fine, and put it amongst the butter; season with Cayenne pepper.

PARSLEY SAUCE.

Melt a good piece of butter; scald some parsley, by immersing it in boiling water for a minute or two; chop it down, and add it to the melted butter.

EGG SAUCE.

Melt a good piece of butter the same way as for other sauces, only substituting milk for water; boil one or two eggs very hard; peel and chop them down, and mix them amongst the melted butter; add a little Cayenne.

CELERY SAUCE.

Cut down a head or two of celery into pieces of an inch long; parboil them in water; make a sauce, the same as for egg sauce, either of milk or cream; put the celery to this, and season with grated nutmeg and white pepper; let it come to the boil, but not more, as the cream is apt to break by boiling.

ONION SAUCE.

Parboil a dozen young onions; make a sauce of melted butter; if the sauce be wanted very white, use cream or milk instead of water; put the onions to this, and season with white pepper and salt. If the onions be old and large, they should be beat through a sieve and put amongst the sauce.

FISH.

TO BOIL SALMON.

Clean the fish well with a wet cloth, without either washing or scaling it; put it on in a fish-kettle, with plenty of cold water, and a handful of salt; allow twelve minutes for every pound of fish, and, when ready, lift the drainer, and place it across the top of the fish-pan to drip before dishing. It should be served on a dish covered with a napkin, and garnished with green parsley. For sauce, plain melted butter, or parsley, or lobster-sauce, may be served, besides a sauce-tureenful of the liquor in which the fish was boiled, as that is sometimes preferred to any other sauce.

TO BROIL SALMON.

Cut slices from the thick of the fish, dry them, and dust them with flour. Broil them on a gridiron over a clear fire; when ready, rub them over with butter, and serve hot, with any of the sauces used for salmon.

TO KIPPER SALMON.

Cut up and clean the fish without washing; rub it over with salt, raw sugar, and a little saltpetre. The fish should lie for two days with a board placed above to press it down; it should then be hung with pieces of wood across, to keep it from folding together. When to be dressed, it must be cut into slices, and broiled on the gridiron; and when done, rubbed over with sweet butter.

TO BOIL TURBOT.

Choose a thick fish, and of a cream-coloured white; before boiling, it should be soaked in salt and water, with the addition of a little vinegar; put it on in a fish-kettle, with plenty of cold water, a handful of salt, and a cupful of vinegar. A turbot should be boiled for half an hour after it has come to the boil. It may be garnished with any small fish fried, or with parsley. For sauce, lobster or oyster sauce should be used, or plain melted butter.

TO DRESS TURBOT.

Cut a small turbot into slices; dip them amongst beat eggs; roll them in bread-crumbs, minced parsley, white pepper, and salt; bake them in a dish well buttered, and baste frequently. The sauce used for this is made of the trimmings of the fish, butter, and flour, browned and thinned with stock or water, to which must be added part of a lobster parboiled, or oysters scalded and pickled, and seasoned with Cayenne and salt, and a little mushroom ketchup; lay the fish neatly on a dish, and pour the sauce round them; or, the fish may be prepared as above, and fried amongst butter, and served with plain sauce.

TO BOIL HALIBUT.

Wash and clean the fish well, and boil it in cold water, with a handful of salt; scum it well. Ten minutes is considered enough for every pound of fish. Garnish with parsley, and serve with melted butter or oyster-sauce.

TO DRESS HALIBUT.

Cut the fish into slices, rub it over with flour, dip it in beat egg, and strew bread-crumbs over it, and fry amongst fresh dripping; or, it may be fried without the eggs and bread-crumbs, only dusted with flour, and fried with butter, and served with plain melted butter or oyster-sauce.

TO FRY FLOUNDERS.

Clean them well, taking out the gut; dry them with a cloth, dust them with flour, dip them in beat egg, strew bread-crumbs over, and fry amongst as much dripping as will cover them. When done to a nice light brown, lay them before the fire for a few minutes, and dish them with the back downwards. Garnish with parsley.

TO DRESS A COD-HEAD AND SHOULDERS.

Procure a good grey cod, clean it well, and take out the gills; lay it all night amongst salt. When to be used, cut off the head, and as much of the shoulders as you think may be required for the size of the dish you want; skin it, and bind it with a cord to keep it firm; a small piece of the tail part put into the mouth preserves it from breaking down; boil it in cold water, with a handful of salt, from twenty minutes to half an hour. When ready, set it on your drainer, over the top of your fish-pan, to drip; brush it over with a beat egg; strew bread-crumbs over it, and stick pieces of butter thickly over the top; set it before a clear fire to brown; take a piece of butter, and brown it with flour in a stew-pan; thin this with beef stock or gravy, or the skin and trimmings of the fish, boiled with an onion and a sprig or two of parsley, and strained amongst the butter; then add a little Cayenne pepper, salt, the squeeze of a lemon, two or three spoonfuls of ketchup, and a glass of sherry wine; scald and pick a hundred oysters, and put amongst the sauce. When dished, lay the sauce round the fish, not over the top, as that spoils the appearance of the fish.

ANOTHER WAY.

Clean the fish as before, and boil it with the skin on; boil it for half an hour, and when to be dished, scrape off the skin, and pour oyster-sauce over the fish,

TO DRESS THE MIDDLE CUT OF A COD.

Clean and skin the fish, and make a stuffing of bread-crumbs, parsley, and onions chopped small, pepper and salt, and a bit of butter; skewer this into the open part of the fish, and rub it over with beat egg; strew bread-crumbs, and stick pieces of butter over it, and set before the fire to bake; serve with beat butter or oyster-sauce.

TO FRY COD.

Cut slices from the tail about an inch thick; dust them with flour, and rub them over with beat egg; strew bread-crumbs over them, and fry them with dripping. When nicely browned, lay them on a drainer before the fire for a few minutes. Garnish with parsley, and serve with oyster-sauce.

TO DRESS HADDOCKS.

Take two good well-sized haddocks; gut and wash them clean, but do not scrape them; they are firmer and better if they lie all night among salt; dry them, and cut off the fins; slip a knife in at the neck, and take off the skin, taking care not to tear the fish; cut them neatly from the bone, dividing each side into two parts; dust them with flour, and dip them amongst an egg well beaten; then strew bread-crumbs over them. In the meanwhile, have some fresh dripping in a flat pan, sufficient to cover the fish; be careful that the dripping is not too hot to scorch the fish; the best means of knowing this, is, when it gives over crackling, and settles quietly in the pan; then put in the fish, and turn them carefully. When they are nicely browned, lay them before the fire on a drainer for a few minutes to drip. Garnish with fried parsley; put the dripping through a hair sieve, and it will serve again.

TO FRY WHITINGS.

Clean the fish without washing, as that softens them, and from the delicate nature of the whitings, they will not fry whole after being much handled; dust them with flour, and dip them amongst beat egg, and strew bread-crumbs over them, and fry them amongst dripping, with the tail turned through the eyes. Garnish with fried parsley.

TO BAKE HADDOCKS.

Take two or three good haddocks, clean them, and lay them all night amongst salt. When to be used, skin them, and cut off the heads; make a stuffing of bread-crumbs, chopped onions and parsley, pepper and salt, and a little bit of butter; sew this into the belly of the fish; rub them over with butter, and strew bread-crumbs over them, and bake them in a Dutch oven before the fire.

FISH AND SAUCE.

Take two or three haddocks, clean them, and lay them all night amongst salt. When to be used, skin them, and cut off the heads, tails, and fins; boil these for half an hour, or three-quarters, to make a little stock for the fish; brown a little flour and butter slightly in a stew-pan; strain and pour in your stock amongst the butter; add sliced onions and chopped parsley, salt and a little Cayenne pepper, and a spoonful of ketchup; when this is nearly ready, put in your fish, cut into several pieces, and boil for ten minutes.

TO BOIL SKATE.

Choose a nice thick grey skate, with prickly back; it is more generally liked when salted slightly, and hung for a day; boil it in cold water, and before serving, scrape off the skin; serve with melted butter, or lobster or oyster sauce.

TO FRY SKATE.

Clean and skin the fish, and cut it into slices; rub it with flour, dip it in beat egg, strew bread-crumbs over it, and fry amongst butter or fresh dripping; it may be fried without the egg and bread-crumbs, only rubbed with flour; serve with plain beat butter, or parsley sauce.

TO CRIMP SKATE.

Clean and skin the fish, and cut into slices; roll them up and tie them with tape, or fasten them with a small wooden skewer; boil them in cold water, with a good handful of salt; drain them, take off the tape or skewer, and serve with plain melted butter, or parsley sauce.

TO STEW OYSTERS.

Pick and beard the oysters, and put them in a pan with a very little of their own liquor, a good piece of sweet butter, a little flour, and some Cayenne pepper. Let them stew for a few minutes, and add a table-spoonful or two of sweet cream. Serve hot.

TO SCALLOP OYSTERS.

Pick and scald the oysters in their own liquor; strain them from the juice; lay them on a dish, and heap bread-crumbs over them mixed with pepper and a little fine salt; stick pieces of butter thickly over the bread-crumbs, and bake before the fire.

TO FRY OYSTERS.

Make a batter of eggs, flour, pepper and salt, and dip the oysters amongst it, having first washed them in their own liquor; brown a piece of butter in a frying-pan, and fry them over a quick fire. A sauce may be made of their own juice poured amongst the butter (having first lifted out the oysters), and thickened with flour, and seasoned with Cayenne and a little ketchup. A grate of lemon peel may be added, if the flavour be liked. Mussels may be dressed in the same manner.

TO BAKE HERRINGS.

Take ten or a dozen fresh herrings; clean them, by wiping them with a wet cloth, but do not wash them, as that takes away the richness of the fish; split them, and cut out the centre bone; cut off the heads, and roll them up with pepper and salt inside; lay them neatly in a pie-dish, and stick bits of butter over the top; shake pepper and salt, and pour vinegar over them, and bake in an oven.

TO BOIL HERRINGS.

Clean the herrings in the manner directed above; boil them in a flat pan, with half water half vinegar.

BREAD.

It is more difficult to give rules for making bread than for any thing else, it depends so much on judgment and experience. In summer, bread should be prepared with cold water; during a chilly, damp spell, the water should be slightly warm; in severe cold weather, it should be mixed quite warm, and set in a warm place during the night. If your yeast is new and lively, a small quantity will make the bread rise; if it be old and heavy, it will take more.

Flour bread should have a sponge set the night before. The sponge should be soft enough to pour, mixed with water, warm or cold, according to the temperature of the weather. One gill of lively yeast is enough to put into sponge for two loaves. I should judge about three pints of sponge would be right for two loaves. The warmth of the place in which the sponge is set should be determined by the coldness of the weather. If your sponge looks frothy in the morning, it is a sign your bread will be good; if it does not rise, stir in a little more emptings; if it rises too much, taste of it, to see if it has any acid taste; if so, put in a tea-spoonful of pearl-ash when you mould in your flour; be sure the pearl-ash is well dissolved in water; if there are little lumps, your bread will be full of bitter spots. About an hour before your oven is ready, stir in flour into your sponge till it is stiff enough to lay on a well floured board or table. Knead it up pretty stiff, and put it into well-greased pans, and let it stand in a cool or warm place, according to the weather. If the oven is ready, put them in fifteen or twenty minutes after the dough begins to rise up and crack; if the oven is not ready, move the pans to a cooler spot, to prevent the dough from becoming sour by too much rising. Common sized loaves will bake in three quarters of an hour. If they slip easily in the pans, it is a sign they are done. Some people do not set a soft sponge for flour bread; they knead it up all ready to put in the pans the night before, and leave it to rise. White bread and pies should not be set in the oven until the brown bread and beans have been in half an hour. If the oven be too hot, it will bind the crust so suddenly that the bread cannot rise; if it be too cold, the bread will fall. The chief error fallen into in preparing bread at home, is the giving of it too firm a consistency, and not raising it so well as the bread of bakers.

Those who make their own bread should make yeast too. When bread is nearly out, always think whether yeast is in readiness; for it takes a day and night to prepare it. One handful of hops, with two or three handfuls of malt and rye-bran, should be boiled fifteen or twenty minutes, in two quarts of water, then strained, hung on to boil again, and thickened with half a pint of rye and water stirred up quite thick, and a little molasses; boil it a minute or two, and then take it off to cool. When just about lukewarm, put in a cupful of good lively yeast, and set it in a cool place in summer, and warm place in winter. If it is too warm when you put in the old yeast, all the spirit will be killed.

In summer, yeast sours easily; therefore make but little at a time. Bottle it when it gets well a-working; it keeps better when the air is corked out. If you find it acid, but still spirited, put a little pearl-ash to it, as you use it; but by no means put it into your bread unless it foams up bright and lively as soon as the pearl-ash mixes with it. Never keep yeast in tin; it destroys its life.

The most wholesome bread that can be eaten is that made from wheat ground altogether, that is, the fine and the common flour mixed, with the addition of the rougher particles of the inner rind of the grain. This mixed flour makes excellent and nutritious brown bread, and to most people it is much more pleasant to the palate than pure white bread; but it is seldom prepared for sale by bakers, from the prejudices of the public in favour of clear white loaves, and will in most places require to be made at home. Those accustomed to make white bread will have no difficulty in managing it. The inhabitants of London have a strong prejudice against any bread but that which has a certain degree of whiteness, and suffer accordingly. To procure the necessary standard whiteness, the very best wheaten flour or certain adulterating substances must be employed; and as the finest flour is too dear, the process of adulteration is preferred. The principal substances alleged to be employed by various bakers in the adulteration of bread, are, gypsum, or plaster of Paris, chalk, Cornish pipe-clay, bean-flour, peas-meal, potatoes, bone-ashes, alum, carbonate of ammonia, and blue vitriol. The object in using these is, generally speaking, to bleach the bread white, and raise it, so as to have the appearance of lightness. Some of the ingredients are far from being noxious, but others are most injurious to the stomach, cause contraction of the intestines, and so hurt the health of the consumers.

BEER.

Beer is the best family drink, and is preferable to either porter or strong ale. Beer may be easily brewed. The utensils are a large pot, a tub, and barrel. The estimate is a handful of hops to a pailful of water, and a half-pint of molasses. Malt mixed with a few hops makes a weak kind of beer; but it is cool and pleasant, and needs less molasses than hops alone. The rule is nearly the same for all beer. Boil the ingredients two or three hours; pour in a half-pint of molasses to a pailful while the liquor is scalding hot; strain the beer, and when nearly lukewarm, put a pint of lively yeast to a barrel; leave the bung loose till the beer is done working, which can be ascertained by observing when the froth subsides. Beer keeps better bottled than in casks. The beer should have an agreeable bitterish taste; should sparkle in some degree when poured out; but it is not necessary that it should have more than a mere surface of cream or froth. If any kind of beer turn sour, it may be cured in drinking by putting a pinch of the carbonate of soda into the glass. This makes it effervesce, and gives it an agreeable pungency, while no injury ensues to the drinker. Carbonate of soda is a white flour-like substance, which may be purchased from chemists.

Inasmuch as the brown bread above noticed is better for our constitutions than white, so is good plain beer better as a beverage than porter. London porter, however innocent to strong constitutions and those who take a great deal of exercise, is allowed to be injurious in many respects, if not procured unadulterated. Many people think that porter should have froth on its surface, otherwise it is not fresh, and so, to give it the desired head, a variety of ingredients, particularly green vitriol, alum, and common salt, are used: other compounds are also in requisition, as the extract of a poisonous berry named cocculus indicus, extract of quassia and liquorice, powder of gentian root, sulphate of iron, sugar boiled down, &c., nearly all of which less or more injure the stomach, promote headach, and cause other evils. There is no doubt that there is much genuine London porter used; but it would be advisable to be careful from what source it is procured, as well as to remember that frothing is no proof of its purity or excellence.

GINGER BEER.

Ginger beer is made in the following proportions:— One cup of ginger, one pint of molasses, one pail and a half of water, and a cup of lively yeast. Most people scald the ginger in half a pail of water, and then fill it up with a pailful of cold; but in very hot weather some people stir it up cold. Yeast must not be put in till it is cold, or nearly cold. If not to be drunk within twenty-four hours, it must be bottled as soon as it works.

SEASONS FOR MEATS, &c.

Among the best works on cookery now in use, are the "Cook and Housewife's Manual, by Mistress Margaret Dods, of the Cleikum Inn, St Ronan's," and the "Practice of Cookery, by Mrs Fraser." The work of the former is an instructive and amusing publication, and has had a large sale among the higher classes of families. The accomplished authoress has the following notices of the principal meats, fish, and vegetables, in season in the different months of the year:—

January.—Beef and mutton, which are to be had good all the year round, are both prime in this month, though they begin to get dearer than in the fall of the year; veal to be had good, but dear at this season; house-lamb and pork generally both dear. *Poultry*—Turkeys, geese, ducks, fowls, pullets, tame pigeons, wild ducks, hares and rabbits, plentiful; the latter about the cheapest. *Fish*—Turbot, halibut, skate, cod, haddocks, soles, plaice, flounders, oysters; prime turbot is now scarce; lobsters and crabs hardly to be got at this time; prawns plentiful. *Vegetables*—The same sorts of vegetables are in season, with little variation, from the beginning of November till the end of February: they are Savoys, cabbage, and greens of all the sorts, Brussels sprouts, broccoli, sulphur-coloured and purple; spinach, leeks, onions, beet-root, parsnips, turnips, celery, carrots, potatoes, cresses, parsley, cucumber, endive, and forced asparagus, and mushrooms.

February.—Meat the same as in January, but veal and house-lamb generally rather cheaper. *Fish* the same, but cod and haddocks fallen off; lobsters more plentiful; barbel and dace got. *Fowls* and *Game* the same, and spring chickens and ducklings in addition, but always enormously dear. Pea and Guinea fowl now come in, and continue till July. *Vegetables* the same.

March.—Meat as in January, and grass-lamb; house-lamb now cheaper; and mountain-mutton, which begins to fall off about mid-winter, now not so good, particularly in severe seasons; veal gets cheaper. Poultry the same as last month's; no hares, close-time till September; green geese, ducklings, tame pigeons (cheaper); wild pigeons; moor-game close. *Fish*—Salmon is now got, but dear; indeed, it is to be had in London almost the whole year round. Fish, in an open spring, are plentiful about this time, but still more so in April; mackarel, shrimps, and prawns, are now seen. *Vegetables*—Forced cucumbers, young turnips, and turnip tops, spinach, broccoli, radishes, and forced salad herbs.

APRIL.—*Meat of all kinds*—Veal and lamb get cheaper. Poultry same as last three months. *Vegetables* same as the last months, with chervil and lettuce; vegetables now begin to get cheaper. *Fruits*—Green gooseberries and rhubarb for tarts. White fish plentiful.

MAY.—The same in meat as the preceding months, and about Whitsuntide buck-venison comes in season. *Fish*—Turbot, lobster, trout, salmon, eels, and plenty of the smaller white fish in favourable weather; oysters go out of season till August. *Vegetables* of all kinds as before, with forced peas and early potatoes; sea-kale, saladings, and carrots, are now obtained of natural growth.

JUNE.—*Meat of all kinds*, and generally begins to get cheaper. *Fish*—Salmon, turbot, skate, halibut, lobsters, soles, eels, in high season, and getting cheaper. *Vegetables* in great plenty and variety, and cheaper; early cauliflower got, asparagus plentiful, and about the cheapest towards the end of the month. *Fruits* in fine seasons are strawberries, early cherries, melons; also apples for tarts.

JULY.—*Meats of all kinds*—Lamb and veal cheap. Poultry of all kinds as before, and also plovers and wheat-ears. Leverets, turkey-poults, and ducklings, are now worth eating, and cheaper. Wild-ducks are often got about this time. *Fish* is now good of all kinds, and the rarer sorts, as turbot and salmon, are about the cheapest. *Vegetables* of all kinds good and plentiful, as cauliflowers, peas, and French and Windsor beans. *Fruits*—All the small fruits at their best.

AUGUST AND SEPTEMBER.—*Meat of all kinds, and cheap*—Mountain-mutton now excellent. Grass-lamb growing coarse. Veal scarcer. Poultry as before; with moor-game of all kinds after the 12th of August, and partridges and hares from the beginning of September. Geese and ducks now full-grown. *Fish*—Cod becomes good, turbot goes rather out, as does salmon. Fresh-water fish now plentiful, as pike, carp, perch, and trout. Herrings, which are in season from July till March, are now excellent. *Fruits* of all kinds plentiful. Mushrooms most plentiful at this time, also cucumbers.

OCTOBER.—Meat as before, and doe-venison. Pasture-fed beef and mutton are probably at the best in this month. Poultry and game in all variety, but young fowls get dearer. Pheasants now got, and generally wild pigeons, snipes, and wild ducks, begin to appear. *Fish*—Cod, haddocks, brill, tench, and all sorts of shell-fish. Oysters, which come in at London in August, and at Edinburgh in September, are now excellent. *Vegetables*—Beans, broccoli, and cabbage of all kinds; beet, onions, leeks, turnips, carrots, lettuce, cresses, endive, celery, cucumbers, spinach, and dried herbs. *Fruits*—All sorts of apples and pears.

NOVEMBER AND DECEMBER.—*Meat*—Beef and mutton prime. House-lamb and veal. Sucking-pig. Buck-venison goes out. *Fish*—All good about this time. Salmon dear. *Poultry* gets very dear in large towns about this season, but is to be got of all kinds; also woodcocks and snipes.

It is, however, quite impossible rigidly to fix the seasons of provisions, and much less their price. Meat, generally speaking, is cheapest in the latter end of autumn, and dearest in spring. Beef is found prime all the year round, but small natural pasture-fed beef is at the best in October; so is hill-mutton: both fall away in the winter, and are lean in spring. Beef and mutton may be cured for winter-store, or for hams, with most advantage about the beginning of November, both from quality and price.

ON CHOOSING PROVISIONS.

Mrs Fraser's work on cookery is of a useful nature, and has been many years in repute among practical cooks in Edinburgh. Some of her remarks on the choosing of provisions are worthy of being attended to.

Beef.—Ox beef, if young, has a fine, smooth, open grain, of a pleasing carnation red, and is very tender; the fat rather white than yellow, and the suet white. The grain of cow beef is closer, and the fat whiter; but the lean not so bright a red as the other. The grain of bull beef is still closer, the fat hard and skinny, the lean of a deep red, and smells stronger than cow or ox beef.

Mutton.—If young, it will feel very tender; but if old, it will be hard, and the fat fibrous and clammy. The grain of ram mutton is close, the flesh of a deep red, and the fat spongy. The flesh of ewe mutton is paler than the wedder, and the grain closer. Short-shanked mutton is the best.

Lamb.—If the vein in the neck of the fore-quarter appears of a fine blue, it is fresh; but if green or yellow, it is stale. If the hind-quarter has a faint disagreeable smell near the kidney, or if the knuckle be limber, it is not good. The head is good when the eyes are bright and plump, but stale if sunk and wrinkled.

Veal.—The flesh of cow-calf is whiter than that of bull, but not so firm; the fillet of the former is generally preferred, on account of the udder. If the vein in the shoulder is not of a bright red, it is not fresh; and if there be any green or yellow spots in it, it is bad. A good neck and breast will be white and dry; but if clammy, and look green or yellow at the upper end, they are stale. The kidney is apt soonest to taint in the loin, and if stale, it will be soft and slimy. A leg is good if it be firm and white; but bad if limber, and the flesh flabby, with green or yellow spots. The same observations with regard to the lamb's head hold as to this.

Pork.—Measley pork is dangerous to eat. It is known by the fat being full of little kernels. If young, the lean will break on being pinched, the skin will dint by pinching it with the fingers, and the fat, like lard, will be soft and pulpy. If the rind is thick, rough, and cannot be easily pinched, it is old. If the flesh is cool and smooth, it is fresh; but if clammy, it is tainted, and the knuckle part will always be the worst.

Hams.—Those are best which have the shortest shank. If, by introducing a knife under the bone, it come out clean, and smell well, it is good; but if it be daubed and smeared, or has a disagreeable smell, it is bad.

Bacon.—If good, the fat will feel oily, look white, the lean will be of a good colour, and stick close to the bone; but bad, or will be soon rusty, if there are streaks in the lean. The rind of young bacon is always thin, but thick if old.

Turkeys.—If a cock-turkey is young, it will have a smooth black leg, with short spurs, the eyes full and bright, and the feet limber and moist; but see that the spurs are not scraped to deceive. When stale, the feet are dry, and the eyes sunk. The legs of the hen, if she is old, will be rough and red; and if with egg, the vent will be soft and open.

Geese.—A yellow bill and feet, with few hairs upon them, are the marks of a young goose; but these are red when old. The feet will be limber if fresh, but stiff and dry if stale. Green geese are in season from May to June, till they are three months old. A stubble goose is good till it be five or six months old, and should be picked dry. The same rules will hold as to wild geese, with respect to their being young or old.

Ducks.—The legs of a new-killed duck are limber; and if fat, the belly will be hard and thick. The feet of a stale duck are dry and stiff. Those of a tame one are of a dusky yellow, and thick. The feet of a wild duck are smaller than a tame one, and are of a reddish colour.

Hares.—When old, the claws are blunt and rugged, the ears dry and tough, and the cleft wide and large; if young, the claws are smooth and sharp, the ears tear easily, and the cleft in the lip much spread. The body will be stiff, and the flesh pale, if newly killed; but if the flesh is turning black, and the body limber, it is stale: they are not always considered the worse of being kept till they smell a little.

Fish.—The general rule for knowing whether fish are fresh or stale, is by observing the smell and colour of the gills, which should be of a lively red; whether they be hard or easily opened, the standing out or sinking in of the eyes, the fins stiff or limber, or by the gills. Fish taken in running water are always better than those from ponds.

Trout.—All kinds of fresh-water fish are excellent; but the best are red and yellow. The female is most esteemed, and is known by its small head, and deep body. They are in high season the latter end of May.

Salmon, when fresh, is of a fine red, and particularly so at the gills; the scales bright, and the fish very stiff. The spring is the best season for this fish. Pickled salmon is good, if the flesh feels oily, and the scales stiff and shining.

Butter.—In buying fresh butter, trust more to taste than smell. In choosing salt butter, trust rather to smell than taste. If it is in a cask, have it unhooped, and probed to the bottom.

Eggs.—To judge properly of an egg, put the greater end of it to your tongue, and if it feel warm, it is new; but if cold, it is stale; or if, by holding it up before the sun or a candle, the yolk appears round, and the white clear and fair, it is good; but if the yolk is broken, and the white cloudy, it is bad.

ADVICES FOR THE ECONOMICAL.

The following are a few short advices on housekeeping not unworthy of attention:—

Some people are fond of corned or slightly salted beef, which forms a good winter dish. When you merely want to cure meat, all you have to do is to rub in salt plentifully, and lay it aside till it is impregnated with the saline properties. A little saltpetre may be rubbed in before applying the common salt, to make the meat tender; but this should only be done in the winter season.

Sufficient care should be taken in summer to preserve fresh meat from wasting. As soon as it is brought into the house, it should be carefully covered from the flies, and put in a cold, and, if possible, airy situation. If it consist of pieces, they should be spread out, separate from each other, on a large dish, and covered. If not to be cooked soon, it should be sprinkled with salt. The fat and flabby parts should be raised up above the lean, and a little salt strewed in. If there be danger of its wasting, in spite of these precautions, it should be scalded.

All herbs should be kept carefully from the air. Onions should be kept very dry. When green peas become old and yellow, they may be made somewhat tender and green by sprinkling in a pinch or two of pearl-ash when they are boiling. Potatoes should, if possible, always be prepared with steam, which renders them drier and more pleasant in eating than boiling with water. They may be easily steamed by a tin pan, with holes in the bottom, and closed with a lid, fitted into a goblet or stew-pan, in which water is put to raise the steam.

It is a good practice to have all stoneware, china, or glass articles, washed in wooden bowls, as it saves the edges from being chipped, or the vessels from being broken.

It is a good plan to put new earthenware into cold water, and let it heat gradually until it boils, then cool again. Brown earthenware, in particular, may be toughened in this way. A handful of rye, or wheat bran, thrown in while it is boiling, will preserve the glazing, so that it will not be destroyed by acid or salt.

Clean a brass kettle, before using it for cooking, with salt and vinegar.

Skim milk and water, with a bit of glue in it, heated scalding hot, is excellent to restore old, rusty, black Italian crape. If clapped and pulled dry, like nice muslin, it will look as well, or better, than when new.

Do not have carpets swept any oftener than is absolutely necessary. After dinner, sweep the crumbs into a dusting-pan with your hearth-brush; and if you have been sewing, pick up the shreds by hand. A carpet can be kept very neat in this way; and a broom wears it very much.

It is not well to clean brass andirons, handles, &c., with vinegar. It makes them very clean at first, but they soon spot and tarnish. Rottenstone and oil are proper materials for cleaning brasses. If wiped every morning with flannel and Jamaica rum, they will not need to be cleaned half as often.

If you happen to live in a house which has marble fire-places, never wash them with suds; this destroys the polish in time. They should be dusted, the spots taken off with a nice oiled cloth, and then rubbed dry with a soft rag.

Feathers should be very thoroughly dried before they are used. For this reason they should not be packed away in bags when they are first plucked. They should be laid lightly in a basket, or something of that kind, and stirred up often. The garret is the best place to dry them, because they will there be kept free from dirt and moisture, and will be in no danger of being blown away. It is well to put the parcels, which you may have from time to time, into the oven, after you have removed your bread, and let them stand a day.

If feather-beds smell badly, or become heavy, from want of proper preservation of the feathers, or from old age, empty them, and wash the feathers thoroughly in a tub of suds; spread them in your garret to dry, and they will be as light and as good as new.

Jamaica rum, constantly used to wash the hair, keeps it very clean, and free from disease, and promotes its growth a great deal more than Macassar oil. Brandy is very strengthening to the roots of the hair; but it has a hot drying tendency, which rum has not.

About the last of May, or the first of June, the little millers, which lay moth eggs, begin to appear. Therefore brush all your woollens, and pack them away in a dark place covered with linen. Pepper, red cedar chips, tobacco—indeed, almost any strong spicy smell—is good to keep moths out of your chest and drawers. But nothing is so good as camphor. Sprinkle your woollens with camphorated spirit, and scatter pieces of camphor gum among them, and you will never be troubled with moths. Some people buy camphor wood trunks for this purpose, but they are very expensive, and the gum answers just as well.

Pulverized alum possesses the property of purifying water. A large spoonful stirred into a hogshead of water will so purify it, that, in a few hours, the dirt will all sink to the bottom, and it will be as fresh and clear as spring water. Four gallons may be purified by a tea-spoonful.

Woollens should be washed in very hot suds, and not rinsed. Lukewarm water shrinks them.

On the contrary, silk, or any thing that has silk in it, should be washed in water almost cold. Hot water turns it yellow. It may be washed in suds made of nice white soap, but no soap should be put upon it. Likewise avoid the use of hot irons in smoothing silk. Either rub the articles dry with a soft cloth, or put them between two towels, and press them with weights.

Do not let knives be dropped into hot dish-water. It is a good plan to have a large tin pot to wash them in, just high enough to wash the blades *without wetting* the handles. Keep your castors covered with blotting paper and green flannel. Keep your salt-spoons out of the salt, and clean them often.

Do not wrap knives and forks in woollens. Wrap them in good strong paper. Steel is injured by lying in woollens.*

* Some of these scraps are from Mrs Child's "Frugal Housewife," a small volume, well worthy of the extensive sale it has met with both in this country and America.

EDINBURGH: Published by W. and R. CHAMBERS, 19, Waterloo Place; also by ORR and SMITH, Paternoster Row, London; and W. CURRY, Jun. and Co. Sackville Street, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight.

CHAMBERS'S INFORMATION FOR THE PEOPLE will be completed in one volume quarto, forming a comprehensive body of human knowledge on the most important subjects.

Stereotyped by A. Kirkwood, and printed by Ballantyne & Co.

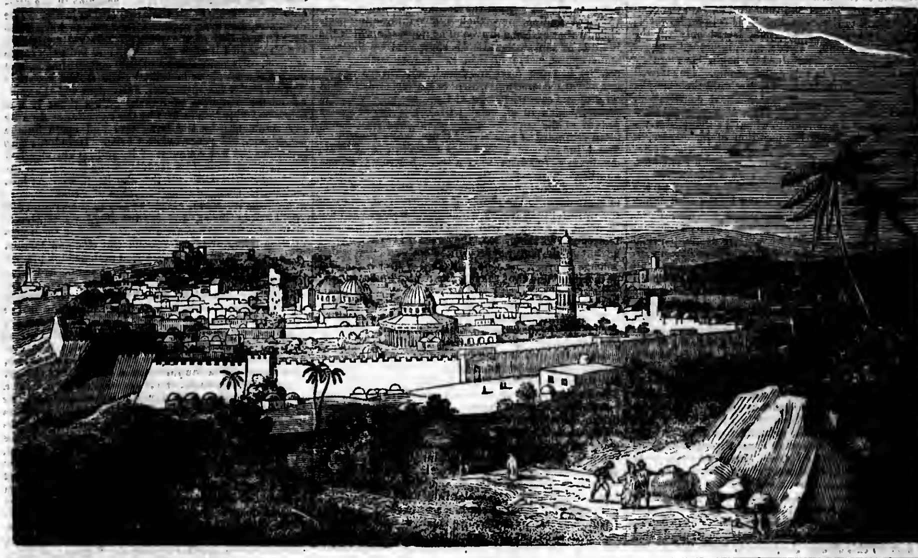
PALESTINE, OR THE HOLY LAND.

VIEW OF JERUSALEM, FROM THE HEIGHTS ABOVE THE VALLEY OF JEHOSHAPHAT.



PALESTINE, or the Holy Land, is that portion of the Asiatic continent, in which took place those remarkable transactions recorded in the books of the Old and New Testament. It lies within the 31st and 34th degree of north latitude, and forms part of Syria, a country situated at the eastern extremity of the Mediterranean Sea, and bounded on the south by the extensive district of Arabia. On the north it has Mount Lebanus, and on the east the river Jordan and the Dead Sea. Within these limits the country measures from two to three hundred miles in length, and about fifty in breadth; and is therefore, in point of size, of nearly the same extent as Scotland. It has been called Palestine, as is supposed, from the Philistines, who were once its possessors; but in the Scriptures, from various circumstances, it has received the appellations of "the Promised Land," "the Land of Canaan," and "the Land of Judea." In modern times, from its connection with the events which occurred within it upon the promulgation of Christianity, it is more generally spoken of under the name of "the Holy Land." In its physical character, this celebrated territory is composed of both a mountainous region and level plains, as will be subsequently described.

The prevailing character of Palestine scarcely corresponds with its ancient fertility. This is chiefly to be attributed to the miserable state of vassalage in which the inhabitants are held. The devastating effects of perpetual wars, and some physical changes, have also contributed to the destruction of agricultural industry. Yet, after all, so excellent would the soil appear to be, and so ample its natural resources, that Canaan may still be characterised as a land flowing with milk and honey. Its pastures are extensive, and of the richest quality; and the rocky country is covered with aromatic plants, yielding to the wild bees who live in the hollow of the rocks such an abundance of honey, that the poorer classes use it as a common article of food. Dates, which are found springing up in the midst of the most arid districts, are also another important article of consumption. If to these we add olive oil, an article so essential to an Oriental, the ancient fertility of even the most barren part of Judæa becomes easily accounted for. Delicious wine is still produced in some districts, and the vallies bear plentiful crops of tobacco, wheat, barley, and millet. Among other indigenous productions may be enumerated, the cedar and other varieties of the pine, the cypress, the oak, sycamore, mulberry-tree, fig-tree, the willow, accacia, aspen, arbutus, myrtle, tamarisk, oleander, oshar, doom, the turpentine, almond, peach, chaste, and locust trees; the mustard-plant, aloe, citron, apple, pomegranate, and many flowering shrubs. Other indigenous productions have either disappeared or are confined to circumscribed districts. Iron is found in the mountain-range of Libanus, and silk is produced in abundance in the plains of Samaria.

Generally speaking, the climate is mild and salubrious. From May to August the sky is clear and cloudless, but during the night there falls a copious dew, which moistens the soil. Intensely cold nights, however, frequently succeed to very sultry days—a vicissitude more than once referred to in Scripture. Rain falls in sufficiency during the rest of the year, to which, in the absence of springs, the fertility of Palestine is mainly attributable. The streams with which it is watered, with the exception of the river Jordan, are merely brooks or torrents fed by the copious periodical rains. In the dry season, not one of them retains its water, and the only resource of the natives is in the wells, or tanks of water collected during the rainy season, when the torrents pour down from the hills with a violence which sweeps every thing before it. To avoid the destruction consequent upon such visitations, is probably the reason why the towns and villages of Palestine are almost uniformly found built upon elevated ground.

With respect to the zoology and ornithology of this country, our information is very imperfect. The other objects of interest which it contains seem to have the effect of almost totally withdrawing the attention of travellers from its natural history. The wilder animals referred to in Scripture, such as the lion, wolf, leopard, &c., have almost totally disappeared. Hasselquist says, that the only animals which he saw were the porcupine, jackall, fox, rock-goat, and fallow-deer. Captain Mangles describes an animal of the goat species as large as the ass, with long knotty upright horns. The horse does not appear to have been adopted till after the Babylonish captivity, the wild ass being deemed worthy even for the purposes of royalty. The breed of cattle reared in Bashan and Gilead were remarkable for their size, strength, and fatness; but this is far from being the case now. In ornithology, the vulture, falcon, jackdaw, green wood-spite, bee-catcher, nightingale, field-lark, goldfinch, partridge, quail, and the quail of the Israelites, the turtle and ring dove, are found, and various descriptions of land and water game are abundant. The Holy Land is infested with a frightful number of lizards, different kinds of serpents, vipers, scorpions, and various insects. Flies of every species are also extremely annoying. Ants are very numerous in some parts: one traveller describes the road from El Arisch to Jaffa, as, for three days' journey, one continued ant-hill.

THE HISTORY OF PALESTINE.

In the patriarchal ages, it appears to have been a pastoral country, inhabited by independent chiefs similar to those who now traverse the extensive plains of Arabia. On the return of the Israelites from Egypt, it is described as a land flowing with milk and honey; very considerable progress had been made in agriculture, and the vices of luxury had made alarming progress. A series of events having delivered this country into the hands of the Israelites, it was divided by Joshua among the ten tribes: Judah, Benjamin, Simeon, Dan, Ephraim, Zebulun, Nephtali, and part of Manasseh, had their portion allotted on the western, commonly called *this* side of Jordan; while Reuben, Gad, and the remaining part of Manasseh, were placed on the eastern side, commonly called *beyond* Jordan. Israel, after remaining without any regular government, but ruled by occasional judges, was at length, on the demand of the people, converted into a monarchy, of which Saul was the first king. Under the reigns of David and Solomon, it became one of the most flourishing kingdoms of Asia. On the east it extended as far as the Euphrates, and having obtained ports on the Red Sea and the Mediterranean, was even as to commerce the rival of Tyre. This prosperity suffered a great declension in consequence of the schism which took place in the kingdom by the separation of the ten tribes, and the establishment of the rival kingdoms of Samaria and Judæa. They continued both considerable, however, till the rise of the great empires of the Euphrates, which were destined to swallow up all the west of Asia. The kings of Nineveh and Babylon experienced such an obstinate resistance, that they conceived it impossible to complete the conquest, unless by carrying captive first Israel and then Judah, into the eastern provinces of their empire. This eclipse, however, of the Jewish name and nation, lasted only till the downfall of Babylon. Cyrus, an enlightened and generous conqueror, determined to begin his reign by an act of clemency to this exiled people. He allowed them to return to their country, to rebuild their temple, and to re-establish their ecclesiastical constitution. Judæa continued thus a province of Persia till after the conquest of Alexander, to whom it submitted without resistance. After the partition of his empire, it fell naturally under the power of the kings of Syria, though exposed also to the invasion of the Ptolemies. Several of the Syrian kings having attempted to enforce the adoption of Grecian idolatry instead of the worship of the true God, were met by the most determined resistance. On this occasion the Maccabees, in a series of glorious conquests with the most unequal means, successfully asserted the religious and political liberties of their country. Judæa now became an independent country, and was governed for more than a century by a race of sovereign high priests called Asmoneans. They could not, however, prevent the country from falling under the wide-spread dominion of Rome, which established the Herods as tributary kings, leaving, however, the civil and ecclesiastical administration to a great extent in the hands of the natives. It was at this crisis that Judæa became the theatre of those events which form the foundation of the Christian faith, but which must be too familiar to our readers to require mention here. Enraged by repeated insurrections, the Romans, under Titus, entered Judæa with a large force, took Jerusalem, rased it to the ground, carried captive the whole nation, and dispersed them through the different provinces of the empire. The Jews have never recovered from this fatal overthrow. Yet, though dispersed among all nations, and every where oppressed and despised, they have never mixed with any other people, but have retained undiminished all the peculiarities of their religion and manners. The Romans, on obtaining full possession of this country, divided the part on this side of Jordan into three tetrarchies, Judæa Proper, Samaria, and Galilee. The country continued long in a troubled state, in consequence of the insurrections of the remaining part of the Jews. On the conversion of the Romans, however, to Christianity, Judæa became an object of religious veneration. The Empress Helena repaired in pilgrimage to the Holy Land, viewed all the spots which had been the scene of the great events of gospel history, and built splendid temples on their site. The Holy Land was now enriched by the crowd of pilgrims who came from all parts of the Christian world. The destinies of Judæa, however, were changed by the invasion of the fanatical followers of Mahomet, in the sixth century, and soon fell under their sway; the caliphs, or Arabian monarchs, however, still viewed her holy places with reverence, and were induced to encourage pilgrimage, from the gain which it afforded. When the Turks, an ignorant and barbarous race, poured in from the north, they no longer observed the same courtesy. They profaned the holy places, and committed outrages of every kind upon the visitants to the Holy Land. The pilgrims on their return related the dangers they had encountered. These representations kindled the religious zeal of the Christians in Europe into a flame, and a general ardour was awakened to "free the holy sepulchre from thrall." Now ensued a series of warlike expeditions, termed crusades, for the recovery of Palestine from the Mohammedans. After various successes and disasters, the crusades terminated at the middle of the thirteenth century, leaving the Holy Land still in the possession of a barbarous Mohammedan people. We shall subsequently advert to some of the scenes distinguished in the wars of the crusades. In the year 1517, Palestine was finally swallowed up in the Turkish empire. After ceasing for many centuries to have any political existence, it was drawn into notice by Bonaparte's invasion of Syria, and his celebrated siege of Acre, in the defence of which British valour was so conspicuously displayed.

Few countries are more unhappily situated, as to political relations, than Palestine. It suffers equally from the tyranny and the weakness of the Turkish government, which has strength sufficient to oppress the people, and deprive them of the fruits of their industry, yet lacks the vigour of defending them against the hordes of Arabs who people the surrounding deserts. The unfortunate husbandman is thus deprived on all hands of any security of enjoying the fruit of his labours. Its lot depends greatly upon the character of the pacha under whose sway it happens to be placed. Palestine, as to administration, is included partly in the pachalic of Acre, and partly in that of Damascus. The former comprehends all the sea-coast, while the latter extends over the interior; and they are separated by a line drawn from north to south through the whole length of Palestine. With regard to the civil government of the country, it has been remarked, that the pachas are so frequently changed, or so often at war with each other, that the jurisdiction of the magistrates in cities is so undefined, and the hereditary or assumed right of the sheiks of particular districts so various, that it is extremely difficult to discover any settled rule by which the administration is conducted. The whole Turkish empire, indeed, has the appearance of being so precariously balanced, that the slightest movement, within or from without, seems likely to overturn it. Every where is seen absolute power stretched beyond the limits of all apparent control, but finding, nevertheless, a counteracting principle in that extreme degree of acuteness to which the instinct of self-preservation is sharpened by the constant apprehension of injury. Hence springs that conflict between force and fraud, not always visible, but always operating, which characterises society in all despotic countries. In the minute subdivision of power, which in all cases partakes of the arbitrary nature of the supreme government, the traveller is often reminded of patriarchal times, when there were found judges and even kings exercising a separate dominion at the distance of a short journey from one another. This affectation of independence is every where exhibited in the Holy Land, from the pachas of cities down to the sheiks of villages, who, aware of the uncertain tenure by which their masters remain in office, are disposed to treat their orders with contempt. Like them, too, they turn to their personal advantage the power of imposition and extortion which belongs to every one who is dressed "in a little brief authority;" and thus they sell justice and mercy to the highest bidder.

Palestine has been conquered and occupied by such a variety of foreign races, that it would be difficult to decide who form the basis of its present population. The Turks, as elsewhere throughout the empire, occupy all the civil and military posts; while the inhabitants of the eastern empire, under the name of Greeks, form a very numerous part of the population. The country districts, however, are filled to a great extent with nomadic Arabs. The dress of this people in the Holy Land is very simple: it consists of a blue shirt, descending below the knees, the legs and feet being exposed, or the latter sometimes covered with the ancient cothrosmas or buskin. A cloak is worn of very coarse and heavy camel-hair cloth, almost universally decorated with black and white stripes passing vertically down the back: this is one square piece, with holes for the arms: it has a seam down the back. Upon their heads they wear a small turban, or dirty rag like a coarse handkerchief, bound across the temples, one corner of which generally hangs down, and this, by way of distinction, is generally fringed with strings in knots. The Arab women are not so often concealed from view as in other parts of the Turkish empire: they render their persons as disagreeable in appearance as any of the natives who inhabit the islands of the South Sea. Their bodies are covered with a long blue shift. Upon their heads they wear two handkerchiefs, one as a hood, and the other bound over it as a fillet across the temples. Just above the right nostril they place a small button, sometimes studded with pearl, a piece of glass, or any other glittering substance. Their faces, hands, and arms, are tattooed, and covered with hideous scars—their eyelashes and eyes being always painted, or rather dirtied with some dingy black or blue powder: their lips are dyed of a deep and dusky blue, as if they had been eating blackberries: their teeth are jet black: their nails and fingers brisk red: their ears are loaded with ponderous rings: and, altogether, it might appear as if some demon had employed his ingenuity to disfigure the loveliest work of the creation. The true Arab is always the inhabitant of the desert, a name given to any solitude, whether barren or fertile. Their usual weapons consist of a lance, a poniard, an iron mace, a battle-axe, and sometimes a matchlock gun. The moveables of a whole family seldom exceed a camel's load. They reside always in tents, on the open plain, or upon the mountains. The covering of their tents is made of goats' hair, woven by their women. Their mode of life very much resembles that of the gipsies in England—men, women, children, and cattle, all lodging together. In their disposition, though naturally grave and sedate, they are very amiable, considering hospitality as a religious duty, and always acting with kindness to their slaves or inferiors.

In our topographical description of Palestine, we shall commence with the capital,

JERUSALEM.

Few cities have been more frequently described than Jerusalem, and yet it is astonishing what diversity prevails in the accounts of it which we meet with in the more recent works upon Palestine. Sometimes the mantle of him who sung

"How Salem's shrine was won, and how adored,"

seems to have fallen upon the shoulders of the traveller, and tinctured his imagination with the hues of poetry, so that the holy city appeared to his eyes as rivalling, in the magnificence of its buildings, the most gorgeous edifices of modern times. Another, in traversing the desolate labyrinth called the valley of Jeremiah (a route usually followed in approaching the city), appears to have been inspired with the gloomy genius of the place; and, according to him, Jerusalem is a heap of filth and ruins, whose respectability is only here and there redeemed by a gaudy mosque or a glittering minaret. From these conflicting accounts we shall make as judicious a selection as possible, after giving a short

HISTORY OF THE CITY.

A contemporary of Abraham, Melchisedec, is called King of Salem, 2000 years before Christ. This Salem is supposed to be the city subsequently called Jerusalem. After this it came into the possession of the Jebusites; and when the Israelites conquered the land of promise, 1500 years before Christ, it was assigned in the division of the country to the tribe of Benjamin. The Jebusites, however, appear afterwards to have recovered possession of the place; for David conquered the city, called it after his name, and built the castle of Zion. His son Solomon greatly embellished it, and caused the temple to be built by the skilful artists of Tyre. Under his successors, Jerusalem was the capital of the kingdom of Judah. Five times it was taken and plundered: first by the Egyptians; then by the Arabians; by the Israelites; and again by the Egyptians, 611 years before Christ. Herodotus also mentions the last conquest of it, calling the city Kadytus, which resembles Kedushah the Holy; and the Mohammedans still call the city El Kods. At last, Nebuchadnezzar, during the reign of Zedekiah, conquered the kingdom, rased the city to the ground 586 years before Christ, and carried the Jews captive to Babylon. Seventy years after, Cyrus gave them permission to return and rebuild the city and temple. This was done under the direction of their high priests, Ezra and Nehemiah, whose successors governed them a long time. The story of Alexander's making a pacific visit to Jerusalem, after his conquest of Tyre, is considered a Jewish invention, as Josephus is the only author who mentions it. Alexander's successor, Ptolemy, captured Jerusalem, and carried a great number of the better sort of Jews to Alexandria. For a long time after it was taken by Antiochus the Great, it remained under the jurisdiction of the Syrian kings. Under the Maccabees, the Jews were again free for a considerable time, and chose their own rulers. One of the last of these, Aristobulus, invited Pompey the Great into the country, and thus Jerusalem came under the Roman dominion sixty-four years before Christ. But as it continued to have its own kings, at least in name, and also high priests, together with the Roman governors, this occasioned constant troubles, which were finally ended by the destruction of the city, and extermination of the inhabitants, by Vespasian and Titus, after a bloody siege, A. D. 70. Some buildings, however, were left among the ruins. The Jews again collected together, built on the place, and once more rebelled against the Romans, which so provoked the Emperor Adrian, that, in the year 118, he ordered all that Titus had spared to be destroyed. He commanded a new city to be built on its place, called Ælia Capitolina, in which no Jew was permitted to dwell. Constantine the Great, and his mother Helena, from pious motives, ordered all the Heathen monuments to be destroyed, and erected many new Christian edifices. Julian conceived the idea of rebuilding the old temple of the Jews, but is said to have been hindered from executing his plan by the eruption of subterranean fire. The city remained under the government of the eastern emperors, till Chosroes, King of Persia, conquered it in the year 614. It was recovered, however, by the Emperor Heraclius, in the peace of 628. This prince prohibited the Jews from dwelling there, and so alienated the patriarch of Jerusalem, Sophronius, by sectarian differences, that the Saracen Caliph Omar found little difficulty in making himself master of the city, A. D. 637. The Saracens, unwilling to forego the profits of pilgrimage, allowed the Christians to resort thither as formerly, upon the payment of a considerable tax, so that Jerusalem was nearly as much frequented as ever, till the inroads of the Turks in 1076. That barbarous people committed such outrages on the pilgrims, that they could no longer visit the holy sepulchre in safety; and this formed one of the moving causes of the crusades, in one of which Jerusalem was taken, and ruled, along with the surrounding territory, during upwards of sixty years, by five Latin kings, when it yielded to the arms of Saladin. After changing successively its Moslem masters, it was annexed, in 1517, to the Turkish empire, of which it has ever since formed a part.

GENERAL DESCRIPTION OF JERUSALEM.

This celebrated city of Palestine is situated at the distance of about forty-five miles east from the shores of the Mediterranean Sea, within the jurisdiction of the pacha of Damascus. Its environs are barren and mountainous. The city lies on the western declivity of a hill of basalt, surrounded with rocks and deep vallies, with a much colder climate than one would expect from its geographical situation. It is now only between two and three miles in circuit, and can be walked round in forty-five minutes. The town is built irregularly, somewhat in the form of a square, has pretty high walls, and six gates, which still bear Hebrew names. The houses are of sandstone, three stories high, and without windows in the lower story.

This lifeless uniformity is only diversified here and there by the spires of the mosques, the towers of the churches, and a few cypresses. The population has been variously estimated at from 20,000 to 25,000. "It can hardly," says Mr Carne, in his Letters from the East, "exceed twenty thousand; ten thousand of these are Jews, five thousand Christians, and the same number of Turks. The lower division of the city," he continues, "towards the east, is chiefly occupied by the Jews; it is the dirtiest and most offensive of all. Several of this people, however, are rather affluent, and live in a very comfortable style; both men and women are more attractive in their persons than those of their nation who reside in Europe, and their features are not so strongly marked with the indelible Hebrew characters, but much more mild and interesting. But few passengers in general are met with in the streets, which have the aspect, where the convents are situated, of fortresses, from the height and strength of the walls the monks have thought necessary for their defence. Handsomely dressed persons are seldom seen, as the Jews and Christians rather study to preserve an appearance of poverty, that they may not excite the jealousy of the Turks. The women, in their close veils and white dresses, look like walking corpses. The streets are unpaved, and filled either with heaps of dust or with mire. Nothing is to be seen but veiled figures in white, insolent Turks, and stupid or melancholy Christians." That Jerusalem is no place for the cultivation of the arts or sciences, one may easily conjecture from the malignant genius of Turkish despotism, and the forbidding aspect of Christian superstition. Weavers and slipper-makers are the only artisans. A multitude of relics, which are probably not all manufactured in the city, but are sent in also from the neighbourhood, are sold to the credulous pilgrims. Nevertheless, this city forms a central point of trade to the Arabians in Syria, Arabia, and Egypt. The people export oil, and import rice by the way of Acre. The necessaries of life are in profusion, and quite cheap, the game excellent, and the wine very good. The pilgrims are always a chief source of support to the inhabitants at Easter; they often amount to 5000. But few of them are Europeans. Jerusalem has a governor, a cadi or supreme judge, a commander of the citadel, and a mufti, to preside over religious matters. The citadel, which is pretended to have been the castle of David, is a Gothic building throughout. It is called the Pisan Tower, probably because it was built by the Pisans during the crusades. All the pilgrims go to the Franciscan monastery of the Holy Saviour, where they are maintained a month gratuitously. Besides this, there are sixty-one Christian convents in Jerusalem, of which the Armenian is the largest. They are supported by benevolent contributions, principally from Europe. The church of the Holy Sepulchre has been for 1500 years the most sacred place in Jerusalem. The temple of the Mohammedans, which is regarded as one of their greatest sanctuaries, is magnificent. No Jew or Christian is permitted to enter the inner sanctuary. Besides many old Jewish monuments, there are a great many Greek and Roman, several Christian, and especially Gothic monuments, which originated in the times of the crusades.

THE MOSQUE OF OMAR.

The most splendid edifice which Jerusalem, and indeed the Turkish empire, contains, is the Mosque of Omar, the St Peter's of Turkey. We have said that no Christian is allowed to enter it. Dr Richardson, however, succeeded in obtaining admission, and was conducted through the interior by the sacristan, who pointed, "in the pride of his heart, to the elegant marble walls, the beautifully gilded ceiling, the well where the true worshippers drink and wash (with which we also blessed our palates and moistened our beards), the paltry reading-desk with the ancient Koran, the handsome columns, and the green stone with the wonderful nails. As soon as we had completed this circuit, pulling a key from his girdle, he unlocked the door of the railing that separates the outer from the inner part of the mosque, which, with an elevation of two or three steps, led us into the sacred recess. Here he pointed out the patches of Mosaic in the floor, the round flat stone which the prophet carried on his arm in battle; directed us to introduce our hand through the hole in the wooden box, to feel the print of the prophet's foot, and through the posts of the wooden rail, to feel as well as to see the mark of the angel Gabriel's fingers, into which I carefully put my own, in the sacred stone that occupies the centre of the mosque, and from which it derives the name of Sakhara or Locked-up, and over which is suspended a fine cloth of green and red satin. It was so covered with dust, that, but for the information of my guide, I should not have been able to tell the composing colours. Finally, he pointed to the door that leads into the small cavern below, of which he had not the key. I looked up to the interior of the dome, but, there being few lamps burning, the light was not sufficient to show me any of its beauty farther than a general glance. The columns and curiosities were counted over again and again, the arches were specially examined and enumerated, to be sure that I had not missed nor forgotten any of them."

Dr Richardson having been permitted to visit this splendid edifice during the day, he found that the dimensions of the enclosure in which it stands are about fifteen hundred feet in length and a thousand in breadth. In this place the followers of the prophet delight to saunter or repose, as in the elysium of their devotions; and, arrayed in the gorgeous costume of the east, add much to the interest, the beauty, and solemn stillness of the scene. The Sakhara itself is a regular octagon of about sixty feet a side, and is entered by four spacious doors, each of which is adorned with a porch projecting from the line of the building, and rising considerably on the wall. All sides of it are panelled. The centre stone of one panel is square, of another it is octagonal, and thus they alternate all round, the sides of each running down the angles like a plain pilaster, and giving an appearance as if the whole were set in a frame. The marble is white, with a considerable tinge of blue; square pieces of the latter colour being introduced in different places, so as to confer upon the exterior a very pleasing effect. The upper story is faced with small tiles painted of different colours, and some of them are written over with sentences from the Koran. At this height there are seven elegant windows on each side, except where the porches interfere, when they diminish the general appearance of the edifice.

The interior fully corresponds to the magnificence and beauty just described. There are twenty-four marble columns, placed parallel to the eight sides of the building; three opposite to each side, so as still to preserve the octagonal form. Eight of them are large plain pillars belonging to no particular order of architecture, and all standing opposite to the eight entering angles of the edifice, and deeply indented on the inner side; so that they furnish an acute termination to the octagonal lines within. Between every two of the square columns there are two of a round figure, well proportioned, and resting on a base. They are from eighteen to twenty feet high, with a sort of Corinthian capital. A large square plinth of marble extends from the top of the one column to the other, and above it there is constructed a number of arches all round, which support the inner end of the roof or ceiling, the outer end resting upon the walls of the building. This is composed of wood or plaster, highly ornamented with a species of carving, and richly gilt.

This magnificent temple owes its origin to a large oblong shaped stone, which occupies the centre of the building. Like the Palladium of Troy, it is reported to have descended from heaven on the identical spot where it now stands; it happened when prophecy began at Jerusalem, and was used by those who were endowed with the gift of vaticination. Like the stone in the fairy tale which changed its hues with the fortunes of the possessor, this stone manifested sympathy in the fate of the prophets when they were compelled to evacuate Jerusalem, even so far as to give indications of a desire to accompany them in their flight. But, by the interposition of the angel Gabriel and Mahomet, it was found immediately in the place where it now stands, and around it the Caliph Omar reared his gorgeous temple.

In the interior of the rock whereon the Sakhara stands, there is a cave into which Dr Richardson could not obtain admittance. It is a room forming an irregular square of about eighteen feet surface, and eight feet high in the middle. The roof is that of a natural vault, quite irregular. In descending the staircase, there is upon the right hand, near the bottom, a little tablet of marble, bearing the name of El Makam Souleman, the Place of Solomon. A similar one upon the left is named El Makam Daoud, the Place of David. A cavity or niche on the south-west side of the rock is called El Makam Djibrila, the Place of Gabriel; and a sort of stone table at the north-east angle is denominated El Makam El Hoder, the Place of Elias. In the roof of the apartment, exactly in the middle, there is an aperture almost cylindrical through the whole thickness of the rock, about three feet in diameter. This is the Place of the Prophet.

Leaving the Mohammedan temple of worship, we shall now proceed to describe one of far more interest to the Christian reader, namely,

THE CHURCH OF THE HOLY SEPULCHRE.

Mount Calvary, the spot on which the crucifixion of Christ took place, was originally a rising ground without the walls, but was afterwards enclosed within the city, altered entirely in its outlines, and made the site of a church founded by the Empress Helena. This Church of the Holy Sepulchre, as it is called, is about one hundred paces in length, and sixty in width. It is in the form of a circle, having a heavy dome or cupola, the frame of which is made of the cedars of Lebanon, and covered with a kind of stucco. It has a spacious and magnificent appearance, the Corinthian order of architecture prevailing.* Mr Carne, in his "Letters from the East," describes it as follows:—

"There was a guard of Turks in a recess just within the door, to whom every pilgrim is obliged to pay a certain sum for admission; but we were exempted from this tax. In the middle of the first apartment is a large marble slab, raised above the floor, over which lamps are suspended; this is said to be the space where the body of the Redeemer was anointed and prepared for the sepulchre. You then turn to the left, and enter the large rotunda, which terminates in a dome at the top. In the centre of the floor stands the holy sepulchre; it is of an oblong form, and composed of a very fine reddish stone brought from the Red Sea, that has quite the appearance of marble. Ascending two or three low steps, and taking off your shoes, you enter the first small apartment, which is floored with marble, and the walls lined with the same. In the centre is a low shaft of white marble, being the spot to which the angel rolled the stone from the tomb, and sat on it. You now stoop low to enter the narrow door that conducts you to the side of the sepulchre. The tomb is of a light brown and white marble, about six feet long and three feet high, and the same number in breadth, being joined to the wall. Between the sepulchre and the opposite wall the space is very confined, and not more than four or five persons can remain in it at a time. The floor and the walls are of a beautiful marble; the apartment is a square of about seven feet, and a small dome rises over it, from which are suspended twenty-seven large silver lamps, richly chased and of elegant workmanship—presents from Rome, of the courts and religious orders of Europe; these are kept always burning, and cast a flood of light on the sacred tomb, and the paintings hung over it, one Romish and the other Greek, representing our Lord's ascension, and his appearance to Mary in the garden. A Greek or Romish priest always stands here with the silver vase of holy incense in his hand, which he sprinkles over the pilgrims.

Wishing to see the behaviour of these people, who come from all parts of the world, and undergo the severest difficulties to arrive at this holy spot, we remained for some time within it; and the scene was very interesting. They entered: Armenians, Greeks, and Catholics, of both sexes, with the deepest awe and veneration, and instantly fell on their knees; some, lifting their eyes to the paintings, burst into a flood of tears; others pressed their heads with fervour on the tomb, and sought to embrace it; while the sacred incense fell in showers, and was received with delight.

In an apartment a little on the left of the rotunda, and paved with marble, is shown the spot where Christ appeared to Mary in the garden. Near this begins the ascent to Calvary, which consists of eighteen very lofty steps; you then find yourself on a floor of beautifully variegated marble, in the midst of which are three or four slender white pillars of the same material, which support the roof, and separate the Greek division of the spot from that appropriated to the Catholics; these pillars are partly shrouded by rich silk hangings. At the end stand two small and elegant altars; over that of the Catholics is a painting of the crucifixion, and over the Greek is one of the taking down the body from the cross. A number of silver lamps are constantly burning, and throw a rich and softened light over the whole of this striking scene.

The street leading to Calvary has a long and gradual ascent; the elevation of the stone steps is above twenty feet; and if it is considered that the summit has been removed to make room for the sacred church, the ancient hill, though low, was sufficiently conspicuous. The very spot where the cross was fixed is shown; it is a hole in the rock, surrounded by a silver rim, and each pilgrim prostrates himself, and kisses it with the greatest devotion. Its identity is probably as strong as that of the cross and crown of thorns found a few feet below the surface; but where is the scene around or within the city that is not defaced by the sad inventions of the fathers?"

The priests connected with these sacred places keep up a system of religious ceremony, in some of which it would be impossible to say whether solemnity, fervour, superstition, ignorance, or sheer madness, most predominates. The ceremonies which take place during the season of Easter are ridiculous and absurd in the extreme. Upon Good Friday night the monks enact a sort of tragedy of the death of our Lord, in which they severally perform the various characters, such as Joseph of Arithmathea and Nicodemus. They have a figure of Christ as large as life nailed to a cross. This these solemn tragedians parade before them as they walk in procession, and go through a representation of the awful drama of his death, in which no circumstance of moment is omitted, from the singing of the hymn to the anointing of the body for burial, and its deposition in the sepulchre. The transactions of Easter day partake more of comedy than tragedy. It is a scene of superstitious riot and pitiful absurdity, which we think is unnecessary to describe. The reader may have some idea of it by imagining to himself what would be the consequences if bedlam were let loose upon the holy sepulchre. It is only doing justice, however, to those who have the keeping of the "place where our Lord lay," to observe, that some of the ceremonies are both solemn and impressive, without much admixture of absurdity. It is impossible, however, to read the exhibitions of Easter day and eve, without a painful misgiving as to every thing connected with the holy city. The reader will perhaps inquire, can we give any credit to the historical statements and local descriptions derived from individuals as ignorant, superstitious, and corrupt, as the priests and Christians of Jerusalem? Our religion can in no way be affected by the determinations of such questions as those, regarding the precise spot where our Saviour suffered, or where his body was laid. But still with such places there is a hallowed interest associated, and that any doubt should remain upon the subject, is a source of regret and disappointment. The obliteration which the surface of a conquered country generally suffers from its enslavers, must have ob-

* Represented in our view of Jerusalem, as the large edifice in the centre of the picture, within the outer wall.

erured many of the finer lines by which we might identify various localities; nevertheless, the great natural landmarks remain; and we may conclude with Chateaubriand, that although minute details are open to suspicion, the general outline is correct. With respect to the holy sepulchre, Dr Clarke, who throws doubt indiscriminately on all the traditions connected with the holy places, observes, "If Helena had reason to believe she could identify the spot where the sepulchre was, she took especial care to remove every trace of it, in order to introduce the fanciful and modern work which now remains." The place may be the same pointed out to her, but not a remnant of the original sepulchre can now be ascertained.

MOUNTS ZION AND MORIAH.

On crossing the small ravine which divides the modern city from Mount Zion, the attention is attracted to three ancient ruins, covered with buildings comparatively modern—the house of Caiaphas, the place where Christ held his last supper, and the tomb or palace of David. The first of these is now a church, the duty of which is performed by the Armenians: the second, consecrated by the affecting solemnity, with the memory of which it is still associated, presents a mosque and a Turkish hospital; while the third, a small vaulted apartment, contains only three sepulchres, formed of dark-coloured stone. This holy hill is equally celebrated in the Old Testament and in the New. Here the successor of Saul built a city and a royal dwelling; here he kept for three months the ark of the covenant; here the Redeemer instituted the sacrament, which commemorates his death; here he appeared to his disciples on the day of his resurrection. The place hallowed by the last supper, if we may believe the early fathers, was transformed into the first Christian temple the world ever saw, where St James the Less was consecrated the first bishop of Jerusalem, and where he presided in the first council of the church. Finally, it was from this spot that the Apostles, in compliance with the injunction given them, went forth to teach all nations.

A shallow vale, called the valley of Millo, separates Mount Zion from Mount Moriah, on which the temple stood; this was originally an irregular hill, separate from Mount Zion and Acra, as well as from Beretha. For the purpose of extending the appendages of the temple over an equal surface, and to increase the area of the summit, it became necessary to support the sides, which formed a square, by immense works. In order to connect it with Mount Zion, it was necessary to throw a bridge across the valley of Jehoshaphat. According to Josephus, the execrable but magnificent monarch, Herod, rebuilt the second temple; but there is reason to suppose that he only added considerably to its extent. Its fate is well known: the prediction of our Saviour, that one stone should not be left upon another, was literally fulfilled. After the Caliph Omar took Jerusalem, buildings were erected on the spot where Solomon's temple stood, the rock was enclosed with walls, and, by subsequent additions and embellishments, it became the splendid mosque which we have already described.

Leaving the city at the gate of St Stephen, the pilgrim is conducted to the spot nearly contiguous, where it is considered he suffered martyrdom. He is then shown the church of the sepulchre of the Virgin Mary, situated in the valley between the Mount of Olives and Jerusalem, founded by St Helena. This is a small square building, flat on the roof, with a door on the south side, by which there is a descent into the interior by steps, having on the right hand a small chapel, with the tomb of St Ann, the mother of Mary. On the left is another similar to the former, where Joseph, the husband of the latter, was interred. Although the authenticity of such assertions depends on the probabilities of tradition, yet the solemn stillness of the place, the sepulchral gloom, and, above all, the associations which are calculated to affect the mind in seeing every object about this city, combine to render a visit to this consecrated spot so deeply interesting, that a traveller of the least sensibility never can forget it.

MOUNT OF OLIVES, &c.

Passing along a small bridge thrown over the Kedron, the Mount of Olives next presents itself. About half way towards the summit, there are several grottos excavated labyrinthically in the rock. Higher up is another cavern, or subterraneous church, as it is now formed, consisting of several arched vaults, where the Apostles composed the creed bearing their name; but this is almost filled with rubbish. About fifty yards farther, the spot is pointed out where Christ looked down upon Jerusalem in grief, and pronounced that ever memorable prophecy which has been so awfully and strikingly fulfilled. On the top of the Mount are the remains of a small church or chapel, in the octagon form, with a cupola, denominated the Ascension. This was built by St Helena, who, through the means of her son Constantine, may be considered as possessed of the treasures of the Roman world, and has left behind her, not only in and about Jerusalem, but in other parts, innumerable monuments of "her faith and labours of love." Here there is shown the impression of the left foot or sandal of a man, which is ten inches in length and four in breadth, made on a rock or stone, said by the guides to be that of Christ, when his foot last touched the earth, though of course this is one of those modern inventions which prevail throughout the region.

GARDEN OF GETHSEMANE.

The garden of Gethsemane, of all the gardens in the world the most hallowed and interesting, is situated at the foot of the Mount, and near the Brook Kedron. It is a piece of ground surrounded by a coarse loose wall of a few feet in height, and about the third part of an acre in extent. There are seven olive trees of enormous magnitude remaining, and separate from each other, said to have been in existence since the time of our Lord; they are highly venerated by the Christians, who consider any attempt to cut or injure them as amounting to an act of profanation. Should a Catholic be known to pluck any of the leaves, it subjects him to a sentence of excommunication from church privileges. Beads are made of the stone of the olive, and a string of them is the most sacred object that can possibly be presented to a traveller.

It was to this garden that Christ had occasion to resort with his disciples, to engage in devotional meditation, and a view of it is well calculated to impress the Christian mind with the deepest religious awe. At the upper end is the place where the Apostles, Peter, James, and John, fell asleep during the passion of their divine Master, and, in the middle of the garden, the place where Judas betrayed him. Many other interesting places and grottos are here pointed out, and among them is one which is supposed to be the scene of the agony and the bloody sweat.

VALLEY OF JEHOSHAPHAT.

After leaving the garden of Gethsemane, the traveller enters the valley of Jehoshaphat towards the south, on the eastern side of it. Among the first objects which are pointed out is the pit of Nehemiah, where the avenger of Israel discovered the sacred fire which had been concealed there during the Babylonish captivity. There is also shown the spot where Isaiah is said to have been sawn asunder. A little farther from the scene of the martyrdom, and on the same side of the valley, is the pool of Siloam, so particularly alluded to in Scripture, the water of which is of a brackish disagreeable taste, and flows several miles distant under the city of Jerusalem, and is emptied here into a sort of a basin inclosed by a wall. At a short distance from, and over against the pool, is the "Mountain of Offence," as it is termed, where Solomon committed acts of idolatry, by offering sacrifices to the gods of the Moabites and other nations. Near the foot of it, the Field of Blood is shown, where Judas hanged himself; and beyond it two massy pieces of antiquity, one of which is named the Tomb of Zechariah, and the other that of Absalom, formed in an extraordinary manner out of the natural rock, about eighteen feet in height, and ornamented with some columns of architecture, after the Ionic order, hewn in the same entire stone, supporting a cornice over which rises a pyramidal roof. The latter, since Absalom was not supposed to be buried in the valley, is conjectured to have been formed during the life of that prince. Such is the antipathy of the Jews to this monument, that it is their practice in passing to throw stones against it, as a mark of their reprobation of the unnatural rebellion of Absalom against his father. Near it is the sepulchre of Jehoshaphat, which gives the name to the valley. It is a cavern which is more commonly called the Grotto of the Disciples, from an idea that they went frequently thither to be taught by their divine Master. The front of this excavation has two Doric pillars of small size, but of just proportions. In the interior are three chambers, all of them rude and irregular in their form; in one of which were several gravestones, removed, we may suppose, from the open ground for greater security. Like all the rest, they were flat slabs of a long shape, from three to six inches in thickness, and evidently a portion of the limestone-rock which composes the adjoining hills.

Chateaubriand is of opinion, that, except the pool of Bethesda at Jerusalem, we have no remains of the primitive architecture of its inhabitants. The tombs in the valley of Jehoshaphat display an alliance of Egyptian and Grecian taste, mixed with the peculiar style of the Hebrews. In the valley of Jehoshaphat the Jews have a place of sepulture, which contains a number of gravestones, where those who reside in Jerusalem are in the habit of going in procession at certain seasons, for the purpose of observing a religious festival in memory of the dead. There still exists a strong desire in this people to mingle their dust with the ashes of their fathers, and many of them, as well as Christians, entertain the fantastical belief that the valley of Jehoshaphat is to be the scene of the final resurrection. With respect to its present aspect, Chateaubriand beautifully observes, "What with the sadness of Jerusalem, from which there ascends no smoke nor issues any sound—the solitude of the mountains, in which we perceive no living being—and the confusion of the tombs, all broken, shattered, and half open—one could almost believe that the trump of doom had already sounded, and that the dead had begun to rise in the valley of Jehoshaphat."

Besides the places already described in and about the city which tradition has hallowed, are the following:—Beneath the gate of Bethlehem is the spot where Bethsheba was bathing when David beheld her from the roof of his palace, and the present tower of the king is built upon the site of the ancient palace. A small distance within the gate of St Stephen is the pool of Bethesda. It is one hundred and fifty feet long, and forty broad. The sides are walled with large stones joined together by iron cramps, and covered with flints embedded in a substance resembling plaster. Here the lambs destined for sacrifice were washed, and here the Saviour said to the paralytic man, "Take up thy bed and walk." It receives a melancholy interest from the consideration that it is the only remnant which remains of Jerusalem as it appeared in the days of Solomon. A wretched street leads from this to the governor's palace, a spacious and rather ruinous building of Roman architecture. It contains some good apartments, the windows of which command an excellent view of the Mosque of Omar and its large area. In this palace the monks point out the room where Christ was confined before his trial; and at a short distance is a dark and ruinous hall, shown as the judgment-hall of Pilate. You then proceed along the street where Christ bore his cross, in which, and in the streets leading up to Calvary, are the three places, where, staggering under the weight, he fell. These are marked by three small pillars laid flat on the ground. The very house of the rich man also is here, and the spot where Lazarus sat at his gate. A pilgrim who comes to the city must set no bounds to his faith, as he is shown the place where the head of Adam was found, the rock on which the martyr Stephen was stoned, and the place of the withered fig-tree, with the milk of the Virgin Mary, and some of the tears that St Peter wept on his bitter repentance.

BETHANY.

After leaving Jerusalem by the gate of St Stephen, crossing the valley of Jehoshaphat, and passing the garden of Gethsemane and the Mount of Olives, the pilgrim arrives at the village of Bethany, situated about two miles from the city, where Jesus once resided, and appeared to his disciples after his resurrection. On the road, we meet with the village of Bethpage, now a heap of ruins. Bethany is both small and poor: it is, however, beautifully situated, and the view just above it is very magnificent. The cultivation of the surrounding soil is much neglected. The object which first strikes the traveller, is a ruinous castellated pile, which it is said Lazarus occupied. This, however, is one of the oral legends which abound in this interesting country, and, notwithstanding the great and superior claims that all its hallowed spots have upon our most serious affections, weaken the impression of the best authenticated memorials, and effect the association of piety with incredulity and distrust. Not far distant are the ruins of a building, said to have been the house of St Mark. A little to the right are the vestiges of the habitation of Mary Magdalene. But by far the most interesting object is the tomb of Lazarus. The traveller first descends to a cave, probably from fifty to sixty feet under ground, and lands on a small quandrangular space, where there appears to have been a communication with a church adjoining, which is now built up and converted into a mosque. In the wall of this apartment, there is an aperture of about three feet in breadth, formed by the raising of a large stone, as if by some convulsion of nature, which conducts into an arched vault, said to be the spot where the body was laid. It measures about fourteen feet in length, ten in breadth, and eight in height. With respect to the identity of the tomb, Mr Carne observes, "Its identity cannot be doubted—the position of Bethany could never have been forgotten—and this is the only sepulchre in the whole neighbourhood."

BETHLEHEM.

Bethlehem, as being the birth-place of Christ, is one of the most interesting places in the Holy Land. The road leading to it is extremely rocky and barren, only diversified by some cultivated patches bearing a scanty crop of grain, and a profusion of wild flowers. On the way lies the ruined Tower of Simeon, who, upon beholding the infant Messiah, expressed his willingness to leave this world; the monastery of Elias, in which there is said to be a large stone, still retaining an impression of his body; and the tomb of Rachel, rising in a rounded top, like those erected to the memory of a Turkish sultan. Farther on is the well of which David longed to drink, and of which his mighty men, at the imminent risk of their lives, procured a supply. To distinguish this town from another of the same name of the tribe of Zebulun, the Bethlehem we now approach is usually distinguished by the addition of Ephrata, or by a reference to the district in which it is situated. It is a fine village, situated upon a mountain, and surrounded with gardens of fig-trees and olives. The houses are very humble, and flat on the roof, with stairs on the outside.

THE CONVENT OF FRANCISCANS.

The convent of Franciscans stands to the east, and is separated from the town; it is contiguous to the church of St Mary, which was built by Constantine and the Empress Helena, over the place of their nativity, and forms, with the adjacent monasteries, a vast pile, in the shape of a cross. The church is of considerable magnitude, and was considered at one period to be unrivalled in point of beauty and magnificence. The roof is constructed of the cedar of Lebanon, and supported by four rows of lofty marble columns, being about fifty in number. The interior of the walls was encrusted with marble, but robbed of it to adorn the palace of the pacha at Grand Cairo. The choir is spacious, and terminates in a semicircle, in which the principal altar is placed. This part of the edifice is covered with a cupola, adorned with figures in Mosaic. A small staircase conducts to the chapel of the Nativity, which is under ground. Before the altar several massy silver lamps are kept constantly burning; and the spot where it is said Christ was born, is marked with a star, formed of white marble, inlaid with jasper, and surrounded with a radiance or glory. On this there is encircled the following inscription:—

Hic de Virgine Jesus Christus natus est.
Here Jesus Christ was born of the Virgin Mary.

To the right of this is shown the place where stood the manger in which he was laid. It appears to be cut out of the natural rock, and lined with marble. Lamps of silver are always kept burning before it. A narrow passage leads from this chapel into that of the innocents who were slain by the command of Herod, where is a cell, in which, say the monks, St Jerome made a translation of the Bible. A short distance from the convent is a grotto, where, according to tradition, the mother of Jesus concealed herself and child, whilst Joseph was making arrangements for their flight.

Four miles to the south of Bethlehem, in a most secluded situation in the middle of mountains, are situated the celebrated pools or fountains of Solomon. These are three in number, of a quadrangular form, cut out of the living rock. About half a mile below there is a deep valley, embosomed in high hills, where it is said the gardens of Solomon were laid out.

From the top of the church at Bethlehem there is a fine prospect of the surrounding country, extending to Tekoa on the south, and En-gedi on the east. In the latter place is the grotto where David, a native of Bethlehem, cut off the skirt of Saul's garment. Between this point and Jerusalem are several small detached towers, of a square form, built in the midst of vine-lands. These are for the accommodation of watchmen appointed to guard the produce from thieves and wild beasts, as alluded to by the evangelist St Mark. With regard to the tradition respecting the cave of the Nativity, even Dr Clarke admits the indubitable authenticity. This has been established by an unbroken chain of evidence, which extends from the first ages of Christianity to the present time. With respect to the number of inhabitants which it contains, much diversity of opinion prevails. Mr Buckingham says they amount to above 1000; Dr Richardson sets down the number at 300; and Mr Carne at 700, adding at the same time "that they appear to live very meanly." This appears to be the nearest approximation to the truth.

Near to Bethlehem are the ruins of a church and convent, which were erected by the pious empress over the place where the angels appeared to the shepherds. Hardly any part of it has survived the desolation to which every edifice in Palestine has been repeatedly subjected.

CONVENT OF ST JOHN.

On the way back to Jerusalem, the traveller alights on the convent of St John, in the desert. This monastery is built over the dwelling where the Baptist is supposed to have been born. The spot on which he was brought forth is marked with a star of marble, bearing this inscription:—

Hic precursor Domini Christi natus est.
Here the forerunner of Christ the Lord was born.

The church belonging to this establishment has been described as one of the best in the Holy Land. It has an elegant cupola, and a pavement of Mosaic, with some paintings; but the appearance, notwithstanding, is mean and indifferent, as if its votaries were few, and but little concerned in preserving its ancient grandeur. The cave which the second Elias is said to have inhabited, is situated on the brow of a steep mountain, in a most dreary and desolate spot. The grotto, which would seem to be cut out of the rock, is twenty-four feet in length by twelve in breadth, and in front of it flows a spring of water. To the south, and at some distance from the desert, is pointed out the well where Philip baptised the eunuch, as recorded in the Acts of the Apostles.

Quitting these places, the traveller turns his face southward to Tekoa and Hebron. The former, which was built by Rehoboam, and is distinguished as the birth-place of Amos the prophet, presents some considerable ruins, and even a few remains of architecture. It appears to have stood upon a hill, which is described as being about half a mile in length, and a furlong broad. On the north-eastern corner there are fragments of an antique building, supposed to have been a fortress; while about half way up the ascent there are similar indications of a church, now in a ruinous condition. Towards the south, various manifestations of ancient civilization present themselves. Pococke mentions a ruined castle called Creightoun, situated on the side of a steep hill, and a church dedicated to St Pantaleone. At a short distance there is a grotto, which on one occasion is said to have contained 30,000 men; and hence it is supposed to be one of those retreats in the fastnesses of En-gedi, to which David fled from the pursuit of Saul. About two miles to the south-east is the Mount of Bethulia, near a village of the same name, a position which is thought to agree with that of Beth-haccerem, mentioned by Jeremiah as a proper place for a beacon where the children of Benjamin were to sound the trumpet in Tekoa. This strong post is said to have been held by the Knights of Jerusalem forty years after the capital had fallen; but on what authority, we know not.

HEBRON.

Hebron is considerably removed from the common track of pilgrims and tourists; it is a large town, and contains a monument, dedicated to the memory of Abraham, and his immediate descendants. M. Burckhardt, who saw it in 1807, bears testimony to the fact that the sepulchre, once a Greek church, is now appropriated to the worship of Mohammed. The ascent to it is by a large staircase that leads to a long gallery, the entrance to which is by a small court. Towards the left is a portico resting upon pillars. The vestibule of the temple contains two rooms; the one being the tomb of Abraham, the other that of Sarah. In the body of the church is the sepulchre of Isaac; and in a similar one upon the left is that of his wife. On the opposite side of the court is another vestibule, which has also two rooms, being respectively the dormitory of Jacob and of his spouse. At the extremity of the portico, upon the right hand, is a door which leads to a sort of long gallery that still serves for a mosque; and passing from thence, is observed another room, containing the ashes of Joseph, which are said to have been carried thither by the people of Israel. All the sepulchres of the patriarchs are covered with rich carpets of green silk, magnificently embroidered with gold; those of their wives are red, embroidered in the same way.

Hebron is said to contain about four hundred families, of which about a fourth part are Jews. It is situated on the slope of a mountain; has a strong castle; can boast abundance of provisions, a considerable number of shops, and some neat houses. The whole of the country between Tekoa and Hebron is finer and better cultivated than in the neighbourhood of Jerusalem.

We shall now, with Chateaubriand for our guide, proceed to

THE DEAD SEA.

On leaving Bethlehem for the Dead Sea, the traveller goes eastward, through a vale where it is said Abraham was wont to feed his flocks. This pastoral plain is succeeded by a range of mountainous and barren ground. Descending from this, two lofty towers rise from a deep valley, marking the site of the convent of Santa Saba, a very ancient church. Its situation is very dreary, being built amidst precipices on the brink of a deep and gloomy dell, where the brook Kedron flows.

In advancing, the country still presents a desolate aspect. The road at length seeks a lower level, and approaches the rocky border which bounds the valley of the Jordan; when, after a toilsome journey of ten or twelve hours, the traveller at last beholds the Dead Sea, and the line of the river; the landscape, however, is by no means grand or prepossessing. Two long chains of mountains run in a parallel direction from north to south, without breaks, and without undulations. The eastern or Arabian chain is the highest; and when seen at the distance of eight or ten leagues, it resembles a prodigious perpendicular wall. Not one summit, not the smallest peak is distinguishable; only slight inflections are here and there observed, as if the hand of the painter who drew this horizontal line along the sky had trembled in some places. The mountains of Judæa form the range on which the observer stands as he looks down on the lake Asphaltites; it is less lofty and more unequal than the eastern chain, and also differs from it in its nature; exhibiting heaps of chalk and sand, which assume various bizarre forms. The Arabian side, on the contrary, presents nothing but bleak precipitous rocks, which throw their long and gloomy shadows over the water of the Dead Sea. Not a single blade of grass is to be found among these crags; every thing announces the country of a reprobate people, and well fitted to perpetuate the doom pronounced on Ammon and Moab. The valley embosomed in these two chains of mountains displays a soil similar to the bottom of a sea which has long retired from its bed—a beach covered with salt, dry mud, and moving sands, furrowed as it were by the waves. Vegetation is here in a deplorable state; there are a few dreary shrubs which perpetuate a sort of inanimate existence; their leaves are covered with salt, and their bark has a smoky smell and taste. Instead of villages, you perceive the ruins of a few towers. In the middle of this valley flows a discoloured river, which reluctantly throws itself into the pestilential lake by which it is engulfed. Its course amid the sand can be distinguished only by the willows and the reeds that border it; among which the Arab lies in ambush to attack the traveller, and to murder the pilgrim.

We now arrive at the celebrated lake which in Scripture is called the Dead Sea; among the Greeks and Latins, Asphaltites; and among the Arabs, Bahna Looh, or the Sea of Lot. Considerable diversity of opinion has prevailed, both among the ancients and moderns, regarding the exact dimensions of this lake, which as yet are probably not accurately ascertained. Mr Carne says, its length may probably be about sixty miles, and its average breadth eight. Mr Banks, however, who took observations from several neighbouring heights, says that its utmost extent does not exceed thirty miles. This discrepancy places the inaccuracy of travellers, with regard to their topographical descriptions of Palestine, in a very strong point of view. It is surrounded on the east by lofty hills, exhibiting rugged and frightful precipices; on the north it is bounded by the plain of Jericho, through which it receives the river Jordan. Other streams are discharged into it; and there being no visible outlet, while the banks are not overflowed, some have thought there is a subterraneous channel communicating with the Mediterranean; others readily account for the phenomenon, in the evaporation which necessarily takes place in a hot climate. This lake is clear and limpid, resembling the colour of the sea. Its waters are of greater specific gravity than any hitherto discovered; they are in general fatal to animal life, nor do vegetables flourish in their immediate vicinity. The fishes carried hither by the river Jordan, according to the concurring testimony of travellers, speedily perish; but the latest observers affirm that there are some small ones in the lake peculiar to itself, as also that a few inferior vegetables may be seen in it. The water of the Dead Sea holds the following substances in solution:—Muriate of lime, 3.920; Magnesia, 10.246; Soda, 10.360; Sulphate of lime, .054.

Pococke, after bathing here, found his face covered by a thin crust of salt, and the stones which it occasionally overflows are encrusted with the same substance. Mines of fossil salt are found in the neighbourhood. Many absurd fables were formerly circulated respecting the Dead Sea. It was affirmed that the pestiferous vapours hovering over it were fatal to the birds attempting to fly across; but recent travellers affirm that numerous swallows skim the surface, and from thence imbibe the water necessary in the construction of their nests. We would have passed over in silence the fact, that bodies are better buoyed up in this lake than in fresh water or in the ocean, did not travellers dwell upon the circumstance as something marvellous, and look upon the settling of the point, by their swimming upon its waters, as a feat equal to that of Byron's crossing the Hellespont. A glance at the analysis given above will show that it is denser than sea water, and, hence, will bear up substances which there would sink.

Great quantities of asphaltum, or mineral pitch, are always seen floating on the surface of the Dead Sea, and it is driven by the winds to the banks on the east and west; but the statement that a pestilential effluvium hovers over it, is rather apocryphal. Mr Carne informs us that there is nothing of the kind. The neighbourhood of the lake abounds with volcanic products; and although eruptions have ceased for many centuries, earthquakes are still common in Syria and Palestine.

The Dead Sea is always associated with that dreadful catastrophe recorded in Scripture, the destruction of Sodom and Gomorrah. With respect to the agents employed for executing the purpose of divine vengeance, various conjectures have been stated—some suppose that the great cities were swallowed up by a volcano. The opinion of Chateaubriand, who had carefully examined several volcanos, is decidedly opposed to this view of the subject. The learned Frenchman inclines to the opinion of Michaelis and Busching, that Sodom and Gomorrah were built upon a bituminous mine; that lightning kindled this combustible mass; and that the cities were engulfed in this subterraneous conflagration. Malte Brun ingeniously supposes that the stones of which the towns themselves were built might be bituminous, and thus have been kindled by the fire of heaven. These views appear very plausible, when taken in connection with the Mosaic account of the place, that the vale of Siddim, which is now occupied by the Dead Sea, was full of "slime pits," or pits of bitumen. There can be no doubt, however, that combustible matter descended from heaven upon the devoted cities of the plain, for the language of the Scriptural account is precise and explicit: "The Lord rained upon Sodom and Gomorrah, brimstone and fire from heaven." According to Strabo, there were thirteen towns swallowed up in the lake Asphaltites; Stephen of Byzantium reckons eight; the book of Genesis, although it names five as situated in the vale of Siddim, relates the destruction of two only; four are mentioned in Deuteronomy; and five are noticed by the author of Ecclesiasticus. Several modern travellers assure us that they observed fragments of walls and palaces in the Dead Sea, and the ancients speak positively upon the point. Josephus, who employs figurative language, says, that he perceived on the shores of the Dead Sea "the shades of the overwhelmed cities." Strabo gives a circumference of sixty stadia to the ruins of Sodom, which are likewise mentioned by Tacitus. Recent travellers have done nothing to throw light upon this interesting subject; and until something is ascertained with regard to the fact, we are forced to the alternative of looking upon it as apocryphal.

THE RIVER JORDAN.

The river Jordan rises at the foot of the Antilibanus; forms the lake Genesereth; traverses Palestine, of which it is the only important river, from north to south; receives the Kedron; and, after a course of 150 miles, disembogues its waters into the Dead Sea. Hasselquist informs us that the plain, which extends from this to Jericho, a distance of more than three leagues, is, generally speaking, level, but barren and uncultivated. The soil is a grayish sandy clay, and so loose, that horses often sink up to the knees in it. The surface of the earth is covered with salt, in the same manner as on the banks of the Nile, and would prove no less fruitful, were it irrigated with equal sure. The stones on the beach are all various-coloured quartz. Much difference of opinion prevails amongst authors with respect to the width of the Jordan. The Swede above mentioned says, that, at Jericho, it is eight paces over, the banks six feet in height, and perpendicular, the water deep, muddy, and warm rather than cold. Chateaubriand measured it in several places, and found it fifty feet in breadth, and six feet deep, down to the shore. This discrepancy must arise from the different seasons of the year at which the measurements were made. Mr Carne observes, that, when he saw it, it was about twenty yards across, and appeared to be very deep.

JERICHO.

Jericho, which was at one period denominated the City of Palm-trees, was anciently considered only inferior in point of consequence, wealth, and magnificence, to Jerusalem, and was enclosed by walls three miles in circumference. Of its splendid buildings, there remains only the part of one tower, which is supposed to have been the dwelling of Zaccheus the publican. A heap of rubbish marks the line of its ancient walls. It appears, indeed, either as if some cause, fatal to population, were still emanating from the pestiferous vicinity of the Dead Sea, and destined to extirpate the very energies of life, or that the judgments anciently denounced against it by the Almighty were still in full force. It was the first city which the Israelites reduced upon entering the Holy Land. Five hundred and thirty years afterwards, it was rebuilt by Hielel of Bethel, who restored its population and splendour, in which flourishing condition it appears to have continued for several centuries. Mark Antony presented to Cleopatra the whole territory of Jericho. Its walls were sacked by Vespasian during the war which he carried on in the country. It was afterwards more than once restored; but in the twelfth century it was overthrown by the infidels, and has not since emerged from its ruins. It is the opinion of Mr Buckingham, that the true site of Jericho, as described by Flavius Josephus, the Jewish historian, was at a greater distance from the river than the village of Rahab, commonly supposed to represent the city. In descending the mountains which bound the valley on the western side, he saw the ruins of a large settlement, covering at least a square mile, whence, as well as from other remains, he concluded that it must have been a place of some consequence. The distance of Jericho from Jerusalem, as fixed by Josephus at one hundred and fifty furlongs, and, from the river Jordan, at sixty, together with his description of the country, answers exactly to the situation of the ruins just mentioned. The spot lies at the very foot of the sterile mountains of Judea; and these are still as barren, rugged, and destitute of inhabitants, as formerly, throughout their whole extent, from the Lake of Tiberias to the Dead Sea. The distance, by the computation in time, amounted to six hours, or nearly twenty miles, from Jerusalem—the space between the supposed city and the river being little more than one-third of that amount, precisely the proportion indicated by the Jewish historian. Formerly, the soil around Jericho was celebrated for a precious balsam, but in the present day not a tree is found to vegetate on this desolate spot of Judea.

Rahab stands about four miles nearer the river. It consists of about fifty very mean dwellings, every one having in front a fence of thorns, as a protection from the attacks of the Bedouins, whose horses will not approach these formidable thickets. The inhabitants are all Mohammedans; they are shepherds rather than cultivators of the soil—this last duty, indeed, when performed at all, being done principally by the women and children, as the men roam the plain on horseback, and derive their principal means of subsistence from robbery and plunder. They are governed by a sheik, whose influence among them is more of a parental than a magisterial description. It may be observed, as a remarkable coincidence, that the name of this village corresponds to Rahab, the name of the hostess who received into her house the Hebrew spies, and signifies odour or perfume—the slight change on the form of the Arabic term implying no difference in the import of the root whence they are both originally derived.

The traveller whose journey lies between Jerusalem and Jericho still runs the risk of falling among thieves; the journey is most perilous, and seldom undertaken. Sir F. Henniker, however, accomplished it a few years ago, and accordingly suffered for his temerity. We meet with many interesting localities in this line of road. Among the mountains on the eastern side of the Jordan is Pisgah, a towering peak which the travellers delight to recognise. From its summit Moses was permitted to behold the promised inheritance, stretching towards the west, south, and north. When entering the mountains which protect the western side of the plain, the attention of the traveller is invited to the Fountain of Elisha, the waters of which were sweetened by the power of the prophet. They are now received in a basin, whence they issue in a copious stream, which splits into several rills, irrigating the land as far as Jericho.

MOUNTAIN OF QUARANTINA.

The tourist in his progress to the capital soon finds himself at the foot of the mountain called Quarantina, from being the supposed scene of the temptation and fast of our Saviour; the neighbourhood of the lofty eminence is a barren place. Leaving the mountain, the pilgrim returning from the Jordan finds himself on a beaten path, which, since the days of the Jewish legislator, it is probable has connected the rocks of Salem with the banks of the sacred river. Chateaubriand says that it is broad, and in some parts paved, having undergone, as he conjectures, several improvements while the country was under the Roman yoke. On the top of a mountain there is the appearance of a castle, which commands, and may be supposed to have protected the road; and at a little distance, in the bottom of a valley, is the Place of Blood, called in Hebrew, Abdomim, where formerly stood a small town belonging to the tribe of Judah, and where the good Samaritan is imagined to have succoured the wounded traveller who had fallen among thieves. That deep and gloomy dell is still the scene of robbery and murder, and possesses unquestionable right to the horrible distinction which it has so long enjoyed.

Having traversed the country south and east of the capital, we shall now proceed in our account of that which lies to the northward of it.

CAVE OF JEREMIAH AND SEPULCHRES OF THE KINGS.

Leaving Jerusalem by the northern gate, we proceed on the road which leads to Damascus. Near the entrance to the holy city there is a grotto, said to have been for some time the residence of Jeremiah the Prophet. The bed of the holy man is shown in the form of a rocky shelf, about eight feet from the ground; and the spot is likewise pointed out on which he is understood to have written his book of Lamentations. At a little distance from the city stand the sepulchres of the kings, connected with which there still prevails some obscurity. But whoever was buried here, the place discovers so great an expense, both of labour and treasure, that we may well suppose it to have been the work of kings. It is approached on the east side by an entrance cut out of the rock, which opens into a court of about forty paces square. On the south side is a portico nine paces long and four broad, likewise hewn out of the living rock, and having an architrave running along its front adorned with sculpture. The passage into the sepulchre is now so greatly obstructed with stones and rubbish that it is no easy matter to creep through; but, having overcome this difficulty, you arrive at a large room seven or eight yards square, excavated in the solid body of the hill. Its sides and ceiling are so exactly square, and its angles so just, that no architect could form a more regular apartment. From this room you pass into six others, all of the same construction. In every one of these, except the first, are coffins of stone placed in niches. They are of the size of those used in Europe, and have the form of a parallelogram. They had at first been covered with handsome lids, but the most of them have been destroyed. One of white marble was observed by Dr Clarke, adorned all over with the richest and most beautiful carving. There is much taste and skill displayed in the execution of these subterraneans, as well as in the ornaments with which they are embellished. But the most surprising thing connected with them is their doors, which consist of one entire piece of stone, handsomely carved.

BEER, LEBONAH, AND THE MOUNT OF GERIZIM.

The next object of importance which we meet with is a village supposed to be the Mickmash alluded to in Scripture. It is at present distinguished by the name of Beer, signifying a well, and adopted, most likely, from a delicious spring of water flowing through it; near to which are the ruins of a church, built in commemoration of the parents lamenting the loss of our Saviour, who, not being found by them there, was afterwards discovered with the expounders of the law in the temple. It was to this place, also, that Jotham had recourse in order to escape the fury of his brother. Beyond this hamlet, at the distance of about four hours' walk, is Leban, called Lebonah in the Bible, a village situated on the eastern side of a delicious vale. The road between these two places is carried through a wild and very hilly country, destitute of trees or other marks of cultivation, and rendered almost totally unproductive by the barbarism of the government. In a narrow dell, formed by two lofty precipices, are the ruins of a monastery, being in the neighbourhood of that mystic Bethel where Jacob enjoyed his celestial vision. We next arrive at the well of that patriarch, the scene of the conference between our Saviour and the woman of Samaria. Over this fountain Helena erected a large edifice, of which, however, almost nothing now remains. Near this is the narrow valley of Shechem, the Sychar of Scripture, overhung on either side by the two mountains Gerizim and Ebal, memorable as being the theatre on which was pronounced the sanction of the divine law. The Samaritans have, as is well known, a place of worship on Mount Garizim, where at certain seasons they perform the rites of their religion. According to their version of the Pentateuch, it was here that the Almighty commanded the children of Israel to set up great stones covered with plaster, on which to inscribe the body of their law; to erect an altar to offer peace-offerings; and to rejoice before the Lord their God. In the Hebrew edition, Mount Ebal is said to have been the scene of these pious services—a variation which the Samaritans ascribe to the malice of the Jews. In the vicinity of the town is a small mosque, which is said to cover the sepulchre of Joseph, and to be situated in the field bought by Jacob from Hamor, the father of Shechem, as is related in the book of Genesis.

NABLOUS, OR SHECHEM.

The road from Leban to Nablous, or Shechem, is mountainous and rugged. It presents, however, a remarkable picture of industry and cultivation, and, in abundance and wealth, may be styled the Eden of the East. The ancient Shechem is the metropolis of a rich and extensive country, abounding in agricultural wealth, and is one of the most flourishing towns in the Holy Land. It has a very imposing appearance when viewed from the surrounding heights, and looks as if it were embosomed in a delicious paradise. The population, who are principally Mohammedans, have been estimated at 10,000; but this Mr Buckingham thinks an exaggeration.

The Samaritans do not exceed forty in number. They have a synagogue, where divine service is performed every Saturday. Four times a-year they go in solemn procession to the old temple on Mount Gerisim, on which occasion they assemble before sunrise, and read the law till noon. They have but one school in Nablous where their language is taught, though they take much pride in preserving ancient manuscripts of their Pentateuch in the original character. Mr Connor saw a copy, which is reported to be three thousand five hundred years old, but he was not allowed to examine nor even to touch it. The events transacted in the field of Shechem render the localities contiguous to this city peculiarly interesting. Here stands the well of Jacob, and here the sons of the patriarch "drove their flocks a-field," and here they sold to the Ishmaelites their brother Joseph, the future all but potentate of the greatest kingdom then upon the face of the earth. Here, as of old, the shepherds graze their flocks upon the hills of Samaria, and the Ishmaelites come from Gilead, "bearing spices and balm and myrrh"—so imperishable are the customs and manners of the east.

SAMARIA.

Samaria is now called Sebaste, or the Venerable, an appellation conferred on it by Herod. It is computed by modern tourists to be more than forty miles distant from Jerusalem. The situation is extremely beautiful, and naturally strong, occupying the summit of a hill, encompassed all around by a deep valley. But the city which Herod adorned with princely buildings is now a mere village, small and poor, exhibiting only the miserable wreck of former greatness. Here John the Baptist was decapitated, and the Empress Helena erected a church over the place where he pined and suffered; but it has shared the fate of the rest of the city, being now a mere ruin. The prison where the holy blood of the desert-bred was spilled, is, however, pointed out by the Turks, who hold it in high veneration.

We shall now cross the Jordan, and enter the land of Gilead.

GERASA.

In this section of Palestine, the inheritance of Reuben and Gad, several very important discoveries were made by Dr Seetzen in 1806, among which were the ruins of the ancient city of Gerasa, or, as it now is called by the Arabs, Djerash. Approached from the south, the city is entered by a triumphal gateway, nearly entire. The workmanship is remarkably fine, and bears a striking resemblance to the remains of Antinoe, in Upper Egypt. It appears to have been a detached triumphal arch, erected for the entrance of some victorious hero. Within this gateway is an extensive theatre, for the exhibition of sea-fights, and, a little onward, there is seen a second gateway, similar in design to the other. To the left is a large and beautiful colonnade, arranged in a circular form, all of the Ionic order, and surmounted by an architrave. Next succeed a long avenue of columns, in a straight line, supposed to mark the direction of some principal street that apparently extended the whole length of the town. These columns are all of the Corinthian order, and the range on each side is ascended by a flight of steps. The attention of the traveller is now attracted by four magnificent pillars, of considerable dimensions, which probably adorned the front of some principal edifice now destroyed. After passing a square, and various masses of buildings, the tourist comes to the ruins of a temple of a semicircular form, with four columns in front, and facing the principal street in a right line. The spring of its half dome is still remaining, as well as several columns of yellow marble and of red granite. The whole seems to have been executed with peculiar care, especially the sculpture of the friezes, cornices, pediments, and capitals, which are all of the Corinthian order, and considered not less rich and chaste than the works of the best ages. On a broken altar near this ruin is observed an inscription having the name of Marcus Aurelius. Beyond this are temples, colonnades, theatres, arched buildings with domes, detached groups of Ionic and Corinthian columns, bridges, aqueducts, and portions of large buildings scattered here and there. The ground occupied by this city, which was nearly in the form of a square, might have been four miles in circumference. But so complete is now the desolation of this once magnificent place, that Bedouin Arabs encamp among its ruins, for the sake of the rivulet by which they are washed. With respect to the ancient history of this city, so much diversity of opinion prevails, that it were idle to enter into any investigation of the subject.

We now arrive at the hills of Gilead, the rich pasture-lands of the tribe of Reuben, and formerly the kingdom of the gigantic Og, the monarch of Bashan.

seven or eight hundred feet above the level of the Jordan is a district of extraordinary fertility, abounding with the most beautiful prospects, which yield in nothing to the finest parts of Galilee and Samaria. This scenery continues till the traveller reaches the Nahr el Zerkah, or river Jabbok, the ancient boundary between the Amorites and the children of Ammon. On the north begins the kingdom of Bashan, once celebrated for its oaks, its cattle, and the bodily strength of its inhabitants.

LAKE OF GENESARETH.

We come now to the lake, which has passed under different appellations from the sacred writers: such as the "Sea of Galilee," from being enclosed by Galilee; the "Lake of Genesareth, or Gnesar;" to these were added, the "Sea of Cinnereth and Tiberias." This picturesque sheet of water, an object of such high veneration, which, with that of the Dead Sea, may be considered as the two principal lakes in the Holy Land, appears to owe its origin to the waters of Jordan, which flow from Lebanon. The river Jordan enters at the northern, and flows out at the southern extremity, and its course is visibly seen all the way through. The range of mountains, forming its eastern shore, is very lofty, and their steep and rocky sides are barren; the western shore where the town stands is lower; the hills are more picturesque, and divided by sweet vallies clothed with verdure, but destitute of trees. With respect to the size of the lake, we must choose again amongst conflicting statements. It seems to be about fifteen miles in length and five in breadth. The waters are perfectly sweet and clear, and the fish are said to be of a delicious flavour.

It is almost unnecessary to remind the reader that this lake and neighbourhood were places where many important events occurred, mentioned in the New Testament. Here, it will be remembered, Christ embarked in a ship, to go to different places about its borders in the prosecution of his errands of mercy, and from which he instructed the multitude who had assembled on the shore.

Capernaum lies at the upper end of the lake, and is now called Talhewm, or Tel Hoom. It is nothing more than a station of Bedouins, but there are traces of its former importance. The foundations of a magnificent, but now much dilapidated edifice, can still be traced.

Tiberias, which makes a conspicuous figure in the Jewish annals, is the only place on the sea of Galilee retaining any marks of its ancient importance. It is understood to cover the ground formerly occupied by a town of a much remoter age, and of which some traces can still be distinguished. Taberia, as it is now denominated, has the form of an irregular crescent, and is enclosed towards the land by a wall, flanked with circular towers. It lies nearly north and south, along the edge of the lake, and has its eastern front so close to the water on the brink of which it stands, that some of the houses are washed by the sea. The whole does not appear more than a mile in circuit, and cannot, from the manner in which they are placed, contain above 500 separate dwellings. Here there are a mosque and two Jewish synagogues, also a Christian place of worship, called the House of Peter, which is thought by some to be the oldest building used for that purpose in any part of Palestine. The structure is of very ordinary description; but it derives no small interest from the popular belief that it is the very house which Peter inhabited at the time of his being called from his boat to follow the Messias. The population of the town does not now exceed 2000. Of these, about one-half are Jews, the rest are Mohammedans, with the exception of a few of the Christian creed. The warm baths, which have given celebrity to that neighbourhood, are still found at the distance of between two and three miles southward from the town. "Tiberias," says Carne, "is a scene where nature still seems to wear as sublime and lovely an aspect as in the day when it drew the visitations of our Lord. No curse rests on its shores, as on those of the Dead Sea, but a hallowed calm and a majestic beauty, that are irresistibly delightful."

MOUNT TABOR.

An almost uninterrupted ascent conducts from Tiberias to Nazareth. On this route, we have Mount Tor, or Tabor. This mount, which is classed in Scripture with Hermon, and something in the resemblance of a sugar loaf, is insulated on all sides, independent of the mountains around it, and stands with inexpressible dignity at one end of the great plain of Esdraelon, which may be ascended on all points, excepting towards the north, where it is rugged. There is not, perhaps, to be found, in the whole compass of the globe, one spot, from which a believer in the gospel can possibly enjoy a more sublime or glorious prospect, than from the summit of Mount Tabor, which has been so celebrated in the sacred volume, and held during all ages in such high veneration by Christians. In the first place, there is presented to view an extensive plain. On one side of it, on the left hand, are the mountains of Samaria, towards Jerusalem; on the other, to the right, those about Nazareth, especially the memorable hill from which the Jews attempted to precipitate Christ; with the top of Mount Carmel, washed by the ocean, at an opposite extremity of this plain. In another, Hermon, in its lofty dignity; Endor, and Nain, with the mountains of Gilboa. Next, the valley of Jordan, the spacious plains of Galilee, with its sea of Genesareth, and its enclosure of mountains; Dothan, where Joseph was sold, with its rivers, vallies, and little hill, and the village of Saphet, anciently called Bethulia, on an eminence, and presumed to have been the point of elevation alluded to by Christ in his sermon on the mount, from which it is also remarkably conspicuous, and not at a great distance. Again, the sublime height on which he delivered this memorable oration; the route to Damascus. Lastly, Mount Lebanon, towering with prodigious alpine dignity in the background.

Different opinions have been entertained by writers with regard to the extent of ground on the summit, and the cultivation of it. Taking the whole into calculation, it may be nearly two miles in diameter. To the west, there are masses of scattered ruins. At one period, a governor of Galilee surrounded the top of it with walls, which is confirmed by the scattered fragments still to be seen. St Helena, also, in prosecution of her zeal in the cause of Christianity, founded two monasteries, one to the memory of Moses, and the other of Elias. Various historical incidents are connected with this mountain. Here it was that Barak, descending with his ten thousand men from Tabor, discomfited Sisera and all his chariots. In the same neighbourhood, Josiah king of Judah fought in disguise against Necho king of Egypt, and fell by the arrows of his antagonist, deeply lamented. Vespasian reviewed his army in the same great plain. It has been a chosen place for encampments in every contest carried on in the country, from the days of Nebuchednezzar king of the Assyrians, down to the disastrous invasion of Napoleon Bonaparte.

NAZARETH.

Among the places which were honoured with the presence of Christ, and consecrated as the scenes of his benevolence and good-will towards men, Nazareth of Zebulun, and its neighbourhood, present strong claims to our attention. It is about one hundred miles distant from Jerusalem, and is romantically situated upon the bottom and sides of a hill which overlooks it.

It would be tedious to enumerate all that are shown to a traveller, but the following appear most deserving of notice:—The church belonging to the convent, which is rather elegant, and is erected over the grotto or cave where Mary took up her abode. It has no other roof than that which is formed of the natural rock, and is in the shape of a cross.

Among many pictures which adorn this church, there is a pretended likeness of Christ.

The second object shown is the shop where Joseph worked; it is now used as a place of worship. Over the altar, he is represented with the implements of his trade, holding our Lord by the hand, as if in the act of imparting the knowledge of his vocation.

Thirdly, a chapel, in the centre of which is an enormous stone, about nine feet in length, and six in breadth, on which it is affirmed that Christ sat and sat with his chosen few.

Fourthly, the synagogue where Christ, agreeably to his practice, read to the Jews, from the sacred volumes, on the Sabbath.

Fifthly, near the town is pointed out a hill, from which, disregarding the sanctity of that day, they threatened to throw him, in consequence of the dissatisfaction which his addresses had given.

And, lastly, a well of the Virgin, which supplies the inhabitants of Nazareth with water. Mr Carne says, the population may amount to about twelve hundred, and are mostly Christians.

After crossing the plain of Esdraelon, we come to Mount Hermon, the dew of which is so beautifully alluded to by the Psalmist. Near this place stands Nain, which is so called from its pleasant situation, where the widow's son was restored to life by the Saviour. About two miles from Nain, is seen Endor, where the sorceress resided who was consulted by Saul, and in the vicinity are the mountains of Gilboa, where the forces of Israel were collected.

CANA OF GALILEE.

Kaffer, Kenna, or Cana of Galilee, falls next under notice. This village is pleasantly situated on a small eminence in a valley, and contains two or three hundred inhabitants. Many pots, answering to the description given by the Evangelist, are found lying about amongst the ruins; from which it would appear evident, that the practice of keeping water in large stone pots, each holding from eighteen to twenty-seven gallons, was once common in the country. Near the bottom of a field, which is said to be that in which Christ plucked the ears of corn upon the Sabbath, stands the Holy Mount, which has been so eminently distinguished as the spot from whence the multitudes were addressed. It has an elevation of from two to three hundred feet.

The landscape which stretches from the lake of Tiberias to the sources of the Jordan, is in many parts uncommonly fine, presenting luxuriant crops, thriving villages, and other tokens of security and comfort. The mountains that terminate the prospect are magnificent, some of them being covered with perpetual snow.

SAPHET, SEPHOURI, AND ZEBULUN.

The only town of consequence between the ruins of Capernaum and the alpine range of Hermon and Djibbel el Sheik, is Saphet, being one of the four cities consecrated by the religious veneration of the Hebrews. According to Burckhardt, it stands upon several low hills that divide it into quarters, the largest of which is occupied by Jews. The whole may contain six hundred houses, of which one hundred and fifty belong to the people just named, and nearly as many to the Christians. The summit of the principal eminence is crowned with an ancient castle, part of which is regarded by the descendants of Israel as being contemporary with their ancient kings. The Jews have here seven synagogues, and a sort of university for the education of their rabbis. Their attachment to this place arises especially from the traditionary belief that the Messias is here to reign forty years before he assumes the government at Jerusalem. From Nazareth to Acre we proceed over a barren rocky tract of country; on the way we meet with Sephouri or Sepphoris, the Zippor of the Hebrews, and the Diocesarea of the Romans, once the chief town and bulwark of Galilee. The remains of its fortifications exhibit one of the works of Herod, who, after its destruction by Varus, not only rebuilt and fortified it, but made it the principal city of his tetrarchy.

Its chief celebrity is connected with the tradition that it was the residence of Joachim and Anna, the parents of the Virgin Mary. Constantine built a magnificent church over the spot where the devout couple lived, the ruins of which will be found minutely described in Dr Clarke's travels. The vale of Zebulun divides the above village from the ridge of hills which look down on Acre and the shores of the Great Sea. This plain every where presents the most beautiful scenery. On the road, various ruins occur which exercise the ingenuity of the antiquarian traveller. All remains of the strong city of Zebulun have disappeared, and its admirable beauty, rivalling that of Tyre, Sidon, and Berytus, is now sought for in vain among Arab huts and heaps of rubbish. We shall now enter upon that part of Palestine which lies upon the shores of the Mediterranean.

ACRE.

Acre stands close to the sea at the end of a bay extending in the form of a bow, about twelve miles to the point of Mount Carmel at the opposite part, and has a population of ten thousand people. It was originally called Accha, and is alluded to in sacred writ; of this name Acre is evidently a corruption. It is preceded by the words "St Jean," in consequence of the place having been given by Richard of England to the Knights of St John of Jerusalem; at one time it received the name of Ptolemais. This place was visited by the Apostles, but particularly by St Paul. It has been the scene of a variety of bloody contests, especially during the period of the crusades, and was the last place from which the Christians were driven. The Turks ultimately laid hold of it with a numerous army, after a furious siege, when terrible outrages were committed. They have been in possession of it since the year 1291. As Acre is the key not only of all Galilee, but, in general, of the Holy Land, having the best port, it may account for the violent efforts made by the French to grasp it; they were however, as is well known, successfully repelled by British gallantry and perseverance. The most distressing sight in the town is the number of deplorable objects to be met with, whose faces have been dreadfully disfigured by that implacable Herod or tyrant of the day, who struck such dread and terror over this country—namely, Achmet, the former pacha, or Djezzar. This latter appellation is synonymous with cutter or butcher, which he justly merited, from the frightful catalogue of atrocities of which he was the author.

St Jean d'Acre is very strongly fortified, being newly enclosed with high walls, and is considered the strongest place in Syria. The memorable siege which occurred in March 1799, since it gave a blow so fatal to Bonaparte, was a remarkable event, and will be a brilliant page of our national history. The houses are of stone, with roofs like terraces, the entrances to which are narrow, and many appear to communicate with each other. The streets are dirty, and the air impure, from their being contracted, where a loaded camel, in going along, may be considered as occupying the breadth of it. The bazaars are mean, and the inhabitants miserable.

MOUNT CARMEL.

Mount Carmel forms a promontory or majestic headland. It runs from east to west, and is about 2000 feet from the level of the sea, by which its base is washed. Near it runs Kishon, one of the rivers which is particularly alluded to in the sacred writings. Carmel is the most beautiful mountain in Palestine; is of great length, and in many parts covered with trees; and a part of its summit is pointed out as the plane where Elijah prayed for rain, and saw the humid cloud rise out of the sea. On the 20th of July, the Christians proceed to perform acts of devotion in memory of the prophet. There was formerly a monastery here, but it is now abandoned.

Between this point and Jaffa we meet with the ruins of several ancient villages and towns, amongst which is Cesarea. "Perhaps there has not been," says Dr Clarke, "in the history of the world, an example of any city that in so short a space of time rose to such an extraordinary height of splendour as did this of Cesarea, or that exhibits a more awful contrast to its former magnificence, by the present desolate appearance of its ruins." In fact, not a solitary inhabitant remains where once stood the proud city of Herod. Its theatre, its palaces and temples, form a marble desert—

"Whose echoes, and whose empty tread,
Sound like the voices of the dead."

The other places are not of sufficient importance to detain us from entering upon a description of

JAFFA, OR YAFFA, THE ANCIENT JOPPA.

This is one of the most ancient sea-ports in the world. Pliny assigns it a date which stretches far back into the twilight of time, anterior to the deluge itself. Tradition has even assigned this as the place where Noah built his ark! It was here, however, in the most authentic of all records informs us, that Solomon ordered the materials of his temple to be brought by sea from Lebanon; here the prophet Jonah embarked for Tarshish; and here, in apostolic times, St Peter restored Tabitha to life. During the warlike era of the crusades, Jaffa made a conspicuous appearance; and latterly it has been dragged into a sort of disgraceful notoriety, from the well-known circumstance of Napoleon having massacred some prisoners there. The town occupies an eminence in the form of a sugar loaf, with a citadel on the summit. The bottom of the hill is surrounded with a wall twelve or fourteen feet high, and two or three feet thick. The environs are occupied by extensive gardens, the soil being very favourable for the production of fruit. According to Dr Clarke, the harbour is one of the worst upon the Mediterranean, and unfit for shipping. The road is protected by a castle, and there are some store-houses and magazines on the sea-side. The coast is low, and but little elevated above the level of the sea. There are no antiquities in Jaffa. The inhabitants amount to between four and five thousand, who are mostly Turks and Arabs.

Between Jaffa and El Arisch, the extreme point of the Holy Land in this direction, lie the towns of

ASHDOD, GATH, ASKELON, AND GAZA.

It is perhaps unnecessary to inform the reader that these were once famous cities of the Philistines, and repeatedly brought before our notice in the Old Testament. The pathetic exclamation, "Tell it not in Gath, publish it not in Askelon!" must be familiar to every one. Ashdod is situated on the summit of a grassy hill, and, if we are to believe historians, was anciently as strong as it was beautiful. It now, however, can lay claim to neither adjective, except perhaps the latter. Gath, a place of strength in the time of the prophets Amos and Mica, is now similarly circumstanced with Ashdod. Askelon, once one of the proudest satrapies of the Philistine lords, still, to external appearance, maintains something of its ancient character. Its position is strong, and its walls, which are of great thickness and considerable height, are built on the top of a ridge of rock, winding round the town in a semicircular direction, and terminating at each end in the sea. But, alas! they enclose not a living being. How truly has been fulfilled the prophecy of Zechariah, "The king shall perish from Gaza, and Askelon shall not be inhabited." Gaza is truly without a king. It is now only a large village, with narrow streets and houses, which in general are destitute of windows. There is some trade, however, carried on in Gaza, particularly in cotton, and the inhabitants, according to Mr Buckingham, exceed two thousand. This place was formerly of great magnificence and strength; for two months it baffled all the efforts of Alexander to take it. El Arisch, the natural frontier of Palestine on this side, is situated upon a slightly elevated rock in the midst of drifting sands. It has a substantial fortress, and contains about two thousand inhabitants. According to Ali Bey (Burckhardt) almost the whole country of the Philistines is beautiful. It is for the most part composed of undulating hills, of a rich soil, and clothed with exuberant vegetation. There is not, however, either a river or a spring in the whole district; so that the wells and water collected during the periodical rains are the only means of irrigation within the reach of the inhabitants.

It will be necessary to return to Jaffa, in order to take a view of the road which lies between that town and Jerusalem. About nine miles from Jaffa stands Ramla, or Ramali, the ancient Rama of Ephraim, and very probably the Arimathea of the New Testament. It is situated in a rich plain, and contains about 2000 families. Here there are several convents and mosques; and, on a hill to the west of the town, stands a venerable ruin, called the Tower of the Martyrs, a name probably derived from the martyrs of Sebastia, in Armenia, whose bodies have been here deposited. About a league from this is Lydda, still called Loudd, where St Peter cured Æneas of the palsy. This place is now a poor village, with few inhabitants. The country which surrounds it, however, is of a rich and fruitful soil. Farther on is the Arab village of Bethoor, supposed with much probability by Dr Clarke to be the Bethoron of Scripture. We enter now into the country of Judæa. It is very mountainous; "and its scenery," says Dr Richardson, "brought strongly to my recollection the ride from Sanquhar to Leadhills, in Scotland; and to those," he continues, "who have visited this interesting part of my native country, I can assure them the comparison gives a favourable representation of the hills of Judæa." He goes on to say, that the great difference lies in the contrast which the countries present in the character of their roads and inhabitants, those of Palestine being of the very worst description. Among the places of note which lie in the route to Jerusalem, is Modin, well known as the site of the city and tombs of the illustrious and patriotic Maccabees. It is still a place of strength, and goes by the same name. Between this and Jerusalem we meet with nothing of importance, except what has been already described.

TYRE.

Returning to the sea-shore, we have the ancient Tyre, once the mart of nations and the glory of the earth. In the early ages, Tyre, in Phœnicia, is described in Scripture as a renowned city and a stronghold, encompassed with walls and towers; it was allotted to the tribe of Asher; it is now frequently called Sur, and perhaps, of all other maritime cities in the globe, was more highly renowned for riches and commerce, since her very merchants were declared to be as princes, and "every deck a throne;" and a most interesting description of the trades carried on within its walls, has been transmitted to us in the 27th chapter of Ezekiel. It was not, however, merely in a commercial point of view that it was represented to the world at large as an object of wonder and admiration. Among the variety of trades exercised in this city, that of dyeing was most distinguished, on account of the beautiful purple tint, which poets have celebrated as a chief ingredient in the magnificence of the vestments worn by the principal inhabitants. During the time of our Saviour, considerable importance must have been attached to the city, as it is frequently alluded to, with its neighbourhood. Tyre was besieged and taken by Alexander the Great, after whose death it began to recover, and maintain a commercial character. It afterwards submitted, first, to the Roman, and afterwards to the Mohammedan yoke, under the power of which it now remains. It was enclosed with walls, which originally must have been of great strength, furnished with towers, having holes or apertures for making observations, part of which still remains. This town does not appear to be so desolate a place as has been sometimes represented. It contains a few good houses, and nearly 2000 inhabitants. The island upon which the city anciently stood, has of course long disappeared. With Tyre is always associated Sidon, probably from the expression of our Lord, "It shall be more profitable for Tyre and Sidon," &c.

SIDON.

Zidon, or Sidon, owes it name to the eldest of the sons of Canaan, and was comprehended under the "lot," or possessions formally assigned to the tribe of Asher. It appears to have been higher in point of antiquity than Tyre, although both have been classed in the character of sisters, arising, most likely, from their contiguity, and publicly considered as a city of large extent and importance, since it has been distinguished in Scripture by the title of "Zidon the Great." Among various arts and sciences, the invention of the alphabet and arithmetic, making of glass, and skill in casting and sculpture, have been celebrated; and an unrivalled dexterity in hewing of wood will hand down the Sidonian name in the page of history to the latest period of time. The commercial pursuits of this people were also as lucrative as they were extensive; and it was likewise celebrated for its maritime enterprise.

Sidon is now a small town, rising gradually from the sea-shore, very pleasantly situated, and surrounded with rich gardens. The climate is peculiarly mild: the streets are excessively narrow, many of them under archways, as at Jerusalem: the inhabitants are estimated at about seven thousand, of whom two thousand are Christians, who have places of worship; the Jews, also, who may be calculated at two hundred, have a synagogue. Considering its small extent, the trade of this place is pretty considerable, particularly in silk.

The next object of importance is

MOUNT LEBANON,

"Whose head in wintry grandeur towers,
Whitens with eternal sleet;
While summer in a vale of flowers,
Is sleeping rosy at his feet."

This mountain has received the appellation of Lebanon, from the word Leban, signifying white, and, in all probability, from the snow which remains on its heights during the whole year. It has been peculiarly marked in Scripture as affording many glowing images and beautiful metaphors to the sacred writers. The cedars of it have in all ages been celebrated as objects of grandeur, and touched upon as images in ancient prophecy. It may be further added, that the cedars of this mountain, uniting so many qualities for building, afforded ample materials, and were sent by King Hiram to Solomon for the erection of his splendid temple; with respect to which, it has been beautifully said—

"Like some tall palm the noiseless fabric grew."

The highest elevation of Lebanon is 9600 feet. The summits are still shaded with cedars, and beautified with thousands of rare plants.

THE DRUSES AND MARONITES.

The mountains of Lebanon and neighbourhood are inhabited by two races, differing in religion and manners, but similar in their love of independence, the Maronites and the Druses. The country of the former is called Kesraoun, the Castravan of the historians of the crusades. It reaches from the river Kebir to the Kelb. The Maronites, amounting to 120,000, dwell in villages and hamlets. The fervour and devotion which pervade this people recall to us the ideas of the primitive church. An imposing superstition has consecrated a cedar forest which is said to have furnished the timber of Solomon's temple. Only twenty large cedars remain, and this old vegetable race verges fast to its extinction. Every year, on transfiguration day, the Greeks, the Armenians, and the Maronites, celebrate a mass on an altar of rough stones raised at the roots of these venerable trees.

The Druses, also 120,000 in number, live to the south of the Maronites. Their country has several subdivisions, differing from one another in their soil and productions. It is by religious peculiarities that this people is separated from the other inhabitants of Syria. They believe in one God, who, for the last time, showed himself in human form in the person of Hakem, caliph of Egypt, in 1030. Persuaded that all other systems of belief will finally be united in that which they profess, they regard them all with equal indifference, although the Christians have considered them as entertaining a marked contempt for the Mohammedan religion. On the eastern base of Lebanus is the fertile plain, watered by numerous streams, where the ancient city of Damascus stands, the Demeshk, or Sham-el-Demeshy of the Orientalists.

DAMASCUS.

This city was once famous for the manufacture of sabres, which appear to have been made of thin laminae of steel and iron welded together, so as to unite great flexibility with a keen edge. The art of making them is lost, since Tamerlane carried off the artisans to Persia. Sabres are still made here, but of inferior quality. It has a manufacture of excellent soap, and of stuffs made of a mixture of cotton and silk. The cabinet work of fine wood, adorned with ivory and mother-of-pearl, has excited the admiration of the Europeans. This city is enlivened by the bustle of commerce, and the passage of the caravans to Mecca. The great street which crosses it presents two rows of shops, in which the riches of India glitter along with those of Europe. Damascus is seven miles in circumference, and at present the population may amount to 100,000. The private houses in Damascus, simple in external appearance, exhibit in the interior all the splendour and elegance of a refined luxury; great magnificence is also displayed in the mosques, the churches, and the coffee-houses. The large mosque is a fine and spacious building, but no traveller is permitted to enter. The Chan Verdy, or Coffee-House of Roses, is considered as one of the curiosities of the Levant. Various places associated with events mentioned in Scripture are pointed out in the city and neighbourhood. The street still called Straight is that where St Paul is, with reason, said to have lived. It is as straight as an arrow, a mile in length, broad and well paved. A lofty window, in one of the towers to the east, is shown as the place where the Apostle was let down in a basket; and in the way to Jerusalem is the spot where his course was arrested by the light from heaven. There is a tradition that men was made in a meadow to the west of the city; to the east of it is pointed out the place where the host of Neaman the Syrian stood.

At the commencement, we gave a view of the present state of the country. Change and mutability are leading characteristics of all other countries but those in the east. There they remain the same, century after century; and the descriptions of them by travellers, of two hundred years' standing, exactly correspond with those given by travellers of yesterday. It was anticipated by some that Palestine would have been materially affected by the operations of the Pacha of Egypt. Nothing, however, has yet occurred which would justify us in drawing any conclusion as to a change in its civil administration. It would be unpardonable in any account of the Holy Land, to omit mentioning the present state of the Jews, its ancient and highly-favoured inhabitants. We learn, from a statement lately published in Germany, that their numbers amount to between three and four millions, scattered over the face of the whole earth, but still maintaining the same laws which their ancestors received from their inspired legislator more than three thousand years ago. In Europe, there are nearly two millions enjoying different degrees of political privilege, according to the spirit of the several governments; in Asia, the estimate exceeds several hundred thousand; in Africa, more than half a million; and in America, about two thousand. It is supposed, however, on good grounds, that the Jewish population on both sides of Mount Taurus is considerably greater than is here given, and that their given number does not fall short of five millions. In Palestine, of late years, they have greatly increased. It is said that not fewer than ten thousand inhabit Saphet and Jerusalem, and that in their worship they still sing those pathetic hymns which their manifold tribulations have inspired; bewailing, amid the ruins of their ancient capital, the fallen city and the desolate tribes.

Edinburgh: Published by W. and R. Chambers, 19, Waterloo Place; also by Orr and Smith, Paternoster Row, London; and W. Curry, Jun. and Co. Sackville Street, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight.
Chambers's Information for the People will be completed in one volume quarto, forming a comprehensive body of human knowledge on the most important subjects.
Stereotyped by A. Kirkwood, Edinburgh; and printed by Bradbury and Evans, Whitefriars, London.

CHAMBERS'S
INFORMATION FOR THE PEOPLE.

CONDUCTED BY WILLIAM AND ROBERT CHAMBERS, EDITORS OF THE "EDINBURGH JOURNAL" AND "HISTORICAL NEWSPAPER."

No. 19. PRICE 1½*d*.

HISTORY OF THE ISLAND OF GREAT BRITAIN,

From the Commencement of the Civil War, till the Rebellion of 1745.

AT the close of a former sheet bearing the present title, Charles the First and his Parliament were represented as about to commence a civil war. It is now our duty to continue the narrative formerly commenced, so as to afford to the large class who are unable to obtain larger and more expensive works, a brief, but, it is hoped, intelligible and correct view of the progress of British history.

THE REMONSTRANCE.

It was generally allowed by moderate people, that, in the autumn of 1641, by which time the labours of the Parliament had continued one year, the King had granted redress of all the abuses for which the earlier part of his reign, and the British constitution in general, were blameable. If he could have given a guarantee that he never would seek to restore any of these abuses, or attempt to revenge himself upon the men who had been chiefly concerned in causing him to give them up, there would have been no further contention. Unfortunately, the leaders in the House of Commons felt that, if they once permitted the King to resume his authority, there would be no longer any safety for them; and it was deemed necessary by this body of men, that things should be prevented from falling into their usual current. They therefore prepared a paper called the Remonstrance, containing an elaborate view of all the grievances that had ever existed or could now be supposed to exist, and this they not only presented to the King, but disseminated widely among the people, with whom it served to increase the prevailing disaffection.

COMMENCEMENT OF THE WAR.

From this time it was seen that the sword could alone decide the quarrel between the King and the Parliament. Charles made an unsuccessful attempt (January 4, 1642) to seize six of the most refractory members, for the purpose of striking terror into the rest. The effort only served to widen the breach. In the early part of the year just named, the two parties severally employed themselves in preparing for war. Yet, even now, the King granted some additional concessions to his opponents. It was at last, upon a demand of theirs for the command of the army—a privilege always before and since resting with the crown—that he finally broke off all amicable intercourse. He retired with his family to York.

The Parliament found its chief support in the mercantile classes of London and of the eastern coast of England (which was then more devoted to trade than the west), and in the Puritan party generally, who were allied intimately with the Presbyterians of Scotland, if not rapidly becoming assimilated with them. Charles, on the other hand, looked for aid to the nobility and gentry, who were able to bring a considerable number of dependents into the field. The one party was by the other styled *Roundheads*, in consequence of their wearing short hair; while the friends of the Parliament bestowed upon their opponents the epithet of *Malignants*. The Royalists were also, in the field, termed Cavaliers, from so many of them being horsemen.

On the 25th of August, the King erected his standard at Nottingham, and soon found himself at the head of an army of ten thousand men. The Parliament had superior forces, and a better supply of arms; but both parties were very ignorant of the art of war. The King commanded his own army in person, and the Parliamentary forces were put under the charge of the Earl of Essex.

The first battle took place, October 23, at Edgehill in Warwickshire, where the King had rather the advantage, though at the expense of a great number of men. He gained some further triumphs before the end of the campaign, but still could not muster so large an army as the Parliament. During the winter, the parties opened a negociation at Oxford; but, the demands of the Parliament being still deemed too great by the King, it came to no successful issue.

CAMPAIGN OF 1643.

Early in the ensuing season, the King gained some considerable advantages: among the rest he defeated a Parliamentary army under Sir William Waller at Stratton, and soon after took the city of Bristol. It only remained for him to take Gloucester, in order to confine the insurrection entirely to the eastern provinces. It was even thought at this time that he might have easily taken possession of London, and thereby put an end to the war. Instead of making such an attempt, he caused siege to be laid to Gloucester, which the army of Essex relieved, when just on the point of capitulating. As the Parliamentary army was returning to London, it was attacked by the royal forces at Newbury, and all but defeated. Another royal army in the north, under the Marquis of Newcastle, gained some advantages; and, upon the whole, at the close of the campaign of 1643, the Parliamentary cause was not in a flourishing condition.

MILITARY CHARACTER OF THE PARTIES.

In this war, there was hardly any respectable military quality exhibited, besides courage. The Royalists used to rush upon the enemy opposed to them, without any other design than to cut down as many as possible, and, where any part of the army was successful, it never returned to the field while a single enemy remained to be pursued; the consequence of which was, that one wing was sometimes victorious, while the remainder was completely beaten. The Parliamentary troops, though animated by an enthusiastic system of religion, were somewhat steadier, but nevertheless had no extensive or combined plan of military operations. The first appearance of a superior kind of discipline was exhibited in a regiment of horse commanded by Oliver Cromwell; a gentleman of small fortune, who had been a brewer, but was destined, by great talent and address, joined to an unrelenting disposition, to rise to supreme authority over these kingdoms. Cromwell was one of nature's captains; though himself inexperienced in military affairs, he showed from the very first a power of drilling and using troops, which no other man in either army seemed to have. Hence his regiment soon became famous for its exploits.

SOLEMN LEAGUE AND COVENANT.

The English Parliament and the Scottish nation were alike distressed by the royal successes in 1643, which threatened both with the loss of all the political ameliorations they had wrested from the King. They therefore entered, in July, into a *Solemn League and Covenant*, for prosecuting the war in concert, with the view of ultimately settling both church and state in a manner consistent with the liberties of the people. In terms of this bond, the Scots raised an army of 21,000 men, who entered England, in January 1644, and, on the 1st of July, in company with a large body of English forces, overthrew the King's northern army on Long Marston Moor. The conduct of the Scottish nation in this transaction was not so unexceptionable as might be wished. They had been gratified in 1641 with a redress of every grievance they could name; since which time the King had not given them the least cause of complaint. In now raising war against him, they had no excuse but the very equivocal one that it was necessary to guard against the possibility of his ever being able to injure them. They were also acting on English pay, which was unworthy of a nation, which, on many occasions, made very clamorous assertions of its being independent. The mainspring of their proceedings was a hope of being able to establish the Presbyterian religion in England. The Episcopal church being now abolished, divines were nominated by both nations to meet at Westminster, in order to settle upon a new form of worship and church government; and after a long course of deliberation, it was agreed that the Presbyterian system should be adopted, though in England it was provided that the new church should have no connection with or influence over the state.

NEW-MODELLING OF THE PARLIAMENTARY ARMY.

The defeat at Long Marston was severely felt by the King, who gained a victory over Waller at Copredy Bridge, and caused Essex's army to capitulate in Cornwall (September 1); but in consequence of a second fight at Newbury (October 27), in which he suffered a defeat, he was left at the end of the campaign with greatly diminished resources. A new negociation was commenced at Uxbridge; but the terms asked by the Parliament were so exorbitant, as to show no sincere desire of ending the war. In truth, though the Presbyterian party were perhaps anxious for peace, there was another party, now fast rising into importance, who had no such wishes. These were the Independents, a body of men who wished to see a republic established in the state, and all formalities whatsoever removed from the national religion. Among the leaders of the party was Cromwell, whose mind seems to have already become inspired with lofty views of personal aggrandisement. This extraordinary man had the address to carry a famous act called the Self-Denying Ordinance, which ostensibly aimed at depriving all members of the legislature of commands in the army, but was intended solely to displace a few noblemen who were obnoxious to his designs—and also an act for modelling the army anew, in which process he took care that all who might be expected to oppose his views should be excluded. It was this party that prevented any accommodation taking place between the King and his subjects.

MONTROSE'S CAREER IN SCOTLAND.

While the negociation was pending, the Marquis (formerly Earl) of Montrose produced a diversion in Scotland in favour of the King. Having got fifteen hundred foot from Ireland, to which he added a few Perthshire Highlanders, he fell down upon the Lowlands, and on the 1st of September (1644) gained a complete victory over a larger and better-armed force at Tippermuir. At Aberdeen, whither he went for the purpose of increasing his army, he gained another victory over a superior body of Covenanters. He was then pursued by a third army, under the Marquis of Argyle, and, after some rapid movements, seemed to dissolve his forces in the Highlands. Ere his enemies were aware, he burst in the middle of winter into the country of his grand enemy Argyle, which he did not leave till he had made it a desert. Finding himself timidly followed by Argyle, at the head of a large body of Campbells, he turned suddenly, and falling upon them at Inverlochy (February 2, 1645), gained a complete victory. He then moved along the eastern frontier of the Highlands, where he found himself opposed by a fourth army under General Baillie. After sacking Dundee, and eluding Baillie's troops, he encountered a greatly superior force at Auldearn, in Nairnshire (May 4), whom he also overthrew. Then turning upon Baillie, whom he met at Alford, in Aberdeenshire (July 2), he gained a fifth victory, almost as complete as any of the rest. In all these battles he carried every thing before him by the spirit of his first onset, and the slaughter was in general very great. He now descended to the Lowlands, and at Kilsyth, near Glasgow, was opposed by an army of 6000 men, whom the insurgent government at Edinburgh had hastily assembled from Fife and Perthshire. These, with a much smaller force, he also defeated (August 15), killing immense numbers in the pursuit. The Committees of Church and State then broke up and left the kingdom, leaving him in appearance its sole master. His successes had in the mean time given the King hopes of carrying on the war with success; but Montrose had in reality gained no sure advantages. Besides his small army of mingled Irish and Highlanders, there was hardly any portion of the nation who did not regard him as the greatest of traitors. While lying with a diminished force at Philiphaugh, near Selkirk, he was surprised (September 11), by a detachment of the regular Scottish army, under General David Leslie, who completely defeated his troops, and obliged him to leave the kingdom. His having gained six victories in succession, over larger bodies of men, has procured for him a distinguished name; but his cruelty, and the ambition to which his motives were confined, detract greatly from his character.

CONCLUSION OF THE CIVIL WAR.

The English campaign of 1645 ended in the complete overthrow of the King. Throughout the war, his enemies had been continually improving in discipline, in conduct, and in that enthusiasm which animated them so largely; while the Royalists had become, out of a mere principle of opposition, so extremely licentious, as to be rather a terror to their friends than to their enemies. The new-modelling of the Parliamentary army, which took place early in 1645, had also added much to the effectiveness of the troops, who were now nominally commanded by Sir Thomas Fairfax, but in reality by Oliver Cromwell, who bore the rank of Lieutenant-General. The consequence was, that, in a pitched battle at Naseby (June 14), the King was so completely beaten, that he and his party could no longer keep the field. He had no resource but to retire into Oxford, a town zealously affected to his cause, and well fortified.

THE KING TAKES REFUGE WITH THE SCOTTISH ARMY.

He endeavoured, from this forlorn position, to renew the negociations for a peace, but every attempt of that kind was frustrated by the Independents, who, though a minority in the House of Commons, possessed great power through the army, and, as already mentioned, were desirous of effecting greater changes in church and state than those for which the war was originally undertaken. Dreading the influence of this body, Charles retired privately from Oxford (May 1646), on the approach of the Parliamentary forces, and put himself under the protection of the Scottish army at Newark.

It was now the policy of Charles to set himself up, as it were, to auction between the Presbyterian and Independent parties, and put himself at the head of that which should offer him the best terms. The Presbyterian party, including all the Scotch and a vast proportion of the English public, would have reinstated him in power, if he would have sanctioned that religion which, as already mentioned, was now declared to be the established worship of England. On the other hand, if he would have consented to abolish all established forms of worship, and permit every congregation to elect and pay for its own clergyman, the Independents would have perhaps accepted him as the president of their republic, though it is more likely that the leaders of this faction would have been as well pleased to see him sink into ruin through the crooked policy he was now pursuing.

As the views of the Scots throughout the war had been steadily confined to the security of the Presbyterian religion, along with the safety of the King's person and the establishment of a limited monarchy, they received him with great respect at their camp, and entered into negociations for effecting their grand object. If Charles would have acceded to their views, he might have immediately resumed a great part of his former power, and the agitations of many subsequent years, as well as his own life, might have been spared. But it was the misfortune of this monarch to entertain a bigoted favour for the Episcopal forms of worship, and an obstinate conviction of the impossibility of carrying on a monarchy without bishops. He therefore split with the Presbyterians on the very point which they considered the most important.

THE KING DELIVERED UP BY THE SCOTS.

From the time when he first threw himself into the Scottish camp, the English Parliament had made repeated and strenuous demands for the surrender of his person into their hands. The Scots, however, though acting partly as a mercenary army, asserted their right, as an independent nation under the authority of the King, to retain him in their own hands. They had a large claim against the English Parliament for arrears of pay; and it was not till that was compounded for at L.400,000, that they consented to deliver up their monarch. Partly through this consideration, and partly through despair of inducing him to enter into their religious views, they at length gave him up to their brethren of England, though certainly not to the party which afterwards brought him to the block, or with any apprehension that such would be his fate. It must also be stated in favour of the Scots—who have suffered much obloquy on this account, even from a nation whose Parliament would not discharge a just debt without an inducement—that they could not have retained possession of the King any longer without a war with the English, which would have involved a breach of the Solemn League and Covenant, and a desertion of all their religious objects, in favour of an Episcopal and hostile monarch. After surrendering the King, the Scottish army retired (January 1647) to their native country, and was dismissed.

ASCENDANCY OF THE ARMY.

The King was now placed in Holdenby Castle, and negociations were opened for restoring him to power. While these were pending, the Parliament deemed it unnecessary to keep up the army, more especially as its spirit was plainly observed to be of a dangerous character. On the first proposal, however, to dismiss this servant, it rose upon its master, and, inspired and led by Cromwell, put the Parliament completely under restraint. It also contrived to take possession of the King's person, which gave it a great advantage over its opponents.

TRIAL AND EXECUTION OF THE KING.

Charles subsequently escaped to the Isle of Wight, where he was taken under the protection of a kind of neutral power, the governor of Carisbrook Castle. Here he renewed his negociations with both parties, hoping to turn their mutual dread of each other to his own advantage. But he only, by this means, wrought his own ruin. Upon a promise to give Presbytery a trial of three years, he engaged the Scots, or at least a moderate party of them, to take arms in his behalf, and invade the kingdom of England. In July 1648, Cromwell defeated this army, taking its leader the Duke of Hamilton prisoner; and as there was then no Presbyterian force, and no Cavalier or moderate party of any kind, able to meet his army, he might be considered as the military dictator of his country. He immediately proceeded, by violence, to exclude the Presbyterians from the House of Commons, and to obtain from the remainder, who were his own creatures, the appointment of what was called a High Court of Justice, in order to try the King on a charge of having levied war against his subjects, which had recently been pronounced treason by Parliament. This extraordinary trial commenced on the 20th January 1649, in Westminster Hall. Charles from first to last protested against the right of the court to judge of him; but he was, nevertheless, condemned to lose his head. Cromwell, who was the sole mover in this singular and most decisive measure, was no doubt animated by the consideration, that to go back after having advanced so far, was only to ensure his own destruction. He therefore determined to listen to no plea of mercy. On the 30th of January, the King was beheaded in front of his palace of Whitehall, to the horror of his subjects in general, who, however, were unable to interpose in his favour. An army of about eight thousand men in London, and some smaller parties scattered in the provinces, were at this particular crisis sufficient to bring the sovereign to the block, against the inclinations of his people. Charles the First was altogether a martyr to the Episcopal form of church-government, previously and since established in England. He was allowed, even by his enemies, to be a virtuous prince. If he was too strongly prepossessed in favour of particular systems in civil and ecclesiastical government, he only partook of the character of the age in which he lived—an age distinguished by the wildest extremes in all kinds of doctrines. But it is in a great measure absurd to refer the fate of this monarch to his own particular character. It is evident, from the current of popular feeling, that about this time a struggle was to take place in England between the kingly power and the popular privileges, and it appears to us to have signified very little who was to conduct the contest on the former side. In the more important order of events, men are of no more avail to control them, than are vessels able to check the tide by which they are borne along in their course.

ESTABLISHMENT OF A REPUBLIC.

The small remaining part of the House of Commons, which gained the ridiculous epithet of the Rump, now established a republic, under the title of the Commonwealth, the executive being trusted, under great limitations, to a council of forty-one members, while in reality Cromwell possessed the chief influence. The House of Peers was voted a grievance, and abolished, and the people were declared to be the legitimate source of all power—a proposition which fewer might have denied, if the Rump had been itself a fair and free representation of the popular will.

SUBJUGATION OF IRELAND AND SCOTLAND.

The Scots, on the other hand, heard of the execution of the King with great indignation, and immediately proclaimed his eldest son as Charles the Second. In Ireland, moreover, a rebellion of Royalists, and another of the native Catholics, took place at the same time. Cromwell immediately conducted an army into the latter country, and, by dint of monstrous cruelties, had almost reduced it, when he was obliged to turn his attention to Scotland. Early in 1650, the young monarch, who had taken refuge in Holland, sent Montrose with a small force to attempt a Cavalier insurrection in Scotland; but, he being taken and put to death, Charles found it necessary to accede to the views of the Scotch respecting the Presbyterian religion, and he was accordingly brought over and put at the head of a considerable army, though under great restrictions. Cromwell immediately invaded Scotland, for the purpose of putting down this hostile movement. He crossed the Tweed on the 19th of July, and advanced through a deserted country to Edinburgh, where the Scottish army lay in a fortified camp. Sickness in his army, and the want of provisions, soon after compelled him to retreat, and the Scottish army, following upon his rear, brought him into a straitened position near Dunbar, where he would soon have been under the necessity of surrendering. In the midst of his perplexities (September 3), he beheld the Scots advancing from the neighbouring heights to give him battle, and, in a transport of joy, exclaimed, "The Lord hath delivered them into our hands." The movement was solely the result of interference on the part of the clergy who followed the Scottish camp: the better sense of General Leslie would have waited for the voluntary surrender of his enemy. In the fight which ensued, the veteran troops of Cromwell soon proved victorious. The Scots fled in a panic, and were cut down in thousands by their pursuers. This gained for Cromwell the possession of the capital and of all the south-east provinces; but the Covenanters still made a strong appearance at Stirling. Cromwell spent a whole year in the country, vainly endeavouring to bring on another action. During the interval (January 1, 1651), the Scots crowned the young King at Scone, part of the ceremony consisting in his acceptance of the solemn league and covenant. In the ensuing summer, Cromwell at length contrived to outflank the position of the Scottish army; but the result was, that Charles led his troops into England without opposition, and made a very threatening advance upon the capital. Ere the royalists had time to rally around him, Cromwell overtook his forces at Worcester, where, after a stoutly contested fight (September 3, 1651), he proved completely victorious. Charles, with great difficulty, escaped abroad, and Scotland, no longer possessed of a military force to defend herself, submitted to the conqueror. All the courts of the Scottish church were suppressed, and ministers were left no privilege but that of preaching to their flocks. The country was kept in check by a small army under General Monk, and in a short time was declared by proclamation to be united with England. Thus was the independent party, or rather Cromwell, left without a single armed enemy. All the efforts of the people, during twelve years, to obtain limitations upon the monarchy, had ended in a military despotism.

THE PROTECTORATE.

In April 1653, Cromwell, being quite tired of even the slight control imposed upon him by the Rump, entered the house with a party of soldiers, and, turning the whole of the members out of doors, locked the door and took away the key in his pocket. This concluded the Long Parliament, as it was called, which had sat down in November 1640, and at an early stage of its proceedings obtained the King's consent to an act declaring the impossibility of dissolving it without its own consent. Cromwell called a mock Parliament of one hundred and thirty-nine persons, who got the nickname of Barebone's Parliament, in reference to one of the members, a leather-seller, who bore that name. As this assembly obtained no public respect, Cromwell soon dissolved it, and his officers then proclaimed him Protector of the Commonwealth of Great Britain and Ireland. He had now gained the supreme and almost uncontrolled authority of the empire, and his administration, though despotic, and involving many breaches of the most sacred principles of liberty, was not without some popular features. He was successful in a war with Holland, and caused the British name to be more respected in the most of neighbouring countries than it had ever been before, or has almost ever been since. He also, by abolishing preferences of one religion over another, produced a perfect contentment among the professors of all, except perhaps the members of the disestablished church. His government, however, was from first to last the child of mere force, and solely kept up by such means. It had no solid grounds in the affections of the people. It is a remarkable proof of this, that the Parliaments which he from time to time summoned, and which consisted of persons selected chiefly under the authority of his own officers, always troubled him so much with the freedom of their views as to oblige him to dissolve them. The same fact is proved by the difficulty he had in raising money. Thus, though Cromwell had become the greatest man in the empire, he was beset with so many difficulties that he could not be said to have increased his own happiness. He had sufficient clearness of understanding to know that the means by which he arrived at so much power were not honourable, and that his authority was not compatible with the real good of his country. He was also liable to a constant dread of assassination—for men in no rank of life had as yet seen the monstrous wickedness and danger of that expedient. The last Parliament he called was in January 1656; besides the Commons, he summoned the few remaining peers, and endeavoured, by ennobling some of his officers, to make up a kind of Upper House. This assembly proved as intractable as its predecessors, and he contracted such a disgust at the very nature of a representative legislature, as to resolve, like the late King, never to call another. His health finally sunk under the effects of his ill-gotten power, and he died on the 3d September 1658, a day which was thought to be propitious to him, as it was the anniversary of several of his victories. His eldest son Richard, a mild and inenergetic person, succeeded him as Protector, but could not long maintain a rule, which even his father had found the greatest difficulty in managing. He quietly slunk out of public view, leaving the supreme authority in the hands of the Rump, which had taken the opportunity to re-assemble.

THE RESTORATION.

This remnant of an old Parliament continued in power till the autumn of 1659, when it sunk beneath a council of the Cromwellian officers. This latter government, in its turn, gave way to the Rump, which sat down once more in December. The people beheld themselves made the sport of a few ambitious adventurers, and began to long for some more fixed and respectable kind of government. Their efforts for liberty, conducted from the first by armed violence, had ended in a government of which violence was the only principle; and they contracted an unjust disrespect for freedom, and every thing relating thereto, from the effects of their own imprudent ways of seeking it.

At this crisis, General Monk, commander of the forces in Scotland, conceived the design of settling the nation. He left Scotland (January 2, 1660) with a considerable army; and though he kept his thoughts scrupulously to himself, all men bent their eyes upon him, as a person destined to realise their hopes. He reached London (February 3), and was received with assumed respect by the Rump. Some resistance was attempted by Lambert, one of Cromwell's officers, but in vain. Ere long, Monk was able to procure the restoration of the members who had been secluded from Parliament by Cromwell; who, being a majority, gave an immediate ascendancy to anti-republican views. As soon as this was effected, an act was passed for calling a new and freely elected Parliament; after which, the present assembly immediately dissolved itself.

The new Parliament proved to be chiefly composed of Cavaliers and Presbyterians, men alike favourable to monarchy, though differing in many other views. At the first they proceeded with great caution, for such terror had been inspired by the late military tyrannies, that, even when the breathings of almost all men were evidently in favour of a restoration of the monarchy, they could hardly trust themselves to take any steps towards that purpose. At length General Monk informed them that a messenger was in waiting with dispatches from the King, and it was instantly resolved to receive him. The dispatches were found to contain a proposal for the King's restoration to power, with an offer of indemnity for all past offences which the Parliament itself might not think fit for punishment, and a toleration for all tender consciences in the matter of religion. The documents were read with shouts of applause, and money immediately voted for the purpose of bringing over the royal family. They were so glad to escape from the severe and lawless oppressions of the last few years, that they never thought of making any definite arrangement with the King as to the extent of his prerogative. They, and the nation in general, seemed to think there could be no safety except in that almost absolute rule, which they had begun to dispute twenty years before. Charles the Second arrived in London on the 29th of May, his thirtieth birth-day, and was received with such a phrenzy of joy by all ranks of people, that he could not help thinking it his own fault, he said, that he had been so long separated from them.

REACTION OF PUBLIC FEELING.

Excepting in the execution of ten persons, who had been concerned in the death of the late king, and of three popular leaders in Scotland,* the restored monarch showed no desire of revenging the misfortunes of his father, or his own exclusion from the throne. The Parliament which called him home was constituted a legal one by his own ratification of an act for that purpose. In the settlement of other matters, it seemed the prevailing wish that all the institutions of the country should be made as nearly what they were before the civil war as possible. Thus, the Episcopal church was established both in England and in Scotland, though not without causing about a third of the clergy in both countries to resign their charges. The Parliament of the latter country exceeded that of England in loyalty. It declared the power of the King to be hereditary, divine, and indefeasible, and asserted his uncontrolled right to the lives and possessions of his subjects. The change of political feeling was not more remarkable than what took place in religion. The stern and enthusiastic piety which prevailed during the civil war, was now treated with ridicule, and the most of the people vied with each other in that licentious riot and drunkenness which is condemned by all systems of faith. The nation, in fact, seemed intoxicated with the safety which they supposed themselves to have at length gained, in a restoration to the imperfect freedom they enjoyed before the civil war.

DUTCH WAR.

If Charles could have managed these favourable circumstances with common discretion, he might have been the most prosperous of sovereigns. It was not long, however, before his mal-administration revived a great deal of the old feeling against him. With more than ordinary abilities, he was indolent and self-indulgent, and had no conscientious feelings as the director of the destinies of a great nation. His extravagant expenditure soon cooled the affections of his Parliament, and he began to find considerable difficulties in obtaining money. To relieve himself from this embarrassment, he sold Dunkirk, a French port which had been acquired by Cromwell, to the French king for L.40,000. For the same purpose, he married a Portuguese princess, who was not likely to have any children, but who possessed a dowry of half a million. He also commenced (1664) a war against Holland (a country that had afforded him shelter during his exile, and had many claims upon the sympathy of the English), merely that, in applying the Parliamentary subsidies necessary for keeping up hostilities, he might have an opportunity of converting part of the money to his own personal use.

This Dutch war was chiefly conducted by sea. On the 3d of June 1665, an English fleet of 114 sail met a Dutch one which numbered just one ship less, near Lowestoffe, and after an obstinate fight, gained a complete victory, depriving the enemy of eighteen vessels, and compelling the rest to take refuge on their own coast. The commander on this occasion was the Duke of York, the King's younger brother—a man of greater application and more steady principles, but who soon after became unpopular, in consequence of his avowing himself a Catholic.

Some other well-contested actions took place at sea, and the English, upon the whole, had the advantage. Owing, however, to a failure of the supplies, the King was obliged to lay up his best vessels in ordinary, and to send only an inferior force to sea. The Dutch took advantage of this misfortune, to send a fleet up the Thames (June 10, 1667), which, meeting with no adequate resistance, threatened to lay the capital in ruins and destroy its shipping. Fortunately, the Dutch admiral did not think it expedient to make this attempt, but retired with the ebb of tide, after having sunk and burnt nearly twenty vessels, and done much other damage. The King, finding himself rather impoverished than enriched by the war, soon after concluded a peace.

PLAGUE AND FIRE OF LONDON.

In the meantime, two extraordinary calamities had befallen the metropolis. In the summer of 1665, London was visited by a plague, which swept off about 100,000 people, and did not experience any abatement till the approach of cold weather. On this occasion, the city presented a wide and heart-rending scene of misery and desolation. Rows of houses stood tenantless, and open to the winds; the chief thoroughfares were overgrown with grass. The few individuals who ventured abroad, walked in the middle, and, when they met, declined on opposite sides, to avoid the contact of each other. At one moment were heard the ravings of delirium or the wail of sorrow from the infected dwelling; at another, the merry song or careless laugh from the tavern, where men were seeking to drown, in debauchery, all sense of their awful situation. The second calamity was a conflagration (vulgarly believed to have been caused by the Catholics), which commenced on the night of Sunday the 2d of September (1666), in the eastern and more crowded part of the city. The direction and violence of the wind, the combustible nature of the houses, and the defective arrangements of that age for extinguishing fires, combined to favour the progress of the flames, which raged during the whole of the week, and burnt all that part of the city which lies between the Tower and the Temple. By this calamity, 13,200 houses and 89 churches, covering in all 430 acres of ground, were destroyed. The flame at one time formed a column a mile in diameter, and seemed to mingle with the clouds. It rendered the night as clear as day for ten miles around the city, and is said to have produced an effect upon the sky which was observed on the borders of Scotland. It had one good effect, in causing the streets to be formed much wider than before, by which the city was rendered more healthy.

THE PERSECUTION IN SCOTLAND.

Meanwhile, in Scotland, great dissatisfaction had been occasioned by the imposition of Episcopacy upon the church, and advantage had been taken of various acts of resistance on the part of the clergy and people, to visit both with measures of considerable severity. Heavy fines were imposed upon such as failed to attend the ministrations of the established clergy, on the suspicion that, when not at church, they were hearing the ejected clergymen in some private place. A small standing army was kept up to enforce the fines, and, till these were paid, free quarters were exacted. Tired of suffering, a few of the peasantry in Galloway rose in rebellion (November 1666), and, advancing through the disaffected districts of Ayrshire and Lanarkshire, gradually assumed a threatening appearance. An unfortunate movement towards Edinburgh, where they expected accessions, thinned their numbers, and they were overpowered by General Dalyell at the Pentland Hills. Thirty-four of the prisoners were executed as rebels, chiefly at the instigation of Archbishop Sharpe, who, with the other prelates, was peculiarly zealous in behalf of the government. Besides these sufferers, fifty persons were forfeited, including fifteen clergymen. Some attempts were made, at the desire of the King, to induce the ejected clergy to come into the church; but very few took advantage of a leniency which the sovereign would have extended also to Catholics, and which involved their acknowledgment of his supremacy in spiritual affairs. About the year 1670, these divines began to hold conventicles in secluded parts of the country, to which the country people used to come with arms. At these places, a far warmer kind of devotion was felt than could be experienced under tamer circumstances; and, as may be supposed, such meetings were not calculated to diffuse or foster a sentiment of loyalty. Sensible of this, the government obtained an act, imposing very severe fines on all who should preach or listen at conventicles; but without producing any effect. The penalties with which they were threatened, seemed only to make the people more attached to their peculiar modes of worship and church government.

THE TRIPLE ALLIANCE—THE FRENCH ALLIANCE.

The kingdom of France was at this period rising into a degree of power and wealth, under its monarch Louis the Fourteenth, which it had never before known. Louis had some claims through his wife upon the Netherlands (since called Belgium), which was then part of the Spanish dominions. He accordingly endeavoured to possess himself of that country by force of arms. A jealousy of his increasing power, and of the Catholic religion professed by his people, induced the English to wish that his aggressions should be restrained. To gratify them, Charles entered into an alliance with Holland and Sweden, for the purpose of checking the progress of the French king. In this object he was completely successful, and consequently he became very popular. The Parliament, however, having disappointed him of supplies, he soon after entirely changed his policy, and, with the assistance of five abandoned ministers, Clifford, Ashley, Buckingham, Arlington, and Lauderdale, who were called the Cabal, from the initials of their names forming that word, resolved to render himself, if possible, independent of Parliament; in other words, an absolute prince. In consideration of a large bribe from Louis the Fourteenth, he agreed to join France in a war against Holland, with the view of utterly exterminating that example of a Protestant republic. War was accordingly declared in May 1672, and the naval force of England was employed in meeting that of the Dutch by sea; while Louis led a powerful army across the Rhine, and in a very short time had nearly reduced the whole of the Seven Provinces. In this emergency, the Dutch could only save themselves from absolute ruin, by laying a great part of their country under water. The English, who had not entered heartily into this war, soon began to be alarmed for the fate of Holland, which was almost their only support against the dread of Popery, and, though forbidden, under severe penalties, to censure the government measures, they soon contrived to exhibit so much dissatisfaction, as to render a change of policy unavoidable. The King found it necessary to assemble his Parliament (February 1673), and it was no sooner met, than it passed some acts highly unfavourable to his designs (among which was the Test Act, for excluding Catholics from office), and, above all things, declared it would grant no more supplies for the Dutch war. The King resolved to prorogue the assembly; but before he could do so, they voted the alliance with France, and several of his ministers, to be *grievances*. Charles, who, in wishing to be absolute, had been inspired by no other motive than a desire of ease, now saw there was a better chance of his favourite indulgence in giving way to his subjects, than in any other course; and he at once abandoned all his former measures, and concluded a separate peace with Holland. This country was now beginning, under the conduct of the Prince of Orange, to make a good defence against the French; which it was the better enabled to do, by obtaining the friendship of Germany and Spain. In the year 1678, after a war, which, without any decisive victories, will ever reflect lustre upon Holland, a peace was concluded. The Prince of Orange, in the previous year, had married the Princess Mary, daughter of the Duke of York, and educated in the reformed faith—an alliance which pleased the English, from its strengthening the Protestant interest, and which was destined, some years after, to bring about wonderful effects.

THE POPISH PLOT.

Throughout the whole of British history for a century past, one of the grand moving-springs was an intense detestation and fear of the Catholics, though these religionists were not only of limited number, but cannot be observed during the whole time to have ever combined for any purpose against their Protestant brethren. This sentiment was now inflamed by the avowed Catholicism of the Duke of York, the heir-presumptive of the crown, and by the late intrigues of the King with France. It raged, in short, to such an extent as to give the whole community the appearance of suffering under a fit of lunacy. In 1678, an account of a plot, supposed to have been formed by the Papists for burning London, massacring the Protestants, and destroying the King and the Protestant religion, was circulated by one Kirby, a chemist; Tong, a weak, credulous person; and Titus Oates, one of the most abandoned miscreants that ever appeared in history. The circumstances

* The Marquis of Argyle, Johnston of Warriston, and Mr Guthry, a clergyman.

attending this pretended discovery were so perfectly incredible and monstrous, that, if the nation had not been in a state of hallucination at the time, they never could have been for a moment listened to. However, the plot was not only generally believed by the people, but also by the Parliament and the court; and such was the extent of the excitement, that a general massacre of the Catholics was apprehended. Even the King, though incredulous, was obliged to give way to the prevailing delusion. Meanwhile letters were seized, which discovered the Duke of York's correspondence with France, in opposition to the religion and interests of his country; the correspondence of the King's minister Danby, which involved the King in the disgrace of similar machinations, was detected; and, to crown the whole, Sir Edmondsbury Godfrey, the magistrate, who first gave publicity to the plot, was found in the fields dead, with his own sword stuck through his body. For two years this horrible delusion reigned over the public mind, and under its influence many innocent Catholics were judicially murdered. At length the execution of a venerable nobleman, the Viscount Stafford, excited a general sensation of pity, and the people gradually saw and repented of the excesses which they had committed.

THE EXCLUSION BILL.

The Parliament having impeached Danby, the King resolved to dissolve it, and call another. The new assembly, however, proved as incontrollable as its predecessor. It carried, by a majority of 79, a bill excluding the Duke of York from the succession; declared the King's guards and standing army illegal; and passed the *Habeas Corpus* act, which has ever since been considered as so effectual a protection of the personal freedom of the subject. The House of Commons now for the first time began to assume the forms and character it has since generally retained. The court party were called Tories, from the word *tore* (give me), used by the Irish banditti, who were Cavaliers; and the party who opposed the court in favour of the people, acquired the name of Whigs, from the sour milk so called, which formed a chief part of the food of the proscribed Presbyterians in Scotland. The latter party always greatly predominated in the Parliaments of Charles the Second, and their measures were of so liberal a cast, that Mr Fox considered this tyrannical reign as in one respect, the brightest era of British freedom. Though the bill for excluding the Duke of York was thrown out by the Upper House, that prince found it necessary to retire from popular odium, first to Brussels, and afterwards to Scotland, while the Duke of Monmouth, eldest natural son of the King, and believed by many to be legitimate, began to be looked to by the Presbyterians and liberal party in general as a preferable heir to the crown. In these agitations, the populace of London was particularly active; and it was at this period that the term *mob* was first used. The word was an abbreviation of *mobile vulgus*, a phrase signifying "the unsteady vulgar," which the court contemptuously applied to the crowds which daily assembled.

PERSECUTION IN SCOTLAND.

The persecution in Scotland for field-meetings was so severe, that, before the year 1678, it was supposed that seventeen thousand persons had suffered by it, many of them very severely. A bond was attempted to be imposed upon the people, in which conventicles were renounced; and to enforce it in the west country, an army of ten thousand Highlanders was permitted to range there at free quarters. Nothing, it was found, could break the resolution of the people to adhere to their favourite modes of worship; on the contrary, all these severe measures inspired a deep resentment against the government, as well as the prelates. On the 2d of May 1679, as Archbishop Sharpe was going in his coach to St Andrew's, he was beset by a body of desperate men, who cruelly slew him. An insurrection of the west country conventiclers immediately followed, and a party of dragoons, sent against them under Captain Graham of Claverhouse, was gallantly repulsed. In a brief space, about five thousand men were found in arms against the state, among whom were many of the minor gentry. The rebellion was considered so formidable, that the Duke of Monmouth was sent down to head the troops for its suppression. He found them posted advantageously at Bothwell Bridge (June 22); but divisions on certain religious and political points unfitted them for making a good resistance. After defending the bridge for a while, they turned in a panic, and fled. Three hundred were killed in the pursuit, and twelve hundred taken prisoners. This unfortunate insurrection, being followed up by fresh severities, effectually subdued all disposition to resistance, except in a small party of the non-conformists, whose principles were of an unusually enthusiastic kind. Twenty armed men, professing these principles, were assailed by a detachment of dragoons, in Airsmoss (1680), when their leader Cameron, a clergyman, and several others, were killed, after a desperate resistance. Cargill, another preacher of that extreme sect, soon after held a conventicle at Torwood, near Stirling, where he formally excommunicated the King, his brother, and ministers. These proceedings had a highly injurious effect, in so far as they gave occasion for fresh severities against the whole party; but they were inspired by such pure and pious motives, and brought down such calamities upon the unshrinking heads of those concerned in them, that they have ever since been regarded in Scotland with great respect. The more uncompromising party soon after arranged themselves into what they called a Secret Society, and (January 12, 1682) openly appeared at Lanark, and published a declaration of their principles, among which a renunciation of all allegiance to Charles the Second was the most remarkable. The dispute between the government and its subjects had now arrived at such an extremity, that individuals were shot in the fields by military law, if they merely refused to acknowledge the royal authority. The most of the people, unable or unwilling to resist, were therefore obliged to give an external reverence to the prelatical church imposed upon them, or at least to the irregular clergy who had received an indulgence. A great disposition prevailed to emigrate to the American colonies, as the only means of escaping the oppressive restraints under which they laboured at home.

THE KING BECOMES ABSOLUTE—THE RYE-HOUSE PLOT.

In the meantime, an extraordinary revolution took place in England. About the time that popular feeling was recovering from the Popish Plot mania, the House of Commons had shown stronger symptoms than ever of a determination to seek the exclusion of the Duke of York from the throne. The time was unfortunate, for men were beginning to suspect that they had been deceived in many of their surmises about danger from the Catholics. The object, moreover, however necessary it might be to freedom, was one which touched upon a principle which many men in that age deemed sacred—that of hereditary succession; nor was it possible to blame the King for opposing a measure so unfavourable to the interests of his nearest blood relation. In fact, the liberal party of the House of Commons pushed their favourite measure to such a point as to cause a kind of reaction against them.

The King called a new Parliament to meet at Oxford, resolved, in the event of its not proving more tractable, to dissolve it, and call no other such assembly. It met on the 21st of March 1681, and the Whigs soon showed that the Exclusion Bill was still paramount in their minds. The King permitted one of his Ministers to propose, that, at his death, the Princess of Orange should reign as regent, and the new King be for ever banished five hundred miles from his dominions. But they would not listen to this concession. Charles then dissolved them, as utterly intractable, and, strange to say, was generally applauded for the act. Popular feeling had now taken a decided turn in favour of royalty; and the representative branch of the legislature, long regarded with veneration by the English, was permitted to go down without a struggle. The King henceforth ruled entirely without control, being secretly supplied with money by France, in consideration of his non-interference with the conquests of that country. The liberal party was completely baffled and broken, and all its power as a check upon the royal measures lost, through an unfortunate inadvertency to the state of public feeling.

A fit of slavishness now befell the English nation, as remarkable in its extent as the late fury against the court and the Catholics. Supported by this mood of the people, Charles caused all the corporations in the kingdom to give up their old charters, and accept of new ones, by which he became all-powerful over the elections of magistrates, and, consequently, over those of Parliamentary representatives, should ever another election of that kind take place. The leaders of the late majority in Parliament, comprising the Duke of Monmouth, Lord Russell (son of the Earl of Bedford), the Earl of Essex, Lord Howard, the famous Algernon Sydney, and John Hampden, grandson of the patriot who first resisted Charles the First, being reduced to absolute despair, formed a project for raising an insurrection in London, to be supported by one in the west of England, and another under the Earl of Argyle in Scotland, and the object of which should be confined to an amelioration of the government. They were betrayed by an associate Rumsay, and implicated, by a train of unfortunate circumstances, in a plot for assassinating the King (styled the Rye-house Plot), of which they were perfectly innocent. Russell and Sydney perished on the scaffold for this ill-starred movement, and the triumph of the King was rendered the more complete. After a despotic reign of nearly four years, he died (February 6, 1685), professing himself a Catholic, and was succeeded by the Duke of York.

ACCESSION OF JAMES THE SECOND.

Charles the Second, with all his faults, had conducted himself towards his subjects with so much pleasantness, and had so well calculated his ground before making any aggression upon popular liberty, that he might probably have pursued his arbitrary career for many years longer. But his brother James, though much more respectable as a man, more industrious and more sincere, wanted entirely that easiness of carriage and that penetration which were the grounds of the late King's popularity and success. He was, moreover, a declared Catholic, and inspired by an ardent desire of reforming the nation back into that faith. These circumstances, though they at first seemed to threaten very bad consequences, will soon be found to have proved the means of saving these nations from the complete establishment of a despotic government.

He began his reign by declaring before the Privy Council his intention of governing solely by the laws, and to maintain the existing church; and such was the confidence in his sincerity, that he soon became very popular. Addresses poured in upon him from all quarters, professing the most abject devotion to his person. He called a Parliament in order to obtain money, and, by reason of the control which the crown had acquired over the boroughs, he was not disappointed in his wishes. The House of Commons voted him an ample revenue, and expressed the greatest servility towards him in all things. The doctrines of passive obedience, and the divine right of the sovereign, were now openly preached. The Scottish Parliament declared the King's *sacred, supreme, and absolute authority*, which they offered to support with their lives and fortunes. In fact, it seemed as if the civil liberties of the British people were now to be surrendered to the crown, as a possession which it was no longer safe or expedient to retain.

EXPEDITIONS OF MONMOUTH AND ARGYLE.

The remains of the Whig party still existed, though in exile, and there were some districts of the country where they thought they had considerable influence. The Duke of Monmouth and the Earl of Argyle (the latter of whom had been condemned to death in Scotland for garbling the test oath, but had escaped), met in Holland, and projected two separate invasions, for the purpose of expelling the Catholic James. The former soon after landed in the west of England with a small retinue, and quickly found himself at the head of five thousand persons, though irregularly armed. At several places, he caused himself to be proclaimed King, which offended many of his principal adherents, as inconsistent with his previous engagements. Upon the whole, his conduct was not energetic enough for the management of such an enterprise. Being attacked by the King's troops near Bridgewater, his infantry fought with some spirit, but, being deserted by the cavalry, and by the duke himself, were obliged to give way. Monmouth himself was taken, and executed. His followers were many of them hanged without form of trial by the royal troops, and others were afterwards put to death with hardly any more formality, by the celebrated Chief Justice Jefferies, whom the King sent down with a commission to try the offenders. The butchery of several hundred men of low condition, who were unable to do any harm to the government, was looked upon as a most unjustifiable piece of cruelty, not to speak of the illegal way in which it was done; and the King was greatly blamed for it.

The Earl of Argyle sailed in May with a corresponding expedition, and landed in his own district in the West Highlands. Unfortunately, the government had received warning, and seized all the gentlemen of his clan, upon whom he had chiefly depended. He nevertheless raised between two and three thousand men, and made a timid advance to Glasgow, in the expectation of being joined by the persecuted Presbyterians of that part of the country. Being surrounded on the march by various parties of troops, he dispersed his army, and sought to escape in disguise, but was taken, brought to Edinburgh, and executed. Thus terminated the last effort made by the Whig party to ameliorate the iron sway of the Stuarts.

ARBITRARY MEASURES OF THE KING.

Encouraged by his successes, James conceived that he might safely begin the process of changing the established religion of the country. On the plea of his supremacy over the church, he took the liberty of dispensing with the test oath in favour of some Catholic officers, and thus laid low an act which was looked upon, under existing circumstances, as the chief safeguard of the Protestant faith. His Parliament, servile as it was in temporal matters, took the alarm at this spiritual danger, and gave the King so effectual a resistance, that he resorted to a dissolution. The same phenomenon was acted in Scotland.

Heedless of these symptoms, he proclaimed an universal toleration, for the purpose of embracing the Catholics, and thus assumed the highly unconstitutional right of dispensing with acts of Parliament. The nation was thrown by this measure, and by the numerous promotions of Roman Catholics, into a state of great alarm; and even the clergy, who had been formerly so eager to preach passive obedience to the regal will, began to see that there might be a danger in that doctrine. James having commanded that his proclamation of toleration should be read in every pulpit in the country, only two hundred of the clergy obeyed. Six of the bishops joined in a respectful petition against the order; but the King declared that document to be a seditious libel, and threw the petitioners into the Tower. In June 1688, they were tried in Westminster Hall, and, to the infinite joy of the nation, acquitted.

Blinded by religious zeal, the King proceeded on his fatal course. In defiance of the law, he held open intercourse with the Pope, for the restoration of Britain to the bosom of the Romish church. He called Catholic lords to the privy council, and even placed some in the cabinet. Chapels, by his instigation, were every where built, and monks and priests went openly about his palace. A court of high commission—the most flagitious instrument of tyranny under

Charles the First—was erected, and before this every clerical person who gave any offence to the King, was summoned. He also excited great indignation by violently thrusting a Catholic upon Magdalen College, at Oxford, as its head, and expelling the members for their resistance to his will. To crown the general feeling, a son was born to the King (June 10, 1688), who promised to perpetuate the Catholic religion in the country, and whom many suspected to be a supposititious child, brought forward for that purpose only.

GENERAL DISAFFECTION.

The disaffection produced by these circumstances extended to every class of the King's subjects, except the small body of Roman Catholics, many of whom, even, regarded the royal measures as in the highest degree imprudent. The Tories were enraged at the ruin threatened to the Church of England, which they regarded as the grand support of conservative principles in the empire. The Whigs, who had already made many strenuous efforts to exclude or expel the King, were now more inflamed against him than ever. The clergy, at this time a popular and influential body, were indignant at the injuries inflicted upon their church; and even the dissenters, though comprehended in the general toleration, saw too clearly through its motive, and were too well convinced of the illegality of its manner, and of the danger of its object, as affecting the Protestant faith, to be exempted from the general sentiment. But for the birth of the Prince of Wales (whose birth they suspected erroneously), the people at large might have been contented to wait for the relief which was to be expected, after the death of the King, from the Princess of Orange, who was a Protestant, and united to the chief military defender of that interest in Europe. But this hope was now shut out, and it was necessary to resolve upon some decisive measures for the salvation of the national religion.

PRINCE OF ORANGE CALLED OVER.

In this crisis, some of the principal nobility and gentry, with a few clergymen, united in a secret address to the Prince of Orange, calling upon him to come over with an armed force and aid them in protecting their faith and liberties. This prince, who dreaded that England would soon be joined to France against the few remaining Protestant powers, and also that his prospects of the succession in that country (for he was nephew of the King) were endangered, listened readily to this call, and immediately collected a large fleet and army, comprising many British refugees. His preparations were conducted with great secrecy, and James was partly blinded to them by a rumour that the only object was to frighten him into a closer connection with France, in order to make him odious to his subjects. When he was at length assured by his minister in Holland that he might immediately expect a formidable invasion, he grew pale, and dropped the letter from his hands. His delirium of power vanished, and he found himself on the brink of a dreadful precipice, which had hitherto been concealed from his view by the illusions of religious zeal. He now saw the necessity of providing for his own safety, as well as of endeavouring to conciliate the affections of his people. He immediately ordered his fleet to be assembled, and his army to be recruited with new levies. He sent for troops from Scotland and Ireland; and to his no small satisfaction, found his land forces amount to forty thousand men.*

Nor was the King less liberal of his civil concessions than vigorous in his military preparations. He had already issued writs for the meeting of Parliament on the 27th of the ensuing November. He followed these with a declaration, that it was his fixed purpose to endeavour to establish a legal settlement of an universal liberty of conscience for all his subjects; that he had resolved to preserve inviolate the church of England; and he protested that it was his intention Roman Catholics should remain incapable of sitting in the House of Commons. He gave orders to the Lord Chancellor, and the Lord Lieutenants of the several counties, to replace all the Deputy Lieutenants and Justices who had been deprived of their commissions for their adherence to the Test and the Penal Laws against non-conformists; he restored the charter of London, and the charters of all the corporations in the kingdom; he annulled the court of ecclesiastical commission; he reinstated the expelled president and fellows of Magdalen College; and he invited again to his councils all the bishops whom he had so lately persecuted and insulted, assuring them that he was ready to do whatever they should think necessary for the security of the Protestant religion and the civil rights of his subjects.

But these concessions, though important in themselves, were made too late to be allowed much merit; and being generally supposed to be extorted by fear, they were coldly received by the nation. Nor was the conduct of the King, in other respects, answerable to such conciliating measures. He recalled the writs for the meeting of Parliament, without issuing any new ones; a step which created universal suspicion of his sincerity, and begot a belief that all his concessions were no more than temporary expedients. He shewed, however, a laudable zeal for his own honour, in obtaining a legal proof of the birth of the Prince of Wales; but by an imprudence approaching to insanity, the heir of the crown was baptized in the Romish communion, and the Pope, represented by his nuncio, stood godfather to the boy.

Meanwhile, the Prince of Orange continued his preparations. A powerful fleet was ready to put to sea; the troops fell down the Maese from Nimeguen; the transports, which had been hired at different ports, were speedily assembled; the artillery, arms, ammunition, provisions, horses, and men, were embarked; and William, after taking formal leave of the states, and calling God to witness that he had not the least intention to invade, subdue, or make himself master of the kingdom of England, went himself on board. His whole armament, which sailed from the Brille and Helvoetsluys, on the 19th of October, consisted of fifty stout ships of war, twenty-five frigates, and an equal number of fire-ships; with five hundred transports, carrying about fifteen thousand land forces, including five hundred and fifty-six officers. Admiral Herbert, who had left the service of James, led the van; the Zealand squadron, under Vice-Admiral Evertsen, brought up the rear; and the Prince of Orange in person commanded in the centre, carrying a flag with English colours, and his own arms surrounded with these popular words—"THE PROTESTANT RELIGION AND THE LIBERTIES OF ENGLAND." Under this inscription was placed the appósite motto of the house of Nassau:—*Je maintiendrai*, "I will maintain!"

This great embarkation, the most important which had for some ages been undertaken in Europe, was scarce completed, when a dreadful tempest arose at south-west, and drove the Dutch fleet to the northward. The storm raged for twelve hours, and the prince was obliged to return to Helvoetsluys. But he soon repaired his damages, and again put to sea. An east wind carried him down the Channel, where he was seen from both shores, between Dover and Calais, by vast multitudes of anxious spectators, who felt alternately the extremes of hope and fear, mingled with admiration, at such a magnificent spectacle. After a prosperous voyage, he landed his army in Torbay (November 5), without the smallest opposition either by sea or land.

The same wind which favoured the enterprise of the Prince of Orange, confined the English fleet to its own coast. Lord Dartmouth, who was inviolably attached to James, lay near Harwich with thirty-eight ships of the line, and twenty-three frigates; a force sufficient to have disconcerted the designs of William, if it could possibly have put to sea; so that the success of the revolution may be said to have depended upon the winds! The destruction of the Dutch fleet, even after the landing of the Prince, would have discouraged his adherents, and proved fatal to his undertaking. Sensible of this, Dartmouth came before Torbay, with a fixed resolution to attack the Hollanders as they lay at anchor. But his fleet was dispersed by a violent storm, and forced to return to Spithead, in such a shattered condition as to be no more fit for service that season.

The Prince of Orange, immediately on his landing, dispersed a printed declaration, which had been already published in Holland, and contributed not a little to his future success. In that elaborate performance, written originally in French by the pensionary Fagel, and translated into English by Dr Burnet, the principal grievances of the three British kingdoms were enumerated; namely, the exercise of a dispensing and suspending power; the revival of the court of ecclesiastical commission; the filling of all offices with Catholics; the open encouragement given to popery, by building every where places of worship, colleges, and seminaries for that sect; the displacing of judges, if they gave sentence contrary to the orders or the inclinations of the court; the annulling the charters of all the corporations, and thereby subjecting elections to arbitrary will and pleasure; the treating of petitions to the throne, even the most modest, and from persons of the highest rank, as criminal and seditious; the committing of the whole authority in Ireland, civil and military, into the hands of Papists; the assuming of an absolute power over the religion and laws of Scotland, and openly exacting in that kingdom an obedience without reserve. He concluded with protesting that the sole object of his expedition was to procure a redress of these grievances; to get a legal and free Parliament summoned, that might provide for the liberty and security of the nation, and examine the proofs of the legitimacy of the Prince of Wales, in regard to which he expressed the most violent suspicions.

Though this declaration was received with ardour by the nation, the prince for some time after his landing could not boast of his good fortune. A great deal of rain having fallen, the roads were rendered almost impassable, and he possessed neither cattle nor carriages sufficient to convey the baggage of his army. He proceeded, however, to Exeter; but without being joined by any person of eminence, either on his way or for eight days after his arrival at that place. His troops were discouraged, he himself began to think of abandoning his enterprise, and actually held a council of his principal officers, to deliberate whether he should not re-embark. Impatient of disappointment, he is said even to have publicly declared his resolution to permit the English nation to settle their own differences with their King, and to direct his father-in-law where to punish, by transmitting to him the secret correspondence of his subjects.

The friends of the court exulted mightily at the coldness of William's reception, but their joy was of short duration. One Burrington having shewn the example, the prince was speedily joined by the gentry of the counties of Devon and Somerset, and an association was signed for his support. The Earl of Abingdon, Mr Russell, son of the Earl of Bedford, Lord Wharton, Mr Godfrey, Mr Howe, and a number of other persons of distinction, repaired to Exeter. All England was seen in commotion. Lord Delamere took arms in Cheshire; the city of York was seized by the Earl of Danby; the Earl of Bath, governor of Plymouth, declared for the prince; and the Earl of Devonshire made a like declaration in Derby. Every day discovered some new instance of that general confederacy into which the nation had entered against the measures of the King. But the most dangerous symptom, and that which rendered his affairs desperate, was the defection of the army. Many of the principal officers were inspired with the prevailing spirit of the nation, and disposed to prefer the interests of their country to their duty to their sovereign. Though they might love James, and have a due sense of the favours he had conferred upon them, they were startled at the thought of rendering him absolute master, not only of the liberties, but even of the lives and properties of his subjects; and yet this, they saw, must be the consequence of suppressing the numerous insurrections, and obliging the Prince of Orange to quit the kingdom. They therefore determined rather to bear the reproach of infidelity, than to run the hazard of becoming the instruments of despotism.

The example of desertion among the officers was set by Lord Colchester, son of the Earl of Rivers, and by Lord Cornbury, son of the Earl of Clarendon. The King had arrived at Salisbury, the head-quarters of his army, when he received this alarming intelligence; but as the soldiers in general seemed firm in their allegiance, and the officers in a body expressed their abhorrence of such treachery, he resolved to advance upon the invaders. Unfortunately, however, for his affairs, the Dutch had already taken possession of Axminster. A sudden bleeding at the nose, with which he was seized, occasioned a delay of some days; and farther symptoms of defection appearing among the officers, he judged it prudent to retire toward London. Lord Churchill, afterwards the great Duke of Marlborough, and the Duke of Grafton, natural son of Charles the Second, who had given their opinion for remaining at Salisbury, fled under cover of the night to the Prince of Orange. Successive misfortunes poured in on the unfortunate monarch. Trelawney, who occupied an advanced post at Warminster, deserted with all his captains, except one. Prince George of Denmark, the King's son-in-law, and the young Duke of Ormond, left him at Andover. Every day diminished the number of his officers; and to increase his accumulated misfortunes, he found, on his arrival in London, that his favourite daughter, Anne, Princess of Denmark, had secretly withdrawn herself the night before, in company with Lady Churchill. All his firmness of mind left him; tears started from his eyes; and he broke out into sorrowful exclamations, expressive of his deep sense of his new lost condition. "God help me!" cried he, in the agony of his heart; "my own children have forsaken me!"*

Henceforth, the conduct of the infatuated James is so much marked with folly and pusillanimity, as to divest his character of all respect, and almost his sufferings of compassion. Having assembled, as a last resource, a council of the peers then in London, he issued, by their advice, writs for a new Parliament, and appointed the Marquis of Halifax, the Earl of Nottingham, and Lord Godolphin, his commissioners to treat with the Prince of Orange. Thinking the season for negociation past, William continued to advance with his army, at the same time that he amused the commissioners. Though he knew they were all devoted to his cause, he long denied them an audience. Meanwhile, James, distracted by his own fears, and alarmed by the real or pretended apprehensions of others, sent the Queen and the Prince of Wales privately into France, and embraced the extraordinary resolution of following them in person. He accordingly left his palace at midnight, attended only by Sir Edward Hales; and in order to complete his imprudence and despair, he commanded the Earl of Feversham to disband the army, recalled the writs for the meeting of the Parliament, and threw the great seal into the Thames.

If James had deliberately resolved to place the Prince of Orange on the throne of England, he could not have pursued a line of conduct more effectual for that purpose. Besides the odious circumstances of seeking refuge with the heir of the crown in a country distinguished for popery and arbitrary power, and recalling the writs for a free Parliament, the anarchy and disorder which ensued on the sudden dissolution of government, made all men look up to William as

* The following account of the Revolution is from Russell's History of Modern Europe. The rest of the sheet is carefully condensed from the larger histories of England and Scotland—a process of no small degree of difficulty.

* A less melancholy anecdote than this is related. Prince George of Denmark, husband of the King's second daughter, and who was a man of weak character, used to express himself to his Majesty as very much surprised at the defections which every night took place, always saying, when any lord or officer was mentioned as having retired, "Est il possible?" At length Prince George himself followed the general example; which being told to the King, he cried, with a sneer, "What, *est il possible* gone too!"

the saviour of the nation. The populace rose in London, and not only destroyed all the Popish chapels, but even rifled the houses of the ambassadors of Catholic princes and states, where many of the Papists had lodged their most valuable effects. Riot and devastation every where prevailed. The whole body of the people, released from the restraints of law, felt one general movement; and new violences were apprehended from the licentious soldiers, whom Feversham had disbanded without either disarming or paying them.

In order to remedy these evils, and restore public tranquillity, an office which seemed now beyond the power of the civil magistrate, such of the bishops and peers as were in London assembled in Guildhall, and, erecting themselves into a supreme council, executed all the functions of royalty. They gave directions to the mayor and aldermen for keeping the peace of the city; they issued their commands, which were readily obeyed, to the fleet, to the neglected army of James, and to all the garrisons in England. They ordered the militia to be raised; and they published a declaration, by which they unanimously resolved to apply to the Prince of Orange to settle the affairs of the nation, deserted by the King, through the influence of evil counsellors.

William was not backward in assuming that authority which the imprudence of James had devolved upon him. He exercised, in his person, many acts of sovereignty; and in order to make his presence more welcome in London, he is said to have propagated a report that the disbanded Irish had taken arms, and begun a general massacre of the Protestants. Such a rumour at least was spread all over the kingdom, and begot universal consternation. The alarm bells were rung, the beacons fired; and men fancied they saw at a distance the smoke of the burning cities, and heard the dying groans of those who were slaughtered by the enemies of their religion! Nothing less than the approach of the Prince of Orange and his Protestant army, it was thought, could save the capital from ruin.

William had advanced to Windsor, when he received the unwelcome news that the King had been seized in disguise, by some fishermen, near Feversham in Kent, on supposition that he was some Popish priest, or other delinquent, who wanted to make his escape. This intelligence threw all parties into confusion. The Prince of Orange sent orders to James not to approach nearer to London than Rochester. But the messenger missed him on the way, and he once more entered his capital amid the loudest acclamations of joy. The people forgot his misconduct in his misfortunes, and all orders of men seemed to welcome his return.

This, however, was only a transient gleam before a new storm. Scarce had the King retired to his bedchamber, when he received a message from the prince, desiring him to remove to Ham, a house belonging to the Duchess of Lauderdale; and the following night, as he was going to rest, the Dutch guards, without further notice, took possession of his palace, and displaced the English, to the great disgust of the army, and no inconsiderable part of the nation. James set out next morning, by permission, for Rochester, in preference to Ham, under a Dutch guard.

Afraid of being taken off either by poison or assassination, and mortified at his present abject condition, he continued to meditate his escape; and as the backdoor of the house in which he lodged was intentionally left without any guard, he found no difficulty in accomplishing his design. He privately withdrew at midnight, accompanied by his natural son, the Duke of Berwick, and went on board a large sloop, which waited for him in the river Medway. After some obstructions, he safely arrived at Ambleteuse, in Picardy; whence he hastened to St Germain's, where the Queen and the Prince of Wales had arrived the day before.

The same day that James left Whitehall, William arrived at St James's. It happened to rain very heavily, and yet great numbers came to see him; but, after they had staid long in the wet, he disappointed them. Being an enemy to show and parade, perhaps from a consciousness of his ungraceful figure, he went through the park to the palace. Even this trifling incident helped to alter the sentiments of the people; and being now cool, they judged more impartially. They considered it as an unnatural thing for the Prince of Orange to waken his father-in-law out of his sleep, and force him from his own palace, when he was ready to submit to every thing; they began even to suspect that this *specious undertaking* would prove to be only a *disguised* and *designed usurpation*. The public bodies, however, waited upon the Prince, and expressed their zeal for his cause; and, among others, the gentlemen of the law, with old Sergeant Maynard at their head, who, when William took notice of his great age, and said he must have outlived all the lawyers of his time, wittily replied, "I should have outlived the law itself, if your highness had not come over!"

THE REVOLUTION SETTLEMENT.

William was now requested by such of the members of the late Parliaments as happened to be in town, to issue writs for a convention, in order to settle the nation. He was in the same manner requested to call a convention in Scotland, and both assemblages, which were elected by poll, met early in 1689. By the English convention, after a great deal of discussion, it was determined "that, King James the Second having endeavoured to subvert the constitution by breaking the *original contract* between the King and people, and having violated the fundamental law, and withdrawn himself from the kingdom, has *abdicated* the government; and that the throne is thereby become *vacant*." There were some proposals for making the Prince only a regent, while his consort should be declared Queen; but it was eventually found that his powerful aid could not be secured in the present crisis, for a less price than a full participation of the throne along with Mary. They were therefore proclaimed as William and Mary, King and Queen of Great Britain and Ireland. In Scotland, where the Presbyterians had resumed an ascendancy, the convention came to a less timid decision. It declared that James, by the abuse of his power, had *forfeited* all right to the crown—a decision also affecting his posterity—and William and Mary were immediately after proclaimed. By a bill passed in the English Parliament, called the Instrument of Settlement, the succession, failing Mary, was to go to William, then to Anne, the late King's second daughter; and the prerogative of the crown was settled within the limits which it has had ever since. The grand point gained by the Revolution—as the transaction is called—was, that the King, by misgovernment, might as effectually forfeit his right to *allegiance*, as the subject, by misconduct, his title to *protection*. The power of the King was recognised as expressly emanating from the people, and existing solely by their general consent. The security of the Protestant religion, and the exclusion of Catholics from office, were other triumphs, then and long after much appreciated by the English; while in Scotland, the establishment of the Presbyterian church upon a fixed basis gave satisfaction to all except a very small party.

RESISTANCE IN SCOTLAND AND IRELAND.

The leader of this party was the Viscount Dundee, formerly known, under the name of Graham of Claverhouse, for his severities against the recusant Presbyterians. This nobleman retired with a troop of dragoons to the Highlands, where he was quickly joined by the clans. At the same time, the Duke of Gordon held out Edinburgh Castle in behalf of King James. It was with no small difficulty that the new government could obtain the means of reducing these opponents. The castle, after a protracted siege, was given up in June (1689). General Mackay was dispatched by William, with a few troops, to join with such forces as he could obtain in Scotland, and endeavour to suppress the insurrection in the Highlands. He encountered Dundee at Killiecrankie (July 27), and, though his troops were greatly superior in number and discipline, experienced a complete defeat. Dundee, however, fell by a musket-shot in the moment of victory, and his army was unable to follow up its advantage. In a short time the Highland clans were induced to yield a nominal obedience to William and Mary.

In Ireland, a far more formidable resistance was offered to the revolution settlement. The people of this country, being chiefly Catholics, and greatly incensed against their Protestant masters, regarded the cause of King James as their own. He landed in Ireland early in spring, and was soon at the head of a large, though ill-disciplined army. To gratify his Catholic subjects, he passed an act in the Irish Parliament, annulling what was called the Act of Settlement, by which the Protestants had been placed in land originally belonging to persons of the opposite faith. The Protestants, finding themselves thus dispossessed of what they considered their property, and exposed to the vengeance of a majority over whom they had long triumphed, fled to Londonderry, Inniskilling, and other fortified towns, where they made a desperate resistance, in the hope of being speedily succoured by King William. That sovereign now led over a gallant army to Ireland, and (July 1) attacked the native forces under his father-in-law at the fords of the Boyne, near the village of Dunore, where he gained a complete victory. James was needlessly dispirited by this disaster, and lost no time in sailing again to France. In reality, the Irish made a better appearance, and fought more vigorously, after the battle of the Boyne, than before it. The Duke of Berwick and the Earl of Tyrconnel still kept the field with a large body of cavalry, and the infantry were in the meantime effectually protected in the town of Limerick. William invested this town, and, in one assault upon it, lost two thousand men, which so dispirited him, that he went back to England, leaving his officers to prosecute the war. The Irish army afterwards fought a regular battle at Aghrim, but, partly owing to the loss of their brave leader, St Ruth, were totally routed. The remains of the Catholic forces then took refuge in Limerick, where they finally submitted upon very advantageous terms, not only to themselves, but to all their countrymen of the same persuasion. It was agreed that they should receive a general pardon; that their estates should be restored, their attainders annulled, and their outlawries reversed; that Roman Catholics should enjoy the same toleration as in the days of Charles the Second; that they should be restored to all the privileges of subjects on merely taking the oaths of allegiance; and that such as chose to follow the fortunes of James (of which there was a vast number) should be conveyed to the Continent at the expense of government.

TROUBLES OF THE NEW GOVERNMENT.

Though all military opposition was thus overcome, William soon found difficulties of another kind in the management of the state. The Tories, though glad to save their religion by calling in his interference, had submitted with no good grace to the necessity of making him King, and no sooner was the danger past, than their usual principles of hereditary right were in a great measure revived. James's hopes of a restoration were thus for a long time kept alive, and the peace of William's mind was so much embittered as to make his sovereignty appear a dear purchase. Nothing, indeed, could so fully testify that the hope of gratitude for public services is fallacious, than the jealous and illiberal spirit with which a great part of the English nation treated this great benefactor of their country. Perhaps the only circumstance which reconciled the King to his situation, was the great additional force he could now bring against the ambitious designs of Louis the Fourteenth. Almost from his accession he entered heartily into the combination of European powers for checking this warlike prince, and conducted military operations against him every summer in person. The necessity of having supplies for that purpose, rendered him unfit, even if he had been willing, to resist any liberal measures proposed to him in Parliament, and hence his passing of the famous Triennial Act in 1694, by which it was appointed that a new Parliament should be called every third year—a point in the claims of freedom which had been gained from Charles the First, but abandoned in compliment to his son, and which was afterwards lost once more. In this year died Queen Mary, without offspring; after which, William reigned as sole monarch.

GLENCOE MASSACRE—DARIEN EXPEDITION.

While William was treated in England with less than justice, he deservedly lost all his popularity in Scotland, in consequence of two separate acts, which must now be related. An order had been issued, commanding all the Highland chiefs, under pain of fire and sword, to give in their submission before the final day of the year 1691. One individual—Macdonald of Glencoe—was prevented by accident from observing the day, and letters of fire and sword, signed by the King, were accordingly issued against him. The military party entrusted with this duty, instead of boldly advancing to the task, came among the clan as friends, partook of their hospitality and amusements, and never indicated their intentions till the morning of February 13, when they attacked the unsuspecting people in their beds, and mercilessly slew all that came in their way. Thirty-eight persons, including the chief and his wife, were slaughtered, and many others died in the snow, as they vainly tried to escape. A more atrocious action does not stain modern history. Two or three years after, the Scottish people began to turn their attention to commerce, by which they saw such advantages gained by neighbouring states, and they planned a colony on the Isthmus of Darien, which they thought might become an emporium for American and Indian produce. They subscribed among themselves, for this purpose, no less than L.400,000; to which was added more than as much again by the merchants of London and Holland. The jealousy of other trading companies, and the remonstrances of the Spaniards, who apprehended some interference with their colonies, induced the King to withdraw his countenance from the scheme, after he had sanctioned it by act of Parliament; but nevertheless (1698), a gallant expedition was sent out by the Scots, who founded a town called New Edinburgh, about midway between Portobello and Carthagena, and under the ninth degree of latitude. During the winter months, every thing seemed likely to answer the expectations of the colonists; but summer brought disease, and, on their provisions running low, they found, to their infinite consternation, that they could get no supplies, the Spanish and British colonists of the neighbouring countries being alike forbidden to deal with them. In May and September 1699, ere intelligence of these circumstances could reach home, two other expeditions had sailed, containing eighteen hundred men, who were involved on their arrival in the same disasters. After disease had swept off many hundreds, the remainder were attacked by the Spaniards, who pretended a right to the country; and to these haughty enemies, who were countenanced in their proceedings by the British sovereign, the unfortunate colony was obliged to surrender. Very few ever regained their native country, and the large sums vested in the undertaking were irrecoverably lost. The massacre of Glencoe, and the Darien expedition, were thenceforward words to call up the most infuriated feelings against the King, in the breasts of the Scottish nation; among whom the Jacobite party, or friends of the exiled James, thenceforward began to assume a formidable appearance.

END OF THE REIGN OF WILLIAM THE THIRD.

The peace of Ryswick, concluded in 1697, by which the French power was confined to due limits, permitted William to spend the concluding years of his reign in peace. In 1700, in consideration of the childlessness of William and his sister-in-law Anne, the famous Act of Succession was passed, by which the crown, failing these two individuals, was settled upon the next Protestant heir, Sophia, Duchess of Hanover, daughter of Elizabeth, the eldest daughter of James the First. The wars carried on by William having been so expensive as to outrun the resources of the nation, it was in his time that a public debt first began to be contracted.

About this time, the causes of a new war took their rise in certain disputes respecting the succession to the crown of Spain. The title to that sovereignty, in the event of the death of the existing King without heirs, was claimed by the King of France, the Elector of Bavaria, and the Emperor of Germany, through various female lines of descent. A treaty, to which England was a party, was entered into for preventing the whole from falling into the hands of Louis, whose empire would then have been so great as to be inconsistent, it was thought, with the independence and safety of the neighbouring states. When the King died, Louis, without regard to the treaty, established one of his grandsons as King of Spain, and other important dominions belonging to it, among which was the kingdom of Naples. About the same time, in defiance of the treaty of Ryswick, he acknowledged the son of James the Second [this exiled prince died in September 1701] as King of Great Britain. The British monarch was indignant at both events, and the nation at the latter; and war was accordingly in preparation, when King William died (March 2, 1702), in consequence of a fall from his horse.

MARLBOROUGH'S WARS.

The movement against Louis had not been confined to Great Britain: it was a combination of that power with the Emperor of Germany and the states of Holland. Anne, the successor of William, found it necessary to maintain her place in the Grand Alliance, as it was termed; and the Duke of Marlborough was sent over to the Continent with a gallant army, to prosecute the war in conjunction with the allies. Now commenced that career of glory which has rendered the reign of Anne and the name of Marlborough so famous. In Germany and Flanders, under this commander, the British army gained some signal successes, particularly those of Blenheim and Ramillies: in Spain, a smaller army, under the chivalrously brave Earl of Peterborough, performed other services of an important kind. The war, however, was one in which Britain had no interest—for it has been seen that Spain has continued under a branch of the House of Bourbon, without greatly endangering other states. A party, consisting chiefly of Tories, endeavoured, in 1706, to put an end to the war; and France was so much reduced in strength as to concede all the objects for which the contest had been commenced. The people, however, were so strongly inspired with a desire of humiliating France, which in trade and religion they considered their natural enemy, that some ambitious statesmen of a contrary line of politics were enabled to set the treaty adrift. Among these was the Duke of Marlborough himself, who, being permitted to profit, not only by his pay, but by perquisites attached to his command, wished the war to be protracted, merely that he might make his enormous wealth a little greater. It was by these unnecessary interferences with continental politics, which yet were urged only by the people, and by a popular class of statesmen, that the foundation was laid for the existing national debt.

UNION OF ENGLAND AND SCOTLAND.

Since their religious enthusiasm had been laid at rest by the Revolution Settlement, the Scots had been chiefly animated by a desire of participating in the commerce of England. The shameful treatment of their expedition to Darien had now inspired them with a bitter feeling against their southern neighbours, and they resolved to show their power of counter-annoyance, by holding up threats of dissenting from England in the matter of the succession. In 1703, their Parliament passed the Act of Security, by which it was ordained that the successor of her Majesty should not be the same person with the individual adopted by the English Parliament, unless there should be a free communication of trade between the countries, and the affairs of Scotland thoroughly secured from English influence. Another act was at the same time passed, for putting the nation under arms. The English ministers then saw that an incorporating union would be necessary, to prevent the Pretender from gaining the Scottish crown, and to protect England from the attacks of a hostile nation. For this purpose, they exerted themselves so effectually in the Scottish Parliament, as to obtain an act, enabling the Queen to nominate commissioners for the arrangement of an union. The men appointed, thirty on each side, were, with hardly an exception, the friends of the Court and of the Revolution Settlement; and the treaty accordingly was framed without difficulty. In October 1706, it was submitted to the Scottish Parliament, and was found to contain the following principal points—that the two nations were to be indissolubly united under one government and legislature, each, however, retaining its own civil and criminal law; the crown to be in the house of Hanover; the Scottish Presbyterian church to be guaranteed; forty-five members to be sent by the Scottish counties and burghs to the House of Commons, and sixteen elective peers to be sent to the Upper House by the nobles; the taxes to be equalised, but, in consideration of the elevation of the Scotch imposts to the level of the English (for the latter people already owed sixteen millions), an equivalent to be given to Scotland, amounting to nearly four hundred thousand pounds, which was to aid in renewing the coin and other objects. These terms were regarded in Scotland as miserably inadequate; and the very idea of the loss of an independent legislature and status among governments, raised their utmost indignation. Nevertheless, by dint of sheer bribery, the union was carried through Parliament; and, from the 1st of May 1707, the two countries formed one state, under the title of the Kingdom of Great Britain.

HIGH CHURCH MANIA.

Soon after this period, there occurred one of those changes in the current of popular sentiment, which have already been alluded to as characterising our history. For some years, Whig ascendancy, the exclusion of the Pretender, the humiliation of France, and the military glory of Great Britain, had been the grand objects of the people. Tired now of these, they gradually began to cry up Toryism, hereditary succession, and the Church of England, and thought more of the expenses of the war and its empty objects, than its glory. What tended greatly to bring about this change, was the prosecution, by the ministry, of a divine named Henry Sacheverell, for a violently enthusiastic sermon which he had preached before the Lord Mayor and Aldermen of London, and in which he seemed to call upon the people to take up arms in defence of their endangered church. The ministers were so weak as to give this absurd man a solemn trial, which only inflamed the people in favour of him and the church—the latter being an institution then invested with much public respect on account of its independent conduct in resisting James the Second. The people rose so tumultuously for Sacheverell, that the ministry, after procuring a condemnation, could inflict only an appearance of punishment. After the trial, he received more marks of public reverence and honour than were ever bestowed on the greatest national benefactor; and the Tory and High Church party gained so much strength in a new Parliament then elected, as to expel the Whigs. A Tory ministry—the famous Tory ministry of Queen Anne—then came into power (1710), being headed by Harley Earl of Oxford, and the celebrated Viscount Bolingbroke.

PEACE OF UTRECHT.

The members of this new cabinet immediately applied themselves, though very secretly, to the business of bringing about a peace. When their plans were matured, the consent of the House of Commons was easily gained, seeing that that assembly contained a majority of Tories; but the Lords having shown some reluctance, it was found necessary to create twelve new peers, in order to overpower the sense of that part of the legislature. After a tedious course of negociation, Britain and Holland concluded a peace at Utrecht (1713), leaving the Emperor of Germany still at war. By this arrangement, Philip the Fifth was permitted to retain Spain and the Indies, but no other part of the dominions which his ambitious grandfather had endeavoured to secure for him; and it was provided that he and his descendants should never inherit the kingdom of France, nor any future king of France accede to the crown of Spain. Britain obtained nothing tangible by all her exertions, except the enviable privilege of being exclusively employed to carry slaves to the Spanish American colonies! In fact, the wars of William and Anne had no object but that of preventing certain continental territories from being amassed by certain sovereigns—an evil which, in hardly any extent, could have ever done serious injury to Britain; while it is evident that the people supported these contests through the influence of the most besotted sentiments, nor saw their inutility till they felt the increase of taxes which they occasioned. There was then, it must be observed, little principle among statesmen, and little information among the people. The Tory ministry obtained the peace only for party ends; and though it really was beneficial, as the termination of a course of error, it was not received very generally in that light; for, after all, the news of a victory in Flanders had a great charm for the public ear; and the army is not a thing that the populace are ever seen to dislike, either in reference to its expense or its liability to become an instrument of oppression.

ACCESSION OF GEORGE THE FIRST.

Queen Anne, who was a good but weak-minded woman, had for some years entertained a wish that the act of settlement should be set aside, and the crown restored, on her death, to the main line of her family, in the person of her brother James, now styled the Pretender. Toryism was hardly so popular as to make it possible to avow this purpose boldly; and accordingly the greatest caution was observed by herself and her ministers in their intrigues for bringing in the Pretender. Before their plans were matured, the Queen took suddenly ill, and died (Aug. 1, 1714); and the Tory ministers, finding themselves under the necessity of acting according to the existing law, proclaimed the Elector of Hanover, son of the late Princess Sophia, under the title of George the First. The new sovereign lost no time in coming over to Britain, and fixing himself in that heritage which his family has ever since retained. He was fifty-four years of age, of a good though not brilliant understanding, and very firm in his principles. Knowing very well that the Whigs were his only true friends, he at once called them into the administration: the Tories he treated with contempt, if not absolute rudeness, being of opinion that it is needless to seek to conciliate enemies. The former party continued in power during the whole of this and the subsequent reign.

REBELLION OF 1715.

During the first year of George the First, the Tories kept up very threatening High Church riots; but the Whigs, gaining a majority in the new House of Commons, were able to check this a little by the celebrated enactment called the Riot Act, which permits military force to be used in dispersing a crowd, after a certain space of time has been allowed. Being completely disappointed in their hopes of office and power, and treated with unnecessary insult by the King, the party resolved to attempt bringing in the Pretender by force of arms. For this end their means were totally inadequate; but it is the characteristic of this party, that they always think their cause so very good in itself, that it cannot fail of success. They believed that all England and Scotland were ready to take arms for the Pretender, when in reality there was but a limited portion of the people so inclined, and that portion unwilling to move, if they saw the least risk. Blind to these circumstances, and without design or concert, they opened the unfortunate civil war of 1715. The Earl of Mar, a member of the late administration, raised his standard at Castleton, in Braemar, without any commission from the Pretender, and was soon joined by Highland clans to the amount of ten thousand men, who rendered him master of all Scotland north of the Forth. There, however, he weakly permitted himself to be cooped up by the Duke of Argyle, who, with a far less numerous force, had posted himself at Stirling. Mar expected a co-operative invasion of England by the Duke of Ormond, and a rise of the people of that country. But the duke completely failed in his design, and no rise took place, except in Northumberland. There Mr Forster, M.P., and the Earl of Derwentwater, with some other noblemen, appeared in arms, but unsupported by any considerable portion of the people. Mar detached a party of eighteen hundred foot, under MacIntosh of Borlum, to join the Northumbrian insurgents, who complained that they had no infantry. The junction was managed with great address, and at the same time some noblemen and gentlemen of the south of Scotland attached themselves to the southern army. The government was singularly ill provided with troops; but it nevertheless sent such a force against Mr Forster as obliged him to retire with his men into the town of Preston, in Lancashire, where, after an obstinate defence, the whole party (November 13) surrendered themselves prisoners at the King's mercy. On the same day, the Earl of Mar met the Duke of Argyle at Sherriffmuir, near Dunblane, where a battle was fought, in which, after the manner of the battles in the civil war, the right wing of each army was successful, but neither altogether victorious. The duke withdrew in the face of his enemy to Stirling, and the earl retired to Perth, resolved to wait for the news of an invasion from France, and for the arrival of the Pretender, whom he had invited to Scotland. He did not for some time become aware of the hopelessness of the former object. Louis the Fourteenth, upon whom the hopes of the party greatly rested, had died in September, leaving the government to the Regent Orleans, who had strong personal reasons for wishing to cultivate the good-will of the British monarch, and of course declined to assist in the present enterprise. The Pretender, nevertheless, sailed for Scotland, and on the 22d of December, arrived incognito at Peterhead, bringing nothing but his own person to aid his adherents. The Earl of Mar, who had already attempted to negociate a submission to the government, brought him forward to Perth, where he was amused for some time with preparations for his coronation. But before he had been many days there, the Duke of Argyle found himself in a condition to advance against the insurgent force; and on the 30th of January 1716, this unfortunate prince commenced a retreat to the north, along with his dispirited army. On the 4th of February, he and the Earl of Mar provided for their own safety by going on board a vessel at Montrose, and setting sail for France: the army dispersed itself into the Highlands. For this unhappy appearance in arms, the Earl of Derwentwater, Viscount Kenmure, and about twenty inferior persons, were executed; forty Scottish families of the first rank lost their estates, and many excellent members of society were exiled for ever.

ADMINISTRATION OF WALPOLE.

The Whig government of George the First derived great additional power and stability from the suppression of this insurrection, and, to secure itself against the inconvenience of consulting the people too often, soon after carried a bill for extending the duration of Parliaments to seven years—a blow against liberty which the Tories in vain endeavoured to ward off. In 1720, the financial schemes of Law, the comptroller-general of France, inspired the British public with similar visionary projects, one of which, entitled the South Sea Company, ended by producing a wide-spread scene of ruin. Peace was slightly disturbed about this time by an attempt of Spain to regain her Italian territories, which was, however, speedily suppressed, and by some schemes of the Jacobites, or friends of the Pretender, which were still more promptly defeated. During the twenty ensuing years, the country was managed chiefly by Sir Robert Walpole, without the occurrence of any event of importance, except the death of George the First, and the accession of George the Second, in 1727. This minister has the merit of having preserved peace during that long period, but will ever be infamous for the system of corruption by which he maintained his ascendancy in the House of Commons. His grand principle was, that every man had his price, and, when that was ascertained, that there remained no difficulty but to raise the necessary sum, or confer the requisite favour. He acted so regularly upon this principle, and with so little decency, that the British Parliament became a mere mockery of a representative or deliberative body. Not that there was wanting a minority who, calling themselves patriots, declaimed loudly against the base practices of the ministry, and affected to stand up for the country. Sir Robert, however, looked upon these persons—and he perhaps was not far wrong—as only individuals whose price he had not been able to compass, or had not thought it worth while to disburse.

WAR WITH SPAIN, 1739.

After twenty years of peace, Walpole was urged, much against his will, into a contest with Spain, on account of some efforts made by that country to check an illicit trade carried on by British merchants in its American colonies. In searching vessels for the prevention of this traffic, the Spaniards had made some trifling aggressions; and British spirit took fire at the indignity of being liable to a search by any power on earth, even for the prevention of a notorious breach of treaty. The community therefore demanded a war, and the minister, with great reluctance, was obliged to comply. One fleet, under Admiral Haddock, was sent to cruise off the coast of Spain, and another, under Admiral Vernon, was sent against the American colonies. The latter gained lustre by taking the important town of Portobello. Another and larger expedition, with ten thousand soldiers, was then sent to reinforce Vernon; but, owing to disputes between him and the commander of the troops, no further triumphs were gained. A timid, ill-concerted, and ill-conducted attack upon the fortifications of Carthagena, lost Britain about twenty thousand men. Meantime, a third fleet, under Anson, sailed to the eastern coast of Spanish America, in order to co-operate with Vernon; but only one of the vessels reached its destination. Anson, thus reduced in naval force, took several prizes off Chili, and plundered the town of Paita, but could venture upon no more hazardous enterprise. He cruised across the Pacific, in the hope of meeting one of the Spanish galleons, which usually contained great quantities of bullion; but did not succeed, till, on his return from refitting at Canton, he took the Manilla transport, with treasure to the amount of three hundred thousand pounds. Though he had failed in all the proper objects of the expedition, the money he brought to the public treasury caused him to be very well received by the people; while the flagrant mismanagement at Carthagena was the subject of general execration.

WAR WITH FRANCE.

The Spanish war now languished for some time, while the attention of Britain was attracted to the proceedings of France. After the death of the Emperor Charles the Sixth of Germany, his dominions fell by inheritance to his daughter, the celebrated Maria Theresa, Queen of Hungary. She was opposed, however, in this succession by the sovereigns of France, Saxony, and Bavaria, who all pretended to have some claims on her dominions. A war was commenced against her; the Elector of Bavaria was crowned Emperor; and such was the success of the French arms, that she was soon reduced to the greatest distress. With this quarrel Britain had no shadow of excuse for interfering; but the King thought his dominions in Germany endangered, and the people had all their usual taste for fighting with the French. War was therefore entered into, Walpole sinking conscientiously beneath the prejudices of his two masters. The phenomenon was then observed of Great Britain paying an army of 16,000 Hanoverians, besides many of her own native troops, to fight the battles of that people. During the progress of the contest, an unusual bitterness animated the opposing parties in the House of Commons. The Ministry had been recruited by the most popular men of the late minority—among whom the most conspicuous were Lord Carteret and the Earl of Bath. It was of course expected that these men would lose no time, after they were in power, to effect some of those improvements in the constitution which they had formerly clamoured for. Indeed, nothing less than a total renovation of the constitution was expected. A number of motions to this purport were accordingly made in both Houses of Parliament; but, to the astonishment of the nation, they were all violently opposed and quashed, by the very men who had lately maintained the principles on which they were founded, and whose former speeches had suggested many of them. The most important of these motions were the following three:—One for appointing a committee to "inquire into the conduct of affairs during the last twenty years;" one for bringing in a bill to "repeal the act for septennial Parliaments;" and one "for excluding pensioners from the House of Lords." Though German subsidies, standing armies, and continental connections, had been the constant objects of the indignation of these men while out of place, and had furnished them with the occasion of some of the finest strokes of their popular eloquence, they extended their complaisance to the King in all these particulars, much farther than their execrated predecessors. Besides providing for subsidies to Denmark and Hesse-Cassel, they procured a vote of half a million to the Queen of Hungary; they augmented the land forces to 62,500; they transported to the Low Countries 16,000 British troops under the Earl of Stair, to make a diversion in favour of Maria Theresa; and they ordered these troops to be joined by 6000 Hessians, and the above-mentioned 16,000 Hanoverians in British pay. The community of the present day, whatever they may occasionally think of those at the head of affairs, have certainly reason to congratulate themselves on the great increase of both moral and political principle which has taken place in that exalted class of men since the days of the Walpoles and the Baths.

BATTLE OF DETTINGEN.

About the time when Great Britain entered into this struggle, the affairs of the Hungarian queen took a surprising turn, and her armies, under her husband the Grand Duke of Tuscany, Prince Charles of Lorraine, and other eminent commanders, began to drive all her enemies forth from her dominions. France, having lost 100,000 men in the contest, sued for peace; but this the queen haughtily refused, in the hope of gaining still greater triumphs by means of Britain. The aid of that power, as it turned out, was of little service to the queen. The Earl of Stair had permitted his army to get into a position of great difficulty at Aschaffenburg, on the Upper Maine, and, but for a blunder of the French, it would probably have been starved into a surrender, along with the King and prime minister (Carteret), both of whom had recently joined it. The blunder consisted in an attack made by the Duke of Grammont, with 30,000 troops, upon the British and Hanoverian infantry, upon a plain near the village of Dettingen. The infantry, cheered by the presence of the King, who rode between the lines with his sword drawn, received the charge of the French cavalry with great firmness, and compelled them to retreat—a movement which communicated a panic to the whole French army, and might have been attended with the most disastrous consequences, if the British monarch would have permitted his advantage to be followed up.

BATTLE OF FONTENOY.

The death of the Emperor Charles the Seventh, for whom this great European contest appeared to have taken its rise, might have now given an opportunity for the cessation of hostilities; but the French thought the war still necessary, in order to prevent the husband of Maria Theresa from being elected emperor, and the British were still animated by their usual antipathy to that people. A campaign was therefore opened in Flanders, the troops of the former nation being commanded by Count Saxe, distinguished for military genius and experience; while the British and Hanoverian army was under the charge of the young Duke of Cumberland, second son to the King. To animate the French troops, the King (Louis the Fifteenth) and the Dauphin attended the camp. The French having invested Tournay, it was resolved by the English to hazard a battle, in order to save that strong city. The rencounter took place (May 1745) at Fontenoy, near the bridge of Colome. The British infantry advanced under Cumberland, and, notwithstanding a tremendous fire, which swept them off in whole ranks, attacked the centre of the position of the French army, which they beat back in so furious a style, that Saxe advised the King to retire for the safety of his person. Louis bravely refused to stir, being apprehensive that a retrograde motion on his part would decide the day against his army. Ashamed to desert their sovereign, the French returned to the charge; the cavalry renewed their efforts; and other circumstances conspired to give a turn to the battle. The British cavalry were prevented by a mistake from giving their support to the infantry; and the Dutch and Austrian part of the army was found totally ineffective. Assailed on all sides, fatigued with their great exertions, and galled by the French batteries, the infantry was obliged to retire, with a loss of seven thousand men, after having beaten every regiment in the French army. The Duke of Cumberland, though able to withdraw in good order, did not venture after this disaster to face the enemy during the whole campaign. Nevertheless, the Queen of Hungary at this time gained the summit of her wishes by the election of her husband to the imperial throne.

REBELLION OF 1745.

The misfortunes of the British arms on the Continent, and the distractions which prevailed among the people and the Parliament, encouraged Prince Charles Stuart, eldest son of the Pretender, to make an attempt at this time to recover the throne of his ancestors. In the previous year, he had been furnished by France with a large fleet and ample stores to invade the British dominions, but had been driven back by a storm, and prevented from again setting sail by a superior fleet under Sir John Norris. The object of France in this enterprise was to produce a diversion in favour of her own army in the Netherlands; at present, in consequence of their victory at Fontenoy, such a division was not necessary; but though the French monarch would not grant him any farther supply, Charles nevertheless resolved to make the proposed attempt, trusting solely to the generosity and valour of his friends in Great Britain. He therefore landed from a single vessel, with only seven attendants, on the coast of Inverness-shire, where the clans most attached to his family chiefly resided. By merely working upon the ardent feelings of the Highland chiefs, he soon induced several of them to take up arms, among whom were Lochiel, Clanranald, Glengary, and Keppoch. On the 19th of August, he raised his standard at Glenfinnin, within a few miles of the government fort entitled Fort William, and found himself surrounded by about fifteen hundred men. The government was at first inclined to disbelieve the intelligence of these proceedings, but was soon obliged to take steps for its own defence. A reward of thirty thousand pounds was offered for the head of the young prince, whose family, it ought to be stated, was under attainder by act of Parliament; and Sir John Cope, commander of the forces in Scotland, was ordered to advance with what troops he had, into the Highlands, and suppress the insurrection at once. Cope proceeded on this mission with about fourteen hundred infantry, but on finding the Highlanders in possession of a strong post near Fort Augustus, thought it necessary to go aside to Inverness. Charles, taking advantage of this ill-judged movement, immediately poured his clans down into the Lowlands, gaining accessions every where as he advanced, and, there being no adequate force to oppose him, took possession successively of Perth, Dundee, and Edinburgh.

At the latter city Charles took up his residence in Holyroodhouse, and caused his father to be solemnly proclaimed King, and himself Prince Regent, of the British dominions. He was here joined by a thousand fresh troops from the Highlands, but found it impossible to raise any recruits in the city. Having learned that Cope had transported his troops into the Lowlands by sea, and was advancing through East Lothian to meet him, he marched his army to Tranent (September 20), and there came in sight of the English troops, which had taken up a position on the field to the east of Preston. The two armies amounted each to about 2000 men; but Cope had the advantage of dragoons and artillery. The prince lay all night on a peas-field in the midst of his Highlanders, and, before daylight next morning, led his forces by stealth into the plain on which the royal troops were reposing, where he formed them in two lines, the best armed clans occupying the front. A rapid advance was then made against the English army, which had hardly time to arrange itself, when the Highlanders, after a discharge of fire-arms, rushed upon them sword in hand. The uncertain light, the suddenness of the attack, and the ignorance of the troops as to the mode of warfare pursued by Highlanders, all tended to inspire a panic in the assailed party. The two regiments of dragoons instantly fled, leaving the foot comparatively defenceless. The artillery was also but once discharged, when the Camerons overpowered those who had the charge of it. Some companies of infantry alone stood firm, under the direction of Colonel Gardiner, but in a few minutes the whole were cut down or swept off the field, and there was only a confused flight, in which the broadswords of the clans were used with unsparing vigour. Nearly the whole infantry, fourteen hundred in number, were either killed or taken prisoners, and the military chest and other stores of the army became a prize to the victors. Charles returned next day to Edinburgh in triumph, and the fruits of his success were soon seen in the large accessions of force which he received, including the Earls of Kelly and Kilmarnock, Lords Elcho, Pitsligo, Ogilvie, Balmerino, and other noble and distinguished persons.

Such was the defenceless condition of England at this juncture, and such the consternation inspired by the defeat of Cope, that, if Charles could have led four or five thousand men into that country, he could hardly have been prevented from taking possession of the capital. He was detained six weeks, however, before he could collect forces to that amount, and in the meantime troops more numerous in proportion were brought over from Flanders to oppose his progress. He commenced his march, November 1, and entered England at the western border. Carlisle, after holding out three days, surrendered to him. He pressed on through Westmoreland, disregarding a small army under General Wade at Newcastle, and, November 29, entered Manchester. He expected that before this time the English Jacobites would have been flocking to his standard; but they still waited to see the risk of such a movement somewhat reduced. Two hundred recruits, whom he raised at Manchester, and placed under the command of a Catholic gentleman named Townly, was all the addition he could gain to his army in England. To oppose his march, an army of ten thousand men was now rendezvoused in Staffordshire, under the Duke of Cumberland. Nevertheless, he still pushed on, hoping that Wales would produce some considerable reinforcements. By a dexterous movement, he eluded Cumberland's army, and, December 4, reached Derby, where he was only a hundred miles from the metropolis.

No. 20. PRICE 1½d.

THE BRITISH EMPIRE, AND ITS RESOURCES.

THE power, commerce, and wealth of Great Britain, so far surpass all that has been witnessed in former times in the world, that they have become an object of wonder to every thinking person, both in this and other countries. It is naturally asked, What can have elevated so small an island to power and influence so unexampled? What can have given to a people of only twenty millions in number, wealth and resources surpassing those of the most populous nations on the face of the globe? The phenomenon of British greatness having excited so much curiosity, both among the learned and unlearned, it is the purpose of the following sheet briefly to unfold its origin, and to exhibit its great and almost incredible extent.

The first cause undoubtedly of the internal prosperity of Britain, has been her insular situation, which placed her aloof from many of the wars which devastated the Continent. Every invader was there a destroyer also, and aimed not so much to possess the country, as to crush its rising manufactures and institutions: while, in the civil wars of England, the different candidates for the crown sought rather to conciliate the people, and to preserve from devastation what they hoped to inherit: hence, whatever manufacture was once established in England, took root there firmly, and had little hazard of being eradicated. Another principal cause of British prosperity, has been the happy form of her government. From a very early period, the commons of England had a voice with the great barons in the enactment of the laws, and in the granting of taxes. They had it, therefore, in their power to do the king considerable service or disservice in the matter of supplies; and it became his interest to conciliate them, by granting such privileges as assured them in the quiet prosecution of their crafts, and in the possession of their property. Another of the moving causes of the prosperity of Britain, was the early revolution in the state religion, by which the people were brought into the enjoyment of an extraordinary degree of liberty of opinion or conscience, before they were put in possession of the civil rights which they have latterly enjoyed. In other countries, where the political revolutions have *preceded* that of religion, every thing has gone wrong—their social system has been rendered defective, and will not work. This bad management of surrounding nations has been an additional cause of the prosperity of this country of freedom. These are some of the causes which first sowed the seeds of British prosperity; but one of the most remarkable sources of her wealth, it must never be forgotten, lies in the unexampled industry of her people. Habits of activity and enterprise are common to most islanders, and are generated in them by the natural necessities of their situation; but in no other case have these been quickened and directed by that quenchless thirst for improvement, whose results have raised these countries to such a pitch of eminence. The industry of the British nation, from the wealthiest merchant to the meanest tradesman, is unceasing and unwearied; their very hours of leisure are generally employed in some useful pursuit. The country weaver, who is eleven hours every day at his loom, finds yet another hour to hoe his potatoes, to attend to his pig or tame rabbits, or to cultivate his garden; and we have seen several who employed their spare moments in constructing optical instruments, or toys in bone and ivory. Thousands of those ingenious inventions in the mechanical arts, which have contributed so much to facilitate the working of machines, and the saving of labour, have been contrived in the leisure hours of industrious workmen. Even apprentices struggle to have some spare time, that they may devote it to reading and acquiring knowledge, or to some pursuit which has become a favourite with them. We do not assert that all are so occupied; but we say that a habit of unceasing industry is the general character of the people; and that it is this national trait, operating in all the concerns of life, which renders the British so wealthy at home, and so powerful abroad. Such industry could not indeed exist, except under a government which assured to every one the possession of the fruits of his own exertions; and it has been the fortunate chance of the British islands to possess institutions which fulfil that inestimable condition to its greatest extent.

FORM OF THE BRITISH GOVERNMENT.

Every regular government may be divided into two parts: one which frames the laws of the country, and which is called the *Legislative*; and another, called *Executive*, which is charged with the duty of seeing the laws obeyed, and of preserving the public peace against foreign or internal enemies. In Britain, the legislative part of the government is composed of two deliberating bodies, with the king at their head, without whose sanction none of their resolutions are valid. The one of these bodies is called the *House of Lords*, the other the *House of Commons*. The persons who compose the House of Lords form a separate class or rank in the nation, which is called collectively the Peerage, and whose members enjoy certain exclusive privileges and honours in virtue of their birthright, which will be explained afterwards: this body consists at present of about 430 members, but may be enlarged at pleasure by the king, a power which is in general very sparingly used. The other legislative body is called the *House of Commons*, and is composed of members who are chosen for that purpose by certain classes of the people; the privileged electors in each district appointing one, and in some populous places two: the whole number is 658. These two houses, with the king, have the power to pass laws, impose taxes, borrow money, make inquiries into the management of the public revenues, or the transactions of the great officers of government, and even to bring the latter to trial, if necessary. They inquire into the manner in which all great public institutions or boards of management are conducted, such as those for education, for purposes of charity, for the erection of lighthouses on the coast, for the construction of harbours, and generally, indeed, into all the business which is entrusted to the executive part of the government; they cannot direct what is to be done, but may always make scrutiny into it afterwards, if any error or mismanagement has taken place. The discussions on these subjects are often very warm and eager, and bring to light facts of great public importance. No act of the two deliberative bodies becomes valid as a law, without the assent of the king; and all propositions relating to money to be raised for the public service, must originate with the House of Commons, the lords merely giving their assent as a matter of form, without being allowed to alter any thing. This circumstance gives a much larger share of influence to the commons than is possessed by the lords; the former having it in their power, whenever they are dissatisfied with the measures of government, to stop the supplies of money, and bring the whole machinery to a stand. Parliament generally sits in London for the dispatch of public business, six or seven months each year, and is summoned together or prorogued for that purpose by the king: the members of the House of Commons must be elected anew at least once every seven years, though in fact the re-election takes place generally every fourth or fifth year, the king having it in his power to dissolve one parliament and call another at his pleasure. The parliament is always dissolved on the death of the king.

Each of the two houses has one presiding member, whose duty it is to preserve order, and see that the regulations of the assembly be attended to by the members; he is also the person through whom any communication passes between the house and the king, he alone having the privilege of addressing his majesty in name of the house. Hence, in the House of Commons this officer is called the *Speaker*; in the House of Lords he is commonly known as the *Lord Chancellor*, from another office which he holds; but the duties of the latter are quite the same as those of the Speaker of the commons. There are numerous forms established for the regularity of business in parliament, but of these there are only a few which need be mentioned here. Any proposal which is laid before either of the houses, in order to pass into a law, must be made out by its promoter *in the form* of an act of parliament, but is only known by the name of a *bill* while under discussion: permission must first be obtained to introduce the bill, and it must then be read and considered by the house three several times, besides being once scrutinised more closely by a committee or select number of the members, and, if a public bill, by the whole house sitting as a committee, where each member is permitted to speak as frequently as he sees occasion, whereas in the regular sittings of the house no one is allowed to speak more than once, except to explain where his first statements have been misunderstood. If it is not rejected in any of these three readings, or given up in the committee, the bill is said to have passed. It must then go through the same process in the other house, where it is sometimes adopted, sometimes rejected; but if any alterations are made in it here, they must be reported to the house where it first originated. If the two cannot agree on the changes proposed, the bill falls to the ground; but some modification is generally contrived which satisfies both parties. It still remains to obtain the sanction of the king, which is hardly ever refused, when the *bill* becomes an *act of parliament* or *law*.

The members of both houses have certain personal privileges, which are deemed necessary for enabling them properly to attend to their public duties. In Parliament, they enjoy absolute freedom of speech, and cannot be questioned out of the house for any thing said in the debates; they and their servants are exempted from arrest (except in criminal cases) during their attendance in Parliament; and they can receive and send a certain number of letters daily through the post-office, without payment.

The Executive.—The king, who forms the chief of the legislative body, is also the head of the executive part of the government. In this capacity he is charged with the duty of seeing the laws enforced which Parliament has enacted, of levying taxes granted for the public service, of protecting the internal peace of the country against crime and violence, and of defending it against foreign enemies. He also conducts all intercourse with the rulers of other nations, forming treaties and alliances, declaring war or concluding peace. He has the duty of protecting the persons and trade of British subjects in foreign countries. For this purpose, he has the sole appointment of the officers who perform these duties; of judges in the several courts of law; of officers in the army and navy; of public ambassadors, and of consuls at foreign ports for the safety of trade; and of the officers who levy the taxes. He has also large forces, both naval and military, at his disposal, which are stationed in different parts of the empire where he or his advisers think that they are wanted for the time. The task of managing all these extensive concerns, which would fall into confusion in the hands of one man, is deputed by the king to a number of persons, who are denominated his *Ministers*, and sometimes the *Cabinet*. These are nominally selected and appointed by the king himself; but as his choice would be in vain if it were to fall on men who were disagreeable to Parliament (which might in that case refuse to grant money for carrying on the public business), the ministry is generally chosen from among such men as enjoy the confidence of the public. They have all some high public office. The chief is the *First Lord of the Treasury*, whose nominal duty is the receiving and issuing of the public money, while his actual station is that of leader of the administration; he is the first who is appointed in any ministry, and generally selects all the other members, according to his own views of their abilities, or of the influence they possess in the country or in Parliament; and any changes afterwards made are generally at his suggestion, or at least with his full assent. Next is the *Lord High Chancellor*, who presides in the highest law-court of the kingdom, and is Speaker of the House of Lords; he is chief adviser of the king in all that relates to the laws of the country, and has the disposal of a great number of clerical and law offices. After him are the principal secretaries of state, who are five in number, each having a separate charge; the first is Secretary for the Home Department, after whom are the Secretaries for Foreign Affairs and for the Colonies, the Secretary at War, and the Secretary for Ireland. These, with the *Chancellor of the Exchequer*, and several others of the high officers of state, form what is called the *Ministry*, the *Cabinet*, or the *Cabinet Council*; and all the measures of the executive government are settled by their deliberations.

This regular division of labour which is established in the British government, is one of its chief excellencies; because every secretary, or other officer of state, having a particular department assigned to him, the responsibility for any error or mismanagement is established at once, and may be either rectified or punished. Parliament itself has its own duties; and when these are not performed to the satisfaction of the electors, the members can be dismissed at next election, to make way for others who deserve better. The British constitution has also the invaluable property of admitting gradual amendments without violence to the general system; and by this principle it has accommodated itself, without any convulsion, to the changes and improvements which for many generations have been going on in society. The late reform bill is an instance of this, and others (though not all to the same extent) have occurred in every age within the reach of history.

REVENUE AND EXPENDITURE.

The revenue of the British empire has varied exceedingly of late years; from 1761 to 1774, which was a period of peace, it increased from L.6,800,000 to L.10,265,673; and since that time, from the various wars in which the country was engaged, the immediate expenses, and the interest of public debts, it has continued to augment till within these last ten or twelve years. From 1775 to 1783, which was the period of the American war, it rose from ten millions to twelve millions, and during the peace which followed till 1793, it was increased to seventeen and a half millions, a-year.

After this period the French revolutionary war commenced. That war was by no means unpopular with the nation; and it was besides gilded by the many splendid victories which continued to be obtained by British seamen as long as the enemy had a fleet to appear at sea. Heavy taxes for defraying the expenses of this war were therefore submitted to without remonstrance, and the public revenue rose accordingly to a very large amount. From 1794 to the peace of Amiens in 1801, which only lasted two years, the revenue was increased from seventeen and a half millions to twenty-eight millions; and from 1803 till 1816, the year after the final conclusion of peace, it had risen to L.76,834,494, which was the largest sum raised by taxes in one year. After this it was gradually reduced, till it now amounts to about L.46,000,000 (1833).

The sums thus raised in taxes, large as they were, did not, however, meet the expenditure of the country during these periods of war. In order to defray the great charges which arose, it became necessary also to borrow to a great amount. The following table will show the sums raised by the taxes, the sums borrowed, and the total expenditure for each of the years specified.

Year.	Raised in Taxes.	Borrowed.	Total Expenditure.
1794	L.17,674.395	L.5,079,971	L.22,754,366
1801	28,085,829	33,532,159	61,617,988
1803	38,401,738	23,072,742	62,373,480
1806	53,898,124	22.358,672	78,056,790
1810	66,029,349	22,763,202	88,792,551
1814	70,926,215	52,309,445	122,235,660
1816	76,834,494	54,471,464	130,305,958

These sums will appear altogether enormous, and must give the most extraordinary idea of the resources of a government, which, while it raised such a large yearly amount in taxes, had yet credit to borrow the immense additional sums which were wanted. This happened too, it must be recollected, at the most critical periods of a war, wherein it was continually asserted that the independence, nay, the very existence of the nation, was at stake.* It may be easily believed that when shrewd capitalists were willing to advance such sums on the credit of the revenues and public faith of the country, there was little real danger in the case; these men saw that the boundless resources of Britain were sufficient to carry her through the contest in which she was engaged, and scrupled not to lend her government treasures which were greater than the revenues of any empire in the world, and which will be the astonishment of all history. The whole sum which was expended in the wars of the revolution, from 1794 to 1816, amounted to 1700 millions of pounds sterling, a sum so far beyond all ordinary dealings, that we can have little conception of its amount or value. All the mines that are at present wrought in Europe and America would not furnish gold and silver equal to it in less than 310 years.

Expenditure of 1831 and 1832.—Having noticed the expenditure during war, we shall now give an account of that of the present period of peace. The whole charges of government amounted in 1831 to about fifty millions; which are distributed in the following manner:—

1. *Interest and charges on money borrowed in the time of war.*—This amounts to twenty-eight millions yearly, and forms a permanent charge, which cannot be reduced except by paying off the debt itself. A small part of it, which was borrowed by annuities on lives, is terminable.

2. *The Dead Weight.*—This is a phrase employed to denote the money paid by government to persons who are not at present rendering any service in return. It includes the pensions granted to aged or disabled soldiers and officers; the half-pay of officers whose services are not required, but who, by the regulations, cannot be discharged; pensions to widows of officers; and, lastly, allowances to retired ambassadors, law-officers, to the members of the royal family, and to various others. This portion of the public expenditure amounts to about six millions, and is, like the former, nearly a permanent charge from year to year; its decrease depending only on the death of the pensioners. The total pensions, allowances, half-pay, &c., to persons connected with the army, is three millions; of which the pensions to disabled and aged soldiers form L.1,434,502. The total to the navy is L.1,290,381; of which the pensions to private sailors form L.250,000. Another class, comprising the royal family (not the king), retired ambassadors, &c., receive L.648,782; of which the royal family have one-third part. And the fourth class, called the *civil dead weight*, consists of persons who have been employed in the public offices, such as the Treasury, Post Office, Exchequer, &c., and who are now supposed to be unfitted for their duties. The amount is L.962,370.

3. *Charges for Effective Service.*—The sums yet mentioned do nothing towards carrying on the government of the country, paying its armies, fleets, magistrates, courts of law, &c. After defraying the interest of the debt, and the dead weight, there remains out of the whole fifty millions, about sixteen millions for these purposes. This is distributed as follows:—

Charge for collecting the revenue .	L.3,401,345
Management of the debt and finance .	417,401
Expenses of the army . .	5,123,166
——— navy . . .	3.295,251
Executive, legislation, law, and justice	1,192,477
Expenses of the colonies . . .	220,375
Expenses of ambassadors and consuls in foreign countries . . .	264,616
Civil government and miscellanies .	891,710
Public works	490,750
Trade and manufactures (bounties, quarantine, expenses, &c.)	273,580
Expenses of the royal establishment and household	435,000

Some farther particulars on the principal of these items is given in another page.

TAXATION.

The taxes are raised upon a great variety of different articles, which are all, however, reduced to the following heads.

1. *The Customs.*—These are taxes levied upon the foreign commerce of the country, being the duties paid upon articles imported from abroad, such as sugar, coffee, &c. They include also a few on some goods exported, such as coals, wool, and skins. Their whole amount is L.17,940,264; of this sum about three millions arises from duties on foreign spirits, brandy, gin, &c.; four and a half millions from wines; three millions from tobacco and snuff; from corn and grain of all kinds imported, L.614,138; from foreign fruits, such as currants, raisins, oranges, &c., L.646,000; from sugar, four and a half millions; from timber, one million and a quarter; from coffee, half a million; besides smaller sums from a vast variety of other articles.

2. *The Excise.*—The excise taxes are those which are levied on goods of British manufacture, such as glass, malt, paper, &c. The duty is paid back again to the maker, if the commodity is to be exported to foreign countries. This class of taxes yields altogether L.17,339,614. The principal articles are malt, which yields about four and a half millions; home-made spirits, yielding five millions; tea (which is reckoned here, though a foreign product) about three millions and one-third. Glass yields half a million; paper, two-thirds; soap (now lowered) gave above a million.

3. *Stamp Duties.*—These consist of the prices affixed to stamped papers, upon which the law makes it imperative that every document for the transfer of property, or other obligation, shall be written; deeds, settlements, and bills; bills of exchange, receipts (above a certain small amount), and a great variety of other instruments of business, are required to be stamped in this manner; and the prices affixed to the stamps, which are often high, bring a large revenue. Under the head of stamps, are also included indentures, cards and dice, duties on plate, and other anomalous items. The whole amount is L.7,070,773. The principal sources are from deeds, probates of wills, legacies, &c., three millions and a half; from bills, receipts, stamps on bankers' notes, and other commercial instruments, L.885,840; marine and fire insurances, one million; newspapers, almanacks, pamphlets, and advertisements, L.665,151; stage-coaches and post-horses, L.654,342; gold and silver plate, L.74,216; quack medicines, L.38,618.

4. *The Taxes.*—What are technically called "the taxes," are those duties which are levied on land and houses, on windows, servants, riding-horses, dogs, &c.—all of which, except the *land-tax*, are called also *the assessed taxes*. The amount of this class is L.5,217,741; the produce of the land-tax by itself is a little above one million; the house tax and window tax produce together two and a half millions; riding-horses and carriages give L.649,301; game duties, L.125,431; and dogs, L.161,002.

5. *Post Office.*—There is a considerable revenue derived from the Post Office, after paying all the expenses of the establishment; and from the great convenience and regularity of the system, which is kept working at all hours from one end of the country to the other, the additional charge is not much felt or grudged. The amount is L.2,227,354.

6. The income derived from rentals of *crown property*, and the sale of timber, bark, &c., from the crown lands (with other incidents), yield a yearly revenue of L.373,769.

7. There are some small *miscellaneous branches* of revenue, which amount to L.159,530. Of this sum the duty on hackney coaches gives L.35,695; that on hawkers and pedlars, L.35,207; and those on offices, pensions, and personal estates, L.39,255.

8. Some *incidental revenues* are derived from matters connected with the regular taxes; such as duties collected at the Isle of Man, L.21,860; fines, and goods seized for taxes, L.24,654; these, with a number of other casual receipts, amounted, in 1832, to L.67,838.

The whole revenue derived from these sources in the above year was L.50,806,137; last year, as we have already stated, by a better management, only about forty-six millions were required.

This sum is still reckoned large; but, besides its amount, it is said that the same sum might be levied in a manner which would do much less injury to the various interests which pay it. Some of the taxes, particularly those on home manufactures, such as bricks, glass, soap, and paper, are said to prevent the extension of the manufactures on which they are levied, and by this means to keep a number of workmen out of employment. Others, such as those on olive oil, dye stuffs, drugs, timber, &c., prevent the cheap introduction of articles of prime necessity in different trades and manufactures, which are thereby much cramped, and prevented from increase. The high duty (L.8 per tun) on olive oil (which is as useful as tallow in making soap) renders us entirely dependent on the Russians for their tallow, and enables them to raise the price at pleasure. The corn and grain duties are also strongly objected to in their present shape; the duties on tobacco, foreign spirits, and silks, are at present so high, that large profits can be made by smuggling them; and there is a necessity for keeping up a large force along the coast in order to prevent this illegal traffic. The yearly cost of this service is L.644,352, most of which, it is believed, might be saved, were the duties on the articles we have mentioned lowered, so as to make smuggling unprofitable; while the increased consumption at the lower price, and the enlarged trade of the legal dealer, would prevent the revenue from suffering any thing. In answer to these objections to particular taxes, it is said that ministers are quite sensible of the bad effects of duties on such articles as glass, soap, paper, &c.; but that it is so difficult to find a new tax as a substitute (every class refusing to submit to any burden for the purpose of relieving others), that they cannot act as they would wish. As for the high duties on foreign spirits, tobacco, &c., which are the chief source of smuggling, we believe that measures are in contemplation to have the evil removed.

There is another objection stated to some of the taxes, which we cannot but notice. It is said that most of the articles on which duties are levied are of such a nature as to be more in demand by the poor and the middle classes than by the rich; so that the weight of taxation is made to fall chiefly on those who are least able to bear it. The following taxes are mentioned to show that this is the case:—On butter and cheese (imported); on hops, malt, soap, home-made spirits, and tobacco—these taxes are supposed to fall almost entirely on the poor, and amount to about fourteen millions. The next are a set of taxes which are reckoned to fall chiefly on the middle classes and people in business, such as those on licences and certificates, bills of exchange and receipts, insurances, stage-coaches, brandy, and gin—these amount to about four and a half millions. In short, by those who hold this doctrine, it is maintained, that, of the whole taxes, the rich pay only about seven

* It will be observed that in this paper we enter into no inquiry as to the policy or impolicy—the justice—or necessity, of these wars. Our only object is to show what the resources of the country have been able to effect.

millions, in which is included the land-tax.' There can be no doubt of the truth of this statement; it is obvious, indeed, on a bare inspection of the tables: but we must at the same time remark, that the inequality arises from no intention to oppress the poor man or favour the rich, but merely from the circumstance that taxes, to be really productive, must be laid on articles which are in very general use, such as malt, tobacco, spirits, sugar, coffee, &c. Now, these are consumed in much larger quantities by the mass of the working classes than they can by the few who are rich; and, therefore, the former are necessarily left to pay the larger part of the tax. Taxes imposed on commodities which are used only by the wealthy, produce hardly any thing if they are low; and when they are raised, the rich give over using the article. The duty on race horses, for instance, produces only L.1317; that on gold and silver plate brings L.74,218; on armorial bearings, L.54,889; but if the duties on these last were raised, fewer would use them, and the amount collected would not increase. The most odious taxes to the general community are those which are of a *direct* nature, such as the house and window duties; large sums being exacted by tax-collectors, without giving any apparent equivalent. These are felt additionally burdensome in towns where the local assessments are generally heavy.

We shall now mention the taxes levied upon a few of the principal articles of use or luxury.

British spirits, in England, per gallon	7s 0d
Do. in Ireland and Scotland	3s 4d
Brandy and gin	22s 6d
Rum	6s 0d
Sugar, from British West Indies, per lb.	0s 2¼d
Do. from foreign colonies (Brazil, &c.)	0s 6¼d
Coffee, from British West Indies	0s 6d
Do. from British East Indies	0s 9d
Tea—The duty is equal to the price on fine teas, and a small fraction less when the price is below 2s. (This is to be changed somewhat after April next year, when the East India Company charter ends.)	
Butter (imported)	0s 2d
Cheese (Do.)	0s 1d
Malt, per quarter	20s 0d
Tobacco, from British possessions in America, per lb.	2s 0d
Do. from any other country	3s 0d
Do. in segars, or otherwise manufactured	6s 0d
Starch	0s 3½d
Olive oil, per tun	169s 0d
Raisins, from L.2, 2s. 6d. to L.1, 2s. and L.1.	
Wines—Cape, 2s. 9d.; French, and all other foreign wines, of whatever quality, per gal.	5s 6d
Lemons and oranges three-fourths of their value.	
Seeds from foreign places—Carrot seeds, 9d. per lb.; clover and grass seeds, L.1 per cwt.; all forest and garden seeds not mentioned in the lists, 6d. per lb.; onion and leek, 1s. 6d. per lb. &c.	
Paper, per lb.	0s 3d
Glass—Plate, per cwt. L.3; crown, L.3, 13s. 6d.; broad, L.1, 10s.; green (for bottles, &c.) 8s. 2d.	
Cinnamon, cloves, mace, and nutmegs, from 2s. 6d. to 3s. 6d. per lb.	
Pepper of all kinds from British colonies	1s 0d

Wheat imported—The duty varies according to the prices in the home market, being low when British wheat is dear, and higher when it is cheap. When that is selling at 73s., the duty is 1s.; and when British wheat is on an average for six weeks at 62s., the duty on foreign wheat imported rises to 24s. 6d.; after which, for every shilling that the home article falls, the duty on the foreign is increased by the same sum.

THE ARMY AND NAVY.

The Army.—The efficiency of the British army has been demonstrated by so many splendid triumphs, that it does not here require an eulogy. The army doubtless owes its efficiency, in the first instance, to the firmness and energy of the national character. The same cause which gives rise to the industry of our people, is the origin also of the successful gallantry of our soldiers. The next cause is, that the British army was generally well served with all necessary stores; and that its higher officers, who were sent out on active service, were men trained and experienced in military operations.

The army at present consists of the following numbers and descriptions of force:—

	Horses.	Men.	Officers and non-commissioned officers.	Expense, pay, clothing, &c. £
Cavalry.				
Guards, 3 Regts.	822	1,053	258	87,129
Line, 21 Regts.	5,240	5,876	1,129	336,850
Infantry.				
Guards, 3 Regts.	-	5,104	613	194,074
Line, 91 Regts.	-	66,322	8,635	2,224,330
Total 118 Regts.	6,362	78,357	10,635	2,842,196

To the account of expense mentioned above, there is to be added about L.340,576 for recruiting, for medicines, chaplains, &c.; and there is also what is called the civil department of the army, or the army management, consisting of the salary of the Secretary at War and his office, the Commander-in-chief and his office, the medical departments, &c., which amount altogether to L.194,210. Reckoning the military actually on duty, the average yearly cost of each man (privates and officers together) is about L.36. There are nearly 10,000 officers in the British army, or one to every six men; this number is considered greatly too high, the French, with a well-disciplined army, having only one to each twenty-four men.

Besides the cavalry and foot regiments, there is another description of force called the ordnance, which includes artillery, engineers, miners, &c. They have the management of fortifications, with their guns, stores, &c.; the making of rockets, and different kinds of shot for great guns. The number of men is 7841, and the yearly expense of the force, with its equipments, L.010,779.

The distribution of the army may be stated as follows:—In Great Britain, 25,636; in Ireland, 20,415; in the colonies, 30,437.

The statements which we have made above relate entirely to the effective force of the army, which is either on active duty or ready to be so employed. But, as we have already remarked under the head of Expenditure, there is a great number of persons attached to the army, who do no duty, though receiving pay like others. Some of these are pensioners, who have either been long in service, or have suffered by wounds, &c., so that their allowances are not grudged; but there are also a number of young people who have purchased half-pay commissions, upon which they go on receiving pay; and some of them are even promoted to high rank in that condition, without ever having really been in the army at all. There has been also a large number of general officers created, who all receive the pay of their rank, though there are no duties for so many commanders. By the terms of the constitution, a permanent standing army is not held to be legal; the army is therefore maintained from year to year by the passing of what is called the Mutiny Act; and if this act of Parliament were not regularly passed, the whole of the standing army would be virtually disbanded. The army now acts almost entirely as a military police, and, as such, is chiefly required in Ireland, and in the vicinity of the large towns in England and Scotland.

THE NAVY.

If the army of Britain has been distinguished for its efficiency and the triumphs it has gained, her navy has added not less to the fame of the country. The series of victories, indeed, which were achieved by the fleets of Britain during the late war, were altogether unparalleled in history; nothing approaching them either in importance or splendour has been written in the annals of any other nation. In regard to the navy, the truth of the remark which we made concerning the effect of the national character on the composition of our military force, will be still more clearly seen; there is no one who doubts that the whole efficiency of our marine is owing to the excellent nursery afforded it by the merchant service: a *sailor* who has never been at sea but in a *man-of-war*, is hardly thought worthy of the name; it is only in merchant vessels that good mariners are trained. A law exists, by which men may be *pressed* into the service of the royal navy without their consent. This is a most unfortunate characteristic in the formation of our sea forces, and its continuance is held as disgraceful by the country at large, especially since good pay would form a sufficient temptation to enlistment.

We shall first mention the expenditure for the navy, and then the nature and distribution of the force. The *civil department* costs altogether L.138,504; this includes the salaries of the Lords of the Admiralty and their office, surveyors, store-keepers, draughtsmen, &c.; pay-office, naval college, and school for ship-building; royal observatory at Greenwich, &c.

The navy expenses, properly so called, may be stated as follows:—

Wages of 28,065 seamen and marines	L.923,175
Dock-yards for repairing and building ships	590,790
Materials, timber, sailcloth, cordage, &c.	457,297
Victualling Office—provisions, L.495,517; management, L.179,805	675,322
Miscellaneous	150,453

The average pay of a sailor is L.2, 7s. per month, with victuals, which are estimated at about L.1, 4s. additional. Much complaint is made of the high salaries paid to people about the dock-yards; the master-workmen receiving L.250 per annum, and the artificers from 5s. to 12s. 6d. per day. During the war, Great Britain had upwards of 1000 ships, manned by 184,000 seamen. The present number of vessels, and their description, will appear from the following table:—

	Number of Guns. 90-120	50-84	43-48	24-39	16-22
Ships in commission	3	19	18	19	42
Ships in ordinary	16	101	69	20	33
Ships building	9	15	30	3	10
Total (409)	28	137	117	42	85

This does not include the smaller vessels, sloops, yachts, bombs, &c., which amount to about 200 additional; making the whole 606 (1827).

The ships in ordinary are vessels which are dismantled, and put aside in a harbour, with only a few persons on board to take care of them. A ship in service, or even thus taken care of, will waste and rot, it is said, in fourteen or sixteen years; but a plan has lately been devised by which those not in service may be hauled up out of the water, and placed under a dry shed, which would make them stand much longer.

There are six marine arsenals or dock-yards—Deptford, Woolwich, Chatham, Sheerness, Portsmouth, Plymouth. The principal foreign stations for the navy are Gibraltar and Malta, in the Mediterranean; Halifax and Quebec, in North America; Jamaica and Antigua, in the West Indies; Trincomalee and Bombay, in the East.

MANUFACTURES.

The manufactures of Great Britain surpass in extent and variety those of any other country, and indeed of all other countries; they are sought for and exported to the most remote and unknown regions, as well as to the most refined and wealthy. Their principal branches are those of cotton, woollen, silk, linen, and hardware.

The Cotton Manufacture is the most extensive of the whole, both in respect to the capital which it occupies, and the number of people to whom it gives employment; it is supposed to form one-fourth part of the total industry of Britain. The number of work-people in its various departments (reckoning spinners, weavers, bleachers, &c.; engineers, smiths, and others engaged in the works) is estimated at 1,200,000; and their wages at five and a half millions. The capital invested in it at present is reckoned at about seventy-five millions; the total value of goods made is supposed to be above thirty-six millions; of which nearly one-half is consumed at home, the other half being exported to foreign countries.* The raw material, or cotton-wool, is brought chiefly from America, and a part also from the East Indies and Egypt. The chief seats of the manufacture are Manchester, Glasgow, and Paisley; and the magnificent apparatus of factories, machinery, warehouses, with which these cities are filled, for this sole business, are the astonishment of all visitors.

The reason why the cotton goods of Britain are so much more in demand than those of any other country, is chiefly the superior excellence of the machinery which her manufacturers have contrived and applied to this purpose; it is calculated that the various inventions now in use enable one man to do as much work as one hundred and fifty could have done when spinning and weaving by the hand were the only methods known. Even after deducting the cost of the machinery, the goods can therefore be sold greatly cheaper than formerly; and as no other nation has either such a variety of experienced workmen for the different kinds of machinery, or for the other departments of the business (such as printing, dyeing, &c.), none of them offer to compete with Britain. The whole of this manufacture has been created since 1760, at which time its produce did not amount to L.200,000.

The Woollen Manufacture.—This manufacture was the earliest established in England; it gives employment to above half a million of people, who receive on an average, men, women, and children, about L.15 per annum. The goods manufactured are valued at twenty millions; the finer qualities of the raw material are imported from Germany, or from our colonies of Australia; the coarser are produced at home: the value of the whole is estimated at six millions. The goods exported amount to about five millions and a quarter. This manufacture, particularly the finer kinds, is chiefly carried on in the north of England; some of the coarse fabrics, such as plaidings, duffles, &c., are made at Galashiels in Scotland; and Kilmarnock and Stirling drive a thriving trade in carpets, bonnets, &c. In the finest kind of broadcloths, the Prussians of Eupen are said to excel the English.

The Silk Manufacture has been carried on in this country for a long time, having been first introduced in the fifteenth century by emigrants from France. It was for many years confined chiefly to Spitalfields in London, and to Coventry. There were then prohibitory duties on all foreign silks, but this, instead of fostering the manufacture, as was intended, only encouraged its proprietors in indolence, as they knew that they had the home market to themselves. These prohibitions have been partly removed since 1824, and those regulations which confined the manufacture to some particular spots, are also done away with; so that the trade has been roused from its inactivity, and a great deal more business is done than formerly. The quantity of silk for working imported in 1823 (the year before removing the restrictions) was two and a half millions of lbs.; the average quantity of the same material imported since, has been three and a half millions. The consumption of silk goods at home has increased more than a half. The annual produce of the manufacture is now estimated at eight millions; and it is supposed to give employment to 700,000 work-people. Its chief seats are London, Coventry, and latterly Manchester, Paisley, and Glasgow, where some of the most beautiful fabrics are now made.

The Leather Manufacture is of considerable importance. The value of the different articles of which it is the material, is estimated at L.15,000,000: this includes gloves, saddlery, boots and shoes, &c. The increase of this trade in late years has been very great; *hides* are imported from all quarters of the world, and the quantity has doubled within a few years. The number of lamb and kid *skins* imported, in 1830, was about three millions.

Iron, Cutlery, and Hardware.—This is one of the manufactures in which Britain particularly excels. The abundance of her mines of iron, copper, tin, lead,

* In America, the whole produce of the cotton manufacture is less than six millions, or one-sixth of that of Britain; yet, either from want of skill, and consequent loss of time, or from the higher rate at which work-people are paid, the amount of wages is about two and a half millions, or nearly one half of those of Britain.

and coal, and the easy access which can be had to them at all points by sea, river, or canal, give facilities which are possessed by no other country. The annual value of the manufactured goods is estimated to be above L.17,000,000, and employment is given to 370,000 men in the working of copper, brass, pewter, steel, tin, and other metals. The declared value of the exports, in 1827, was L.1,387,204. The chief seat of the manufacture of the finer and more skilled articles, is Birmingham, Sheffield, and the immediate vicinity; and from these districts metal goods of all descriptions, implements of war, and the most elegant ornaments of peace, are dispatched to all parts of the world. For heavy cast-iron goods, cannon, parts of machinery, &c., Carron, in Scotland, has been long celebrated. The quantity of iron smelted from the ore in 1827, was 700,000 tons, from 284 furnaces, the greater number of which are in the west of England and in Wales.

The Earthenware, China, and Glass Manufactures, rank next to those we have mentioned. The number of people employed cannot be easily estimated; but as no money has to be sent abroad to purchase any part of the material of these works, the whole proceeds of the goods go to pay wages at home. The annual value of the glass manufactured is about two and a half millions, and that of the pottery and earthenware about three and a half.

The whole value of the manufactures of all kinds produced annually in Great Britain, is reckoned to be about a hundred and fifty millions of pounds sterling.

COMMERCE.

The commerce of Britain next demands our attention. The local situation of the British islands gives them many advantages for carrying on traffic with their own people in different districts, and also with the countries by which they are in some manner surrounded. Their abundance of minerals, tin, salt, coals, iron, gave them materials for trade in very early ages. As soon as the monarchies of Europe began to have intervals of peace after their feudal commotions, the British set about to avail themselves of their advantages, and to prosecute commerce in earnest. They gradually shook themselves free at home of many monopolies and restrictions which long continued to fetter the internal trade of other nations. Colonies were settled, which by degrees gave them civilised communities to purchase their goods, where formerly there had been only savages and a wilderness. These occurrences began to take place chiefly during the peaceful reign of James the First (1601–1624). At that time the exports of England amounted to two and a half millions; the number of seamen in merchant-ships to 10,000; but the good-will of the mercantile interest began now to be an important consideration with the government, from the taxes which it paid. The civil wars of 1642–50 did not interrupt its progress, both parties willingly conceding it their protection; and the naval successes of the republic over the Dutch, with the increased respect which these brought to the country among the other nations of Europe, greatly accelerated the rapid steps which it was now enabled to make. Jamaica, the possession of which was the origin of our West Indian connection, was first occupied by Cromwell, in 1655. Since the middle of the last century, the rapid progress of improvement in our manufactures has continued to afford new materials and goods for exportation, and the increase of trade has been in proportion.

The following table and explanations will give an idea of the trade of Britain with all parts of the world, in 1829:—

	Official value of imports.	Official value of exports, British and colonial.
Europe . .	L.14,525,883	L.34,057,078
Africa . .	1,189,106	1,357,750
Asia . . .	7,985,106	6,807,924
America & its islands	18,632,374	23,837,918
Total .	L.42,332,549	L.66,180,668

In the European trade, the imports from Russia, chiefly tallow, hemp, and timber, are about four millions; the exports to that country a little above three. To Germany, which sells a great deal of our manufactures to other countries (Poland, Hungary, Turkey, &c.) the exports are ten and one-fourth millions; the imports from thence only one and a half. Our trade with France is very inconsiderable, owing to the number of restrictions and high duties on both sides, which fetter commerce. Our imports are only two millions, and the exports not one million. Gibraltar takes nearly a million of British manufactures, which are principally smuggled into Spain, a country where all manner of difficulties and high duties are thrown in the way of trade. Italy takes about four millions in value of British goods; not sending one million of imports; one of her chief articles, olive oil, is almost prohibited by a high duty.

Of the trade to Asia, nearly eight millions of imports, and six and a half of exports, belong to the East Indies and China. The trade of our settlements in Australasia amounts to L.125,720 imports, and L.344,649 exports from Britain.

Of the American commerce, eight and a half millions imports, and six millions exports, belong to the British West Indies; nearly one million imports, and two exports, to the Canadian colonies. The United States have, of imports and exports, each about six millions. Buenos Ayres, about half a million imports, and one and a third million exports, chiefly manufactured goods. Brazil takes, of manufactured goods, four and a half millions.

Kinds of British Goods exported.—The following table will show what were the principal articles of British export in 1828. (The declared value is stated.)

Brass and copper manufacture .	L.678,786
Bacon and beef, butter and cheese .	712,017
Cotton manufactures . . .	17,244,417
Earthenware of all kinds . .	502,215
Herrings	157,532
Glass	500,356
Hardware and cutlery . .	1,387,204
Tin and tinware . . .	413,532
Iron and steel, wrought and unwrought	1,226,617
Linen manufactures . . .	2,000,000
Leather manufactures (saddlery, gloves, &c.)	275,976
Machinery and mill-work . . .	262,115
Silk manufactures	255,871
Woollen manufactures . . .	5,125,983

Description of articles imported.—The following quantities of foreign goods were imported and returned for home consumption in 1828, being some of the principal articles of foreign commerce:—

Coffee, lbs.	17,114,635
Corn—Wheat, quarters . .	805,849
Do. All other grain . . .	351,072
Do. Wheat, meal, and flour, cwts.	126,703
Hemp, undressed	460,544
Flax, tow, and codilla of hemp . .	882,286
Furs of different kinds, number .	1,694,311
Hides untanned, cwts. . .	214,735
Indigo, lbs.	3,064,915
Molasses, cwts.	383,761
Oil—Olive, gallons . . .	1,753,336
Do. Palm	120,509
Pepper and pimento, lbs. . .	2,237,900
Clover seed, cwts. . . .	136,000
Flax seed, bushels	1,965,800
Silk (raw material), lbs. . .	4,546,529
Spirits (brandy and geneva), gallons	4,048,070
Sugar, unrefined, cwts. . . .	3,001,405
Tallow	1,040,806
Tea, lbs.	29,305,757
Timber—(From the various different shapes in which this article is imported, it is impossible to guess at the whole quantity.)	
Tobacco unmanufactured, lbs. .	18,504,510
Cotton wool	208,987,744
Sheep's wool	31,031,461
Wine of all different kinds, gallons	7,162,376

Internal Trade.—These tables, and the explanations we have given, will convey some idea of the foreign commerce of Britain. But an equal source of activity and wealth remains in the inland trade, which is far superior in importance to that with foreign nations. To prove this, we need only state, that, of the whole quantity of cotton goods manufactured, one-half is consumed in the home market. Of hardware, the whole amount made is estimated at L.17,300,000; the quantity exported hardly rises to three millions. The value of woollen goods produced is estimated to be above twenty millions; the quantity exported is only stated at five millions. In like manner, the linen trade, which produces annually (according to the best estimates) about eleven millions, does not export on an average so much as two. There are also a vast number of manufactures, which are carried on exclusively for home consumption, such as beer and porter, in which the mere wages of labour (exclusive of the material) amount to L.3,200,000. Haberdashery, hats, straw manufactured into bonnets, making of furs into muffs, &c.; in these the wages of labour only amount to about L.3,000,000. In like manner, the wages expended on soap, candles, bricks and tiles, and gunpowder, amount to L.2,650,000. Those on steam-engines, machinery, &c. to L.1,200,000. All these articles are for home consumption alone; and as there are a vast variety of other articles of the same kind, it will be seen, that, though the foreign trade of the country is important in furnishing *materials* for many manufactures, and employment to others, it by no means constitutes the largest portion of the industry of the country. The people of Britain are in truth their own best customers; and, from their great wealth and unceasing industry, this fact cannot surprise any one.

The Commercial Marine.—The number of ships employed in the trade of Britain is in proportion to its great extent. The following is an account of their number, tonnage, and crews, in 1830:—

	Vessels.	Tonnage.	Men.
United Kingdom .	19,675	2,168,016	130,000
Guernsey, Jersey, & Man	499	32,676	3648
British plantations	4549	330,227	21,163
Total	23,723	2,531,819	154,809

The following is an official abstract of the number of steam-vessels in 1829:—

	Vessels.	Tons.
England - -	241	20,611
Scotland - -	75	5953
Ireland - -	26	4791
Total	342	31,355

None of these accounts include, of course, the vast number of canal-boats, or, what forms a very considerable item, the number of fishing-boats of from ten to fourteen tons, with which many parts of the coast are swarming.

PUBLIC WORKS, CANALS, RAILROADS, BRIDGES, DOCKS, &c.

Connected with our manufactures, are the great works of the civil engineer, which cover every part of the kingdom—the canals, roads, docks, bridges, piers, &c.—works which attest, more obviously than any others, the activity, power, and resources of the country. Magnificent as they are, however, they seldom attract the admiration which they merit. They are, for the most part, seen rather as a matter of chance, and passed by with a gaze of idle wonder, than studied as monuments of art, and as ministering largely to public utility. It is to the facility of internal communication, afforded by these works, that the heaviest goods, though manufactured in the interior of the country, can be carried to sea-ports for exportation, without any burdensome addition to their price; and materials for their different manufactures can be carried to inland towns from sea-ports, by canal or railroads, with the same advantage. Had we had bad roads, few bridges, and no canals, all trade must of necessity have been confined to the sea-coast.

The length of the turnpike-roads, in 1823 (the latest authentic account), was 24,531 miles; annual income, L.1,214,716; debt, L.5,200,000. The income, of course, was from tolls, and was intended for repairing the roads, and paying the interest of the money borrowed for constructing them. The total length of the canals, in the same year, was 2869 miles; the income on these canals amounted to L.13,205,116, which, besides keeping them in repair, afforded an average profit to the proprietors of 5¾ per cent. on their capital.

The *Bridges, Aqueducts, and Tunnels*, which have been erected in connection with roads and canals, are more magnificent and numerous than those of any other country in the world. To estimate their number would be difficult; but we may mention, that, in London, the Waterloo and London bridges alone cost very nearly two and a half millions of money. The iron bridges which have been erected in different places, are the admiration of all foreigners. Their arches are constructed of a number of strong ribs of metal, standing apart from each other like the joists of a house, and on these the floor or roadway is formed. Bridges of suspension are now also common, in which the roadway is suspended by iron bars, from strong chains which are fixed in the earth, and then hung over high pillars at each end of the bridge; by this means bridges can be constructed over deep and broad waters, where it would have been altogether impossible to stretch an arch of any other kind. There is a fine specimen of this kind of bridge at Montrose, over a tide current, whose rapidity did not admit of stone arches and piers; it carries the road over 432 feet of water; the cost was L.20,000. On a well-frequented road, bridges costing L.14,000 or L.19,000 are often constructed merely to shorten the distance by a mile or two, or to avoid an inconvenient ascent in the old track. Were it possible to estimate the amount of capital laid out on this kind of improvement alone, it would be a matter of astonishment.

The number of *Railroads* at present in active employment is above sixty. They are of various magnitude; but few of them, except the yet unequalled one betwixt Manchester and Liverpool, are more than twelve or fifteen miles in length. The latter celebrated work is thirty-three miles long, having double tracks laid with iron; and it is constructed almost on a perfect level, over bogs, through banks of rock and gravel, and at some hollow places raised several feet above the soil in order to preserve the level. The cost was about one million of money, and the yearly expenses of the moveable steam-engines which are employed to drag along the carriages, are high, from their liability to wear and to accidents; but yet the company, notwithstanding that they have greatly reduced the price both of carriage and travelling on this road, make very liberal profits, amounting, we understand, to eight or nine per cent. on the capital expended. The original shares, which were L.25, are now selling at L.52. The success of this great enterprise has encouraged the undertaking of a great many others of a similar kind. Nine new railways received the sanction of Parliament this season; among which, there is a remarkable one from London Bridge to Greenwich, of 3¾ miles in length, which it is proposed to carry over the tops of houses and through streets, for two miles and a half, upon arches and pillars of iron. Another of great extent is also begun from London to Birmingham; this will cost two and a half millions, and is to be of 112½ miles in length, with ten tunnels; the rate of travelling to be twenty miles per hour. As it may gratify our readers to know the distribution of the money laid out in these undertakings, we subjoin an account of the estimates for another magnificent work of the same kind, that is proposed to be made between London and Bristol, which will be 120 miles long. The country, except a short distance next Bristol and Bath, is remarkably level.

Parliamentary and other preliminary expenses	L.50,000
Purchase of land, including compensations for damages	340,000
Entrances to London, Bristol, and Bath, with the erection of warehouses, &c.	223,000
Excavations and embankments, including tunnels and their masonry . . .	835,300
Bridges and masonry, exclusive of that of tunnels	474,800

Rails, and laying ditto, making road, &c.	L.620,700
Lesser depôts, stopping places, and lighting tunnels	28,000
Moveable or dragging steam-engines, and water stations . . .	78,500
Total estimated expense of railway	L.2,650,300

On these railways, a moveable or drag steam-engine draws along waggons conveying merchandise of 240 tons, at the rate of fourteen and fifteen miles an hour. It would take 100 horses, working for a day on a good turnpike-road, to do what a single steam-engine can effect in an hour and a half on a railroad. From the cheapness with which all kinds of goods or passengers can be carried in either direction on these iron roads, every disposable article fetches a higher price by the difference of carriage; and some that could not formerly be sold at all, become highly valuable—such as building materials, &c., for the new erections that start up along their line. From these reasons, the construction of a railroad in a track judiciously chosen, increases at once the value of land and the rate of wages along its whole line. In making the Bristol railroad, about two millions will be expended in paying work-people.

We have been a little particular on the subject of railroads, from the vast employment which the new works of that kind now constructing are thus affording to all kinds of industry, from the engineers who plan the line or construct the steam-engines, to the thousands of workmen who are occupied in the manual labour of the immense operations which are required. The improvement which they promise to afford in the matter of carriage, the saving of time, of labour, and of expense, will be to this generation a boon similar to that of the new cotton machinery of the last.

Docks, Piers, and Lighthouses.—Docks are artificial basins built of stone for the reception of ships: they are of two kinds, wet and dry. A dry dock is a receptacle where vessels are built or repaired; after which the tide is admitted by flood-gates, and they are floated out to sea. Wet docks are constructed for the use of ships when loading and unloading, it being found that when they are allowed to settle down unequally on the mud or sand of rivers and harbours, their timbers are strained, and the vessels considerably damaged; in the wet docks they are kept always afloat. The capital expended by some of the dock companies in London is immense: that of St Catherine's is L.2,252,800; the docks and buildings cover twenty-four acres of ground, and ships of 800 tons are received into them without difficulty. The capital expended by the London Dock Company in purchasing ground (chiefly the sites of houses and streets) was more than one million; and the whole cost of the works was L.3,038,310: this undertaking, however, has not paid the original subscribers, the shares being now worth only about L.60.

The docks at Liverpool have a water-room of one hundred and eleven acres, and the quay space is eight miles in total length. The business transacted may be conjectured from the fact that the dues paid by vessels using them in 1830 was L.151,328. The dues received at Bristol in the same year were L.24,754; at Hull, in 1827, L.22,381. Few of the large seaports are without the accommodation which docks yield to commerce: those at Leith contain ten acres of water-room, and have cost L.285,108. It would be idle to attempt a description or even enumeration of the immense number of piers and harbours which have been constructed at the different sea-ports. At every place where the profits of trade seemed to authorise such erections, capital was seldom wanting to complete them.

The *Lighthouses* of Britain are perhaps the most remarkable part of the nautical apparatus of the islands. The capital expended upon them has been large, and the skill with which some of them, such as the Bell-Rock and Eddystone lighthouses, are constructed for durability in the midst of a tempestuous sea, could only have been erected in a country where mechanical science existed in its highest perfection; and there is hardly a dangerous or doubtful point along the coast where the mariner is not guided by a light on some headland or rock. There is, however, much complaint concerning the dues levied from ships for lighthouse expenses; some of them are held as profitable tolls by private families, and in others money is applied to purposes quite unconnected with lighting. Many of the dues are thought, by commercial people in general, to be greatly too high.

AGRICULTURE.

The improvements which British industry has introduced into agriculture, have not done less to advance the wealth of the country than those effected in commerce and mechanics. The regular and scientific rotation of crops, according to the nature of soils and of the different plants; the creation of the turnip husbandry, and of artificial grasses; the management of different kinds of manure; the systematic attention to improvement in the breeds of cattle, horses, and sheep; the perfection of the different kinds of agricultural machinery. In all these, Britain has made advances which no other nation has yet thought of: some have improved their breeds of sheep, others have soils which raise large crops of grain with less expense than ours, but the total produce of a given quantity of land is in no country to be compared to the value of that in Britain. This produce also is raised with less labour than the smaller returns of foreign countries. In France, two-thirds of the population are required for the mere cultivation of the soil, while in England and Scotland that business is performed far more productively by one-third part of the people. A great part of the work which is done in France by men is in this country performed by machinery (such as *fanners* for winnowing, and mills for thrashing the corn), or by horses and other cattle. It is calculated that by the two latter aids (cattle and machinery) the farming interest of Britain have brought into operation a force greater than twelve times the number of labourers whom they employ. In France, the assistance derived from the same sources is only five times the force of the labourers employed. Bengal is reckoned one of the most fertile countries of the East, and it is nearly of the same size as Great Britain; yet, with all its advantages of rich soil and warm climate, the inhabitants can only raise from it crops of the average value of L.1 per acre, of which, from their want of skill, three-fourths are consumed in the expenses of cultivation. In Britain, the *average* produce of the cultivated land of all qualities is L.5 per acre; and the expense of cultivation does not exceed one-third of this return; so that the profit or remainder for rent and outlay of capital in Bengal is only five shillings, while in England it is L.3, 6s. 8d. Such is the unskilfulness of farmers in that country, that it takes four-fifths of the people to do the work of cultivation, leaving only one-fifth for all other trades: in Britain, as we have seen, farming work brings five times as much gross produce, and leaves eleven times as much for rent and profit of capital—employing only a third of the population, and leaving two-thirds for other occupations. These results are entirely owing to the superior industry and ingenuity of the people, for our soil and climate are greatly inferior either to those of Bengal or France.

The following statement is taken from a report of the emigration committee, 1829:—

Acres.	Cultivated.	Wastes capable of improvement.	Unprofitable.	Total.
England & Wales	28,749,000	3,984,000	4,361,400	37,094,400
Scotland . .	5,265,000	5,950,000	8,523,930	19,738,930
Ireland . .	12,125,280	4,900,000	2,416,664	19,441,944
British Islands .	383,690	166,000	569,469	1,119,159
Total .	46,522,970	15,000,000	15,871,463	77,394,433

In England and Wales, it is calculated that the cultivated land is distributed in the following proportions: Three and a quarter millions of acres are in wheat; four and a half millions in the other grains—barley, oats, rye, pease, &c.; 2,400,000 in green crops, one half for grass, and the other for turnips, &c.; 2,100,000 fallow; 17½ millions pasture; 10,000 pleasure grounds; 1,200,000 hedge-rows, copses, and woods; and there are 1,300,000 acres in roads, highways, and water courses.

RELIGION AND THE CHURCH.

All religions are allowed to exercise their different forms of worship in Great Britain, and no violence can be offered to any man in matters of conscience. Every different denomination of Christians have their own churches, employ whom they please as their pastors, and are equally under the protection of the law in the performance of their sacred rites.

The churches of England and Scotland, or, as they are commonly called, the established churches, enjoy a pre-eminence over the other denominations. Their clergymen are provided with salaries, paid by taxes or tithes levied on all men equally, whether of that particular sect or not.

The income of the church of England is given as follows, on rather a low estimate:—

Income of the parish clergy .	L.3,447,138
Incomes of bishoprics . .	150,000
Do. deans and chapters . .	275,000
Total revenue of English church	L.3,872,138

The following table exhibits a summary of the value of the income of the parish ministers of Scotland:—

172	parishes at	L.150 each .	L.25,800
200	do.	200 . .	40,000
200	do.	250 . .	50,000
200	do.	300 . .	60,000
100	do.	325 . .	32,500
76	do.	350 . .	26,600
948			L.234,900
948 houses and glebes, valued at L.30 each,			28,440
Total income of Scottish church			L.263,340

In Scotland the stipends of the established clergy are paid by landholders, who have all had their tithes commuted upon an old and very low valuation. In no part of this country, therefore, is the church felt to be burdensome in a pecuniary sense, except in Edinburgh, where the clergy are supported by a money-tax levied from a certain class of the inhabitants. The incomes of the Edinburgh clergy average about L.600 a-year each, which enhances the amount in the above table.

The aggregate revenue of the church of Ireland is reckoned to be nearly L.1,300,000. The latter sum is much grudged by reformers, because it appears, that, out of a population of seven millions, Ireland contains scarcely half a million who attend this church, five and a half millions being Roman Catholics, and the rest Presbyterians or Dissenters of various denominations.

The total income of the established church in England, Scotland, and Ireland, is therefore L.5,307,470. There are many complaints, in England particularly, as to the distribution of this money, and of the large sums received by the bishops and other dignitaries, who are not actively employed in any church duties, or of others who hold two or three offices merely for the sake of the salaries. The inferior clergy who minister to the congregations are said at the same time to be ill paid. Lord Henley states that the duty in 4530 parishes is performed by curates (*assistants*), one sometimes serving two parishes; about 3000 of these assistants have less than L.150 per annum; 248 have under L.40, and 60 have less than L.30.

It would give us pleasure, had there been space, to enumerate some of the splendid buildings which have been erected in this country for the convenience of religious worship, and which are an equal proof of the wealth and of the correct habits of the people. We do not allude merely to those which have been raised at the public expense, but to others erected by different denominations of Christians, which decorate some of the finest streets of our cities, or give interest to the solitary beauty of many of our remote villages. A school or a dissenting chapel, in the latter kind of places, are proofs at once of industry and devotional feeling among their humble inhabitants, which are the surest pledges of national prosperity. In England, the number of congregations of the establishment is 10,000; of dissenters, 6500.

EDUCATION.

There are several great and richly endowed universities for the education of young men devoted to the learned professions. The establishment of Cambridge and Oxford in England, those of Edinburgh, Glasgow, Aberdeen, and St Andrew's in Scotland, with the Dublin University for Ireland, thereby conferring a sort of elevated rank on a class of the professors of learning, have served to give it importance in many circles where it might have been neglected, had it appeared in a humbler shape. But it is not to these that we would principally direct the reader's attention at present: the academies which are rising in every town of any considerable size, for the education of young people of the middle and commercial classes, are an object of deeper interest, and of more extensive utility: of these we are sorry that we cannot estimate the number, nor their proportion to the population; we can only say that there are few of our large towns, where, by the exertions and subscriptions of the inhabitants, one has not been established, in which all the requisite branches of knowledge are taught by men of the most respectable qualifications. In other parts of Europe there are many public institutions and colleges; but of academies like these, supported by the private wealth of the citizens for their own service, Britain shows the only example.

With regard to the provision made for the education of the great body of the people, considerable pains have been taken by Parliament to collect what information could be found. A committee was appointed in 1816 for this purpose, in regard to England and Wales; and the result of their inquiries was as follows:—

England and Wales.

	No. of Schools.	Scholars.
Endowed schools (rev. L.303,342)	4,376	173,058
Unendowed day-schools .	14,854	501,825
Sunday schools . .	5,463	477,226

Scotland.

Parish schools (rev. L.20,611)	912	54,161
Endowed schools (rev. L.13,679)	212	10,177
Unendowed day-schools .	2,479	112,187

The number of unendowed schools varies from year to year, but the Parliamentary Commissioners saw reason to think they were gradually increasing, and that they have been augmented considerably since 1818. Great exertions are now making by the people to educate themselves, in which they are a good deal assisted by those of the wealthier classes, who have the sense to reflect that knowledge promotes industry, and leads the labouring people to have a pride in depending for every thing on their own exertions. In the unendowed schools, the number of children under tuition at present is about one million.

In Ireland, the number of teachers is about 12,500, and the scholars 568,964. Many of these schools are of the poorest kind, with teachers of a very low class, whose appearance and character can inspire their scholars with no respect for learning. Government has lately appropriated funds for the assistance of such school-districts as may consent to use lessons that can be read without offence by either Protestants or Catholics, so that both may attend the school; and this measure promises to do much for the diffusion of education in Ireland.

The *country parts* of Scotland are much benefited by their parish-schools, an institution which has long existed in that kingdom: this advantage, however, is not felt by the population of towns and burghs, where the original form and use of the parish-school, as applicable to the wants of the working classes, are no longer known. This inequality is the more felt, that the population is becoming continually more concentrated in large towns, where the advantages of a Scottish education are no longer within their reach. The case of towns in this respect deserves the careful attention of government.

YEARLY INCOME OF THE EMPIRE.

A curious estimate has been formed of the total annual income of all classes of people in Britain, with the aggregate value of the articles of use and luxury which each produces in the course of the year. This cannot of course be considered as perfectly accurate, but it serves as an approximation, to exhibit the surprising amount of *goods* or wealth created yearly by the inhabitants of this country, and shows at the same time the relative importance of each class in respect of production.

Agriculture—		
Grain of all sorts	L.86,700,000	
Green crops of all kinds	122,000,000	
Gardens, nurseries, seeds, timber	6,400,000	
Cheese, butter, eggs	6,000,000	
Cattle	3,500,000	
Hemp and wool	12,000,000	
		L.236,600,000
Mines and minerals—		
Slate, chalk, stone, gravel	1,000,000	
Salt and alum	600,000	
Metals	7,900,000	
Coal	11,000,000	
		21,400,000
Inland trade—Profits		41,425,000
Coasting trade—Do.		2,550,000
Fisheries—Produce		3,400,000
Shipping and foreign commerce—Profits		34,398,059
Bankers' profits		4,500,000
Foreign income, from estates in West Indies, interest on money lent abroad, &c.		4,500,000
Manufactures—(The separate articles under this head are mentioned in another page)		148,050,000
Total of produce and property annually created in Great Britain		L.503,823,059

ESTIMATE OF THE PUBLIC AND PRIVATE PROPERTY IN THE EMPIRE.

An estimate has also been formed of the value of the whole property, public and private, which has been created and accumulated by the people of this country, and which they now actually possess. This value, when the sum is expressed by figures, is so immense, that it eludes the imagination to conceive it; the relative proportions of the different parts may, however, be understood, and are really interesting; as for instance, whether there is more money laid out by the country in shipping, or in agricultural property and implements, &c. We subjoin the table:—

Capital invested in the following articles.

I. Productive Property.	
In cultivated land of all kinds	L.1,600,000,000
Tithes due to laymen	106,000,000
Mines and minerals	109,800,000
Canals, tolls, railroads, and rough timber	66,200,000
Dwelling-houses, warehouses, factories, &c.	533,000,000
Manufactured goods unfinished, finished, and on sale	186,300,000
Foreign merchandise paid for	53,300,000
British shipping of all kinds for trade	35,300,000
Agricultural property, consisting of grain, hay, straw, cheese, butter, &c., with implements of husbandry	59,900,000
Animals tame and trained, horses, cattle, sheep, hogs, goats, asses, poultry, game	242,000,000
Fisheries on the coasts and rivers	13,200,000
Total productive private property	2,995,000,000
II. Unproductive Private Property.	
Waste lands, at present unproductive	L.176,000,000
Household furniture in dwelling-houses	246,000,000
Wearing apparel	27,000,000
Plate, jewels, and ornamental articles in houses	58,000,000
Coin and specie in circulation and hoarded	19,900,000
Money in saving banks	14,400,000
Money belonging to suitors in Chancery	38,900,000
Total unproductive private property	580,700,000
Total private property	L.3,575,700,000
III. Public Property.	
Public buildings, as palaces, churches, hospitals, prisons, bridges, &c.	L.35,200,000
Public arsenals, castles, forts, &c., with the artillery, stores, &c., thereto belonging	22,000,000
Dock-yards, and all materials of ship-building and repairing	13,000,000
Ships of war of all descriptions	20,000,000
Military, naval, and ordnance stores	13,000,000
Total public property	L.103,800,000
Total public and private property	L.3,679,500,000

By *productive property* in the above valuation is meant all such as is held chiefly for the purpose of being employed in the production of other articles: all kinds of tools, machinery, cultivated land, agricultural live stock, roads, canals, &c., are therefore *productive property*. The name *unproductive property*, again, is given to such articles as are held without any purpose of being made useful in producing new commodities; under this head are household furniture, horses not kept by business-people, pleasure ground employed merely as such, and so forth.

The wealth of the empire is distributed in the following proportions between the three countries:—

	Productive private property.	Unproductive private property.	Public property.
England	2,054,000,000	374,300,000	42,000,000
Scotland	318,100,000	51,100,000	3,000,000
Ireland	622,100,000	116,400,000	11,900,000

The proportion which these values bear to the population in each country is not suggested by the table; but in England (taking productive and unproductive property together) the ratio is L.186 to each person; in Scotland, L.160; and in Ireland, L.96.

Were it possible to procure tables of the same kind as these two, with regard to the other countries of Europe, the comparison would show in a strong light the immense superiority of Britain in the industry and wealth of her inhabitants. Instead of there being L.186 of property for each person as in England, L.160 as in Scotland, or L.96 as in Ireland, it would be found that in most of these countries there would hardly be L.15 for each, in some much less, and (excluding Holland) not L.30 in any of them.

EFFECTIVE POWER AT WORK IN BRITAIN.

In the absence of tools, machinery, and trained animals, every kind of labour would have to be performed by the mere strength of men. There are many things now done, indeed, which no mere human strength could effect, such as the draining of deep mines, and many others; but supposing that some method were discovered of applying men's strength to all these, it would be a curious inquiry to discover what number of men would be able to exert power sufficient for producing all the force now yielded by steam-power, machinery, and the power of animals, in Great Britain. The researches of a foreign statist, Mons. Dupin, have enabled us to give an answer (or at least an approximation) to this curious question.

The population of England and Scotland may be taken in round numbers at fifteen millions; from this number are to be deducted females, children, old people, men not engaged in any productive or mechanical employment; and the remainder, actually at work, will be 6,397,339.

Agricultural force.

Men—effective labourers	2,132,446
Animals—horses, a number equal in power to	8,750,000 men
Do. oxen, a number equal in power to	13,750,000 men
Estimate for Ireland; power of men and animals, equal to	7,455,701
Total living force in agriculture, equal to	32,088,147 men

Force employed in Manufactures.

Men—effective labourers	4,264,893
Animals—equal in power to	1,750,000 men
Estimate for Ireland—men and animals	1,260,604 do.
Total living force in manufactures	7,275,497 men
Mills and water power	1,200,000 men
Windmills	240,000
Wind and navigation	12,000,000
Steam-engines	6,400,000
Estimate of mechanical force for Ireland	1,002,667
Total inanimate or mechanical force in manufactures	20,842,667

Taking all these together, it appears that the whole force of men, animals, and machinery, which is in operation in Great Britain and Ireland for agriculture and manufactures, is equal to the strength of more than sixty millions of working men; and this power, it must be recollected, is created and managed by little more than a tenth part (6,397,339) of that actual number of people, which is the whole proportion really at work.

In France, notwithstanding that the population is much larger (about thirty-one millions), the force applied to manufactures is only about eleven millions and a half; while the total force employed in agriculture, and the arts of all kinds, affords only the result which would be given by the strength of forty-nine millions of working men. Thus, though the population of Britain be less than that of France in the proportion of twenty-three millions to thirty-one millions, the power of labour in Britain is greater in the proportion of sixty to forty-nine, or nearly five to four.

POPULATION.

An account of the population of the empire has been taken at intervals of ten years from 1801; and the following table will show the gradual increase which has occurred during these intervals:—

	1801.	1811.	1821.	1831.
England and Wales	8,872,980	10,163,676	11,978,875	13,894,569
Scotland	1,599,068	1,805,688	2,093,456	2,365,807
Ireland	—	4,500,000	6,801,827	7,734,365
Army and navy	470,598	640,500	319,300	277,017
Totals	10,942,646	17,109,864	21,193,458	24,271,758

The increment from 1811 to 1831 is forty-one per cent. When the population of a country is thus steadily on the increase, it is the best proof that the comforts and means of living among the people are also gradually improving. When the people, on the other hand, are becoming poorer and more destitute, families have not means to rear up their young children, by affording them those comforts and attentions which are necessary for protecting life at that tender age; hence numbers of them die early. It is calculated that in Russia one-half of all the children die before they are a year old; while in Britain there are not more than thirty in the hundred who do not survive that time. This proceeds solely from the miserable and degrading poverty of the Russian parents, and the comparatively comfortable circumstances of those in England. The same cause makes persons who fall into weakly health much more liable to a fatal issue in poor and barbarous countries, than where the population enjoys a moderate degree of comfort. And, accordingly, it is found that people on an average live much longer in this country than in most others of Europe. A statement was lately published by Mons. Moreau de Jonnes, from which it appears, that, in Italy, 1 person in every 30 dies during the year; in France, 1 in every 39; in Germany, Denmark, and Sweden, 1 in 45; in Ireland, 1 in 53; in England, 1 in 58; and, in Scotland and Iceland, 1 in 59. The author attributes this difference in the number of deaths solely to the effect of climate, concluding that men in general live longer in northern countries than in the south. It appears, however, that the cause of the difference depends almost altogether on the proportion of civilisation and comfort existing among the labouring classes in each country.

The increase has been greatest in the manufacturing districts, where, in some instances, it has been double of those which are merely agricultural; as, for example, the increase in the manufacturing counties of England, from 1821 to 1831, was 22 per cent., while, in the agricultural counties, it was only 10½. The increase in the population of towns and considerable villages has also been large and steady, while that of the merely rural districts has remained the same, or has in some cases even diminished, particularly in Scotland. The reason of this difference in both cases is the same, viz. the greater facility of procuring employment in manufacturing places, and in towns which attract settlers from the farming districts, and the more rapid increase of population, arising from this greater ease of making a subsistence for families.

Much discussion has taken place among people learned in such matters, whether the means of the country to maintain her people has increased at an equal rate with the population itself; that is, whether there be an equal stock of necessaries in the country for giving employment to each person now, when the population is twenty-four millions, as there was in 1811, when it was only seventeen millions. Has the *capital* (or stock of goods, machines, and subsistence) increased at an equal rate with the numbers of the people? This is a question which admits of a very ready answer; for, as it is confessed on all hands that the bulk of the people are now in more comfortable circumstances than they were in 1811, or at any former period, and as the same fact is proved by the greater average length of human life, which has gone on increasing for the last century, there cannot be a doubt but that capital has increased much faster than population; that is, that every provident individual is richer, or in more comfortable circumstances, than he could have been at any former period. When we look into the houses of any of the labouring classes, such as fishermen, for example, and find them stocked with neat and comfortable clothing—their room furnished with a wainscot or perhaps a mahogany table, a large bible, and an eight-day clock—when we see that they are now able to provide these things for themselves by their own industry, while thirty or forty years ago it would have been impossible—what is this but a proof that the capital of these men has increased faster than the number of their families? The same observation may be extended to all classes, for the circumstances of all are much more comfortable than they were fifty years ago; at which time one *hodden gray coat* (home-done grey) was made to last with a countryman for his Sunday's dress during a whole life; when country houses had no fire-places but a corner of the floor, and no chimneys but straw plastered with coarse clay. It is surely needless to say, that every person has better means of living now than he had then; and if the goods of each individual be increased, the *capital* of the country is increased in the same proportion; that is, it has increased a great deal more rapidly than the number of the people; and each of the people, though their numbers be greater, has a better stock of necessaries and comforts than he had at former periods. We do not mean to deny that there are several classes who are in distress (such as the hand-work weavers, who are obliged to compete against the cheaper steam-loom), or that there are some important interests which labour under heavy difficulties; our position refers only to the general state of the country, which is manifestly improved.

DIFFERENT CLASSES OF PEOPLE.

The Peerage.

There is, properly speaking, only one body of individuals in the empire which can be said to form a separate and distinct class, having rank and privileges different from those of the other subjects. This class is called the *peerage*, and sometimes the *nobility*, or *aristocracy*: its members are distinguished by certain titles, which are the badges of their rank; some of them being of higher degree than others. The titles stand in the following order, from the lowest to the highest:—Baron, viscount, earl, marquis, duke, and prince: the last title is conferred only on members of the royal family. These titles are at the disposal of the king only, and are given to men who have distinguished themselves in any high situation in the service of the state; such as judges, admirals, and the commanders or great officers of armies; and they are also bestowed on the heads of wealthy and influential families, to whom it is thought right, by such means, to give additional weight in their several neighbourhoods. The title, once bestowed, becomes hereditary in the representatives of the first possessor: hence the existence in the country of aristocratical or titled families as a distinct class. They are in general wealthy, as well as titled; and, by intermarriages with the rich mercantile classes, they preserve in their families a show of great opulence. There is an order, however, commonly called the *high aristocracy*, which intermarry only amongst themselves: the incomes of some of these are very large, reaching, it is said, in two or three instances, to L.300,000 per annum. It may be mentioned, however, that, rich as many of the aristocracy are individually, their whole income is but a drop in the bucket compared with that of the other classes; on the largest calculation, they cannot have more altogether than fourteen or fifteen millions from their estates annually; while the rest of the country has two hundred and forty-six millions from agriculture alone, and from all sources more than five hundred millions. The circumstance of the aristocracy living much together as a body, and possessing certain privileges which confer distinction upon them in Parliament and about the court, attracts an attention to their families, which, were wealth alone regarded, they could not enjoy. Any individual peer is entitled to demand an audience of the king, and to state to his majesty his opinion upon public measures under discussion. British peers have seats in the House of Lords in virtue of their birth, and those of Ireland and Scotland elect a certain proportion of their own number to sit there; the Irish elected peers sitting for life, those of Scotland during the Parliament for which they have been chosen. A peer can only be tried, in any criminal case, by a jury of persons of his own rank. These privileges, and some others, give to individuals of this rank an elevation and distinction in the eyes of the other classes, which generally makes their company or alliance much courted and sought after. Of late years, many different opinions have been broached as to the utility of their legislative functions, but this is not a place to argue such a point.

The number of the peerage varies from time to time, by the creation of new families, and the extinction of titles to which heirs are not found in the prescribed lines. The number of the British peers, or those who sit in the House of Lords, is about 400; of which titles, about one-half have been conferred within the last fifty years, and only forty-seven existed before the year 1700. The Irish peerage is about one hundred and sixty in number; of whom twenty-two have titles of earlier date than 1700. The Scots peers are about eighty, whose titles are all dated before 1707, and about twenty before 1600. Twenty or thirty of the Scots peers are also British peers, and have seats in the House of Lords.

The Clergy.

The clergy, though apparently existing as a separate order, are so in regard to their profession only—in the same manner as lawyers, merchants, and others. They are composed of men sprung from all orders of the community—the richer benefices in the church being open to all young men of the wealthy classes who are not dissenters, and the lesser livings and curacies to every order of aspirants who can procure the requisite education. The revenues of the church have been already mentioned, together with some particulars in regard to their distribution. The English clergy have a gradation of rank among themselves, with a number of titles unknown to the Presbyterian churches: as, for instance, archbishops, of whom there are two in England; bishops, of whom there are twenty-five; deans, and sub-deans. There are also certain clerical offices belonging to the cathedrals, such as prebendaries and others. These dignities are generally held by some of the parish clergy in conjunction with their parochial office.

The Law.

The nature of their education and business detains lawyers chiefly in the capitals of the three kingdoms, at least those of them who aspire to eminence in their profession; and as they are an influential body, associating much with one another, and having many interests in common, they assume somewhat of the appearance of a separate class. They furnish individuals for occupying the most important offices of the state, and those on which peace and justice through the country most immediately depend—as the Lord Chancellor, the whole of the judges, the assessors (or interpreters of law), who are appointed to assist magistrates of towns in the discharge of their duties, and many others. Men of property or large business are generally obliged to have an adviser from the same body, to inform them on matters where there is any difficulty of law. A great part of the most important transactions of the country, therefore, pass through the hands of men of this profession. There appears to be a disposition at the present time, among the highest members of this body, to remove some of those antiquated legal incumbrances whose delays and expenses the people so often feel to be a denial of justice.

The Mercantile and Manufacturing, or Middle Classes.

These classes are united more by being engaged in similar occupations, and having the same interests, than by standing in one rank in society; for they are of all gradations, from the small capitalist or manufacturer, who struggles for a living, to the wealthy merchant or owner of factories, who could raise and depress prices and wages almost at his own pleasure, were it his interest to do so. It is on the industry, foresight, and economy of this large class, that the prosperity of the country mainly depends. Were they rash and ill-informed, instead of a continual progress of the whole body to increased opulence and larger capital, there would only be a succession of bankruptcies and commercial panics, which would ruin the trade of the country in a few years. But they are *in general* men of sound views, trained to a practical acquaintance with the objects of trade, and the means which are necessary for its success. The merchants and great manufacturers of Britain are frequently the best educated and most liberal men of the country; for as their occupations lead them to associate with persons of different countries and of all professions, they acquire a knowledge of the interests and habits of all, and have both their knowledge and their curiosity enlarged at the same time.

With regard to the lesser class of capitalists and manufacturers, we generally find them to be men who have risen in life by the skill and economy they have displayed in surmounting difficulties of a very arduous kind, and who are silently laying the foundation of a still higher ascent for themselves, or, if that be too late, preparing their children by an useful education to rise from the step which they have gained. It is by this useful ambition, and the industry and economy to which it gives rise, that the capital of the country keeps always ahead of its increasing population.

Farmers, and the Agricultural Class.

British farmers, generally, occupy a much higher status in society than the cultivators of the soil in other European countries. But their situation is said to have become much worse of late than it was twenty years ago; rents, it is alleged, have not fallen in proportion to the fall in the prices of grain and other agricultural produce; so that the farmer has no encouragement for laying out money in improving either his land, his breeds of stock, or his modes of labour. Yet there is as great a competition for farms as ever; and the farmers themselves, by their offers, will not allow rents, of which they complain, to fall. The reason of the latter circumstance (which is the source of the whole) is, that the family of a farmer, living with him in a kind of seclusion, apart even from villages, see and know nothing as they grow up but their father's business, and that of other farmers, so that they learn to neglect every other as matters in which they have no concern. It is different with young persons brought up in towns or large villages, who daily encounter people of many different professions, and seldom adopt that of their father. The sons of farmers, on the other hand, see no occupation but one, at least so as to become familiar with them; hence most of the young men become passionately attached to that one, and there are almost always too many bidders for every farm. Though the profits of agriculture have fallen, the wages of farm servants continue nearly steady, which is owing to the increased demand for men in manufacturing places.

Mechanics and other Operatives.

There is a great difference between the value of the time of different mechanics, according to the different degrees of strength, skill, or delicacy of handling which their businesses require. Hence there are almost as many different grades of society and ways of living among the class of tradesmen as among those of higher rank. Those whose business requires great skill and tedious apprenticeships, receive very high wages; and if they have a taste for neatness and comfort at home, they are able to furnish their dwellings in a style of much good taste, and even elegance; besides giving their children a correct and useful education.

Our article on POLITICAL ECONOMY treats so largely of the principles affecting the condition of the operative classes, that nothing need here be added on this branch of our subject.

Summary of Classes.

It has been ascertained, that, in 1831, there were of the classes belonging to the aristocracy in Great Britain, from 3000 to 4000 families; of squires and gentlemen, who are land-proprietors, stock-holders, money-lenders, &c., from 50,000 to 60,000 families; of learned professions—36,000 clergy of all denominations, about 30,000 lawyers, and 50,000 physicians, surgeons, apothecaries—making 116,000 families, with half as many more dependents; of farming tenants, about 250,000 families, and of their labourers, 400,000 families; of merchants, shopkeepers, and general traders, 900,000 families; of artizans, 200,000 families; of manufacturers in all lines, 500,000 families; of labourers, porters, and servants, 600,000 families; and of destitute paupers, soldiers, &c., 800,000 families.

THE COLONIES.

The foreign possessions of Great Britain are much more extensive and populous than those of any other country recorded in history. They may be divided into three different classes:—First, colonies occupied and cultivated by people who have emigrated from this country, and which, in respect of language, manners, and religion, are not different from Britons. Second, slave colonies, in which the greater part of the population are black slaves, and the proportion of Britons who live among them do so in the capacity of proprietors, masters, overseers, merchants, skilled workmen, &c., being in every respect the ruling and superior class. Third, countries which have been conquered from their own inhabitants, and which Britain still holds as conquests; the people having the occupation of the soil, but the right of making and enforcing laws, of placing and displacing magistrates, &c., being in the hands of the conquerors, and such servants as they may appoint for that purpose.

1. With regard to the first kind of colonies, or those which are occupied entirely by emigrants from Britain, and their descendants, it may be remarked, that this country has been the only one which has ever succeeded in rearing such establishments, and making them thrive. The experiment was tried by France in Lower Canada, and in settlements on the river Mississippi; but the colonists who were sent out, though the best for the purpose that France could afford, have never made any advances in prosperity; and instead of becoming wealthy or powerful, either retained, as in Canada, all the old-fashioned and inconvenient practices of French agriculture, or fell, as in the settlements on the Mississippi, into association with the savages of the forest, and adopted their habits. Canada, after it had been 210 years in possession of the French, had only 27,000 inhabitants (1714). The Spanish colonies, though much older than those of Britain, are, *except in the great towns*, in a state little removed from barbarism; the mixed descendants of the European settlers are few in number, and content themselves with the pride of being descended from white people, without seeking any distinction from superior intelligence; and the black and copper-coloured population are mere tillers of the ground, without knowledge, without arts, and without trade. Were we asked what has made Britain successful, where other nations more populous and as powerful have failed, we must answer that it is entirely owing to the state of information, and to the character of the people in the different countries. Britain has abundance of men skilled in all the arts which are necessary in a new colony—carpenters, boat-builders, mill-wrights, machine-smiths, &c.; each of these, in general, with a little capital, besides being full of energy from confidence in the resources and intelligence of himself and his comrades. The French colonists, again, were only poor uninformed creatures, without capital, and without trust in themselves; and the country had no others which it could spare to send away.

The principal colonies of this description which Britain retains in her possession, are those of Canada, New Brunswick, and Nova Scotia, in North America; with New South Wales and Van Dieman's Land, in Australia. The colonies of Upper and Lower Canada, particularly the former, are those to which the attention of emigrants is at present principally drawn. This country possesses resources for maintaining a population many times larger than that of Europe. The following table will give an idea of the present state and resources of these colonies:—

	Population, 18[illegible].	Cultivated Lands.	Uncultivated Lands.	Estimated value of annual productions and fisheries.	Exports from England, 18[illegible].
Lower and Upper Canada	612,188	8,066,656	100,000,000	L.9,737,102	L.1,117,421
New Brunswick	72,932	800,000	20,000,000	2,651,982	274,922
Nova Scotia	142,548	1,333,333	12,000,000	3,476,440	
Cape Breton and Prince Edward's Island	83,561	106,666	3,200,000	380,980	297,968
Newfoundland				1,420,792	373,817

About 100,000 have been added to the population of Canada, by emigrants, since the date of the above census.

The value of property, public and private in the same colonies, is estimated as follows:—

	Public property, Forts, Arsenals, &c.	Private property, viz. Buildings, Implements, Merchandise, Fisheries, Ships, and Specie.
Canada, Upper and Lower	L.2,133,333	14,951,145
New Brunswick	13,333	3,399,664
Nova Scotia	600,000	8,336,932
Cape Breton and Prince Edward's Island	156,909	1,254,330

Prince Edward's Island and Cape Breton are important in the hands of a naval power, as commanding the entrance of the river St Lawrence. The latter has an additional value, from the excellent coal which is found there, and which can be carried by sea to all parts of the adjoining coasts, both of the British possessions and those of America.

The average expenditure for the government and protection of these colonies is about L.348,000, part of which is defrayed by Britain, part by the colonies themselves: the latter portion is L.233,356; so that Britain pays L.115,361.

Australian Colonies.—The other colonies settled by emigrants from Britain are those in the southern hemisphere—New South Wales, Van Dieman's Land, and Swan River. The first of these settlements was only planted in 1788: their progress since that time has been remarkable: the population in 1828 was 39,684. The estimated value of property in buildings, ships, merchandise, money, &c. L.2,045,000; and they had about 300,000 acres of cultivated land. Their annual exports from Britain amount to L.96,123. They produce finer wool than any European country, and import large quantities of it into Britain, which are bought with avidity. Great part of the original population of these colonies consisted of criminals, sent thither for punishment and hard labour: their descendants are said to betray no symptom of such an origin. The expense of the Australian colonies, in 1829, was L.294,998; of which, however, only the sum of L.10,103 was paid by Britain.

The emigration to all these colonies has increased greatly of late years, as the following interesting Parliamentary document will show:—

Emigrants from Britain in the under-mentioned years—

	1827.	1828.	1829.	1830.	1831.	1832.
To the British colonies in America—Canada, Nova Scotia, &c.	12,648	12,084	13,307	30,574	58,067	66,339
To the C. of Good Hope	114	135	197	204	114	196
To the Australian colon.	715	1056	2016	1242	1561	3733
To the United States	14,526	12,817	15,678	24,887	23,418	32,872
Total	28,003	26,092	31,198	56,907	83,160	103,140

The number of emigrants who have sailed for Canada this year (1833) has not been so large, not perhaps exceeding 30,000, on account, it is believed, of the alarm excited by cholera among the inhabitants and some emigrants last season. A large number also now proceed to Canada by way of the United States, as being more commodious. Of these it is impossible to say how many reach and settle in Canada.

Slave Colonies—West Indies.

The principal of the British slave colonies are in the West Indies; they form part of a chain of islands which stretch across the outside of a large bay or gulf betwixt North and South America. The islands are all remarkably fertile, and most of the tropical productions are furnished by them. Sugar, cotton, tobacco, coffee, cocoa, the different kinds of pepper, &c., are indigenous and abundant. They are not, however, very healthy for English residents, and hence most of the labour is done by slaves brought from Africa. Their total population is reckoned at 776,500, of whom 626,800 are slaves. Jamaica, the largest and most populous of the islands, is supposed to have 402,000 people, of whom 37,000 are whites, and 342,098 slaves: Barbadoes, the next in respect of population, has 15,000 whites, 5000 free blacks, and 79,000 slaves; Trinidad, 4000 whites, 16,000 free people of colour, and 24,500 slaves. The other islands, which are smaller, have their population from 10,000 to 30,000 divided into similar proportions of free people and slaves.

The quantity of cultivated land in these islands is about two and a half millions of acres, or about one-twentieth of the cultivated land of England. The estimated value of their gross annual produce is twenty-two and a half millions of pounds sterling, of which they export five and a half millions, chiefly to Britain. The estimated value of public property, in fortifications, artillery, court-houses, &c., is about four millions; of private property, thirty-nine millions, including agricultural stock, warehouses, merchandise, shipping, specie, &c. The value of the negro slaves, whom it was customary to reckon as part of the stock of their farms, was stated by the colonists so high as forty-two and a half millions. Government have agreed to allow them twenty millions as compensation, in order to have the slaves set at liberty at the end of seven years. The injustice and oppression of slavery will, therefore, no longer have the sanction of British influence, and cannot, on being deprived of that support, exist much longer in any part of America.

The expense of governing the West Indian colonies amounts to L.550,303, of which the mother country pays only L.70,213. In this, however, is not included the large naval and military expenditure for their defence, and their military police, which falls upon Britain.

In concluding our notice of these colonies, and those of North America, we must remark, that many faults have been found with the way in which they are managed; principally in regard to their not being left free to buy and sell in those markets which best suit their necessities; and, in the mother country, being *thirled* (as the Scots express it) to them by a line unprofitable bond. It is also said that much waste and favouritism has taken place in regard to their revenues. These complaints have all some foundation, both in the West Indian and Canadian colonies; but it is evident, notwithstanding, that they have both been better managed than the colonies of any other European country, *because they are comparably more thriving.* In raising these countries (as well as our old colonies, the United States of America) to their present state, the British government, and people have performed a service to humanity, by filling the desert with civilization, which no other nation, from the beginning of the world, has ever effected or approached to.

The only other considerable slave colony possessed by Britain, is that of Mauritius, a small island in the Indian Ocean, near Africa, conquered from the French. Its population, in 1832, consisted of 8844 whites, 15,851 free coloured people, and 76,774 slaves; total, 101,469. The quantity of cultivated land, 106,060 acres; the exports, under half a million; and imports, somewhat above that sum. The value of private property, in houses, merchandise, ships, &c., is about L.5,793,890, to which the planters add four and a quarter millions more, as the value of their negroes.

The Cape of Good Hope.—This African colony originally belonged to the Dutch, and most of the white population is originally from Holland. This is an important settlement, in respect of our Indian possessions, and might afford many useful resources for their defence, should an attack be meditated by any European power, all of whom are sensible that they could neither take nor hold India while we occupy the Cape. Emigration from Britain has not lately flowed in that direction, though the wages of mechanics are fully 6s. per day, with a fine climate and cheap provisions. The importance of having a British population gradually introduced into such a colony, cannot be easily appreciated, and should not be forgotten by government. The population of the Cape colony, in 1831, was 55,075 whites, 37,352 free coloured people, and 35,509 slaves; in all, 129,036. The land under cultivation is estimated at 400,000 acres. The value of private property of all kinds (except land) is L.3,870,000.

Britain has some other possessions in Africa, such as Sierra Leone, Senegal, Goree, and Fernando Po. Little national importance or value is attached to these settlements: their population altogether amounts to 1487 whites, and 23,153 free coloured people. Their exports from the United Kingdom are about half a million; the private property about L.800,000.

CONQUERED COUNTRIES—BRITISH INDIA.

This is by far the most extensive and important of all the foreign possessions of Britain. It has long been under the separate management of an incorporated company, who conducted both its trade, military defence, and civil government. Their charter has now expired, and in future they are not to interfere at all in commerce, while the business of government is still to rest with them under the superintendence of the ministries of this country.

India affords no direct revenue or tribute to England, as conquered countries are in general supposed to do. The only advantages which we derive from our occupation of these immense countries, are the undisputed possession of their trade, and the fortunes (sometimes very large) saved out of their salaries by British subjects who are appointed to discharge the duties of government. It is to the trade of the country, however, that we must look for any considerable and permanent advantage; and as this can only be made to increase by the cultivation of peace and order through the country, the interest of Britain becomes directly involved in maintaining henceforth the peace of India. The improvement which a few years of peace effects in these fertile countries, is astonishing: the population of a certain portion is supposed to have nearly doubled in the period of comparative peace from 1811 to 1830, being in the former year only forty-five and in the latter almost ninety millions. Till she came under British rule, India never enjoyed twenty years of peace and orderly government in all her former history. There are many faults and oppressions laid to the charge of the English in India, from which it is impossible to defend them. The taxes (which fall chiefly upon the *land* and the poor peasantry) are very oppressive, and are rendered more so by the unprincipled conduct of the natives who are employed to collect them. Justice also is administered in a foreign language (Persic), and the courts are so few that districts which are larger than Scotland have hardly one to each. Notwithstanding all this, the preservation of public order and of peace has conferred advantages on the country of the most inestimable kind.

The territorial extent of the British possessions in India is 514,190 square miles; the population, as far as it has been ascertained, 89,577,206; to which may be added eleven millions more for districts not included in the census. There are several states which are under British *protection*, though not directly governed by our establishments; these have an area of 614,610 square miles, and a population estimated at forty millions. The number of Europeans resident in India not in the public service was, in 1830, 2016. The amount of exports from Great Britain in 1829 was L.4,100,264; the imports to India, L.6,218,284. The total revenue of British India in the same year was L.22,753,041; the expense and charges of its government L.22,162,101. The following table will give some other particulars:—

	British India
Population	100,577,206
Dependent states	40,000,000
Troops, Native	187,057
—— European	36,604
Cultivated lands, acres . . .	134,200,000
Public or government property .	L.15,529 243
Estimate of private property, houses, stores, merchandise, &c. . .	L.800,000,000
Colonial shipping	L.593,000

In this estimate is not included Ceylon, a fertile island, and capable of great improvement, lying near the south point of India. It contains two millions and a half of acres, cultivated or capable of cultivation, and has a population of one million; the property on the island is estimated at four millions nearly; its exports to Britain L.202,668, and its imports from thence L.46,496.

The number of Christians in Calcutta, the capital of India, as reported in 1822, was 13,138; of whom 10,884 were half-castes, or children of native women by Europeans. These are now becoming a numerous and influential class; and as they are educated in a familiar knowledge of the English, as well as of some native languages, they are exceedingly useful; their total number in India in 1822 was about 20,000; the attornies generally belong to this class.

Britain has several other foreign possessions which are useful in a political or military view, though not of great extent—such are Gibraltar, Malta, the Ionian Islands, in the Mediterranean; and St Helena and Ascension on the African coast; Bermuda, in the North Atlantic.

EXTENT OF THE BRITISH EMPIRE.

The great extent of the British empire, and the immense space over which its parts are distributed, form one of the most remarkable phenomena ever exhibited to the world. She has dominions in North America, which are themselves larger than the Roman empire at its greatest extent. She possesses seventeen rich islands in the West Indies; the countries of Australia, which are themselves larger than all Europe, are entirely at her disposal, and will one day be occupied by a population speaking her language, and proud of their descent from her people. In India she has another large and populous empire, which is her own not only in right of conquest, but almost in right of creation; for it is the regular government, the suppression of internal wars, and the leisure for agriculture, which she has bestowed, that have rendered India what it now is, and what it never was formerly, either in respect to population or commerce. The population of these immense dominions, lying in four quarters of the globe, speaking different languages, and having interests entirely different from each other, look to Britain for protection, for the regulation of their laws and government, and for the continuance of a prosperity which the foreign possessions of no other country have ever enjoyed. The number of people in all the different British possessions may be recapitulated as follows:—

Extent and Population of the Empire.

	Population.	Sq. Miles.
British Islands . .	24,271,758	90,948
British dependencies in Europe	247,701	
North America, Canada, &c.	1,068,208	1,930,060
West Indies . . .	884,050	
Australian colonies . .	39,683	1,496,000
Islands of Ceylon & Mauritius	1,034,730	23,000
British possessions in Africa	154,046	91,000
East Indian empire .	89,577,206	826,650
	117,375,390	4,457,598

This table shows that Britain rules over a population about five times as numerous as her own, and over an extent of country fifty times as large as the whole British Islands.

WILL THE PROSPERITY OF BRITAIN CONTINUE?

The question is often asked, Will this singular people always remain as prosperous, and as much superior to the other nations of the world, as they now are? Will not their far-extended empire, made up of so many different elements, one day crumble in pieces? Will not their unrivalled manufacturing skill be one day surpassed, and driven from the market?—their points, on which their grandeur is founded, be given to others?—and their immense national wealth dissipated, in vain rivalship with more skilful competitors? We may answer this question by simply asking another—On what does the superiority of Britain rest? It is not on her large armies, or her powerful fleets. These, whatever they are, are supported and created by her resources, and do by no means give birth to them. It is her admirable form of government, the equality of her laws, the advantages of her insular situation, and, above all, the steady industry and perseverance of her people, which have given her her present superiority; and the same causes which have bestowed, will maintain it, till some other nation be found better governed, more secure from foreign invasion, furnished with better roads, canals, and harbours, &c., and with a people more industrious and skilful.

EDINBURGH: Published by W. and R. CHAMBERS, 19, Waterloo Place; also by ORR and SMITH, Paternoster Row, London; and W. CURRY, Jun. and Co. Sackville Street, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight.
Stereotyped by A. Kirkwood, Edinburgh, and printed by Bradbury and Evans (late T. Davison), Whitefriars, London.

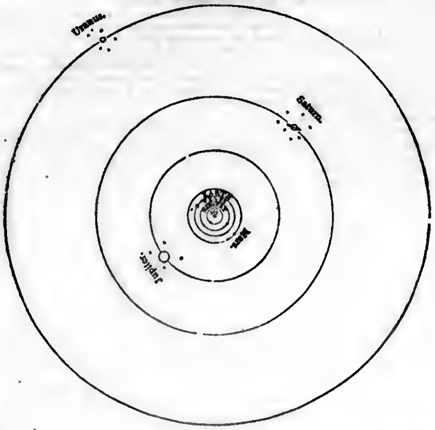
A POPULAR VIEW OF ASTRONOMY.

THE SOLAR SYSTEM.



SATURN.

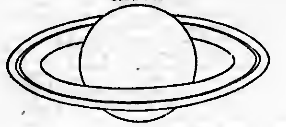


ILLUSTRATION OF THE SEASONS.

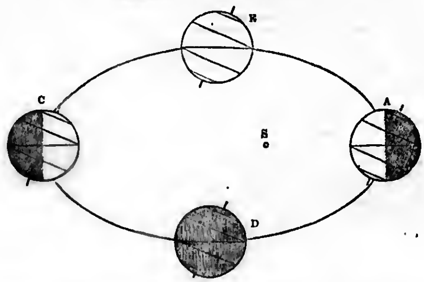

THE term Astronomy is derived from two Greek words, signifying the laws of the stars. This science, therefore, treats of the magnitudes, motions, periods, eclipses, and all other phenomena connected with the heavenly bodies. It is a sublime subject of investigation, perhaps the most sublime to which the human mind can turn its attention, as it undoubtedly was the earliest. The bare aspect of the starry firmament, as it appears to the naked eye, is calculated alike to excite curiosity and astonishment. But when it is examined by those subtile instruments made use of by astronomers, and we ascertain that the solid contents of the sun exceed those of our globe, gigantic as it appears to be, nearly a million and a half times, and to an absolute certainty that it is removed from us to the distance of ninety-five millions of miles, the imagination becomes overpowered, and seeks in vain to form any thing like an adequate idea of such magnitudes of matter and quantities of space. In proportion, however, as the magnificence and grandeur of the subject developes itself to a reflecting intellect, it more and more excites a desire to know something of its details. It is for the purpose of gratifying in some degree this desire, that we have undertaken to give such an account of astronomy as will be generally intelligible, and at a rate which will place an acquaintance with the subject within the reach of every one who wishes it. The algebraic formulæ in which the sublime truths of the science are usually disguised (of course with reference to the general reader), has hitherto kept back many from following out the study; and although we confess that the universe, in all its grandeur and magnificence, can only be displayed to the eye which contemplates it through the radiant atmosphere of a sublime geometry, still a very intelligible idea of the nature and laws of the heavenly bodies can be obtained without it. Others, again, are deterred from proceeding farther than the threshold of inquiry, from the natural vastness of the subject overawing them into a hopelessness of ever attaining to any thing like a definite understanding of it. But this is a very erroneous idea. The pyramids of Egypt present at a distance a very formidable appearance, and to reach their summits seems utterly impossible. But when we approach nearer to them, the illusion vanishes. We find them provided with a series of steps which reach from the bottom to the top, and render the ascent comparatively easy. This will be found to be the case with astronomy, and indeed every science. Moreover, by frequently contemplating vastness of size, we become familiar with it, and it soon ceases to overawe, almost to excite astonishment. The mind enlarges, as it were, its own dimensions to the measure of that which it surveys.

SYSTEM OF THE UNIVERSE.

The idea to which astronomers have arrived respecting the universe, is, that it consists of an infinite multitude of *suns*, like that in our own sky, round which revolve *planets* similar to our own globe, being in all probability the residences of *intelligent beings* akin in nature to ourselves. These suns are so distant from us, that the nearest of them appear as only little specks of light in the sky; while others are far beyond the reach of even the most powerful telescope. Astronomy chiefly concerns itself with the *system* connected with our own sun; which consists, so far as ascertained, of that luminary, as a fixed centre, eleven primary planets whirling at different distances around it, and eighteen secondary planets, which revolve round certain of the primary ones, as our moon revolves round the earth; besides which there are several eccentric bodies called comets, the nature and motions of which are not as yet well explained. The names of the planets, in the order of their nearness to the sun, are, Mercury, Venus, the Earth, Mars, Vesta, Juno, Ceres, Pallas, Jupiter, Saturn, Uranus. One moon attends upon the Earth, four upon Jupiter, seven upon Saturn, and six (it is supposed) upon Uranus.

Almost all this information is contrary to the notions of an uninstructed person, who sees, as he thinks, the earth firmly fixed, as a level plain, beneath his feet, while the sun, moon, planets, and stars, are all whirling around him. To reconcile the appearances of the system to its realities is our present office; and, in performing it, we shall first exhibit the general laws of matter and motion, as observed in that portion of the universe which is under our own immediate control.*

* Before proceeding farther, we must make mention of an awkwardness which will frequently occur, and from which there is no possibility of entirely extricating the subject. From the close and intricate manner in which the different branches of it are interwoven with each other, in order to prove the truth of one given point, we must occasionally take another for granted, the demonstration of which will appear afterwards in its own proper place.

PROPERTIES OF MATTER.

The essential properties of matter, or those characteristics of which it is impossible to deprive it, are, *extension, figure, divisibility, impenetrability, attraction*, and what is called inertia: it is only in the two latter that we are at present particularly interested. Motion is sometimes denominated a property of matter; but, strictly speaking, it is no more so than colour or sound. Motion, however, is an accidental quality, or one with which it can be endowed, and, as such, is intimately connected with the succeeding observations. The tendency of particles of matter, however minute, and of masses of matter of whatever kind and magnitude, to unite together, and form, as it were, one mass, is found to operate universally wherever man has been able to extend his scrutiny, either upon the objects of which the globe he inhabits is composed, or upon the celestial bodies which without number people space. Examples of it arrest our attention wherever we turn our eyes. We witness it in the globular form of the dew-drop which lies upon the flower, in the descent of a stone to the earth when thrown upwards, and, as we shall see, in the motion of the heavenly bodies. Like the puzzle of Columbus, this law appears very simple, and easily comprehended, when once shown to exist; notwithstanding this, however, its universality is a discovery of comparatively recent date.

GRAVITATION AND INERTIA.

The descent of a body to the earth, when deprived of support in the air, was witnessed from age to age, without the occurrence giving rise to any speculation as to the cause worth mentioning. But, in the seventeenth century, there sprung up a man, whose appearance may be compared to the rising of the brightest of those luminaries, for a correct knowledge of whose laws we are so much indebted to him. The fall of an apple before the eye of Newton, laid the foundation of that noble superstructure which the science of astronomy may be now entitled. The doctrine which he deduced from this every-day event, was, that all the heavenly bodies mutually attract each other. Might not, he all-wisely reasoned, the same power which draws the fruit to the ground be that which draws the moon to the earth, the earth to the sun; and, if so, may not the law be extended to all the heavenly bodies? But, before the reader can fully appreciate the important nature of this profound conjecture, and see the beauty of the theory which resulted therefrom, he must first be informed of another equally important principle which belongs to matter, namely, its inertia, or that innate disposition which it has to resist any change. Dr Arnott calls it figuratively an obstinacy, or stubbornness, and the words very well express the idea. By this we are to understand, that a body at rest would for ever remain so, if something external to itself did not set it in motion; and that, when once set in motion, it would continue for ever to move, if its course were not interrupted by some other power. If, for instance, we project a stone through the air, that stone, we are certain, would proceed onward through infinite space, and never come to rest, if it were not impeded by some cause or causes: the principal one is that power or property which the earth has of drawing every body towards its centre. We have not said any thing with regard to the resistance offered by the atmosphere to all bodies passing through it, because that is at present foreign to our subject. Here, then, we have two grand antagonist forces operating continually in nature—centrifugal force, from two Latin words, signifying *centre-fleeing*; and *centripetal* force, from two words in the same language, signifying *centre-seeking*. The former is the result of gravity, and the latter of inertia. In philosophical works, the power of gravitation is said to be directly, as the masses of matter; and inversely, as the squares of their distance from each other. Thus, the greater the quantity of matter in the attracting bodies, and the nearer they are to each other, the more is the force of the gravity exercised. It may be added, that the large body invariably draws the small one towards it; not that the latter is entirely destitute of attraction for the former—for it is mutual between them—but its strength depending upon the quantity of matter, the large body, being superior in this respect, attracts the small one to its centre; and this is the cause of a stone, or any other substance, falling to the earth.

CENTRIFUGAL AND CENTRIPETAL FORCE.

Centrifugal force, as may have been gathered from what we have already said, is that force with which a body, revolving round a centre or about another body, endeavours to recede from that centre or body. Thus, if a stone be whirled round at the end of a cord, it will stretch the cord by its tendency to fly, or centre-fleeing force; and if the velocity be sufficiently increased, the cord will at length be broken, and the stone will fly off at what is called a tangent. There are two kinds of centrifugal force, viz., that which is given to bodies moving round another body as a centre, usually called the projectile force, of which we have just given an example; and that which bodies acquire by revolving upon their own axis. We shall have to give an example of both in the diurnal and annual revolution of the earth. But in order that the reader may clearly understand this important law, we shall in the meanwhile illustrate it by a familiar one. We have seen, in the case of the stone whirled round by the string, that the greater the velocity, the greater the tendency of the stone to fly off, or the greater the centrifugal force. Suppose, then, any circular body, as a coach wheel, is placed so as to turn freely round upon an axis. Let small pieces of any tenacious substance, as clay, be attached to the spokes, beginning at the upper extremity, and gradually coming downwards to the opposite ends next the nave. If the wheel be now set in motion, these pieces of clay on the outside will fly off first, those below them next, and so on, in a progressive degree, to those situated undermost. This plainly arises from the centrifugal force being generated to a greater extent at the place where the motion is most rapid; and this depends upon the distance at which it is placed from the centre of the motion.

Centripetal force, which is a term of the same import with attraction and gravitation, is that force with which a moving body is perpetually urged towards a centre; and, instead of proceeding in a straight line (for all bodies when set in motion have a tendency to proceed in a rectilinear or straightforward path), is made to revolve in a curve.

GENERAL LAWS OF MOTION.

Motion is the act of shifting from one place to another; it is the opposite of remaining at rest; and the power which puts the body in movement is called *force*; and if the force act but momentarily, it is called force of percussion or impulse; if it act constantly, it is called accelerative force; if constantly and equally, it is called an uniform accelerative force. In that immortal work, Newton's Principia, are the three following laws, usually called Newton's laws of motion. He was not the first inventor of them, however, since they are found in a work of Des Cartes (another great astronomer), which was published before the Principia.

Law I. Every body perseveres in its state of rest, or uniform motion in a straight line, unless it is compelled to change that state by forces impressed thereon.

Law II. The alteration of motion, or the motion generated or destroyed in any body, is proportional to the force applied, and is made in the direction of that straight line in which the force acts.

Law III. To every action there is always opposed an equal reaction, or the mutual action of two bodies upon each other, are always equal, and directed to contrary points.

There are various laws of compound motion, upon which our limits will not permit us fully to enter. We can only refer the reader to that noblest production of the human mind, where they were first clearly propounded, Newton's Principia. Two of them, however, we shall notice, as indispensable to a full understanding of the subject. 1st, "That the curvilinear or circular motions of all the planets arise from the uniform projectile forces of bodies in straight lines, and the universal power of attraction which draws them off from these lines." 2d, If one body revolve round another, so as to vary its distance from the centre of motion, the projectile and centripetal forces must each be variable, and the path of the revolving body will differ from a circle.

The proof and illustration of these laws brings us at once to the subject of celestial motion. The earth being the planet in which we are most particularly interested, demands our first attention.

FIGURE AND MAGNITUDE OF THE EARTH.

The Earth is a globe measuring 24,856 miles in circumference. That such is its figure, is proved by many circumstances, but particularly these two—that its shadow, seen upon the moon during an eclipse, is circular, and many navigators have sailed round it. When we say its figure is that of a globe, we mean that it is nearly so. It measures 26 miles less in diameter between the north and south poles, than between any two points in the contrary direction. In order to demonstrate this in a more satisfactory manner, it will be necessary to take a view of the terrestrial globe, as it appears delineated by geographers.

THE TERRESTRIAL GLOBE.

Astronomers, for the convenience of their science, have supposed certain lines to pass through and around the globe. One passing through the centre, between north and south, is called the axis of the globe, from a Greek word signifying axle. The two extremities are called the poles, from the Greek word *polos*, signifying a pivot. A line girding the globe in the middle is styled the equator; all to the north and south of which are respectively called the northern and southern hemispheres. The circuit of the earth, both in its girth between east and west, and between north and south, is divided into 360 parts, called degrees. At the distance of twenty-three and a half nearly of these degrees from the equator, in both directions, are two parallel lines called the tropics, and at the same distance from each pole is a parallel circle, styled in the one case the arctic, and in the other the antarctic circle. The space between the tropics is called the torrid zone, because the sun, being always vertical in some part of that space, produces a greater degree of heat than what is felt elsewhere. The spaces between the tropics and the arctic and antarctic circles are called the temperate, and the spaces within these latter circles the frigid zones. Lastly, a line which cuts the equator obliquely, touching upon opposite points of the tropics, is called the ecliptic. The ecliptic and equator are called greater circles, because they cut the earth at the thickest parts; the others are called lesser circles. A series of lines drawn from pole to pole over the earth's surface (like the division lines of a peeled orange), and cutting the equator at right angles, are called meridians (from the Latin word *meridies*, mid-day) or lines of longitude. Every place upon the earth is supposed to have one of these passing through it, although only twenty-four are described upon the terrestrial globe. When any one of these is opposite the sun, it is then mid-day or twelve o'clock with all the places situated on that meridian, and, consequently, midnight with those on the opposite meridian on the other side of the earth. The exact situation of a place upon the earth's surface, or its latitude and longitude, is determined by means of these circles. They are all divided, as already hinted, into 360 parts, which parts are called *degrees*; these degrees again into 60 equal parts, called minutes; the minute into 60 others, called seconds, and so on. They are all indicated by certain signs placed behind the figure, and near the top of it—thus, 8° 5′ 7″ is eight degrees, five minutes, seven seconds. A degree is 60 geographical miles, or 69 English statute miles; a minute is the 60th part of that; and so on. The *latitude* of a place is its distance measured in that manner from the equator. If it lies north of that line, it is in north latitude; if south of it, in south latitude. There being only 360 degrees in the circumference of the earth, and the distance from the equator to either of the poles being only a fourth part of it, a place can never have more than 90° of north or south latitude. The longitude of a place is the distance of its meridian from another, which is called the first meridian. The first meridian is quite arbitrary, and it is a matter of indifference through what point we draw it, provided it be settled, and well known, which one we adopt, so as to prevent mistakes. Foreigners fixed upon the principal observatories of their respective countries. In Germany, the island of Ferro is generally adopted; in France, the observatory of Paris; and in England, that of Greenwich. Of course, longitude is reckoned either east or west of the first meridian; and as a meridian stretches from pole to pole, it must therefore contain 180 degrees. Some geographers, however, reckon longitude all the way round the globe. From the shape of the earth, which we have observed is flat at the poles, the degrees of longitude decrease as we approach these in either direction. The degrees of latitude, however, never vary in length, because the meridians on which they are reckoned are all of the same dimensions.

The other great circle called the ecliptic is divided into twelve parts, called signs, which bear the name of the constellations through which this circle passes in the heavens, as shall be afterwards explained. There are other smaller circles which run round the earth parallel to the equator; these are called parallels of latitude, because, being every where at the same distance from the equator, the latitude of every point contained in any one of them is the same. In this manner are artificial globes and maps of the world, and of particular countries, formed. A globe, or general map of the heavens, may also be constructed, and the stars laid down in their proper situations. This is called *uranography*, from two Greek words, *uranos*, the heavens, and *graphos*, to write; this subject will be afterwards treated of. In geography, it is necessary to take notice of the parts of the earth's surface occupied by sea and land, the configuration of the latter as broken into mountain and valley, and also the changes which its figure undergoes from various causes, such as the action of the sea on the land. But as these have been fully described in our "Account of the Globe," No. 6 of this work, we refer the reader to it.

MEASUREMENT OF DEGREES.

The earth, we have said, is of a spheroidal shape; that is, somewhat of an oval. This notion originated in observations on pendulum clocks, which being fitted to beat seconds in the latitudes of Paris and London, were found to move slower as they approached the equator, at which place it was found necessary to shorten the pendulum about one-eighth of an inch, to make the clock keep proper time. It is well known that the longer a pendulum is, the slower it moves; and heat, by expanding bodies every way, of course increases its length. The first conjecture was, that the error might be easily accounted for in this way, because the heat continually increases as we approach the equator, where it is greatest. However, Sir I. Newton, and Huygens, a celebrated Dutch mathematician, thought the difference much greater than could result from heat alone, and separately they discovered that the earth was flattened at the poles. It is weight which causes the pendulum to move; and if weight be decreased, it will oscillate slower. Under the head centrifugal force, we have explained the way in which gravitation is affected by it, or, what is the same thing, weight; the latter decreasing as the former increases. Suppose, then, the earth to revolve upon its axis, the farther bodies are removed from this centre of motion, the greater will be their tendency to fly off. Weight will thus vary at various situations of the earth's surface; in mountain elevations less than on low-lying ground; and at the equator more than the poles; and this has been proved to be the case by incontestible experiments.

But still this was not sufficient to account for the difference; and Sir I. Newton clearly demonstrated, that the distance from the centre of the earth to the equator must be greater than to either of the poles; in other words, that the earth is heightened at the equator, and flattened at the poles. He finally arrived at the conclusion, that "the diameter of the earth at the equator, is, to its diameter from pole to pole, as 230 to 229."

It is evident that the measurement of a degree of latitude at various parts of the earth's surface, was of essential importance in determining its exact figure and dimensions. The king of France, at his own expense, ordered the measurement of two degrees, one as near the pole as possible, and the other at the equatorial regions. The result confirmed the calculations of Newton. Since that time, degrees have been frequently measured, and calculations made regarding the earth's figure and magnitude; and it has been found that its equatorial diameter is 7924 miles, and its polar diameter 7898 miles; the mean being 7916, and the difference twenty-six miles. What its exact shape is, has never been accurately demonstrated; and all that can be gathered from works upon the subject, is, that the earth is *something more flat at the poles than at the equator*. The flattening is accounted for by supposing that it was originally in a fluid state, as the spheroidal form is that which a fluid body would take in revolving upon an axis.

WEIGHT OF BODIES IN DIFFERENT SITUATIONS.

Weight, we have seen, depends on gravity, and gravity is counteracted by centrifugal force. Bodies, then, should weigh less upon the tops of mountains than in places lying near the level of the sea. This has been proved to be the case by experiment. But let no erroneous impression be entertained upon this point. Bodies are relatively of the same weight on all parts of the earth's surface. A pound of tea, being weighed at the equator and at the poles, on the sea-shore and on the top of Chimborazzo, is neither more nor less than *one* pound of tea; for it is evident that the pound weight undergoes the same change from heaviness to lightness as the substance that is weighed; so that they remain always of the same weight in relation to each other. If the earth, then, revolves upon its axis, the elevated portions of its surface will thus move round with the greatest velocity; but there is no occasion to be alarmed in scaling a mountain of any height; for even at the equator, where the centrifugal force is greatest, that of gravity is still 288 times greater.

From a calculation of the sun's magnitude, and the quantity of matter which it contains, it is proved that a mass which weighs 170 lbs. on our earth, would there weigh 4743 lbs. Man, therefore, as he is constituted, could not possibly exist on a globe so large as the sun, because his strength would be inadequate to bear up under the force of attraction exercised over his body, which would accordingly be crushed to pieces. It is incompatible with our limits to enter farther into this interesting subject; but we will have occasion afterwards to notice facts connected with it.

In fine, we are to consider attraction as universally exercising an influence, wherever matter is to be found, at once over the minutest particles composing the masses of our own earth, and over the most gigantic globe in the universe.

DIURNAL MOTION OF THE EARTH.

The motion of the earth was denied by the ancients, and the movement of the heavenly bodies was adopted, and generally entertained, until the beginning of the sixteenth century, when Copernicus discovered the diurnal and annual rotation of the earth. His theory is now universally assumed to be true, and goes by the name of the Copernican system. Succeeding astronomers have produced such a number of forcible arguments in favour of its truth, that every impartial inquirer must give his assent to it. The earth, then, has two principal motions—a daily one round its own axis, and a yearly one round the sun. In reference to the slow movement of a pendulum at the equator, we have already given one strong argument in favour of the earth's diurnal motion. There are a number of others, many of which, however, cannot be demonstrated without using mathematical symbols, which are incompatible with the nature of this treatise; but still a few remain that are independent of such proof, and which are calculated to carry conviction to the mind.

One very striking argument in favour of the earth's moving, is, that if it were not the case, almost every star must move with a velocity different from the rest, for which difference of velocities not the shadow of reason can be assigned. Indeed, the supposition of millions of these bodies revolving round an imaginary line with various velocities, yet all moving through their circles in precisely the same time, so as to account for appearances, is one that we cannot entertain for a moment, when we consider that all is satisfactorily accounted for, and the observed laws of matter and of motion strictly fulfilled, by simply granting the rotation of the earth upon its axis. The latter hypothesis is greatly strengthened by the observance of a like motion in the planets, and also by their shape. For instance, Jupiter is found to be flattened at the poles in the same way as our earth, and the flattening in both cases no doubt arises from the same cause—namely, the centrifugal force resulting from rotatory motion upon their axes. Moreover, it has been proved that a stone dropt from a considerable elevation falls a little eastward of the perpendicular, precisely what would happen if the earth turned upon its axis from west to east. In order to prove this, we have only to recall to the reader's recollection the observations made upon centrifugal force. The top of any building—say St Michael's Tower, in Hamburgh, where a German philosopher performed the experiment—moves more rapidly round than the base; hence there is greater centrifugal force there. Now, a ball of, say a pound weight, let fall from it, having a greater velocity at the time it was dropt than the base of the tower, must move a little more in the direction in which the earth moves, than a plumb-line which is made to strike the foot of the tower; because the plumb-line being lower down, has less impulse eastward. On the other hand, a ball shot perpendicularly into the air returns to the exact spot from whence it departed; because, however high it may have ascended, it does not on that account receive any additional impulse eastward, but only retains that which it possessed when fired off.* Many additional reasons might be given, some of which will appear in the sequel, but these are quite decisive of the point. It is no argument against the earth's diurnal motion that we do not feel it; for it must be familiar to every one who has been carried along in the cabin of a ship in smooth water, that neither his own nor the ship's motion was perceived. Neither does the earth's motion cause bodies to fall from it, or rather scatter them about by its centrifugal force, because they are held firm to the earth by the power of attraction. Under the head "Trade-Winds" there will be found a most convincing proof, if any were wanting, of the earth's rotatory motion.

We are, then, fully entitled to conclude that the earth has a diurnal motion upon its axis, from which evidently results the vicissitude of day and night. This motion, which is from west to east, accounts for the apparent diurnal motion of all the heavenly bodies; hence they seem to rise and set by turns according to their various situations.

CIVIL AND SIDERAL DAY.

The revolution is performed in twenty-three hours fifty-six minutes four seconds; and this is what is called a sideral day, because the earth is then in the same relation to the stars as it was the day before. The fixed stars are so immensely distant from our earth, that its whole orbit is in respect to them but a point; so that no sensible difference is produced by its revolving round the sun. But the sun being a great deal nearer us, any movement made by the earth can be appreciated. The time which elapses from the sun's being on the meridian of any place to its returning to the same spot next day, is exactly twenty-four hours, and is called an astronomical day. The natural day would always be the same as the sideral day, if the earth had no other motion than that upon its axis. But in the same time that it has performed one of its daily revolutions eastward, it has also advanced about a degree westward, or in the opposite direction, which is the course it takes round the sun; so that, before the sun can shine exactly upon the same meridian, the earth must make up as it were its lee-way, and this it does in three minutes fifty-six seconds, the difference of time between a natural and sideral day. If the earth, then, had no other than its diurnal motion, we should have 366 days in the year.

DAY AND NIGHT.

From the revolution of the earth upon its axis results the vicissitude of day and night. At noon-day, or twelve o'clock, we come to a position where the sun is at its highest, or the meridian altitude; and of course this point varies in every situation on the earth's surface. All those parts of the earth to the east of us have this position of the sun earlier than us; while, on the contrary, the parts to the west of us have it later. Thus, the hour of the day varies in every part of the globe where the longitude or meridian line is different. When it is twelve o'clock noon with us in any particular part of Britain, it will be twelve o'clock at midnight in a corresponding point on the opposite side of the globe, near New South Wales; and the intermediate hours, sooner or later, will all lie in the countries between these two points, exactly according to their position or degrees of longitude. Although the earth's daily revolution is performed without any perceptible motion by us, yet any place at the equator is carried along at the prodigious rate of 1000 miles per hour; and we do not feel it, because every thing around us in the earth and the air is carried along at the same time. This motion, however, has an effect on the atmosphere, and influences the direction of the trade-winds, as we shall afterwards find. For the appearance of twilight, we are principally indebted to the light reflected by the atmosphere; as, were it not for this, the moment the sun went below the horizon, or edge of the circle of the earth, we would have complete darkness. On the contrary, while the sun is sinking to a certain distance below the horizon, his rays are projected to a portion of the air visible to us, from whence light is reflected to the earth; and all that gorgeous array of many-coloured clouds results from the refraction of the rays of light.

As we have mentioned the reflective power of the atmosphere, we may also mention another singular and important property which it has, namely, the power of refraction.

THE ATMOSPHERE, AND REFRACTION OF LIGHT.

The atmosphere is that invisible fluid called air, which surrounds the earth all round to the height of between forty and fifty miles. This aërial ocean, which has the sea and land for its bed, is considered to be of nearly equal thickness at all parts of the earth's surface, but of very unequal density, the lower portions being much more compact, and containing a great deal more matter, bulk for bulk, than those higher up. This arises from the pressure which the under portions sustain from those superimposed upon them. Clouds (which are just thick mists, or particles of vapour drawn together by attraction) float in this thin envelope of our globe, just as mud does in water; and the greatest height to which they rise is about ten miles. The atmosphere is subject to great fluctuations, of the nature of waves similar to those of the ocean. These are well known under the name of winds, for which see below. One property which air possesses enters as a provision to be allowed for into the nicest calculations of astronomy; that is, its power of *refracting the rays of light*, or bending them from the straightforward course which they would otherwise take. When a ray of light proceeding from the sun, moon, or a star, enters the upper regions of the air, it does not descend in a straight line to the eye of the spectator, but takes an oblique path. It is a law of optics, that light passing from a rare to a dense fluid or substance, such as water or oil, and called technically a medium, is bent to the denser medium. Now, there being something approaching to a vacuum, that is, a place destitute of any matter whatever, beyond the atmospheric region, when the beam of light penetrates the comparatively dense medium of the air, it is of course twisted from its rectilinear course to one *nearer a perpendicular to the zenith of the observer.* Hence, all the heavenly bodies appear higher than they really are; and the nearer they are to the horizon, the greater will be the refraction or difference between their apparent and true altitudes. At noon the refraction is the least. The sun and the moon appear of an oval figure sometimes near the horizon, by reason of refraction, for the under side being more refracted or raised than the upper, the vertical diameter will be less than the horizontal one, which remains unaltered. This, however, is not the reason of the dilated size which the sun and moon assume near the horizon; this is a mere illusion of the judgment, arising from the proximity of these bodies to terrestrial objects, with which they are thus brought into close comparison. Insulated in the boundless expanse of sky, we have no means of valuing their magnitudes, which are hence underrated.

TRADE-WINDS.

Winds in general are caused by the heat of the sun expanding the air, which becoming thus specifically lighter, rises upwards in a current, while colder air rushes in to supply the place which it has left. But two other causes operate in the formation of the trade-winds—the unequal exposure of the earth's surface to the sun's rays, by which it is continually more heated in one place than at others, and also the rotation of the earth from west to east. The sun is constantly vertical over some part of the tropics, so that the earth in that quarter has a temperature much above what obtains in those regions to the north or south of it nearer the poles. Hence two currents of air are continually flowing to and from either of the latter, over and above which is the rarified air of the equator, and are below the cold and dense air of the poles, which rushes in, according to the laws of hydrostatics, to occupy the comparative void which has been left; thus a perpetual circulation is kept up. It is self-evident, that, if there be no disturbing cause, these winds will be simply northerly and southerly; but this is not the case—they are permanently *north-easterly* and *south-easterly* winds. The cause is to be sought for in the rotation of the earth. On that point we explained that the equatorial regions were whirled round with greater velocity than the polar. Now, as any thing upon the surface of the earth just has the same motion as the earth at any place where the object is situated, columns of air setting in from the north and south poles towards the equator, will come into contact with regions travelling a great deal faster than themselves; and unable all at once to acquire this new velocity, they are left behind the general movement, or rather they are partially impelled to follow a new direction, and from being south and north become north-east and south-east winds. Their easterly tendency diminishes as they approach the equator, where it is lost altogether; and, besides, the two currents there meet and mutually destroy each other. The result is the production of two great tropical belts: in the northern one a north-easterly, and the southern a south-easterly wind, always prevails, while between them there is an equatorial belt, where the winds are comparatively free from any particular tendency like the others. The south-west and westerly gales which prevail in our latitudes, and the universally westerly direction of the North Atlantic winds, are due to the heated air which flows from the equator. It is evident that the drag which the polar winds hang upon the earth and atmosphere will have a tendency to retard the motion of the former upon its axis, but, on the other hand, the upper winds which blow from the equator have a tendency to accelerate the earth's rotation, and thus an equilibrium is maintained. What wisdom, what design, is apparent in those things, which at first would appear only irregularities of nature! In fine, we may remark, that the direction of the trade-winds affords another proof of the diurnal motion of the globe.

ANNUAL MOTION OF THE EARTH.

The annual motion of the earth will be readily admitted after its daily rotation has been granted; for either the earth moves round the sun in a year, or else the sun revolves round the earth in that time—a supposition which is at total variance with the laws of matter and motion. To conceive of the sun as revolving round the earth, would be to suppose that the lesser body had the greater power of gravity, which is contrary to nature and fact. Attraction is invariably in proportion to the quantity of matter; and as the sun very greatly exceeds the earth in size, it must follow, therefore, if there be any consistency in the laws of nature, that the earth moves round the sun. It is also evident that its motion is from west to east; for if the sun be observed to rise with any fixed star near the ecliptic, or line in which the earth revolves round the sun, in a few days it will appear to the eastward of that star, and in the course of a year it will arrive at the same star again. But a direct proof of the orbital motion of the earth is afforded by the aberration of light, for which see below.

The earth is at a mean distance of ninety-five millions of miles from the sun, and performs its revolution round him in a sideral year, which is 365 days 6 hours 9 minutes 11 seconds, mean solar time. The earth travels at the rate of 68,000 miles per hour. Besides this motion, which is common to all the inhabitants of the earth, those at the equator are carried 1042 miles every hour by the diurnal revolution of the earth upon its axis, while those in the parallel of London are carried only about 644 miles per hour. The earth's orbit is not a circle, but an ellipse, the sun being situated in one of the foci, that is not in the centre, but near one of the ends of the oval-shaped figure, a discovery which was made by Kepler, a celebrated German astronomer. Neither does the earth go round the sun in an upright or perpendicular position; its axis is slanting or oblique. The degree of obliquity is 23° 28′. The points at which the ecliptic cuts the equator, are called nodes: the period of time at which it does this, the equinoxes (a Latin term, signifying equal nights, for the days and nights are then of equal length all over the world). In consequence of this obliquity, during

* The fact is, that it would fall a little to the westward, and still be a proof of the earth's diurnal motion.

one part of the earth's course the north pole is turned towards the sun, and the south is dark; and during another part of its course, the south pole is turned to the sun, and the north is dark; and this is the cause of the difference of seasons, which will be better understood by referring to the figure in our first page, entitled, "Illustration of the Seasons."

THE SEASONS.

Let S represent the sun, and A B C D the earth at various places of its annual circuit; when the earth is at B or D, these are the periods of the equinox, when the line of the equator intersects or cuts through the line of the ecliptic. At this period, one-half of the globe is illuminated from pole to pole, or there is over all the earth an equal day and night of twelve hours. But when the earth has proceeded to A, the pole or axis still keeping the same position, or pointing to one particular place in the starry heavens, it will be turned more directly from the sun; a greater proportion of his rays will shine on any particular spot of the northern half of the globe, and the period of day, or sunlight, will exceed that of darkness by the proportion of the light and shade parted in the circle of the earth. It will be observed, also, that within the circle of the north pole, the sun will shine continually as the earth revolves on its axis, or, in short, to the inhabitants of that part of the globe the sun will never set for several months. When the earth has proceeded on to D, one-half of its annual course is finished, or this is the spring equinox, or equal day and night. At C, again, the earth has arrived at our longest day in summer, when the axis is turned to the sun, and the regions around the pole are in the light for a greater period, while darkness, or night, prevails for a less. It will be seen, too, that now the pole and circle around it revolve in perpetual light; or to the inhabitants of that region, the sun never sets for some months, but they have one continued and uninterrupted day. At the other, or south pole, the same changes take place, only matters are reversed—there it is summer while we have winter, and the winter of the north pole is the summer of the south—in the middle regions of the earth, or around the equator, the sun's place does not suffer a very great change; and, accordingly, there the heat is nearly of the same intensity all the year through; and the length of their days and nights is nearly equal, or nearly the same as at the periods of the equinoxes. But the orbit in which the earth travels round the sun is not an exact circle; it is, as we have already mentioned, an ellipse, and the sun is placed near one end of it, as at the small circle and letter S. In consequence of this circumstance, the sun is much nearer us at one period of the year than another, and this happens in our winter; accordingly, the sun appears about one-thirtieth part larger in January than in June. But in proportion as the earth approaches in her orbit the sun, her motion is quickened, and she passes over the winter half year in nearly eight days' less time than the summer. It is principally from this circumstance, as well as the shorter period of the day, that although the sun be nearer us in winter, and, consequently, his power of imparting heat greater, yet the actual quantity imparted is, on the whole, much less in the one season than the other. We have said that the north pole of the earth always points to a particular spot in the heavens; this is not, strictly speaking, correct; the pole or axis makes a circle round the centre of the axis of the ecliptic in a long period of years, and it is this motion that gives rise to the precession of the equinoxes, which will be afterwards described under that title.

A very natural question here arises, how it happens that, when the earth is at A in its perihelion, or nearest point to the sun, it should not be fairly drawn into collision with it by the force of gravity? for, in that situation, it is more powerfully attracted to the great centre of motion than in any other. Startling as this may appear to the uninitiated reader, it admits of the happiest explanation. We have already shown, that, as the earth approaches the sun, her motion is quickened, consequently her *centrifugal force* is increased; and this, invariably acting in opposition to attraction, or *centripetal force*, compensates for the increased tendency of the earth to be drawn to the sun; nay, more, it overcomes it for the time being. It does not, however, overcome it so much as to carry the planet off at a tangent, but just to an extent sufficient to take it a little farther away from the sun, as it appears at B. It is by the unerring operation of the same laws, that the earth, at its aphelion in the opposite extremity of the ellipse, instead of going beyond the sun's attraction altogether, is made to bend in its course, and move round it in a curve; for, although gravity be there least, centrifugal is also there least. Thus, these two grand powers of nature go on increasing and decreasing at equal rates, and acting continually as mutual checks upon each other. Indeed, the very cause which augments the one, increases the other likewise, so that error or derangement is impossible. Perhaps there is nothing in the whole system of the universe so grand yet so simple, so admirable in design, and so efficient in operation, as this law. We may observe, that the earth is nearer the sun when in perihelion, than in aphelion, by somewhat more than three millions of miles.

ABERRATION OF LIGHT.

Although the most convincing proof of the earth's orbital motion is not to be found in any circumstance of which the senses can take immediate cognisance, but is afforded by the full developement of the planetary system, there is, however, one direct proof of it in a phenomenon discovered by Bradley, an illustrious astronomer. It is called the aberration of light, and is manifested by a small difference between the apparent and true places of a star, occasioned by the motion of light combined with that of the earth in its orbit. Vision, it is well known, arises from rays of light proceeding from any object, and entering the eye; and we see the object in the direction in which the rays have come. If both the body giving forth light and that one which receives it be at rest, the former will be seen in its true place, at least in so far as aberration is concerned; but let either of the bodies move, and this will not be the case. In order to render this plain, suppose a shower of hail to fall perpendicularly upon a number of tubes—say the pipes of an organ; if the organ remain stationary, the hailstones will descend sheer from the top to the bottom without any deviation right or left; but move the organ in any direction, and they will strike the side opposite to the direction in which the motion is made. Now, it is just in this way that the eye misses the perpendicular ray, and, meeting an oblique one, receives an impression that the star lies in that direction. The object thus appears displaced, and the amount of displacement is *aberration*. The earth travels at the rate of about nineteen miles per second, and therefore is every instant changing its direction. Time is also occupied by light in traversing space, which it does at the amazing rate of 192,000 miles per second; so that also requires to be calculated for by astronomers. The effect of aberration is to make a star apparently describe a small ellipse in the heavens, in the centre of which it would be seen if the earth were motionless. The reader must carefully distinguish between aberration and refraction; their effects are the same—namely, to displace the ray-projecting object—but they proceed from very different causes. Besides these corrections which astronomers have to make in their calculations, there is another, resulting from what is called parallax, which may be as well introduced in this place.

PARALLAX.

The word parallax, in its general signification, denotes change of place; but in astronomical books it has a conventional meaning, and implies the difference of apparent positions of any heavenly luminary when viewed from the surface of the earth and from its centre. The centre of the earth is the general station to which all astronomical observations are referred; the situation of a heavenly body, observed from the surface of the earth, is called the apparent place; and that at which it would be seen from the imaginary place of observation at the centre of the earth, the true or mean place. Hence the altitudes of the heavenly bodies are depressed by parallax, which is greatest at the horizon, and decreases as the altitude of the object increases. This may be rendered very plain, by supposing that two persons placed individually at the end of a straight line, look at a candle removed at, say, 100 yards' distance from them. It is evident that the burning body will appear to be projected upon the wall of an apartment, or any other background, at very different positions to each of the spectators. The angle which this difference of position makes, is similar to parallax. The farther they remove from the light, allowing them still to remain at the same distance from each other, the more obtuse the angle would become, and the less the parallax. Thus, the fixed stars, being so far removed from us, when viewed from any two positions upon the earth's surface, are seen at the same place upon the celestial sphere, and hence have no perceptible parallax. It is different, however, with the luminaries belonging to our system, and by this means astronomers have been enabled to estimate the quantity of space which separates us from them. For a complete account of the means by which this is accomplished, we must refer the reader to more elaborate treatises than the present. A general and correct enough idea of it may be formed from the familiar example we have given. In the same manner, suppose two observers, one in the northern the other in the southern hemisphere, at stations on the same meridian, observe on the same day the meridian altitudes of the sun's centre. "Having thence derived the apparent zenith distances," says Sir J. Herschel, whose language would be deprived of clearness were it abridged, "and cleared them of the effects of refraction, if the distance of the sun were equal to that of the fixed stars, the sum of the zenith distances thus found would be precisely equal to the sum of the latitudes north and south of the places of observation; for the sum in question would then be equal to the meridianal distance of the stations across the equator. But the effect of the parallax being in both cases to increase the apparent zenith distances, their observed sum will be greater than the sum of the latitudes by the whole amount of the two parallaxes. This angle, then, is obtained by subducting the sum of the latitudes from that of the zenith distance; and this once determined, the horizontal parallax is easily found, by dividing the angle so determined by the sum of the signs of the two latitudes." It may be observed, that the angles are determined by means of very nice instruments. The parallax thus obtained is called the *daily* or geocentric, in contradistinction to the annual or heliocentric, by which, in general, is understood the difference of place of a heavenly body, as seen from the earth and from the sun; in particular, however, it denotes the angle formed by two lines from the ends of the diameter of the earth's orbit to a fixed star, which, as we have already observed, from the immense distance of the latter, is inappreciable. Some idea of the importance of parallax may be obtained from the fact, that before the sun's was determined, the distance of that luminary from us was not estimated at within thirteen millions of miles of its true value. Its parallax is a very minute quantity of course, only 8″ 6.

OF SOLAR, SIDERAL, AND ANOMALISTIC YEARS.

There are three different periods at which the sun may, in different senses, be said to return to the same position—when he returns to the same equinox at which he was before; when he returns to the same point in his orbit, or the ecliptic; and when, being in perigee (least distance from the earth), or apogee (farthest distance from the earth), he comes back to either again; or, which is the same thing, when, having been at a given distance from any of these points, he returns to the same point with respect to them. Each of these may be said to be a completion of the revolution of the sun (strictly speaking, it is a revolution of our own earth round him), and a revolution thus performed is called *a year*. The first and shortest is the equinoctial, solar, or tropical year; for his time of returning from tropic to tropic, they being situations holding the same relation to the equinox for the time being, is obviously the same as that from equinox to equinox. The value of this year is 365 days 5 hours 49 minutes nearly. But although the earth has thus returned to the same equinox, it has not made the entire circuit of its orbit, but must travel a little farther to arrive at the same point it was in a year before. This arises from a backward movement of the equinoctial point. (See "Precession of the Equinoxes.") The second is the sideral year, which consists, as we said before, of 365 days 6 hours 9 minutes 9 seconds 6, reckoned in mean solar time, or *a day more*, reckoned in sideral time. Here, then, there is a remarkable difference between solar and sideral time, which requires explanation. If the reader will recollect what was said with regard to a solar and sideral *day*, the discrepancy between the times of the years will become apparent. In the course of twelve months, all the little daily deficiencies, as it were, amount to twenty-four hours, which constitutes the difference between the two years. The sun's apparent *annual* motion among the stars is performed contrary to the apparent *diurnal* motion of the sun and stars; hence the stars gain every day three minutes fifty-six seconds on the sun, which makes them rise that portion of time earlier every day. In the course of a year, the sun will fall behind the stars a whole circumference of the heavens, or one revolution, which deficiency he must make up to complete the number of days in a year. It is evident, then, that the sun apparently, or the earth really, turns 366 times round upon its axis; and had it no other motion, there would be as many days in a year. After the earth or sun has completed a sideral year, before it can finish an anomalistic year it must describe a farther arc of 11″ 6 to arrive at its original position in perihelion, the latter having moved forward to that amount. In so doing it occupies 4′ 39″ 7, which must be added to the sideral period, making the anomalistic year 365 days 6 hours 13 minutes 49 seconds 3 in length. All these periods have their uses in astronomy, but the one in which mankind are most particularly interested is the tropical year, or that on which the seasons depend, and which is a compound phenomenon depending chiefly and directly on the annual revolution of the earth round the sun, but subordinately also, and indirectly on its rotation round its own axis.

MEASUREMENT OF TIME.

Although the sideral day, from its uniformity, is well adapted for astronomical purposes, yet it is scarcely sufficiently marked for the ordinary wants of life. No person but an astronomer ever attends to the culmination of a star; on this account, the diurnal return of the sun to the same meridian has been universally adopted as the measure of time; and this is called a *civil day*. Most nations reckon the beginning of their day from midnight, but astronomers count from noon to noon. The day thus determined is called the astronomical or solar day, and, being regulated by the true motion of the sun, the time which is measured by it is called true or apparent time. Two causes conspire to render astronomical days unequal: first, the variable velocity of the sun in his orbit, and, second, the obliquity of the ecliptic. A mean astronomical day, which is independent of any causes of inequality, has been obtained by astronomers introducing into the system two imaginary suns. These two fictitious bodies are supposed to move uniformly, the first in the ecliptic, the second in the equator; and as the circles are both equal, the actual motion of each of the bodies is equal. To those desirous of studying this part of the subject, we would recommend them to peruse the article *Astronomy* in the new edition of the Encyclopædia Britannica, page 778, where it is well illustrated. The correction or equation, by which apparent time is reduced to mean time, is technically called the *equation of time*. There are only four days in the year when the apparent and mean time are the same, and the equator of time nothing. In the interval between the first and second of these, that is, December 24th and April 15th, and, again, in that between the third and fourth, that is, June 15th and September 1st, the apparent is always later than the mean time, or the clock is before the sun; in the other intervals which complete the year, the reverse is the case, and the clock is after the sun. The greatest difference between solar and true time amounts to between fifteen and sixteen minutes. Tables of equation are constructed for the purpose of correcting the differences.

With regard to terrestrial time-keepers, we have clocks, chronometers, clepsydras, and hour-glasses; the two former are now all that are in use in astronomy. The pendulum clock and balance-watch has been so improved and refined, as to constitute it emphatically a chronometer (from two Greek words, signifying to measure time). To such a degree of perfection have these instruments now been brought, that they do not vary more than a few tenths of a second in twenty-four hours. But the best of these must be corrected by those means which nature has afforded. The fractional parts of time only are measured by clocks; nature counts out for us whole days; and hence, astronomers correct the errors of their clocks, by the transit (or passage over the meridian of an observer) of a bright fixed star, which is always equal. The subject of dialling we have not limits to enter upon.

THE CALENDAR.

It is obviously necessary, for many purposes, not only of chronology and history, but even of every-day convenience, to have the means of dividing time into definite periods of considerable length. The most obvious period to adopt is that which comprehends the natural phenomena of the seasons; seed-time and harvest, summer and winter; and all these are included in an *equinoctial year*. It is the position of the sun, with regard to the equinox, which determines the character of the season; and in his passage through his whole round, from one equinox to another, he occasions the vicissitudes of the seasons, no matter what time he takes to it. This revolution, therefore, has been adopted as the unite of long duration by all civilised nations, and is termed emphatically *a year*, or *the civil year*. It is evident that great inconvenience would result from the year not commencing with the beginning of a day, which, from there being odd hours in the year, would happen, if the length of the civil year were not fixed in some definite manner. In this consists the adjustment of the calendar; and many attempts have been made, at different times and in various countries, to establish an accurate and complete one. It is unnecessary to enumerate here all those which belong to distant ages; but there is one we must notice, famous alike by the celebrity of the individual under whose auspices it was made, and as being, besides, the groundwork of the adjustment now used. The Roman calendar had fallen into great confusion, there being no regular method of correcting it, until the time of Julius Cæsar, who, perceiving that the year was longer than 365 days by nearly six hours per annum, added a day every fourth year to the calendar. It is evident, however, that this was too much, because the difference is only five hours, forty-eight minutes, and odd seconds; so that, multiplying these by four, they do not make a day in four years. The error began to accumulate to such an extent, that the derangement of the seasons was perceived by every one. Accordingly, Pope Gregory the Thirteenth, in 1582, reformed the calendar, by cutting out ten days, and calling the 5th of October the 15th. It was also provided, that, in future, the intercalary day should at certain intervals be omitted. As the excess is about one day in 130 years, it amounts to rather more than three days in 400 years; and, accordingly, it was ordered that the centenary years, 1700, 1800, and 1900, though according to the Julian correction bissextiles, should not be considered leap years; the intercalary day should not be inserted; but inserted in the year 2000, not inserted in 2100, 2200, and 2300, and so on, for succeeding centuries. This is called the *Gregorian correction of the calendar*, and the degree of its accuracy may be easily estimated, in the same way as we have estimated that of the Julian correction; the latter, we found, would introduce an error of a day in about 130 years; the Gregorian will introduce an error of a day in 4000 or 5000 years. The new style was introduced into England on the 14th September 1752, which would have been called, according to the old style, the 3d. The revolutions of the sun and moon are not very easily reduced to proper measurement, the solar year containing twelve lunations, and almost eleven days. But a philosopher discovered, more than two thousand years ago, that nineteen solar years contain exactly two hundred and thirty-five lunations; and this determination is so accurate, that it makes the lunar month only about half a minute too long. Hence it happens, that, in every period of nineteen years, the moon's age is the same on the same day of the year.

URANOGRAPHY.

It is well known, that, besides terrestrial, there are celestial globes, in which the heavens have been maped out, and drawn with lines, to which the distances of stars, clusters of stars, &c., are referred, in the same way as towns and continents upon the earth. The firmament has its north and south poles, and its equator, in the same way as the earth. Indeed, strictly speaking, the earth owes these to the heavens; for it is by observations made on the celestial sphere, that we are enabled to delineate the globe as we do.

The celestial sphere is divided into the same number of degrees as the terrestrial. The celestial poles correspond to those parts of the heavens to which the terrestrial poles always point. The celestial equator corresponds also to the terrestrial, and is, like it, every where ninety degrees distant from the poles. The equator of the earth thus lies directly under that of the heavens; the ecliptic does exactly the same, and cuts the former also at an angle of twenty-three degrees twenty-eight minutes. Instead, however, of a series of zones, we have groups of stars called constellations, which have received the names of men and animals, for the convenience of description and reference. There are also great natural districts in the heavens, such as the milky way, and remarkable regions, such as the zodiac, which may be compared to the continents of our earth.

The place where the ecliptic cuts the equator at the vernal equinox, is called the first point of Aries; and from this point the distance of all celestial bodies eastward and westward of it is measured. This is called their *right ascension*, and corresponds to the terrestrial longitude. Their latitude is determined by their distance from the equator, and is called their *declination*. The declination of the sun or other heavenly body is therefore called north or south declination, according to its proximity to the north or south pole of the heavens. Hence it follows, that when the sun's declination is 10° north, he is vertical at a place whose latitude is 10° north. But the right ascensions do not so correspond with the longitudes, simply because the first point of the constellation Aries does not correspond to the first meridian, Greenwich; and because the longitudes are not measured quite round as the right ascensions are. The sun, which is always in the ecliptic, has of course no latitude, but he passes through all the degrees of longitude in a year. When any other celestial object has the same longitude as the sun, he is said to be in *conjunction* with him; and when the difference of longitude amounts to 180°, half the circle of the heavens, it is said to be in *opposition* to him. Both these terms are comprehended in that of *syzygy*, which, when applied to any celestial object, means that it is either in conjunction or opposition to him. What is called an *equinoctial colure*, is a great circle supposed to be drawn through the pole of the ecliptic and the points where it intersects the equator. The *solstitial colure* is a similar circle, which passes through the solstitial points at right angles to it. The former colure is a secondary to the ecliptic, and the latter a secondary to both it and the equator. The equinoctial points are Aries and Libra, where the ecliptic cuts the equator. The solstitial points are Cancer and Capricorn; and when the sun is in either of them, he is at his farthest distance above or below the equator.

Thus, then, by "comparing things in heaven with things on earth," has the starry sky been maped out, and the places of celestial objects determined and marked down like towns and other places upon the surface of the earth. Unlike those, however, which maintain unchangeably their distances from each other, some of those in the celestial sphere are continually shifting their places; and the whole, indeed, have a certain degree of motion. The former, however, are so very few in number compared to the multitude of luminaries "which no man can number," and the latter is so exceedingly trifling as scarcely to be discernible from one thousand years' end to another, that the aspect of the heavens may be said to possess invariable uniformity. The heavenly bodies are broadly distinguished into two grand classes—those among which no change of relative situation can be detected, unless after many years' observation, and hence called fixed; and those which are changing place continually, and so rapidly as to be discernible by the naked eye; hence called erratic or wandering. These are the planets and comets of

THE SOLAR SYSTEM.

This, as we have previously shown, consists of a centre of light, heat, and motion, denominated the sun; with eleven primary planets, eighteen secondary ones, and an unascertained number of comets, revolving round that centre from west to east in eliptic orbits. The periods depend on the distance of the planet from the sun, those which are near performing their circuit in less time than those which are more remote. They have likewise a rotation upon their axis, which is inclined to the plane of their orbits, and in which they are retained by the same laws as those which regulate the movements of the earth. Moreover, they all make the entire tour of the heavens, and nearly in the plane of the ecliptic. To make this understood, suppose an immense circular plain or level, expanded from the sun all round, and cutting through the earth, stretched to the remotest planet in the system; then the whole of those planets move in the neighbourhood of it, when they sink below it or rise above it, never proceeding very far either way. From the unequal angular motion of the planets (a result of their various distances from us and the sun), some very curious phenomena arise. Mercury and Venus appear to move occasionally backwards and forwards; so that, if their apparent track was maped down by observations made from day to day, it would have a zigzag appearance. This arises, however, from our not observing them from their proper centre of motion. Several facts regarding the planets will strike every observer, that they are exactly circumstanced as the earth is with regard to the sun. They are found really to be globes, of a size equal to, and sometimes surpassing, that of the earth. Their distances from us are in a state of continual change, periodically increasing and decreasing within prescribed limits, which has an obvious relation to their elongations from the sun, and not to the earth, as a centre or focus. Lastly, some of them exhibit phases like those of the moon. If we refer their movements to the sun as a centre, all the apparent irregularities disappear, and every thing assumes an aspect of perfect order and beauty. We perceive a striking resemblance between all the planets—a family likeness as it were. One influence pervades the whole of them, one impulse directs their movements. We shall here only notice facts about which there is no dispute, leaving out of view entirely all those ingenious conjectures which are calculated to amuse the fancy rather than to satisfy the judgment. Let us, in the first place, attend to the laws by which they are retained in their orbits, which are known in astronomy by the name of

THE LAWS OF KEPLER.

Previous to the establishment of the law of universal gravitation by Newton, several great discoveries had been made which cleared the way for it; and amongst the most remarkable and important of these, were the laws of the courses of the planets round the sun. These were deduced by Kepler, a great German astronomer, from observations by Tycho Brahe, and are known in philosophy by the name of the Laws of Kepler. They form the basis of the science, and a knowledge of them will greatly facilitate a right understanding of the movements of the planets. The first is, that the planets do not move in circles, as Copernicus had supposed, but in elipses or ovals. The second is, that an imaginary straight line from the sun to the planets always describes equal sections in equal times. And the third, and by far the most remarkable, and fraught with momentous results, is, that, in the motion of the planets, the squares of the times of revolution are as the cubes of the mean distances from the sun. It is not compatible with our limits to enter into any details respecting these laws; it is sufficient to say, that the application of them affords a beautiful explanation of the movements of the bodies composing the solar system. The expression of the third law, however, requires a slight modification when we come to extreme niceties in calculation, arising from the influences of the masses in the greater planets.

The following table shows at a glance the magnitudes, relative positions, &c. of the bodies which compose the solar system:—

Globes.	Sidereal Revolution.		Rotation.			Distance from the Sun.	Diameter.	Inclination to the Ecliptic.			
	years.	*days.*	*days.*	*hours.*	*min.*	*miles.*	*miles.*	*degrees, &c.* °	′	″	
Sun	-	-	25	14	-		882,000				
Mercury	-	88	1	-	5¼	37,000,000	3,180	7	0	9	1
Venus	-	225	-	23	21	68,000,000	7,800	3	23	28	5
The Earth	-	365¼	-	23	56	95,000,000	——	——			
The Moon	-	27⅓	27⅓	-	-	——	2,160	——			
Mars	1	321	-	24	40	143,000,000	4,100	1	51	6	2
Vesta	3	249	Not ascertained			225,000,000	Not ascertained, but very small. Pallas is supposed to be only eighty miles in diameter.	7	8	9	0
Juno	4	130				254,000,000		13	4	9	7
Ceres	4	220				263,000,000		10	37	26	2
Pallas	4	220				263,000,000		34	34	55	0

THE SUN.

The mass of this magnificent luminary exceeds that of all the planets which revolve round it put together, eight hundred times. The density of the sun is, however, a great deal less than that of the earth, so that it must consist of far lighter materials, especially when we reflect how much the central parts must be condensed by the force of the immense superincumbent mass. Hence it has been supposed, that a great heat prevails in its interior, which gives it an elasticity sufficient to neutralise the effect of this tremendous pressure. The extent of solar gravity we have already noticed. The rotatory motion of the sun, which, like that of the earth, is from west of east, has been ascertained by means of a variety of dark spots which are discovered by the telescope on his disc. They first appear on his eastern limb, and, after a period of about thirteen days, disappear in the western. These spots vary both in number, magnitude, and shape; sometimes forty or fifty, and at other times only one or two, are visible. Most of them have a very dark nucleus, or central part, surrounded by an umbra, or faint shadow. Some of the spots are as large as would cover the whole continent of Europe. We have already spoken of the apparent motion of the sun, and shown that it results from the real movement of the earth. The sun is affected by the attractive power of the planets, from which a minute motion results. These various "perturbations" will be explained afterwards. From the observations of Sir William Herschel, it appears probable that the sun is a solid and opaque body, surrounded with luminous clouds, which float in the solar atmosphere, and that the dark nucleus of the spots is the opaque body of the sun appearing through occasional openings in its atmosphere.

The temperature at the visible surface of the sun is supposed to be very elevated; but how the enormous conflagration is kept up, if such it really be, there is no satisfactory means of accounting for.

We have already enumerated some of the benefits which we derive from the sun. "His rays," says Sir J. Herschel, "are the ultimate source of almost every motion which takes place upon the surface of the earth"—we may add, and that of every other planet in the system, of which he is the *active verb*. It is by his heat, as we have seen, that winds are produced, that vapour is exhaled into the atmosphere, from whence it descends in showers to fertilise the soil. In a word, by the efficiency of the sun, the elements of matter have imparted to them that vital energy by which they are enabled to go through their endless rotation of existence, and perpetuate the multiform varieties of organic life which people the globe.

About the months of April and May, after sunset, or at the opposite months of the year before sunrise, there is a curious phenomenon observed, called the *zodiacal light*. Extending from the horizon obliquely upwards, and following generally the course of the sun's equator, there is to be seen at these times and seasons a faint stream of light, and of a conical shape. It is supposed to be a thin lenticularly formed atmosphere, which surrounds the sun, and certainly extends beyond the orbits of Mercury and Venus; but any thing more definite regarding it has not been ascertained.

In his apparent motion among the stars, he is said to enter such and such a sign, at such and such a definite period of the year. These signs are constellations belonging to the zodiac, a region of the heavens which we have more than once mentioned, and one to which we shall hereafter frequently refer, so that an account of it is necessary before we proceed farther.

THE ZODIAC.

The word zodiac is derived from the Greek, and signifies animals; the region of the heavens to which it refers has been so entitled, because its various divisions have been named after animals. It is an *imaginary* ring, or broad circle, in the firmament, in the form of a belt or girdle. It extends eight or nine degrees on each side of the ecliptic, which runs through or round the middle of it. It is divided into twelve parts, each of thirty degrees, called the signs of the zodiac. The names of the signs, and the days in which the sun enters them, are as follow:—*Spring signs*—Aries, the Ram, 21st of March; Taurus, the Bull, 19th of April; Gemini, the Twins, 20th of May. *Summer signs*—Cancer, the Crab, 21st of June; Leo, the Lion, 22d of July; Virgo, the Virgin, 22d of August. These are called northern signs, being north of the equinoctial. *Autumnal signs*—Libra, the Balance, 23d of September; Scorpio, the Scorpion, 23d of October; Sagittarius, the Archer, 22d of November. *Winter signs*—Capicornus, the Goat, 21st of December; Aquarius, the Water-bearer, 20th of January; Pisces, the Fishes, 19th of February. These are called southern signs. Within the zodiac are performed the revolutions of all the principal planets. The accounts given of the signs of the zodiac, and of the constellations, are contradictory, and involved in fable. It is conjectured, however, that they have reference to the seasons of the year, and are a hieroglyphical representation of the characteristics of each month. Thus the spring signs were distinguished for the production of those animals which were highly esteemed, such as sheep, black cattle, and goats; the latter, being the most prolific, were represented by the twins. When the sun enters *Cancer*, he changes his course backwards, and this retrograde motion was typified by the crab, which apparently goes backwards; and so on with the other signs. The constellations to the north of the zodiac are called northern constellations, and those on the south of it, southern constellations. They are named in the same fanciful manner as the zodiacal signs. The whole constellations amount to between ninety and a hundred in number.

With regard to the sun's entering the zodiacal signs, some important particulars will be found under the head "Precession of the Equinoxes."

THE MOON.

Next to the sun, the moon is to the inhabitants of the earth the most remarkable and important of all the heavenly bodies. The mean horizontal parallax of the moon is 57′ 48″; and her mean distance from the earth 236,847 miles. Like the sun, the moon advances in the heavens in a motion contrary to that of the stars. Notwithstanding the vast distance she is from us, it is little more than one-fourth of the sun's diameter, and the globe of that magnificent luminary would nearly *twice* include the whole orbit of the moon! It has various motions; as a secondary planet, it revolves round the earth, which is its primary. Along with the latter, it revolves round the sun, and it has a rotatory motion upon its own axis. Owing to the sun's apparent movement in the heavens being in the same direction with that of the moon, only slower, the latter has to make up for that slowness in the same way as we have mentioned with regard to the earth, and the time it takes constitutes the difference between the sideral and synodic month or lunation. The sideral month is 27 days 7 hours 43 minutes 11 seconds 5, in which time the moon performs a complete revolution round her primary; and the other is 29 days 12 hours 44 minutes 2 seconds 87, the time which elapses between two new moons, or two conjunctions of the sun with the moon. It happens that its revolution upon its axis is performed in the same time as its revolution round the earth, so that the same side of her orb is always presented to the latter planet. Although the moon's rotation on her axis is uniform, her motion in her orbit is not so, and we are by this means enabled at times to obtain a peep of the equatorial portions of her eastern and western sides. Her axis, also, is not perpendicular to her orbit, and a small part of each of her poles alternately becomes visible. These phenomena are known by the name of *librations* of the moon, and they are of two distinct kinds, the result of different causes. The moon being the nearest to us of all the heavenly bodies, by the aid of telescopes we have been enabled to examine her more minutely than any of the other planets. In the first place, great inequalities are discovered on her surface, which are evidently caused by mountains and vallies. That mountains of considerable height exist, is certain, from the jagged appearance which the illuminated edge of the moon presents, and from their casting long black shadows on the plains. The height of these elevations has, from measurements, been ascertained to be about one and three-quarters English miles. These mountains are very numerous, occupying by far the larger portion of the surface, and are almost universally of a circular cup-shaped form, with flat bottoms. Many of those with broad bases have a high conical summit, exactly corresponding to the form of volcanic mountains on the earth. Indeed, in some of the principal ones, decided appearances of successive deposits or layers of ejected matter, may be clearly traced. Dr Herschel more than once saw volcanos burning with great violence in the moon. Nothing corresponding to the appearance of oceans or large sheets of water is discernible in the moon, although there are large portions of the surface perfectly plain and level; neither has the moon any clouds or indications of an atmosphere.

PHASES AND ECLIPSES OF THE MOON.

The phases and eclipses of the moon depend upon the position which she is in with regard to the earth and sun. At new moon, this body is in a direction between the sun and the earth. As she gradually revolves in her monthly orbit, she recedes from this position, until she comes to the first quarter, when she is half illuminated, or seen with one-half of her face turned to the sun; another quarter's advance brings her to a position opposite to the sun, when his beams shine full on her disc, and it becomes full moon. In a clear state of the atmosphere, an appearance is often witnessed at new moon of the faint illumination of the remaining part of the disc, or the new moon is said to have the old in its arms. This arises from the strong reflected light sent from the earth.

The wisdom and beneficence of the Deity are strikingly displayed in the economy of moonlight, as distributed to our globe during various seasons of the year. The remarkable phenomenon of the *harvest* moon is familiar to every one. During the time that our satellite is full, and for a few days before and after, in all about a week, there is less difference between the time of her rising on any two successive nights, than when she is full in any other month of the year. By this means, an immediate supply of light is obtained after sunset, so beneficial for gathering in the fruits of the seasons. To conceive of this phenomenon, it must be recollected that the moon is always opposite to the sun when she is full; that she is full in the signs Pisces and Aries, these being the signs opposite to Virgo and Libra, which the sun passes through in September and October, our harvest months. Thus, although, whenever the moon enters the two former signs (and she does so twelve times in a year), the same circumstance takes place with regard to the time of her rising; yet it is not observed on these other occasions, just because she is not *full* at the time. The reason of there being little difference in the time at which she rises on several consecutive nights, is, that, at these periods, her orbit is nearly parallel to the horizon. The harvest moons are as regular in south latitude as with us in north latitude, only they happen at different periods of the year.

Solar eclipses are caused by the moon coming between the earth and the sun, and lunar eclipses by the earth coming between the sun and the moon. The places of the earth's orbit and the moon's do not exactly coincide, but cross or intersect each other; and the consequence is, that, in general, the moon, when she is in conjunction with the sun, either passes on one side or the other, and therefore does not intercept the sun's rays, or produce an eclipse. An eclipse of this kind can only take place when the earth and moon are in conjunction in that part of their orbits which cross each other (called the nodes), because it is then only that they are both in a right line with the sun. If the orbit of the moon were parallel to that of the earth, an eclipse would happen every month. Partial eclipses, again, are caused when the moon, in passing the earth, is not directly in a line with the sun, but a little on either side; the consequence of which is, the edge of one side of the moon only dips into the sun's disc. When the sun is eclipsed, the total darkness is confined to one particular part of the earth, but the lunar eclipses can be seen from every part of the earth, when the moon is above the horizon; and both circumstances prove that the earth is a good deal lower than the moon. The moon arrives very nearly at the same situation with respect to the earth, after making two hundred and twenty-three revolutions, which are performed in eighteen years, of three hundred and sixty-five days, fifteen hours, seven minutes, and forty-three seconds, each. So that, after a period of about eighteen years, the series of eclipses recommences nearly in the same order, a circumstance observed by the ancients. The mean number of eclipses which occur in a year is about four, and there are sometimes as many as seven. There must necessarily be two solar eclipses, but it is possible that there may not be even one lunar. A remarkable eclipse, called an annular (or circular) solar eclipse, happens when the moon being in conjunction with the sun, the edge of the latter appears for a few minutes as a narrow ring of light encircling all round the dark disc of the moon. A great solar eclipse, visible in England, will take place May 15, 1836; another in March 15, 1858, and a still more remarkable one, when the whole disc will be nearly covered, in August 19, 1887.

The eclipses of some of the satellites are of great importance in astronomy, and will be noticed when we come to speak of these bodies generally.

TIDES.

The ebb and flow of the sea evidently result from the attraction which the moon exercises over the earth. The land is as much attracted as the water; but the cohesion of solids prevents their parts from being affected as those of fluids are, which easily yield to the force of gravity; and, in consequence of this, the waters immediately below the moon are drawn up in a protuberance, producing a full tide, or high water, at the place where it happens. So far all is perfectly simple. But since the earth only turns *once* upon her axis during the twenty-four hours, and, in consequence, can only, in the same space of time, show any meridian of her surface to the moon no more than *once*, or, in other words, that any individual portion of the sea is *once* under the influence of the moon's attraction in the course of a day, how comes it, then, that there are *two* full tides in that time?—and, what is still more singular, how does it happen that our antipodes should have high water at the very same time as ourselves? The opposite tide is rather more difficult to explain than that which is drawn up under the moon, and yet it admits of a perfectly satisfactory explanation. Let the reader suppose placed before him a globe, of a foot diameter, which is for the present destitute of any attraction but that of the particles for the centre of the one-foot globe. On the outside of this sphere, there is a fluid, such as water, which is one inch thick all round. Bring another globe, of similar dimensions, within two feet of it, at which distance we shall suppose the latter has the power of attracting the former; the point attracted is, for the moment, say the north pole, that directly opposite being the south pole. Now, at this vanishing north pole, the waters are heaped up by the attractive power of the last introduced globe, say to the depth of one and a half inches. A little farther on either side of the point where the water-encircled globe is nearest to the other sphere, the depth will be less, say an inch; because the attraction must there be less, for the force of the latter always decreases according to the distance. As the latter increases, the former loses its intensity, and the depth becomes less and less, until we arrive at that part which is equi-distant from either pole (corresponding to the equator), where it is least. Still, however, the attraction is greater there than at the south pole, where it evidently must be smallest. But, observe, it is not the *water* alone that is attracted, it is the *whole* globe; so that the latter is drawn away from one extremity of its moveable surface, and thus leaves a protuberance. The tide at the point most strongly attracted is produced by the waters receding from the earth; at the opposite side, it is the earth fleeing or receding from the waters. The earth is continually *falling*, or *drawn out* in an oblong shape towards the moon, the two high tides being always at the two points from which, if a line were drawn, it would measure most. The tides, then, are just a broad wave which sweeps round the earth, following the apparent track of the moon. When the elevated part of this billow strikes our coasts, it is high water; when the lower touches us, it is low water. By the sun's attraction, a similar wave is also produced. When the solar and lunar attractions coincide, and act in the same way, we have what are called spring or large tides; when they act in opposition to each other, we have neap or small tides. The spring tides happen twice a-month, when the moon is at full and at change; and the neap, when the moon is 90° from the sun. The reason of the tides being about three-quarters of an hour later, is, that the earth takes that time above the twenty-four hours in bringing any given meridian again beneath the moon. The tides are thus retarded for the same reason that the moon rises three-quarters of an hour later every day. It is evident that the tides will be greatest at that point of the earth's surface which is nearest to the moon, or where the latter is vertical. She is so at the torrid zone; and, accordingly, the tides are there greatest, and they diminish as we approach either poles. The moon is not vertical to any given spot where high water may be, because, as the earth revolves from west to east, the waters of the deep have a motion in that direction, and, by the law of inertia, formerly explained, have a *stubbornness* to resist any change. The waters, therefore, do not immediately give way to her attraction, and the effect is not complete till three hours after she has passed the meridian, when it is full tide. Twice a-year—namely, in March and September—the tides are higher than at other times, because then the attractions of the sun and moon are the strongest. A number of causes connected with the relative position of land and water conspire to disturb the regularity of the tides; but a detail of these we have not space for. The influence of the sun and moon, also, produces a minute tide in the atmosphere.

THE OTHER LUMINARIES OF THE SYSTEM.

Some of the peculiarities of the inferior planets, Mercury and Venus, we have already noticed. The intense brilliancy of the latter luminary precludes observers from discerning any thing distinctly. A uniform brightness, however, can be perceived, and neither mountains nor shadows similar to those perceptible in the moon. These two planets perform their circuit as attendants upon the sun. They are sometimes seen to the east of it, when they appear just after sunset in the west as *evening* stars; and sometimes to the west of it, when they appear before the rising of that luminary as *morning* stars.

Mars, however, exhibits a different aspect. Seas and continents can be distinctly traced; the former are greenish, and the latter of a ruddy hue; in both cases the colour no doubt arises from that of the reflecting surface. An atmosphere of some extent has also been ascribed to it, and a whiteness at its poles has led some to conjecture, and with a degree of probability, that snow is by no means a phenomenon.

Jupiter is a remarkable planet, being furnished with four satellites, which revolve round him as the moon does round our earth. A series of dark belts cross his disc in one direction, which never changes, and is parallel to the equator of the planet. It is supposed that they are the opaque body of the planet appearing through tracts of clear sky. The figure of Jupiter, as we formerly observed, is spheroidal, like that of the earth, and it has been calculated, with a remarkable degree of correctness, that, comparing its oblateness at the poles with that of the earth, it exactly corresponds with the dimensions of the planet, and the immense rapidity of its rotatory motion.

Saturn.—This is probably the most interesting of all the planetary bodies. He has no less than seven moons revolving round him, and is moreover surrounded with two broad, flat, extremely thin rings, nearly of a circular form, both lying in one plane, and separated by a very narrow interval from each other throughout their whole circumference, but at a considerable distance from the body of the planet itself. An idea of them may be formed from the engraving on the first page, entitled Saturn. Round the outer edge the exterior ring measures one hundred and seventy-six thousand miles; the interval between the body of the planet and the interior ring is nineteen thousand miles; the interval between the two rings nearly eighteen hundred miles, while their thickness is about one hundred miles. The ring is known to be a solid opaque substance. Saturn exhibits the appearance of an atmosphere, with belts running parallel to the supposed equator. The rings have a revolution of their own around this planet, and with nearly the same rapidity as his daily revolution, and the adjustment of form and velocity must be nicely balanced, in order to preserve such comparatively thin and fragile bodies from falling in, and becoming part of the planet. It is evident that this catastrophe is prevented by their rapid motion producing a high degree of centrifugal force.

Uranus was discovered by Herschel the elder, in 1781. This planet presents only a uniformly illuminated disc, without spots, rings, or belts. It is attended by satellites, two of which are clearly distinguishable, and it would seem to have six.

Ceres, *Pallas*, *Juno*, and *Vesta*, the four very small planets discovered about the beginning of this century, are too small in dimensions, and too distant from us, to present any thing remarkable.

OF THE PLANETS IN GENERAL.

A glance at the tabular view which we have given of the solar system is sufficient to show us, that, as far as we may judge, by appearances from the different distances at which the bodies composing it are from their common centre, the sun, some of them must experience a scorching degree of heat, and others an extreme of cold, which would hermetically seal up the vital energies of man; and also, that what we call *weight* and *inertia* must exhibit, taking them collectively, as great varieties as temperature. That the power of gravity at the surface of any given planet will just be according to the mass of matter which the planet contains, there can be little reasonable doubt. Hence it has been calculated, that bodies weigh three times more on Jupiter than they do on the earth, and at the moon only one-sixth, while Saturn is supposed to consist of materials not much heavier than cork! But, with regard to temperature, various difficulties present themselves, which preclude us from drawing any satisfactory conclusions upon the subject. We may speculate, that the surface of this planet, from its proximity to the sun, endures a heat considerably above that of boiling water; and that the surface of another, in virtue of its enormous distance from the sun, must be bound up for ever in chains of "thick-ribbed ice." But the fact is, that the manner in which heat is excited upon our own globe is by no means a settled point. We know very well that heat and light *apparently* proceed from the sun; but, instead of supposing heat and light to be material bodies sent off from that luminary, may the effect not be produced by some peculiar action which it exercises upon an exceedingly rare ethereal medium, which fills the void betwixt the planets and sun, and probably exists throughout all space? This appears by far the most plausible conjecture that can be formed upon the subject. But even allowing that the sun is a body in a state of conflagration, there may be circumstances which modify extreme heat at the surface of those planets very near him, and compensate for the want of it in those far removed from his influence. With regard to their being inhabited, all we can say is, that, reasoning from analogy, there is every likelihood that they are so. If, upon the earth, there is not a withered leaf which the autumn blast strews upon the heath, but teems with animated existence, we carry reason along with us when we say, that the stars are the abodes of races of beings, whether similar to ourselves or not we cannot determine, and it would be of little moment although we could.

OF THE SATELLITES.

The earth, we have seen, is attended in her annual circuit round the sun by one satellite, the moon, which revolves round her as a centre. Strictly speaking, both move round a common centre of gravity in an elliptic orbit, the regularity of which is disturbed by their mutual attractions, so that it is undulated or waved, thus, ... The number of undulations in a whole revolution is, however, only thirteen, so that the deviation from the ellipse is exceedingly trifling. Jupiter, Saturn, and Uranus, are all attended by satellites, as we have seen; and they form, as it were, each of the primaries with its attendant moons, a sort of miniature system, entirely similar in the laws by which they are governed to the great system to which they all belong, where the sun may be termed the primary planet, and the primary planets the satellites. Their orbits are circles or ellipses of small eccentricity, the primary occupying one focus. Of these systems, that of which Jupiter forms the head, has been studied with the greatest attention. The discovery of Jupiter's satellites by "the starry Galileo," was one of the first fruits of the invention of the telescope, and forms a remarkable era in the history of astronomy. From it resulted a solution of the great problem of the longitude, and the grand discovery of the aberration of light, of which we have already spoken. It also established completely the Copernican system, and confirmed the laws of Kepler. The satellites of Jupiter revolve from west to east like the moon, but they are much less in comparison with their primary than it, whilst their orbits are of smaller dimensions, and less inclined to the ecliptic of their primary than that of our satellite. The largest of them is about 3377 miles, and the least about 2068 miles in diameter. The satellites of Saturn have been much less studied, and have fewer peculiarities. Those of Uranus, however, are remarkable, inasmuch as their orbits are nearly perpendicular to the ecliptic, and in these orbits they have a retrograde motion—that is, from *east* to *west*, instead of from *west* to *east*, like the other planetary bodies. No satisfactory cause for this departure from the general rule can be given. It is by accurate observation of the satellites that the densities of the planets, or their weight as proportioned to their bulks, have been ascertained; as also, by watching their frequent eclipses, that the velocity with which light travels from the heavenly bodies to the earth has been brought within our calculation.

COMETS.

All the bodies which we have hitherto noticed are seen from the earth in every part of their orbits, and they all move in ellipses which deviate comparatively little from the circular form. But there are others, which occasionally make their appearance in the sky, whose motions and nature, as far as is known, entirely differ from these. They are called comets (*coma*, hair), from the stream of faint light or nebulosity which frequently attends them. Shooting down from the remote regions of space with inconceivable velocity, and suddenly appearing amongst the more steady and regular bodies of our system, accompanied sometimes, too, with a luminous tail which flames over many degrees of the heavens, they are calculated to excite both terror and dismay. Accordingly, in superstitious ages, their sudden and unexpected apparition was more than once mistaken for the announcement of that catastrophe which, we are led to believe, is to consummate the destinies of all terrestrial things. At first, their appearance is small, and their light feeble; as they approach the sun, their magnitudes and brilliancy increase, and frequently present a magnificent spectacle. Having reached the point of their orbits nearest the sun, they again recede to enormous distances, and disappearing gradually, at last vanish altogether. With respect to their motions, instead of being confined to a particular zone, and moving from west to east like the planets, they range the sky indifferently in all directions. The ellipses in which most of them move are so eccentric or elongated as to approach the form of the parabola. They are visible only in a small part of their orbit, which, being that nearest the sun, is passed over with prodigious rapidity. They seldom continue visible longer than six months. Their number is entirely unknown; but, during the last two centuries, upwards of 150 have been observed, and their orbits computed.

Comets, for the most part, consist of the head, which is a large and brilliant, but ill-defined body of light. The centre is usually bright, and has the appearance of a vivid *nucleus*, like a star. Opposite to the direction in which the sun is situated from the comet, shoots off the tail, a magnificent appendage, though not an invariable one, consisting of two streams of light, which sometimes unite at a little distance behind the head, sometimes continuing distinct for a great part of their course. The matter of which comets are composed must be extremely light and filmy, as stars are visible through them. For a more particular account of comets, see Chambers's Journal, Nos. 31 and 33.

PERTURBATIONS.

The name of perturbations has been applied to those inequalities in the lunar and planetary motions, which arise from the universality of attraction. Thus, not only does the sun attract the earth, and the earth the moon, but the latter attracts the preceding, and both are again influenced in their movements by the great centre of the system to which they belong. Not only is this the case, but every individual planet in the system attracts, and is attracted by, all the rest, although certainly in a very trifling degree, when compared with that exercised by the sun over the whole of them. But in those miniature systems, such as the moon and earth, Jupiter and his satellites, &c., the perturbations thus arising, though insensible in short intervals, become apparent when accumulated, and derange the elliptic motions and relations. The calculation of the effects of these disturbing forces is famous in the history of analysis, under the name of *The Problem of the Three Bodies*. It is so worded, because the Sun, Moon, and Earth, and the Sun, Jupiter, and Saturn, form each separately a system little influenced by the rest. Any thing like an attempt to exhibit the method by which these nice calculations are made, is impossible in this place; of its difficulty, some idea may be formed, when we consider, what is apparent to every one, that the situations of the bodies under investigation are continually shifting their relative distances from each other, and altering the intensity of the disturbing force, which evidently must materially increase the abstruseness of the calculation. One of the principal effects produced on our globe by this play of gravitation is called

THE PRECESSION OF THE EQUINOXES.

The equinoctial points we have already explained, are, Aries and Libra, where the ecliptic cuts the equator. They are also termed nodes, and the line which joins the two is called the line of the nodes. The longitudes of the stars, as has been also observed, are counted on the ecliptic from the vernal equinox Aries Now, if the line of the nodes is invariable, the longitude of the stars will of course remain the same from age to age. But, on comparing the actual state of the heavens with the recorded observations of ancient astronomers, it is perceived that the longitudes of the stars have considerably increased; so that, to explain the circumstance, we must either suppose that the whole firmament has moved in the order of the zodiacal signs, or else that the equinoctial points have gone backwards, or retrograded westward; since these points depend entirely upon the motion of the earth, which was far more likely to be disturbed by some cause or other, than that the countless multitude of stars should have a motion relative to these points. Accordingly, the phenomenon has been explained, by attributing to them a retrograde motion from *east* to *west*, in consequence of which the sun arrives at them sooner than if they had remained at rest. Hence the equinoxes, spring and autumn, and the other seasons, happen before he has completed an entire circuit. This motion, however, is extremely slow, amounting only to a degree in about seventy-six years; so that the equinoctial points will take nearly 26,000 years to make an entire revolution of the heavens. This motion was known in very ancient times, and its discovery is ascribed to Hipparchus, who lived about 140 years before Christ. The consequence of this retrograde movement is, that the sun's place amongst the zodiacal signs, at any season of the year, is greatly different from what it formerly was. The vernal equinox now happens in the constellation Pisces; the summer solstice in Gemini; the autumn equinox in Virgo; and the winter solstice in Sagittarius. Astronomers, however, still count the signs from the vernal equinox, which always corresponds to the intersection of the ecliptic with the equator; and on this account it is necessary carefully to distinguish between them.

The cause of precession is to be found in the combined action of the sun and moon upon the protuberant mass of matter accumulated at the earth's equator, the attraction of the planets being scarcely sensible. The attracting force of the sun and moon upon this shell of matter, is of a twofold character; one is parallel to the equator, and the other perpendicular to it. The tendency of the latter force is to diminish the angle which the plane of the equator makes with the ecliptic; and were it not for the rotatory motion of the earth, the planes would soon coincide; but by this motion the planes remain constant to each other. The effect produced by the action of the force in question, is, however, that the plane of the equator is constantly, though slowly, shifting its place in the manner we have described.

NUTATION.

The action of the sun and moon in producing precession is various, at different periods of the year, according to the relative distance of the earth from them. Twice a-year, the effect of the sun in producing it is nothing; and twice a-year, namely, at the solstices, it is at maximum. On no two successive days is it alike, and, consequently, the precession of the equinoctial points must be unequal, and the obliquity of the ecliptic subject to a half-yearly variation; for the sun's force, which changes the obliquity, is variable, while the rotation of the earth, which counteracts it, is constant. By this means, the plane of the equator is subject to an irregular motion, which is technically called the *solar nutation*. Its amount, however, is so exceedingly small, as not to be appreciable by observation. That resulting from the moon's action, however, is sufficiently so, as to have been discovered by Bradly before theory had indicated its existence. Its period depends upon the revolution of the moon's nodes, which is performed in 18½ years, and in about that period of time the axis of the world describes a small circle in the heavens, about eighteen seconds in diameter, contrary to the order of the signs. This apparent vibratory motion is denominated the nutation of the earth's axis. The two phenomena of precession and nutation are intimately connected, or rather are constituent parts of the same phenomenon, and dependent upon the same cause, as noticed above under Precession. It is impossible here to enter more minutely into the subject, or explain it more in detail. For an admirable account of it, we refer the reader to Herschel's Treatise on Astronomy, p. 333. We also to the same admirable work would direct the inquirer for further information upon the subject of perturbations, comprising all the complicated varieties of motion. In general, they may be said to arise from the play of attractions kept up by the whole of the planets amongst themselves; they with the sun, and the sun with them; the distances of the bodies from each other, which are always varying; and the masses of matter, and the shape of the bodies, which are invariable. In concluding this part of our subject, we may remark, that it is by means of the perturbations of those planets which have no satellites, that astronomers have arrived at a knowledge of their masses. Every planet produces an amount of perturbation in the motions of any other, proportioned to its *mass*, and to the degree of advantage or *purchase* which its situation in the system gives it over their movements.

OF THE FIXED STARS.

We have now passed in review before us the bodies belonging to our own system, and, being much nearer us than the other luminaries which stud the ethereal vault, are more within the range of correct observation. They, however, form but a very minute portion of the starry multitude, which people space to an extent far beyond the most powerful telescope to embrace, or even the imagination to conceive of. The fixed stars, we have already observed, have been divided into various constellations or clusters. These, again, are separated into classes, according to their brilliancy, and so on. The brightest are called stars of the first magnitude, those inferior to them of the second magnitude, and so on, to the sixth or seventh magnitude, which are the smallest visible to the naked eye. By the aid of powerful telescopes, however, others a great deal smaller can be detected, and astronomers are familiar with those whose magnitudes are as low as the sixteenth; indeed, no reasonable limit can be assigned to the progression. The classification is wholly a matter of convenience, and the lines of demarcation are exceedingly equivocal. Sir William Herschel, from experiment, concluded the light given by the stars of each of the classes to be comparatively as follows:—The first magnitude was equal to a hundred, the second to twenty-five, the third to twelve, the fourth to six, and fifth to two, and the sixth to one. The son of that eminent astronomer, heir to his genius as well as his name, found that the light of Sirius, the brightest of all the fixed stars, was 324 times that of an average star of the sixth magnitude.

CONSTELLATIONS.

The science of the constellations is called *astrognosy*. The division of the stars into groups was begun in the earliest ages, and, with regard to the whole of them, it is sufficient to mention, that their names are entirely arbitrary, and that any resemblance which they bear to the terrene realities after which they have been called, is entirely imaginary. For instance, the best known of the constellations, the Great Bear, might with equal propriety have been denominated the great tree, Charles's Wain a steamboat, and the plough a cart or horse. However, these fanciful appellations answer the purpose very well, and any portion of the heavens, when referred to, can, by this means, be turned up at once like a book that is paged and paragraphed. Constellations have been formed from age to age, and some of the old ones have been cut up to form new ones. Thus, Orion was curtailed of his fair proportions to form a Napoleon.

There is something very remarkable in the local distribution of the stars over the heavens. "If we confine ourselves," says Sir J. Herschel, "to the three or four brightest classes, we shall find them distributed, with tolerable impartiality, over the sphere; but if we take in the whole amount visible to the naked eye, we shall perceive a great and rapid increase of number as we approach the borders of the milky way. And when we come to telescopic magnitudes, we find them crowded, beyond imagination, along the extent of that circle, and of the branch which it sends off from it; so that, in fact, its whole light is composed of nothing but stars, whose average magnitude may be stated at about the tenth or eleventh." The remarkable natural region of the heavens here mentioned demands a separate description.

THE MILKY WAY.

The milky way, or galaxy, is a long luminous zone, or band, which encompasses the heavens every evening, forming a great and complete circle of the celestial sphere. It is inclined to the plane of the ecliptic, at an angle of about 60°, and cuts it nearly at the solstitial (sun-standing) points. It is divided in one part of its course, sending off a kind of branch, which remains separate from the principal body for about 150°, and then unites with it. The ancients had many singular notions respecting this phenomenon, and from the accounts of it which they have left us, it would appear still to maintain exactly the same relative situation among the stars. When powerful telescopes are brought to bear upon this radiant belt, it is found to be entirely composed of stars, which, as they pass the aperture of the instrument, are counted off at the rate of nearly half a million per hour! Sir William Herschel informs us, that, in the most crowded part of the milky way, he has had fields of view that contained no less than 588 stars, which were continued for many minutes. The same eminent astronomer supposes that it is a nebula, of which the sun forms one of the component stars; and hence, it appears immensely greater than other nebulæ which are scattered over the firmament. Taking this in connection with the fact, that, notwithstanding the apparent contiguity of the stars which compose the milky way, their distances from each other cannot be less than 100,000 times the radius of the earth's orbit, how are our views of the extent and magnificence of the universe enlarged! Imagination wanders over the general heavens, in the quaint but graphic language of Milton, "powdered with stars"—glittering like a desert of sand beneath a tropical sun, and seeks for some boundary where it might rest, and again renew its flight in search of a termination; but it seeks in vain. Clusters of stars, each a separate universe, stretch out before it in numberless array, and seem to lengthen as it flies.

NEBULÆ.

Clusters of stars, for the most part imperceptible to the naked eye, are so called from their confused luminous, or rather *cloudy* appearance. Much ingenuity has been expended in conjectures respecting their nature. They are very numerous and of different kinds. In some of them, stars are clearly distinguishable; in a second class, their existence is only faintly indicated, and in a third there is no appearance of stars whatever. In some instances, the nebula presents the phenomenon of a faint luminous atmosphere of a circular form, and of large extent, surrounding a star of considerable brilliancy. There is a remarkable nebula in the constellation Andromeda, which, from its being visible to the naked eye, has been known from the earliest ages. It is described as having the appearance of a candle seen through horn, that is, a diluted light, increasing in density towards the centre. A class of nebulæ, which, from presenting the appearance of planets, are called planetary nebulæ, are very extraordinary objects. Their discs are round, or slightly oval; and some have bright parts equal in vividness to actual planets. Sir William Herschel, who devoted much of his attention to this subject, gives a catalogue of 2000 nebulæ. He ingeniously conjectured that they are the matter out of which nature elaborates the suns and systems of the universe; and those who wish a full account of his views and reasoning upon the point, will find them explained in the Philosophical Transactions for 1811. "What," says the distinguished son of the above-named astronomer, "What, we ask, is the nature and distinction of this nebulous matter? Is it absorbed by the stars in whose neighbourhood it is found, to furnish by its condensation their supply of light and heat? Or, is it progressively concentrating itself by the effect of its own gravity into masses, and so laying the foundation of new sideral systems, or of insulated stars?"

PERIODICAL AND VARIABLE STARS.

Some of the fixed stars undergo periodical variations of brilliancy, a phenomenon which may be reckoned one of the most remarkable connected with these bodies. Several stars, again, formerly remarkable by their splendour, have entirely disappeared; others are conspicuous which do not appear to have been formerly visible; and there are some which entirely vanish and re-appear, or, as we have observed, where light undergoes great periodic changes. One of the most remarkable of these periodic stars is that called *Omicron*, which appears about twelve times in eleven years. There are on record several striking instances of stars suddenly blazing forth with extraordinary lustre, remaining for a short while, and then dying away,

> "Leaving in yonder silent sky
> No vestige where they flew."

MULTIPLE AND COLOURED STARS.

Many of the stars, which to the naked eye appear single, are, when examined with the telescope, found to consist of two, and occasionally three individuals, placed near each other. Sir W. Herschel has enumerated upwards of 500 double stars, in which the individuals are within half a minute of each other. The number of double stars in general has been greatly added to since his day; and they now amount to several thousands. The most remarkable circumstance connected with them, is the regular motions which some of them possess. There is a double star, called *Ursa Majoris*, in which the two stars perform a regular revolution round each other in sixty years. Others accomplish it in a much shorter period; and some again are calculated to take 1200 years! Their orbits are eccentric, like our own. Quadruple and quintuple stars have likewise been observed, which also appear to revolve round a common centre of gravity, like the planets of the solar system round the sun.

Some of the double stars present the remarkable aspect of contrasted colours, "communicating male and female light," as spoken of by Milton, and floating before the eye of the observer like atoms of the rainbow. They generally assume the complementary tints, the yellow being opposed to blue or green, and so on. Sir J. Herschel endeavours ingenuously to make out a case of beautiful provision in nature with respect to these coloured stars.

DISTANCES, MAGNITUDES, AND MOTIONS OF THE STARS.

Sirius, the brightest of the fixed stars, and whose parallax has been guessed at, is supposed to be twenty billions of English miles distant from the earth. Imagination can scarcely conceive of an object placed at such a distance; but it may derive assistance from the statement that a ray of light, which darts from the sun to our globe in eight minutes seven seconds, would take three years and three-quarters to reach us from the star. A spider's thread before the eye of a spectator at that distance would conceal the orbit of the earth, and the breadth of a hair blot out the whole planetary system! The distances of the greater number of the fixed stars are, however, beyond all computation. With regard to their magnitudes, astronomers are equally at a loss. Sir W. Herschel calculated the volume of one of them to be twenty millions of times that of the sun. With regard to their number, no satisfactory conjecture can be formed. It is supposed that the eye, through a good telescope, can take in at once seventy-five millions of them; the number of sands on the sea-shore afford us, therefore, scarcely an adequate object of comparison. The science of astronomy is not yet matured enough to allow of its professors forming any sure conclusions as to the motions of the stars. It may, however, be stated generally, that their apparent directions are various, and seem to have no marked tendency to one point more than another of the heavens. The sun, for instance, and his system, have a proper motion in some direction; but whither he is tending with his shining train, it is needless to conjecture. The same may be said of the other bodies of stars, in whom proper motion has been observed.

CONCLUDING REMARKS.

It is usually the case in treatises upon astronomy, to give an outline of its history; but we have considered it of more importance to present to the reader, as far as was compatible with our limits, a picture of what the science *is* at present, in preference to exhibiting the successive steps by which perfection has been attained. The *plan* of a temple is sufficient for the great majority of those who wish to examine the fabric; the architect alone requires to see it in *section*, and know the quarry from whence the materials have been brought. An account of astronomical instruments, also, generally forms a part of such works as the present; but, to continue our metaphor, the introduction of the trowel and the plumb-line into the foreground of the building, would not increase its effect; and the methods by which they are employed in elaborating the rude and stubborn blocks into beauty and symmetry, can only be of material importance to those who are engaged in such occupations.

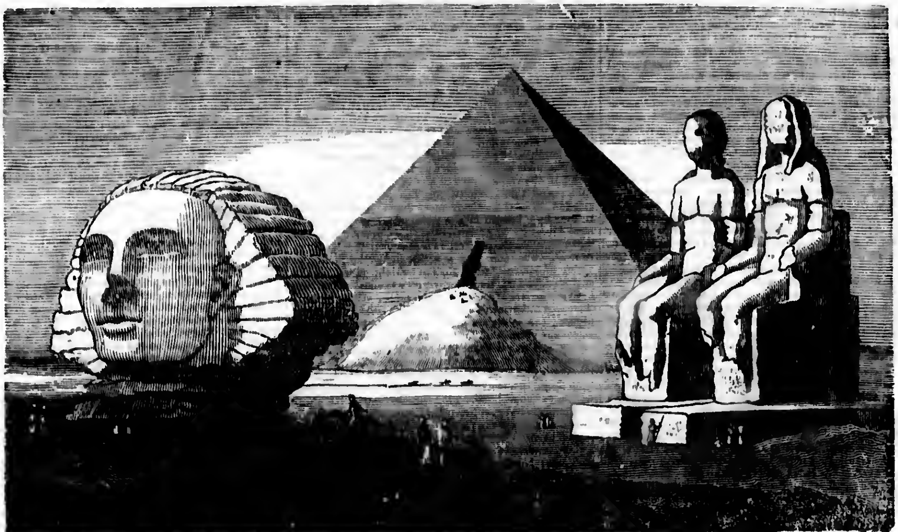
No. 22. PRICE 1½d.

EGYPT.



In the centre of the above engraving is a representation of one of the Pyramids of Egypt. The Head on the left side is that of the celebrated Sphinx. On the right are two gigantic Statues vulgarly called Shamy and Damy, one of which is supposed to be the Vocal Memnon. For a particular account of these extraordinary remains of antiquity, see pages 172 and 173.

EGYPT is an extensive and important kingdom of Northern Africa, alike remarkable for its ancient history and present state. In arts, learning, and civilization, it preceded Greece and Italy by many ages, and there is no country whose laws and institutions can be traced to a remoter antiquity. One circumstance above all others attracts our attention to modern Egypt; that is, the stupendous monuments of ancient grandeur with which it is literally covered. The sites of Babylon and other magnificent capitals, once the glory of Asia, are now only to be identified with heaps of ruins, the magnitude of the cities being estimated by that of the piles of rubbish which are now all that represent them. The sculpture and architecture of Greece and Rome have come down to us shattered and impaired, but the edifices of Egypt, which go back far beyond the records of authentic history, bear scarcely any traces of the lapse of time which has had such a destructive influence over the other memorials of the mechanical skill of mankind. They do not exhibit, indeed, that perfection of taste and skill which was reached in succeeding ages by Greece and other nations, but they are probably more interesting, as they display to us entire the arts and the power of the first generations of men. They are also remarkable, inasmuch as their magnitude is commensurate with their antiquity. In both respects the remains of ancient Egypt far excel those of every other country.

The name by which we recognise this country comes to us from the Greeks, by whom we are informed that a certain king called Ægyptus gave his name to his dominions, which previously were called Aëria, which signifies the land of heat and blackness. In the Hebrew Scriptures it is entitled Mizraim; Mizr, evidently the singular of that word, being the appellation by which it is recognised amongst the Arabs at the present day. By its ancient inhabitants it was called Chemia, a name which it still retains amongst the Copts, and which has probably some connection with Cham, the son of Noah. The word Egypt itself is of very doubtful origin; this, however, has been ascertained as certain, that amongst the ancient Greeks, Ægyptus was employed in reference to the land, to the river Nile, and to an ancient sovereign. The etymology of the word shares the obscurity which veils the source of the river and the ancient history of the country, so that it is unnecessary to occupy the time of the reader with conjectures upon the subject, which at best can only be probable.

In physical aspect, Egypt may be called an immense valley or longitudinal basin about 600 miles in length and of various breadth, the mean of which is supposed to be about nine miles. On either side it is enclosed by two mountain ridges and a barren expanse of desert. Egypt, it has been said, is the gift of the Nile, which traverses it from south to north. From Syene, the highest-up town in Egypt, and which borders upon Nubia, down as far as the straits called Djebel Silsili, a distance of about forty miles, the river occupies the middle of the valley, having very little arable land on its banks; but there are some islands, which, from their low level, easily admit of irrigation. Beyond the mouth of the Djebel Silsili, the Nile runs along the right side of the valley, which in several places has the appearance of a steep line of rocks, cut into peaks, while the ridge of hills on the left side is always accessible by a slope of various degrees of declivity. These western mountains begin near Siout, above 200 miles below Syene, and, gradually diverging to the west, extend to Fayoum, a distance of above 150 miles, so that between them and the cultivated valley there is a desert space gradually becoming wider, and bordered in several places on the valley side by a line of sandy downs, lying nearly north and south. The mountains which confine the upper part of the basin are intersected by defiles, leading, on the one side, to the Red Sea, and, on the other, to the Oasis. The strip of desert land, which generally extends along each side of the valley, parallel to the course of the Nile, and which must not be confounded with the ocean of barren sand lying on each side of Egypt, now contains two very distinct kinds of land. The one immediately at the bottom of the mountains consists of sand and round pebbles; the other, composed of light drifting sand, covers an extent of ground formerly arable. The surface on both sides declines from the margin of the river to the foot of the hills—a circumstance remarked also on the banks of the Mississippi, and some other rivers. Near Beni Souef, which is sixty miles south of Cairo, the valley, much widened on the west, has on that side an opening through which is obtained a view of the fertile plains of Fayoum. These plains are, properly speaking, a sort of table land, separated from the mountains on the north and west by a wide valley, a part of which, being always laid under water, forms what the inhabitants call Birket-el-Karroon. Near Cairo, the capital of the country, the mountains diverge on both sides; the one ridge, under the name of Djebel-el-Nairon, running in a north-westerly direction to the Mediterranean; the other, called Djebel-el-Attaker, running due east to Suez. In front of these chains extends a vast plain composed of sands, covered with the mud of the Nile. At the place called Bahr-el-Bakara, the river divides into two branches; the one flowing to Rosetta, the other to Damietta, and containing between them the present Delta. We here see the river Nile occupying so important a place in the physical economy of Egypt, that, before proceeding farther in our description of the country, we shall introduce an account of it.

THE NILE.

The source of this magnificent stream is still concealed from the eager gaze of mankind. The origin of its name is also a matter of learned doubt, with which, however, we shall not interfere. Amongst the Greeks and Romans, it excited the greatest interest—from its being the largest known to them—from its inundation, of which they had no other examples, and

were ignorant of the cause—and from its unknown origin. The true Nile is formed by the confluence of the Bahr-el-Abiad (white river), and the Bahr-el-Azrek (blue river), in lat. 15° 40′ north. The former, rising in Abyssinia, to the south-west of lake Dembea, comes from the south-east, and was considered by Bruce as the Nile. The latter, however, which comes from the south-west, and is supposed to rise in the Mountains of the Moon, in the centre of Africa, brings down the greatest mass of water, and is considered by Calliaud as the true Nile. In lat. 17° 40′ it receives the Tacazze from the east; enters Egypt in 24°, following nearly a northern course; and below Cairo (30° 15′ north) divides into the two main arms, as we have already mentioned. There were anciently reckoned seven principal mouths, by which its waters were poured into the Mediterranean: only those of Damietta and Rosetta are at present navigable; the others have been choked up. The distance from the confluence of its two head branches to the sea, is about 1500 miles; from its highest sources probably not far from 2500 miles. The Cataracts, so much celebrated by the ancients, modern discoveries have shown to be insignificant, hardly any thing more than what are called rapids in America. In Upper Egypt, it is confined, as we have seen, between two ranges of mountains, which leave only a narrow strip on each side of the river. Near Cairo, the river valley widens, and the level nature of the country below allows it to spread itself over a broad plain.

The depth and rapidity of the Nile vary in different parts, and at different seasons. In its ordinary state, no vessel exceeding sixty tons can ascend as high as the Cataracts. The mouth of Damietta is between seven and eight feet deep when the waters are low: that of Rosetta does not exceed four or five; but when the waters are high, each has forty-one feet more, and carevels of 24 guns can sail up to Cairo.

The grand phenomenon connected with the Nile, is its annual overflow of the banks which border it—an event looked for with as much certainty as the daily rising of the sun. These inundations of the Nile are owing to the periodical rains which fall between the tropics. They begin in March, but have no effect upon the river until three months later. Towards the end of June it begins to rise, and continues rising at the rate of about four inches a-day, until the end of September, when it falls for about the same period of time. Herodotus informs us, that, in his time, a rise of sixteen cubits was sufficient to water the country. At present, twenty-two cubits are considered a good rise. A rise of twenty-six cubits in 1829 destroyed a great many villages, with their inhabitants. After the waters of the Nile have subsided, the earth is found covered with mud, which has been left there by the river. This mud, which is principally composed of argillaceous earth and carbonate of lime, serves to fertilise the overflowed land, and is used for manure for such places as are not sufficiently saturated by the river; it is also formed into bricks and various vessels for domestic use. When the French invaded Egypt, the *savans* attached to the army undertook to measure the depth of alluvial soil which had been deposited by the river, by digging pits at different intervals. It was also attempted to ascertain the annual rate at which this substance is deposited, and by this means ascertain the antiquity of the monuments of art in the neighbourhood of the river. No reliance, however, can be placed upon the conclusions indicated by this species of chronometer. Dr Shaw informs us that Egypt has gained forty-one feet eight inches of new soil since the deluge. In Upper and Middle Egypt, there are immense numbers of canals on the left bank of the river. Mehemmed Ali, the present pacha, has opened many of the old canals, which had been closed for centuries, and dug new ones; among the latter, the canal of Mahmoud, connecting the harbour of Alexandria with the Nile, near Fouah, forty-eight miles long, ninety broad, and eighteen deep, is a magnificent work. The Delta is bordered by a number of maritime lakes, or lagoons, which at different periods have undergone considerable changes; some of them had been dried up, when, from various causes, their connection with the ocean, which had been interrupted, was again resumed, and the exhausted basins replenished with water. In the ancient Egyptian mythology, the Nile was revered as the tutelary deity of the country. In the city of Nilopolis the temple was erected. His attributes are the crocodile, the sphinx, the hippopotamus, and the dolphin. The Nile has been personified in several statues, particularly in a very noble one of black marble now in the Vatican.

TERRITORIAL DIVISION.

Egypt seems naturally divided into two parts, Upper and Lower, the latitude of Cairo forming the line of demarcation. Besides this division, there is another, of great antiquity, by which it was separated into three parts; the first of these was called the Delta, and occupied the Mediterranean coast. The third, called the Thebaid, corresponded to the narrow valley of Upper Egypt; whilst to the second, called the Heptanomis, was allotted the intermediate space. In modern times, the Arabs have changed the classical appellation of Thebaid into Said, or Upper Egypt, and the Heptanomis into Vostani, or Middle Egypt, and the Delta into Bahari, or Lower Egypt.

THE DELTA.

The Delta of the Nile is that tract of land at the bottom of the river formed by the mud which is deposited by the latter. It owes its name to its shape, which somewhat resembles the Greek letter Δ, or delta, answering to our D. The base of this triangle, which is washed by the Mediterranean Sea, is about 150 miles long; and the two angles, which, proceeding from the extremities of the base, converge till they meet at a point, are each about 1[illegible]0 miles in extent. This piece of insulated land was in former times much larger—being bounded on the east by the Pelusian branch, which is now choked up with sand, or converted into marshy pools. On the west, it was bounded by the Canopic branch, which is now partly confounded with the canal of Alexandria, and partly lost in lake Etho. The correspondence of the level of the surface to that of the present Delta, and its depression as compared with the level of the adjoining desert, together with its greater verdure and fertility, still mark the limits of the ancient Delta; although irregular encroachments are made by shifting banks of drifting sand, which are on the increase. The tract comprehended in the Bahr-Bilama, more properly Bahr-bela-mach, and the basin of the Natron Lakes, is one of the most remarkable features in the geography of the country. It lies on the western side of the Delta, fifteen miles distant from it at the nearest. These two vallies are separated by a low ridge, and run parallel to each other for about sixty miles. The mountain of Natron skirts the whole length of the valley of the same name. It contains none of the rocks which are found scattered about in the vallies, such as quartz, jasper, and petrosilex; and this circumstance has given rise to the opinion that the stones must have been conveyed thither by a branch of the Nile, which is supposed to have found its way formerly in this direction through what is called the Waterless Valley, to the Mediterranean. There is now a series of six lakes in the valley of Natron, the banks of which, as well as the surface of the waters, are covered with crystallizations both of muriate of soda and carbonate of soda or natron. The vegetation in these vallies has a wild and dreary aspect; the palms are mere bushes, and bear no fruit. Caravans occasionally visit it in quest of natron. The valley of Barh-bela-mach has, for the most part, a breadth of eight miles. In the sand, with which the surface is every where covered, trunks of trees have been found in a state of complete petrifaction, together with a vertebral bone. That these countries have undergone violent revolutions, is certain; but at what period or periods the changes took place, can only be conjectured. With regard to the extent of the modern encroachments of the desert, authorities are much at variance; but it appears evident that the Delta has been reduced by them. Almost the whole productive soil of Egypt consists of mud deposited by the Nile, and the Delta is entirely composed of it and sand.

Middle and Upper Egypt may be described as a narrow belt of land stretching from Syene to Cairo, a distance of 500 miles, and hemmed in on each side by two ridges of grey sandstone mountains, approaching sometimes within five or six miles of each other; and down this extended valley the majestic Nile rolls the waters which it had drawn from the Mountains of the Moon, to the Mediterranean Sea. Egypt contains about 200,000 square miles, of which only about 16,000 miles in the valley of the Nile are susceptible of cultivation. In round numbers, this is 10,000,000 of acres, or nearly one-half that of Ireland.

The total population of Egypt is estimated at about 2,500,000, which would give about 156 to every square mile. Its relative population, therefore, though not equal to that of Ireland, almost comes up to that of France, and far exceeds that of Austria, Russia, or Spain. Nearly one-half of this territory, it is supposed, is either periodically inundated, or capable of artificial irrigation. The remaining part requires a more laborious cultivation, and yields a more scanty produce. The inundated lands, though they have successively borne one crop, and frequently two, yearly, without intermission, for more than 3000 years, still retain their ancient fertility without requiring any tillage. Where the inundation does not reach, the crops are, however, very poor; but for maise and millet, the soil is particularly adapted. Taking, then, into consideration the quantity of land once arable, which is now covered with sand, the double harvest, and, of some productions, more than semi-annual crops, the smaller quantity of food which is requisite to sustain life in southern latitudes, and the extent to which the more barren soil was formerly rendered available by the cultivation of the olive, the fig-tree, the vine, and the date-palm, we shall no longer be at a loss to account for the immense fertility and populousness of ancient Egypt.

PRODUCTIONS.

The following are the principal productions of the country:—Wheat, barley, rice, millet, maize, flax, anise, sisamum, mustard, beans, lupins, lentils, vetches, Egyptian trefoil, the sugar-cane, indigo, saffron, hinneh, and tobacco. Melons and cucumbers grow "almost visibly;" they gain an inch in bulk every hour. A few pot-herbs are cultivated in the neighbourhood of the towns. Fayoum is distinguished for the cultivation of rose-bushes, from which is obtained the rose-water, which is in so great request all over the East. There are also some olive plantations in this province, and some Christians manufacture an indifferent wine. The vine is no longer cultivated in any other part of Egypt, except for the sake of its shade and its grapes, and the olive-tree is only to be met with in gardens.

The almond, the walnut, and the cherry, will not grow in Egypt; and neither the pear, the apple, the peach, nor the plum, comes to any perfection; but the citron, the lemon, and the pomegranate, the apricot, and the banana or plantain, flourish luxuriantly. The sycamore or Pharoah's fig-tree (less valued for its fruit than for its deep broad shade), the carob-tree, the jujube, the tamarind, and other trees, are also found here. But, in point of usefulness, as well as number, the date-palm is pre-eminent. It is cultivated both in the inundated and the irrigated lands, and groves of it are to be seen, consisting sometimes of several thousands, valued at a piaster each.

Another celebrated production of Egypt is the lotus. The plant usually so denominated is a species of water-lily, which, on the disappearance of the inundation, covers all the canals and pools with its broad round leaves, amid which the flowers, in the form of cups of bright white or azure, expand on the surface, and have a most elegant appearance. The roots of this vegetable were used as food by the ancient Egyptians. There is also the papyrus, not less celebrated in ancient times than the lotus. The colocasium is still cultivated in Egypt for its large esculent roots. The banks of the river and of the canals sometimes present coppices of acacia and mimosa; and there are groves of rose-laurel, willow, cassia, and other shrubs. Fayoum contains impenetrable hedges of cactus or Indian fig. But though so rich in plants, Egypt is destitute of timber, and all the fire-wood used is imported from Caramania.

CLIMATE AND SEASONS.

The soil of Egypt is never at rest, and the harvests are very rich. They follow each other at the distance of about six or eight weeks, according to the different kinds of grain, leaving time in most cases for a succession of crops wherever there is a full command of water. The cold season commences with December, and continues for about two months. Early in February, spring appears, when the atmosphere acquires a delightful warmth, and the trees put forth their blossoms. The period of summer may be said to commence in June, and to end at the close of September. The transition from the one season to the other is so imperceptible, that it is scarcely possible to say when the one begins and the other ends. During these four months, the heat is intense; the fields to which the swelling river has not attained, are parched like a desert, and no green leaf is seen but such as are produced by artificial irrigation. Autumn, which is only marked by a slight diminution of temperature, commences about the middle of October, when the leaves fall, and the Nile retires within its channel; and till the approach of that season, which can only be called winter from its situation in the calendar, the face of the country resembles a beautiful and variegated meadow. Volney's description is thus a matter of fact, that Egypt assumes in succession the appearance of an ocean of fresh water, of a miry morass, of a green level plain, and of a parched desert of sand.

From the nature of the surface, and the universal aridity of the surrounding desert, Egypt is much hotter than most other countries under the same parallel. From March to November, the atmosphere is inflamed by a scorching sun and a cloudless sky, the average height of the thermometer being about 90°; during the other six months, it is about 60°. At sunset, the winds fall, and the nights are generally cool, and the dews heavy. Except along the sea-shores, rain is a phenomenon in Egypt. At Cairo, there are on an average four or five showers in the year; in Upper Egypt, one or two at most: nor are they considered as beneficial to the agriculture of the country. Thunder and lightning are still more uncommon, and are likewise completely divested of their terrific qualities. Showers of hail, sweeping from the hills of Syria, are sometimes known to reach the confines of Egypt; but ice is a commodity so extremely rare, that instances have occurred of its being sold at a high price.

The winds are almost strictly periodical on the banks of the Nile. The northerly breezes predominate, blowing nine months in the year. Those from the south are the most changeable, as well as the most unhealthy. At their approach, the sky becomes black, the air is darkened with clouds of impalpable sand, so that it is sometimes necessary to use candles at noon-day. The effects thus produced upon the animal and vegetable creation are most pernicious; and when the simoom continues longer than three days, it becomes quite insupportable. It is remarkable that the southerly breeze, which in the spring of the year is attended with an intolerable heat, is during the winter noted above all others for an intense and penetrating cold. In the latter season, the rays of the sun fall more obliquely on the desert, and the current of air which descends on Egypt is chilled by the snowy mountains of Abyssinia.

NATURAL HISTORY.

In its geological features, Egypt presents great variety, including specimens of almost every formation, from the earliest to the most recent. Several granitic chains of hills stretch to a considerable extent. These contain vast quarries of syenite, from which the ancients drew the stupendous masses required for their colossal statues and obelisks. Between Assoun and Esna lies the sandstone, or middle district, which supplied slabs for the temples; and beyond it, the northern or calcareous district stretches to the southern angle of the Delta. This last chain supplied materials for the Pyramids, and many public buildings. The limestone extends from Syene to the Mediterranean, and, in Lower Egypt, from Alexandria to the Red Sea, in the vicinity of Suez. Other valuable rocks are abundant in Egypt, and various precious minerals are found. In zoology, the camel, so emphatically named the ship of the desert, has long been domesticated in the country. The giraffe, or cameleopard, has been occasionally seen. A quadruped, called virrera ichneumon, is one of the most celebrated animals in the country. Amongst the ancients, it was venerated with a species of worship. Ichneumons are domesticated in Egypt, where they perform the duties of our domestic cat, in ridding the houses of the smaller animals. The names of the crocodile and hippopotamus are familiarly associated with Egypt and the Nile. The number of the latter animal is now declined, and he is seldom seen below the Cataracts. A species of lizard, called the monitor of the Nile; the common cameleon; the lizard; the sorex, or shrew; and, of the marmot tribe, a particular genus called the dipus, or jerboa; the goat, sheep, and the animals which figure in the Egyptian mythology, such as the dog, ape, buffalo, &c.; still belong to the zoology of the country. Of birds, the ostrich, the ibis, of which there are several species, and the Egyptian vulture, are most famous. With respect to fishes, the country presents nothing remarkable.

INHABITANTS OF EGYPT.

The present natives of Egypt consist of—1. The Copts, the supposed descendants of the ancient Egyptians, and more certainly the feeble remnant of a once numerous Christian population. 2. The Fellahs, who compose the bulk of the labouring class, and who are supposed to be a mixture of ancient Egyptians, Arabians, and Syrians; they are rigid Moslems. 3. The Bedouin Arabs, the same in character, manners, and customs that they are every where, and apparently ever have been since the days of the patriarchs, regarding with disdain and proud independence all other classes of mankind, but more especially those of their own nation who have degraded themselves by taking up their abodes within walls. 4. Arabian Greeks; that is, the descendants of ancient Greek colonists, who have lost their ancient language, and speak a kind of Arabic. Many of them are mariners, but, in general, they pursue the inferior and handicraft trades. 5. Jews. To these must be added, as inhabitants of Egypt—6. Syrian-Greeks and Maronites, who have, within the last century, greatly increased in numbers, and have proved successful rivals of the Copts and Jews as merchants and agents. 7. Armenians. 8. Turks. 9. Franks. 10. Mameluke. 11. Moggrelins, or Western Arabs. 12. Ethiopians and other Africans. The following is as near an approximation as can be obtained of the relative numbers of the different divisions of this motley crew:—Copts 160,000; Arab Fellahs 2,250,000; Bedouin Arabs 150,000; Arabian Greeks 25,000; Jews 20,000; Syrians 20,000; Armenians 10,000; Turks and Albanians 20,000; Franks or Levantines 4000; Mamelukes 500; Ethiopians, &c. 7500; which amount in all to 2,667,000.

The Arabs have been divided into three classes; first, the wild independent Bedouins who occupy the desert; second, the pastoral tribes, who feed their flocks upon the borders of Egypt, and occasionally enter the cultivated provinces; and, lastly, the peasants, or Fellahs, who are devoted to agriculture and the arts. The latter, who form the bulk of the population, are described as a fine race of men in their persons, active in agricultural employments, and possessed of many good qualities. In their dress, and household economy in general, though not strangers to comfort, they are so to every thing like luxury. Their food is very plain, and none but the higher orders, or those of dissolute lives, ever taste wine. The Arabs carry on the common trades of civilised life, but in a very unskilful and imperfect manner. We shall have occasion afterwards to speak of the general state of trade and manufactures in Egypt.

The Arabs have seldom more than two wives; in general only one. The women for the most part can neither read nor write; but the better sorts are taught embroidery and ornamental needle-work, in which they mostly pass their time. The features of the Arab-Egyptian women are by no means regular. They are taller in general than our European women. Their hair is black and long, their skin of a disagreeable mulatto colour, and they stain various parts of their body with colouring matter. The tented Arabs still maintain their ancient character of proud independence, and in manners and customs are the same people they were three thousand years ago.

COPTS.

This singular and equivocal race of people, the supposed representatives of the ancient Egyptians, have been very variously described. Volney and Malte Brun say they have exactly the countenance of a mulatto. Dr Hume differs from them materially in his description; and Dr Richardson remarks, that "neither in their features nor in their complexion have the Copts the smallest resemblance to the figures of the ancient Egyptians represented in the tombs at Thebes, or in any other part of Egypt." He with much probability supposes them to be a mixed race, bearing traces of an alliance to the great Circassian family, and distinct from the aboriginal Egyptians. On the other hand, the Nubians found on the island of Elephantina are described by him as black, and possessing features similar to those found pourtrayed upon the ancient Egyptian tombs. A third and distinct race is also mentioned by the learned traveller; and, upon the whole, it may be concluded that the Copts are a mixed race, and not the pure descendants of the original inhabitants, who were, as regards colour, black, but without any mixture of the negro physiognomy. The conclusion seems to be, that they are Egyptian Greeks, with not less Grecian blood perhaps than the modern Albanian of the Morea.

Compared with other languages, the Coptic is said to exhibit some feeble indications of an ancient connection with the Hebrew and the Ethiopian, while it has received a mixture of modern Arabic. Arabic is now the language of Egypt, while the Italian is much used both by Franks and Copts. The Coptic is for the most part a dead language, being understood by few, though used in the service of the church. The Copts and the Jews are the general shopkeepers in Egypt. The Turks have grave features, an indolent habit of body, and in every thing an air of weight, which they associate with the idea of nobleness. The Greeks, who are now reckoned foreigners, present the regular features and the delicacy of their ancestors. There are said to be about 5000 descendants of the ancient Greek colonists, who form quite a distinct race from the modern Greeks. They have lost their original tongue, and speak a kind of Arabic.

Something still remains to be stated with regard to the present inhabitants of Egypt; but it is necessary that we should advert, in the first place, to its ancient history, and also to present such a picture of the ancient inhabitants as is to be gathered from the written records of the past, but more particularly from those ample and splendid memorials which they have left to all future ages—their works of art and mechanical skill.

HISTORY OF EGYPT.

The history of Egypt carries us far back "into the depth of ages past." An obscurity, however, envelopes it on every side, and the inquirer receives but little illumination upon this subject, by being told that the first king was called Menes, and that he reigned, according to Dr Hales, 2412 years before the birth of Christ. This monarch is said to have greatly improved Egypt by works of extensive utility. He was succeeded by a race of native princes, who, with their founder, reigned 253 years. The country was then invaded by the Shepherds (supposed to be the progenitors of the Philistines), who established a new dynasty, which lasted 260 years. During their sway, it is supposed that Abraham visited Egypt, and the first pyramid was begun. After their expulsion, we find a third dynasty of native sovereigns, from the commencement of whose rule, and the exode of the Israelites, 251 years elapsed. Then a fourth dynasty began to rule, which lasted to the death of Mœris, embracing a period of 340 years, and bringing us to the year 1308 before the Christian era. We come now to the renowned conqueror Sesostris, the son of the last-named king. This monarch, the first Alexander, if the name of the Macedonian may be used as the generic appellation of conquerors, spread the terror of his arms over Asia. He, however, devoted himself to the arts of peace as well as those of war; and the erection of many magnificent temples and public works, of great extent and utility, has been ascribed to him. The reigns of the successors of this monarch are not characterised by any thing remarkable. Up to the year 679 before Christ, when the annals of Egypt begin to be divested of fable, the names of Amasis or Ammosis, Cetes, Cheops, Sabacon, Sethon, and others, fill up the void of history. This period embraces the fifth and sixth dynasties, and a period of 635 years. The seventh dynasty commences with twelve contemporary kings, to whom succeed the famous names of Psammetichus, Necho, Psammis, Apries or Pharaoh Hophra, Amasis, and Psammenitus. Between the reigns of the two latter monarchs, Egypt was conquered by Cyrus; but that famous warrior exercised a liberal policy towards the inhabitants, and allowed them a degree of national independence, which it is supposed they abused so much, as to draw down upon their heads the vengeance of his successor Cambyses, who reduced the country, at the same time blotting his triumphs with the most wanton cruelties. The government of Persia lasted 112 years; then came a dynasty of Egyptian kings, who reigned 81 years, when the name of Alexander the Great is added to the list of Egypt's subjugators. Upon the division of the Macedonian empire, Egypt fell to the share of Ptolemy Lagus, one of Alexander's generals, and in every respect worthy of the throne of the Pharoahs. To this prince literature and philosophy owe many obligations, of which our limits will not permit us to speak. It may be mentioned, however, that he was the founder of the celebrated Alexandrian library. The period embraced by his successors, the renowned Ptolemies, is one of the brightest in the annals of the country. With one of the last of these princes, we find the name of Cleopatra associated in the government, the administration of which, however, was in a great measure in the hands of the Romans. The joint rule of Ptolemy Dionysius and Cleopatra was of short continuance, and a civil war consummating the dissension, the latter was compelled to seek refuge in Syria. Soon after this, the fate of Rome and the world came to be decided upon the plains of Pharsalia. The exiled sovereign was protected by the situation of affairs, and succeeded in obtaining, through the instrumentality of Cæsar, the share of power which she had lost. This gave rise to a war, in which Ptolemy, and the last remains of Egyptian independence, perished together. Cleopatra was indeed nominally the sovereign of the country, conjointly with her brother, a mere child. He, however, soon after fell a victim to the furious passions which at that period dishonoured the descendants of the great Ptolemy, and the beautiful and accomplished, but abandoned Cleopatra, became at once the mistress of Egypt and of Cæsar. After the victory of Octavius at Actium, she committed suicide, and Egypt became a Roman province. This took place 30 years before Christ, and remained 670 years in the hands of the Romans. The Christian religion, during this period, gained footing in this country, and was accompanied by the same enthusiasm, sectarianism, and mental gloom, which, in the earlier history of Egypt, had accompanied the pagan mysteries. Anchorites and monks had their origin here. After the division of the great Roman empire, in the time of Theodosius, into the western and eastern empires, Egypt became a province of the latter, and sunk deeper and deeper in barbarism and weakness. It was the prey of the Saracens; Amru, their general, under the Caliph Omar, taking Alexandria, the capital, by assault. This happened A.D. 640, when Heraclius was the emperor of the East. As a province of the caliphs, it was under the government of the celebrated Abbasides (Haroun-al-Raschid and Al-Mamon), and that of the heroic sultan Saladin. The last dynasty was, however, overthrown by the Mamelukes (1250), and under these formidable despots the last shadow of former greatness and civilisation disappeared. Selim, sultan of the Turks, eventually (1516, 1517) conquered the last Mameluke sultan, Tumanial, and Egypt became altogether a Turkish province, governed by a pacha. It has since been the theatre of continual internal wars of the Mameluke beys against the Turkish dominion, which has been several times, especially under Ali Bey (1766), nearly extinguished in this country.

Before giving a sketch of the more recent history of Egypt, we shall here present a view of its ancient literature, science, and civil and religious institutions.

ANCIENT EGYPTIAN CHARACTER.

If we contemplate the ancient Egyptians in their private life and political character, taking into view their manners, customs, and laws, we shall find a solution for many perplexities respecting this peculiar people. The gloomy religion of the Egyptians banished gaiety from their private circles. They were serious, devout, and superstitious; songs, dances, and sports, they disliked; but they nevertheless possessed good temper and politeness. The government of the state was mostly in the hands of females. Every priest might have at least one wife; to the laity the number was not limited by law. The Egyptian was distinguished for temperance in eating and drinking, and his dress was very simple. The sovereign, however, and those who immediately surrounded him, glittered in oriental pomp and magnificence. The power of the Pharoahs (the general name of the earlier kings of Egypt) was unlimited; but the will of the ruler was subject to the control of the priests. Justice was administered by an efficient police, who took care that criminals should be constantly employed. As early as the time of Joseph, there was a workhouse for imprisoned slaves. Written laws were handed down by Menes, Tnephactus, Bocchoris, and Amasis. All causes were tried before a supreme court of justice. The parties themselves were obliged to conduct them in writing without the aid of advocates. The children were brought up to the trade of their father, and instructed by the priests. Few were taught reading and writing, although the Egyptians were the first people who could write, that history mentions, after the Babylonians and Phœnicians. The people were divided into seven castes—priests, soldiers, shepherds, swineherds, mechanics, interpreters, and fishermen. At the head of them all stood the priests, the first and most influential caste. They maintained this rank as teachers of the people and patrons of science; from them all the offices of state were filled; they were the physicians, judges, architects, astronomers, astrologers, &c. The religion and philosophy of the Egyptians differed at different periods of their civil history. The former was wholly founded upon astronomy. Osiris and Isis, the sun and moon, who were revered as beings of unlimited power, were the two principal deities; and the Nile was supposed to be very nearly related to them. The period of 360 days, computed from the regular inundation of the river at the summer solstice, constituted the religious year; the natural solar year consisted of 365 days and 6 hours. The planets and the signs of the zodiac were reverenced as deities and rulers of the several seasons of the day and year. To each divinity was assigned a particular order of priests. Pilgrimages and sacrifices were a part of their religious system, and till the time of Amasis, even human victims were offered. Besides the heavenly bodies, some kinds of animals were worshipped, not as mere symbols, but as actual gods, like the Apis and Mnevis. The most singular part of the Egyptian creed was the doctrine of the transmigration of souls, in which they believed.

COMMERCE AND PHILOSOPHY

The first important impulse received by the Egyptians in intellectual culture, was subsequent to the subjugation of the country by foreign nations. Previously to this, however, there were astronomers in the country. The Egyptian solar year contained twelve months and five supplementary days, like the republican calendar of the French. The form of the earth was known to Egyptian scholars. Solar and lunar eclipses were calculated. The moon they regarded as another earth, the fixed stars as flaming torches. Sun-dials and water-clocks were known to them; the immense ring of Osymandyas seems to have been used for this purpose; and they would appear to have been acquainted with the quadrant. Their progress in arithmetic must therefore have been considerable. Their acquaintance with geometry and mathematics is certain; and, from their water-screws, canals, sluices, &c., they must also have possessed a knowledge of mechanics, hydraulics, and hydrostatics. The Egyptian music is the basis of the Hebrew, Greek, and Roman. The first musical instrument, the three-stringed lyre, was invented amongst them by Hermes. They had also other instruments, but musical notation does not seem to have been known to them. Their knowledge of natural history was confined to their native country and its productions, and their natural philosophy was mystical. They penetrated a good way into chemistry and mineralogy; and the art of mining was carried on amongst them upon a grand scale. They probably made considerable progress in the art of healing. The gods of health were Osiris, Isis, and Hermes. Particular diseases had a particular class of physicians, who were priests. The king, as well as the lowest peasant, was subjected to the regimen prescribed by them. Their dietetics became celebrated in other countries. Care of the skin, a thorough cleanliness, preserved by frequent bathing, and the practice of circumcision, were their principal prescriptions. From their skill in embalming the dead, we may judge of the anatomical knowledge of the Egyptians. Their acquaintance with navigation they owed to the great Sesostris, by whom commerce was established. It prospered most under the Ptolemies. Alexandria became the first emporium; the famous Pharos was erected; and the canal, 1000 stadia in length, joined the Red Sea with the Mediterranean. When Egypt became a Roman province, it lost its previous commercial distinction. The Egyptians were particularly devoted to agriculture, and their measures for promoting it were bold, both in contrivance and execution. Their trade was confined for a long time to the sale of their own productions to foreigners who visited Egypt to purchase them. In the time of Psammetichus they began to export for themselves. Measures, weights, and money, they were acquainted with; and their skill in weaving and colouring supplied them with articles of exchange.

LITERATURE.

The ancient literature of Egypt does not call forth our admiration, like that of Greece or Rome. No splendid specimens of composition have survived the vicissitudes of time, and come down to us; but that they had made considerable progress, is beyond a doubt. Tatian informs us that the Greeks learned how to write history from perusing the Egyptian annals. Their chronicles seem to have been originally written in verse, which were inscribed on stones in pictorial characters, of which we shall shortly speak. From various ancient authorities, we learn that historical treatises were numerous in Egypt. Strabo even praises the simplicity of their style. As early as the reign of Osymandyas, 1308 years before the commencement of our era, a library was established at Thebes, and another at Memphis, the two capitals of the country. Indeed, much of the admiration which the Greeks call forth from us, belongs in some respect to the Egyptians; for there is every reason to believe that most of the scientific and literary acquirements which distinguished the Greeks, while the rest of Europe was in a state of barbarism, were derived from their intercourse with the scholars of Thebes and Memphis. The Egyptians had a peculiar method of notation, an inquiry into which has lately engaged much attention, but the subject is too extensive to be here entered upon. As to the poetry, eloquence, and polite literature of that remarkable people, we are still too ignorant of the Coptic language to form any judgment upon. Their progress in the arts will be seen when we come to examine the gigantic remains which they have left us. We may only here remark, that the architects of Thebes, the pyramids, &c., must have had considerable knowledge both of mechanics and chemistry.

HIEROGLYPHICS.

The method employed by the ancient Egyptians for expressing their ideas was that of pictorial writing, the original expedient of mankind in every age and country for giving permanency to his conceptions. When America was first discovered, it was found to be in use amongst the natives, and it is the vehicle of thought with the Chinese of the present day. The term hieroglyphic literally signifies sacred writing, but it has been extended to the emblematical style in general, of which there were three kinds, named according to the characters of the individuals by whom each was used. These distinctions are recognised by Clemens Alexandrinus in a passage of his works, a paraphrastic translation of which we shall give by the learned author of "A View of Ancient and Modern Egypt."

"Those who are educated among the Egyptians," says he, "learn first of all the method of writing called the Epistolographic; secondly, the Hieratic, which the sacred scribes employ; and, lastly, the most mysterious description, the Hieroglyphic, of which there are two kinds; the one denoting objects in a direct manner, by means of the initial sounds of words, the other symbolical. Of the symbolical signs, one class represents objects by exhibiting a likeness or picture; another, by a metaphorical or less complete resemblance; and a third, by means of certain allegorical enigmas. Thus, to give an example of the three methods in the symbolical division, when they wish to represent an object by the first, they fix upon a distinct resemblance, such as a circle when they want to indicate the sun, and a crescent when their purpose is to denote the moon. The second, or metaphorical, allow a considerable freedom in selecting the emblem, and may be such as only suggests the object by analogous qualities. For instance, when they record the praises of kings in their theological fables, they exhibit them in connection with figurative allusions which shadow forth their good actions and benign disposition. In this case the representation is not direct, but metaphorical. Of the third method of symbolical writing, the following will serve as an example: they assimilate the oblique course of the planets to the body of a serpent, and that of the sun to the figure of a scarabæus." In the above extract there is mention made of that species of hieroglyphics which express objects by the initial letters, a remark that is now perfectly intelligible, but which, till the year 1814, presented a most perplexing enigma to the ablest scholars in Europe. For this discovery we are indebted to Dr Young, whose investigation, with those of Champollion and others, have thrown considerable light upon this mystical subject. But notwithstanding all the discoveries which have been made, our knowledge of ancient Egyptian literature is still very limited, and we must not, therefore, estimate the extent of their acquirements by the scanty remains of their labours which have survived the wasting hand of time and the violence of man. Diodorus Siculus informs us that in the tomb of Osymandyas 20,000 volumes were deposited.* These works were unquestionably of high antiquity, for which, as well as for the importance of their subjects, they were ascribed to Thoth or Hermes, an individual of extraordinary intelligence. In conclusion, we may remark, that, from the Egyptian hieroglyphics sprung the regular alphabet, and that Cadmus conveyed his gift of sixteen letters across the Mediterranean from Egypt. This invention contributed in a great measure to the improvement of the Greeks, and laid the foundation of their literary fame—perhaps their future glory in all respects. The arrival of the renowned adventurer above named, from the banks of the Nile, continues to be recognised as the epoch when civilisation and a knowledge of the fine arts were first received by the barbarians of eastern Europe.

Before proceeding with the topographical details, it may be proper in this place to introduce a description of some of those magnificent remains of art and mechanical ingenuity which they have left us. By this means we will obtain a more complete view of the progress which they had made in civilisation, and how much other countries have been anticipated in their discoveries by that remarkable people who inhabited Egypt three thousand years ago. We shall here only bring forward those which are the most remarkable, and with the names of which the reader is probably most familiar, leaving the remainder to be noticed as they occur in their local order.

PYRAMIDS.

Amongst the extraordinary remains of mechanical ingenuity and art which the ancient Egyptians have bequeathed to the admiration of all future times, the pyramids are conspicuous. Their number scattered over Egypt is very great, and in magnitude and antiquity are alike remarkable. They are of a quadrangular shape, having a broad base, gradually contracting towards the top, generally built of large limestones, of different heights, usually having a base equal to the height, with their four sides facing the cardinal points. During several thousand years they have attracted the curiosity of the traveller, and exercised the ingenuity of the learned. By far the most magnificent are those of Djizeh, Sakhara, and Dashour, in the neighbourhood of Grand Cairo, the capital of the country.

The pyramids of Djizeh, the largest and most remarkable of these stupendous remnants of the past, stand upon a bed of rock 170 feet above the desert, and 163 feet above the river, which contributes to their being seen from a very great distance. The largest of these, which has been ascribed to Cheops, a tyrannical and profligate sovereign, is a square of 746 feet, and its perpendicular height is 461 feet, being 24 feet higher than St Peter's at Rome, and 117 feet higher than St Paul's at London. The effect which it produces upon the mind from a distance is very fine. From the purity of the atmosphere, the upper gradations of the pyramid are as distinctly visible as the upper layers of a pile of bricks, which materially increases the illusion of the vast dimensions of the structure, and accounts for the discrepancy that prevails amongst travellers as to their actual height. From there being no neighbouring object with which to compare the fabric, no adequate idea is formed of its real magnitude until the traveller arrives at its base, and finds the first tier of stones on a level with his chest; of these there are 206, which vary from one to four feet in height, the square of each tier being smaller than the one below, so as to leave the space of two or three feet all around, forming what are called the steps. Each step is from a foot to a foot and a half in breadth, and the average height is about two feet and a quarter, so that the ascent is comparatively easy; and about the middle the steps are much broken, but at the angles they are perfectly entire. On the summit is an area, about thirty feet square, consisting of six square blocks of stone irregularly disposed. These measurements of the great pyramid are those of Davison, who was very careful in making them, and are probably a very near approximation to the truth. Six millions of tons of stones are supposed to have been consumed, and 100,000 men for twenty years are said to have been employed in the erection of this the most stupendous sepulchre that ever contained the ashes of men. The view from the summit, though limited, is, from association, impressive. The internal aspect of this wonderful structure is not less astonishing than its gigantic exterior; upon the sixteenth step, and nearly in the centre of the side which faces the north, an entrance is obtained. A small narrow passage descends into the interior for about ninety-two feet. After various circuitous windings, the traveller arrives at an apartment, called the queen's chamber, which is 17 feet long, 14 high, and 12 wide; immediately above it, is another, called the king's chamber; it is nearly twice the size of the former. In this room stands a sarcophagus of red granite, which, however, contains nothing but granite and dust. Above this, is a third apartment, called Davison's chamber, and named in honour of the discoverer. To the same individual we are indebted for the first examination of the well, which is referred to by Pliny as being eighty-six cubits in depth. This achievement was accomplished by Mr Davison after great labour and skill, and even personal danger. It was afterwards explored by Mr Caviglia, a traveller who has now been familiarly associated with Egyptian antiquities, but he added little to the information previously given by the individual who preceded him. We are indebted to him, however, for the latest and most complete survey of the caverns in the pyramid of Cheops. In prosecution of his indefatigable labours to penetrate these mystical labyrinths, after having discovered a new passage, and succeeded in ventilating the interior, he arrived at a chamber sixty feet long, and twenty-seven broad, with a flat roof, and nearly filled with large stones and rubbish. It has the appearance of an unfinished excavation, and was probably employed for the performance or solemnization of sacred mysteries. Other passages were found, but their discovery led to no results of importance.

To the celebrated Belzoni we are indebted for a knowledge of the interior of the pyramid of Cephrenes, brother and successor of Cheops, but any detail of his labours would carry us far beyond our limits. Suffice it to say, that they were directed with remarkable skill, and a perseverance which no obstruction could arrest. It stands upon a rather higher elevation than that of Cheops, and is built of the same species of limestone, and joined with the same kind of cement. Its base is 684 feet, and its height 456. The steps are much splintered and broken, but it can be ascended to a certain extent on the southern side without great difficulty. The opening of this pyramid presents to us a striking instance of discrimination and tact. Herodotus had declared that it contained no chambers, and modern travellers had taken this as *dit* for granted. The practised eye of Belzoni, however, detected certain indications of an entrance, and, after many days of labour upon the hard stone, he found himself at last in a chamber hewn out of the solid rock, from the floor to the roof, which last is of the same stone as the pyramid itself. In the sarcophagus were the bones of an animal, very generally supposed to be those of a sacred bull, an object of veneration among the ancient Egyptians. On the wall at the west end of the chamber he perceived an Arabic inscription, from which it has been inferred that the two larger pyramids had been explored, at the distance of many years, by some of the caliphs. The third large pyramid is that of Mycerinus; but it is a good deal less, and not so important an object as the others. There is also a fourth large pyramid, although travellers are in the habit of speaking of the pyramids of Djezeh as only three in number. Those of Sakhara, or Dashour, appear to be a continuation of the great cemetery to which those of Djezeh belong. Two of them only are very large, and they are all more dilapidated than those we have described; hence, a higher antiquity has been ascribed to them. With regard to the other pyramids, they are, in their leading characters, nearly similar to those described, and the end for which they were constructed we infer was the same; but what was the primary object of the ancient Egyptians erecting these immense fabrics? Upon this point we have nothing satisfactory to say, except that, whatever might have been their use at first, they became receptacles for the dead at last. Some maintain that they were consecrated to the sun, others that they were used for astronomical observations, others for transmitting historical information, and so on. With regard to their antiquity, the most probable conjecture is, that they were erected at a

* Manetho reduces the number to between three and four thousand.

period between 1000 and 800 years before the Christian era.

SPHINX AND TUMULI AROUND THE PYRAMIDS.

Numerous ruined edifices and tumuli lie scattered about at random among the other pyramids, like graves in a churchyard, and extend north and south along the left bank of the Nile as far as the eye can reach. The stone buildings, supposed to be mausoleums, are generally of an oblong form, having their walls slightly inclined from the perpendicular inwards, the peculiar characteristic of ancient Egyptian architecture; flat-roofed, with a sort of parapet round the outside, formed of stones; rounded at the top, and rising about a foot above the level of the terrace. The walls are constructed of large masses of stone, of irregular shape. The various chambers of these edifices were found to be profusely embellished with sculptures and bas-relief paintings, many of which were spirited and beautiful. In one of them were found the remains of several mummies, and in another the fragments of a figure as large as life. An important circumstance remains to be noticed: In each of these edifices there was discovered a well, from the bottom of which a passage led to a subterranean chamber. Caviglia cleared out one of these shafts, which was sixty feet deep; and in the chamber he found a plain but highly-finished sarcophagus, nearly of similar dimensions with that in the pyramid of Cheops. This supplies a strong argument in favour of the hypothesis, that the pyramids are tombs.

By far the most brilliant of Mr Caviglia's discoveries, are those to which he was led in the laborious task of uncovering the great sphinx in front of the pyramid of Cephrenes. On the stone platform on the foreground, and centrally between the outstretched paws of the sphinx, was discovered a large block of granite, which fronted the east, and was highly embellished with sculpture in bas-relief. Two other tablets of calcareous stone, similarly ornamented, were supposed, with that of granite, to have constituted part of a temple, by being placed one on each side of the latter, and at right angles to it. One of them in fact was still remaining in its place. Of the other, which was thrown down and broken, the fragments are now in the British Museum. A small lion couchant, in front of this edifice, had its eyes directed towards the sphinx. There were, besides, several fragments of other lions, rudely carved, and the forepart of a sphinx, of tolerable workmanship. In front of the temple was a granite altar, with one of the four "horns" still retaining its place at the angle. From the effects of fire evident on the stone, this altar, it would seem, had been used for burnt-offerings. Inscriptions were found upon the digits of the paws, but of no moment.

Like every thing else in Egypt, this singular monument has been the subject of very opposite representation. The general accuracy of Dr Richardson induces us to lay his account of it before the reader. "The breast, shoulders, and neck, which are those of a human being, remain uncovered; as also the back, which is that of a lion. The neck is very much eroded, and, to a person near the head, seems as if it were too heavy for its support. The head-dress has the appearance of an old-fashioned wig, projecting out about the ears like the hair of the Berberi Arabs; the ears project considerably; the nose is broken; the whole face has been painted red, which is the colour assigned to the ancient inhabitants of Egypt, and to all the deities of the country except Osiris. The features are Nubian, or what from ancient representation may be called ancient Egyptian, which is quite different from the negro feature. The expression is particularly placid and benign, so much so that the worshipper of the sphinx might hold up his god as superior to all the other gods of wood and stone which the blinded nations worshipped." As to the dimensions, the same author informs us that the stretch of the back is about 120 feet, and the elevation of the head above the sand from thirty to thirty-five. The head of this sphinx is supposed to be that of a man, a *beard* which was found between the paws being considered as decisive of the point. With respect to its antiquity, Dr Richardson thinks, that, although it is not mentioned by Herodotus, it must have been in existence in his time.

RUINS OF MEMPHIS.

The very site of this once famous city of Egypt has been a subject of learned dispute. According to Herodotus, its foundation was ascribed to Menes, the first king of Egypt. It was a large, rich, and splendid city, and the second capital of Egypt. Among its buildings were a number of remarkable temples and palaces of astonishing grandeur and magnitude. In Strabo's time (A.D. 20), it was in population and size next to Alexandria. Edresi, in the twelfth century, describes its remains as extant in his day, and of a magnificence which no language could convey any idea of. Its ruins then extended nine miles in every direction; but the destruction has since been so great, that, although Pocock and Bruce fixed upon Matrahenny as the site, a village which lies a few miles above the pyramids, it was not accurately ascertained until the French expedition to Egypt, when the discoveries of numerous heaps of rubbish, of blocks of granite covered with hieroglyphics and sculpture, and of colossal fragments scattered over a space three leagues in circumference, seem to have decided the point. And this is all that remains of the once lofty city.

RUINS OF THEBES.

The glory of Thebes, once the capital of the Thebaid or Upper Egypt, must now be traced in four petty villages, Luxor, Karnac, Medinet Abou, and Gornoo, situated about 400 miles above Cairo. Thebes is famous as "the city of a hundred gates," the theme and admiration of ancient poets and historians, the wonder of travellers, "that venerable city," as Pocock eloquently remarks, "the date of whose destruction is older than the foundation of other cities, and the extent of whose ruins, and the immensity of whose colossal fragments, still offer so many astonishing objects, that one is rivetted to the spot, unable to decide whither to direct the step or fix the attention." These ruins extend about eight miles along the Nile, from each bank to the sides of the enclosing mountain, and describe a circuit of twenty-seven miles. The most remarkable objects on the eastern side are the temples of Karnac and Luxor; and on the western are the Memnonium, or palace of Memnon, two colossal statues, the sepulchres of the kings, and the temple of Medinet Abou. Almost the whole extent of eight miles along the river is covered with magnificent portals, obelisks decorated with the most beautiful sculpture, forests of columns, and long avenues of colossal statues. The largest of these temples, and of any in Egypt, is that at Karnac, on the site of the ancient Diospolis.

In respect to the magnificence and beauty of its several parts, this temple has been pronounced as having no parallel in the whole world. It has twelve principal entrances, each of which is composed of several propyla and colossal gateways, besides other buildings attached to them, in themselves larger than most other temples. The sides of some of these are equal to the bases of the greater number of the pyramids in Middle Egypt. One of the propyla is entirely of granite, adorned with the most finished hieroglyphics, and many of them have been furnished with colossal statues. The avenues of sphinxes that lead in several directions to the propyla, one of which was continued the whole way across the plain to the temple at Luxor, nearly two miles distant, correspond to the magnificence of the principal structure; and the body of the temple, which is preceded by a large court, consists of a prodigious hall or portico, the roof of which is supported by one hundred and thirty-four columns, some twenty-six, others thirty-four feet in circumference; four beautiful obelisks then mark the entrance to the shrine, which consists of three apartments, built entirely of granite. The dimensions of this great edifice are about 1200 feet in length and 420 in width. But the principal fane, grand and imposing as it is, sinks into nothing when compared with the extent and number of the buildings which surround it; the prodigious gateways of polished granite, covered with sculpture and adorned with colossal statues; the subordinate temples which any where else would be esteemed magnificent piles; and the avenues, which approach it from almost every point of the compass, miles in length, and guarded by rows of sphinxes of vast size, cut out of single blocks of syenite. The field of ruins at Karnac is about a mile in diameter. Probably the whole of the space was once, in the prouder days of Thebes, consecrated entirely to the use of the temple.

About a mile and a quarter above Karnac are the village and temple of Luxor. This temple, though not of such vast dimensions as that of Karnac, is in a superior style of architecture, and in more complete preservation. The entrance is thought to surpass every thing else that Egypt presents, and the two obelisks are considered the finest in the world. But the objects which most attract attention are the sculptures which cover the east wing of the northern front. They contain, on a great scale, a representation of a victory gained by one of the ancient kings of Egypt over their Asiatic enemies. The number of human figures introduced amounts to 1500, 500 on foot and 1000 in chariots.

The disposition of the figures, and the execution of the whole picture, are equally remarkable, and far surpass all preconceived ideas of the state of art at the remote era to which we must attribute them. After passing several gateways, we enter what is conjectured to be the palace of the great Osymandyas. These ruins of Luxor and Karnac represent only one-half of ancient Thebes. The temples of Medinet Abu are also splendid, and upon a grand scale. It was so placed as to be exactly opposite to that of Luxor, on the other side of the Nile, while the magnificent structure at Karnac was fronted by the Memnonium or temple of Dair; and hence all these grand objects formed so many stages or prominent points in the religious processions of the priests. Though the tabernacle of Jupiter dwelt at Karnac, the proper Dicopolis, yet it was carried over the river every year, and remained a few days in Libya; and we find, from a general estimate, that there was a space of between nine and ten miles over which they might exhibit the pomp and parade of their superstition both going and returning. Almost every part of the road through this immense theatre was lined with sphinxes, statues, prepylas, and other objects calculated to inflame the ardour of devotion.

MEMNONIUM AND STATUE OF MEMNON.

This celebrated relic of antiquity, the palace of King Memnon, faces the east, and is fronted with a stupendous propylon, of which 234 feet of its length are still remaining. To the minute Dr Richardson we are indebted for the most elaborate account of it, only a small portion of which, however, we can afford space for. The temple is in a rather dilapidated condition. Every stone in the propylon appears to have been shaken and loosened, as if from the concussion of an earthquake. The passages which conduct to the chambers are so broken and filled up, as hardly to admit of examination. The walls are in various parts ornamented with sculptures, and other pictorial devices. One of the most striking is a battle scene. The various situations of victors and vanquished are represented in a very lively manner, and the whole sculpture, though but roughly executed, is full of fire. In the Memnonium there is still to be seen the statue of Osymandyas, or Sesostris, which is allowed to be the finest relic of art which the place contains, although shattered and broken. It is about twenty-six feet broad between the shoulders, fifty-four feet round the chest, and thirteen feet from the shoulder to the elbow. There are on the back hieroglyphical tablets, extremely well executed, which identify this enormous statue with the hero whose achievements were sculptured on the walls of the temple.

The above figure has sometimes been confounded with that of Memnon, so long celebrated for its vocal qualities. The latter, however, is one of the two statues vulgarly called Shamy and Damy, which stand at a little distance from Midenet Abou, in the direction of the Nile. These, we are told, are about fifty-two feet in height. They rest on thrones, which are respectively thirty feet long, eighteen broad, and between seven and eight high. They are placed about forty feet asunder, are in a line with each other, and look towards the east, directly opposite to the temple of Luxor. The southern one appears to be of one entire stone. The face, arms, and front of the body, have suffered so much, that not a feature of the countenance remains. The head-dress is beautifully wrought, as also the shoulders, which, with the back, are uninjured. The massy hair projects from behind the ears like that of the sphinx. The sides of the throne are highly ornamented with elegant devices. The colossus is in a sitting posture, with the hands resting upon the knees. On the outside of each of the limbs there is a small statue, and another between the feet.

The gigantic statue which stands on the north side, would appear, from various circumstances, to be that of the vocal Memnon, who was said to play a lively strain when the sun rose, and a melancholy one when he set. It presents the same attitude as its companion, with a similar figure between the feet and on each side of the legs. It has, however, been broken over at the waist, and half of it taken away; but the figure has been again completed by courses of common sandstone. It is entirely fashioned like the upper part of the other, having several hieroglyphics, and other emblems, sculptured between the shoulders, but they are not of so elegant a character. These statues stand on either side of an avenue leading to a place of worship, and evidently were followed by a series of other colossal figures, as the remains of some of them are still visible. Belzoni here found a handsome statue of black granite, which is now within the precincts of the British Museum. Dr Richardson is of opinion that this ruined temple is the Memnonium, and not that where the broken statue of Osymandyas is to be met with.

SEPULCHRES.

Nothing about the ancient Egyptians appears to our European ideas more remarkable than their magnificence in adorning their places of sepulture. With them the abodes of the dead were as carefully constructed, and as lavishly decorated, as those of the living. The number of caves, and grottoes, and suits of catacombs, not only for the reception of human bodies, but those of the lower animals, as we shall afterwards see, is prodigiously great. Some of the most remarkable of these tombs are in the vicinity of Thebes. The mountains on the western side of that once gorgeous metropolis, have been nearly hollowed out as tombs for the inhabitants; and a solitary valley in the neighbourhood is also full of these gloomy receptacles for the dead. Those farther up the river, at Eleithias, though less splendid than the Theban sepulchres, contain more illustrations of the private life of the Egyptians. The Egyptian sepulchral chambers are in general entirely covered with fresco paintings and bas-reliefs, and frequently contain statues, vases, &c. Some of them, the royal sepulchres for instance, consist of suits of spacious halls and long galleries of magnificent workmanship. Those of private individuals vary according to the wealth of the deceased, but they are often very richly ornamented. Mr Belzoni, who possessed an infallible instinct for detecting the secret accesses to these gloomy abodes, discovered several vaults of a most splendid description. The chambers were of ample dimensions, and lavishly adorned with paintings and sculptures. In one of them was found a sarcophagus of beautiful workmanship, and in all respects superior to any thing of the kind ever brought to Europe.

Dr Young discovered among the drawings copied from this tomb, the names of Necho and Psammis, kings of Egypt, the former of whom conquered Jerusalem and Babylon, and the latter warred with the Ethiopians. Hence, it appears evident that these tombs contained the ashes of the two Pharaohs above named, who flourished nearly 2500 years ago.

Every one must be familiar with those tombs of the ancient Egyptians, called catacombs. Those of Alexandria are the most celebrated, but in spaciousness, general arrangement, and embellishment, they are inferior to the sepulchres already described.

The ancient Egyptians embalmed all their dead, and deposited them in subterraneous vaults, such as we have described. An immense number of them has been found in the plain of Saccava, near Memphis; hence called the Plain of the Mummies, consisting not only of human bodies, but of various animals. Many of the mummies are two or three thousand years old, and are all in a state of wonderful preservation. We may also observe, that some of the lower animals had like honours paid to them, and that catacombs set apart for their reception had been discovered.

RUINS OF DENDERA, OR TENTYRA.

This scene of ruins is about half an hour's ride from the river, and about 140 miles below Syene. They are more than a mile in length, and half a mile in breadth. The grand object of interest here is the temple, a very celebrated ruin. This magnificent building presents one of the most striking examples of that sumptuous architecture and profuse ornament which the Egyptians lavished upon their sacred edifices. Some idea of its grandeur may be gathered from the circumstance recorded of the French army during its campaign in Egypt. When the soldiers first beheld the ruins, they were so overpowered with their gigantic size and extraordinary beauty, that they exclaimed, as with the heart and voice of one man, such a sight more than repaid them for all the sufferings and dangers of the war. It is supposed to have been consecrated to the worship of Isis, who was the principal deity in the Egyptian Pantheon. The temple itself still retains all its original magnificence. Time has only rendered it more venerable and imposing in appearance. The gateway which leads to the temple has in particular excited universal attention, on account of its magnificence. On the corners of the roof are several apartments, in one of which is the circular zodiac.

Denon, who is extravagant in his praise of this celebrated place, copied the zodiac, and the celestial planisphere. These have excited much discussion amongst philosophers, as they are supposed to indicate an antiquity inconsistent with the chronology of Scripture. But nothing satisfactory has resulted from this learned inquiry.

LAKE MŒRIS AND CANALS.

Amongst the great works of the ancient Egyptians, lake Mœris is worthy of a place, both for its vast extent and for its patriotic object. It is situated in Middle Egypt, about 48 miles above Cairo. Herodotus informs us that the circumference of this vast sheet of water was 450 miles, and that it had two pyramids of great height in the centre. He adds, that it was entirely the product of human industry. At present, the lake is between thirty and forty miles long, and six miles broad at the greatest. The details collected by Herodotus and other writers must therefore have applied to the works which were necessary not only to connect the Nile with the lake, but also to regulate the ebb and flow of the inundation. The canal called Joseph's River is about 120 miles in length.

The most remarkable of the many Egyptian canals is that which connected the Nile, near Bubastis, with the Red Sea, near Arsinöe, in the vicinity of the modern Suez. The length of it was about ninety-two miles, of which it appears that sixty-five were accomplished by human labour; and of that portion about one-half yet exists in a state more or less perfect. Its breadth varied from 100 to 200 feet, according to the character of the country which it traversed. Its depth has not been so accurately determined, but it also must have varied according to circumstances; in some parts it was ten and in others probably thirty feet. Some have ascribed the execution of this great work to Sesostris, and others to Nechos; but the settling of the point is a matter of small moment.

The Labyrinth is mentioned by Herodotus as one of the greatest wonders of Egypt, and a most surprising effort of human ingenuity and perseverance. It exceeded, he says, all that can be said of it, and far surpassed the temples of Greece. Considerable doubt rests as to the situation and remains of this extraordinary fabric. The Greek historian places it beyond the lake Mœris, near the city of Crocodiles, now known as Arsinöe, or the Arabian name of Medinet-el-Fayoum; and here, accordingly, it has been diligently sought for by various modern travellers. Pliny places it at the west end of the lake Mœris, in the neighbourhood of Terna; and here Belzoni, the sagacious and indefatigable, found some beautiful marble and granite remains, which induced him to adopt the opinion of the Roman naturalist. Its use is also a matter of learned doubt, and so we must still let it remain. After what we have already seen of the remains of Egyptian art, he would be a bold theorist who would decide, from its size or splendour, that it was a palace for the living any more than a sepulchre for the dead.

The general physical characteristics of Egypt we have already given, as well as the remains of ancient art; and we have only now to notice the places of note, and any local peculiarities of moment, situated in each of its three divisions, which may not previously have been mentioned.

LOWER EGYPT—ALEXANDRIA.

One traveller has cleverly remarked, that, in the new city of Alexandria, the capital of Lower Egypt, we find a poor orphan, whose only inheritance has been the venerable name of its father. From the most flattering accounts of this city, it would appear to be but a miserable apology for that built by Alexander the Great, and destined by him to be the centre of his empire and the commerce of the world. According to Pliny, it was fifteen miles in circuit, and contained a population of 300,000 individuals. It shone in all the pomp of architectural magnificence, and contained streets of immense breadth, which intersect it from end to end. Its public edifices were of the most splendid description, and its library contained 400,000 volumes, including all the Greek and Latin literature, of which we only possess but single fragments. This treasure has been irreparably lost to the world. An order of Theodosius the Great, that all the heathen temples throughout the Roman empire should be overthrown, was the cause of it. A crowd of fanatical Christians stormed and destroyed the temple of Jupiter Serapis, where the library was, and the volumes were either burned or dispersed, and, like the lost tribes of the Jews, they have never been found. When Alexandria succumbed to the caliph Omar, it contained 4000 palaces, 4000 baths, 400 theatres or public edifices, and 12,000 shops, and a population which may be estimated by its including 40,000 Jews. Its appearance now is most melancholy and wretched, resembling, at a distance, according to one traveller, with its ruins grey, and flat-roofed houses, a town newly laid desolate by an enemy. The streets are narrow, dirty, and irregular, and usually crowded with "half-fed, half-clad, half-sarkit" human beings. The very climate of the place has been cursed. From having been once salubrious, it is now very unhealthy. "Still Alexandria," says Sir Robert Wilson, "must be pronounced the key of Egypt, although insulated by water and desert from the surrounding country, since in its harbour alone security can be found for shipping of any burden throughout the year." The modern town does not occupy the site of the old one, which lies to the south, and presents an immense field of confused ruins. Over a space of from six to seven miles in circuit, is spread an assemblage of broken columns, obelisks, and shapeless masses of architecture, which are interspersed with some more modern buildings, such as churches, mosques, and monasteries. Amid this scene of widespread devastation, a few objects rise conspicuous, the most remarkable of which is "Pompey's Pillar;" it is about ninety feet high, and consists of a pedestal, a very fine shaft, and a Corinthian capital, each being composed of one entire piece of granite. Vulgar belief ascribes the erection of this pillar to Cæsar, in commemoration of his triumph over Pompey, but this is now generally considered as erroneous. The most plausible conjecture is, that it was reared by a governor of Egypt, named Pompey, in honour of the Emperor Dioclesian. The next remarkable objects are the two obelisks vulgarly called Cleopatra's Needles, one standing erect, and the other laid prostrate. They are composed each of a single block of granite, nearly sixty feet high, and entirely covered with hieroglyphics. This circumstance indicates an Egyptian origin, and it is conjectured that they were conveyed thither from Memphis. The ancient canal between Cairo and Alexandria has lately been restored by Mehemmed Ali, and the commerce of the place by this means greatly improved. We cannot leave Alexandria without noticing that spot the most interesting to a Briton, where the French were defeated by our troops under the gallant Abercrombie, who fell in the action. The field of conflict lies three or four miles from the town, on the road to Rosetta. Of the maritime tract which lies between this place and Alexandria, our topographical knowledge is limited, and the sites of several ancient cities is doubtful.

ROSETTA.

This place is situated on the western bank of the Bolbitinic branch of the Nile, about four miles from its mouth. Its proper name is Raschid, and here, say the natives, the renowned Al Raschid was born. Rosetta is rather a handsomely built town, and is nearly surrounded with gardens. The great mosque is very large, and its roof is supported by a number of columns. The French found in this place a stone covered with hieroglyphics, which has since become celebrated under the name of the Rosetta stone. The town, however, is not of high antiquity, having been built, it is supposed, by the caliphs in the ninth century. The population is about 9000, and its trade rather good, but on the decline; and, besides its gardens, there is no object of curiosity to retain the traveller from proceeding to

DAMIETTA.

On the road thither, besides several towns, is the village of Sa-el-hajar (Sa of the Stone), near which are found the supposed ruins of Sais, the ancient metropolis of the Delta, and the mother city of the Athenians. The ruins are very interesting, including fragments of ancient columns, statues, and stones, with hieroglyphical inscriptions. Farther on are the towns of Menouf, Semennood, the ruins of Beybalt, Mansourah, and Menzaleh, besides several lakes and immense canals. Damietta is a town of considerable size, situated on the eastern bank of the Delta. It does not appear to occupy the site of any ancient town of note, nor did it rise to consideration till after the destruction of the more easterly mouths had attracted the maritime commerce of Egypt to its port. About the twelfth century it was considered of vast importance, and was fixed upon by the leaders of the sixth crusade as the principal object of their expedition. It was taken by assault; and of a population of 70,000, 3000 were the only remaining relics. At present the number of inhabitants is supposed to amount to between 25,000 and 30,000. Damietta is the grand emporium for rice, of which great quantities are here stored in immense magazines. Of the country lying between Rosetta and the Damietta arms, we have no detailed description. Between Damietta and lake Burulice is an extensive tract of desert or morass, supposed to be the Elearchia or Bucolia of the ancients, the country of marshes and buffalo herds. The lake we have named extends across a considerable portion of the basis of the present Delta. It takes its name from the ancient Paraloe (or Paralion), situated on the western side of the Sebennytic mouth. On the southern side of the lake was the ancient Buto, Pheneto, or Phthenothes, which possessed several splendid temples, now to be traced to a few scattered ruins. Nearly in the centre of the Delta, in a fertile tract, is situated Tantah, or Tandeta, a populous town. It owes its prosperity chiefly to the crowds of pilgrims who at the vernal and summer solstice come to visit the tomb of a Moslem saint who lies buried here. On the southern bank of lake Menzaleh are the remains of the ancient Tanis (probably the Zoan of the Hebrew scriptures). The place is now called Saun, and the French found here fragments of seven obelisks, remains of a colossus, monolithic temples, and other edifices of vast dimensions scattered over a great extent of ground. Upon the Syrian frontier are the remains of the ancient Pelusium, which are a few fragments of granite. On our way to Cairo, besides several less important places, we meet with Bubastes, once famous for its temple and other magnificent buildings, of which a few scattered fragments remain.

GRAND CAIRO.

The whole way from the coast to this place is strewed with ruined sites and decayed towns, interspersed with wretched villages, at once indicative of extinct grandeur and present misery and oppression. New Cairo, the present capital of Egypt, or as the orientals call it, by way of eminence, Grand Cairo, was built about A. D. 971, by Almanzor, the first of the Fatimite dynasty who reigned over Egypt. It is situated about a mile and a half from the Nile, and extends eastward nearly two miles to the mountains, being, according to Pocock, seven miles in circumference. It is surrounded with a stone wall, surmounted by five battlements, and fortified with numerous lofty towers. There are three or four beautiful gates, which unite simplicity with grandeur and magnificence. It is traversed by the canal which enters on the south, and goes out at the north. It is from fifteen to twenty feet broad, and is kept in bad repair. When the waters of the Nile begin to increase, the mouth of the canal is closed with earth, and a mark placed upon it to indicate the time for opening this and all the other canals in the kingdom. This is when the inundation has reached its height, and the opening is celebrated with great festivities and rejoicing. Like every other Mahommedan capital, Cairo, of course, contains a great number of mosques, some of which are very splendid, being adorned with the plunder of Heliopolis and Memphis. The largest mosque is that of Azhar, which stands in the middle of the city; on the east of the town is the castle, situated on a projecting point of Mount Mokattem. It completely commands the city, but is itself commanded by a mountain ridge behind, where a fort has been erected by the present pacha. The interior of the castle is spacious, and contains the pacha's palace, the mint, and, in the middle, the famous well of the famous Saladin. It is 45 feet in circumference at the orifice, and descends through a calcareous rock to 270 feet, where it opens a spring on a level with the Nile. The water is raised by machinery. There is in Cairo another celebrated well, which is named after Joseph, but it has nothing to recommend it but its great size. The new and the old citadel cover an immense extent of ground; they were formerly separated, but the French united them. All the splendid remains of antiquity are in the new citadel. Old Cairo, now called Fostat and Misr, is supposed to occupy the site of the Egyptian Babylon, which was said to have been built by the followers of "the great Persian conqueror, Cambyses." It is now about two miles in circumference, although, in the twelfth century, its length and breadth were nine miles each. Here there is a Coptic church, in which it is said Joseph and Mary dwelt with the infant Jesus. Adjoining to it is the castle of Babylon, in which resides the Greek patriarch of Alexandria. According to Mr Mengin, Cairo contains 240 principal streets, 46 public places, 11 bazaars, 140 schools, 300 public cisterns, 1166 coffee-houses, 65 public baths, 400 mosques, and 1 hospital, a wretched affair. The population is supposed to exceed 250,000. Amongst the remarkable places near Cairo, are the ruins of the city of On, the Heliopolis of the Greeks. They are a mile and a half in circumference, and consist of shattered obelisks, statues, and the other remains which characterise an ancient Egyptian city. The pyramids we have already described, and also the numerous tumuli which surround them. The whole intermediate space between the borders of lake Mœris and Djizeh is so completely occupied with catacombs, temples, pyramids, and mausoleums, as to render the supposition probable, that it was one vast cemetery, in the centre of which stood the far-famed city of Memphis. Of these we have already given as detailed an account as our limits will permit of. Except these, and some other remnants of antiquity, of no particular importance, together with a few insignificant modern towns, there is nothing to detain us from entering upon a description of

MIDDLE EGYPT.

The seven governments into which Middle Egypt was divided, are now comprised in the five provinces of Djizeyeh, Attafieh, Fayoum, Beni Souef, or Behnesawiyeh, and Oshmunein or Minyet. The first of these presents nothing of importance. The second is an island which divides the Nile at the most southern pyramid of the Dashour group. Attafieh, the capital, is said to be a place of some consideration; but it has been seldom visited by travellers, so that we are but very imperfectly acquainted with it. The others we shall notice as they occur in our peregrinations up the Nile. Next to Cairo, the most considerable place in this part of the country is Beni Souef, the capital of a beydom of the same name under the Mamelukes. It is situated at about 114 miles above Cairo, in one of the richest and most extensive tracts of corn land in Egypt. Penetrating a pass of the sylvan chain of mountains, at about fifteen miles west-south-west of this town, we enter the district of Fayoum. Medinet-el-Fayoum, the capital, is situated in lat. 29° 20′ north, long. 31° 1′ 30″ east, built from the materials and partly on the site of the ancient Crocodilopolis, the name of which was changed to Arsinöe, by Ptolemy Philadelphus, in honour of his sister. It contains about 5000 inhabitants, chiefly Moslems, with the usual proportion of mosques and baths. A canal from the Bahr Yousuf divides it into two parts, which are connected by five bridges. The principal remains of the ancient city lie to the north of the present town, occupying an area nearly two miles and a half from north to south, and two miles from east to west. Amongst the ruins are numerous fragments of statues, obelisks, &c. The name of Arsinöe was one of the most celebrated in Egypt, and so late as the time of the Romans contained a flourishing population. Fayoum is still reckoned the most productive part of Egypt, and all the country as far as lake Mœris is well cultivated. This celebrated lake, and the interesting ruins on its banks, we have already adverted to. The next place of any consideration is Mincet or Minyeh, which is reckoned forty-seven leagues from Cairo. It is the principal town in the province of Oshmunein, and is large and handsome. About three leagues higher up on the other side of the river, near a ruined village called Beni Hassan, are some remarkable caves and grottoes, formerly the abodes of eremites. About eight miles to the south-east, are the ruins of the Roman city Antinöe. They are extensive, and exhibit the remains of considerable architectural magnificence. Nearly opposite them, on the western side of the river, is a considerable village called Al Rairamoun, where Ali Pacha has established a sugar-manufactory and a distillery. In the environs are extensive sugar-plantations, and there is a saltpetre-manufactory in the neighbourhood. About six miles to the south-west of this place are the remains of Hermopolis, an ancient town, whose representative is a large village called Oshmunein. About a league to the south of it is the large and well-built town of Mellane; and ten leagues farther on, and near the western shore, that of Manfaloot, anciently a place of great trade. It is a sort of capital, and the see of a Coptic bishop. The adjacent country is very fertile, particularly in fruits. About two leagues farther up, on the eastern side of the river, are several pits in which are deposited the mummies of crocodiles. But we have now entered the Said, or Upper Egypt, which properly begins with Manfaloot, which is a sort of frontier town. The valley of the Nile is in this part about eight miles from mountain to mountain, and, above Manfaloot, a cultivated place, commences on the eastern side of the river. For many miles the left bank of the river is perforated with excavations, which, however, have not been explained.

UPPER EGYPT.

Upper Egypt, or the Thebaid, is now divided into the three provinces of Siout, Djirdjeh or Ikhmim, and Kenneh or Thebes, comprising a native population of rather more than 600,000 souls. This estimate includes Maufelatiyeh.

Siout, or Suyut, situated in lat. 27° 10′ N., long. 31° 13′ E., may now be considered as the capital, being the residence of Ahmed Pacha, the son of Mehemmed. Under the Mamelukes, the capital of the Said was Djirzeh. Siout is well situated, about a mile and a half from the western bank of the Nile, an amphitheatre of hills rising behind it.

This town, which would appear to be barely respectable in appearance, contains about 20,000 inhabitants. It is supposed to occupy the site of the ancient Lycopolis, which derived its name from the worship of the jackall. The only vestiges of this ancient city are some mounds of rubbish outside the town, and some sepulchral excavations in a neighbouring mountain. They are adorned in the same manner as the other Egyptian tombs which we have already described. About thirty-four miles to the south of Siout, on the opposite shores of the river, are the villages which bear the names of the eastern and western Kau or Gaw, the Tkôu (Tulonoo) of the Copts. The vestibule of a temple, large quarries, and numerous sepulchres, attest the ancient consequence of the place, but the name is unknown. Between this place and Ikhmim, which is about eight or nine miles farther up, are several villages and ruins, none, however, of any great moment. This interesting country is well cultivated, although some parts of it suffer a great deal from the inundation. In this portion of the country, the traveller meets with, for the first time, the Thebaid palm-tree, which differs materially from the common palm.

Ikhmim, the capital of a province of the same name, and one of the most ancient places in Egypt, is situated about a mile and a half from the river. It contains about 10,000 inhabitants. Opposite this town, on the western bank, is Menshich, or Munshyet, supposed to be the ancient Ptolemais Hermii, of which, except the ruins of a quarry, no vestige remains. The modern town is a place of some trade. In the neighbourhood of Ikhmim, one traveller counted upwards of thirty villages on both sides of this river, but none of them require particular mention. About fifteen miles to the south-east of Menshich, on the western bank of the river, stands the former capital of Upper Egypt, Djirzeh. It is situated in a fertile territory, enjoys some trade, but contains no antiquities. Above this place is the province of Farshut, where the greatest quantity of sugar is made. A few miles to the south of Djirzeh, and about six miles inland, is Arabat Matfooner, or Afra Madfrun, the ancient Abydos. Here, in 1818, a valuable hieroglyphic tablet was discovered, which was found to be a genealogy of the immediate predecessors of Sesostris. This place is supposed, by Strabo, to have been the residence of Memnon, and the remains of a magnificent structure seem to justify the conclusion; the latter is supposed to be the Memnonium, or royal residence of Memnon.

The next place of importance that we meet with is Dendera, the ruins of which we have already described. A little above Dendera, on the opposite shore, stands Kennet, the ancient Cainopolis, a place of considerable trade, and remarkable for its potteries. About thirty miles farther up the river, stand the ruins of Thebes, also described, together with the grottoes of Eleithaca. Farther up lies Emeh, the ancient Salopolis, whose only remains is a ruined temple in the middle of the town, which is a respectable place. A few miles onward lies Edfou, a town containing about 2000 inhabitants. This is the ancient Appolonias Magna, the principal remains of which are the ruins of a temple at the north-western corner of the village. It is a magnificent building, and, though inferior in size, does not yield in effect to either that of Dendera or Karnec. It is decorated with sculpture within and without: near it is another small temple; but the emblems seem to indicate that it was dedicated to the genius of population, rather than to the destroyer Typhon, whose dreadful image frowns down upon the beholder from several parts of the building. A short distance above Edfou, are some ancient quarries, of considerable size, which have been fashioned into dwellings and shrines, and covered with sculpture and hieroglyphics. Dr Richardson observed in one part a sphinx, half cut out in another, stones merely outlined, and in other instances blocks nearly disengaged, and the splinters lying about with so fresh an appearance, that it seemed as if the labourer had left his work only the evening before, and might be expected to return to resume it. But that yesterday was 2000 years ago, and the morrow never came. Along the banks of the river are numerous tablets, devices, and excavations, resembling tombs or temples cut in the perpendicular face of the rock.

After passing a strait, and entering upon a well-cultivated soil, the noble ruin of the temple of Ombos presents itself to view. It stands upon the western bank of the river, and fronts the *west*, rather a singular circumstance, as all the other temples face the *east*. The Ombites seem to have worshipped the crocodile as an emblem of Osiris, as the serpent, the ibis, and the hawk, were symbolical of other deities.

SYENE.

The next town of any consequence is that of Syene, or, as it is now called, Assoun, the upper frontier town of Egypt. It is situated in lat. 24° 5′ 23″ north, long. 32° 54′ 49″ east. Its natural position, so well adapted for a frontier town, has rendered it at all times a place of importance. It was formerly a bishopric, but no Christians are now found here. Ruined churches and convents strike the eye of the traveller, but the Christian faith is unknown. Not only is it the last town in Egypt, but it is the last place in this direction in which the Arabic is spoken as the vernacular tongue.

The present town of Assoun has been built a little to the north of a former town of Saracenic origin, the ruins of which are seen above it, and which was itself built upon the ruins of a Roman city. The whole town is encompassed with vestiges of buildings; the most interesting are about the old town, which occupies a strong and commanding position; the walls still remain, and, though slight and of sun-dried brick, are very entire. They are flanked with towers at unequal distances. Many of the walls of the houses are also standing, but they are all unroofed. From the interior of many of them, passages lead down to the chambers of houses belonging to the ancient city, which are now under ground; of the old town a few insignificant ruins are all the remains.

ISLAND OF ELEPHANTINA.

This island is now called Djeziret-sel-sahir, the flowery island, and is about 2000 feet in length, and 600 feet in breadth. The northern end is low and alluvial, well cultivated, and shaded with palm-trees. Here are the ruins of Roman fortifications, opposite to which, on the eastern bank of the Nile, are remains of Arabian works. There is an ancient quarry, from which large columns have been excavated; the marks of the workman's chisel and wedge are as fresh as if they were of yesterday. Some are lying blocked out and partly wrought, and a large sarcophagus is two-thirds cut out of the rock. There are a number of architectural remains, sculptures, and hieroglyphical tablets. This beautiful island is inhabited by Nubians, who are perfectly black, without having any resemblance in their features to the negro.

BERENICE.

In the most southerly part of the vast desert of the Thebaid, which lies between the valley of the Nile and the Red Sea, is the site of the ancient city of Berenice, delightfully situated in an extensive plain almost surrounded with mountains. Its ruins are still perceptible even to the arrangement of the streets, and in the centre is a small Egyptian temple, adorned in the usual manner: it is nearly covered with sand. Opposite to the town is a very fine natural harbour, open towards the north, the entrance of which has been deep enough for small vessels, but the bar is now impassable at low water. Belzoni supposes this city may have contained 2000 houses and 10,000 inhabitants.

THE OASES.

Oasis is a Coptic word, and means an inhabited place. The Oases of Egypt are those spots of fertile land which are found at intervals "few and far between," in the middle of that vast plain of arid sand called the Lybian Desert. There are several of them, and are named, according to their size or situation, the Great, Little, Western, Northern, &c.

The Northern or Oasis of Siwah.—This place, which is about 300 miles distant from Cairo, and about 100 from the Nile, is peculiarly interesting, from its being supposed to enclose the far-famed temple of Jupiter Ammon. The Oasis is about six miles long, and from four to five broad. It is pretty fertile, and contains about 8000 inhabitants. The capital is called Siwah. Besides the splendid remains of the temple, supposed to be that of Jupiter Ammon, are the ruins of other sacred places, and a number of sepulchral excavations.

Great Oasis.—This Oasis is formed of a number of fertile isolated spots, which lie in a line parallel to the course of the Nile, and to the mountains which bound the valley of Egypt on the west. It is about two days' journey from the nearest part of the valley of the Nile. The patches of firm land are separated from one another by deserts of twelve or fourteen hours' walk—so that the whole extent of this Oasis is nearly 100 miles, the greater proportion consisting of a desert. It contains many gardens watered with rivulets, and its palm groves exhibit a perpetual verdure. According to a more recent account, it contains Egyptian ruins covered with hieroglyphic inscriptions. The principal town is called El-Kargeh. Here are the remains of a temple beautifully situated in the midst of a rich grove of palm trees. Near El-Kargeh there is also a regular Necropolis or cemetery, containing 200 or 300 buildings of unburned brick, chiefly of a square shape, and each surmounted by a dome similar to the small mosques erected over the graves of sheiks. At distances of a few miles, some other remains of ancient temples are found. This whole oasis has always been and still is dependent on Egypt. None of the other oases of the desert present us with any object worthy of being dwelt upon.

RECENT HISTORY AND PRESENT STATE OF EGYPT.

The civil and political aspect of modern Egypt, involves in it the history of Mehemmed Ali, the present pacha. On the landing of the French in Egypt, he had a contingent of 300 men placed under his command, with the title of *Bin-Boushi*. In the first battle in which he engaged, against a division of the French, he lost the greater part of his men; but his spirited conduct attracted the notice of the Capitan Pacha, who selected him to head an attack upon the fort in which the French had posted themselves, in which he was successful. The next military enterprise was against the Mamelukes, for the unfortunate issue of which, whether guilty or not, he was severely censured by the viceroy Kusrouf Pacha. The latter, having been apprised that Ali was in correspondence with his enemy Taher Pacha and his Albanians, desisted from some designs which he had formed against Ali. The viceroy was soon after expelled from his capital by the troops of Ali and Taher, the latter of whom assumed the reins of government, and invited the Mamelukes to Cairo. He was, however, soon after assassinated by the Turks. From this moment the career of Ali was rapid He commenced an intrigue with the Turk, the Mameluke, and the Albanian, either as an ally or enemy, according to the ends which he contemplated. The new viceroy became very unpopular, and the people called out for Ali to assume the supreme authority; and the wishes of the people were very soon acceded to by the Porte, which constituted him a pacha of three tails, with the government of Egypt. His elevation was signalised by a victory obtained over the English before Rosetta. By the liberal policy which he adopted, the prosperity of the country advanced with extraordinary rapidity. He was guilty, however, of an atrocity, which not a little stains his character. In 1811, he invited the Mamelukes to Cairo, with a show of friendship, whilst he had laid plans for basely assassinating them. He effected his purpose, but not without creating a dreadful tumult, and being nearly blown up himself in the train he had fired. He next carried the terror of his arms into Arabia, from whence, however, he was recalled by the news of Napoleon's escape from Elba. The victory of Waterloo, however, soon left his mind easy regarding the designs which his great contemporary might have upon Egypt. He next directed his attention to the army, which he attempted to organise upon European rules; but, owing to the resistance which he met with, his efforts were for the present in vain. At a subsequent period, however, he completely effected his purpose; and his motley army of Turks, Mamelukes, &c., were taught the military art by European officers. The war against the Wahabis, in Arabia, was prosecuted by his son, with considerable spirit, till 1818, when the capture of the stronghold of the enemy put an end to it. In 1820, an army was fitted out for Sennaar, in Africa, which was finally brought under subjection to the yoke of Mahommed. In 1824, he conceived the idea of forming a camp for the instruction of officers destined for the command of the new levies required for the war. He began by sending his own Mamelukes or body-guards and attendants, with those of the principal officers of the state. Colonel Seve, formerly aid-de-camp to Marshal Ney, was engaged as instructor, who, after displaying great firmness and skill, succeeded in breaking in the wild Turks to regular discipline.

In a country like Egypt, where the administration of government depends almost exclusively on the individual nominated to the supreme authority, the mere form is of little consequence. But in nothing is the sagacity of the present Pacha more manifest by innovating less in the external structure of the constitution, than in those internal regulations, by means of which he has created for himself an influence incalculably great, and which is diffused to the very verge of the vast province over which he presides. Virtually independent, he has hitherto continued formally to acknowledge the Ottoman superiority, whilst, at the same time, he wields the sceptre with as little restraint as the most arbitrary of oriental despots. The administration is in the hands of the following officers:—The Keaya Bey, who may be styled prime minister; the Aga of the Janissaries, who is at the head of the war department; the Ouali, or head of the military police; the Mohtesib, or superintendant of the markets; and the Bash-aga, or master of the civil police. In every district a headsman is appointed to determine differences by arbitration, and to watch over the peace and good order of his neighbourhood. The civil officers have no fees, but are allowed fixed salaries, and so effectually are the duties of police performed, that the streets of Cairo are as safe as those of London. Criminal prosecutions are settled by a Cadi or judge, sent annually from Constantinople, and assisted by a certain number of sheiks learned in the law. The cost of a civil process is about four per cent. on the value litigated, of which the cadi receives four-fifths and his assistants the remainder. Besides the public officers above mentioned, there are many subordinate functionaries in the civil and military departments. The domestic establishment of the Pacha alone comprehends no fewer than fifteen hundred individuals.

Before the accession of Ali, the representative of the sultan was satisfied with a *miri*, or a land-tax. The present viceroy, however, has taken the greater part of the territorial possessions into his own hands, and granted a yearly pension, in name of compensation, to the former proprietors; and those who still hold possession of the land cannot dispose of any part of the crops until the government agents take away as much as they think fit at their own price. In place of the established *miri*, the retainers of the court are served with agricultural produce at one-half its current value, and the Pacha himself regulates the price of what can be spared for exportation. No wonder then that travellers should view with astonishment the richness of the harvests, contrasted with the wretched state of the villages. The fellahs or agricultural labourers are liable to be called from their mud hovels to the camp in case of emergency, but the improvement in food and clothing seems no adequate compensation for the precarious liberty of which they are thus for a time deprived.

The revenue of Egypt is estimated at L.2,249,379, arising from land-tax, customs, the resumed lands amounting to almost the whole of the cultivated soil, the conquered territories of Darfur, Sennaar, Nubia, and a large part of Arabia, a monopoly of nearly all the Egyptian commerce, together with an excise on manufactures and raw productions. The annual expenditure is calculated at L.1,757,500: of this, one-half is required for the army; L.90,000 remitted by way of tribute to Constantinople; L.14,000 to the support of the church and the law; nearly an equal sum expended on the pilgrimage to Mecca; and about L.200,000 on the Pacha's own household.

The improvement in manufactures, in arts, and sciences, effected by this wonderful personage, are truly astonishing. Having experienced much difficulty and disappointment, so long as he had to employ foreigners in his different undertakings, he has persevered in the scheme which he adopted some years ago, in sending young men of talent to Italy, France, and England, to study the respective arts of these enlightened countries. Many of the Egyptian pupils have visited London, and other parts of Great Britain, where they have made themselves acquainted with every philosophical discovery or ingenious mechanical invention likely to contribute to the pleasure of their sovereign, or the benefit of their country. Schools have been instituted, where young persons of all ranks, and especially the Arabs, are instructed in mathematics, fortification, gunnery, foreign languages, and the best European tactics. The latest inventions are imported from France and England; the most expensive apparatus and instruments procured; in a word, all the mysteries of gas, steam, and lithography, are not only known, but are topics of familiar conversation in the Egyptian capital. We cannot here omit mentioning one of his most magnificent undertakings, a canal which connects the harbour of Alexandria with the Nile, near Fouah; a work forty-eight miles in length, ninety feet broad, and eighteen in depth, and which supplies the means of bringing the whole produce of the country to the best place of exportation, without danger or delay. For his indefatigable exertions in forwarding this grand undertaking, he has received universal praise. The whole excavation was completed in little more than six weeks, and the canal was opened with great pomp on 7th December 1819. The great increase of trade at the port of Alexandria has already compensated the Pacha for his exertions, and evinced the wisdom of his plan. Accident, however, has conferred upon him, as upon many others, in the cultivation of the cotton-tree, a boon far greater than could have been derived from even the previous wise arrangement of his gifted mind. The discovery of the plant by M. Jumel, in the garden of a Turk, he propagated afterwards with so much success and skill, as almost to have changed the commerce and statistics of Egypt. Near Cairo, a most superb establishment, equal if not superior to the finest European manufactory, has been erected, for the spinning, weaving, dyeing, and printing of cotton goods. Here, also, are the latest improvements in machinery—steam, the moving power—gas, the artificial light. And so great is the achievement of the Pacha, notwithstanding the infancy of the manufacture, and many disadvantages, at this moment he is able to compete with the European manufacturer in every market to which he is admitted, and can even undersell the merchants of India in their own ports. Besides cotton, similar attention has been bestowed on silk, flax, and the sugar-cane. As an additional proof that Egypt is keeping pace with the progress of the age, we may add that a newspaper is published under the auspices of this enterprising monarch. In fine, nothing seems wanting but a more enlightened experience, and the enjoyment of greater freedom on the part of the cultivator, to render the dominion of Mehemmed Ali the richest country on the face of the globe.

SYRIAN CAMPAIGN.

The origin of the quarrels of the Pacha of Acre with Mehemmed Ali—into which we cannot now particularly enter—in a great measure justifies the hostile pretensions of the latter. In 1822, Abdallah Pacha had rendered himself obnoxious by his extortions, and took it into his head also to seize Damascus. The neighbouring Pacha formed a league against him, and laid siege to his capitol, when Mahommed Ali negociated his pardon for a sum of 60,000 purses, which the people readily paid. Interest soon prevailed over gratitude; for the Pacha of Acre, conceiving there was far more to be gained from Constantinople than from Cairo, sought every opportunity of separating himself from Mehemmed Ali, and exciting the jealousy of the Porte against him. Some Egyptian fellahs having taken refuge under the guns of Abdallah Pacha, offered an admirable opportunity to Ali. He demanded the men, but the governor of Acre refused to deliver them up, at the same time referring the arbitration to the Porte, who, with a singular expression of humanity, bewailed the condition of the Egyptian peasantry. Hence the origin of the war. This was at the close of the year 1831. The moment was favourable for the viceroy's great and ambitious designs. The exactions of the Ottoman government had extended to every object of production and industry in Syria, whilst the military conscription decimated the most industrious part of the population; and, therefore, it is not at all surprising that the Egyptians should be hailed as their deliverers. Ibrahim Pacha, the stepson of Ali, was placed at the head of the Egyptian army; and associated with him was Solyman Bey, formerly an officer in the staff of Marshal Grouchy; and to him may be chiefly ascribed the success of the Egyptian arms. At the head of 32,000 regular troops and 4000 Bedouin Arabs, Ibrahim took the same route as Bonaparte, and advanced rapidly against St Jean d'Acre. Of Jaffa, Caipha, Jerusalem, and Naplousia, he made himself master without firing a shot. Taboneh and all the country between Gaza and Acre submitted at his approach. On the 27th Nov. 1831, he planted himself before St Jean d'Acre. The defence of this place by Abdallah Pacha was obstinate, and the siege was carried on with various success for nearly six months, when, on the 27th May 1832, a general assault was made at day-break, which lasted twelve hours, and was finally successful. The capture of this place insured to Ibrahim the possession of Lower Syria, and enabled him to continue his progress with perfect security. Whilst Ibrahim thus actively pushed on the campaign, the Porte organised an army of twice the strength, and placed it under the command of Mahommed Pacha, who displayed culpable negligence upon the occasion. She also fulminated her bull of excommunication, and at the same time proclaimed to the great powers of Europe that Egypt was in a state of blockade. Nicholas of Russia recalled his consul from Alexandria, and even proffered a fleet with an auxiliary corps d'armée; Austria, alike hostile to revolution as improvement, threatened also the viceroy; England preserved the strictest neutrality; while France was employing all her influence strenuously for an accommodation, but in vain. The Divan, having refused to listen to Ali's demands, the matter was referred to Hussein Pacha, the field-marshal, who by his formal delays retarded the advance of the army. The news of the fall of Acre having reached Hussein, he found it imperative to occupy the passes of Syria, and march immediately to Antioch, in order to cover Beylew. Before this movement was effected, Ibrahim had descended into the valley of the Orontes, and entered the town of Damascus, after an unimportant skirmish. All the operations of the Turkish army were marked, as usual, with the most unaccountable inertness; and it was not till July that Hussein was able to effect any progressive movement. The march at last commenced; but neglecting to issue rations to the troops, when they reached Horn (a place he should have marched upon immediately after leaving Antioch) they were almost lifeless with hunger and defeat. At the gates of the city was encamped the Seraskier of Aleppo, with his irregular troops; but without deigning even to think of the enemy, or issue rations to their starving troops, they spent their time in vain and useless ceremonies. Intelligence at length arrived, that the Egyptian army was within two hours' march of them. Dreadful was the disorder that ensued. The half-famished soldiers dragged themselves in masses to meet the Arabs. It is unnecessary to enter into details which must be familiar to every reader of the newspapers. The whole Turkish army was disgracefully put to flight, and pursued by the enemy's cavalry, till the approach of night alone saved the Turks from utter destruction. The loss of the Sultan's forces amounted to 2000 killed, and 2500 prisoners. Meanwhile, Ibrahim still advanced, recalling his garrisons, and making new levies in the mountains. As he prosecuted his march, the whole country declared in his favour, and the castle of Aleppo was delivered up to him. On the 5th of August, the Egyptians made themselves masters of Antioch, after an action of only two hours. The route continued more like an easy march than a conquest; and it has been asserted, that at one time the viceroy had the idea of attacking, in person, the Turkish capital by sea, whilst Ibrahim should threaten to invade it from Scutari. It was well that Mehemmed abstained from this attempt, as most assuredly Russia would have interfered. An armistice for five months took place, when Ali, finding that the Porte would agree to no equitable terms, commenced another campaign, and almost annihilated the second army of the grand seignior; and Redsched Pacha, the field-marshal, after performing prodigies of valour, fell severely wounded into the hands of the Egyptians. This was a decisive stroke, and nothing but the timely intervention of Russia saved the empire of Mahommed.

Mehemmed Ali is now an independent sovereign, and it is to the manner in which he appreciated the military genius of Europe he owes his glory. He now lays claim to Syria, and that part of Caramania which lies between Taurus and the sea, a territory where she will find those resources she most requires—materials for ship-building, &c.; but, above all, a Christian population, among whom, it is to be hoped, the seeds of European civilisation will be soon implanted. If not prematurely exhausted by that system of monopoly too rigidly enforced at present, Egypt will realise her ancient glory, and become an empire powerful in all that is great, and virtuous, and good. In contemplating this grand consummation, however, one reflection forces itself upon us. It is, that, although Egypt under Mehemmed Ali has made rapid and extraordinary strides in the march of civilisation, yet she has to push forward many a long day's journey before she can bring herself in a line with even the rear ranks of European states. Indeed, it is impossible, that, during the life of the present ruler, the modern innovations will have had time to take root in the soil, so as to propagate themselves spontaneously, independently of the individual who may be the supreme head of government.

EDINBURGH: Published by W. and R. CHAMBERS, 19, Waterloo Place; also by ORR and SMITH, Paternoster Row, London; and W. CURRY, Jun. and Co. Sackville Street, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight.

LIFE OF BENJAMIN FRANKLIN.

PARENTAGE AND BOYHOOD.

BENJAMIN FRANKLIN was born at Boston, in New England, North America, on the 17th January 1706, and was the youngest but two of a family of seventeen children, two daughters being born after him. His ancestors, as far as they can be traced back (at least three hundred years), were petty freeholders at Eaton, in Northamptonshire; but if we may judge by the surname of the family—the ancient Norman appellative for a country gentleman—we may conclude they had originally been of some consequence. After the Reformation, the immediate progenitors of Benjamin continued zealously attached to the church of England till towards the close of the reign of Charles the Second, when his father Josias, along with his uncle Benjamin, became dissenters. These men were both bred to the trade of silk-dyeing. Josias married early in life; and about the year 1682 he emigrated, with his wife and three children, to America, on account of the persecutions to which he was exposed for his dissenting principles. On arriving in New England, he embraced the occupations of soap-boiler and tallow-chandler, of which businesses he previously knew nothing, but only from their being at the time the likeliest to provide maintenance for his increasing family. He appears to have been a man of great penetration and solid judgment; prudent, active, and frugal; and although kept in comparative poverty by the expenses of his numerous family, was held in great esteem by his townsmen. In no respect was his practical good sense more conspicuous than in the education of his children; and his illustrious son frequently alludes, in terms of thankfulness and gratitude, to the many exemplary precepts and sound moral lessons he received while under the paternal roof. The following passage may be read with no little instruction by the heads and members of all families similarly circumstanced:—"He was fond of having at his table, as often as possible, some friends, or well-informed neighbours, capable of rational conversation; and he was always careful to introduce useful or ingenious topics of discourse, which might tend to form the minds of his children. By this means, he early attracted our attention to what was just, prudent, and beneficial in the conduct of life. He never talked of the meats which appeared on the table; never discussed whether they were well or ill dressed, of a good or bad flavour, high-seasoned or otherwise, preferable or inferior to this or that dish of a similar kind. Thus accustomed, from my infancy, to the utmost inattention as to these objects, I have since been perfectly regardless of what kind of food was before me; and I pay so little attention to it even now, that it would be a hard matter for me to recollect, a few hours after I had dined, of what my dinner had consisted. When travelling, I have particularly experienced the benefit of this habit; for it has often happened to me to be in company with persons, who, having a more delicate, because a more exercised taste, have suffered in many cases considerable inconvenience; while, as to myself, I have had nothing to desire." Benjamin was at first designed to be a clergyman, and at eight years of age was put to the grammar-school with that view, having previously been taught to read. His uncle Benjamin, who had likewise emigrated, encouraged this project. This individual appears to have been an equally eccentric and ingenious man. He cultivated the Muses with a success that gave himself, at least, entire satisfaction. But what he was most proud of was a species of short-hand of his own invention, wherewith he had carried off from the conventicles in England several volumes of sermons whole and entire; and these he designed for his nephew's stock-in-trade, when he should set up as preacher. But young Franklin had not been a year at school when his father perceived that his circumstances were quite inadequate to the expenses necessary to complete his son's education for the clerical profession. He accordingly removed him from the more learned seminary, and placed

PORTRAIT OF FRANKLIN.

him under a humble teacher of reading and writing for another twelvemonth, preparatory to binding him to some handicraft trade.

APPRENTICESHIP.

When his term at school was expired, being then ten years of age, he was taken home to assist his father in his business; but he soon testified such repugnance to the cutting of wicks for candles, running errands, waiting in the shop, with other drudgery of the same nature, that, after a tedious and ill-borne trial of two years, his father became afraid of his running off to sea (for which he confesses to have had a predilection), as an elder brother had done, and resolved to put him to some other occupation. After much deliberation, therefore, he was sent on trial for a few days to his cousin (a son of Benjamin), who was a cutler; but that relative being desirous of a larger apprentice-fee than his uncle could spare, he was recalled. His brother James, a short time previous to this period, had returned from England, whither he had been sent to learn the printing business, and set up a press and types on his own account at Boston. To him, therefore, after no little persuasion, Benjamin at last agreed to become apprentice, and he was indentured accordingly for the term of nine years; that is, until he should reach the age of twenty-one.

The choice of this profession, as it turned out, was a lucky one; and it was made after much careful and correct observation on the part of the parent. He had watched his son's increasing fondness for books, and thirst for information, and that, too, of a solid and instructive sort; and he therefore judiciously resolved to place him in a favourable situation for gratifying this propensity in the youthful mind; while he would, at the same time, be instructed in a profession by which he could always independently maintain himself, wherever almost his fortunes might lead him, within the bounds of the civilised world. Franklin thus speaks of his early and insatiable craving after knowledge:—

"From my earliest years I had been passionately fond of reading, and I laid out in books all the money I could procure. I was particularly pleased with accounts of voyages. My first acquisition was Bunyan's collection, in small separate volumes. These I afterwards sold in order to buy an historical collection by R. Burton, which consisted of small cheap volumes, amounting in all to about forty or fifty. My father's little library was principally made up of books of practical and polemical theology. I read the greatest part of them. There was also among my father's books, Plutarch's Lives, in which I read continually, and I still regard as advantageously employed the time devoted to them. I found, besides, a work of De Foe's, entitled, An Essay on Projects, from which, perhaps, I derived impressions that have since influenced some of the principal events of my life." It seems to have been lucky for himself and mankind that the last named author's most celebrated work, Robinson Crusoe, did not fall into his hands at this period.

By his assiduity Franklin soon attained great proficiency in his business, and became very serviceable to his brother. At the same time, he formed acquaintance with various booksellers' apprentices, by whose furtive assistance he was enabled to extend the sphere of his reading. This gratification, however, was for the most part enjoyed at the expense of his natural rest. "How often," says he, "has it happened to me to pass the greater part of the night in reading by my bed-side, when the book had been lent me in the evening, and was to be returned the next morning, lest it might be missed or wanted!" His studious habits and intelligent conversation also attracted the notice of a wealthy merchant who was in the habit of coming about the office, who invited him to his house, and gave him the use of an excellent library.

It is a singular peculiarity of all minds of an active and aspiring character, that they uniformly endeavour to do whatever others have done, and from which they themselves have derived enjoyment or benefit. Franklin, from the delight he took in the perusal of books, at last bethought him of trying his own hand at composition; and as has happened, we believe, with a great proportion of literary men of all ages, his first efforts were of a poetical nature. His brother having come to the knowledge of his attempts, encouraged him to proceed, thinking such a talent might prove useful in the establishment. At the suggestion of the latter, therefore, he finished two ballads, which, after being printed, he was sent round the town to sell; and one of them, the subject of which was a recent affecting shipwreck, had, he says, a prodigious run. But his father having heard of the circumstance, soon let down the pegs of the young poet's vanity, by analysing his verses before him in a most unmerciful style, and demonstrating, as Franklin says, what "wretched stuff they really were." This sharp lesson, which concluded with a warning that versifiers were almost uniformly beggars, effectually weaned him from his rhyming propensities.

Franklin immediately afterwards betook himself to the composition of prose, and the first opportunity of exercising his pen and his faculties in this way occurred in the following manner:—He had a young acquaintance of the name of Collins, who was, like himself, passionately fond of books, and with whom he had frequent and long arguments on various subjects. In narrating this circumstance, Franklin comments, in passing, on the dangerous consequences of acquiring a disputatious habit, as tending to generate acrimony and discord in society, and often hatred betwixt the best of friends. He dismisses the subject with the following singular enough observation:—"I have since remarked, that men of sense seldom fall into this error; lawyers, fellows of universities, and *persons of every profession educated at Edinburgh*, excepted!" But to proceed: Franklin and his companion having as usual got into an argument one day, which was maintained on both sides with equal pertinacity, they parted without bringing it to a termination; and as they were to be separated for some time, an agreement was made that they should carry on their dispute by letter. This was accordingly done; when, after the interchange of several epistles, the whole correspondence happened to fall into the hands of Franklin's father. After perusing it with much interest, his natural acuteness and good sense enabled him to point out to his son how inferior he was to his adversary in elegance of expression, arrangement, and perspicuity. Feeling the justice of his parent's remarks, he forthwith studied most anxiously to improve his style; and the plan he adopted for this purpose is equally interesting and instructive.

"Amidst these resolves," he says, "an odd volume of the Spectator fell into my hands. This was a publication I had never seen. I bought the volume, and read it again and again. I was enchanted with it, thought the style excellent, and wished it were in my power to imitate it. With this view I selected some of the papers, made short summaries of the sense of each period, and put them for a few days aside. I then, without looking at the book, endeavoured to restore the essays to their due form, and to express each thought at length, as it was in the original, employing the most appropriate words that occurred to my mind. I afterwards compared my Spectator with the original. I perceived some faults, which I corrected; but I found that I chiefly wanted a fund of words, if I may so express myself, and a facility of recollecting and employing them, which I thought I should by that time have acquired, had I continued to make verses. The continual need of words of the same meaning, but of different lengths for the measure, and of different sounds for the rhyme, would have obliged me to seek for a variety of synonymes, and have rendered me master of them. From this belief, I took some of the tales of the Spectator, and turned them into verse; and after a time, when I had sufficiently forgotten them, I again converted them into prose. Sometimes, also, I mingled my summaries together; and, a few weeks afterwards, endeavoured to arrange them in the best order, before I attempted to form the periods and complete the essays. This I did, with a view of acquiring method in the arrangement of my thoughts. On comparing afterwards my performance with the original, many faults were apparent, which I corrected; but I had sometimes the satisfaction to think, that, in certain particulars of little importance, I had been fortunate enough to improve the order of the thought or style; and this encouraged me to hope that I should succeed in time in writing decently in the English language, which was one of the greatest objects of my ambition."

But it was not only by such rigorous self-imposed tasks that this extraordinary man, even at so early an age, endeavoured to chasten his mind, and make every animal propensity subservient to his sense of duty. He also began to exercise those acts of personal self-denial which the heyday of youth, the season for animal enjoyment, feels as the most intolerable of all restrictions. Having met with a work recommending a vegetable diet, he determined to adopt it. Finding, after some days' trial, that he was ridiculed by his fellow-boarders for his singularity, he proposed to his brother to take the half of what was now paid by that relative for his board, and therewith to maintain himself. No objection was, of course, made to such an arrangement; and he soon found that of what he received he was able to save one-half. "This," says he, "was a new fund for the purchase of books, and other advantages resulted to me from the plan. When my brother and his workmen left the printing-house to go to dinner, I remained behind; and dispatching my frugal meal, which frequently consisted of a biscuit only, or a slice of bread and a bunch of raisins, or a bun from the pastry-cook's, with a glass of water, I had the rest of the time till their return for study; and my progress therein was proportioned to that clearness of ideas and quickness of conception which are the fruits of temperance in eating and drinking."

Another remarkable instance of the resolute way in which he set about making himself master of whatever acquirement he found more immediately necessary to him at the moment, is the following:—Having been put to the blush one day for his ignorance in the art of calculation, which he had twice failed to learn while at school, he procured a copy of Cocker's Arithmetic, and went through it all, making himself completely master of it, before turning his mind to any thing else! He soon after, also, gained some little acquaintance with geometry, by perusing a work on navigation. He mentions, likewise, his reading about this time Locke's Essay on the Understanding, and the Art of Thinking, by Messrs du Port Royal. Having found, in some essay on rhetoric and logic, a model of disputation after the manner of Socrates, which consists in drawing on your opponent, by insidious questions, into making admissions which militate against himself, he became excessively fond of it, he says, and practised it for some years with great success, but ultimately abandoned it, perceiving that it could be made as available to the cause of wrong as that of right, while the prime end of all argument was to convince or inform.

About three years after Franklin went to his apprenticeship, that is to say, in 1721, his brother began to print a newspaper, the second that was established in America, which he called the New England Courant; the one previously established was the Boston News Letter. The new publication brought the most of the *literati* of Boston about the printing-office, many of whom were contributors; and Franklin frequently overheard them conversing about the various articles that appeared in its columns, and the approbation with which particular ones were received. He became ambitious to participate in this sort of fame; and having written out a paper, in a disguised hand, he slipped it under the door of the printing-office, where it was found next morning, and submitted, as usual, to the critics when they assembled. "They read it," he says; "commented on it in my hearing; and I had the exquisite pleasure to find that it met with their approbation; and that in the various conjectures they made respecting the author, no one was mentioned who did not enjoy a high reputation in the country for talent and genius. I now supposed myself fortunate in my judges, and began to suspect that they were not such excellent writers as I had hitherto supposed them. Be this as it may, encouraged by this little adventure, I wrote and sent to press, in the same way, many other pieces which were equally approved—keeping the secret till my slender stock of information and knowledge for such performances was pretty completely exhausted." He then discovered himself, and had the satisfaction of finding he was treated with much more respect by his brother and his friends than heretofore.

The two brothers, however, lived together on very disagreeable terms, in consequence of the hasty and overbearing temper of the elder; and Benjamin anxiously longed for an opportunity of separating from him. This at last occurred. His brother was apprehended and imprisoned for some political article which offended the local government, and, upon his liberation, was prohibited from ever printing his newspaper again. It was therefore determined that it should be published in Benjamin's name, who had managed it during his brother's confinement with great spirit and ability. To avoid having it said that the elder brother was only screening himself behind one of his apprentices, Benjamin's indenture was delivered up to him discharged, and private indentures entered into for the remainder of his time. This underhand arrangement was proceeded in for several months, the paper continuing to be printed in Benjamin's name; but his brother having one day again broke out into one of his violent fits of passion, and struck him, he availed himself of his discharged indentures, well knowing that the others would never be produced against him, and gave up his employment. Franklin afterwards regretted his having taken so unfair an advantage of his brother's situation, and regarded it as one of the first *errata* of his life. His brother felt so exasperated on the occasion, that he went round all the printing-houses, and represented Benjamin in such a light that they all refused his services.

PROCEEDS TO PHILADELPHIA.

Finding he could get no employment at Boston, as well as that he was regarded with dislike by the government, he resolved to proceed to New York, the nearest town in which there was a printing-office. To raise sufficient funds for this purpose, he sold part of his library; and having eluded the vigilance of his parents, who were opposed to his intention, he secretly got on board of a vessel, and landed at New York on the third day after sailing.

Thus, at the age of seventeen, Franklin found himself three hundred miles from his native place, to which he was in some sort a runaway, without a friend or recommendation to any one, and with very little money in his pocket. To complete his dilemma, he found, on applying, that the only printer then in the town could give him no employment. That person, however, recommended him to go to Philadelphia, where he had a son, who, he thought, would give him work; and he accordingly set off for that place. His journey was a most disastrous one both by water and land, and he frequently regretted leaving home so rashly. He reached his destination at last, however, and in a plight which certainly did not bode over-auspiciously for his future fortunes. His own graphic description of his condition and appearance, on his first entrance into Philadelphia, is at once interesting and amusing:—

"I have entered into the particulars of my voyage, and shall in like manner describe my first entrance into this place, that you may be able to compare beginnings so unlikely with the figure I have since made. I was in my working dress, my best clothes being to come by sea. I was covered with dirt; my pockets were filled with shirts and stockings; I was unacquainted with a single soul in the place, and knew not where to seek a lodging. Fatigued with walking, rowing, and having passed the night without sleep, I was extremely hungry, and all my money consisted of a Dutch dollar, and about a shilling's worth of coppers, which I gave to the boatmen for my passage. At first they refused it, because I had rowed, but I insisted on them taking it. A man is sometimes more generous when he has little than when he has much money, probably because he is, in the first place, desirous of concealing his poverty.

"I walked towards the top of the street, looking eagerly on both sides, till I came to Market Street, where I met a child with a loaf of bread. I inquired where he had bought it, and went straight to the baker's shop which he pointed out to me. I asked for some biscuits, expecting to find such as we had at Boston; but they made, it seems, none of that sort at Philadelphia. I then asked for a threepenny loaf; they made no loaves of that price. I then desired him to let me have threepence worth of bread, of some kind or other. He gave me three large rolls. I was surprised at receiving so much. I took them, however, and having no room in my pockets, I walked on, with a roll under each arm, eating the third. In this manner I went through Market Street to Fourth Street, and passed the house of Mr Read, the father of my future wife. She was standing at the door, observed me, and thought with reason that I made a very singular and grotesque appearance. I then turned the corner, and went through Chestnut Street, eating my roll all the way; and, having made this round, I found myself again on Market Street wharf, near the boat in which I arrived. I stepped into it to take a draught of the river water; and finding myself satisfied with my first roll, I gave the other two to a woman and her child who had come down the river with us in the boat, and was waiting to continue her journey. Thus refreshed, I regained the street, which was now full of well-dressed people all going the same way. I joined them, and was thus led to a Quakers' meeting-house, near the market place. I sat down with the rest, and, after looking round me for some time, hearing nothing said, and being drowsy from my last night's labour and want of rest, I fell into a sound sleep. In this state I continued till the assembly dispersed, when one of the congregation had the goodness to wake me. This was consequently the first house I entered, or in which I slept, in Philadelphia."

Having with some difficulty procured a lodging for the night, he next morning waited on Mr Bradford, the printer to whom he had been directed. That individual said he had no work for him at present, but directed him to a brother in trade of the name of Keimer, who, upon application, made him the same answer; but, after considering a little, set him to put an old press to rights, being the only one indeed he possessed; and in a few days gave him regular work. Upon this, Franklin took a lodging in the house of Mr Read, his future father-in-law.

Franklin had been some months at Philadelphia, without either writing to or hearing from home, and, as he says, trying to forget Boston as much as possible, when a brother-in-law of his, a master of a vessel, having accidentally heard where he was, wrote to him, pressing his return home in the most urgent terms. Franklin's reply, declining compliance with the request, happened to reach his brother-in-law when the latter was in the company of Sir William Keith, governor of the province, and the composition and penmanship struck him as so much superior to the ordinary style of letter-writing, that he showed it to his excellency. The governor was no less pleased with it, and expressed the utmost surprise when told the age of the writer. He observed, that he must be a young man of promising talents, and said that if he would set up business on his own account at Philadelphia, he would procure him the printing of all the public papers, and do him every other service in his power. Franklin heard nothing of this from his brother-in-law at the time; but one day, while he and Keimer were at work in the office, they observed through the window the governor and another gentleman (who proved to be Colonel French of Newcastle, in the province of Delaware), finely dressed, cross the street, and come directly for the office, where they knocked at the door. Keimer ran down, in high expectation of this being a visit to himself; "but the governor (says Franklin) inquired for me, came up stairs, and with a politeness to which I had not at all been accustomed, paid me many compliments, desired to be acquainted with me, obligingly reproached me for not having made myself known to him on my arrival in town, and wished me to accompany him to a tavern, where he and Colonel French were going to taste some excellent Madeira wine! I was, I confess, somewhat surprised, and Keimer was thunderstruck. I went, however, with the governor and Colonel French to a tavern at the corner of Third Street, where, while we were drinking the Madeira, he proposed to me to establish a printing-house. He set forth the probabilities of success, and himself and Colonel French assured me that I should have their protection and influence in obtaining the printing of the public papers for both governments; and as I appeared to doubt whether my father would assist me in this enterprise, Sir William said that he would give me a letter to him, in which he would recommend the advantages of the scheme in a light which he had no doubt would determine him to agree to do so. It was thus concluded that I should return to Boston by the first vessel, with the letter of recommendation from the governor to my father. Meanwhile, the project was to be kept secret, and I continued to work to Keimer as before. The governor subsequently sent for me every now and then to dine with him. I considered this as a very great honour; and I was the more sensible of it, as he conversed with me in the most affable, friendly, and familiar manner imaginable."

In pursuance of the above arrangement, Franklin set out on his return homewards, in the end of April 1724, having been absent about seven months, during which time his parents and relations had heard nothing of him whatever, his brother-in-law never having written to inform them where he was. All the family, with the exception of his brother James, were delighted to see him; and not the less so, perhaps, that he was apparelled in a complete new suit of clothes, had an excellent silver watch, and about five pounds sterling in his pocket. His father was exceedingly surprised when informed of the object of his visit, and still more at the contents of Governor Keith's epistle. After long deliberation, he came to the resolution of refusing compliance with the request, on account of his son being too young to undertake the management of such a speculation; adding, that he thought the governor a man of little discretion in proposing it. He promised, however, when his son should attain his twenty-first year, that he would supply him with what money he required to set him up in business, praising him highly, at the same time, for his industry and good conduct. Franklin, accordingly, was necessitated to return to Philadelphia with the news of his bad success, but left Boston on this occasion accompanied by the blessings of his parents. When he arrived at Philadelphia, he immediately waited upon the governor, and communicated the result of his journey. Sir William observed that his father was "too prudent;" but added, "since he will not do it, I will do it myself." It was ultimately arranged, therefore, that Franklin should proceed personally to London to purchase every thing necessary for the proposed establishment, for the expense of which the governor promised him a letter of credit to the extent of L.100, with recommendations to various people of influence.

SAILS FOR ENGLAND.

It had been arranged that Franklin was to go to England in the regular packet-ship; and as the time of her sailing drew near, he became importunate for the governor's letters of credit and recommendation, but the latter always put him off under various pretences. At last, when the vessel was on the point of departing, he was sent on board, under the assurance that Colonel French would bring the letters to him immediately. That gentleman accordingly came on board with a packet of dispatches tied together, which were put into the captain's bag, and Franklin was informed that those intended for him were tied up with the rest, and would be delivered to him before landing in England. When they arrived in the Thames, accordingly, the captain allowed him to search the bag, but Franklin could find no letters directed either to himself or addressed as to his care; but he selected six or seven, which from the directions on them he conceived to be those intended for his service. One of these was to the king's printer, and Franklin accordingly waited upon that gentleman with it; but the latter had no sooner opened it, than he exclaimed, "Oh, this is from Riddlesden!—(a well-known rascally attorney at Philadelphia); I have lately discovered him to be an arrant knave, and wish to have nothing to do either with him or his letters." So saying, he turned on his heel, and resumed his occupation. In short, it turned out that none of the letters were from the governor; and he soon learned from a gentleman of the name of Denham, who had been a fellow-passenger with him, and to whom he explained his awkward situation, that the governor was a complete cheat, deceiving people, from vanity and a love of self-consequence, with promises which he neither intended nor was able to fulfil; and laughed at the idea of a man giving a letter of credit for L.100 who had no credit for himself.

Franklin's situation was now even more desolate than when set ashore, ragged, hungry, and almost penniless, at Philadelphia, little more than a twelvemonth before. But the heart, at eighteen, is not naturally inclined to despond, and never was one less so than that of Franklin. He immediately applied for and obtained employment in the office of the celebrated Mr Palmer. Amongst other works on which he was set to work here, was a second edition of Wollaston's Religion of Nature. Conceiving some of the positions assumed in it to be weak or erroneous, he composed and published a small metaphysical treatise in refutation of them. This pamphlet acquired him considerable credit with his master as a man of talent; but that gentleman reprobated, with the utmost abhorrence, the doctrines maintained in his publication, which, truth compels us to say, were completely irreligious, so far as regarded the Christian faith, or any other acknowledged system of belief. Free-thinking, however, was then in fashion among the higher and more learned classes, and his pamphlet procured him the countenance of various eminent individuals; amongst the rest, of Dr Mandeville, author of the Fable of the Bees, and Dr Pemberton, Sir Isaac Newton's friend. He was likewise waited upon by Sir Hans Sloane, who had been informed of his bringing some curiosities with him from America; amongst others, a purse of asbestos—a natural substance which resists the action of fire, and then very little known—for which he paid Franklin a high price. From Mr Palmer's office he removed to Mr Watt's, for the consideration of a higher wage. Here he gave a striking proof of that resolute adherence to temperance, industry, and frugality, which were amongst the leading features of his character. Whilst Mr Watt's other workmen spent generally five or six shillings a-week on beer, which was brought into the office to them during the day, he drunk nothing but water; and they were surprised to see that he was much stronger than any of them, while he himself had the additional comfort and satisfaction of being always clear-headed. At first they ridiculed his abstinence, and conferred on him the soubriquet of the *American Aquatic*; but as his character rose amongst them, his example, he says, "prevailed with several of them to renounce their abominable breakfast of bread and cheese, with beer; and they procured, like me, from a neighbouring house, a good basin of warm gruel, in which was a small slice of butter, with toasted bread and nutmeg. This was a much better breakfast, which did not cost more than a pint of beer, namely, three halfpence, and at the same time preserved the head clearer." His assiduous application to business, at the same time, together with remarkable quickness in *composing* (setting up the types), recommended him to his employer, and procured him all the most urgent and best-paid work; so that, with his frugal mode of living, he quickly laid past money.

RETURNS TO AMERICA.

After having been about eighteen months in London, much to his advantage in every respect—for, besides becoming more proficient in his business, he had stuck to his books as sedulously as ever, even although he frequently went to the play, made little pleasure excursions, and mingled a good deal in society—he was about to set out on a tour through Europe, with a young intelligent fellow-workman (designing to maintain themselves during their pilgrimage by means of their calling), when he accidentally met with Mr Denham, before noticed as being his fellow-passenger from America. That gentleman was on the eve of returning to Philadelphia, to open a merchant's store, and offered Franklin the situation of his clerk, with a salary of L.50 per annum. This sum was less than he was making as a compositor; but an anxious desire to revisit his native country induced him to accept of it. They set sail accordingly—Franklin now supposing he had relinquished the composing-stick for ever—and arrived at Philadelphia on the 11th of October 1726. Franklin had just entered his twenty-first year at this time; and he mentions having drawn up for himself in writing, during the voyage, a plan for the regulation of his future conduct. This interesting document was afterwards unfortunately lost; but he tells us himself that he pretty faithfully adhered to the rules thus early laid down, even into old age. Upon his arrival, he found his old acquaintance, the governor, had been supplanted in his office, and was held in general contempt. They met several times, but no allusion was ever made by Franklin to the disgraceful imposture the other had practised on him.

Franklin's new employer had only been in business for a few months, when both were seized at the same time with a violent disorder, which carried off the master in a few days, and brought the clerk to the brink of the grave. On his recovery, being thus once more left destitute, he was fain to accept employment as a printer from his old master Keimer, who was now somewhat better off in the world, but still utterly ignorant of his profession. The whole charge of the office, with that of instructing four or five ignorant apprentices, devolved on Franklin. "I also," says he, "upon occasion, engraved various ornaments, made ink, gave an eye to the shop—in short, I was, in every respect, the *factotum*." But he likewise, at this time, gave another remarkable instance of his versatile ingenuity.

"Our press," says he, "was frequently in want of the necessary quantity of letter, and there was no such trade as that of letter-founder in America. I had seen the practice of this art at the house of James, in London, but had at the time paid it very little attention. I, however, contrived to fabricate a mould. I made use of such letters as we had for punches, founded new letters of lead in matrices of clay; and thus supplied, in a tolerable manner, the wants that were most pressing." Franklin's inventive mind would seem here to have obtained a distant glimpse of the principle of *stereotyping*, which has since been carried to such a height of usefulness and perfection, as exemplified in the various publications of the editors of this miscellany.

Keimer having engaged Franklin solely with the view of having his apprentices so far initiated in the art as that he could dispense with their instructor's services, took the first occasion to quarrel with him when he thought he had sufficiently attained his object. Upon their separation, one of Keimer's apprentices, named Meredith, who, like all the others, had conceived a great veneration for Franklin, proposed that they should enter into partnership together—Meredith's friends undertaking to furnish the capital necessary for purchasing the materials, &c. This offer was too advantageous to be refused; and types, press, &c., were forthwith commissioned from London; but while preparing to put their plan into execution, Franklin was induced, during the interval, to return again to Keimer, at the urgent solicitation of the latter. The motive for this humble entreaty was that individual's having taken a contract for the printing of some paper-money for the state of New Jersey, requiring a variety of new cuts and types, which he knew well nobody in that place but Franklin could supply. This also presents us with a very striking instance of Franklin's remarkable gift of invention.

"To execute the order," says he, "I constructed a copperplate printing-press! the first that had been seen in the country. I engraved various ornaments and vignettes for the bills, and we repaired to Burlington together, where I executed the whole to the general satisfaction, and he (Keimer) received a sum of money for this work, which enabled him to keep his head above water for a considerable time longer."

At Burlington, Franklin formed acquaintance with all the principal personages of the province, who were attracted by his superior abilities and intelligence. Amongst these was the inspector-general, Isaac Decon, "who," says Franklin, "was a shrewd and subtle old man. He told me that his first employment had been that of carrying clay to the brickmakers; that he did not learn to write till he was somewhat advanced in life; that he was afterwards employed as underling to a surveyor, who taught him his trade; and that, by industry, he had at last acquired a competent fortune. 'I foresee,' said he, 'that you will soon supplant this man (speaking of Keimer), and get a fortune in the business at Philadelphia.' He was wholly ignorant at the time of my intention of establishing myself there, or any where else."

ENTERS INTO BUSINESS.

Franklin had scarcely returned from Burlington, when the types commissioned for himself and Meredith, from London, arrived; and having settled matters with Keimer, the partners immediately took a house, and commenced business. They were in the act of opening up their packages, when a countryman came in to have a job done; and as all their cash had been expended in their various purchases, "this countryman's five shillings," says Franklin, "being our first fruits, and coming so seasonably, gave me more pleasure than any crown I have since earned." A number of young men having, during the preceding year, formed themselves, at Franklin's suggestion, into a weekly club for the purpose of mutual improvement, they were so well pleased with the beneficial results they experienced from their meetings, that, when the originator of their society set up in business, every one exerted himself more than another to procure him employment. One of them obtained from the Quakers the printing of forty sheets of a history of that sect, then preparing at the expense of the body. "Upon these," says Franklin, "we worked exceeding hard, for the price was very low. It was in folio, upon *pro patria* paper, and in the *pica* letter, with heavy notes in the smallest type. I composed a sheet a-day, and Meredith put it to press. It was frequently eleven o'clock at night, sometimes later, before I had finished my distribution for the next day's task; for the other little jobs that came in kept us back in this work; but I was so determined to compose a sheet a-day, that one evening, when my form was imposed, and my day's work, as I thought, at an end, an accident broke the form, and deranged two complete folio pages. I immediately distributed and composed them anew before I went to bed." This unwearied industry, which soon became known, acquired Franklin great reputation and credit amongst his townsmen, and business began rapidly to flow in upon them.

STARTS A NEWSPAPER.

The establishment and management of a newspaper seems to have all along been a favourite project with Franklin; probably because, from his former experience in it, and the consciousness of his powers of writing, he felt himself so well adapted for the task. The partners soon found themselves in circumstances to enable them to make the trial; but Franklin having incautiously divulged their intention to a third person, that individual informed their old master Keimer of the fact, who immediately took steps to anticipate them, and issued a prospectus of a paper of his own. The manner in which Franklin met and defeated this treachery is exceedingly characteristic. There was another paper published in Philadelphia by Mr Bradford, which had been in existence for some years, but was such a miserable affair, that it only preserved its vitality because no other arose to knock it on the head. In order to keep down Keimer's publication, however, Franklin saw the policy of supporting the old one, until prepared to start his own. He thereupon set about writing a series of amusing articles for it, which the publisher, Bradford, was of course very glad to insert. "By this means," says Franklin, "the attention of the public was kept fixed on that paper, and Keimer's proposals, which we burlesqued and ridiculed, were disregarded. He began his paper, however; and, after continuing it for nine months, having at most not more than ninety subscribers, he offered it to me for a mere trifle. I had for some time been prepared for it; I therefore instantly took it upon myself, and in a few years it proved very profitable to me." In fact, it obtained notoriety and applause at the very first number, in consequence of some observations therein by Franklin, on an important colonial question; and various members of Assembly exerted themselves so well in his behalf, that the printing of the House was speedily transferred from Bradford to his two young rivals. In the management of his newspaper, Franklin pursued a system of unflinching integrity. He steadfastly refused to give admission into his columns of any article containing personal abuse of particular individuals. Whenever he was requested to publish any thing of this sort, his answer was, that he would print the piece by itself, and give the author as many copies for his own distribution as he wished. He very wisely considered that his subscribers expected him to furnish them with useful and entertaining information, and not with personal slander or private discussions with which they had no concern.

COMMENCES BUSINESS BY HIMSELF.

Luckily for Franklin, almost at the commencement of the newspaper, an opportunity occurred of getting rid of his partner Meredith, who had become an idle drunken fellow, and had all along been of comparatively little use in the concern. Meredith's father failed to implement the bargain for advancing the necessary capital to pay the demands of the paper merchant, and other expenses necessarily attending their speculation, when they became due. A suit was accordingly instituted against the partners, and as Meredith's father declared his inability to pay the amount of the claims upon them, the son offered to relinquish the whole concern into Franklin's hands, on condition that the latter would take upon him the debts of the company, repay his father what he had already advanced, settle his own little personal debts, and give him thirty pounds—and a *new saddle!* By the kindness of two friends, who, unknown to each other, came forward simultaneously and unasked to his assistance, Franklin was enabled to accept the offer. The agreement was carried into effect, and thus do we find this extraordinary man, at the age of twenty-four, and in the place where he had arrived penniless only seven years before, settled down in business, with a thriving trade; proprietor of an extensively circulated newspaper, and a firmly established reputation of no ordinary kind. All this success, however, the result of his own good conduct, perseverance, and frugality, had no undue effect on his well-regulated mind, or could induce him to assume those airs of arrogant superiority and pretension, which have but too frequently blemished the character of those who have praiseworthily achieved their own elevation in society. On the contrary, he dressed more plainly, and deported himself more humbly, than ever; and to show that he was not above his business, he sometimes wheeled home on a barrow, with his own hands, the paper which he purchased at the stores.

Although we are, in a manner, only arrived at the commencement of that long career of usefulness as a citizen, a statesman, and a philosopher, which has rendered his name so illustrious, and, to use the expressive language of the poet,

> "Made him loved at home—revered abroad,"

we have undoubtedly got through the most interesting part of his biography. We have noted by what means—by what patient exertion, self-control, industry, frugality, temperance, and integrity, he overcame all obstacles, and attained the station at which we have seen him arrive; fitted himself for the discharge of those important duties to which the voice of his country called him; and acquired those fixed habits of study, observation, and inquisitive research, by which he afterwards penetrated so deep into the arcanum of nature's mysteries. It will be needless for us, therefore, to trace his private history so inquisitorially as we have hitherto done through the remainder of his eminently successful fortunes.

Soon after getting the whole printing and newspaper concern into his hands, there was an outcry among the people for a new emission of paper-money. Franklin took up the cause, and by his arguments in a pamphlet which he published on the subject, contributed so greatly to the success of the proposal, and obtained himself so much popularity, that upon its being resolved to issue the notes, Franklin was selected to print them. He then opened a stationer's shop, and from his success in business, began gradually to pay off his debts. He took care, he says, not only to be *really* industrious and frugal, but also to avoid every appearance to the contrary—was plainly dressed, and was never seen in any place of public amusement; never went a-fishing or hunting. A book, indeed, enticed him sometimes from his work, but even that indulgence was seldom, and by stealth. Meanwhile, his old master Keimer went fast to ruin, and, with the exception of old Mr Bradford, who was rich and did not care for business, he was the only printer in the place. He shortly afterwards married Miss Read, the lady named in a former part of this memoir. Franklin's behaviour to this young lady had not been altogether blameless. Previous to his sailing for England he had exchanged pledges of affection with her; yet, all the while he was away, he only sent her one letter. Her friends and herself concluding that he either never meant to return, or that he wished to drop connexion with her, she was induced to accept the hand of another suitor, and on his return to America Franklin found her married—an event that seems to have given him extremely little uneasiness. The lady's husband proved a great rogue, deserted her, and it was subsequently ascertained that he had still a former wife living. After being established in business, and rising in the world, the intimacy between Franklin and her family was renewed, and it was not long, ere, despite her dubious situation, they hazarded a fulfilment of their early vows. The lady was about Franklin's own age, and proved, according to his own testimony, "an honour and a blessing" to him.

In 1731, Franklin drew up proposals for a public subscription library at Philadelphia, being the first project of the sort that had been started in America. Fifty persons at first subscribed forty shillings each, and agreed to pay ten shillings annually; and the establishment was put under such judicious rules of management, that in the course of ten years it became so valuable and important as to induce the proprietors to get themselves incorporated by royal charter. This library afforded its founder facilities of improvement of which he did not fail to avail himself, setting apart, as he tells us, an hour or two every day for study, which was the only amusement he allowed himself.

In 1732, Franklin began to publish his Poor Richard's Almanack, so called from his giving it forth under the name of Richard Saunders. It was chiefly remarkable for the numerous and pithy maxims it contained, all tending to exhort to industry and frugality. It was continued annually for twenty-five years, and the proverbs and trite moral observations scattered throughout it were afterwards thrown together into a connected discourse, under the title of the "Way to Wealth." So highly esteemed is this production amongst his countrymen, that copies of it are to this day to be found framed and glazed in the houses even of the wealthiest people in Philadelphia, and indeed in every province of North America. As it is replete with that practical wisdom, drawn from experience, which is applicable to the every-day concerns of busy life, and which cannot be too constantly kept before the eye of mankind, it falls as appropriately as legitimately to be quoted in a work, the prime object of which is to farther popular instruction.

"*The Way to Wealth, a Preliminary Address to the Pennsylvania Almanac, entitled Poor Richard's Almanac, for the year* 1758.

I stopped my horse lately where a great number of people were collected at an auction of merchants' goods. The hour of sale not being come, they were conversing on the badness of the times; and one of the company called to a plain, clean, old man, with white locks, "Pray, father Abraham, what think ye of the times? Won't these heavy taxes quite ruin the country? How shall we ever be able to pay them? What would you advise us to?" Father Abraham stood up, and replied, "If you have my advice, I'll give it to you in short; 'for a word to the wise is enough; and many words won't fill a bushel,' as poor Richard says." They joined in desiring him to speak his mind; and, gathering round him, he proceeded as follows:—

"Friends (says he) and neighbours, the taxes are indeed very heavy; and if those laid on by the government were the only ones we had to pay, we might more easily discharge them; but we have many others, and much more grievous to some of us. We are taxed twice as much by our idleness, three times as much by our pride, and four times as much by our folly; and from these taxes the commissioners cannot ease or deliver us, by allowing an abatement. However, let us hearken to good advice, and something may be done for us; 'God helps them that help themselves,' as poor Richard says in his Almanac.

"It would be thought a hard government that should tax its people one tenth part of their time, to be employed in its service; but idleness taxes many of us much more, if we reckon all that is spent in absolute sloth, or doing of nothing, with that which is spent in idle employments, or amusements that amount to nothing. Sloth, by bringing on diseases, absolutely shortens life. 'Sloth, like rust, consumes faster than labour wears, while the key often used is always bright,' as poor Richard says. 'But dost thou love life? then do not squander time, for that's the stuff life is made of,' as poor Richard says. How much more than is necessary do we spend in sleep! forgetting that 'the sleeping fox catches no poultry, and that there will be sleeping enough in the grave,' as poor Richard says. 'If time be of all things the most precious, wasting time must be (as poor Richard says) the greatest prodigality;' since, as he elsewhere tells us, 'Lost time is never found again; and what we call time enough, always proves little enough.' Let us then up and be doing, and doing to the purpose; so by diligence shall we do more with less perplexity. 'Sloth makes all things difficult, but industry all easy,' as poor Richard says; and 'He that riseth late must trot all day, and shall scarce overtake his business at night; while laziness travels so slowly, that poverty soon overtakes him,' as we read in poor Richard; who adds, 'Drive thy business, let not that drive thee;' and,

> 'Early to bed, and early to rise,
> Makes a man healthy, wealthy, and wise.'

"So what signifies wishing and hoping for better times? We make these times better if we bestir ourselves. 'Industry needs not wish,' as poor Richard says; 'He that lives upon hope will die fasting.' 'There are no gains without pains; then help, hands, for I have no lands; or if I have, they are smartly taxed;' and (as poor Richard likewise observes) 'He that hath a trade hath an estate, and he that hath a calling hath an office of profit and honour;' but then the trade must be worked at, and the calling well followed, or neither the estate nor the office will enable us to pay our taxes. If we are industrious, we shall never starve; for, as poor Richard says, 'At the working-man's house hunger looks in, but dares not enter.' Nor will the bailiff or the constable enter; for 'Industry pays debts, but despair increaseth them,' says poor Richard. What though you have found no treasure, nor has any rich relation left you a legacy? 'Diligence is the mother of good luck,' as poor Richard says; and 'God gives all things to industry: then plough deep while sluggards sleep, and you will have corn to sell and to keep,' says poor Dick. Work while it is called to-day; for you know not how much you may be hindered to-morrow; which makes poor Richard say, 'One to-day is worth two to-morrows;' and, further, 'Have you somewhat to do to-morrow, do it to-day.' 'If you were a servant, would you not be ashamed that a good master should catch you idle? Are you, then, your own master? be ashamed to catch yourself idle,' as poor Dick says. When there is so much to be done for yourself, your family, and your gracious king, be up by peep of day: 'Let not the sun look down, and say, Inglorious here he lies!' Handle your tools without mittens; remember that 'The cat in gloves catches no mice,' as poor Richard says. It is true, there is much to be done, and perhaps you are weak-handed; but stick to it steadily, and you will see great effects; for continual dropping wears away stones, and by diligence and patience the mouse ate into the cable; and 'light strokes fell great oaks,' as poor Richard says in his Almanac, the year I cannot just now remember.

"Methinks I hear some of you say, 'Must a man afford himself no leisure?'—I will tell thee, my friend, what poor Richard says, 'Employ thy time well, if thou meanest to gain leisure; and since thou art not sure of a minute, throw not away an hour.' Leisure is time for doing something useful; this leisure the diligent man will obtain, but the lazy man never; so that, as poor Richard says, 'A life of leisure and a life of laziness are two things.' Do you imagine that sloth will afford you more comfort than labour? No; for, as poor Richard says, 'Troubles spring from idleness, and grievous toils from needless ease: many without labour would live by their own wits only; but they break for want of stock.' Whereas industry gives comfort, and plenty, and respect. 'Fly pleasures, and they'll follow you; the diligent spinner has a large shift; and now I have a sheep and a cow, every body bids me good-morrow;' all which is well said by poor Richard.

"But with our industry, we must likewise be steady, and settled, and careful, and oversee our own affairs with our own eyes, and not trust too much to others; for, as poor Richard says,

> 'I never saw an oft-removed tree,
> Nor yet an oft-removed family,
> That throve so well as one that settled be.'

"And again, 'Three removes are as bad as a fire;' and again, 'Keep thy shop, and thy shop will keep thee;' and again, 'If you would have your business done, go; if not, send.' And again,

> 'He that by the plough would thrive,
> Himself must either hold or drive.'

"And again, 'The eye of the master will do more work than both his hands;' and again, 'Want of care does us more damage than want of knowledge;' and again, 'Not to oversee workmen is to leave them your purse open.' Trusting too much to others' care is the ruin of many; for, as the Almanac says, 'In the affairs of the world, men are saved not by faith, but by the want of it; but a man's own care is profitable; for,' saith poor Dick, 'Learning is to the studious, and riches to the careful, as well as power to the bold, and heaven to the virtuous.' And, further, 'If you would have a faithful servant, and one that you like, serve yourself.' And again, he adviseth to circumspection and care, even in the smallest matters, because sometimes 'A little neglect may breed great mischief;' adding, 'For want of a nail the shoe was lost; for want of a shoe the horse was lost; and for want of a horse the rider was lost;' being overtaken and slain by the enemy, all for want of care about a horse-shoe nail.

"So much for industry, my friends, and attention to one's own business; but to these we must add frugality, if we would make our industry more certainly successful. A man may, if he knows not how to save as he gets, 'keep his nose all his life to the grindstone, and die not worth a groat at last.' 'A fat kitchen makes a lean will,' as poor Richard says; and,

> 'Many estates are spent in the getting;
> Since women for tea forsook spinning and knitting,
> And men for punch forsook hewing and splitting.'

"'If you would be wealthy (says he in another Almanac), think of saving, as well as of getting; the Indies have not made Spain rich, because her outgoes are greater than her incomes.'

"Away then with your expensive follies, and you will not have much cause to complain of hard times, heavy taxes, and chargeable families; for, as poor Dick says,

> 'Women and wine, game and deceit,
> Make the wealth small, and the want great.'

"And, further, 'What maintains one vice would bring up two children.' You may think, perhaps, that a little tea, or a little punch now and then, diet a little more costly, clothes a little finer, and a little entertainment now and then, can be no great matter; but remember what poor Richard says—'Many a little makes a mickle;' and farther, 'Beware of little expenses; a small leak will sink a great ship;' and again, 'Who dainties love shall beggars prove;' and moreover, 'Fools make feasts, and wise men eat them.'

"Here you are all got together at this sale of fineries and nick-nacks. You call them *goods*; but if you do not take care, they will prove *evils* to some of you. You expect they will be sold cheap, and perhaps they may for less than they cost; but if you have no occasion for them, they must be dear to you. Remember what poor Richard says—'Buy what thou hast no need of, and ere long thou shalt sell thy necessaries.' And again, 'At a great pennyworth pause awhile.' He means, that perhaps the cheapness is apparently only, or not real, or the bargain, by straitening thee in thy business, may do thee more harm than good. For in another place he says, 'Many have been ruined by buying good pennyworths.' Again, as poor Richard says, 'It is foolish to lay out money in a purchase of repentance;' and yet this folly is practised every day at auctions, for want of minding the Almanac. 'Wise men (as poor Dick says) learn by others' harms, fools scarcely by their own; but *Felix quem faciunt aliena pericula cautum.* Many a one, for the sake of finery on the back, have gone with a hungry belly, and half starved their families; 'Silk and satins, scarlet and velvets (as poor Richard says), put out the kitchen fire.' These are not the necessaries of life; they can scarcely be called the conveniences; and yet only because they look pretty, how many want to have them! The artificial wants of mankind thus become more numerous than the natural; and as poor Dick says, 'For one poor person there are a hundred indigent.' By these and other extravagances the genteel are reduced to poverty, and forced to borrow of those whom they formerly despised, but who, through industry and frugality, have maintained their standing; in which case it appears plainly, 'A ploughman on his legs is higher than a gentleman on his knees,' as poor Richard says. Perhaps they have had a small estate left them which they knew not the getting of; they think 'It is day, and will never be night;' that a little to be spent out of so much is not worth minding. 'A child and a fool (as poor Richard says) imagine twenty shillings and twenty years can never be spent; but always be taking out of the meal-tub, and never putting in, soon comes to the bottom;' then, as poor Dick says, 'When the well is dry, they know the worth of water.' But this they might have known before, if they had taken his advice: 'If you would know the value of money, go and try to borrow some; for he that goes a-borrowing goes a-sorrowing, and, indeed, so does he that lends to such people when he goes to get it in again.' Poor Dick further advises, and says,

'Fond pride of dress is sure a very curse;
Ere fancy you consult, consult your purse.'

And again, 'Pride is as loud a beggar as Want, and a great deal more saucy.' When you have bought one fine thing, you must buy ten more, that your appearance may be all of a piece; but poor Dick says, 'It is easier to suppress the first desire, than to satisfy all that follow it.' And it is as truly folly for the poor to ape the rich, as the frog to swell in order to equal the ox.

'Vessels large may venture more,
But little boats should keep near shore.'

'Tis, however, a folly soon punished; for 'Pride that dines on vanity, sups on contempt,' as poor Richard says. And in another place, 'Pride breakfasted with Plenty, dined with Poverty, and supped with Infamy.' And, after all, of what use is this pride of appearance, for which so much is risked, so much is suffered? It cannot promote health, or ease pain; it makes no increase of merit in the person; it hastens misfortune.

'What is a butterfly? At best
He's but a caterpillar drest;
The gaudy fop's his picture just,'

as poor Richard says.

But what madness must it be to run in debt for these superfluities! We are offered, by the terms of this sale, six months' credit, and that perhaps has induced some of us to attend it, because we cannot spare the ready money, and hope now to be fine without it. But, ah! think what you do when you run in debt. You give to another power over your liberty. If you cannot pay at the time, you will be ashamed to see your creditor; you will be in fear when you speak to him; you will make poor, pitiful, sneaking excuses, and by degrees come to lose your veracity, and sink into base downright lying; for, as poor Richard says, 'The second vice is lying; the first is running in debt.' And again, to the same purpose, 'Lying rides upon debt's back;' whereas, a freeborn Englishman ought not to be ashamed nor afraid to speak to any man living. But poverty often deprives a man of all spirit and virtue. 'It is hard for an empty bag to stand upright,' as poor Richard truly says. What would you think of that prince, or that government, who would issue an edict, forbidding you to dress like a gentleman or gentlewoman, on pain of imprisonment or servitude? Would you not say that you were free, have a right to dress as you please, and that such an edict would be a breach of your privileges, and such a government tyrannical? And yet you are about to put yourself under that tyranny when you run in debt for such dress! Your creditor has authority, at his pleasure, to deprive you of your liberty, by confining you in jail for life, or by selling you for a servant, if you should not be able to pay him. When you have got your bargain, you may, perhaps, think little of payment; but 'Creditors (poor Richard tells us) have better memories than debtors;' and in another place he says, 'Creditors are a superstitious sect, great observers of set days and times.' The day comes round before you are aware, and the demand is made before you are prepared to satisfy it; or if you bear your debt in mind, the term which at first seemed so long, will, as it lessens, appear extremely short. Time will seem to have added wings to his heels as well as at his shoulders. 'Those have a short Lent (saith poor Richard) who owe money to be paid at Easter.' Then since, as he says, 'The borrower is a slave to the lender, and the debtor to the creditor,' disdain the chain, preserve your freedom, and maintain your independency; be industrious and free; be frugal and free. At present, perhaps, you may think yourselves in thriving circumstances, and that you can bear a little extravagance without injury; but

'For age and want save while you may,
No morning sun lasts a whole day,'

as poor Richard says. Gain may be temporary and uncertain; but ever, while you live, expense is constant and certain; and 'It is easier to build two chimnies, than to keep one in fuel,' as poor Richard says. So, 'Rather go to bed supperless than rise in debt.'

'Get what you can, and what you get hold,
'Tis the stone that will turn all your lead into gold,'

as poor Richard says. And when you have got the philosopher's stone, surely you will no longer complain of bad times, or the difficulty of paying taxes.

This doctrine, my friends, is reason and wisdom; but, after all, do not depend too much upon your own industry, and frugality, and prudence, though excellent things; for they may be blasted, without the blessing of Heaven; and therefore ask that blessing humbly, and be not uncharitable to those that at present seem to want it, but comfort and help them. Remember Job suffered, and was afterwards prosperous.

And now, to conclude, 'Experience keeps a dear school; but fools will learn in no other, and scarce in that; for it is true we may give advice, but we cannot give conduct,' as poor Richard says. However, remember this, 'They that will not be counselled cannot be helped,' as poor Richard says; and further, that 'If you will not reason, she will surely rap your knuckles.'"

Thus the old gentleman ended his harangue. The people heard it, and approved the doctrine, and immediately practised the contrary, just as if it had been a common sermon; for the auction opened, and they began to buy extravagantly, notwithstanding all his cautions, and their own fear of taxes. I found the good man had thoroughly studied my Almanacs, and digested all I had dropped on those topics during the course of twenty-five years. The frequent mention he made of me, must have tired every one else; but my vanity was wonderfully delighted with it, though I was conscious that not a tenth part of the wisdom was my own, which he ascribed to me, but rather the gleanings that I had made of the sense of all ages and nations. However, I resolved to be the better for the echo of it; and though I had at first determined to buy stuff for a new coat, I went away, resolved to wear my old one a little longer."

As Franklin advanced in worldly prosperity, he endeavoured to make his personal acquirements keep pace with his upward progress in society; and amongst other accomplishments applied himself sedulously to the study of the dead and modern languages, of which, besides his native tongue, he as yet scarcely knew any thing. The following is his own account of his private *curriculum*:—

"I had begun in 1733 to study languages. I soon made myself so much a master of the French, as to be able to read the books in that language with ease. I then undertook the Italian. An acquaintance, who was also learning it, used often to tempt me to play chess with him. Finding this took up too much of the time I had to spare for study, I at length refused to play any more, unless on this condition, that the victor in every game should have a right to impose a task, either of parts of the grammar to be got by heart, or in translations, &c., which tasks the vanquished was to perform upon honour before our next meeting. As we played pretty equally, we thus beat one another into that language. I afterwards, with a little pains-taking, acquired as much of the Spanish as to read their books also. I have already mentioned that I had only one year's instruction in a Latin school, and that when very young, after which I neglected that language entirely; but when I had attained an acquaintance with the French, Italian, and Spanish, I was surprised to find, on looking over a Latin Testament, that I understood more of that language than I had imagined, which encouraged me to apply myself again to the study of it; and I met with the more success, as those preceding languages had greatly smoothed my way."

CIVIC PREFERMENTS AND DUTIES.

It was not to be supposed that a man of Franklin's comprehensive mind, and useful practical talents, would be allowed to remain long in the ranks of private life. Accordingly, in the year 1736, he was appointed clerk to the general assembly at Pennsylvania. No opposition was made to his appointment the first year; but on the next election, a new member of the house opposed his return in a long speech. Franklin was, however, again elected, much to his satisfaction; for although the place was one of almost no direct emolument, it gave him an opportunity of making friends amongst the members, and ultimately to secure to himself the printing of most of the public papers, which was previously shared with his rivals. The new member who had resisted his re-election, was a man of talents and character; and Franklin, although too independent to pay any cringing servility to him, perceived the propriety of gaining his good opinion; and the expedient he hit upon for this purpose affords another instance of his shrewdness and knowledge of human nature. Having learned that the gentleman possessed a very rare and curious book, he wrote him a polite note, requesting that he would do him the favour of lending it for a few days. The book was immediately sent; and in about a week was returned by the borrower, with a short epistle, expressive of his gratitude for the favour. The member was so much conciliated by the circumstance, that the next time he met him in the house, he addressed him with great civility; manifested ever afterwards a great desire to serve him; and they became, in short, intimate friends. "This is another instance," observes Franklin, "of the truth of an old maxim I had learned, which says, 'He that has done you a kindness, will be more ready to do you another, than he whom you yourself have obliged.' And it shows how much more profitable it is prudently to remove, than to resent, return, and continue, inimical proceedings." He was thereafter re-elected to the same post, without opposition, for several years successively. In the following year, 1737, he supplanted his rival in trade, Bradford, in the office of deputy-postmaster for the state of Pennsylvania. These honourable preferments induced him to incline his thoughts to, and take a more active part in, public affairs than he had hitherto done.

He first turned his attention to the state of the city police, which was then in a shameful condition; and he soon effected a thorough reformation in the whole system. He suggested and promoted the establishment of a fire insurance company, the first that was projected in America. He afterwards successively exerted himself in organising a philosophical society, an academy for the education of youth, and a militia for the defence of the province. In short, every department of the civil government, as he tells us, and almost at the same time, imposed some duty upon him. "The governor," says he, "put me into the commission of the peace; the corporations of the city chose me one of the common council; and the citizens at large elected me (1747) a burgess to represent them in Assembly. This latter station was the more agreeable to me, as I grew at length tired with sitting there to hear the debates, in which, as clerk, I could take no part, and which were often so uninteresting, that I was induced to amuse myself with making magic squares, or circles, or any thing, to avoid weariness; and I conceived my becoming a member would enlarge my power of doing good. I would not, however, insinuate that my ambition was not flattered by all these promotions—it certainly was; for, considering my low beginning, they were great things to me; and they were still more pleasing as being so many spontaneous testimonies of the public good opinion, and by me entirely unsolicited."

About this period (1739), the celebrated preacher Whitfield arrived at Philadelphia from Ireland. He was at first permitted to preach in some of the town churches; but the clergy soon took a dislike to him, and he was compelled to exercise his eloquence in the open streets or fields. This circumstance, however, like all displays of persecution in matters exclusively connected with private opinion, only rendered him the more popular; and the effects of his oratory speedily manifested themselves.

"It was wonderful," says Franklin, "to see the change soon made in the manners of our inhabitants. From being thoughtless or indifferent about religion, it seemed as if all the world were growing religious, so that one could not walk through the town in an evening without hearing psalms sung in different families of every street; and it being found inconvenient to assemble in the open air, subject to its inclemencies, the building of a house to meet in was no sooner proposed, and persons appointed to receive contributions, than sufficient sums were soon received to procure the ground and erect the building, which was one hundred feet long and seventy broad; and the work was carried on with such spirit as to be finished in a remarkably short time."

On leaving Philadelphia, Mr Whitfield went, preaching all the way, through the colonies to Georgia. The settlement of that province had then been recently commenced, and was attempted by people entirely unfit for such an experiment. They were unable to endure the fatigues and hardships of their situation, and perished in great numbers, leaving many helpless children with nothing to feed or clothe them. "The sight of their miserable situation," says Franklin, "inspired the benevolent heart of Mr Whitfield with the idea of building an orphan house there, in which they might be supported and educated. Returning northward, he preached up this charity, and made large collections; for his eloquence had a wonderful power over the hearts and purses of his hearers, of which I myself was an instance. I did not disapprove of the design; but as Georgia was then destitute of materials and workmen, and it was proposed to send them from Philadelphia at a great expense, I thought it would have been better to have built the house at Philadelphia, and brought the children to it. This I advised; but he was resolute in his first project, rejected my proposal, and I, therefore, refused to contribute.

"I happened soon after to attend one of his sermons, in the course of which I perceived he intended to finish with a collection, and I silently resolved he should get nothing from me. I had in my pocket a handful of copper, three or four silver dollars, and five pistoles in gold. As he proceeded, I began to soften, and concluded to give the copper. Another stroke of his oratory made me ashamed of that, and determined me to give the silver; and he finished so admirably, that I emptied my pocket wholly into the collector's dish, gold and all!

"At this sermon there was also one of our club, who, being of my sentiments respecting the building in Georgia, and suspecting a collection might be intended, had, by way of precaution, emptied his pockets before he came from home. Towards the conclusion of the discourse, however, he felt a strong inclination to give, and applied to a neighbour who stood near him to lend him some money for the purpose. The request was fortunately made to perhaps the only man who had the firmness not to be affected by the preacher. His answer was—'At any other time, friend Hopkinson, I would lend thee freely; but not now, for thee seems to me to be out of thy right senses!'"

Franklin, who was employed by Mr Whitfield to print his sermons, journals, &c., and had otherwise much intercourse with him, warmly repudiates the charges brought against him of appropriating any part of the collections he made, ostensibly for charitable purposes, to his own use. Speaking of his style of enunciation, he says, "He had a loud and clear voice, and articulated his words so perfectly, that he might be heard and understood at a great distance, especially as his auditories observed the most perfect silence. By repeated trial, in retiring to a distance from him while preaching, I computed that he might well be heard by more than thirty thousand; and I was reconciled to the newspaper accounts of his having preached to 25,000 people in the fields, and to the history of generals haranguing whole armies, of which I had sometimes doubted."

At this time there was no military defensive force in Pennsylvania. The inhabitants were mostly Quakers, and neglected to take any measures of precaution against the dangers to which, from the French possessions in Canada, they were continually exposed. All the exertions of the governor of the province to induce the Quaker assembly to pass a militia law, proved ineffectual. Franklin thought something might be done by a subscription among the people; and to pave the way for this, he wrote and published a pamphlet called "Plain Truth." In this he clearly exposed their helpless and perilous situation, and demonstrated the necessity of co-operating for their mutual defence. The pamphlet had a sudden and surprising effect. A meeting of the citizens was held, at which proposals of the intended union, previously drawn up and printed by Franklin, were distributed about the room, to be signed by those who approved of them; and when the company separated, it was found that above twelve hundred signatures had been appended to the papers. Other copies were distributed through the province, and the subscribers at length amounted to upwards of ten thousand! All these individuals furnished themselves, as soon as they could, with arms; formed themselves into companies and regiments; chose their officers, and had themselves regularly instructed in military exercises. The women made subscriptions amongst themselves, and provided silk colours, which they presented to the companies, embellished with devices and mottoes furnished by Franklin. Such influence has one master-mind amongst his fellows in a time of emergency!

Franklin's modesty, however, was more than commensurate with his patriotism. The officers of the companies composing the Philadelphia regiment unanimously chose him for their colonel, but he declined the office in favour of a man of greater wealth and influence, who, on his recommendation, was immediately elected. These exertions of Franklin procured him great confidence from the governor and council, who consulted him on all their public measures. Notwithstanding, too, of the passive principles of the Quakers, it was soon seen that the precautions of military defence were any thing but disagreeable to them. A distinguished individual of their number, Mr Logan, published an address declaring his approbation of defensive war, and supporting his opinion by able and elaborate arguments. This gentleman, who came over from England when a young man, as secretary to the famous William Penn, used to relate an anecdote respecting his old master, which is sufficiently amusing.

During their voyage, they were chased by an armed vessel, supposed to be an enemy. Their captain prepared for defence, but told Penn and his company of Quakers that he did not expect their assistance, and that they might retire into the cabin. This notification they all complied with, excepting Logan, who remained on deck, and was quartered to a gun. The supposed enemy proved a friend, so that there was no fighting; but when the secretary carried the joyful news for his friends in the cabin, Penn reproved him severely for staying on deck, and lending his assistance in defence of the vessel, as being a breach of the principles of their society. Logan, nettled at this comment on his courageous conduct, which was made before the whole company, replied, "I being thy servant, why did thee not order me to come down? but thee was willing enough that I should stay and help to fight the ship, when thee thought there was danger!"

ELECTRICAL AND OTHER PHILOSOPHICAL DISCOVERIES.

It would, perhaps, have been desirable to have followed Franklin through the remainder of his public and political career, without pausing to advert to other pursuits, entirely unconnected therewith, to which he devoted himself. We find, however, that the chronological violence of which we would in that case necessarily be guilty, would only serve to confuse our narrative. We will now, therefore, proceed to introduce him to our readers in an entirely new character from any in which they have yet seen him; for, in the language of the poet, his truly was

> "A mind so various that he seemed to be
> Not one, but all mankind's epitome."

Down to the close of the sixteenth century, all that was known of the principle of electricity was the discovery of a power inherent in amber,* and one or two other substances, to attract to them, when rubbed, light bodies, such as small bits of paper, straw, &c. In the year 1600, Dr Gilbert of London considerably enlarged the catalogue of these electrical or attractive substances, including the diamond and other precious stones, glass, sulphur, sealing wax, rosin, &c. For above a century afterwards, however, electricity was little attended to, although Dr Wall, Sir Isaac Newton, Guericke, and others (the latter of whom first observed the repulsive power and explosive quality of electricity), added some important facts. In 1728, it was discovered that electricity may be communicated from one body to another, even without these bodies being in contact.

The beginning of the year 1746 is memorable in the annals of electricity for the accidental discovery of the possibility of accumulating large quantities of the electric fluid, by means of what was called the Leyden jar, or phial. M. Cuneus, of that city, happened one day, while repeating some experiments which had been originally suggested by M. Von Kleist, Dean of the Cathedral in Camin, to hold in one hand a glass vessel, nearly full of water, into which he had been sending a charge from an electrical machine, by means of a wire dipped into it, and communicating with the prime conductor, or insulated non-electric, exposed in the manner we have already mentioned to the action of the excited cylinder. He was greatly surprised, upon applying his other hand to disengage the wire from the conductor, when he thought that the water had acquired as much electricity as the machine could give it, by receiving a sudden shock in his arms and breast, much more severe than any thing of the kind he had previously encountered in the course of his experiments. The same thing, it was found, took place when the glass was covered, both within and without, with any other conductors than the water and the human hand, which had been used in this instance; as, for example, when it was coated on both sides with tinfoil, in such a manner, however, that the two coatings were completely separated from each other, by a space around the lip of the vessel being left uncovered. Whenever a communication was formed by the interposition of a conducting medium between the inside and outside coating, an instant and loud explosion took place, accompanied with a flash of light, and the sensation of a sharp blow, if the conductor employed was any part of the human body. The first announcement of the wonders of the Leyden phial excited the curiosity of all Europe. The accounts given of the electric shock by those who first experienced it are perfectly ludicrous, and well illustrate how strangely the imagination is acted upon by surprise and terror, when novel or unexpected results suddenly come upon it.

The extraordinary phenomena of the Leyden jar, soon, of course, attracted the attention of Franklin, and his inquisitive mind set itself to find out the reason of such strange effects, which astonished and perplexed the ablest philosophers of Europe. Out of his speculations arose the ingenious and beautiful theory of the action of the electric influence which is known by his name, and which has ever been received as the best, because the simplest and most complete, demonstration of the phenomena that has yet been propounded. His earliest inquiries were directed to ascertain the *source* of the electricity, which friction made manifest in the glass cylinder. This he demonstrated, by experiments, to be in the pores of the glass, and not in the coating, as previously supposed. After the cylinder, or phial (as it is frequently termed), was charged, he removed the coating, and found, that, by applying a new coating, the shock might still be received. He showed clearly, that, when charged, the cylinder contained no more electricity than before, but that as much was taken from one side as was thrown on the other, and that by making a communication between the inside and outside coating, by which, as has already been seen, a loud explosion was caused, the equilibrium was at once restored. In order to determine whether the virtue was created by the friction in the electric, or only communicated to it by other bodies, he resorted to the very simple experiment of endeavouring to electrify himself—that is to say, having insulated himself, and excited the cylinder by rubbing it with his hand, he then drew off its electricity from it in the usual manner into his own body. But he found that he was not thereby electrified at all, as he would have been by doing the same thing, had the friction been applied by another person. No spark could be elicited from him, after the operation by the presentment of a conductor. It was plain, therefore, that the electricity had passed in the first place out of his own body into the cylinder; which, therefore, in communicating it to him in the second instance, only gave back what it had received, and, instead of electrifying him, only restored him to his natural state. To prove this still farther, he insulated two individuals, one of whom he made to rub the cylinder, while the other drew the electricity from it. In this case, they were both affected; the one having given out as much electricity to the cylinder in rubbing it, as the other had drawn from it. In proof of this, he made them touch one another, when both were instantly restored to their usual state. The spark produced by their contact was also greater than that which took place when either of them were touched by an unelectrified person. From these results, then, Franklin constructed his theory, that every body in nature has a natural quantity of electricity, which may be diminished or increased in the way we have just described. In the former case he regarded the body as *negatively*, in the latter as *positively*, electrified. In the one case it had less, in the other more, than its natural quantity of electricity; in either, therefore, supposing it to be composed of electricity and common matter, the usual equilibrium or balance between its two constituent ingredients was for the time upset or destroyed.

But to return to the Leyden phial: Franklin was not contented with merely ascertaining the principle of it. He made also a very happy application of this principle, which afforded a still more wonderful manifestation than had yet been obtained of the powers of accumulated electricity. Considering the waste that took place, in the common experiment, of the fluid expelled, during the process of charging, from the exterior coating, he conceived the idea of employing it to charge the inner surface of a second jar, which he effected, of course, by the simple expedient of drawing it off by means of a metal rod communicating with that surface. The electricity expelled from the outside of this second jar was conveyed, in like manner, into the inside of a third; and, in this way, a great number of jars were charged with the same facility as a single one. Then, having connected all the inside coatings with one conductor, and all the outside coatings with another, he had merely to bring these two general conductors into contact or communication, in order to discharge the whole accumulation at once. This contrivance he called an *Electrical Battery*. The general sketch we have thus given will put the reader in possession, at least, of the great outlines of the Franklinian theory of electricity, undoubtedly one of the most beautiful generalizations to be found in the whole compass of science.

We now advert to another brilliant discovery by this illustrious philosopher, namely, the similarity between lightning and electricity. The Abbé Nollet had, before him, hinted his suspicions of this resemblance, but only in the most loose and distant way.

In a paper, dated Nov. 7, 1749, Franklin enumerates all the known points of resemblance between lightning and electricity. In the first place, he remarks, it is no wonder that the effects of the one should be so much greater than those of the other; for if two gun-barrels electrified will strike at two inches distance, and make a loud report, at how great a distance will ten thousand acres of electrified cloud strike, and give its fire; and how loud must be that crack! He had known for some time the extraordinary power of pointed bodies, both in drawing and in throwing off the electric fire. The true explanation of this fact did not occur to him; but it is a direct consequence of the fundamental principle of his own theory, according to which the repulsive tendency of the particles of electricity towards each other, occasioning the fluid to retire, in every case, from the interior to the surface of bodies, drives it with especial force towards points and other prominences, and thus favours its escape through such outlets; while, on the other hand, the more concentrated attraction which the matter of a pointed body, as compared with that of a blunt one, exerts upon the electricity to which it is presented, brings it down into its new channel in a denser stream. In possession, however, of the fact, we find him concluding the paper we have mentioned as follows:—"The electric fluid is attracted by points. We do not know whether this property be in lightning; but since they agree in all the particulars in which we can already compare them, it is not improbable that they agree likewise in this. Let the experiment be made."

Full of this idea, it was yet some time before he found what he conceived a favourable opportunity of trying its truth in the way he meditated. A spire was about to be erected in Philadelphia, which he thought would afford him facilities for the experiment; but his attention having been one day drawn by a kite which a boy was flying, it suddenly occurred to him that here was a method of reaching the clouds preferable to any other. Accordingly, he immediately took a large silk hankerchief, and, stretching it over two cross sticks, formed in this manner his simple apparatus for drawing down the lightning from its cloud. Soon after, seeing a thunder storm approaching, he took a walk into a field in the neighbourhood of the city, in which there was a shed, communicating his intentions, however, to no one but his son, whom he took with him to assist him in raising the kite: this was in June 1752.

The kite being raised, he fastened a key to the lower extremity of the hempen string, and then insulating it by attaching it to a post by means of silk, he placed himself under the shed, and waited the result. For some time no signs of electricity appeared. A cloud, apparently charged with lightning, had even passed over them without producing any effect. At length, however, just as Franklin was beginning to despair, he observed some loose threads of the hempen string rise and stand erect, exactly as if they had been repelled from each other by being charged with electricity. He immediately presented his knuckle to the key, and, to his inexpressible delight, drew from it

* The term electricity is derived from the Greek word *electron*, amber.

the well-known electrical spark. He said afterwards that his emotion was so great at this completion of a discovery which was to make his name immortal, that he heaved a deep sigh, and felt that he could that moment have willingly died. As the rain increased, the cord became a better conductor, and the key gave out its electricity copiously. Had the hemp been thoroughly wet, the bold experimenter might, as he was contented to do, have paid for his discovery with his life. He afterwards brought down the lightning into his house, by means of an insulated iron rod, and performed with it, at his leisure, all the experiments that could be performed with electricity. But he did not stop here. His active and practical mind was not satisfied even with the splendid discovery, until he had turned it to a useful end. It suggested to him, as is well known, the idea of a method of preserving buildings from lightning, which is extremely simple and cheap, as well as effectual, consisting, as it does, in nothing more than attaching to the building a pointed metallic rod, rising higher than any part of it, and communicating at the lower end with the ground. This rod the lightning is sure to seize upon, in preference to any part of the building; by which means it is conducted to the earth, and prevented from doing any injury. There was always a strong tendency in Franklin's philosophy to these practical applications.

Franklin's discoveries did not at first attract much attention in England; and, in fact, he had the mortification to hear that his paper on the similarity between lightning and electricity had been ridiculed when read in the Royal Society. Having fallen, however, into the hands of the naturalist Buffon, that celebrated man translated and published it at Paris, when it speedily excited the astonishment of all Europe. What gave his book the more sudden and general celebrity was the success of one of its proposed experiments for drawing lightning from the clouds, made at Marly. This engaged the public attention every where. The "Philadelphia experiments," as they were called, were performed before the king and court, and all the curious of Paris flocked to see them. Dr Wright, an English physician, being at Paris at the time, wrote to a member of the Royal Society of London, with an account of these wonders, and stating the surprise of all the learned men abroad of Franklin's writings being so little noticed in England. The society were thus in a manner compelled to pay more attention to what they had previously considered as chimerical speculation, "and soon," says Franklin, "made me more than amends for the slight with which they had before treated me. Without my having made any application for that honour, they chose me a member, and voted that I should be excused the customary payments, which would have amounted to twenty-five guineas, and ever since have given me their Transactions gratis. They also presented me with the gold medal of Sir Godfrey Copley for the year 1753, the delivery of which was accompanied with a very handsome speech of the president, Lord Macclesfield, wherein I was highly honoured."

Although the numerous important public duties which Franklin was called upon latterly to discharge, chiefly engrossed his time, he still returned to his philosophical studies on every occasion that offered, and made several curious and interesting discoveries. Amongst others, was that of producing so intense a degree of cold, by the evaporation of ether in the exhausted receiver of an air-pump, as to convert water into ice. This discovery he applied to the solution of a number of phenomena, particularly a singular fact, which philosophers had previously laboured in vain to account for, namely, that the temperature of the human body, when in health, never exceeds 96° of Fahrenheit's thermometer, though the atmosphere which surrounds it may be heated to a much greater degree. This he attributed to the increased perspiration, and consequent evaporation, produced by the heat.

The tone produced by rubbing the brim of a drinking glass with a wet finger, had been generally known. This subsequently gave rise to the art of playing tunes on a variety of glasses of different sizes, now called "musical glasses." The sweetness of the tones induced Dr Franklin to make a variety of experiments; and he at length formed that elegant instrument which he called the Armonica.

Perhaps no philosopher ever stood on a prouder eminence in the world's eye than Franklin during the latter half of his life. The obscurity of his origin served but to make his elevation the more brightly conspicuous, and honours were showered on him from all quarters of the civilised world. In 1766 he visited Holland and Germany, and was received with the greatest testimonies of respect from all men of science and distinction. At Paris, Louis the Fifteenth honoured him with the most distinguished marks of his favour. Some years afterwards he visited Scotland with his son, when the University of St Andrew's conferred upon him the degree of Doctor of Laws. Its example was followed by Edinburgh and Oxford; and he was also elected a member of almost every learned society throughout Europe.

POLITICAL CAREER.

This part of Franklin's life need only be very generally touched on, the scenes and transactions in which he bore a part having long since become matter of history, with which almost every individual is now more or less acquainted. We have before mentioned that he was elected a member of the General Assembly of Pennsylvania as burgess for the city of Philadelphia in 1747. Warm disputes at this time subsisted between the assembly and the proprietaries,* each contending for what they conceived to be their just rights. Franklin, a friend to the interests of *the many* from his infancy, speedily distinguished himself as a steady opponent of the claims of the proprietaries, and he was soon looked up to as the head of the opposition. His influence with the Assembly is said to have been very great. This arose not from any superior powers of elocution; he spoke but seldom, and he never was known to make any thing like an elaborate harangue. "His speeches," says his intimate friend, the late Dr Stuber of Philadelphia, "frequently consisted of but a single sentence, or of a well-told story, the moral of which was always obviously to the point. He never attempted the flowery fields of oratory. His manner was plain and mild; his style of speaking was, like that of his writings, simple, unadorned, and remarkably concise. With this plain manner, and his penetrating and solid judgment, he was able to confound the most eloquent and subtle of his adversaries, to confirm the opinions of his friends, and to make converts of the unprejudiced who had opposed him. With a single observation, he has rendered of no avail an elegant and lengthy discourse, and determined the fate of a question of importance."

Franklin had conducted himself so well in the office of postmaster for the state of Pennsylvania, and had shown himself so well acquainted with the business of that department, that it was thought expedient to raise him to a more dignified station. In 1753, he was appointed deputy-postmaster-general for the British colonies. It is said that the revenue from this source, in Franklin's hands, yielded to Great Britain three times as much as that of Ireland. In 1754, Franklin drew up the celebrated "Albany Plan of Union," the purpose of which was the establishment of a general government in the colonies, to be administered by a president-general, appointed by the crown, and by a grand council, consisting of members chosen by the representatives of the different colonies; the whole executive authority to be committed to the president-general; the legislative to the grand council and president jointly; and all laws to be approved of by the king. This plan was unanimously approved of by the commissioners for the crown and the colonies appointed to consult on the question, but its final fate was singular. It was rejected by the Ministry of Great Britain as too democratical, and by every local assembly as too despotic. These verdicts were, perhaps, the best proof of its excellence, and of its having steered exactly in the middle betwixt the interests of both.

The British government having thus rejected a proposal of internal defence in the colonies, they were soon obliged to adopt measures of another sort for their protection. Aggressive operations were again threatened by the French; and in 1754, General Braddock was dispatched from England with two regiments of regular English troops to resist them. The troops were landed at Alexandria, and marched thence to Fredericktown in Maryland, where they halted for carriages to transport their baggage, ammunition, &c., to the frontiers. Great reluctance was manifested by the country people to supply these, and, in fact, so few were sent in, and so many other difficulties occurred, that the general was about to abandon the expedition altogether. In this dilemma he was fortunately joined by Franklin, who, aware of the necessity and importance of the expedition, asked General Braddock what recompense he would afford to the owners for the use of their waggons and horses. General Braddock referred the terms to himself; they were drawn up, and accepted; and Franklin immediately published them in an advertisement, with an animated appeal from himself to the loyalty and patriotism of his countrymen. The consequence was, that, in two weeks, 150 waggons and 260 horses poured into the camp, the owners of whom, however, declined the security of the British commander for compensation, and insisted on having the personal bond of Franklin. This he accordingly gave them, and even advanced several hundred pounds of his own in present payment.

The expedition accordingly set forward, and its disastrous issue must still be well remembered. Although a brave man, Braddock had far too much confidence in the prowess of his regular troops, and too much contempt for the Americans and Indians. About one hundred of the latter joined him on his march, who would have proved of the utmost use to him as guides and scouts, but he treated them so slightingly that they all left him. No appearance of the enemy was seen until the troops had penetrated far into the interior; and the first intelligence which they had of the approach of a foe, was in finding that they had fallen into an ambuscade, where they were mowed down in hundreds by invisible antagonists secreted amongst the trees and bushes. A general rout and confusion almost immediately ensued. The drivers cut their horses' traces and fled, abandoning the waggons, which also obstructed the retreat of the soldiers. The general was with difficulty brought off severely wounded; and, out of eighty-six officers, sixty-three were killed or wounded, with seven hundred and fourteen privates killed, out of eleven hundred who fell into the snare. All the artillery and stores, of course, were left to the enemy.

As soon as the news of the defeat, and the loss of the waggons and horses became generally known, the owners came in a body upon Franklin for the amount of their claims for which he had given bond, amounting to nearly L.20,000! It was with difficulty that many of these claimants were prevented from suing him, until government had time to examine into their charges and order payment; but the matter was at length satisfactorily settled.

In the above affair, Franklin gave a striking proof of his prudent and sagacious character. Before receiving news of the defeat, two gentlemen came to Franklin with a subscription paper, for raising money to pay the expense of a grand firework, which it was intended to exhibit on receiving the news of taking Fort Duquesne. Franklin told them gravely that he thought it would be time enough to prepare for rejoicing when they knew they should have occasion to rejoice. They seemed surprised that he did not immediately comply with their proposal. "Why," said one of them, "you surely do not suppose that the fort will not be taken?" "I don't know," replied Franklin, "that it will not be taken; but I know that the events of war are subject to great uncertainty." The plan was fortunately abandoned.

The assembly now laid a tax, to raise money for the defence of the province, and Franklin was appointed one of the commissioners to dispose of it. He had also carried a bill through the house for establishing and disciplining a voluntary militia. To promote the association necessary to form the militia, he wrote a dialogue upon the subject, which was extensively circulated, and thought to have great effect. While the several companies in the city and country were forming, and learning their exercise, the governor prevailed upon Franklin to take charge of the north-western frontier, which was infested by the enemy, and provide for the defence of the inhabitants, by raising troops, and building a line of forts. Franklin did not think himself very well qualified for the military, but was willing to be of all the service in his power. He received a commission from the governor, with full authority, and a parcel of blank commissions for officers, to be given to whom he thought fit. Five hundred and sixty men were soon raised and placed under his command.

The first place selected for the erection of a fort was Gnadenhutten, a small settlement of Moravians, and thither Franklin set out in the middle of winter, amid torrents of rain, and through almost impassable roads. Upon arriving at the village, he lost not a moment in planning and marking out the fort, with a circumference of 455 feet; and the men were instantly set to work with their axes to cut down trees for palisades. Seeing the trees fall so fast, Franklin had the curiosity to look at his watch when two men began to cut at a pine. In six minutes they had it upon the ground, and it was fourteen inches in diameter. Each pine made three palisades of eighteen feet long, pointed at one end. While these were preparing, other men dug a trench all round, of three feet deep, in which the palisades were to be planted. When these were set up, the carpenters built within them a platform of boards all round, about six feet high, for the men to stand on and fire through the loopholes. They had one swivel gun, which they mounted, and fired as soon as it was fixed, that the Indians might know they had such pieces. Thus their fort, such as it was, was finished in a week, though it rained so hard every other day that the men were almost unable to work.

"This gave me occasion to observe," says Franklin, "that when men are employed they are best contented. For on the days they worked, they were good-natured and cheerful, and, with the consciousness of having done a good day's work, they spent the evening jollily. But, on our idle days, they were mutinous and quarrelsome, finding fault with the pork and the bread, and were continually in bad humour; which put me in mind of a sea captain, whose rule it was to keep his men constantly at work; and when his mate once told him that they had done every thing, and there was nothing further to employ them about, '*O*,' said he, '*make them scour the anchor.*'

"This kind of fort," he continues, "however contemptible, is a sufficient defence against Indians who have no cannon. Finding ourselves now posted securely, and having a place to retreat to on occasion, we ventured out in parties to scour the adjacent country. We met with no Indians, but we found the places, on the neighbouring hills, where they had lain to watch our proceedings. There was an art in their contrivance of those places that seems worth mentioning.

"It being winter, a fire was necessary for them; but a common fire, on the surface of the ground, would, by its light, have discovered their position at a distance; they had, therefore, dug holes in the ground about three feet in diameter, and somewhat deeper; we found where they had, with their hatchets, cut off the charcoal from the side of burnt logs lying in the woods. With these coals they had made small fires in the bottom of the holes, and we observed, among the weeds and grass, the prints of their bodies, made by their lying all round, with their legs hanging down in the holes, to keep their feet warm; which, with them, is an essential point. This kind of fire, so managed, could not discover them either by its

* The descendants of the original settlers who had received grants of land from the British government, who claimed exemption from all taxes and other privileges.

light, flame, sparks, or even smoke; it appeared that the number was not great, and it seems they saw we were too many to be attacked by them with prospect of advantage.

"We had for our chaplain a zealous Presbyterian minister, Mr Beatty, who complained to me that the men did not generally attend his prayers and exhortations. When they enlisted they were promised, besides pay and provisions, a gill of rum a-day, which was punctually served out to them, half in the morning and half in the evening, and I observed they were punctual in attending to receive it." Franklin advised that the rum should be distributed just only after prayers, and never were prayers more generally or more punctually attended.

Franklin's military career was, however, a short one; for he had scarcely completed his defensive preparations, when he received a summons to attend the assembly, where his advice and assistance were found indispensable.

The disputes between the proprietaries and the people, before referred to, continued to increase in 1755 and 1756, although a war was then raging on the frontiers—the French having still possession of Canada. The popular assemblies insisted on the justice of taxing the proprietary estates; but the governors constantly refused to assent to such a measure. The assemblies at last resolved to appeal to the mother country; and a petition was accordingly made out, addressed to the king in council. Franklin was appointed to present this address, as agent for the province of Pennsylvania, and departed for England in June 1757. During this time, the governor passed a law imposing a tax, in which no discrimination was made in favour of the estates of the Penn family, which were immensely large. The Penns thereupon used their most strenuous exertions to prevent its passing into a law. After long debate and deliberation, a proposal was made that Franklin should *personally* engage that the proprietary estates should pay no more than a just proportion of the tax. This he agreed to do—the proprietaries withdrew their opposition, and tranquillity was once more restored to the province. The manner in which this dispute was terminated sufficiently evinces the high confidence entertained of Franklin's honour and integrity, even by those opposed to his political views. After this, Franklin remained some time at the British court, having, besides Pennsylvania, been also appointed agent for the states of Massachusetts, Maryland, and Georgia.

The French in Canada still continuing to molest and interrupt the trade of the other colonies, Franklin published his famous Canada pamphlet, in which he in a forcible manner pointed out the advantages which would result from the conquest of that province. An expedition was accordingly sent out under General Wolfe, the result of which is well known. At the treaty in 1762, France ceded Canada to Great Britain, and by her cession of Louisiana at the same time, relinquished all her possessions on the continent of America.

In the summer of 1762, Franklin returned to America, and received the thanks of the Assembly of Pennsylvania, as well for the faithful discharge of his duty to that province in particular, as for the many and important services done to America in general, during his residence in Great Britain. A compensation of L.5000, Pennsylvania currency, was likewise decreed him for the services he had performed in England. He was also immediately re-elected to his seat in the Assembly.

Upon the breaking out of the fatal disturbances in consequence of Mr Grenville's stamp act, Franklin had again returned to England, as agent for Pennsylvania and other states. During his residence in England, he consulted, with unremitting industry, the best interests of his native country. He was every where received with respect, on account of his reputation as a writer and philosopher. In 1766, he made a visit to Holland and Germany, and received the greatest marks of attention from men of science. In the following year he travelled into France, where he was received with much kindness and favour. He became acquainted with a number of literary men, and was introduced to the king, Louis the Fifteenth. Difficulties had now commenced between Great Britain and her provinces in America. Franklin was unwearied in his efforts to bring about a reconciliation. He had frequent interviews with Lord Howe and Lord Chatham, and other distinguished English statesmen, who entertained for him the highest respect and esteem. Most of the time during his present residence in England was occupied in these vain efforts. It is well known that the first violent demonstrations against the imposition of the stamp act, broke out in Franklin's native place, Boston, the capital of the state of Massachusetts. The governor, Hutchinson, and other functionaries, wrote to the home government, recommending the adoption of the most rigorous coercive measures, and inveighing in unmeasured terms against the leading characters of the state. By some unaccountable means, these letters fell into Franklin's hands ere they reached their destination. He instantly transmitted them back to the Assembly at Massachusetts, who, enraged at the conduct of the governor, sent a petition to the king, praying for his dismissal, and Franklin was appointed to present it. As might have been expected, the petition was dismissed as "frivolous and vexatious;" and Franklin incurred so much obloquy for his interception of the governor's dispatches (the mode of which was never discovered), that he was dismissed from his office of deputy-postmaster-general. He still continued in England, however, and left nothing untried to effect a reconciliation between the mother-country and the colonies; but finding all his endeavours unavailing, he returned to America in 1775. The day after his arrival, he was elected by the legislature of Pennsylvania as a delegate to Congress. Hostilities had then commenced; but it would be repeating a thrice-told tale to enter into any account of the protracted and bloody struggle that ensued, or the nature of its termination. In 1778, Franklin was sent as ambassador to the court of France, where he soon brought about an alliance between that nation and the North American states. When the British ministry at length saw the necessity of recognising the independence of the states, the definitive treaty to that effect was signed at Paris on the 3d of September 1783, by Dr Franklin, Mr Adams, and Mr Jay, for the states, on the one hand; and by Mr David Hartley, for Great Britain, on the other. Franklin continued at Paris for the two following years; but at last, by his own urgent request, was recalled. Shortly after his return, he was elected president of the supreme executive council, and lent all his still perfect energies to consolidating the infant government. Age and infirmities, however, claimed their usual ascendancy; and in 1788 he retired wholly from public life.

DEATH.

Franklin's last public act—and it was one in beautiful accordance with the whole tenor of his life—was putting his signature, as president of the Anti-Slavery Society, to a memorial presented to the House of Representatives, praying them to exert the full powers entrusted to them to discourage the revolting traffic in the human species. This was on the 12th of February 1789. From this day forward, he was confined almost constantly to bed with the stone, from which he suffered the most excruciating agony. Yet when his paroxysms of pain drew forth, as they did occasionally, an irrepressible groan, he would observe, he was afraid he did not bear his sufferings as he might—acknowledged his grateful sense of the many blessings he had received from the Supreme Being, who had raised him from small and low beginnings to such high rank and consideration among men, and made no doubt but his present afflictions were kindly intended to wean him from a world in which he was no longer fit to act the part assigned him. He latterly sunk into a calm lethargic state; and, on the 17th April 1790, about eleven o'clock at night, he quietly expired. He was then aged exactly eighty-four years and three months. The following epitaph, written by himself many years previous to his death, was inscribed on his tombstone:—

"The Body of BENJAMIN FRANKLIN, Printer (like the cover of an old book, its contents torn out, and stript of its lettering and gilding), lies here food for worms; yet the work itself shall not be lost, for it will (as he believed) appear once more in a new and more beautiful edition, corrected and amended by THE AUTHOR."

CHARACTER.

In looking back on Franklin's career, it is evident that the principal feature in his character was *worldly prudence*—not in the usual and selfish acceptation of the term, but that prudence, founded on true wisdom, which dictates the practice of honesty, industry, frugality, temperance—in short, all those qualities which may be classified under the name of "moral virtues," as being the only certain means of obtaining distinction, respect, independence, and mental cheerfulness. There is no other writer who inculcates lessons of practical wisdom in a more agreeable and popular manner, and we much regret that the limits of this work prevent our giving many extracts illustrative of this quality. His whole conduct and writings, indeed, present the somewhat singular union of great genius with practical good sense, and of singular worldly shrewdness, with the loftiest integrity of principle. The greatest worldly honours—and few have attained higher—could not for a moment make him forget or deviate from the principles with which he started in life. Ever keeping before his mind his own origin and rise, he justly considered every man to be originally on a par in as far as regarded real intrinsic worth; and, equally by precept and example, contributed more, perhaps, than any individual who ever existed, to breaking down those invidious bars to eminence and success in life which the conventional habits and artificial feelings of society had theretofore interposed to the elevation of those unblessed by birth and fortune.

As the present biography must be considered as more immediately instructive to the industrious and productive portion of mankind, we shall conclude it by giving the following "Advice to a Young Tradesman," written by Franklin at the time when his industrious and frugal habits were just beginning to be rewarded with independence and worldly respect.

"Remember that *time* is money. He that can earn ten shillings a-day by his labour, and goes abroad, or sits idle one-half of that day, though he spends but sixpence during his diversion or idleness, ought not to reckon *that* the only expense; he has really spent, or rather thrown away, five shillings besides.

Remember that *credit* is money. If a man lets his money lie in my hands after it is due, he gives me the interest, or so much as I can make of it during that time. This amounts to a considerable sum where a man has good and large credit, and makes good use of it.

Remember that money is of a prolific, generating nature. Money can beget money, and its offspring can beget more, and so on. Five shillings turned is six; turned again is seven and threepence; and so on till it becomes a hundred pounds. The more there is of it, the more it produces every turning, so that the profits rise quicker and quicker. He that kills a breeding sow, destroys all her offspring to the thousandth generation. He that murders a crown, destroys all that it might have produced, even scores of pounds.

Remember that six pounds a-year is but a groat a-day. For this little sum (which may be daily wasted either in time or expense, unperceived) a man of credit may, on his own security, have the constant possession and use of a hundred pounds. So much in stock, briskly turned by an industrious man, produces great advantage.

Remember this saying, 'The good paymaster is lord of another man's purse.' He that is known to pay punctually, and exactly to the time he promises, may at any time, and on any occasion, raise all the money his friends can spare. This is sometimes of great use. After industry and frugality, nothing contributes more to the raising of a young man in the world, than punctuality and justice in all his dealings; therefore never keep borrowed money an hour beyond the time you promised, lest a disappointment shut up your friend's purse for ever.

The most trifling actions that affect a man's credit are to be regarded. The sound of your hammer at five in the morning, or nine at night, heard by a creditor, makes him easy six months longer; but if he sees you at a billiard-table, or hears your voice at a tavern, when you should be at work, he sends for his money the next day; demands it before he can receive it in a lump.

It shows, besides, that you are mindful of what you owe; it makes you appear a careful as well as an honest man, and that still increases your credit.

Beware of thinking all your own that you possess, and of living accordingly. It is a mistake that many people who have credit fall into. To prevent this, keep an exact account, for some time, both of your expenses and your income. If you take the pains at first to mention particulars, it will have this good effect—you will discover how wonderfully small trifling expenses mount up to large sums, and will discern what might have been, and may for the future be saved, without occasioning any great inconvenience.

In short, the way to wealth, if you desire it, is as plain as the way to market. It depends chiefly on two words—*industry* and *frugality*; that is, waste neither *time* nor *money*, but make the best use of both. Without industry and frugality nothing will do, and with them every thing. He that gets all he can honestly, and saves all he gets (necessary expenses excepted), will certainly become *rich*—if that Being who governs the world, to whom all should look for a blessing on their honest endeavours, doth not, in his wise providence, otherwise determine."

About forty years later, after a long life of experience, he penned the following similar admonitions, entitled, "Necessary Hints to those that would be Rich;"—

"The use of money is all the advantage there is in having money.—For six pounds a-year you may have the use of one hundred pounds, provided you are a man of known prudence and honesty.—He that spends a groat a-day idly, spends idly about six pounds a-year, which is the price for the use of one hundred pounds.—He that wastes idly a groat's worth of his time per day, one day with another, wastes the privilege of using one hundred pounds each year.—He that idly loses five shillings' worth of time, loses five shillings, and might as prudently throw five shillings into the sea.—He that loses five shillings, not only loses that sum, but all the advantages that might be made by turning it in dealing; which, by the time that a young man becomes old, will amount to a considerable sum of money.—Again: he that sells upon credit, asks a price for what he sells equivalent to the principal and interest of his money for the time he is to be kept out of it; therefore, he that buys upon credit, pays interest for what he buys; and he that pays ready money, might let that money out to use; so that he that possesses any thing he has bought, pays interest for the use of it.—Yet, in buying goods, it is best to pay ready money, because, he that sells upon credit, expects to lose five per cent. by bad debts; therefore, he charges, on all he sells upon credit, an advance that will make up that deficiency.—Those who pay for what they buy upon credit, pay their share of this advance.—He that pays ready money, escapes, or may escape, that charge.

A penny saved is twopence clear;
A pin a-day's a groat a-year."

HISTORY OF THE ISLAND OF GREAT BRITAIN,

From the Rebellion of 1745, till the end of the reign of George IV.

REBELLION OF 1745 CONCLUDED.

DERBY was the utmost point of that daring inroad into England which was described at the end of the preceding sheet. The dangers which surrounded the Highland army on all hands except in the rear, now determined the chiefs of the enterprise, all except Prince Charles himself, to return to Scotland. The retreat was accordingly commenced, December 6, and conducted with such skill and expedition, that the army of the Duke of Cumberland never came up with the insurgents. A garrison, which had been left in Carlisle, surrendered to the duke, who, being recalled on the rumour of a French invasion on the southern coast of England, left General Hawley to prosecute the war in Scotland.

Prince Charles conducted his forces by Glasgow to Stirling, where he was joined by large reinforcements from Perth, while the English general concentrated his troops in Edinburgh. The two armies, nearly equal in number, came to an action, January 17, 1746, at Falkirk, which ended in the disgraceful retreat of the royal army. The prince, however, being unable to make any use of his victory, soon after found it necessary to withdraw his forces to the neighbourhood of Inverness, where he spent the remainder of the winter. The Duke of Cumberland now returned to put himself at the head of the royal troops, which had been augmented by 6000 auxiliaries under the Prince of Hesse. During the months of February and March, the Highland army was cooped up within its own territory, by the Hessians at Perth, and the royal troops at Aberdeen. At length, April 16, Prince Charles met the English army in an open moor at Culloden, near Inverness, and experienced a total overthrow. He had himself the greatest difficulty in escaping from the country, and the Highlands were subjected for several months to the horrors of military violence in all its worst forms. To complete the subjugation of this primitive people, the hereditary jurisdictions under which they and the rest of the people of Scotland still lived, and by which the nobles and gentry were enabled to administer justice at their own discretion, were abolished by act of Parliament. Another act put an end to the tenure of wardholdings, by which the land-proprietors were enabled to command the personal services, in peace and war, of those who lived on their estates. A third act prohibited the use of tartan and the ancient Highland fashion of clothes, which were supposed to have the effect of keeping alive the warlike spirit of the mountaineers. The two former of these measures produced a marked improvement in the social state of the Scottish people, and, with the suppression of the Stuart cause, enabled the people to direct their energies towards commerce and manufactures. This is indeed the era of that rapid advancement in wealth and domestic comfort, for which Scotland has latterly been as much distinguished, as she was formerly for poverty and sloth.

PEACE OF AIX-LA-CHAPELLE.

During the remainder of the war in which Britain and other powers were now engaged with France, the latter was generally successful by land, and unfortunate at sea. It is indeed a curious fact, that, from the time of Marlborough to that of Wellington, Great Britain hardly ever succeeded in any military, or failed in any naval enterprise. In 1748, the two countries found, after nine years of contention, that their losses were equal, though in different departments of their strength. Thirty millions had been added to the national debt of Britain, and France had expended an equal sum. They therefore agreed, by a treaty formed at Aix-la-Chapelle, mutually to restore their respective conquests, and to go back to exactly the same condition in which they had stood before the war. A more signal illustration could have scarcely been held forth, of a truth which ought at every opportunity to be impressed upon nations—that war is to the parties in general only a means of waste and loss, and can do no good to any man, except at the expense of his neighbour.

ADMINISTRATION OF MR PELHAM.

For several years after this period, the national resources were greatly improved under the peaceful administration of Mr Pelham, whose commercial and financial schemes were generally very successful. The prosperity of Britain, unfortunately, roused the jealousy of the French, who, seeing the great advantages which their neighbours derived from colonies and naval force, were extremely anxious to take the same means of bettering their own circumstances. Nations were then, and in some measure still are, in the same state as individuals before their moral faculties are cultivated. A child or a savage can see no better way of bettering himself than by violating the rights or diminishing the property of his neighbours; while an enlightened person knows, that, without a respect for the interests of his fellow, he will not reap nearly the full advantages of his own labour. The French on this occasion acted like the former: instead of honestly and peaceably endeavouring to extend their own external resources, they began by trying to diminish those of the British—a mode of procedure which could only produce general loss, and retard the period of their own prosperity, as a man by robbing or cheating only injures others in order to mar his own good.

While many parts of the world still remained open for the occupation of an European people, the French, from their settlements in the East Indies and in Canada, commenced an aggressive system upon the neighbouring possessions of the British; in particular, they drew a line of forts along the back settlements of the whole range of the British American colonies, from the Gulf of St Lawrence to the Mississippi, so as to prevent the settlers from advancing beyond the Appalachian mountains. For two or three years, the British government suffered these aggressions, and even insults of a more decided character, to pass unresented; but at length it was found necessary in 1756 to proclaim war. A campaign of a novel and difficult character was opened in North America, for the purpose of driving the French from their forts. All the first movements were attended with defeat and disaster. The French had gained the exclusive affection of the native Indians, who proved a dangerous and barbarous enemy to the British. Several of the forts were attacked, but without success: in one instance—that of Ticonderago—two thousand men were killed. At length, a more auspicious era commenced under the administration of Mr Pitt, afterwards Earl of Chatham. The British troops and provincials became more experienced in the nature of the service. One after another, the principal forts fell into their hands; and a diversion was created by an attack upon Canada. In September 1759, General Wolfe reduced the town and fort of Quebec, though at the expense of his own life; and the whole colony soon after submitted to the British arms. In fact, the French were punished for their improper attempts to extend their colonies, by losing those which they formerly had.

While Britain was thus successful in one quarter of the world, she experienced a different fortune on the continent. Austria, Russia, and Poland, had combined with France against the new and rising power of Prussia, which was at present directed by Frederick II., commonly called Frederick the Great. Britain on this occasion became the ally of the Prussian monarch, not from any regard to her own interests, but in order that the king might be able to protect his Hanoverian dominions. Immense sums of money were raised from the British people, for the purpose of paying the troops of those very countries which the king was anxious to defend: the Duke of Cumberland was appointed their commander. This prince, who never was successful except at Culloden, was so unfortunate, September 1757, as to bring an army of forty thousand men into an angular piece of country, from which there was no escaping, so that the whole were obliged to lay down their arms to the French, who then became masters of Hanover. Notwithstanding this failure on the part of his ally, Frederick was able, by his extraordinary military genius, and by British subsidies, to defend his dominions for several years against all the forces that Austria, France, and Russia, could bring against him.

ACCESSION OF GEORGE III.

In the midst of this war, October 25, 1760, George II. died suddenly in the 77th year of his age, and was succeeded by his grandson George III., then only in his twenty-third year. The new king espoused, in the ensuing September, the Princess Charlotte of Mecklenburg-Strelitz, by whom he had a large family.

THE BUTE ADMINISTRATION—PEACE OF 1763.

One of the earliest measures of the new king was to introduce his preceptor, the Earl of Bute, into the cabinet as secretary of state. This, with other alterations, infused a peaceful disposition into his majesty's councils, which was not much relished by Mr Pitt. That minister, having secretly discovered that Spain was about to join France against Britain, and being thwarted in the line of policy which he consequently thought it necessary to assume, retired with a pension, and a peerage to his wife; after which the ministry was rendered still less of a warlike temper. A negociation for peace was entered into with France, which offered, for that end, to give up almost all her colonial possessions. The demands of the British were, however, rather more exorbitant than France expected, and not only was the treaty broken off, but Spain commenced those hostilities which Mr Pitt had suspected. Nevertheless, Britain continued that splendid career of conquest which, except at the beginning, had been her fortune during the whole of this war. In a very few months, Spain lost Havannah, Manilla, and all the Philippine Isles. The forces of that country were also driven out of Portugal, which they had most unjustly invaded. At sea, the British fleets reigned every where triumphant, and at no period of her annals was she in so proud a situation respecting her neighbours. The ministry, however, were sensible that war, even with all this good fortune, was a losing game; and they therefore, much against the will of the nation, concluded a peace in February 1763. By this treaty, Great Britain gave up a certain portion of her conquests in exchange for others which had been wrested from her; but she was nevertheless a gainer to an immense amount. She acquired, from the French, Canada, that part of Louisiana east of the Mississippi, Cape Breton, Senegal, the islands of Grenada, Dominica, St Vincent's, and Tobago, with all the acquisitions they had made upon the Coromandel coast in the East Indies since 1749. From Spain, she acquired Minorca, East and West Florida, with certain privileges of value. The continental states in alliance with Great Britain were also left as they had been. These advantages on the part of Great Britain had been purchased at the expense of an addition of sixty millions to the national debt (which now amounted in all to L.133,959,270); but as that country had been dragged unwillingly into the war, the losses are only to be considered in the light of a misfortune, which the evil dispositions of neighbouring powers had rendered unavoidable. But what are we to say of the case of France, which had commenced hostilities for the purpose of increasing her resources, but, as a due punishment for the improper means she had taken for that end, was left denuded at last of even those resources she had formerly possessed, with a vast addition to her public burdens besides!

CASE OF MR WILKES.

Ever since the accession of the Brunswick family in 1714, the government had been chiefly conducted by the Whig party, who formed a very powerful portion of the aristocracy of England. Walpole, Pelham, Newcastle, and Pitt, had all ruled chiefly through the strength of this great body, who, till a period subsequent to the rebellion of 1745, seem to have had the support of the greater part of the people. After that period, when the Stuart claims ceased to have any effect in keeping the government in check, a division appears to have grown up between the governing and the governed, which was manifested in various forms even before the demise of George II., but broke out in a very violent manner during the early years of his successor. George III. had imbibed Tory principles from the Earl of Bute, and, on ascending the throne, showed an evident disposition to extend the power of the crown, and to exact from the people a more implicit obedience to the measures of the state than had been demanded by any sovereign since the Revolution. The administration, indeed, of the Earl of Bute, was the commencement of that long period of Tory ascendancy, which has continued with little interruption down almost to the present day.

Partly on account of his Tory notions, partly on account of his being a native of Scotland, the Earl of Bute was the most unpopular minister that had served the crown since the days of the Cabal. The newspaper press was at this time rising in strength and influence, and a great part of its force was directed, with an almost savage degree of malignity, against this unfortunate minister. He was particularly blamed for concluding the war, though nothing can be clearer than that more was lost than gained even by such a career of conquest as the British arms had lately experienced. To this storm the Earl of Bute at length yielded, by retiring, April 8, 1763.

Among the public writers who assailed the ministry, none was more virulent than Mr John Wilkes, member for Ailesbury, and editor of a paper entitled the North Briton. Mr George Grenville, who succeeded Bute, commenced his career by prosecuting Wilkes for a libel, contained in the forty-fifth number of his paper, in which he had directly accused his majesty of falsehood. The king's messenger, being provided with a general warrant against the editor, printers, and publishers of the North Briton, entered the house of Mr Wilkes, and apprehended him. After being examined before the secretaries of state, he was committed to the Tower, and his papers were seized and sealed up. A few days after, he was brought to Westminster Hall by *habeas corpus*, and released by Chief Justice Pratt, in consideration of his being a member of parliament. The parliament ordered the seditious paper to be burnt by the hands of the common hangman—an operation that produced a riot, not in itself dangerous, but serving to discover the angry spirit of the populace. Mr Wilkes was soon after expelled from the House of Commons, and found it convenient to retire to the continent; but the effects of his case were favourable to liberty. A prosecution which he instituted against the secretary of state, on the plea that his seizure was illegal, terminated in a verdict of damages, and a declaration by Chief Justice Pratt, that general warrants were inconsistent with the laws of England.

AMERICAN STAMP-ACT.

The administration of Mr Grenville is memorable for the first attempt to tax the American colonies. In March 1765, an act for imposing stamps on those countries was passed, almost without comment, and by a great majority; no one apparently dreaming of the resistance it was to meet with. The people of America were the descendants, in many instances, of persons who had fled from their native country, in order to enjoy more liberal institutions in a world of their own forming. They might in some measure be described as a more liberalised class of Englishmen, with none of those aristocratic grades and institutions which served to control the popular spirit at home. The attempt to subject them to taxation, while they had no representation real or supposed in the House of Commons, appeared to them as the commencement of a system of tyranny, which, if not resisted at the first, would in time reduce them to absolute bondage. They therefore combined almost universally to resist the introduction of the stamped paper by which the tax was to be raised. Resolutions were passed in the various assemblies of the states, protesting against the assumed right of the British legislature to tax them. The act itself was publicly and ignominiously burnt. The stamps, on arriving, were seized by an enraged multitude, and destroyed. Those who had accepted commissions to act as distributors were forced by public oath to renounce all concern in them. In short, partly by popular violence, and partly by the declarations issued by the local legislative assemblies, the object of the act was completely defeated.

The conduct of the Americans produced great embarrassment in his majesty's councils, and it was long debated whether there would be most disadvantage in forcing the acceptance of the stamps, or in giving way to the demands of a people almost in open rebellion. It was at length agreed to repeal the act, but to accompany the favour by a declaration of the right of Great Britain to impose taxes on her colonies. The Americans appeared satisfied with the relief they had thus obtained from the immediate pressure of taxation, and did not seem to regard much the accompanying declaration, which was looked upon as only a salvo for the injured honour of the government.

Between the stamp act and its repeal, a change had taken place in the administration: the latter measure was the act of a Whig ministry under the Marquis of Rockingham, which, however, did not long survive. From the very commencement of his reign, George III. had shown that disposition which characterised him through life, to place his confidence chiefly in some favourite near his own person, and to render his responsible ministers only the instruments by which the policy so suggested was to be carried into effect. It was generally believed by the nation that the Earl of Bute still had the chief direction of affairs; and such was the odium in which ministers were sure to be held under such degrading circumstances, that even the splendid reputation of Mr Pitt, on his accepting office in 1766, was unable to bear up against it. This minister, now created Earl of Chatham, was the most popular of all that directed British affairs during the eighteenth century. His wisdom, energy, and eloquence, were only to be equalled by the liberal spirit which seemed to animate all his actions; and the only fault attributed to him in his public character was a certain imperiousness towards his ministerial associates, which sometimes lost to him a support of which he and the country stood much in need. If he now submitted to form part of a government in which an irresponsible favourite of the king had the chief sway, it can only be ascribed to the decline of his faculties under the ravages of ill health—for no circumstance could be less characteristic of Chatham in his best days.

At the suggestion of Mr Charles Townsend, who formed part of this new cabinet, it was resolved in 1767 to impose taxes on the Americans in a new shape, namely, upon British goods imported into the colonies, for which there was some show of precedent. An act for imposing duties on tea, glass, and colours, was accordingly passed with little opposition. Soon after this, Mr Townsend died, and Lord Chatham, who had been prevented by illness from taking any share in the business, resigned. The Americans met the new burdens with the same violent opposition as formerly, and finally (1770) obliged the ministers to give way on all the various articles, except tea, which the colonists therefore refused to import from the mother country. The affections of the Americans were now very generally alienated from the British government, the lofty measures of which were even at home exciting no small degree of dissatisfaction.

THE WILKES TUMULTS.

At the general election of 1768, Mr Wilkes re-appeared in Britain, though a sentence of outlawry still stood against him. He even ventured to become candidate for the county of Middlesex, where he was returned by a large majority. Having previously surrendered to the jurisdiction of the King's Bench, his outlawry was reversed; but, by virtue of the verdicts which two courts had given against him, he was subjected to a fine and two years' imprisonment. On his arrest, Mr Wilkes quietly committed himself to the officers of justice, but was forcibly rescued by the populace; and in a riot subsequent to this violence, a young man, who had no participation in the tumult, was killed. During his imprisonment, Mr Wilkes was formally expelled the house, on the pretext that by the vote of censure passed by the preceding parliament, he was for ever disqualified from being a representative of the people. This decision incensed a great portion of the community, and the man came to be identified in their estimation with the liberties of the nation itself. Four times did the county of Middlesex return Mr Wilkes; but the rival candidate, Colonel Luttrell, with only a fourth of the votes, was accepted by the house. These proceedings occasioned many keen debates in the House of Commons, where a Whig Opposition of much talent and ardour of purpose now took up every popular question. Tumults of a dangerous character were constantly taking place; the cry of "Wilkes and Liberty" resounded every where, except in Scotland, where his scurrility against the Scottish nation had rendered him detested; the magistrates and public bodies of London signalised themselves by several warm remonstrances to the king against the overbearing character of his government; and a series of letters, the most pointed in style and forcible in invective that had ever appeared in the English language—though by an author still unknown—from time to time directed the public indignation against both the men and the measures of the cabinet. Still the young monarch persevered in his course, fully two-thirds of the House of Commons being favourable to whatever measure his ministers might propose.

AMERICAN WAR OF INDEPENDENCE.

In the meantime, the merchants of Britain found the state of things in America highly opposed to their interests; and the East India Company, in order to regain the market for their tea, was enabled, by a drawback granted to them by government, to reduce the price of the article so low as to cover the duty, which was only threepence a-pound. In the confident expectation that the Americans would give way to this expedient, immense shipments of tea took place to American ports. Such a transaction only demonstrates how little able the British people were to appreciate the nature of the American dissentients. It was not for a trifling addition to the price of tea that they were threatening resistance to the mother country; it was to the principle of a right in the House of Commons, where they were not represented, to impose taxes upon them, or to interfere with their internal affairs: it was, in fact, as they always most pathetically represented, the question of their slavery or freedom. Accordingly, at New York and Philadelphia, the cargoes of tea were forbidden to land; in Charleston it was permitted to land, but put into stores, and prohibited from being sold; while at Boston, a ship-load, which had been introduced into the harbour, was seized by a lawless mob, and tossed into the sea. This last act of violence was resented by the passing of a bill for interdicting all commercial intercourse with the port of Boston, and another for taking away the legislative assembly of the state of Massachusetts. The former measure was easily obviated by local arrangements; and in reference to the latter, a congress of the various states met at Philadelphia in September 1774, when it was asserted that the exclusive power of legislation, in all cases of taxation and internal policy, resided in the provincial legislatures. The same assembly denounced other grievances, which we have not particularly adverted to, especially an act of the British legislature for trying Americans, for treasonable practices, in England—the act, perhaps, of all others in the eighteenth century, that now appears most characterised by a spirit of arbitrary and vindictive barbarity. The congress also framed a covenant of non-intercourse, by which the whole utility of the colonies to the mother country, as objects of trading speculation, was at once laid prostrate. The colonists still avowed a desire to be reconciled, on the condition of a repeal of the obnoxious statutes. But the government—partly encouraged by their own immediate subjects—had now resolved to attempt the reduction of the colonists by force of arms. Henceforth, every proposal from America was treated with a proud silence on the part of the British monarch and his advisers, as if they had considered themselves under no obligation to depart a single iota from their erroneous position, when the sacrifice of a small sum of money, and a few lives to both parties, was so sure to bring the recusants to their feet.

As it is probable that we shall have occasion in another part of the present series, to give a full account of the American revolution, we shall be very brief in this place. The war was opened in summer 1775, by skirmishes between the British troops and armed provincials, for the possession of certain magazines. At the beginning, there seemed no hope of the contest being protracted beyond one campaign; and indeed one unlucky British officer—a Colonel Grant—offered to enter the American territory with five regiments of the line, and drive the rebels, as they were called, from one end of the country to the other. The population of the colonies was at this time only three millions, and they were greatly inferior in discipline and appointment to the British troops. They possessed, however, an indomitable zeal in the cause they had agreed to defend, and fought with the advantage of being in the country of their friends. The British government was rather surprised to find at the end of one year that no progress had been made towards a reduction of the Americans, and sent out an offer of *pardon* to the colonists, on condition that they would lay down their arms; a proposal that only excited ridicule. On the 4th of July 1776, the American congress took the decisive step of a declaration of their independence, embodying their sentiments in one of the most solemn and dignified documents that ever was penned. For two campaigns, the war continued, and the slender forces of the new republic were hardly able any where to face the large and well-appointed armies of Great Britain. Much misery, as may easily be supposed, was endured by this patriotic people, in resisting the invaders of their country. Besides the civilised soldiers brought against them, they had to protect themselves from the savages of the wild, whom the British ministers had deemed it proper to bribe and debauch into their service, and whose warfare was one of extermination. Notwithstanding every disadvantage and many defeats, America remained unsubdued, to the infinite astonishment of Great Britain, her king, her ministers, and her people, the last of whom had reflected less upon the justice of their cause against America, than upon the hopes which were held forth of the cheap and speedy conquest of the country.

WAR WITH FRANCE, SPAIN, AND HOLLAND.

So much had Britain now reduced her resources, increased her expenses, and engrossed her naval and military strength in a distant and unprosperous warfare, that one after another almost all the powers of Europe became her enemies. The French, in 1778, formed an alliance with America as a separate state, and sent out large auxiliary forces to aid in the securing of her independence. The Spaniards soon after joined the French in a war against Britain, and in 1780 Holland was added to the number of her enemies. Russia then put herself at the head of what was called an Armed Neutrality, embracing Sweden and Denmark, the object of which was indirectly hostile to Britain. So tremendous was the force reared against Britain in 1779, even before all these powers had entered into hostilities, that it required about three hundred thousand armed men, three hundred armed vessels, and twenty millions of money annually, merely to protect herself from her enemies. Even her wonted superiority at sea seemed for a long time to have deserted her.

STATE OF THE GOVERNMENT.

The ministry was headed, throughout all these troubles, by Lord North; but the sovereign himself was the chief director of affairs. Had the parliament been more nearly a representation of public feeling, it seems highly questionable that such a career of national loss and injury would have ever been entered upon. But the general sense of the people found no response within the House of Commons, except from a small minority, which, though animated by the eloquence of a Fox and a Burke, spent its force in vain upon a cabinet fortified by so many servile votes. The ministers received their first alarm at the end of 1777, in the surrender of an army of ten thousand men under General Burgoyne to the American commander. But for a long time, they were so bound up in the idea that there could be no good without the subjugation of America, and that that event was certain, that every disaster and obstruction was overlooked as only a temporary inconvenience. The defence put forward by the friends of the government chiefly referred to the necessity of curbing the spirit of insubordination, both in America and at home, which was always represented as of a dangerous and vicious character. It must be acknowledged that the popular check upon the measures of state, was not then so enlightened or so well regulated an organ as it has since become, and that it did not uniformly act with that moderation and dignity, or with that absence of a factious spirit, which are necessary to gain respect for every public cause. On an attempt of the government, in 1780, to take away the penal statutes resting on the Catholics, the London populace committed several riots of a most alarming kind, in which they showed that the spirit of freedom did not animate them in one of its purest forms. At the beginning of June, exasperated by the rejection of one of their petitions by the House of Commons, they kept the capital in a state of anarchy for five days, during which many houses and property to a large amount were destroyed; nor was it till the king himself directed the military to attack the rioters, two hundred of whom were killed, that order was restored. These and other circumstances tended unquestionably to rank upon the ministerial side many respectable and wealthy persons, whose good sense would have disposed them to take an unfavourable view of the existing policy. The king, moreover, with all his faults, exhibited a haughty virtue and a conscientious firmness in adhering to certain principles, that gained for him and his measures much confidence and approbation, which he could not otherwise have obtained, and which the factious spirit sometimes observable in his opponents tended to increase.

CONCLUSION OF THE WAR—ROCKINGHAM ADMINISTRATION.

At the end of the year 1781, another large army under Lord Cornwallis surrendered to the French and American generals at Yorktown; after which, though several posts were still maintained, no British troops appeared openly in America. The ministry began to sink under the prevailing sense of the inexpediency and hopelessness of the war. The House of Commons, though chiefly the representatives of the aristocracy, or at least of a narrow portion of the people, had given way so far to the popular sentiment in 1780, as to leave the ministers in a minority on Mr Dunning's celebrated resolution against the increase of the crown influence. The Protestant riots had since then taken so much from the respectability of the Opposition, as to enable the ministers to proceed; but in the beginning of 1782, on finding the balance of their majority reduced on a certain motion to eight, they gave up the places which, for twelve years, they had held so much to the injury of the national interests. During that time, the prosperity of the country had been retarded, a hundred millions added to the national debt, three millions of the people alienated for ever, and, besides America, several colonies lost to the enemy; while not one positive triumph had been gained either by sea or land.

The new administration was formed, as usual in such cases, out of the Opposition. The Marquis of Rockingham was made prime minister, and Mr Fox one of the secretaries of state. The new ministers lost no time in taking measures for the restoration of peace. Unfortunately for their credit with the nation, Sir George Rodney gained his important victory over the French fleet off the island of Dominica, April 12, 1782, after the ministers had dispatched another officer to supersede him in the command. On this occasion thirty-seven British vessels encountered thirty-four French, and chiefly by the dexterous manœuvre of a breach of the enemy's line, gained one of the most complete victories recorded in modern warfare. The triumph was imminently necessary, to recover in some measure the national honour, and enable the ministers to conclude the war upon tolerable terms. In November, provisional articles for a peace with the United States of America, now acknowledged as an independent power, were signed at Paris, and the treaty was concluded in the ensuing February. War was soon after concluded with France, Spain, and Holland, but not without some considerable concessions of colonial territory on the part of Great Britain.

The conclusion of this war is memorable as a period of great national suffering, which partly arose from the depression of commerce, and partly from a bad harvest. This, however, is also the era of Arkwright's invention of the cotton-spinning machine, by means of which Britain has immensely increased the aggregate of her manufactures, and endured expenses under which she must have otherwise sunk. The principles of prosperity were so firmly fixed in the country, that, immediately after the first distresses had passed away, every department of the state resumed its wonted vigour, and, during the ten ensuing years of peace, a great advance was made.

The death of the Marquis of Rockingham, in July 1782, proved the destruction of a ministry which might have been expected to conduct the national affairs for many years. His place being given to the Earl of Shelburne, Mr Fox and other leading members of the cabinet gave in their resignations. Among the new appointments subsequently found necessary, was that of Mr William Pitt, second son of the illustrious Chatham, and now only in his twenty-third year, to the office of chancellor of the exchequer. This young statesman had already signalised himself by taking an active part in the proceedings out of parliament, for a reform of that body; a measure which the legislative proceedings of the last few years had convinced many to be highly necessary.

COALITION MINISTRY.

The present ministry was opposed by two parties of very different principles, namely, the adherents of the North administration, and the friends of those Whigs who had lately retired from the cabinet. These two parties, notwithstanding that they had been opposed to each other throughout all the late war, coalesced for factious or ambitious purposes, and, being triumphant over the ministry, forced themselves upon the king's councils. Then was formed, April 2, 1783, what was called the Coalition Ministry, in which Lord North and Mr Fox acted together as secretaries of state, though two years had hardly elapsed since the latter had breathed the most violent threats in parliament against not only the power, but the life of his present brother. This unprincipled and vicious state of things, in which the aristocratic influences of the House of Commons threatened to usurp both the royal prerogative and the supposed privileges of the people, lasted only for a short time. Mr Fox had prepared and carried through the lower house his famous bill for the regulation of the East India Company, by which all authority was to devolve on seven directors eligible by the House of Commons—in other words, by which the immense patronage of this offshoot of the empire was to fall into the hands of the ministry. The people had beheld the unseemly association with disgust; and now the king perceived that a power was rising under him, which would soon be able to set him at defiance. He therefore used his personal influence, in no very covert way, to induce the House of Lords to throw out the bill; a measure which certainly saved the country from a tyranny of a very ominous kind. He then sent, December 18, to demand the seals of office from his over-ambitious ministers, appointing Mr Pitt to be the prime minister and chancellor of the exchequer of a new cabinet, consisting chiefly of his majesty's friends. The beneficial uses of a king and house of lords under such a constitution as that which then existed, was shown by these transactions in a very marked manner.

The various departments of the state were now thrown into a relative position which had never been known before, and has never recurred since. The king and his ministers, backed by a decided majority of the public, were opposed by two powerful aristocratic factions in the House of Commons, who defeated every measure that was introduced, refuted the usual supplies, and voted again and again resolutions against the continuance of the present men in office, which they denounced as unconstitutional. In the course of a few weeks, however, the influence of the Opposition was sensibly reduced; the public sentiment and the power of the court began to take effect even on this intractable body; and when at length their majority had been worn down to *one*, which happened on a motion by Mr Fox, the king dissolved the parliament; a measure which, whatever it might promise to him, he did not previously think justifiable. So far were the motives of the coalition from being based on popular support, that, in the new election, no fewer than one hundred and sixty members lost their seats. The new House of Commons was of course so favourable towards the king and his young minister, as to enable the public service to go on without farther interruption.

MINISTRY OF MR PITT—FROM 1784 TO THE COMMENCEMENT OF THE FRENCH REVOLUTION.

In 1786, Mr Pitt established his celebrated but fallacious scheme for redeeming the national debt, by what was called a Sinking Fund. The revenue was at this time above fifteen millions, being about one million more than was required for the public service. This excess he proposed to lay aside annually, to lie at compound interest; by which means he calculated that each million would be quadrupled at the end of twenty-eight years, and thus go a great way towards the object he had in view. To this scheme Mr Fox added the infinitely more absurd amendment, that, when the government required to borrow more money, one million of every six so obtained should be laid aside for the same purpose. The scheme was so well received as to increase the popularity of the minister, and it was not till 1813, when it was exposed by the late Professor Hamilton, in his work on the National Debt, that its fallacy was generally acknowledged. The discovery, unfortunately, was made twenty years too late—for, during the whole of the French revolutionary war, the reliance upon the Sinking Fund tended to reconcile the people to an expenditure against which they would have otherwise remonstrated in a more effectual manner.

In the same year commenced the parliamentary proceedings against Mr Warren Hastings, for alleged cruelty and robbery exercised upon the natives of India, during his governorship of that dependency of Great Britain. These proceedings were urged by Mr Burke and other members of the Liberal or Whig party, and excited so much public sentiment against Mr Hastings, that the ministry was obliged, though unwillingly, to lend their countenance to his trial, which took place before parliament in the most solemn manner, and occupied one hundred and forty-nine days, extending over a space of several years. The result was the acquittal of Mr Hastings.

The eldest son of the king had now been for several years of age, and exempted from the control of his father. He had no sooner been set up in an establishment of his own, than he plunged into a career of vice and prodigality, forming the most striking contrast with the chastened simplicity and decorum of the paternal abode. He also attached himself to the party of the Opposition, though rather apparently from a mere principle of contradiction to his father, than a sincere approbation of their political objects. The result was the complete alienation of the Prince of Wales from the affections of the king.

In November 1788, an aberration of intellect, resulting from an illness of some duration, was observed in the king, and it became necessary to provide some species of substitute for the exercise of the royal functions. To have invested the Prince of Wales with the regency appeared the most obvious course; but this would have thrown out the ministry, as it was to be supposed that his royal highness would call the chiefs of his own party to his councils. Mr Fox contended that the hereditary nature of the monarchy pointed out an unconditional right in the prince to assume the supreme power under such circumstances; but Mr Pitt asserted the right of parliament to give or withhold such a character, and proposed to assign certain limits to the authority of the intended regent, which would have placed the existing ministry beyond his reach. The Irish parliament voted the unconditional regency to the prince, but that of Great Britain was about to adopt the modified plan proposed by Mr Pitt, when, March 1789, the king suddenly recovered, and put an end to the difficulty. The debates on the regency question show in a very strong light the readiness of statesmen to abandon their most favourite and strongest principles, on the call of their own immediate interests.

FRENCH REVOLUTION.

The country had for several years experienced the utmost prosperity and peace, when it was roused by a series of events that took place in another state. The proceedings of the French nation for redressing the political grievances under which they had long laboured, commenced in 1789, and were at first very generally applauded in Britain, as likely to raise that nation to a rational degree of freedom. Ere long, however, the abolition of hereditary privileges, the destruction of the Bastile, the open disrespect for religion, and other symptoms of a violent spirit, manifested by the French, produced a considerable change in the sentiments of the British people. The proceedings of the French were still justified by the principal leaders of Opposition in parliament, and by a large class of the community; but they inspired the government, and the propertied and privileged classes generally, with great alarm and distrust. Under the impulse of the example of France, a number of associations were formed throughout the country, for the purpose of urging that reform in the House of Commons, which had so long been called for; the society in London being headed by Mr (afterwards Earl) Grey, and Mr (afterwards Lord) Erskine. There also appeared a profusion of pamphlets in favour of a general amelioration of the social and ruling systems—particularly several by Mr Thomas Paine, a writer who had formerly distinguished himself as a literary partisan of liberty in the United States. The public mind was greatly agitated by the various events and discussions which were constantly taking place; all the more ardent, and speculative, and benevolent minds entering heartily into the views of the French, while the more cautious, and the more wealthy, and in general all those who are least ready to think well of the species, expressed their fears for the result. A considerable number of those accustomed to oppose government took this opportunity to join its ranks; the chief of whom was Mr Burke, who, in November 1790, published his celebrated pamphlet on the French Revolution, in which he employed unexampled eloquence, and a vast range of historical illustration, to show that it was founded on principles adverse to real liberty and to public security.

The improvement of the public institutions of France would have probably taken place without any material consequences, if it had not been deranged by external events. That national weakness which had been the main cause of the revolution, prompted two ambitious powers—Austria and Prussia—to form a scheme (summer 1791) for overrunning France, and, while they restored the king to full apparent authority, disabling his country for opposing them in future, by a partition of its best provinces, after the manner of a recent transaction in Poland. This treaty was believed to have provided that Austria should obtain Bavaria in exchange for the Netherlands, part of which belonged to France, but was to be conquered by him, and transferred in exchange to the elector of Bavaria. The archduke Charles was to have the duchy of Lorraine; Strasburg and Alsace were to be restored to Germany; the king of Sardinia was to have Dauphiné, provided he should accede to the coalition; other parts of the French dominions were to be bestowed on Spain and Switzerland. The intelligence of these designs produced the utmost indignation among the French, and was the first cause of the more violent proceedings at Paris. In reply to a question from France respecting the troops assembling on the frontier, Frances II. of Austria made no scruple to avow an intention, with his ally, to interfere in the settlement of the French government; the consequence was a proclamation, by France, of war against Austria, Prussia, and Sardinia. In the summer of 1792, the combined powers placed an army under the charge of the Duke of Brunswick—reinforced by large bodies of the fugitive noblesse of France—for the purpose of invading that country, which they had no doubt, after their late success in Poland, they would speedily find at their mercy. A manifesto issued by the duke at Coblentz, called upon all the French authorities, in the most insolent terms, to submit to the king, under the pain of military execution, and threatened to give up the city of Paris to spoliation, if the least injury should be offered to the royal family, who were invited to come under the protection of the allied army. The result was an universal rising of the military spirit of the French against the invader, who, before the end of the year, was ignominiously defeated, and driven from the country, by troops of raw but enthusiastic recruits; while the king, having, by an attempted flight, given reason for suspicion that he was disposed to regain his former power by means of foreign assistance, was deposed (August 10, 1792), and thrown with his family into confinement.

WAR DECLARED AGAINST FRANCE, 1793.

The circumstances attending the latter revolution were unhappily of so violent and even bloody a character, as, together with the establishment of a republic, to convey unavoidable alarm wherever hereditary institutions were known, and excite, amongst good but timid people, a spirit highly adverse to the progress of liberal ideas. The French convention increased this unfavourable feeling, November 1792, by a decree, intended as a retaliation for the conduct of Austria and Prussia, proffering aid to any people who might be inclined to reform their institutions; and still farther, by bringing their deposed king to the block, January 21, 1793. Previous to the last incident, they had overrun the Netherlands, and opened the navigation of the Scheldt, which Great Britain was obliged by treaty to keep shut for the advantage of Holland. The decree, and the opening of this river for general commerce, afforded to the British government an excuse for entering into a war with France, while the real motives were exactly similar to those which animated Austria and Prussia—a desire of restoring monarchy in France, and preventing the contagion of French doctrines in Britain. The French convention, who made peace one of their first principles, offered to explain away the decree, and to give up the question of the Scheldt; but the ministry, with the same ill-omened haughtiness which had been displayed towards America, paid no attention to the proposal. It was confidently expected by the king, his ministers, and the great body of respectable persons who rallied round the throne and the aristocracy on this occasion, that the French republic had not strength to stand a single campaign against Britain and the other powers combined against it. The bulk of the nation, high and low, was either eager for the war, or made no opposition to it. Comparatively few of the common people were then capable of reflecting upon such a subject; and there had even been riots at Birmingham, July 1791, against the friends of liberal institutions. The few who penetrated the evil consequences likely to arise from the war, and still maintained a demand for reform in our own country, were overpowered by numbers, and branded as enemies to religion and civil order: some were tried for high treason and sedition, though only in the cases of Muir, Palmer, and two or three others, in Scotland, were verdicts obtained. Through a feeling of alarm respecting her monarchy, her church, and her aristocracy, Great Britain plunged into a war, which was to add six hundred millions to her debt, and desolate Europe, and retard civilisation for twenty years

UNEXPECTED SUCCESSES OF THE FRENCH.

After alliances had been formed with the other Anti-Gallican powers, Great Britain sent an army into the Netherlands to co-operate in reducing the fortresses in possession of the French, while the town of Toulon, being inclined to royalty, put itself into the hands of a British naval commander. At first, the French seemed to fall somewhat in their defences; but on a more ardently republican party acceding to power under the direction of the infamous Robespierre, the national energies became much increased, and the Duke of Brunswick experienced a series of disgraceful reverses. Prussia, having now taken new views of the case of France, began to withdraw her troops, on the pretext of being unable to pay them; and though Britain sent her nearly a million and a quarter to keep her nine months on the field, she contrived to do nothing towards the general cause, and soon retired altogether from the contest. In 1794, the French experienced a severe defeat at sea; but they not only drove the combined armies out of the Netherlands, but, taking advantage of an unusually hard frost, invaded Holland by the ice which covered the Rhine, and reduced that country to a republic under their own control. The successes of the British were limited to the above naval victory achieved by Lord Howe, the temporary possession of Corsica and Toulon, the capture of several of the French colonies in the West Indies, and the spoliation of a great quantity of the commercial shipping of France; against which were to be reckoned the disgraceful expulsion of her army from the Netherlands, the loss of ten thousand men in an unsuccessful descent upon the west coast of France, and some considerable losses of her shipping—not to speak of immense sums squandered in vain, and an increase of annual expenditure from about fourteen to near forty millions. In 1796, the French invaded Italy under Bonaparte, and were there so successful as not only to add greatly to the territory of the republic, but to bring Austria to a humiliating peace. The British government would have now been glad to obtain peace also, and took some steps for that purpose, which were as deficient in dignity as its declaration of war had been replete with pride. But France was found unwilling to make sufficient concessions of her conquests, to satisfy Great Britain. The year 1797 was distinguished by the great naval victories of St Vincent and Camperdown; but the finances of the country were now becoming so much embarrassed as to compel the government to relieve the bank of England from the duty of paying gold for their notes; a measure which had the effect of increasing the prices of all goods, and rendering the money that was borrowed by the nation greatly less in value than what they afterwards stood indebted for, when cash payments had to be resumed: in fact, the national obligations were, by this single act, immensely increased. It is almost inconceivable to a Briton born since that period, how the nation should have advanced so far in so hopeless and ruinous a course. Much of the delusion is attributed to the dread of an invasion by the French; an event, from its very singularity, regarded with horror by the British people, and to obviate which, almost every man in the country took up arms. In fact, the two parties mutually invigorated each other during the course of the war. The British, by their attempts to overturn the new French government, gave it a firmness it could not otherwise have had, and drew forth such powers in the nation as it had never exhibited even in its best days, under Louis XIV. and his famous financier Colbert. The French, on the other hand, by their threats of invading Britain, touched on a string which vibrated as strongly, and rendered a peaceful country of merchants one universal camp, in which defiance to French doctrines and influence was every where breathed.

EXPEDITION TO EGYPT—NEW COALITION AGAINST FRANCE.

In 1798, the French overrun and added to their dominions the ancient republic of Switzerland, which gave them a frontier contiguous to Austria, and enabled them eventually to act with increased readiness and force upon that country. The great eastern powers, which had commenced the war with the design of parting France like the garments of a criminal among themselves, thus saw her after a few years of warfare, not only preserve her own proper soil, but add to it all the neighbouring countries. In this year the directors of the French republic beginning to be afraid of the ambition of their general, Bonaparte, sent him at the head of an expedition to reduce and colonise Egypt, intending from that country to act against the British empire in the East Indies. The expedition was successful in its first object; but the fleet which had conveyed it was attacked in Aboukir Bay, by Nelson, and almost totally destroyed or captured. While so much of the strength of the French army was thus secluded in a distant country, the eastern powers thought they might safely recommence war with the republic. Austria, Naples, and Russia, formed a confederacy for this purpose; and Britain, to supply the necessary funds, submitted to the grievance of an income tax, amounting in general to ten per cent., in addition to all her previous burdens. Our government had at this time to contend with a perplexity of a new kind—namely, a rebellion in Ireland, which, though fomented and assisted by the French, was suppressed without much bloodshed, and led two years after to an incorporating union of the two countries.

The new confederacy against France was so successful in 1799, as to redeem the greater part of Italy from her dominion. In the campaign which produced this result, the Russian army, under the famous Suwarof, acted the most prominent part; but at the close, attempting to expel the French from Switzerland also, this large force was nearly cut to pieces in one of the defiles of that mountainous country. In August of the same year, Great Britain made a corresponding attempt to expel the French from Holland. Thirty-five thousand men, under the Duke of York, formed the military part of the expedition. The fleet was successful at the first in taking the Dutch ships; but the army, having landed under stress of weather at an unfavourable place for their operations, was obliged, after an abortive series of skirmishes, to make an agreement with the French, purchasing permission to go back to their country by a surrender of eight thousand prisoners from England.

BONAPARTE ELECTED FIRST CONSUL—HIS OVERTURES OF PEACE.

The reverses which France experienced in 1799 were generally attributed to the weakness of the directory—a council of five, to which the executive had been entrusted. Bonaparte suddenly returned from his army in Egypt, and, by a skilful management of his popularity, overturned that species of government, and caused himself to be appointed the sole depository of the executive power of the state, under the denomination of First Consul. He immediately wrote a letter to King George III., making overtures of peace, but was haughtily answered, that no dependence could be placed by Great Britain on any treaty with France, unless her government were again consolidated under the Bourbons. Bonaparte was so sincere in his desire of peace, as to reply to this note, vindicating France from the charge brought against her by the British secretary, of having commenced a system of aggression inconsistent with the interests of other states, and asserting her right to choose her own government—a point, he said, that could not decently be contested by the minister of a crown which was held by no other tenure. But the British government was at this time too much elevated by the expulsion of the French army from Italy, and the late changes in the executive, which, in their estimation, betokened weakness, to make peace with a country, which, in the favourite phrase of the times, was "at enmity with order, religion, and morality." Two years before, when this moral war was at a still greater height in France, Britain had thought proper to make peaceful overtures, through a channel which might almost be called mean; but at that time the Anti-Gallican cause was blessed with inferior success, and England herself found some rather alarming difficulties at the bank. In fact, the profession of fighting for the support of "order, religion, and morality," was only heard of when Britain and the other powers were flattering themselves with a hope of extirpating this example of a republic.

SUCCESSES OF BONAPARTE.

The events of 1800 formed as complete a punishment for this infidelity to principle, as those of 1793 and the few subsequent years had proved in regard to original design of dismembering France, and dictating to her respecting her internal affairs. Sir Sidney Smith, who commanded the British forces in Syria, had made a treaty with the French army after it had been deserted by Bonaparte, whereby it was agreed that the French should abandon Egypt, and retire unmolested to their own country. The British government, in their present elevation, refused to ratify this arrangement; the consequence was, that the French overthrew an immense Turkish army at Grand Cairo, and made themselves more effectually than ever the masters of the country, so that Britain had to send an army next year, under Sir Ralph Abercromby, to accomplish, at an immense expense and a great waste of human life, what the French had formerly agreed to do without firing a shot or shedding one drop of blood. In Europe the same cause was equally unsuccessful. By one of his most dexterous movements, Bonaparte eluded the Austrians, led an army over the Alps by the Great St Bernard into the Milanese, and, having gained a decisive victory at Marengo, at once restored the better part of Italy to French domination. Contemporaneously with his own movements, Moreau led another army directly into Germany, overthrew the Austrians in several battles, and advanced to within seventeen leagues of Vienna. These reverses obliged Austria to make a peace next year, by which France became mistress of all Europe west of the Rhine and south of the Adige.

CHANGE OF MINISTRY, AND PEACE OF AMIENS, 1801.

At the commencement of 1801, Britain had not only to lament this unexpected turn of fortune, but to reckon among her enemies the whole of the northern states of Europe, which had found it necessary to place themselves on a friendly footing with Bonaparte, and, though they did not declare war against Britain, yet acted in such a manner as to render hostilities unavoidable. Nelson sailed in March, with a large fleet, against Copenhagen, and proved so successful against the Danish fleet, as to reduce that country to a state of neutrality. The death of Paul, which took place at the same time, and the accession of Alexander, who was friendly to Britain, completely broke up the northern confederacy. Yet the great achievements of France on the continent, joined to the distresses of a famine which at this time bore hard on the British people, produced a desire for that peace which only a year before might have been gained upon so much better terms, but had been so insultingly rejected. With a view, apparently, to save the honour of Mr Pitt and his friends, a new ministry was appointed under Mr Addington, by whom a peace was at length, in the end of the year (1801), concluded with France, which was left in the state of aggrandisement we have just described.

RESULTS OF THE WAR.

The war of the French revolution placed Great Britain in possession of a considerable number of islands and colonies in the East and West Indies and elsewhere; and while two war-ships was the whole amount of our losses at sea, we had taken or destroyed eighty sail of the line, 181 frigates, and 224 smaller ships belonging to the enemy, together with 743 privateers, fifteen Dutch, and seventy-six Spanish ships. The triumphs of the British fleets were indeed numerous and splendid, and had the effect of keeping the national commerce almost inviolate, during the whole of the war, while that of France was nearly destroyed. There was, however, hardly the most trifling instance of success by land; and the expenses of the contest had been enormous. The supplies usually voted before the war were fourteen millions; those for 1801 were L.42,197,000, being double the amount of the whole land-rent of the country. The result was stated not more epigrammatically than truly by Mr Sheridan in the House of Commons. "The late minister (Pitt) had told us," said he, "that the example of a Jacobin government in Europe, founded on the ruins of a bloody altar, and the tomb of a martyred monarch, was a spectacle so dreadful and infectious to Christendom, that we could never be safe while it existed, and could do nothing short of our last effort for its destruction. For these fine words we had laid out near two hundred thousand lives, and nearly three hundred millions of money—and had gained Ceylon and Trinidad." The whole contest is to be looked upon as one of the most extensive displays of the weaker and worse of the human passions that has ever taken place.

WAR RENEWED WITH FRANCE, 1803—BONAPARTE MADE EMPEROR.

The evil, however, was not yet at an end. It was only one of the results of the war against French independence, that the country was led by the course of events to place herself under the control of her chief military genius, Napoleon Bonaparte; a man whose spirit, though relieved by qualities which men have hitherto called illustrious, was innately narrow and selfish. It was soon perceptible that Bonaparte did not relish the condition of peace. Having taken undue advantage of several points left loose in the treaty, Great Britain retaliated by retaining possession of Malta; and the war was accordingly recommenced, in May 1803. Britain immediately employed her superior naval force to seize the French West India colonies; while France took possession of Hanover, and excluded British commerce from Hamburgh, which, during the late war, had been one of its principal depositaries. Bonaparte collected an immense flotilla at Boulogne for the avowed purpose of invading England; but so vigorous were the preparations made by the whole British population, and so formidable the fleet under Lord Nelson, that he never found it possible to put his design in execution. In the year 1804, he was elevated to the condition of Emperor of the French; and France once more exhibited the formalities of a court, though not of the kind which the European sovereigns wished to see established. In April of the same year, the Addington administration was exchanged for one formed by Mr Pitt, and of which he formed the chief.

SUBJUGATION OF AUSTRIA BY NAPOLEON.

In 1805, a new coalition of European powers, consisting of Russia, Sweden, Austria, and Naples, was formed, under the fostering influence of Great Britain, against Napoleon. He, on the other hand, had drawn Spain upon his side, and was making great exertions for contesting with Britain the empire of the sea. A fleet of thirty-three sail, partly French and partly Spanish, met a British fleet of twenty-seven, under Nelson, off Cape Trafalgar, October 25, 1805, and was completely beaten, though at the expense of the life of the British commander. Britain thus fixed permanently her dominion over the seas and coasts of the civilised world. At this time, however, Napoleon was asserting with equal success his supremacy over continental Europe. By a sudden, rapid, and unexpected movement, he conducted an army into Germany, where the Austrian troops were already making aggressions upon neutral territory; on the 17th, took the fortress of Ulm, with its artillery, magazines, garrison of 30,000 men, and the commander, General Mack; entered Vienna without resistance on the 15th November; pursued the fugitive court of Vienna, and the allied armies of Russia and Austria, into Moravia; and on the 2d of December, gained the decisive victory of Austerlitz, which put an end to the coalition, and rendered Napoleon the dictator of the continent.

DEATH OF MR PITT—AND OF MR FOX.

This series of events caused a gloom in the British councils, and proved, with the impeachment of his colleague, Lord Melville (for malpractices in the Admiralty), and other painful circumstances, a deathblow to Mr Pitt, who expired on the 23d of January 1806, completely worn out with state business, at the early age of forty-seven, half of which time he had spent in the public service. A writer of much talent* says—"Mr Pitt merits the praise of patriotism as a man, and talents as a minister; but if he might claim the gratitude, he had at least equal reason to entreat the forgiveness of his country at his last hour. The elements were contrasted in him, like that allegorical statue of Persepolis, which the beholder was alternately disposed to admire and to destroy." Mr Pitt's ministry was succeeded by one composed of the friends of Lord Grenville and Mr Fox, and which was comprehensively called Whig, notwithstanding the modified Toryism of the former individual. This new cabinet, in the course of 1806, made a strenuous but not undignified attempt to obtain a peace from France, which now threatened to bring the whole world to its feet. But the Grenville administration encountered serious difficulties from the king, who now more than ever had recourse to that confidential and irresponsible cabinet, which was formed in his own court, and went by the name of the Back-stairs Influence. Exhausted by his ungrateful labours, Mr Fox died, September 13, 1806. "Frank and simple," says the writer just quoted, "he knew no theatric artifice, no politic concealment, no factitious diversity of personage between the statesman and the man. The errors which prove the weakness of humanity were in him as undisguised as the endowments which ennoble it. Without those weaknesses and errors, his character would have been nearer perfection, but not more grand—and his generous sympathies might have been less active and redundant. His last effort as a minister was to procure peace; his last act to propose the abolition of the slave trade." The war was thus, among its other evil consequences, breaking the hearts of the most able and worthy of the sons of England.

* Mr W. Wallace, in his Life of George IV., Lardner's Cabinet Library.

PRUSSIA REDUCED—THE BERLIN DECREES.

A new coalition, excluding Austria, but involving Prussia, had been subsidised by Britain, and was now preparing to act. With his usual decision, Napoleon led what he called his "Grand Army" by forced marches into Prussia; gained, on the 14th of October, the battles of Jena and Averstadt, which at once deprived that country of her army, her capital, and her fortresses; and then proclaimed the famous "Berlin Decrees," by which he declared Great Britain in a state of blockade, and shut the ports of Europe against her merchandise. The King of Prussia, Frederick William III., took refuge with his court in Russia, which now was the only continental power of any importance that remained unsubdued by France.

RUSSIA COMPELLED TO MAKE PEACE.

Towards that country Napoleon soon bent his steps, taking assistance on his march from Poland, which he promised to restore to independence. After a series of skirmishes and battles of lesser importance, he met the Russian army in great strength, June 14, 1807, at Friedland, and gave it a total overthrow. He might now have easily reduced the whole country, as he had done Austria and Prussia; but he contented himself with forming a treaty (at Tilsit), by which Russia agreed to become an ally of France, and entered into his views for the crippling of Britain by the exclusion of her commerce from continental ports. France had thus the glory of disarming, in the course of a few years, the whole of Europe, excepting Great Britain; an amount of military triumph for which there was no precedent in ancient or modern history.

CHANGES OF ADMINISTRATION.

The Grenville administration was displaced in spring 1807, in consequence of the difference between its members and the king, on the subject of the Catholic claims, which had long been urged by the Whig party, with but an imperfect support from the people. The next ministry was headed by the Duke of Portland, and included Lords Hawkesbury and Castlereagh (afterwards Earl of Liverpool and Marquis of Londonderry), and Mr Canning, as secretaries; Mr Spencer Perceval, recently a solicitor, being chancellor of the exchequer. It is generally allowed to have been one of the most incapable ministries ever known; yet it was as good as could be obtained at the time to conduct the affairs of a country, where, on the one hand, the will of the sovereign and borough-proprietors, and on the other the clamours of the people, presented so many obstacles to an efficient course. One of the first acts of this cabinet was the dispatch of a naval armament to Copenhagen, to seize and bring away the Danish shipping, in order that it might not be, by possibility, employed for the injury of Britain. The end of the expedition was easily gained; but it was the means of lowering the honour of Britain in the eyes of foreign states.

FIRST PENINSULAR CAMPAIGN.

The time seems to have now arrived when the retaliation of France upon Europe, for its interference with the revolution, was completed, and when farther measures against neighbouring states became offensive on her part, and accordingly indefensible. France, however, was now given up to the direction of a military genius, who had other ends to serve than the defence of the country against foreign aggression or interference. The amazing successes of Napoleon Bonaparte had inspired him with the idea of universal empire; and so great was the influence he had acquired over the public mind and physical energies of France, that the attainment of his object seemed by no means impossible. There was a difference, however, between the opposition which he met with before this period, and that which he subsequently encountered. In the earlier periods of the war, the armies brought against him could be considered as little else than the mercenaries of the dominant classes in England, and of the despotisms of eastern Europe; henceforth a fiercer and more patriotic spirit rose every where against him: he was looked upon in England and elsewhere as the common enemy of humanity and of freedom; and every exertion made for the humiliation of France was animated by a sentiment of desperation, in which the governors and governed alike participated.

The Spanish peninsula was the first part of the prostrated continent, where the *people* could be said to have taken a decidedly hostile part against Napoleon. He had there gone so far as to dethrone the reigning family, and give the crown to his elder brother Joseph. A sense of wrong and insult, mingled with religious fanaticism, raised the Spanish people in revolt against the French troops; and though their conduct was every where barbarous in the extreme, it was hailed in Britain as capable of being turned to account. In terms of a treaty entered into with a provisional government in Spain, a small army was landed, August 8, in Portugal, which country had been recently taken possession of by the French. Sir Arthur Wellesley, who has since been so famous as Duke of Wellington, was the leader of this force. In an engagement at Vimeira, on the 21st, he repulsed the French, under Junot, who soon after agreed, by what was called the Convention of Cintra, to evacuate the country. Sir Arthur being recalled, the British army was led into Spain under the command of Sir John Moore; but this officer found the reinforcements poured in by Napoleon too great to be withstood, and accordingly, in the end of December, commenced a disastrous though well-conducted retreat towards the port of Corunna, whither he was closely pursued by Marshal Soult. The British army suffered the severest hardships and losses on this occasion, but did not experience a check in battle, or lose a single standard. In a battle which took place at Corunna, January 18, 1809, for the purpose of protecting the embarkation of the troops, Sir John Moore was killed.

CASE OF THE DUKE OF YORK.

Public attention was at this time almost exclusively occupied by an inquiry into a charge against the Duke of York, the commander-in-chief of the army. He was represented as having given commissions to individuals, at the recommendation of a Mrs Clarke, who was his mistress, and who profited to a great extent by her influence. While the country was making such sacrifices to maintain the throne, the two persons nearest to it were sunk in sensualities only comparable to those of the court of Charles II. The Prince of Wales, in order to induce the nation to pay his debts, had, in 1796, married the Princess Caroline of Brunswick, from whom he had lived separated almost ever since, indulging freely in those vices which most tend to degrade our common nature. It now appeared that the Duke of York, though also married, revelled in the grossest debaucheries, for which he did not pay out of his income, but from the public purse. The censure of parliament was only avoided by his resigning his office.

AUSTRIA AGAIN PROSTRATED BY NAPOLEON.

In 1809, Austria was induced once more to commence war with a power by which she had been so often overthrown. Upwards of half a million of men were brought into the field, under the command of the Archduke Charles. Bonaparte, leaving Spain comparatively open to attack, moved rapidly forward into Germany, and, by the victory of Eckmuhl, opened up the way to Vienna, which surrendered to him. After gaining a slight advantage at Essling, the archduke came to a second decisive encounter at Wagram, where the strength of Austria was completely broken to pieces. The peace which succeeded was sealed by the marriage of Napoleon to Maria Louisa, daughter of the Emperor of Austria, for which purpose the former divorced his wife Josephine.

WALCHEREN EXPEDITION.

In the autumn of 1809, the British government dispatched an armament of 100,000 men, for the purpose of securing a station that would command the navigation of the Scheldt. The expedition was placed under the command of the Earl of Chatham, elder brother of the late premier; a nobleman totally unacquainted with military affairs on such a scale—who had never been entrusted by his own brother with any office—but who needed the pay, and was a favourite of the court. Under such management, the enterprise altogether failed. Too much time was put off in the preliminary siege of Flushing; Antwerp was effectually prepared to resist every effort; and the unhealthy season came on before any thing considerable had been done. The army having disembarked on the insalubrious island of Walcheren, was swept off in thousands by disease. The survivors returned in December, without having done any thing towards the object for which they had set out. This tragic affair became the subject of inquiry in the House of Commons, which, by a majority of 272 against 232, vindicated the propriety of the detention of the army for three months in an unhealthy island; and was therefore, in mockery, nicknamed the Walcheren Parliament.

SECOND PENINSULAR CAMPAIGN.

A new expedition in Spain was attended with better success. Taking advantage of the absence of Napoleon in Austria, a considerable army was landed, April 23, 1809, under the command of Sir Arthur Wellesley, who immediately drove Soult out of Portugal, and then made a rapid move upon Madrid. King Joseph, a weak voluptuary in character, came forth with a considerable force under the command of Marshal Victor; and on the 28th of July, attacked the British and Spanish troops in a strong position at Talavera. The contest was obstinate and sanguinary;

and though the French did not retreat, the advantage lay with the British. The government, glad to find that a battle had been fought without defeat, elevated Wellesley to a peerage, under the title of Viscount Wellington of Talavera. He was obliged immediately to fall back upon Portugal, where he occupied a strong position near Santerem. Early in 1810, Napoleon reinforced the army in Spain, and gave orders to Massena to "drive the British out of the peninsula." Wellington posted his troops on the heights of Busaco—eighty thousand in number, including Portuguese—and there, on the 27th of September, was attacked by an equal number of French. Both British and Portuguese behaved well: the French were repulsed with great loss, and, for the first time in the war, conceived a respectful notion of the former troops. Wellington now retired to the lines of Torres Vedras, causing the whole country to be desolated as he went, for the purpose of embarrassing the French. When Massena observed the strength of the British position, he hesitated; and finally, in the spring of 1811, performed a disastrous and harassed retreat into Spain.

It now became an object of importance with Wellington to obtain possession of the Spanish fortresses which had been seized by the French. On the 22d of April, he reconnoitred Badajos, and soon after laid siege to Almeida. Massena advancing to raise the siege was met on fair terms at Fuentes d'Onoro, May 5, and repulsed. Almeida consequently fell into the hands of the British. General Beresford, at the head of another body of British forces, gained the bloody battle of Albuera over Soult, and thereby protected the siege of Badajos, which, however, was soon after abandoned. During the same season, General Graham, in command of a third body of troops, gained the battle of Barossa. At the end of a campaign, in which the French were upon the whole unsuccessful, Wellington retired once more into Portugal.

COMMITTAL OF SIR FRANCIS BURDETT.

The domestic transactions of this period are interesting, though they are far from showing that either the government or the public was in a healthy state. The exclusion of strangers from the House of Commons during the inquiries into the Walcheren expedition, had been made a subject of discussion in a debating-club, the president of which was therefore committed to Newgate for a breach of privilege. Sir Francis Burdett, member for Westminster, made this proceeding the subject of some acrimonious remarks in a letter to his constituents, denying the right of the House of Commons to imprison without trial, and describing that body as "a part of our fellow-subjects, collected together by means which it is not necessary for me to describe." The letter was voted a libel on the house, and a warrant was issued by the speaker for committing Sir Francis to the Tower. A measure so uncommon and so violent, it may easily be imagined, could only happen under a government to which the popular spirit had given occasion for alarm. Sir Francis, denying the legality of the warrant, resisted its execution by remaining in his own house, where he was protected from the officers by immense crowds of people. After suffering a kind of siege for two days, he was forcibly taken by a large train of soldiers, and lodged in the Tower. The capital was convulsed by this bold measure for several days; and in the course of the tumults which took place, a number of lives were lost.

PRINCE OF WALES APPOINTED REGENT.

The intellect of George III., which had experienced several temporary aberrations, gave way at the close of the year 1810, and rendered it necessary that a regent should be appointed. Accordingly, in December, parliament imposed that duty upon the Prince of Wales, though under certain restrictions as to the appointment of officers and other branches of the royal prerogative. The Tory party had not now the same reason to dread the accession of the prince which they had in 1789. His sentiments on the Catholic claims, originally favourable, had in 1804 experienced a decided change, which proved the means of alienating him considerably from the Whigs, with whom emancipation was a leading and unalterable principle. Though he did not at first show any disinclination to take his old friends into the ministry, he contrived, when the first year of restriction had elapsed, to let them remain in their wonted state of opposition, without seeming to have desired it. For the mere purpose of preserving his consistency, he made overtures to the leaders of the Whigs to *enter* the existing cabinet; and, as might have been expected, they refused to coalesce with men differing so much with themselves in principle. In truth, the prince regent was too well pleased with the complaisance of the present ministers, and too sensible of the advantage of the present habitually compliant state of parliament, to wish for their removal. Nor did he lose with the public for thus overlooking the Whigs. "The Whigs," says an acute writer, "had more of parliamentary influence and talent, than of popular support. It should have become apparent to them, from the accession of George III.—at least from the developement of his principles of government at the commencement of his reign—that their only hope of power was in the support of the nation; yet did they still look to the crown as the sole dispenser of office, and never frankly identified themselves with any great popular cause. The coalesced parties of Lords Grey and Grenville joined, it is true, in an enlightened view of the great question of religious freedom. But they were in advance of opinion and the age, and their generous support and promotion of Catholic liberty alienated at the same time the sovereign and the people. Hence the Prince of Wales gained rather than lost with the public by discarding the Whigs, and adopting the Tories."

GREAT DEPRESSION IN ENGLAND.

The year 1811 is generally looked upon as the period of greatest depression and distress which the British empire has known for several ages. At this time, with the exception of an uncertain footing gained in Spain, as much by the superstition and patriotism of the natives as by British valour, the influence of England was unknown on the continent. Bonaparte seemed as firmly seated on the throne of France as any of her former monarchs, while every other civilised European kingdom either owned a monarch of his express appointment, or was in some other way prostrate to his power. By the Berlin and Milan decrees, he had shut the ports of the continent against British goods, so that they could only be smuggled into their usual markets. By British orders in council, which, though intended to be retaliatory, only increased the evil, no vessel belonging to a neutral power—such, for instance, as the United States—was permitted to carry goods to these ports, unless they should previously land and pay a duty in Britain. Thus we at once suffered from the short-sighted despotism of the French emperor, and from our own narrow and imperfect views of commerce, for, by crippling America, we only deprived ourselves of one of our best and almost sole-remaining customers. The consequence of these measures, and of the excessive issue of bank paper which had now for some years been in progress, was, that the paper currency sunk considerably below its usual value in the precious metals; in other words, all necessaries became considerably dearer than they had formerly been; while foreign exchanges were executed at a loss of from fifteen to twenty per cent. At this time, a guinea could not be obtained for less than twenty-seven shillings in bank notes. On the causes of this derangement being explained by a committee of parliament, a panic took place, followed by a number of mercantile failures. Yet even at this time of unexampled distress, the means of redemption were in preparation.

RUSSIAN CAMPAIGN.

The power of Bonaparte, procured and brought about by an antagonism to the old despotisms, might have been permanent, if managed with discretion. It was used, however, in such a way as to produce a decided reaction throughout Europe in favour of those antiquated systems, which, twenty years before, had trembled under the ban of popular sentiment. The exclusion of British goods—a measure which he had dictated in resentment against England—proved the source of inconceivable distress, oppression, and hardship throughout the continent, and was greatly instrumental in exciting a spirit of hostility against him. The very circumstance of a foreign power domineering over their native princes, raised a feeling in favour of those personages, which, being identified with the cause of national independence, acted as a very powerful stimulant. On the other hand, a sense of the grasping ambition of Napoleon—of his hostility to real freedom—of his unscrupulousness in throwing away the lives of his subjects for his own personal aggrandisement—had for some time been gaining ground in France itself.

In 1812, when already the transactions in Spain had done a little to shake the idea of his infallibility, Alexander Emperor of Russia ventured upon a defiance of his decrees against British merchandise, and provoked him to a renewal of the war. With upwards of half a million of troops, appointed in the best manner, he set out for that remote country, determined to reduce it into perfect subjection. Here an accident of nature did that for mankind which they had been unable, with their utmost efforts, to do for themselves. The city of Moscow, after being possessed by the French troops in September, was destroyed by incendiaries, so that no shelter remained for them during the ensuing winter. Napoleon was obliged to retreat; but, overtaken by the direst inclemency of the season, his men perished by thousands in the snow. Of his splendid army, a mere skeleton regained central Europe. Returning almost alone to Paris, he contrived with great exertions to reinforce his army, though there was no replacing the veterans lost in Russia. Early in 1813, he opened a campaign in northern Germany, where the Emperor of Russia, now joined by the King of Prussia, and various minor powers, appeared in open field against him. After various successes on either side, an armistice was agreed to on the 1st of June, and Bonaparte was offered peace on condition of restoring only that part of his influence and his dominions which he had acquired since 1805. Inspired with an overweening confidence in his resources and military genius, he refused these terms—and lost all. At the end of the armistice in August, his father-in-law, the Emperor of Austria, joined the allies, making up a force of 500,000 men against 300,000, which was the utmost he could at present bring into the field. Henceforth he might be considered as overpowered by numbers. By steady though cautious movements, the allies advanced nearer and nearer to France, driving him reluctantly before them, and increasing their own force as the various states became emancipated by their presence. At the close of 1813, they rested upon the frontiers of France, while Lord Wellington, after two splendid campaigns in Spain, had advanced in like manner to the Pyrenees.

DOMESTIC AFFAIRS—WAR WITH AMERICA.

Some changes had in the meantime taken place in the British administration. On the 11th of May 1812, the premier, Mr Percival, was shot in the lobby of the House of Commons, by a man named Bellingham, whom some private losses had rendered insane. Lords Liverpool and Castlereagh then became the ministerial leaders in their respective houses, but were quickly voted down by a majority of four, upon a motion by Mr Stuart Wortley, now Lord Wharncliffe. Another treaty with Lords Grenville and Grey, which this vote rendered necessary, was rendered ineffectual by the intrigues of the regent's personal friends, the Earl of Moira and Mr Sheridan—two men of generally popular qualities, but who sacrificed consistency and even character for their royal patron. The ministry was finally rendered satisfactory to parliament, by the admission of Earl Harrowby as president of the council, Mr Vansittart as chancellor of the exchequer, and Lord Sidmouth (formerly premier while Mr Addington) as secretary for the home department; Lord Liverpool continuing as premier, and Lord Castlereagh as foreign and war secretary. Notwithstanding the successes which were at this period brightening the prospects of Britain, her sovereign and his ministers were highly unpopular. The latter were generally stigmatised as the weak tools of three influences which at this time presided over public affairs—the aristocracy and borough proprietors, the regent, and the secret friends of that latter personage, among whom were reckoned the Hertford family, whose connection with his royal highness was of a nature highly obnoxious to scandal. The regent himself had lost the favour and esteem of his subjects, in consequence of the frivolous and sensual tenor of his private life, and of the persecution which his consort had suffered for many years under his express agency. The general discontents were increased by the effects of the orders in council, for prohibiting the commerce of neutral states. Vast multitudes of the lower orders were thrown idle by the stagnation of manufactures, and wreaked their vengeance in commotion and riot. The middle classes expressed their dissatisfaction by clamours for parliamentary reform. At this unhappy crisis, provoked beyond all patience by the orders in council, as well as by a right assumed by British war-vessels to search for and impress English sailors on board the commercial shipping of America, that country, June 1812, declared war against us. Before the news had reached our shores, the orders had been revoked by the influence of Lord Liverpool; but the Americans, nevertheless, were too much incensed by a long course of injury and suffering to retrace their steps. During the summer and autumn, several rencontres took place between single American and British ships, in which, owing perhaps to superior numbers of men, the former were successful. It was not till June 1, 1813, when the Shannon and Chesapeake met on equal terms, that the British experienced any naval triumph in this war with a kindred people. On land, the Americans endeavoured to annoy the British by assaults upon Canada, but met with no decisive success. The British landed several expeditions on the coast of the States, and were successful at Washington, at Alexandria, and one or two other points, but experienced a bloody and disastrous repulse at New Orleans. The war ended, December 1814, without settling any of the principles for which the Americans had taken up arms. But while thus simply useless to America, it was seriously calamitous for Britain. The commerce with the States, which amounted in 1807 to twelve millions, was interrupted and nearly ruined by the orders in council, and the hostilities which they occasioned: henceforth America endeavoured to render herself commercially independent of Britain, by the encouragement of native manufactures—a policy not immediately advantageous, perhaps, to herself, but infinitely less so to Great Britain. The fatality of the Berlin and Milan decrees to Napoleon, and of the orders in council to the interests of Britain, shows how extremely dangerous it is for any government to interfere violently—for any avowed end whatever—with the large commercial systems upon which the immediate interests of their subjects depend.

PEACE OF 1814—ABDICATION OF NAPOLEON.

At the close of 1813, it was evident that Bonaparte could hardly defend himself against the vast armaments collected on all hands against him. At the end of January 1814, having wrung from France almost every youth capable of bearing arms, he opposed the allies on the frontiers, with a force much less numerous and worse disciplined. Even now he was offered peace, on condition that he should only retain France as it existed before the revolution. But this was too humiliating to his spirit to be accepted; he trusted too much to the faithless hope that, at the worst, his father-in-law would not permit him to be dethroned. Two months were spent in almost incessant conflict with the advancing allies, who on the 30th of March entered Paris in triumph, and, in the course of a few days, substituted the ancient rule of the Bourbons for that of Napoleon, who was granted only the sovereignty of Elba, a small island in the Mediterranean.

CONGRESS OF VIENNA.

In the measures for settling France under Louis XVIII., Great Britain concurred by her representative Lord Castlereagh, who attended the allies during the campaign of 1814; and peace was proclaimed in London on the 20th of June. France was deprived of all the acquisitions gained both under the republic and the empire, and restored to the rule of a family of which it was emphatically said that they had forgot nothing and learned nothing during their exile. The Emperor of Russia and the King of Prussia visited England in June, and were received with all the honours due to men who were considered as the liberators of Europe. Wellington, now created a duke, received a grant of L.400,000 from the House of Commons, in addition to one of L.100,000 previously voted; and had the honour to receive the thanks of the house in person for his services, which were generally esteemed as comparable only to those of Marlborough a century before. Representatives from the various European powers concerned in the war, met at Vienna, October 2, in order to settle the disturbed limits of the various countries, and provide against the renewal of so disastrous a period of war. Ideas of liberalism and of national and individual independence were now suffering under general obloquy, as having been the original cause of the war; it was therefore natural, however wrong, that the congress of Vienna should have been less actuated by a sense of justice than of expediency. The powers in deliberation certainly violated every correct principle in their treatment of Norway, of Saxony, of Poland, of Belgium, of Genoa, and of Italy, which they transferred from one domination to another, without the least regard to the rights or predilections of the inhabitants. It was represented by the friends of the congress, that these alterations of boundaries were dictated by a view solely to the general interests of Europe; but others saw more immediately a spoliation of territory, by which every power except Great Britain directly profited; while the complaints of the nations thus tampered with appealed to a principle with which every people could sympathise.

TEMPORARY RESTORATION OF NAPOLEON—BATTLE OF WATERLOO.

In March 1815, the proceedings of the congress were interrupted by intelligence that Napoleon had landed in France, and was advancing in triumph to the capital. He had been encouraged by various favourable circumstances to attempt the recovery of his throne; and so unpopular had the new government already become, that though he landed with only a few men, he was every where received with affection, and, on the 20th of March, was reinstated in his capital, which had just that morning been deserted by Louis XVIII. The latter sovereign had granted a charter to his people, by which he and his successors were bound to rule under certain restrictions, and with a legislature composed of two chambers, somewhat resembling the British houses of parliament. Bonaparte now came under similar engagements, and even submitted to take the votes of the nation for his restoration, on which occasion he had a million and a half of affirmative voices, against less than half a million of negative, the voting being performed by ballot. His exertions to reorganise an army were successful to a degree which showed his extraordinary influence over the French nation. On the 1st of June, he had 559,000 effective men under arms, of whom 217,000 were ready to take the field.

A Prussian army of more than 100,000 men, under Blucher, and one of about 80,000 British, Germans, and Belgians, under Wellington, were quickly rendezvoused in the Netherlands, while still larger armies of Austrians and Russians, making the whole force above a million, were rapidly approaching—not, it was professed, to make war on France, but against Bonaparte alone, who was denounced as having, by his breach of the treaty, "placed himself out of the pale of civil and social relations, and incurred the penalty of summary execution." Napoleon, knowing that his enemies would accumulate faster in proportion than his own troops, crossed the frontier on the 14th of June with 120,000 men, resolved to fight Blucher and Wellington in detail, if possible. The rapidity of his movements prevented that concert between the Prussian and English generals, which it was their interest to establish. On the 16th, he beat the former at Ligny, and compelled him to retire. He had at the same time entrusted to Marshal Ney the duty of cutting off all connection between the two hostile armies. His policy, though not fully acted up to by his marshals, was so far successful, that Blucher retired upon a point nearly a day's march from Wellington. After some farther fighting next day, he brought his whole forces to bear, on the 18th, against Wellington alone, who had drawn up his troops across the road to Brussels, near a place called Waterloo. The battle consisted of a constant succession of attacks by the French upon the British lines; assaults attended with great bloodshed, but nevertheless resisted with the utmost fortitude till the evening, when Blucher came up on the left flank of the British, and turned the scale against the French, who had now to operate laterally, as well as in front. The failure of a final charge by Napoleon's reserve to produce any impression on the two armies, decided the day against him; his baffled and broken host retired before a furious charge of the Prussian cavalry, who cut them down unmercifully for several miles. On his return to Paris, Napoleon made an effort to restore the confidence of his chief councillors, but in vain. After a fruitless abdication in favour of his son, he retired on board a small vessel at Rochfort, with the intention of proceeding to America, but being captured by a British war-vessel, was condemned by his triumphant enemies to perpetual confinement on the island of St Helena, in the Atlantic, where he died in 1821.

Louis XVIII. was now restored, and the arrangements of the Congress of Vienna were completed. The expenses of Great Britain during this last year of hostilities exceeded seventy millions, and the national debt, which in 1793 had been 230,000,000, now amounted to 860,000,000, or nearly three times the former sum.

HOLY ALLIANCE.

It has been stated that a reaction had taken place throughout Europe, during the latter years of Napoleon, against the innovatory doctrines, which, by producing the French revolution, had been the cause, innocent or guilty, of so much ruinous warfare. Encouraged by this sentiment, the three sovereigns of Austria, Prussia, and Russia, had no sooner settled the new government of France, than they entered, September 26, 1815, into a personal league or bond for assisting each other on all occasions when the least commotion took place among their respective subjects. This treaty was composed in somewhat obscure terms, and from its professing religion to be the sole proper guide "in the councils of princes, in consolidating human institutions, and remedying their imperfections," was burlesquely termed the Holy Alliance. It was published at the end of the year, and communicated to the Prince Regent of England, who approved, but did not accede to it. By the liberal party in England, it was denounced as a hypocritical conspiracy against the liberties of mankind.

The reaction had also its effect in Great Britain, in fixing the power of that strange mixture of aristocratic influences, which, by appointing and composing the two houses of parliament, might be said to constitute the government. The security of this predominating power was indicated by several acts in which their peculiar interests were consulted at the expense of all the remaining classes of the community. In the preceding year had been passed an act, prohibiting the importation of grain from the now opened continent, when the price in this country should be less than eighty shillings per quarter. An attempt to continue the income and property taxes, which pressed with greatest severity on the wealthy and landed classes, was also negatived.

THE PRINCESS CHARLOTTE.

In May 1816, the Princess Charlotte, only child of the prince regent, was married to Prince Leopold of Saxe Coburg, a young officer who had gained her affections when attending the allied sovereigns at the British court. In November 1817, to the inexpressible grief of the whole nation, the young princess died in childbed, after having given birth to a dead son. Her surviving husband continued to enjoy the allowance fixed by parliament upon the pair (L.60,000 a-year), excepting L.10,000, which had been given under the denomination of pin-money to the princess.

In August 1816, a British armament under Lord Exmouth bombarded Algiers, and reduced that piratical state to certain desirable conditions respecting the treatment of Christian prisoners.

PERIOD OF GENERAL DISTRESS.

The year 1816, and the four following years, will always be memorable, as forming an epoch of extraordinary distress, affecting almost every class of the community. The liberation of European commerce at the end of the war, produced a proportionate diminution of that trade which England had previously enjoyed, through her exclusive possession of the seas. While all public burdens continued at their former nominal amount, the prices of every kind of produce, and of every kind of goods, had fallen far below the unnatural level to which a state of war and of bank restriction had raised them; and hence the expenses of the late contest, which had never been felt in the fictitious prosperity then prevalent, came to press with real severity upon the national resources, at a time when there was much less ability to support them. To complete the misery of the country, the crop of 1816 fell far short of the usual amount, and the price of bread was increased to an amount more than double what has since been the average rate. Tumultuary proceedings took place in various parts of the country, and a desire for a reform in the House of Commons, by which alone was there any hope of reducing the public expenditure, began to take deep root among the lower orders. At a large metropolitan meeting of the working classes, in December, a portion of the mass became suddenly animated with what appeared a spirit adverse to the public peace, and, rushing in a riotous manner through the streets of London, gave serious or assumed alarm to the government and its supporters. An apothecary named Watson, and three other persons, were seized and imprisoned for being concerned in this riot. On the 28th of January 1817, when the prince regent was returning from the ceremony of opening parliament, his carriage window was said to have been perforated by a stone and two bullets, the latter supposed to have proceeded from an air-gun. The government then adopted expedients, which have since met with general condemnation, for counteracting the force of the popular spirit. They endeavoured to make it appear that an extensive conspiracy had been formed for the overthrow of the government—though the reports of their parliamentary committees, upon the documents submitted as evidence of that fact, only served by their vagueness of expression to excite suspicions against their ministerial policy. Of the four rioters who were charged with high treason, a conviction was only obtained against one. Such unanimity, however, prevailed between the ministry and the parliament, that, at the close of February, an act was passed for the suspension of habeas corpus, and for several other objects hostile to popular rights. The ministers also sent emissaries into the country, not only for the legitimate purpose of gathering information respecting the state of the public mind, but to mingle with the unemployed and starving workmen, to foment their discontents, and lead them into such partial demonstrations of violence, as might at once enable the ministers to obtain a few victims for the terror of the rest, and, by convincing the wealthier orders of the reality of a conspiracy, induce them to give more effectual support to his majesty's government. Many persons were accordingly imprisoned, and, by virtue of the suspension act, detained at the will of the ministers. Even the liberty of the press, which has always been so dear to the English bosom, was quietly yielded by parliament to Lord Sidmouth, the home-secretary, who, upon the authority of the crown lawyers, gave permission to justices of peace to seize and hold to bail any person whom they might find guilty of publishing seditious or blasphemous papers. It is more gratifying to mention, that, in April, parliament granted half a million for public works, in order to employ the discharged operatives. By another array, however, of proofs of the alleged conspiracy, the suspension of the habeas corpus act was continued beyond the close of the session. In autumn, the ministers experienced a noted defeat, in the prosecution of Mr William Hone, for publishing what were styled blasphemous parodies upon the litany, and other parts of the church service. The severe measures of this administration are chiefly attributed to Lord Castlereagh, a statesman described as personally amiable in a high degree, but actuated by principles which have not for a long period been familiar to the British people.

THE MANCHESTER MEETING OF AUGUST 1819.

A temporary revival of prosperity occurred in 1818, but was quickly followed by the former distress. In the autumn of 1819, the misery of the working classes had reached its greatest height, and still parliamentary reform was demanded as the only measure which could permanently improve their prospects. On the 12th of July, at a public meeting in the unrepresented town of Birmingham, an attorney was elected to proceed to Westminster, and openly claim to be received as a member of parliament on their behalf. On the 16th of August, a vast body of operatives assembled at Manchester, in an open space of ground called St Peter's Field, for a similar purpose, though professedly to petition for parliamentary reform. Though they had come in a kind of regular array, and bearing banners with inscriptions, no symptom of violence was observable in their proceedings; when suddenly a body of troops, consisting chiefly of yeomanry, dashed into the mass, trampling down many persons of both sexes under the horses' feet, and killing and wounding others with their sabres. The meeting was dispersed by these means, and Messrs Hunt and Johnston, the principal orators, were apprehended. But the tragic nature of the event, combined with a consideration of its being an invasion of the popular right of meeting for redress of grievances, produced a very general feeling of resentment throughout the country, even among some who were habitually the defenders of ministerial measures. The magistrates who conducted the attack were instantly thanked by the government; but their fame is not of an enviable character. In a country where social advancement is so great as in Britain, no proceedings, public or private, by which the poorer classes may be led to think themselves objects of persecution or even of neglect with the rich, can receive the unqualified approbation of any considerable portion of the community.

THE "SIX ACTS."

When parliament reassembled in November, there was an evident increase of attachment to the ministry, and, in addition to the strong measures already taken for suppressing popular discontent, six acts were passed, which have since been frequently stigmatised as inimical to the liberty of the subject. One took away the common-law right to traverse an information or indictment from one session to the next. The second imposed a stamp duty on all publications communicating events or occurrences, or conveying remarks on affairs of church and state, if under a certain number of sheets, or published periodically oftener than once in twenty-six days. The third enacted that the publishers of such works should give security before commencing them, and that a second commission of the offence of publishing a blasphemous or seditious libel should be punishable by transportation. The other acts were for the prevention of secret training to arms, which was declared a capital offence—the seizure of arms—and the restriction of the right of calling a public meeting to magistrates. Earl Grey denounced these measures as a new system of government by terror and coercion; but they were nevertheless approved by great majorities. They have not since been repealed; but no party now suffers from them except that by which they were enacted.

The year 1819 was remarkable, among other things, for the provision made, by act of parliament, for the resumption of cash payments at the bank.

ACCESSION OF GEORGE IV.

On the 29th of January 1820, George III. died at Windsor, in his eighty-second year, without having experienced any lucid interval: his consort, Charlotte of Mecklenburgh, had died in November 1817. The prince regent was immediately proclaimed as George IV.; but there was no other change to mark the commencement of a new reign. A few days after the decease of George III., died the Duke of Kent, fourth son of their late majesties, leaving an infant daughter Victoria, who has since become heiress-presumptive.

CATO STREET CONSPIRACY.

The bloodshed at Manchester, and other ministerial measures, inspired a small band of desperate men with the atrocious design of assassinating the ministers at a cabinet dinner, and thereafter attempting to set themselves up as a provisional government. On the 23d of February 1820, they were surprised by the police in their place of meeting, and, after a desperate resistance, five were seized, among whom one Thistlewood was the chief. These unhappy men were tried for high treason, and executed. Nearly about the same time, an attempt was made by the workmen in the west of Scotland to bring about some alteration in the state; and two men, supposed to have been deluded by government spies, were executed. There is little reason to doubt that the violence of the people at this period was solely the result of those severe measures which the government had taken for the repression of what had previously been only an imaginary disposition to insurrection.

THE QUEEN'S TRIAL.

On the accession of the king, his consort's name had been omitted from the liturgy. This and other insults induced her to return to England, June 1820, to the infinite embarrassment of the king and his ministers. Her majesty, who had long been befriended by the Opposition, was received by the people with the warmest expressions of sympathy. Her guilt, if any really attached to her, was overlooked on account of the infinitely more notorious debaucheries of her husband, and the persecutions which she had suffered at his hands for twenty-four years. The king, having had a system of observation planted round her majesty during her late residence in Italy, caused a bill of pains and penalties to be brought into parliament, July 6, against her majesty. The House of Lords thus became a court for her trial. The examination of witnesses occupied several weeks, and daily during that time were the moral feelings of the public shocked by details of the most revolting kind. Yet no evidence of criminality could soften the indignation with which almost all classes of the community regarded this scandalous prosecution. Though the bill was read a second time by a majority of 28, in a house of 218, and a third time by 108 against 99, the government was compelled to abandon it, leaving the queen and the people triumphant.

ROYAL VISIT TO IRELAND, &c.

In July 1821, the coronation of George IV. took place under circumstances of elaborate splendour, contrasting strangely with the depressed state of the country. On this occasion, the queen made an attempt to enter Westminster Abbey, for the purpose of witnessing the ceremony, but was repelled by the military officers who guarded the door; an insult which gave such a shock to her health as to cause her death on the ensuing 7th of August. During this month, the king paid a visit to Ireland, where he was received with much cordiality by all classes of that excitable people, notwithstanding his known hostility to the Catholic claims. In September, he paid a visit to the kingdom of Hanover. In August of the ensuing year, he completed this series of visits by a voyage to Scotland, where he was also received with extreme kindness; a feeling, however, attributable in both cases rather to the novelty of the occasion, and a national feeling of the honour of the royal presence, than to a sincere approbation of either the public measures or the private character of the king. During his absence in Scotland, his leading minister, the Marquis of Londonderry (formerly Lord Castlereagh) put an end to his own life, in consequence of a morbid sense of the difficulty of his position in regard to continental affairs. He had involved himself and his country in the policy of the arbitrary governments, to a degree which threatened to bring both into disgrace, and he did not know how to retrieve his steps. Both in Italy and in Spain, there was a strong disposition to popular ascendancy, and while this was deeply sympathised with in England, the minister was pledged to co-operate in its suppression. This, indeed, was just the crisis between the late reaction for controlling popular movements and the present reaction for giving them play; and Lord Londonderry was the victim at once of his own rashness and of the altered views of his countrymen.

ASCENDANCY OF MR CANNING.

His successor in the direction of foreign affairs was Mr Canning, who had left the cabinet two years before on account of the prosecution of the queen, and was just at this time preparing to leave the country as governor-general of India. Though apparently a willing participator in all the anti-popular measures of the last few years, and a zealous enemy to parliamentary reform, Mr Canning was a man in many respects calculated to please and gain the affections of a people like the English. He very quickly released the country from the obligations under which his predecessor had placed it regarding the movements in Italy and Spain, and, from being a tame follower of the continental despotisms, restored the country to its more proper condition of an arbitress among other nations. From this time, moreover, there was a marked amelioration in the system of home affairs, which, united with the restoration of comparative prosperity, had the ultimate effect of producing a degree of internal tranquillity beyond what had been experienced since the early days of Mr Pitt.

COMMERCIAL DISASTERS OF 1825-6.

The two ensuing years were characterised by an extraordinary activity in almost all departments of trade and commerce. Mr Huskisson, an able commercial minister introduced by Mr Canning, originated several measures of a highly important kind; especially the repeal of all duties on goods passing between Great Britain and Ireland—an alteration in the duties affecting the silk manufacture—the repeal of the combination laws, and of the law against the emigration of artisans; while the executive formed commercial treaties on the reciprocity system, with various countries of Europe, and, acknowledging the independence of the revolted Spanish colonies in America, drew them as additional customers into the British market. Capital so far exceeded the ordinary means of its employment, that many joint-stock companies were formed as a means of giving it a wider range than that to which it was usually limited. Some of these associations professed objects which were by long established usage the business of individuals alone, and of a comparatively humble class. In truth, there seemed to be no kind of employment or traffic so very mean as to be beyond the reach of this mania. The depressed state of trade in 1821 and 1822 had led to a diminished importation and production of goods, and to an advance of prices in 1823. The consequences of this was a sudden and unusually active demand, and a powerful reaction of supply, which did not cease till production had proceeded far beyond the bounds of moderation. The delusion was kept up longer than it would otherwise have been, through the facilities afforded by large issues of paper. The first symptom of something being wrong was the turning of the exchange against England. A diminution of issues at the bank followed. Merchants began to feel a difficulty in answering pecuniary obligations. Then took place a run upon the banks, which began to give way, first in London and then in the country. Between October 1825 and February 1826, fifty-nine commissions of bankruptcy were issued against English country banks, and four times the number of private compositions were calculated to take place during the same period. While the merchant and manufacturer were without credit, their inferiors were without employment, and distress reached almost every class of the community. Some liberal pecuniary measures on the part of the bank of England helped in a short time, rather by inspiring confidence than by actual disbursement of money, to retrieve the desperate circumstances of the country.

MINISTERIAL CHANGES OF 1827-8.

In spring 1827, the illness of Lord Liverpool (followed soon after by his death) opened the way for Mr Canning's promotion to the first place in the administration; on which occasion all the Tories of the old school resigned their places, leaving the reins of government in the hands of a much more yielding and popular party. Mr Canning, however, sunk under the new load imposed upon him, and died in the ensuing August, with more of the regrets of his country than had ever perhaps honoured the memory of any minister. His friend Lord Goderich succeeded as premier, but, finding the duties above his strength, resigned in January 1828, when the Duke of Wellington was appointed in his place.

CATHOLIC EMANCIPATION.

From the year 1805, the Catholic claims had been a prominent subject of parliamentary discussion, and since 1821 they had enjoyed a decided majority in the House of Commons. Almost despairing of their cause, while left to the progress of mere opinion in the English aristocracy, the Irish Catholics had in 1824 united themselves into an association, with the ill-concealed purpose of forcing their emancipation by means of terror. An act was quickly passed for the suppression of this powerful body; but it immediately reappeared in a new shape. In fact, the impatience of the Catholic population of Ireland under the disabilities and degradation to which they were subjected on account of religion, was evidently becoming so very great, that there could be little hope of either peace or public order in that country till their demands were conceded. The English, through the influence of an adverse faith, and a habitual want of sympathy with the complaints of this alien race, lent no weight to the agitation with which the ministry and the local government were assailed; the king, moreover, was decidedly hostile to emancipation: nevertheless, the subject rapidly acquired importance with all classes, and in all parts of the empire. In spring 1828, a kind of preparation was made for the concession, by the repeal of the test and corporation oaths—a measure forced upon the government by a triumph of the Whigs. The ministry soon after received a still more alarming proof of the growing force of the question. Mr Vesey Fitzgerald had vacated his seat for the county of Clare, on becoming president of the board of trade. He was an emancipationist, and possessed great influence in the county; but he was also a member of an anti-Catholic administration. As an expedient for annoying the ministry, the Catholic Association, and all the local influences on that side, set themselves in motion to procure the return of Mr Daniel O'Connell, the most distinguished orator of the Catholic party. To the infinite surprise of the whole nation, Mr O'Connell was returned by a great majority; it was even surmised, upon good authority, that the laws for the exclusion of Catholics from parliament would be unable to prevent him from taking his seat. The Duke of Wellington now began to see the necessity of taking steps towards a settlement of this agitating question; the first and most difficult was to overcome the scruples of the sovereign. At the opening of the session of 1829, in consequence of a recommendation from the throne, bills were introduced by ministers for removing the civil disabilities of Catholics, and putting down the Catholic Association in Ireland; and notwithstanding a great popular opposition, as well as the most powerful exertions of the older and more rigid class of Tories, this grand measure of toleration was carried by a majority of 353 against 180 in the House of Commons, and 217 to 112 in the House of Lords. The ministers gained by this desertion of their professed principles, what every body of men, adopting a similar line of conduct, may reasonably expect—the enmity of their former friends, and a cold distrustful toleration at the hands of their former opponents. In Ireland, public tranquillity was far from being re-established; a matter of wonder to some and of reproach to others, who, having been told that the Catholic disabilities were the principal cause of discontent in the country, expected that their removal would be the signal for the immediate access of a contrary feeling. As well might we expect to see a man newly relieved from the rack, resume at once his usual equanimity, or employ his torn and bleeding limbs in dancing for joy.

DEATH OF GEORGE IV.—AND CONCLUSION.

In June 1830, after a few months' illness, George IV. died of ossification of the heart, in the sixty-eighth year of his age, after having governed in his various capacities of regent and king for nearly twenty years. Being predeceased by his next brother, the Duke of York, he was succeeded by the Duke of Clarence, who ascended the throne with the title of William IV. The reign of this prince was destined, in the course of events, to be the commencement of a most remarkable era of British history—the era of the remodelling of all those institutions which had come down from antiquity, and which had, for nearly a century, been maintained with so much difficulty, against the sentiments of a large portion of the people. Of this extraordinary revolution, so far as it has advanced, our limits do not permit us to give any account in this place; which is perhaps the less necessary, as the most of our readers may, in the meantime, be supposed to recollect the events with sufficient distinctness. We state with more regret that our narrow space has obliged us to treat various incidents of previous history in a more cursory manner than was to have been wished, and even to omit some events and public topics of no small importance. We believe, however, that we have succeeded in accomplishing one main object—which was, to give an *outline of British history, such as the generality of well-informed persons retain in their memories, from reading larger works*; a sketch fully descriptive of the main current of history—of the motives and movements of the government, and of the progress of the great and never-ceasing contest between the governors and governed—but, that it might be the more likely to impress the memory, burdened as little as possible with details and lateral and subordinate transactions. To those who have many things to study, or little time to employ in any kind of reading, these three sheets—containing the matter of a considerable volume—will suffice to communicate as much of this branch of knowledge as they may be able to acquire; and if any one should be disposed to pursue his studies farther, the means are open to him.

MECHANICS.

In the strict sense of the word, Mechanics signifies the method of constructing machines to be put in motion, and to answer some useful end, by certain powers, which are either natural or artificial. It will thus be evident that the nature of the powers themselves is not the object of mechanical investigation, but rather the effect of them upon the passive bodies, which have received the conventional appellation of *Mechanics*, and the constructing of these in such a manner that the powers may act upon them with the smallest possible obstruction. We shall treat of this subject in its application to the various practical purposes of human life, embodying these in our description of what are usually denominated the *mechanic powers*.

INTRODUCTORY DEFINITIONS.*

1. Matter is a term denoting that substance of which every thing perceived by our senses is composed. Its relation to mechanics consists in its extension, impenetrability, and inertness.

2. Body is matter rendered palpable to our senses by its being collected in quantity. *Solid* bodies are such as are composed of particles of matter, with such an adhesive affinity, the one for the other, that they cannot be separated without effort; as exemplified in wood, stone, the metals, &c. There are also *fluid* bodies, whose particles adhere so slightly that they can easily be separated one from the other; as in air, wine, water, &c.

3. Divisibility is either a real or imaginary quality of bodies. Every substance may be divided into surprisingly minute parts by mechanical means; such as grinding, hammering, wiredrawing, &c.

4. Space is usually defined by the order of things which co-exist; in this sense, however, it is a mere abstract idea arising from our notion of the actual or possible situation of things amongst themselves. We may rather call space an extension considered as without bounds, immoveable, but penetrable, by matter. In this sense it may be termed *absolute space*.

5. Relative Space is that variable dimension, or measure of absolute space, which our senses define by its relation to bodies within it.

6. Place, or *absolute place*, is that limited portion of infinite space occupied by a body. *Relative place* is the situation which any body occupies when taken in relation to another body, or set of objects.

7. Mobility is that property by which bodies are capable of being transferred or removed from one part to another, or of existing in different parts of space.

8. Masses.—All bodies are porous, from which cause, taken with the extreme minuteness of the particles of which they are composed, it so happens that fluids have the power of insinuating themselves into all bodies; so that a mixture of two fluids will be less in bulk, and occupy less space, than when they are separate, and that the same bulk may contain different quantities of matter or *masses*.

9. Density, strictly speaking, denotes vicinity or closeness of the particles of which a body is composed. In mechanics, however, it is employed to signify the proportion of the number of equal particles, or the quantity of matter in one body, when compared with the number of equal particles in the same bulk of another body: density, therefore, is directly as the quantity of matter, and inversely as the magnitude of the body. For example, a pound of fir-wood will occupy a much larger space than a pound of lead; hence it is said that lead is a more dense body than wood.

10. Motion is a simple idea. When a boy whips a top, it turns round, or is in motion; but when he desists, it falls down, or is at *rest*.

The motion of bodies is considered either *absolute* or *relative*. A body is in *absolute motion* while it is actually passing from one point in fixed space to another; and in *relative motion* while its position is varying with respect to other bodies.

When a body is in *motion*, as much force is required to make it *rest*, as is required, while at rest, to put it in motion. Thus, suppose a boy strikes a ball from a trap, and another stands by to catch it, it will require as much strength or force to stop the ball, or put it in a state of rest, as the other gave to put it in motion, allowing for the distance the two boys stand apart. No body or part of matter can give itself either motion or rest; and, therefore, a body at rest will remain so for ever, unless it be put in motion by some external cause; and a body in motion will move for ever, unless some external cause stops it. For example, the reason why the top stops when the boy leaves off whipping, is, that the friction of its point upon the ground (or, if a boy were driving a hoop, and desisted from striking it), and the resistance of the air, soon put it at rest. Somewhat, too, might be said on the gravity and attraction between the top and the hoop, and the earth.

A body in motion will always move on in a straight line, unless it be turned out of it by some external cause. Thus we see that a ball rolled along the ice, if the surface be very smooth, will continue its motion in a straight line till it is stopped by the friction of the ice and air, and the force of attraction and gravitation.

The swiftness of motion is measured by the distance of place, and the length of time in which it is performed. Thus, if a golf-ball and a cricket-ball move each of them twenty yards in the same time, their motions are equally swift; but if the cricket-ball moves two yards while the golf-ball is moving one, then is the motion of the cricket-ball twice as swift as the other.

But we must also consider the quantity of the motion measured by its swiftness, as in the above instances, and the quantity of matter moved at the same time. Thus, if the cricket-ball be equal in bulk and weight to the golf-ball, and move as swiftly, then it hath an equal quantity of motion. But if the cricket-ball be twice as big and heavy as the golf-ball, and yet moves equally swift, it hath double the quantity of motion; and so in proportion.

With respect to *relative* and *absolute* motion, Dr Gregory says, "It is obvious that these two kinds of motion can only coincide when the bodies to which the reference is made are fixed: in other cases, a body in relative motion may or may not be in absolute motion. The determination of the absolute motions, by means of observations on the relative motions, is always a matter of great difficulty; nay, is generally absolutely impossible. Thus, when a ball is discharged from a piece of ordnance, it is possible, by means of the ballastic pendulum, and other contrivances of ingenious men, to ascertain its relative motion; that is, its motion with respect to that place on the earth's surface from which it is projected; but, in order to determine its absolute motion, the diurnal and annual motions of the earth about the sun, and probably the motion of that luminary about the centre of some more extensive system, must be taken into the account; so that, on the whole, this apparently simple inquiry becomes sufficiently complex to baffle the proudest efforts of human intelligence."

11. Time.—As motion cannot be instantaneous, the consideration of time is necessarily involved in it.

12. Absolute Time is a portion of duration whose quantity is only known by a comparison with another portion: the relation, therefore, between any two parts of absolute time, is not to be discovered. *Relative time* is a portion of duration which elapses during any motion of a body, or any succession of external appearances.

"There is a striking analogy between the affections of space and time; hence it is, that time may be represented by lines, and measured by motions. Hence, also, we say that an *instant* is the boundary between any two contiguous portions of time, as a point is the boundary of any contiguous lines. A *moment* is any small portion of time. To render time susceptible of mathematical discussion, it must be conceived as measurable; and, to this end, it is necessary to return to some event which we imagine uniformly requires equal times for its accomplishment. We are furnished with such an account in the complete rotation of the earth upon its axis, which makes out a natural day as an apt and obvious unit of time; this is divided into twenty-four equal parts, called hours: each of these into sixty equal parts, called minutes; and each of these, again, into sixty equal parts, called seconds. A second is the unit of time generally employed in mathematical disquisitions."

12. Velocity.—The quantity of motion is determined by velocity. It is that term which expresses the relation between the space described, by a body that is in motion, and the time which elapses during its description. This is determined by the space uniformly described during a given time.

13. The Direction of a Motion.—This is the position of the line, along which a body moves from one point to another. If a body moves on a straight line, it is termed the direction of the body; but if it moves on a curved body or line, its *direction* is continually changing.

14. Force or Power.—This, when applied in a mechanical sense, is that which effects a change in the state of a body, whether that state be rest or motion. The muscular power of animals, as well as pressure, impact, gravity, electricity, galvanism, &c. are considered as forces, or sources of motion. Bodies exposed to the free action of either of these are put into motion, or have the state of their motion changed. All forces, however various, are measured by the effects they produce in like circumstances, whether the effects be creating, accelerating, retarding, or deflecting motions.

15. Equilibrium signifies an equality of weights, powers, or forces of any sort. When bodies are at rest, they are in a state of equilibrium, or when they are acted upon by different forces, so as to be completely balanced, and have no tendency to move in any direction. Bodies are in motion when in a state of equilibrium—when the resistance to motion and the power producing it are so adjusted, that the result shall be uniform motion. It is by an accurate knowledge of both kinds of equilibrium that the theory can be applied to good practical purposes.

Mechanics, therefore, comprehends the doctrine of the *rest*, the *equilibrium*, and the *motions*. It has been divided into two branches, namely, *mechanics*, properly so called, and *hydraulics*. The former of these embraces *statics*, or the balance-rest of solid bodies; and *dynamics*, which is a consideration of the motion of solid bodies, and their force during the continuance of motion. The latter branch comprehends *hydrostatics*, which refers to the resting equilibrium of liquids or non-elastic fluid bodies; and *hydrodynamics*, which treats of such bodies in motion. *Pneumatics*, or the doctrine of the weight, pressure, and effects of elastic fluids, as air and gaseous bodies, is also referable to this branch of mechanics.

OF THE MECHANICAL POWERS.

The mechanical powers comprehend such simple machines as are useful in comparing the velocity of various bodies, and impressing on them at pleasure a greater or lesser degree of their power; such as making a great weight overcome a smaller one. By any of these powers, we may cause a weight of one pound, by moving through the space of ten feet, raise another of ten pounds through one foot, or *vice versa*. But none of the mechanical powers will be able to move a weight of ten pounds through eleven feet; nor by a single pound moving through a space of nine feet are we able to raise a weight of ten pounds through the space of one foot; so that the mechanical powers cannot make any absolute increase of the power applied; they can merely alter the velocity of that power, and thus transfer it either to a larger or smaller body

* For an account of some of the most important properties of matter, and laws of motion, see "A Popular View of Astronomy," No. 21 of this work.

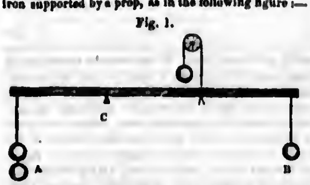
at pleasure. The whole practical part of mechanics depends upon this principle.

The mechanical powers are six in number—namely, the lever, the wheel in axle, the inclined plane, the wedge, the pulley, and the screw.

OF THE LEVER.

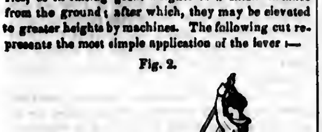
The lever is the most simple of all the mechanical powers, and is generally only a straight bar of wood or iron supported by a prop, as in the following figure:—

Fig. 1.



The weight to be raised is suspended at the short arm of the lever A; and exactly in the inverse proportion of the distance of the weight from the fulcrum, or prop C, is the quantity of weight, as B, necessary to keep it in equilibrio. Thus, if the weight at A be distant one foot, or one inch (for it signifies nothing which), from the prop, it will require an equal weight placed at the same distance on the other side to balance it; that is, if the prop were placed equidistant between where it is at present and the end to which the two balls are suspended. But where it is now placed, it only requires half the quantity of weight to keep it in equilibrio; and if it were removed a tenth part nearer the centre, then only one-third will be required to balance it. It must still be remembered, however, that, if the lever is put in motion, the small or single weight must move through a space ten times as great as that through which the large one passes; so that, in point of fact, there is not any acquisition of power by means of the lever, although it is one of the instruments most commonly used in mechanics, and extremely serviceable in loosening stones in quarries, or in raising great weights to a small distance from the ground; after which, they may be elevated to greater heights by machines. The following cut represents the most simple application of the lever:—

Fig. 2.



The weight to be raised is a log of wood; the lever or handspoke is in the hand of the man; a stone is laid on the ground to act as a prop or fulcrum; the log of wood is to be raised and suspended at the short arm of the lever, on that portion of it which extends beyond the stone.

In making experiments with this sort of lever, it is necessary either to have the short arm greatly thicker than the long one, so that it may exactly balance the longer end, or that portion of it which extends beyond the fulcrum, or a weight must be appended to it exactly sufficient to keep it in equilibrio, otherwise no accuracy can be expected in the experiments.

The lever is the foundation of every kind of balance, whether the common kinds or those known by the name of steelyard, which latter is simply the lever represented in our first cut. For if a scale is appended to the end A of the lever, and a weight, suppose of one pound, be used as a counterpoise to the body which is to be put into the scale, it will show exactly the weight of that body, by putting it at a proper distance from the fulcrum upon the long arm. Suppose the lever to be divided into twelve parts, and if the weight, when placed at the division five from the longer arm, counterpoises that placed in the scale, it shows the body weighs exactly five pounds; if it balances at the sixth division, then it proves that the body weighs six pounds. To this kind of lever may be reduced several useful instruments, such as scissors, snuffers, pincers, &c.

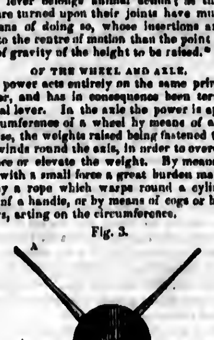
Levers are generally divided into three kinds, according to the respective dispositions of the fulcrum, the power, and the resistance; of these, two are very different in their action. One of these is where the forces act on *contrary* sides of the centre of motion or fulcrum, and another which acts on the *same* side.

The first kind are those where the fulcrum is between the power and the resistance; as the balance, snuffers, scissors, steelyards, &c. The second kind are those where the resistance is between the prop and the power; as oars, rudders of boats, and cutting-knives which are fixed at one end, and doors whose hinges serve as a fulcrum. Those of the third kind are where the power acts between the prop and the resistance; as in sheep-shears, tongs, &c. To this last kind of lever belongs animal action; as the bones which are turned upon their joints have muscles for the means of doing so, whose insertions are much nearer to the centre of motion than the point is to the centre of gravity of the height to be raised.*

OF THE WHEEL AND AXLE.

This power acts entirely on the same principle as the lever, and has in consequence been termed the perpetual lever. In the axle the power is applied to the circumference of a wheel by means of a rope or otherwise, the weights raised being fastened to a rope which winds round the axle, in order to overcome the resistance or elevate the weight. By means of this power, with a small force a great burden may be elevated by a rope which warps round a cylinder, by the aid of a handle, or by means of cogs or bars used as levers, acting on the circumference.

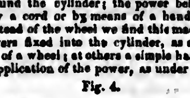
Fig. 3.



Suppose that B C represents the radius of a cylinder, and that B A represents the arm of a lever, by which the power A acts; if the length of B A is to that of B C as three to one, a power of one hundred pounds at A acting in a perpendicular direction at A B will balance a weight E of one hundred pounds. Hence it follows, that to elevate a weight by means of this machine, it is required that the power A should be to the weight E as the radius of the cylinder B C is to the lever B A; or, which amounts to the same thing, as the radius of the cylinder is to the radius of any wheel or handle by which it is turned. If in a state of equilibrium, the power is less than the weight, and that in the proportion of the radius of the cylinder to that of the handle which turns it; so in a state of motion the power has more velocity than the weight, and that in proportion as the radius of the handle or wheel that turns it is to that of the cylinder. This rule supposes that the power is always perpendicular to the radius by which it acts; for the direction of the weight is always perpendicular to the radius of the cylinder, since the cord that sustains it is always a tangent to its circumference.

This machine is often constructed with a cylinder, at the ends of which are placed pivots or axles, turning on solid pieces of timber; and the weight intended to be raised is fixed to the end of a rope, which is coiled round the cylinder; the power being applied either by a cord or by means of a handle. Sometimes instead of the wheel we find this machine made up of levers fixed into the cylinder, as spokes into the nave of a wheel; at others a simple handle serves for the application of the power, as under:—

Fig. 4.

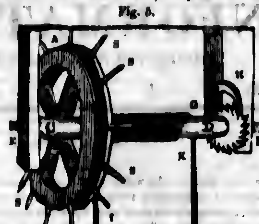


The effect is still the same, only that the rotation is less uniform. In some cases the cylinder is horizontal, as in the above figure, and in some kinds of these machines called cranes; in others it is vertical, as in the capstan, &c. But whether the cylinder be horizontal or vertical, this machine has a manifest advantage over the simple lever in point of convenience; for by the continual rotation of the wheel, the weight may be raised to any height, or from any depth; while by means of a lever it can only be elevated a little way higher than where it rests.

* See some instructive discussions on this interesting topic in Paley's Natural Theology, chapters 7 and 8; also, Animal Mechanics—Library of Useful Knowledge.

Where A B is the wheel (as represented below),

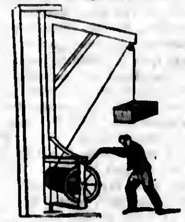
Fig. 5.



and E D F its axle, P the moving power, and W the weight to be raised by means of the rope K coiling itself about the axle, it must be evident that when the large wheel has made one revolution, the weight P will have descended through a space equal to the circumference, and as much of the cord I by which it is suspended will be wound off. On the other hand, the weight W will have ascended only through a space equal to the circumference of the axle; and hence just as much of the rope K will be wound upon it. As the circumference of the wheel, therefore, is to that of the axle, so will the velocity of the moving power be to that of the weight to be raised, and of consequence such will be the force of the machine. Thus, if the circumferences of the wheel be eight, ten, or twelve times as large as that of the axle, one pound applied to the circumference will counterbalance eight, ten, or twelve pounds applied to the axle, and a small additional weight will raise it up.

In great efforts, as it is necessary that the arms of the lever of power should be very long, when, therefore, it is extremely inconvenient to make them so, and when to multiply the number of them would weaken the head of the cylinder too much, it has been the practice to unite the extremities of the radii, or cogs, by a circumference, and form a kind of wheel to which other cogs are adapted, by which it is turned by men; as may be seen in the wheels used in quarries, and for cranes, as represented below.

Fig. 6.

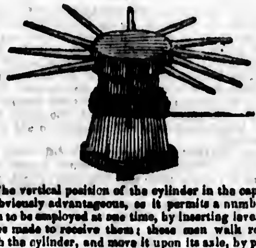


Sometimes cranes are moved by handles S S, &c. (fig. 5.), placed in the circumference of the wheel, which is turned by men's hands. Sometimes the wheel is hollow, and internally provided with steps, on which a man, who is inclosed in the wheel, continually sets his feet, as if he were ascending a stair; the wheel consequently yields to his weight, turns round, and coils up the rope which raises the weight above its axis. When the crane is to be turned by means of men's hands, it may advantageously have cogs all round the circumference, in which a small treddle may be made to work, and be turned by a winch, as represented in fig. 6. Thus, the power of the man who works it will be greatly increased; for his strength will be augmented as many times as the number of revolutions of the winch exceeds that of the axle D, fig. 5, when multiplied by the excess of the winch above the length of the semidiameter of the axle, added to the semidiameter, or half the thickness of the rope K, by which the weight is drawn up. Thus, supposing the weight of the diameter of the rope and axle taken together to be twelve inches, and, consequently, half their diameter to be six inches, so that the weight W will hang at six inches perpendicular distance from under the centre of the axle; let us imagine the wheel A B, which is fixed on the axle, to have eighty cogs, and to be turned by means of a winch, six inches long, fixed on the axis of a handle of eight staves or rounds, working in the cogs of the wheel. Hence is is evident that the winch and handle would make ten revolutions for one of the wheel A B, and its axis D, on which the rope K winds in raising the weight W; and the winch being no longer than the sum of the semidiameters of the great axle and rope, the handle could have no more power on the wheel than a man could have by pulling it round by the edge, because the winch would then have no greater velocity than the edge of the wheel has, which is supposed to be ten times the velocity of the raising weight; so that, in this case, the acquisition of power would be *ten to one*; but if the length of the winch be twelve inches, the power gained will be as *twenty to one*; and if eighteen inches, which is sufficient length for any man to work with, then the acquisition of power will be as *thirty* to *one*; because the velocity of the handle would be thirty times as great as that of the raising weight. And the absolute force of any machine is exactly in proportion to the velocity of the weight raised by it; for none of the mechanical powers are capable of gaining both power and velocity at the same time.

In every kind of crane, it is necessary to have a racked-wheel, as represented at G, on one end of the axle, with a catch H to fall into its teeth, which will at any time support the weight, and keep it from descending if the workman should happen to slip his hold; for in such a case, if there were not a racked or safety-wheel, dreadful accidents would occur in case of suddenly letting go the winch, which would run backwards with such irresistible force, that it would inevitably kill the men working it. For want of this precaution, also, terrible accidents have happened to people inclosed in cranes, by their inadvertently missing a step.

The capstan is a real windlass, and differs only in the position of the cylinder being vertical in place of horizontal, as in the windlass or crane. The manner of power acting upon a resistance or burden, by means of a wheel and axle or windlass, is entirely applicable to the capstan, but the latter is more advantageous. Capstans are often fixed in ships, to raise anchors or other burdens, to which cables are fastened, which are rolled or coiled upon the cylinder, as represented below:—

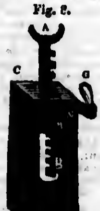
Fig. 7.



The vertical position of the cylinder in the capstan is obviously advantageous, as it permits a number of men to be employed at one time, by inserting levers in holes made to receive them; these men walk round with the cylinder, and move it upon its axle, by pushing the levers before them; and with this additional advantage, that there is no intermission of the power employed.

One of the most useful machines by which a great resistance or weight may be overcome by a small force, is the *creek or jack*. It consists of a perpendicular iron bar, as at A B in the following cut:—

Fig. 8.



This bar is provided with teeth on one of its sides, and works in a moveable case C D; the teeth of the bar fit into those of the nut D D, which turns upon an axle by the means of its handle G N. The action of the nut protrudes the bar, and the weight is raised in consequence, and placed at its head A. When the exertion that each tooth of the nut makes in D to raise the bar, is considered as a weight applied to a lever, it is evident that the power applied to the handle is to that weight as the radius of the nut is to the arm of the handle G N: from which it may be observed, that, by making the radius of the nut very small in proportion to that of the handle, a very considerable weight may be raised by a moderate force.

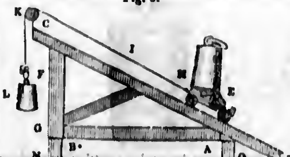
INCLINED PLANE.

The inclined plane is that which forms an angle with the plane of the horizon. This angle may be infinitely small, and then it is confounded with an horizontal line; on the contrary, it may be a right angle, and then the plane becomes vertical; between these two extremes are comprised all the other degrees of inclination.

The principle on which the whole theory of the inclined plane is founded is this: That the time which a rolling body takes to descend upon an inclined plane, is, to the time in which it would descend vertically by its absolute gravity from the highest part of the plane, in the ratio or proportion which the length of the plane bears to its perpendicular height; a body, therefore, placed upon an inclined plane, is partly sustained by the plane itself; and, therefore, a weight or power considerably inferior to that of the body itself is able to support it in its situation on the plane, and even to cause it to ascend. On this account it is, that, in making reservoirs for water, trenches, or fortifications, or in clearing the earth away from the foundations of buildings, the wheelbarrows or other vehicles employed are made to ascend upon a plank in scaffolding, which is placed in the direction of an inclined plane.

This power is represented by the following cut, and the advantage gained by it are exactly in the proportion of the length of the plane to the perpendicular height of it:—

Fig. 9.



Thus, let A B be a plane parallel to the horizon, and C D one inclined to it; suppose, also, the whole length C D to be three times as great as at the perpendicular height G F; in this case the machine E will be supported upon the plane C D, and kept from rolling down upon it by one-third part of its weight.

The force with which a rolling body descends upon an inclined plane will be to that with which it would descend by the power of gravity, as the height of the plane is to the length of it; for, supposing the above machine E to be placed on a plane parallel to the horizon, it will remain at rest on any part of it where it may be placed, and would continue in that situation for ever, unless impelled by some power. But if the plane C D, on which it is above represented, were to be so elevated that its perpendicular height C G would be equal to one-half of its length C D, then the machine E will roll down with half its own weight; for it would require a power (acting in the direction C H) equal to half its weight to keep it from rolling. If the plane C D be elevated so as to be perpendicular to the horizon, the machine E will descend with its whole force of gravity, for this simple reason, that the plane contributes nothing to its support or hinderance of it; for which reason it must require a power equal to the whole force of gravity to keep it from descending.

As the wheels of the machine E are made to move on axles, and the machine is furnished with a staple H, at the back part, for the reception of a rope I, which is fastened to it; if this rope go over the fixed pulley K, and have its other end tied to the ring in the weight L; if the specific gravity or weight of the weight L were equal to the machine E, together with the weight placed on it; and if the length of the perpendicular G F were equal to the length of the plane C D, the weight L would just support the machine E with its appendages; and the application of a very small force would either make it ascend or descend. In the time that the machine would move from C to D, it must rise through the whole height of the plane G F, and the weight will descend from K to N, through a space equal to the whole length of the plane C D.

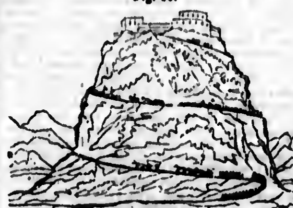
If the plane were now made to move on rollers or wheels placed at N O, and the machine to be supported upon it, the same power will draw the cylinder up the plane, provided the pivots of the wheels be small, and the wheels themselves pretty large. For let the whole machine C D N O be equal in height and length, be furnished with four wheels, and the machine E be laid upon the lower end of the inclined plane C D, and the rope I be extended from the frame of the machine E about six feet parallel to the plane C D, and fixed in that direction to a hook in the wall, this will be sufficient to keep the machine from rolling off the plane. Let the end of a rope be fixed to the end of this apparatus at D, and to the other extremity of this rope let a weight be attached of the same specific gravity as that which drew the machine E up the plane before; and if this is put over a pulley at a little distance, it will draw the whole apparatus C N O D along a horizontal plane, and under the machine E; and when the apparatus has been drawn the length of a plane equal to the length of the apparatus G D, the machine will be raised to C on the inclined plane, which is equal to the perpendicular height G C, above that part B A which may be supposed to represent the horizon.

Hence it is evident that the mechanical advantage gained by the inclined plane is in proportion as the length of the plane exceeds its height. Thus, if a weight of *four* ounces is laid on an inclined plane, the length of which is to its height as two to one, as is the case with that represented above in our cut, it will be counterbalanced by a weight of two ounces, drawing in the line of the rope from H to K, parallel to the plane; or if the length of the plane is to its height as four to one, then the body will be sustained by an ounce only. Hence, in drawing a cart up a hill, if the power of the horse bears the same proportion to the weight of the cart as the height of the hill to its declivity, then the waggon will not run back, and a small additional force will enable it to advance.

The inclined plane, viewed as a mechanical power, may easily be reduced to the lever, because the power acquired by it is always in the proportion of the length to the height, upon the same principle as the power acquired by a lever is in the proportion of the long arm to the short one. To exhibit the reason of the power of an inclined plane, therefore, we have only to construct a lever, the long arm of which is equal to the length of the plane, and the short arm to the height of it; consequently, whatever weight put upon the long arm counterpoises or equilibriates another weight put upon the short one, will also keep the same weight from rolling down the inclined plane.

It is upon the principle of the inclined plane that all roads leading over eminences are constructed. We can easily see that it would be next to an impossibility to ascend a precipitous mountain, as represented in the following cut, without this simple contrivance. The road being cut in a horizontal inclined plane, in the manner of a screw, the inclination is rendered gradual, and it can now be ascended with comparative ease. Waggons filled with stones may be dragged to its summits by the aid of a power equal to about half their weight (varying of course with the inclination of the plane), by the means of horses or other animal power.

Fig. 10.



Although the wedge is ranked as a distinct mechanical power, it must be regarded as belonging to the inclined plane, as it is, in point of fact, nothing more than a *double inclined plane*. To the same mechanical power may also be referred all cutting instruments which act as wedges, as knives, hatchets, &c.

From the same theory of the inclined plane, also combined with that of falling bodies, we deduce some of the most remarkable properties of the pendulum.

THE WEDGE.

The wedge is one of the six simple machines called mechanical powers. It is of a triangular form; the thinnest part is called the point, as in the following cut:—

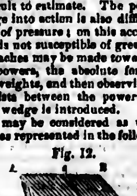
Fig. 11.

and the thicker end B, the head or base of the wedge.

The action of the wedge agrees most with that of the inclined plane. It is made use of to cleave, to raise, or to compress bodies; and to put it in action, the blow or stroke is usually given with a hard body, such as a sledge-hammer or mallet, although sometimes the pressure of a weight is employed. The resistance which may be overcome by means of the wedge often depends upon the tenacity of the parts, which is difficult to estimate. The percussion which puts the wedge into action is also difficult to judge of by the effects of pressure; on this account the theory of the wedge is not susceptible of great precision; although approaches may be made towards accuracy by substituting powers, the absolute force of which is known, as of weights, and then observing what proportion there exists between the power and the resistance when a wedge is introduced.

The wedge may be considered as two equally inclined planes, as represented in the following figure:—

Fig. 12.



Suppose D O F and C E B joined together at their bases *e* E F O, D C is the whole thickness of the wedge at its back A B C D, where the power is applied, E F is the depth, A O the length of one of its sides, equal to C F the length of the other side; and O F as its sharp edge, which is entered into the wood, or other matter to be split, by the force of a hammer or mallet striking perpendicularly upon its base A B C D. Thus, A B in the following cut is drawn into the cleft C D E F.

Fig. 13.

The wedge represented in this figure has a truncated or blunted point; wedges of this shape being always used where the opening is sufficiently wide to admit of an obtuse point being introduced. If the wedge is used for cleaving timber, there is a cleft made for its reception, and it is forced at the back by percussion, as already observed. The friction of the faces of the wedge with the timber should be sufficient to prevent its recoil. But to prevent this, recourse is had to making the sides of the wedge rough; for after the stroke of the mallet, the wedge, unless its weight were equivalent to the attraction of the parts of the timber to be separated, would presently be forced back from the place to which it had been driven by the mallet; and it is chiefly the roughness of the sides of the wedge, and the parts of the wood in contact with it, which, in that operation, keep the wedge from receding. It is that roughness, too, and the bluntness of the edge, which sometimes prevent the wedge from being moved by the stroke of the mallet; for were it not obstructed by roughness and bluntness, it would, according to what we have just now observed, be always driven forward, even by the least percussive force. When the timber does not cleave at any distance before the wedge, there will be an equilibrium between the power impelling the wedge downward, and the resistance of the wood acting against the two sides of the wedge; if the power be to the resistance as half the thickness of the wedge at the back is to either of its sides, and if the power be increased so as to overcome the friction of the wedge, and the resistance arising from the cohesion of the timber, the wedge will be driven in, and the timber split. But when the timber splits, as it commonly does, before the wedge, the power impelling the wedge will not be to the resistance of the timber as half the thickness of the wedge is to one of its sides, but as half its thickness is to the length of the other side of the cleft, estimated from the top or acting part of the wedge; for if we suppose the wedge to be lengthened down to the bottom of the cleft at E F, the same proportion will hold—namely, that the power will be to the resistance as half the thickness of the wedge is to the length of either of the sides; or, which is the same thing, as the whole thickness of the wedge is to the length of both its sides.

To prove this, let us imagine the wedge to be divided lengthways into two equal and similar parts; in which case it will evidently become two equally inclined planes, as may be seen in fig. 12, *e* B E C F. This shape of a wedge may be advantageously used for removing a moulding, or other projection, which is attached to a flat wall. It is evident, that when this half wedge is driven its whole length C F between the wall and mouldings, its inside *e* E F will have separated a quantity of moulding equal to its own length at least. But from what has already been shown concerning the inclined plane, it appears, that, to have an equilibrium between the power impelling the half wedge and the resistance of the moulding, the former must be to the latter as E B to C F, that is, as the thickness of the base which receives the stroke is to the length of the side against which the moulding acts. Since, therefore, the power upon the half wedge is to the resistance against its side as the half back E F is to the whole side C F, it is plain that the power upon the whole wedge, where the whole thickness is double the half back, must be to the resistance of both its sides as the thickness of the whole back is to the length of both sides of the cleft, when the timber splits at any distance before the wedge; for, when the wedge is driven quite into the timber, and the latter splits at ever so small a distance before it, the top of the wedge then becomes the acting part, because the timber does not touch it any where else. And since the bottom of the cleft must be considered as the place where the whole resistance is accumulated, it is plain, from the nature of the lever, that the farther the *power* is from the *resistance*, it acts with the greater advantage.

It has been imagined by some that the power of the wedge was in the proportion of its thickness to the length of its sides; but this cannot be the case, from what we have already shown. We have proved that the wedge is composed of two inclined planes, each of which has a perpendicular height of only one-half the thickness of the wedge itself. It is therefore evident, that, as the power of the inclined plane is always as the length to its perpendicular height, that the power of each of these inclined planes of which the wedge is composed, must be as the length of one side to half the thickness; and, consequently, the power of both must be as the length of both sides to the whole thickness.

If one tumbler is placed within another, as shown at fig. 14, and even a gentle pressure used to the inner tumbler, it is certain to burst the sides in one or more parts. It will be manifest upon a slight consideration.

There is one general theoretical principle, which always seems to hold good respecting the wedge, viz. that its power is increased by diminishing the angle.

Fig. 14.

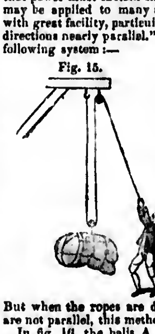
All instruments designed for cutting or stabbing, such as knives, swords, punches, and hatchets, are classed with the wedge. In short, they have at least two inclined planes, sometimes four or more, which form among them an angle more or less acute; nails, pins, and needles, are also included in this class.

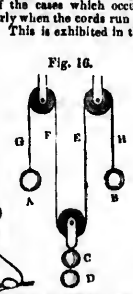
OF THE PULLEY.

The pulley is a small wheel of iron or wood, which is moveable upon its axis, with the circumference hollowed, to receive the cord, which is attached on the one hand to the moving power, and on the other to the resisting force. The wheel or pulley is usually fixed in a block or case, which admits the rope or cord to pass freely over the circumference of the wheel; and the gorge of the pulley, that is, the hollow part of the circumference which receives the cord, is usually hollowed out angularly, and not round; so that the cord, being in some measure pinched or compressed in this angle, will not be liable to glide or slip in its motion. The pulley is said to be *fixed* or *moveable* according as the block is fixed, or rises and falls with the weight. When several pulleys are associated together, they are called a *muffle* or *polyspaston*, of which some are in a fixed block, and others in a moveable one.

Some authors have explained the nature and effects of the pulley, when fixed as a lever, of the first order, and a moveable one as belonging to that of the second order. Others maintain that it is not applicable to the lever; among these was Professor Hamilton, who says that "the pulley cannot properly be considered as a lever of any kind; for when any power sustains a weight by means of a system of pulleys, that power will sustain the same weight if the pulleys be removed, and the ropes be brought over the axles on which the pulleys turned. If the weight were to be raised up, there would in this case be a very great resistance from the friction of the ropes on the axles; and it is merely to avoid this resistance that pulleys are used, which move round the axles with but little friction." "One of the most simple and natural methods," says Dr Gregory, "of computing the power and explaining the effects of the pulley, is by considering that every moveable pulley hangs by two parts of the same rope equally stretched, which must sustain equal parts of the weight; and, therefore, when one and the same rope goes round several fixed and moveable pulleys, since all its parts are equally stretched, the whole weight must be divided equally among all the ropes by which the moveable pulley hangs. And, consequently, if the power which acts on one rope be equal to the weight divided by the number of ropes, that power must sustain the weight. This principle may be applied to many of the cases which occur, with great facility, particularly when the cords run in directions nearly parallel." This is exhibited in the following system:—

Fig. 15. Fig. 16.





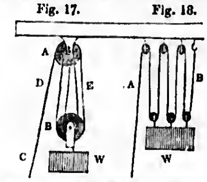
But when the ropes are drawn in directions which are not parallel, this method may lead to error.

In fig. 16, the balls A B are equal in weight to the balls C D; consequently the weight is equally divided by the balls A B, and are in equilibrio; each of the cords G E F H have an equal tension, and the slightest power applied to either of the balls A B would overcome the power of the balls C D; and by pulling the cords, the central balls would be elevated, while the ball A would sink, and B would remain stationary; and thus, by dividing the resistance or weight upon one or more cords, you are able, by pulling the one, to overcome the resistance proportionally. Upon this principle the man represented pulling the rope in fig. 15 can consequently raise nearly twice his own weight, by drawing a cord which has only half of the resistance.

A fixed pulley, fig. 17, A, has no mechanical advantage, as the power and the weight are equal. It is, however, of considerable convenience in accommodating the direction of the power to that of the resistance. Thus, by pulling downwards, we are able to draw a weight upwards. By means of this simple machine, a power, in whatever direction it may be, can be opposed to a resistance in a contrary direction.

The single moveable pulley, or runner, is shown in fig. 16 above, to which the balls C D are attached.

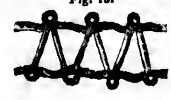
Fig. 17. Fig. 18.



In this machine the same rope extends from C, which represents the power, to the fixed point of the rope, and has an equal degree of tension throughout its whole length. Consequently it is evident that this tension is equal to the power, for in that part of the rope C A between the power and the fixed pulley, the power would be supported by this tension. The weight W is supported by the four cords between D and E. The effect of the weight of the pulley B, if taken into account, it is only necessary to add to it the weight.

In fig. 18, the tension is equally divided among the six ropes, between A and B, which sustain the weight W; and if there were fifty such pulleys, and the ropes running from one to the other in the same manner, each of these would bear its proportional share of the tension. This principle applies to the lacing of stays, beds, &c., as represented below.

Fig. 19.



By the aid of pulleys, burthens are elevated with greater ease, and in a more convenient manner, than they otherwise could be; because the motion is continued, and its direction may be changed so as to bring the whole force which is applied to it into immediate action; for by this means a horse, which can only exert his force in an horizontal direction, is able to overcome a vertical resistance. Burthens are moved more easily by pulleys, because a great weight may be elevated by a small force properly applied. Thus the power applied to a pulley draws in all directions without impediment, in consequence of the cord by which it acts being always a tangent* to the circumference of the pulley, and consequently always perpendicular to the radius. In proportion as the distance of the powers applied to pulleys is more distant from the axis, so is their force the greater in proportion, whether the cords run in several grooves, or several pulleys of different diameters turn upon the same axis. Consequently, those powers which act at the greatest distance from the axis will have the advantage over the other.

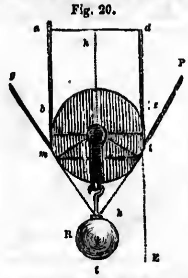
Pullies are of much use in practical mechanics, for by their means great weights may be raised to any height more expeditiously than by any other known method. Besides, their lightness and smallness fit them for being readily and easily conveyed from one place to another. At sea they are of universal utility, for hoisting the sails and yards, and tightening ropes, &c.

It is said that Archimedes, a famous geometrician of Syracuse, who flourished about 220 years before the birth of our Saviour, by means of a machine composed of pulleys, drew up a ship along the strand, in the presence of Hiero, king of Syracuse. But this, although it appears well authenticated, is doubted by various writers, in consequence of the great friction which is attendant on the application of blocks and pulleys, which arises from three causes—1st, The diameter of the axis bearing a considerable proportion to that of the wheels; 2d, Their rubbing against their blocks, or against one another; 3d, The stiffness of the rope that goes over and under them.

* A tangent is a right line drawn perpendicular from the extremity of the radius, and which touches the circumference of a circle without cutting it.

The following figure will explain how a pulley may be considered as a lever of the second order:—

Fig. 20.



This pulley has all the properties of a lever of the second order, when the resistance R is attached to the neck *o i*, and one of the ends of the cord which passes under the pulley is attached to the fixed point *a*, while the other is drawn or sustained by the power *d*; the pulley then becomes what is termed a moveable pulley, and is elevated with the weight; which, consequently, renders it analogous to a lever of the second order *b e*, of which the fulcrum or prop is at *b*, and is divided into two equal parts *b c*, *c e*, by the direction *c* I, of the resistance R. It is on this account only necessary that the power *d* should possess half the force R to keep it in equilibrium; and if the weight is elevated, the power *d* acts through twice the space of that of the resistance R, and consequently with double the velocity. For suppose the centre *c* of the pulley is carried to the point *h*, then there only remains under the line *d a* the portion of the cord which passes under the pulley; the two portions *b a* and *e d*, which mark the space, run through the pulley; then the power has a velocity double to that of the resistance. In this case the cord embraces half the circumference of the pulley, and the directions of the two powers are parallel. The arm of the lever of power is then the diameter *e b* of the pulley, that of the resistance is only the radius *c b*; because, to keep an equilibrium, it is necessary that the power should be to the resistance as the radius is to the diameter.

But if the direction of the power is oblique—as for instance if one end of the cord is attached to the fixed point *g*, while the other is sustained by the power P—it still represents a lever of the second order *m l*, of which the fulcrum will be at *m*, and which will be divided into two equal parts *m i*, *i l*, by the direction *c* I, of the resistance R, as the radius *c b* is to the space *l m* of the arch embraced by the cord.

If instead of drawing the cord upwards it is necessary to draw it downwards, a fixed pulley is placed above the moveable pulley, which makes no change in the effect of the power.

By means of a union of pulleys, a very great weight may be raised by a small force; for it is demonstrable that the force necessary to sustain a weight by means of several pulleys, is to the weight itself as unity is to double the number of moveable pulleys. So that the number of pulleys and the power being given, the weight which the system of pulleys is capable of sustaining is easily found by multiplying the power by double the number of moveable pulleys. For example, suppose that the power is equal to *sixty* pounds, and that the number of moveable pulleys is *three*; *sixty* multiplied by six (being double the number of three) will be equal to three hundred and sixty; which is the weight that this system of pulleys is able to sustain.

By the same mode of calculation, the number of moveable pulleys being given, together with the weight which the tackle is capable of sustaining, the power will be found by dividing the weight by double the number of moveable pulleys. Suppose the weight equal to 1600 lbs., and the number of moveable pulleys to be 8; 1600 divided by 16 (that is, double the number of the pulleys), gives the quotient 200 lbs.; which is the force necessary to sustain 1600 lbs., with such an union of pulleys.

To find the number of moveable pulleys which are requisite to sustain a given weight, with a given power, it will be necessary to divide the weight by the power, and that case half the quotient will be the number sought. Supposing the weight to be 1000 lbs., and the power 100; the apparatus ought to have 10 moveable pulleys; for 1000 divided by 100 gives 20 to the quotient, the half of which is 10.

Mr Nicholson, however, says, "It may be observed that, in all contrivances by which power is gained, a proportional loss is suffered in time. If one man, by means of a tackle, can raise as much weight as ten men could by their unassisted strength, he will be ten times as long about it. It is convenience alone, and not any actual increase of force, which we obtain from mechanics. This is shown by the following example:—

"Suppose a man at the top of a house draws up ten weights, one at a time, by a single rope, in ten minutes. Let him have a tackle of five lower pulleys, and he will draw up the whole ten at once, with the same ease as he before raised up one; but in ten times the time, that is, in ten minutes. Thus, we see the same work is performed in the same time, whether the tackle be used or not; but the convenience is, that if the whole ten weights be joined into one, they may be raised with the tackle, though it would be impossible to move them by the unassisted strength of one man. Or, suppose, instead of ten weights, a man draws ten buckets of water from the hold of a ship in ten minutes, and that the ship being leaky, admits an equal quantity in the same time. It is proposed, that, by means of a tackle, he shall raise a bucket ten times as capacious. With this assistance he performs it, but in as long a time as he employed to draw the ten, and therefore is as far from gaining on the water in the latter case as in the former."

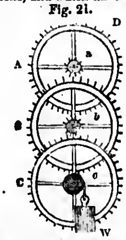
WHEELS may be regarded in the same light as pulleys, to be an assemblage of levers.

There are two kinds of wheels: the first always turn in the same space upon an axis fixed to the centre of the wheel, the journals of which turn in cavities fitted for their reception, and which serve as props; as may be instanced in the wheels of mills, clocks, &c. Wheels of this kind receive or transmit the movement by teeth, or cogs, placed round their circumference.

Those wheels of the other kind which turn upon their circumference, have their centre or axle placed in a direction parallel to the plane on which they move; as may be instanced in the wheels of carts, waggons, and coaches. These have two different movements; the one of their centre, which advances in a straight line; and the other, which consists of all their parts, performing a rotatory motion round the centre. The first kind, or wheels which have but one movement on their own axles, are put in motion by placing on the same axle a small wheel called a pinion, the teeth of which agree or fit into the teeth of another large wheel. In great machines, trundles are frequently substituted for pinions, and perform their office; these are cylinders or spindles, placed parallel to each other, in two plain pieces of wood at the top and bottom. The teeth of the wheel then catch the spindles of the trundle, as they do the cogs of the pinion. The same species of mechanism applies to both; consequently, an explanation of the hooking or catching of wheels and pinions will suffice for both.

This species of wheel is considered as a lever of the first order, the arms of which are the radii of the wheels and pinions, and which have their prop at the axle.

Fig. 21.

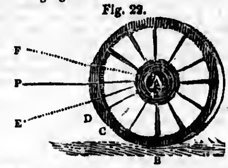


Let A B C, fig. 21, be three wheels of the same diameter, and *a b c* their corresponding pinions; the pinion, or what is the same thing, the cylinder *c*, sustains the weight W; the wheel C, which has the same axle as the cylinder *c*, catches the pinion *b*; the wheel B, which has the same axle as the pinion *b*, catches the pinion *a*; the wheel A, which has the same axle as the pinion *a*, is supposed drawn at its circumference by a rope passing over it at D, to which a power is attached; and the whole system is in equilibrium. In this case the weight W acts by the radii of the pinions, but the power acts by the radii of the wheels. Suppose the radii of the wheels to be four times those of the pinions, and that the first are eight inches, and the other two inches: to preserve an equilibrium, it is necessary that the power should be to the resistance as the product of the arms of the lever of resistance is to the product of the arms of the lever of power; that is, in an inverse ratio of the length of the arms of the lever: these products are found by multiplying the one by the other; that is, the radii of the wheels and the radii of the pinions. The first product will be 512, and the second 8; in which case the supposed power at D ought to be the weight of W, as 8 is to 512, or as 1 is to 64. It consequently follows, that, to preserve the equilibrium, whatever is the diameter of the wheels and the pinions, the power is to the resistance as the product of the radii of the pinions is to the product of the radii of the wheels.

Machines of this form appear capable of giving a great advantage to the force or power over the resistance; this advantage, however, is gained at the expense of time or velocity, when the machine passes from a state of rest to that of motion; because there is a reciprocality betwixt the time lost and the time which is gained.

Respecting wheels of the second order, which have two kinds of motion, such as those of carts, the centre of which advances in a straight line, while the other parts turn round on it, they may be regarded as a lever of the second order, the action of which is repeated as often as there is supposed to be points in the circumference. Each of these points or spokes is the extremity of a radius A B, as represented in the following figure:—

Fig. 22.



These are supported at the end by the ground B; and the other extremity A, charged with the axle which supports the carriage, is at the same time drawn by the power P, which gives it a progressive motion; so that, if the ground were quite level, and the circumference or rim of the wheel devoid of inequalities; if there were no friction between the nave and the axle; and if the direction of the power remained constantly parallel to the plane, then a small force would draw a *very heavy* carriage or carriages, as may be witnessed in one horse drawing on a railway from ten to fifteen tons of coals or other goods; for the resistance which proceeds from the weight rests entirely upon the ground by the radius or spoke A B, or by another spoke which immediately succeeds it. But on common roads these circumstances are seldom or never found to obtain, as roads are never perfectly level, and the wheels of carriages are often so unevenly constructed, besides having the heads of the large nails, by which the rims are attached, left protruding; all of which tend to diminish the animal power employed in propelling carriages and other machines. The consequence is, that, from these causes, the wheels are supported by a radius A C or A D, which is oblique to the direction of the power A P, or to the direction of the resistance A B. Consequently, the weight which is presumed to press at A resists the power, which can only make it advance by causing it to rise as much as the point C or D is above the point B. The animal is therefore obliged to sustain part of the weight of a carriage as if it were placed upon an inclined plane. Even when the circumferences roll upon perfectly level surfaces, there is considerable friction between the axletree and the nave.

These inequalities in the roads have the effect of even changing the direction of the power. For a horse placed higher or lower, in consequence of the unevenness of the road, instead of using his force in the line A P, or parallel to the portion of the plane which supports the wheels, is frequently constrained to employ it by the line A E or A F, which is in an oblique direction to that of the resistance A B, and consequently with diminished power. A single horse may drag a waggon, cart, or carriage, upon a plane with ease, while it will frequently require several to move the same machine up a road or inclined plane.

It has been found by experience, on rough or uneven roads, that to make the horse draw in a rising line is the most effectual, as in the direction of A F; consequently the axle of the wheels should be somewhat lower than the breasts of the horses; as by this means the direction of the power approaches more to the parallelism of each of the small inclined planes which form the inequalities of the road.

Even with the precaution above pointed out, it becomes impossible to overcome some of these obstructions; in which case the next best thing to be resorted to is, to employ larger wheels, as it is evident that small ones are more liable to be entangled and retarded by ruts and hollows in roads than those which are of large diameter, as the radius of the small wheel, which bears against the ground, in rising out of a hollow in the road, is greatly more oblique to the direction of the power than the radius of the greater wheel to the direction A P. Besides, the circumference of a large wheel measures in rolling more of the road than that of the small one, its volutions are swifter, or it makes fewer revolutions in passing over a given distance, which must necessarily save a considerable portion of the friction.

OF THE SCREW.

The screw is the strongest of all the mechanical powers, but must not be accounted a simple one, as it cannot be wrought without the aid of a winch or lever, to assist in turning it. The screw is a long cone or cylinder, as represented below.

Fig. 23.

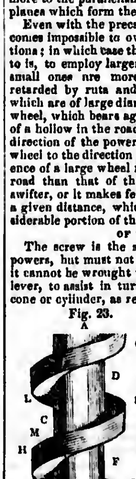


Fig. 24.

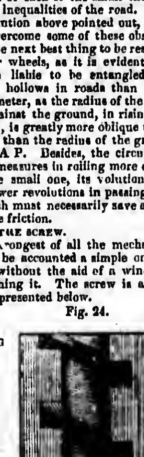
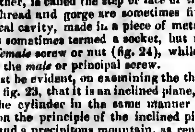


A B is the cylinder, upon the circumference of which is cut a spiral groove or gorge C D E F. The partition G H I J K is termed the thread of the screw, and the distance L M which intervenes between one thread and another, is called the step or face of the screw.

The thread and gorge are sometimes fitted into a cylindrical cavity, made in a piece of metal or wood, which is sometimes termed a socket, but more generally a *female* screw or nut (fig. 24), while the other is called the *male* or principal screw.

It must be evident, on examining the thread of the screw in fig. 23, that it is an inclined plane, and winds round the cylinder in the same manner as a road, formed on the principle of the inclined plane, would wind round a precipitous mountain, as represented at fig. 10. But this will be more easily understood by the following cut, representing part of another screw, where the threads are triangular, or acute, on their surface. The height of this inclined plane is the face or spiral of the screw, or, which is the same thing, the distance of one thread from another, its base is the circumference of the screw, and its length is estimated by that circumference, and the height of the face; for if one of the threads *a b* is developed, it will form with its pace *b c* a triangle *a b c*, and a rectangle at c. of which it is easy to find the side *a*, *b*, since the two others are known, as well as the angle at *c*: hence by a screw turning on its socket, they constitute two inclined planes sliding the one upon the other. See fig. 25, beneath.

Fig. 25.



The threads of screws are differently formed, being made in general to answer some particular purposes Wooden screws have usually angular threads, as in fig. 25, C G F. This form adds greatly to their strength, as their base, which is placed on the cylinder which supports them, is greatly larger. Conical small iron screws ending in a point have also this form of thread; as also those which are fitted for entering wood, in which they form a socket for themselves. Upon this principle also, are constructed drills and gimlets, which enter timber with ease, in proportion to the acuteness of their points. Large metal screws which are used for presses, vices, &c., are generally formed with square threads, as in fig. 23, for the purpose of increasing the friction, by augmenting the surface of each thread; as it not unfrequently happens that the principal effect of screws arises from the closeness of the friction; and as it is found that this form has the effect of preventing the cheeks or chops of vices from swerving backwards, to which they have a natural tendency by the re-action of the metal or other substance which they press between them.

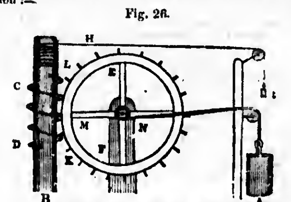
If fig. 25 be attentively examined, it will be evident that the winch E which turns the cylinder must move once round in the time that the thread performs one revolution; and, consequently, if any weight or great power of resistance were applied, the winch must turn once round in the time that the weight would move from one spiral thread to another; for example, from F to H: consequently, the force of the screw will be as the circumference of the whole circle, defined by the lever or winch E by which it is turned, is to the distance between the threads of the screw itself. Supposing, therefore, the threads to be half an inch, and the length of the winch twelve inches, the circle described by the extremity of it, where the power acts, will be nearly *seventy-six* inches, or about 152 times the distance between the threads; whence, a single pound, acting at the end of such a winch, would balance 152 pounds at the extremity of the screw, and as much more as can overcome the friction would turn the winch, and raise up the weight.

The screw is very extensively employed in mechanics. From its great powers in compressing objects, and the great dissimilarity between the speed of the handle and threads of the screw, it is more useful in compressing bodies than any of the other mechanical powers; and the same property admirably fits it for dividing space into an almost infinite number of parts. It is from this cause that it is so extensively used in the construction of many mathematical instruments, such as telescopes, microscopes, &c., where it is necessary to adjust the focus of the eyes of different individuals, by moving the eye-glass a very little nearer or farther from the object-glass. And it is by means of the screw that any degree of compression can be applied to objects. It is also used for raising weights or burdens, or for forcing backwards or forwards certain masses of a determinate quantity. For this purpose, a male and female screw are made use of, one or the other of which serves as a *fulcrum* or prop for the other. Sometimes the male screw is fixed, and the female moveable, or *vice versa*; but in both cases the effect of the screw is the same.

In the application of the screw, one of the two parts is applied to the resistance which is to be overcome, whilst the other acts as a fulcrum or prop to the machine: then, by the act of moving, the socket is made to move upon the screw, or the screw upon the socket. Supposing the machine used to be a handvice, or smith's vice, for example, one of the cheeks is pressed against the other cheek by means of the action of the screw; from which it appears that the power must move one complete round, in order to advance the resistance one pace, or spiral revolution of the screw; that is, the distance of one thread from another. When the power is applied directly to the screw, the space it passes through, or its quantity of motion, is *a c*, fig. 25, which is the measure of the circumference of the screw; and the motion of the resistance is measured by *c b*, which is the width of one space of the screw. It is, however, a common practice to turn screws, more especially large ones, with a lever or winch; hence it follows that *a c* does not measure the motive force of the power, which is, on the contrary, measured by the circumference of the circle, of which the lever D E is the radius. And as it is necessary, in order to maintain an equilibrium, that the powers should be in the inverse ratio of their velocities, it may be established as a general rule in using screws, if we make no account for the friction, that the power is to the resistance as the height of the pace of the screw is to the circumference which the power describes.

The PERPETUAL SCREW differs in many particulars from the common screw. It consists of a cylinder always turning in the same direction, which will be rendered more evident by the following representation:—

Fig. 26.

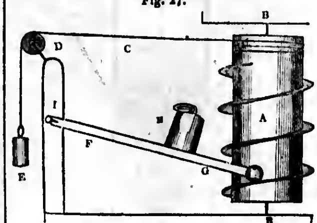


A and B are its two extremities; these being carried upon solid pivots, so that its action is perpetuated—hence its name. The threads C D of this screw, which are usually square, agree with the teeth of a vertical wheel E F, which carries upon its axis a roller or windlass G with a cord, to which is fixed the weight W, which is required to be elevated. A very small force, therefore, applied to a handle, or a light weight I, suspended to a line H, coiled round the cylinder, is sufficient to raise a considerable weight at W. But this operation requires considerable time, from the fixed law in mechanics, which should ever be borne in mind, that whatever is gained in force is lost in velocity.

In order to find the relation between the weight W and the force or power I, it must first be considered that the weight W is counterbalanced immediately by the resistance which the thread C D of the screw opposes to the tooth of the wheel, keeping the direction K L perpendicular to the radius G M. This thread C D, therefore, acts by the radius of the wheel E F, while the weight W acts by the radius or windlass A B; so that, to maintain an equilibrium, the force at M should be to the weight W as G M (the radius of the roller) is to the radius of the wheel G M; hence the relation which the weight W should have to the power I in case of an equilibrium, may be expressed in this manner: the weight is to the power as the product of the radius of the wheel multiplied by the circumference which the radius of the handle describes (if one is used) is to the product of the radius of the windlass, multiplied by the height of the pace of the screw.

The motion of the wheel being exceedingly slow in proportion to that of the handle, it follows that a very small power is capable of raising a considerable weight by means of the perpetual screw, which will be proved as follows:—If a wheel E F, fig. 26, had only nineteen teeth, and a screw which has but one thread, and which, at each round, causes only one tooth of the wheel to pass; suppose the circumference of the windlass G, or axle, to be one foot, and the circumference which the radius of the handle describes, to be five feet: when the wheel E F shall have performed an entire revolution, the weight W will be raised one foot, and the space run through by the power I will be nineteen times five feet, or 95 feet. The speed of the power I will then be to the speed of the weight W as 95 is to one; so that this power, with the effort of one pound, is capable of raising 95 pounds; and if its effort was equal to 30 pounds, it would raise 2850 pounds. If, therefore, the wheel E F had double the supposed number of teeth, that is, 38, or if the radius of the supposed handle were as long again as that which we before supposed, the same power which wrought it would produce a double effect, that is, it would raise 5700 pounds. But without changing the number of teeth in the wheel E F, or the length of the supposed radius of the handle, and if another perpetual screw is placed upon the axis of the wheel, instead of the windlass G, the thread of which ought to catch with the teeth of a second wheel having the same number of teeth as the first, and to which should be annexed the windlass which is to sustain the weight W, then the same supposed power would be capable of raising a weight nineteen times as great; in other words, this power, intrinsically only thirty pounds, would be capable of raising the amazing weight of 54,150 pounds.

Fig. 27.



To enable the reader to perceive the evident connection between the inclined plane and the screw, the accompanying diagram shows that, if instead of the body moving against the inclined plane, the inclined plane be made to move against the body, the same effect is produced. A represents a cylinder, with a spiral plate attached in the form of a screw; and around the top a cord is wound, to the extremity of which is fastened a weight E, and which, by being laid over a pulley, would cause the cylinder to turn on its axles B B.

F G is a rod with a ball at the end, while it turns at the other end on a peg, fastened to the upright post at I. By placing the weight H on the rod F G, the ball leans with considerable weight on the spiral plate; but the weight E causes the cylinder to revolve, and to raise the weight H, although it is much heavier than itself.

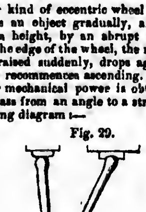
Fig. 28.

The above diagram represents what is termed the eccentric wheel. This is constructed in various ways, but the above is one of the most useful forms. It will be observed, that the axle of this wheel is placed off its centre, and that the wheel is heart-shaped. The use of this wheel is to produce a rising and a falling motion, and is employed in cotton and flax machinery, to effect a roving motion, by gradually raising and depressing the board on which the bobbins are placed, and thus covering the surface equally and gradually with the thread as it is spun. Suppose A B to be the bobbin-board, in its present position it will have nearly gained its highest point, which is, when the point of the heart touches the bottom of the board, after which it gradually sinks, until it has reached the hollow top of the heart at C, when the thread will be gradually wound downwards.

Another kind of eccentric wheel is constructed so as to raise an object gradually, and, when it has reached its height, by an abrupt termination, and hollow in the edge of the wheel, the machinery, which has been raised suddenly, drops again to its lowest range, and recommences ascending.

Another mechanical power is obtained by making two bars pass from an angle to a straight line, as in the following diagram:—

Fig. 29.



It has this property, that the power is greater the nearer it approaches the straight line, and on this account it is well adapted for those purposes where the power is required to increase, as in a printing-press. It is this power which is used by Mr Ritchie of Edinburgh in his presses.

A very simple and ingenious application of the same principle has been invented by Mr James Gall, jun., of Edinburgh, in which the power is much greater, and the machinery more simple, as will be evident from the following diagrams :—

Fig. 30. Fig. 31. Fig. 32.

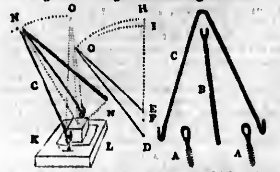


Fig. 32 exhibits the four pieces of which it is composed. A A are two screws, C is a rod of iron bent in the middle and hooked at the extremities, B is a straight bar, with a forked head to support the centre of the bent bar C. In figure 30, K L represents the board into which the screws A A are fixed, so that the hooks of the bar C will enter them, and allow it to turn in the direction N O. Between the two screws is represented a wood-cut, with its face downwards, and placed on a piece of paper with cloth under it. The bar M is then put down on the back of the wood-cut, as represented by the dotted line. Then placing the hand to the top N, and drawing it up to O, when the whole will be perpendicular, the wood-cut is pressed by the middle bar with great violence, sufficient not only to take a sharp and clear impression of the wood-cut, but even to sink the end of the bar M into the wood, or to tear out the screws from the frame.

The nature of this power is exhibited in fig. 31. F G represents the middle bar; D G the bent bar. When the middle bar F G turns on its lower end, it would describe the dotted line G H; but when the bent bar G D is brought up, it would describe the line G I, and therefore the end of the bar D F would be forced down to the point E.

As these two pieces of iron serve all the purposes of the bar, the mechanical power, and the cheeks of a printing-press, we consider this the most ingenious and simple printing-press which has yet been invented.

Having given the mechanical powers in the order in which they are generally placed, we now beg to submit a tabular view of the principles upon which these powers depend, in the manner in which they appear to us naturally to arrange themselves :—

SYNOPTICAL TABLE OF THE MECHANIC POWERS.

MECHANICAL POWERS are methods by which we gain power by losing motion.

- I. By dividing the weight between two or more parts, and giving motion to one part, we gain power.
  - 1. PULLEY. By dividing the weight by suspension on two or more cords.
  - 2. INCLINED PLANE. By dividing the weight between suspension & support.
    - 1. SINGLE INCLINED PLANE.
      - 1. STRAIGHT OR COMMON INCLINED PLANE.
      - 2. CIRCULAR, HORIZONTAL, OR PERPETUAL SCREW.
        - 1. COMMON SCREW.
        - 2. PERPETUAL SCREW.
      - 3. CIRCULAR, PERPENDICULAR, OR ECCENTRIC WHEEL.
    - 2. DOUBLE INCLINED PLANE OR WEDGE.
- II. By varying the velocity between a fixed and a moving point.
  - 1. COMMON LEVER.
  - 2. PERPETUAL LEVER, OR WHEEL & AXLE.
- III. By using only the difference of the motion of two or more bodies.
  - 1. By the combined motion of the extremities of two radii, whose other extremities do not coincide.
    - 1. By making the radii work in *different* circles.
    - 2. By making the radii work in the *same* circle.

OF THE ACCUMULATION OF POWER.

When we have made ourselves acquainted with the influence of the mechanical powers taken separately, or combined, we will perceive that they can only accumulate power, or compress any degree of velocity into a small space. It is this compressed velocity which we call *power*, and this power is again capable of impressing the original degree of velocity upon a body of an equal, or at least nearly equal, size to the first, from which it originally received the impression or impulse; but the *absolute* quantity of motion remains the same without a possibility of augmentation or diminution, by means of levers, screws, pulleys, or wedges. It is by the preserving a small quantity of motion for a certain time that at the end the great accumulation of power has been accumulated. For example, no man can by his own physical power or strength raise a ton weight from the ground, but he may be capable of raising one hundred pounds weight; and by repeating this for twenty successive times, the ton weight will have been raised by him. But even by the assistance of a lever, before a man could raise a ton weight one foot from the ground, with a power or force equal to one hundred pounds, that lever must be *twenty* or *twenty-one* feet long, and a continued force of one hundred pounds must be applied, while he goes up through a space of twenty feet, or, what is the same thing, pulls a rope down through that space. Hence it is evident that the lever only accumulates the power exerted in pulling or carrying the weight of one hundred pounds through twenty feet, and discharges the whole of it upon one foot; consequently any thing which could do this would raise the ton weight as effectually as a lever.

The accumulation of a great power can be effected by means of a long thread, chain, or rope, of sufficient strength; and to this is suspended a heavy weight. The body thus suspended may be set in motion by a degree of power little more than is required for bending the rope or chain, and will vibrate like a pendulum; and, by continuing the impulse as the body returns to the place from whence it was originally projected, it will acquire greater and greater force, or action, as the reversed arches, through which it moves, by becoming continually larger, might be made to act with such amazing force, that the suspended body could overcome almost any force opposed to it. It was upon this principle, that, in ancient times, battering-rams were constructed, for forcing open gates of fortifications, and effecting breaches in walls of garrisons. Still it must be kept in view, from the principles already stated, that the power of one stroke of the battering-ram could never *exceed*, nor even quite equal, the accumulated power of the impulses given to it in order to produce that stroke; because the stiffness of the rope, and the resistance which the weight would naturally meet with in passing through the air, would always diminish to a certain extent that power.

To effect an accumulation of power, various other devices are adopted; such as by using a very heavy wheel or cylinder, made to move upon an axis; either of which may be easily put in motion, and, if long continued, will accumulate to such a degree as to have the effect of raising weights, and overcoming resistances, as could not be effected by the application of the original moving force by itself; but which now becomes easy through the means of these agents, the wheel or the cylinder.

Mr Attwood proved, that, on this principle, a force of twenty pounds, applied for thirty-seven seconds to the circumference of a cylinder of ten feet radius, and weighing 4713 pounds, was capable of giving an impulse—at one foot from its centre—to a musket ball, equal to what it receives from a full charge of gunpowder. Still, however, the cylinder has no absolute principle of motion in itself, and, therefore, can only give that motion which it receives.

An accumulation of motion, however, in heavy wheels, is of great service in the construction of machines for various purposes, rendering them greatly more powerful and easy to be worked by animals, as well as more regular and steady, when set in motion by water, or any inanimate power. It is from this cause that flys, ballast-wheels, and others of a like nature, are usually supposed to increase the power, though, in point of fact, they rather diminish it, and act on a principle totally different.

In machines where flys are used, the first force employed must be considerably greater than what is necessary to move the machine without it, or the fly must have been set in motion some time before being applied to the machine. It is this superfluous power which is collected by the fly, and serves as a kind of reservoir, from which the machine may be supplied when the animal slackens his efforts. It is obvious that this will always be the case with animal power, as they are unable to maintain constant action, and require intervals of rest; and these, even in the very time of their progressive motion, although in many cases this is imperceptible to an observer, but for this an animal's strength would soon be exhausted.

The first efforts of a horse or other animal when applied to a machine are vigorous, and the power exerted very great, by which means he overcomes the resistance of the machine itself, and communicates to the fly considerable power. While the machine is in motion, it yields for a certain period to a smaller impulse, during which time the fly itself acts as a moving power, and the animal in the interim recovers the strength which he has lost. The machine, however, by degrees begins to slacken in its motion, which renders the renewed efforts of the animal necessary. The velocity of the machine in this case would acquire increased rapidity, but for the resisting power of the fly, and the greatest part of the superfluous power being lodged in it; hence the increase of velocity in the machine is hardly perceptible. Thus the animal has time to rest himself until the machine again requires an increased impulse, and so on alternately. The same thing is applicable to any machine which is moved by a water-power, or by means of weight; for although the strength of these cannot be exhausted in the same manner as animal power, still the yielding of the parts of the machine renders the impulse much less after it begins to move; so that the velocity is accelerated for some time, until the impulse becomes so small that the machine requires an increase of power to keep up the necessary motion.

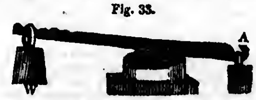
Archimedes is represented on one occasion to have boasted that he could move the earth, provided he could find a place out of it to stand on; and Bishop Wilkins said he would engage to pull up the most stately oak by means of a horse hair; but both of these were vain and extravagant boasts; as, whatever great effects are to be accomplished, a great power must originally be applied; and the great room that an immense lever would occupy, together with the excessive length requisite to make it act with sufficient force, as well as the vast weight necessarily required to give it sufficient strength, must at once show the impossibility of the thing.

COMBINATIONS OF THE MECHANICAL POWERS.

From what we have already said on the virtues of the mechanical powers, it will be seen that none of them are capable of augmenting the actual force of any acting substance; neither can any combination of them effect this: nay, on the contrary, these combinations have the effect of occasioning loss of power by the friction attendant upon their application. This is an obstacle in mechanics which it is not likely will ever be overcome; and the more complicated the machine, the greater must be the loss of power. It must therefore be evident, that, in all mechanical inventions, the simpler their construction the greater must be their effective operations; and that multiplied combinations should never be resorted to, except for the sake of convenience.

When weights are to be raised to a small distance, the lever should always be used, because, in the action of this simple machine, there is less friction than in any other of the mechanic powers. Where bodies have but little elasticity, and are to undergo a long-continued degree of pressure, this machine should always be applied. In this case, the lever of the second kind is the one to be used, which we have given below.

Fig. 33.



It is this kind of lever which is used in pressing cheese, in which case the pressure is required to be long and equable, without any very great exertion of force. A is the point of the lever with a hook, which is put through a staple fixed into a beam. F is the fulcrum on which the lever rests, and which bears upon the cheese-mould, and W is the weight which gives power to the lever.

Where much force is required, screws and wedges are to be used; but these, it must be evident, have both the disadvantage of losing their power of pressure as soon as the materials under their influence have yielded to their force; so that wedges, to have the effect intended, require to be constantly attended to, and driven home, or their power is lost; and, for the very same reason, screws must be frequently turned by means of the lever, to produce a constant pressure. To the first of these are referable the machines called oil-mills, where the pressure is produced by wedges, which are constantly driven home by means of great mallets, lifted by the force of the mill, and allowed to fall, after having been raised to a certain height. To the action of the screw belongs the apothecaries' oil-press, which is constantly turned by means of a long lever, aided by a capstan.

When it becomes necessary to raise a weight to a considerable height, the pulley is resorted to; but then there is great friction. The axis, combined with a single pulley, will generally effect the purpose, and then the friction is less than by more complicated pulleys. Cranes are a combination of these two principles, and are much used in raising packages from vessels, and placing them in warehouses, &c.

It should ever be kept in mind, that whatever a machine gains in power, it loses in time, even if there was no such thing as friction; and, in all cases where a machine gains by complication of the mechanic powers, it will lose a third by friction alone, as no machine hitherto produced has been fitted in all its parts with that accuracy which will free it from friction; and, therefore, the necessity of simplicity is obvious for complication leads to both waste of time and power.

Experience has proved that the best method of obtaining a very great power is by combining a screw with a toothed wheel, which acts in an axle *in perotrochio*, as represented in fig. 26; for by making the threads of the screw very close, and the wheel in which they are to act of a large diameter, we may increase the power to almost any degree we please, without the risk of a great degree of friction. Therefore, upon the principle which we have already pointed out, if space will permit, it will be better to increase the diameter of the wheel without adding another, as a large wheel augments the power without producing any sensible augmentation of the friction. Another thing absolutely necessary is to have the axle as small as it can be made, so that it has sufficient strength to bear the operations of the wheel.

OF THE CENTRE OF GRAVITY.

Dr Gregory defines the centre of gravity of any body, or system of bodies, to be that point about which the body or system, acted upon only by the force of gravity, will balance itself to all positions; or it is a point which, when supported, the body or system will be supported, however it may be situated in other respects.

Or, to render this more plain, gravity is that universal disposition of matter, which inclines or carries the lesser parts towards the centre or greater part, which is called weight or gravitation in the lesser body, but attraction in the greater, because it draws, as it were, the lesser body to it. Thus, all bodies on or near the earth's surface have a tendency or seeming inclination to descend towards its middle part, or centre; and, but for this principle in nature, the earth (considering its form in the universe) could not subsist as it is, for it being nearly round, and suspended in a mighty void or space, and always in motion, what, but this principle, or universal law in nature, of attraction and gravitation, should hinder the stones, water, and other parts of matter, from falling from the surface.

To illustrate this, let us suppose two men standing opposite to each other, on opposite extremes of the globe; and if each of these were to drop an iron ball from his hand, and the balls had sufficient weight and power to displace the other parts of matter of which the earth is composed, so as to make way to the centre, they would there meet, unite together, and remain fixed, and would then lose their power of gravitation, as being at the centre of gravity, and unable to fall, and only retain in themselves the power of attraction.

"The centre of gravity of a body is not always *within* the body itself; thus, the centre of gravity of a ring is not in the substance of the ring, but in the axis of its circumscribing cylinder; and the centre of gravity of a hollow staff, or of a bone, is not in the matter of which it is constituted, but somewhere in its imaginary axis. Every body, however, and every system of bodies, has a centre of gravity."

If a heavy body be sustained by two or more forces, their directions must meet either at the centre of gravity, or in the vertical line which passes through it, as may be observed in the following diagram, representing a painter's palette, whose centre of gravity

Fig. 34.

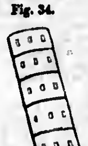


Fig. 35.

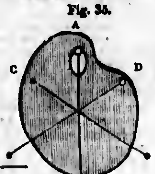
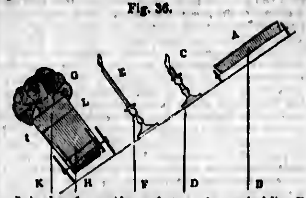


will be found in the following manner:—Supposing it to be hung upon the thumb-hole at A, a perpendicular line from the point of suspension will pass through the centre of gravity, which in this case will be between A and B. Take another point of suspension, as at C, and the line will always cut that line, or, in other words, they will coincide, as may be seen by supposing its point of suspension at D, by which it will be seen all the three lines cut the same point.

A tower, or other object, may be built off the plumb, and still stand, if the centre of gravity be supported; which can easily be ascertained by raising a perpendicular line, or by a plumb-line suspended from its top; and if the vertical line passing through the centre of gravity falls within the base on which it stands, but if that vertical line passes without the base, the tower will fall, unless it be prevented by a prop. There are many instances of walls, steeples, and towers, being built off the plumb, and which have stood for ages.

When the vertical line falls upon the extremity of the base, as at D, fig. 36, the body may stand, but the equilibrium may be disturbed by a very trifling force; and the nearer this line passes to any edge of the base, the more easily may the body be thrown over; the nearer it falls to the middle of the base, the more firmly the body stands, as may be seen at B A, fig. 36.

Fig. 36.

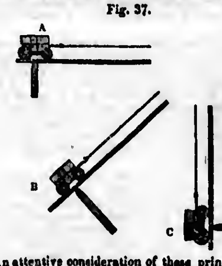


It is therefore evident, that, as the vertical line F cuts at such a remote distance from the base, that the candlestick E could not possibly stand.

It was from due want of attention to this most important principle that coaches were till lately built too high, which subjected them to the continual hazard of being upset, when running on roads or other situations where their sides were transverse to inclined planes, as represented above at H. The centre of gravity being, as above shown by the vertical line K, so much beyond the range of its base, it would be quite impossible for this carriage to move forward without upsetting, and more especially with such a load of luggage G I placed on its top; but if the coach were built no higher than the line at L, the centre of gravity would be in the vertical line H, and therefore it would be less liable to fall, especially as the baggage is placed beneath the carriage, as is now the case with most modern-built stage-coaches, where the base is broad and the gravity low.

In our observations on the inclined plane we did not mention a curious fact which should be borne in mind—that is, that when a carriage of any kind is in motion on the inclined plane, its weight is equally divided between the rope by which it is made to act and its central pressure, which may be seen by the prop supporting the plane at B in fig. 37; and that this balance will continue until the plane assumes a vertical position, as at C, when its whole weight is supported by the rope. Hence it is evident that a rope of half the strength required to support it in this position would have the effect of sustaining it while moving on a plane of almost any inclination. In that part of the diagram A, it will be noticed that the prop is placed perpendicular, in consequence of the plane being horizontal, and hence the weight or gravity is entirely on the wheels of the carriage—that is, pressing perpendicularly downward, and no strain whatever is on the rope, which, under these circumstances, requires to be exactly of the same strength as while on the inclined plane, so as to be able to move it.

Fig. 37.



An attentive consideration of these principles will show that the various motions of animals are regulated consistently with them.

"Thus," says Gregory, "when a man endeavours to rise from his seat, he thrusts forward his body, and draws his feet backward till the vertical line from the centre of gravity falls just before his feet; this enables, or indeed compels him to rise, and, to prevent falling forwards, he advances one of his feet, till the vertical line of direction is brought between his feet, in consequence of which he may stand firmly. In walking, he first extends his hindmost leg and foot almost to a right line, and at the same time bends the knee of his fore-leg a little; by this means his body is thrust forward, and the line of direction from its centre of gravity falls beyond the fore-foot, on which account he is ready to fall, but prevents it by immediately taking up the other foot, and putting it forward beyond the line of direction. After the same manner, he thrusts himself forward by the leg which is now the hindmost, till the line of direction from the centre of gravity be beyond his fore-foot, when he again sets his hind-foot forward, and thus he continues the motion of walking at pleasure. While walking, a man always sets down one foot before the other is taken up, so that at each step he has both upon the ground. But in running, he takes one up before he sets the other down, so that his feet touch the ground alternately for moments of time, and in the intermediate portion he does not touch at all. In walking up a hill, a man bends his body more forward than in walking on a horizontal road; and that the line of direction may be thrown before his feet, in walking down a hill he rather leans backwards, to prevent the line of direction from being too forward, which would occasion his fall."

In using the lever, the utmost attention is to be paid not only to the directions in which the forces are exerted. The want of this has in very many instances been the cause of much error in mechanists while seeking new inventions. One of its most simple principles has been the cause of much disappointment, which is the property of the straight lever, that equal weights, acting at equal distances from the fulcrum or prop on opposite sides, will be in equilibrio; while at unequal distances, the one has more than once been a source of error in unskilful hands.

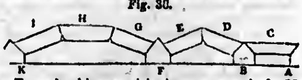
OF ARCHES.

The principle on which arches are built is that of a series of wedge-shaped stones placed in a curved line. However, to give a clear account on strictly scientific principles would occupy a much larger space than we could spare, and indeed would fill a volume. Arches are one of the most important branches of architecture, especially those over broad and rapid rivers, involving difficulties of no ordinary kind, in securing with certainty their durability and firmness, which ought always to be rigidly attended to, where not only the convenience, but also the safety of human beings, are concerned.

By an arch is meant an artful disposition of a series of stones or bricks, the under part of which is shaped like a bow, and their weight producing a mutual pressure, so that they not only support each other, but are by their combined resistance capable of bearing the most enormous weights.

If we conceive an arch in equilibrio to consist of a series of very small hard spheres of polished surfaces touching each other, and centres joined by right lines (being in fact an inverted simple catenary or chain), and that the spheres are so connected that they cannot yield to any other impulsion than that of gravity, it is very plain that the equilibrium will not be disturbed by such inversion of the curve; no part of it will be pushed outward or inward by other parts, but the whole will be supported if the feet are firmly fixed.

Fig. 38.



To render this more plain, let us suppose A, fig. 38, to be an abutment, B a pier, and C a wedge-shaped stone laid between these, it is evident that the greater the pressure which is applied to it, the more firmly it will become fixed between A and B. This is the most simple construction of a bridge, if we except the still more primitive one of a piece of wood or stone laid across a hollow, and supported at both ends from below. Advancing another step, we have only to suppose two wedge-shaped stones D E placed between two piers B F, or two abutments, and it will be evident that no pressure, however great, could force them down. Carrying the principle still farther, we have to suppose an arch composed of three stones G H I, with its sides resting against the piers F K, and it will be observed, that, although this third stone is added, it does not endanger the stability of the arch, being wedge-shaped; and the greater the pressure applied, the greater will be the resistance of the arch. In building arches, the last stone which is inserted, however many there may be, is the central stone H, which is termed the key-stone; as no sooner is it put into its place than the whole are locked firmly together.

In short, to whatever extent arches are built, the same general principle applies; for when we consider the very great quantity of heavy materials suspended in the air, such as is represented in the following cut, and compare the small cohesion which the firmest cement can bestow, we must be convinced that that cement is incapable of keeping the materials of the bridge together; and it cannot possibly be explained by any other principle than the just balance and equilibrium of its parts.

Fig. 39.

In conclusion, there is not an action performed by man in his progress through life, but what has reference to some one or more of the mechanical powers, although he is ignorant at the time by what law this action is performed. The knowledge of the mechanic powers, therefore, it must be obvious, is essentially necessary to every human being; as by our acquaintance how to apply principles so simple, we might overcome, with comparative ease, those obstacles which are daily presenting themselves, and which, without this knowledge, but too often baffle the attempts of mankind to obviate them.

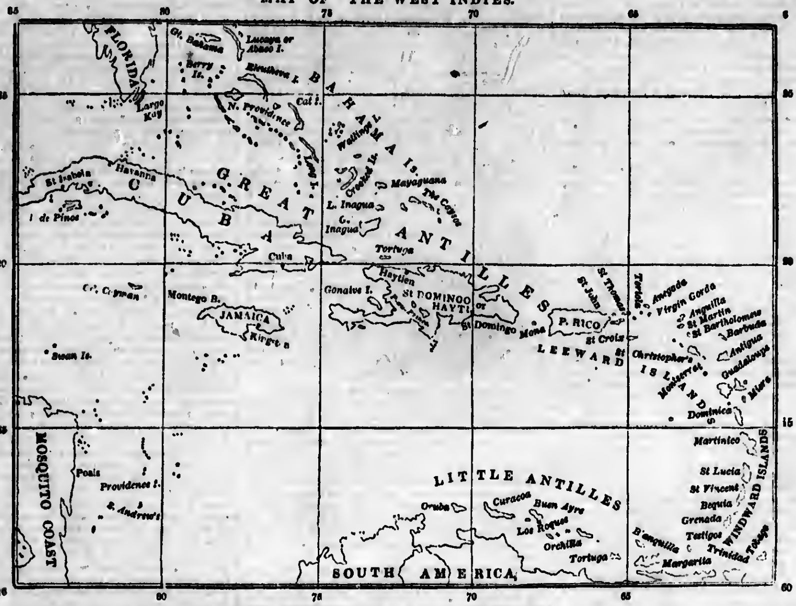
THE WEST INDIES

MAP OF THE WEST INDIES.



GEOGRAPHICAL AND RELATIVE SITUATION.

The name of the *West Indies* is given to a huge belt of islands, stretched in the form of a curve, between the continents of North and South America. They may be, in general terms, described as running in a south-east direction from the coast of Florida, on the former continent, to the Gulf of Paria, on the most north-eastern point of the latter, presenting a sort of convex breastwork to the Atlantic Ocean. They are *nautically* classed by the British under two great denominations—*Windward and Leeward*. The former are the more northern of the group, the latter the more eastern and southern, and include those properly termed the "Carribee Isles." The latter, again, are themselves divided into "*Leeward and Windward*," as will be seen by the diagram prefixed to this article. St Domingo (or Hayti) is the most southern of the Windward Islands; Porto Rico the most northern of the Leeward. Looking at the map, it would seem that these two divisions had derived their distinctive appellations from their relative position to Jamaica. Thus, in returning to Europe from that island, the navigator either holds at first a southerly course across the Carribean Sea, and through the cluster of isles so called, until, having attained the proper degree of southerly latitude, he changes his tack, and slants right across the Atlantic with a side-wind, until he catches the western breeze off the coast of Newfoundland, which enables him to run down upon any desired point of the continent of Europe; or he at once beats direct up to the eastward against the trade-wind, by short tacks, the line of the latter course subtending (to speak mathematically) the angle described by that of the former. These two courses of navigation are respectively termed the *Leeward* and *Windward* passages. It must be observed, however, that the French and Spaniards affix different meanings from the British to these terms, and apply them respectively to the relative position of the various islands.

That portion of the ocean which is thus in a manner separated from the main body of the Atlantic by this huge chain of islands, and contained betwixt them and the respective shores of North and South America (which are connected by the narrow Isthmus of Darien), is also divided into three great basins—the more northern one being called the Gulf of Mexico; the middle one, the Bay of Honduras; and the southern one (as already noticed), the Carribean Sea. The latter takes its name from that class of islands which bound this part of the ocean to the east, and anciently inhabited by a nation of cannibals, denominated Carribs or Charaibs (to be afterwards noticed), and from which Columbus afterwards styled their possessions the Carribean Islands.

The Gulf of Mexico is almost completely separated from the other two basins, by the near approximation of the southernmost point of the island of Cuba to the northernmost part of the coast of Yucatan, South America. The channel between these two points is so shallow that it is supposed they must have been at one time connected.

DISCOVERY—NATIVE INHABITANTS.

These islands were first discovered by Christopher Columbus, when engaged in his adventurous attempt to find out—not a New World, as some historians and geographers assert—but a new route to India by a western navigation, which he was led to think would prove less tedious than by the coast of Africa; and this conclusion would have been found just, if the geography of the ancients, on which it was founded, had been accurate. So firmly, indeed, was the navigator convinced of the truth and certainty of his theory, that even after the discovery of Cuba and Hispaniola (Hayti or St Domingo), he continued firm to his creed, not doubting that these islands constituted some part of the eastern extremity of Asia. Even when the discovery of the Pacific Ocean had proved his mistake, all the countries which he had visited still retained the name of the *Indies*, which he had originally given them; and after the Portuguese had succeeded in reaching India by doubling the Cape of Good Hope, they were called, in contradistinction, the "Indies of the West."* Some of the olden navigators and writers, indeed, in derision of Columbus's assumed title for these islands, designated them *Antila America*, or the Antilles, by which name even some modern geographers distinguish them. But we shall continue to call them by their original designation, by which they are best known.

The boldness and resolution of Columbus, in his first adventurous voyage across the Atlantic, can scarcely be imagined at the present day, even by those who have personally visited these tropical regions; and it is little to be wondered at that it was with difficulty he could restrain his companions from breaking out into mutiny, seizing the vessels, and turning their prows homewards. They had got into an entirely new creation, and the various phenomena they witnessed, and of which they had never before heard—the heat every day becoming more intense, the wind blowing continually in one direction, the variations of the compass, the fish flying in the air—all these things must have struck them with equal astonishment and terror. It was an era of miracles, and the modesty and strict adherence to truth manifested by Columbus in speaking of his wonderful discoveries, renders him a singular exception to the generality of navigators in those early times, and even for many ages after him. The first land discovered by the voyagers was the Bahama Islands, the most northern of the group. He afterwards visited Cuba, Jamaica, and St Domingo; and, in his subsequent voyages, touched at most of the Carribean and Leeward Islands, to one of which he gave his own name—St Christopher's

* Columbus sailed on his first voyage 3d August 1492. In 1494, Bartholemew Dias discovered the Cape of Good Hope; but it was not doubled till the year 1497, by Vasques de Gama.

Respecting the inhabitants found in the West India islands by the early voyagers, it is impossible to trace their origin with certainty, although it is most probable that they must have been the descendants of emigrants from the continents of South and North America, which countries, again, were undoubtedly originally peopled by Asiatics. It was evident, at all events, from the difference which existed in language, personal appearance, and habits, that there were at least two distinct tribes amongst them. The most powerful if not the most numerous of these were the Charaibs, already mentioned, who are by some conjectured to have derived their origin from Florida; by others, from the southern continent. The latter theory seems to be the more probable, from the fact that several similar tribes of Charaibs were subsequently discovered to exist in Guiana by other voyagers, with one of whom Sir Walter Raleigh formed an alliance during his romantic expedition to that coast in 1595.* At the time of Columbus's visit, too, and for ages afterwards, the Charaibs manifested the most implacable hereditary hostility towards the inhabitants of the other islands, whom they believed to be descendants of a tribe of Arouaks, a nation of South America, with whom the Charaibs of that continent were continually at war. These men, indeed, were the constant scourge and terror of their fellow-islanders. They seemed to consider war as the prime occupation of their lives, although amongst themselves they were peaceable, faithful, and affectionate. Like all warlike nations, they were extremely lofty in their sentiments of freedom and personal independence. Neither kings, magistrates, nor laws, existed amongst them. Their frames were extremely robust, muscular, and active; but they disfigured their complexion, which was naturally a clear Spanish olive, with paints and dyes in the most extravagant manner, and even made the most hideous scars and gashes in their cheeks, to render their appearance more terrible to their foes. The children were early initiated into their parents' barbarous habits, being taught to feed on the bodies of the captive Arouaks, and to anoint themselves with the fat of their victims. When a youth wished to assume the duties and privileges of manhood, he was subjected to dreadful bodily tortures, in order to prove his fortitude and endurance of suffering; and still more exquisite tortures were inflicted on him when he aspired to the honour of being a leader or captain. They took as many wives as they felt inclined or able to maintain; and, as in all savage nations, the women were treated with great brutality, and subjected to every species of domestic labour and drudgery. It has been well remarked, that the first decided symptom of a people emerging into civilisation is a display of tenderness towards the female sex. The Charaibs were likewise addicted to that most disgusting and unnatural practice—which seems, indeed, to have been in all ages a custom amongst the savage tribes of tropical climes—namely, flattening the heads of their offspring. This uncouth fashion is, we understand, still kept up amongst the remnant of red Charaibs still existing in the island of St Vincent. Notwithstanding all these barbarous traits of character, however, these savages had, at the time of their discovery, attained astonishing proficiency in many kinds of manufacture. Columbus observed abundance of substantial cotton cloth in all the islands he visited, which the natives possessed the art of dyeing of various colours. Of this cloth they made hammocks, or hanging beds, such as are used at sea; for Europe has not only copied the pattern, but preserved the native name, *amack* or *hamock*. These savages likewise possessed the art of making clay vessels for domestic purposes; beautiful specimens of which are still sometimes dug up in Barbadoes and other islands. Their religion, if it can be so called, was a mere compound of revolting idolatry and superstition, such as has almost uniformly been found to prevail amongst all savage nations; yet it is well worthy of remark, that they entertained those opinions which may be described as the first foundations of true religion—the belief of a Deity, and of a future state of existence; a fact which corroborates the sentiments of the eloquent Bishop Chester, that "such belief is no less conformable to the first natural apprehension of the untutored mind, than to the soundest principles of philosophy."

Such were the Charaibs, to whom the inhabitants of the larger islands—Hispaniola, Cuba, Jamaica, and Porto Rico—presented the most striking contrast in every respect. The latter were indolent and sensual in their habits, but of a peculiarly mild, kindly, and forgiving disposition, affectionate to their wives, and placing their whole happiness in domestic bliss. They were particularly fond of dancing, and various other peaceable amusements and games. Unlike the Charaibean, their government was monarchical. Their kings were called caciques, and their power was hereditary; but there were likewise subordinate chieftains or princes over each district, who were tributaries to the sovereign. They had likewise an established priesthood, although (excepting their belief in a God, and a future state of rewards and punishments) their system of theology was little else than a medley of folly and superstition—the fruits of ignorance and terror. Columbus experienced the greatest kindness from this simple and primitive people, who, when they perceived the avidity of the Spaniards for gold, anxiously supplied them with all of which they were possessed, and afterwards brought them incessant supplies of cloth and provisions. The truth was, they looked upon the strangers as a kind of superior beings to themselves, whose presence was an honour to them, as the negroes in these colonies, even to this day, generally consider their white masters. A remarkable speech has been preserved of an old man, a native of Cuba, to Christopher Columbus, on presenting him with a basketful of fruit, which sufficiently evinces the profound feeling of veneration these simple-minded people entertained for their visitors:—"Whether you are divinities," said he, "or mortal men, we know not. You are come into these countries with a force, against which, were we inclined to resist it, resistance would be folly. We are all, therefore, at your mercy; but if you are men, subject to mortality like ourselves, you cannot but know, that, after this life, there is another, wherein a very different portion is allotted to good and bad men. If, therefore, you expect to die, and believe with us that every one is to be rewarded in a future state, according to his conduct in the present, you will do no hurt to those who do no hurt to you." This remarkable address is, in our estimation, a far more striking specimen of barbarian sentiment and oratory, than the well-known address of Logan, the American chieftain, which consisted chiefly in an egotistical reiteration of the virtues common to savage nations of almost all ages—fidelity towards a foe, and a punctilious observance of the rites of hospitality. It was upon these amiable and hospitable people, nevertheless, that the Spaniards afterwards perpetrated such cruelties as make the blood curdle to contemplate, and which we will require in their due place to notice.

In concluding our notice of these two very different original tribes of West Indians, we cannot help remarking a remarkable similarity betwixt them and the two distinct castes which people the Polynesian, or South Sea islands; those just described resembling (except in the colour of their skin) the pacific and indolent tribe of the South Seas, called Oceanic negroes; while the Charaibs, in their active and warlike habits, bear the closest affinity to the natives of the Georgian and Society Islands.

NUMBER OF ISLANDS—PRESENT POSSESSORS.

No regular official survey having ever been made of the West India islands, it is impossible to state with certainty the actual number of them. It must, however, be immense—a fact which will be evident when we state, that the Bahamas alone are calculated to amount to 500. A great proportion of them, however, are mere barren uninhabited rocks, although furnishing generally fine water, and many of them excellent harbours and roadsteads, which rendered them a convenient rendezvous for ships of war, during the period of hostilities with foreign countries, and for our cruisers, while employed in repressing the slave-traffic.

We shall, therefore, only enumerate the principal colonial possessions in that hemisphere belonging to the British and other European powers, and the free native settlements, with a short historical and topographical sketch of each; and then proceed to give a general view of their appearance, productions, climate, inhabitants, government, trade, &c. And first in point of importance, both as to number and value, are the

BRITISH POSSESSIONS.

1. JAMAICA

is the third island in point of size in the western hemisphere, being inferior only to Cuba and St Domingo. It lies about 100 miles south of the former, and about the same distance west of the latter, between which islands lies what seamen term the "windward passage." The latitude of Kingston, the principal town, is 18° N., and that of the eastmost point of the island (called Morant Point) 17° 56', and its long. 76° 5' W. This island was first discovered by Christopher Columbus, during his second voyage, on the 3d of May 1494, and will continue to be associated with his memory with many painful recollections, having been in a manner the indirect cause of his misfortunes and death. After a slight contest with the natives, he effected a reconciliation with them, and, as the custom then was, took possession of their territories in name of his prince, with the usual formalities. But it was not until his fourth and last voyage, in 1503, that he ascertained any particulars as to the extent and value of Jamaica. This information he acquired under most disastrous circumstances, being forced by tempestuous weather to run ashore the two vessels that survived the storm, at a small harbour in the north side, called from that circumstance *St Christopher's Cove*, to this day. The vessels being too much damaged to be again rendered sea-worthy, and the crew having mutinied and deserted him, Columbus concluded that he must there terminate his miseries and his life. He abode on the island for upwards of a twelvemonth, solitary and half-starved for want of provisions, but was at length rescued and conveyed to his native country, where the disgraceful neglect and ingratitude of his sovereign, together with the hardships he had endured, proved too much for his generous spirit, and he sunk under them—leaving a name which will only be forgotten with the extinction of that world whose boundaries he contributed so greatly to extend. His son Diego, who inherited much of his father's fortitude and firmness, soon after compelled his ungrateful monarch, by legal process, to acknowledge his patrimonial privileges as viceroy and admiral of all the countries discovered by his father, with a right to a share of the mineral wealth found in them; and having himself sailed for Hispaniola (St Domingo), he dispatched Juan de Esquivel with a large retinue to take possession of Jamaica, as deputy-governor. This was in 1509; after which, for many years the colonists were engaged in a perpetual struggle with the natives, whom they at last completely extirpated, not a single native of either sex being left alive when the English took possession of the island in 1655, nor, it is said, for a century before. The traditionary accounts of the cruelties inflicted by the Spaniards upon them, are beyond every thing horrible and revolting. Caves were afterwards discovered literally filled with human bones, supposed to be those of the poor fugitives, who preferred death by starvation to the lingering tortures inflicted on them by their inhuman conquerors; and it is calculated that not less than 60,000 of them were put to death in various ways. They did not perish in silent despair, however, for it appears they succeeded in demolishing the town of Seville, the first founded in the island (by Esquivel), upon the site of which Diego Columbus afterwards (1526) built the town of St Jago de la Vega, still the seat of government in the island, and now commonly called Spanish-Town. From it Diego's son Louis derived the title of Marquis de la Vega, the first and last of his family who bore that distinction. The following is Mr Edwards's account of the manner in which the hereditary sovereignty of this and the rest of their great ancestor's discoveries passed from the descendants of Columbus, and which cannot fail to be interesting to every reader:—His son Diego left three sons and two daughters. His eldest son, Louis, succeeded to his father's honours and extensive claims. Of the daughters, the eldest, Isabella, intermarried with the Count de Galves, a Portuguese nobleman of the house of Braganza. Louis Columbus was an infant of six years of age at the death of his father, but was generally considered as hereditary viceroy and high admiral of the West Indies. The emperor (Charles the Fifth), however, though he treated him with singular distinction, and greatly augmented his revenues, absolutely refused to admit his claim to such extensive authority; and Louis, as his minority expired, instituted, after his father's example, a legal process for the recovery of his birthright. He found it prudent, however, to compromise with the emperor, whereby he transferred all his hereditary rights to the crown, for a grant of the province of Veragua and the island of Jamaica, with the title of Duke de Veragua and Marquis de la Vega. At his death he left no issue to enjoy these possessions and titles; and his brothers also dying without male issue, his sister Isabella, wife of the Count de Galves, became sole heiress of the Columbus family, and conveyed by her marriage all her rights to the house of Braganza, whose property they continued till the year 1640, and then reverted back by forfeiture to the crown of Spain, in consequence of the revolution which placed John Duke of Braganza on the throne of Portugal.

From the continued warfare between the natives and Spaniards, Jamaica was long exposed to the descent of the Buccaneers, who were then roving the southern seas, by whom it was twice taken and plundered between the years 1596 and 1638. In 1655, the Protector Cromwell, in defiance of a treaty of peace then existing between England and Spain, sent out an expedition against Jamaica under Admirals Penn and Venables. They arrived on the 10th May; and so expeditiously and successfully were their operations conducted, that the fleet sailed again for England in the following month, leaving General Fortescue in command of the army. At this time the whole number of whites in the island (exclusive of the army) did not exceed 1500; yet so anxiously did Cromwell encourage British settlers, that, in less than three years afterwards, the population amounted to 4500 whites, and 1400 negroes.* It is curious enough, however, that the first great influx of British settlers consisted of about 3000 soldiers of the disbanded Parliamentary army. "The confusion which overspread England," says Bryan Edwards, "after the death of Cromwell, impelled many to seek for safety and quiet in the plantations. Some of those men who had distinguished themselves by their activity in bringing their unhappy monarch to the scaffold, considered this island as a sure place of refuge. Foreseeing, from the temper which began to prevail amongst all ranks of people in England, especially towards the beginning of the year 1660, that the nation was united in its wishes for the re-establishment of the ancient frame of government, they hoped to find that safety in a colony composed of Cromwell's adherents, which they were apprehensive would shortly be denied them at home."

The negroes, being the slaves imported from Africa by the Spaniards, were still tampered with by their former masters, who, trusting to an insurrection in their favour, had the temerity to make an attack on the island in 1658, but were routed with such tremendous loss, that they never afterwards made any

---

* It is a curious and interesting fact, that the descendants of this tribe in Guiana still fondly cherish the tradition of Raleigh's alliance with them, and to this day show the English colours which he left with them at parting.

* Cromwell did not confine himself to persuasion and bribes alone to promote his colonising system. One of his measures for that purpose was a vote of the "Grand Council of State" in England for listing 1000 girls, and as many young men, in Ireland, and sending them to Jamaica!

serious efforts to regain possession of it. At this time the slaves who had co-operated with the Spaniards fled to the mountains, where they assumed the name of *Maroons*;* and their descendants continued for nearly a century and a half in almost constant hostility with the English. Meanwhile, a regular system of government was established, consisting of a governor, council, and house of assembly; and so rapidly did the influx of settlers and the cultivation of the island proceed, that, in the year 1688, it was computed that the annual importation of African negroes amounted to no less than 10,000. The present state of the population and other matters will be afterwards stated under the proper heads.

In 1692 (June 7), Jamaica was visited by a dreadful earthquake, by which it was estimated about 3000 inhabitants lost their lives. Amongst its other devastations, was the swallowing up of almost the whole of the town of Port Royal, situated on the extremity of a narrow neck of land running out obliquely into the sea, and thus forming the magnificent harbour of Kingston, which, however, was not then built. From its situation, which completely commands the entrance to the harbour, it was one of the earliest fortified and most wealthy places in the island. A most remarkable incident took place on this occasion, as recorded by the following inscription on a tombstone, still preserved near the present town of Port Royal:—

"Here lies the body of Lewis Galdy, Esq., who departed this life, at Port Royal, the 22d December 1736, aged eighty. He was born at Montpelier, in France, but left that country for his religion, and came to settle in this island, where he was swallowed up in the great earthquake in the year 1692, and, by the providence of God, was by another shock thrown into the sea, and miraculously saved by swimming, until a boat took him up."

The epitaph somewhat unnecessarily adds, that "*he lived many years after* in great reputation." The seamen preserve the recollection of the above catastrophe by a current joke amongst them: when they experience any difficulty in heaving up the anchor at this station, they say, "*she has got down one of the chimnies of the old town.*" In 1703, Port Royal had again sprung up to be a place of considerable size, when it was reduced to a pile of ashes by fire. Nor is this all. In 1722, Port Royal the *third*, as it may be termed, was totally overwhelmed by the sea, during a tremendous hurricane which devastated the island, when twenty vessels and 400 persons perished in the harbour. Awed by these repeated calamities, which began to be looked upon as direct visitations of providence, on account of the horrid scenes of vice and depravity, which, as being the rendezvous of all the dissolute crews who visited the station, had from the first disgraced it, the greater part of the inhabitants removed to the land side of the harbour, where they laid the foundation of the now populous city of Kingston. The site of Port Royal, which was thus for many years abandoned, became, however, in process of time, again the scene of traffic and business, and was again almost annihilated by fire so late as the year 1815. This ill-fated spot, however, is now once more rising into importance, from its continuing to be the royal naval station, and containing the naval hospital, soldiers' barracks, and other public establishments.

The only other historical occurrence which it is needful to mention here, in reference to this island, is the celebrated Maroon war, which broke out with great fury in the year 1795. These people, as already noticed, continued to be the scourge of the English from the moment they became masters of the island. These savages lived in caves amongst the fastnesses and forests of the highest ridges of the mountains, where they subsisted by hunting and fishing, and upon the wild roots and fruits which there grow spontaneously. They seized every opportunity of making a descent upon the English plantations, where they uniformly murdered every white person, man, woman, or child, who fell into their hands. In short, their war with the settlers was one of extermination. Every expedient was tried either to awe them or pacify them; but, confiding in their almost inaccessible retreats, they rejected all overtures of a friendly nature. At last they became so formidable, that, in 1737, the assembly resolved to import a body of Indian hunters from the Mosquito shore, to assist in suppressing them, and likewise formed all the free negroes and mulattoes of the island into companies for the same purpose. About two hundred Indians were accordingly imported, who, being liberally paid, entered on the service with spirit, and, by their activity and courage in the practice of bush-fighting, and their skill in tracking the fugitives, harassed the Maroons so much that they were soon glad to capitulate. Accordingly, in 1738, articles of peace were ratified, by which the Maroons were declared free for ever, and 2500 acres of land were assigned to them and their descendants in perpetuity. Excepting as respected outrages on the settlers and their property, they were otherwise placed entirely independent of the English; the only conditional services they were required to perform, being to assist in repelling foreign invasions, and in apprehending runaway slaves, for each of whom they were allowed L.3 per head. After this, the Maroons remained tolerably quiet, although their conduct was always suspicious, until the year 1795. At this time they amounted to 1600 men, women, and children, and possessed four villages, or encampments, called Trelawney Town, Accompony Town, Crawford Town, and Nanny Town, all lying on the north side of the island. In July that year, two Maroons, being detected stealing pigs in Montego Bay, were ordered to be publicly whipped. Upon this, the whole body, conceiving themselves disgraced by this ignominious punishment, rose in arms, and, but for a providential occurrence, would have made themselves masters of the whole island. On the very day of the insurrection, the British fleet sailed for England, with all the troops on board except the 83d regiment. Luckily they took the windward passage, and the governor, Earl Balcarres, aware how frequently the vessels were detained in this course by calms during the night, with a strong lee current, dispatched a fast-sailing boat after them, furnished with oars for rowing during a calm, which luckily overtook the last of the war-ships five days after they had sailed! There is scarcely a doubt, that, but for the reinforcement thus miraculously obtained, the whites would have been at this time completely overpowered, as the Maroons prevailed upon a great part of the slaves to join in the revolt; the latter being the more easily persuaded, from the recent successful example of their brethren in St Domingo. In the conflict which ensued, the Maroons were at first completely successful, from their covert mode of fighting in ambuscade. Concealed among the bushes and in the branches of trees, they fired upon their opponents without being themselves exposed—always marking down the officers first; and several detachments of regulars and militia were thus annihilated without the Maroons losing a man. They had retreats in precipices accessible only to themselves, whence they issued to pillage and burn the neighbouring plantations, murdering the owners with circumstances of most atrocious barbarity. They were every day reinforced with fresh numbers of revolted slaves in proportion to their successes, and their force at last became so formidable, that many of the settlers fled from the island, all business was suspended, the courts shut up, and nothing but terror and anxiety prevailed. In this fearful state of matters, and having to deal with a foe against whom the courage and skill of the best disciplined troops could avail nothing, the assembly came to the resolution of sending to Cuba for a supply of the Spanish-American bloodhounds, not, as has been alleged, to hunt down the Maroons, like wild beasts, but to assist in discovering ambuscades, and tracing the savages to their secret retreats. The colonists have been much but most unjustly blamed for this step, which had become not more a measure of necessity than of positive humanity. The Maroons were not an unarmed, innocent, and defenceless race of men, like the ancient natives, but a horde of plunderers and merciless assassins. They had taken up arms without cause, and conducted the war upon the avowed principle of rooting out the English settlers from the island, to which, be it observed, they had originally no more (if not much less) right than the settlers themselves. The speediest method, therefore, of reducing to submission a body of men who had causelessly vowed extermination against all the rest of the community, was unquestionably the most justifiable, and, as the event in this case proved, the most humane. In fact, not a drop of blood was shed after the arrival of the dogs in the island. By the assistance of these canine allies, ambuscades were detected and defeated; the strongholds of the insurgents were discovered, and the passes to them blockaded;* and they were soon reduced to such extremity for want of water and provisions, that they began to open negociations for surrender, through means of some of the revolted slaves whom they dismissed for that purpose. Although now completely at the mercy of their conquerors, the only atonement demanded of them for all their enormities was, that they should ask pardon of the king upon their knees; that they should reside on whatever part of the island might be allotted to them; and surrender up all the fugitive negroes that had joined them; and they were allowed ten days to consider of these terms. That time having expired without their giving any reply, the English commander (Walpole) ordered the troops to advance upon them; but they had only proceeded a very short way, when a general supplication for mercy was sent in, upon no other condition than the promise of their lives. From the fierce and revengeful disposition of these people, it was judged prudent to break up the community. Six hundred of them were accordingly shipped off to Nova Scotia (Lower Canada), where lands were purchased for them at a cost of L.25,000 to the island. The descendants of the others still reside at Trelawney Town, upon the same terms as before the insurrection. This war cost the island nearly a million sterling, independent of the private damage sustained by the owners of slaves and plantations.

From the above period, until the latter end of the year 1831, the internal peace of Jamaica was, generally speaking, little disturbed; but at that time, owing to the exaggerated hopes of the negroes for immediate emancipation, from the accession of the Whigs to office—encouraged, as was alleged, by the Baptist missionaries—an extensive revolt broke out, the details of which must be still so fresh in the recollection of our readers, as to render a recapitulation of them unnecessary. One circumstance, however, may be noticed, as a feature distinguishing the late insurrection from all previous ones, that, although about a million's-worth of property was destroyed by the slaves, not the slightest violence was offered to any white person, beyond a few hours' personal captivity, and there were even very few instances of this.

Jamaica is divided into three counties—MIDDLESEX, SURREY, and CORNWALL. Middlesex is divided into eight parishes, Surrey into seven, and Cornwall into five. The seat of government is ST JAGO DE LA VEGA, or SPANISH-TOWN (in Middlesex). It is situated on the south-west side of the island, about six miles from the sea, and sixteen from Kingston. There is a superb palace here, maintained for the governor or commander-in-chief; and it is here that the house of assembly meet, and the court of chancery and the supreme courts of judicature are held. KINGSTON, although not the seat of government, is, nevertheless, from its importance, considered the capital of the island. It is situated to the south, upon a gentle slope of about a mile in length, which runs right down to the harbour, the finest, perhaps, in the world, and where the largest merchantmen can ride close in to the shore. The streets are built with almost mathematical regularity, like the New Town of Edinburgh. It contains upwards of 40,000 inhabitants, of whom there are 12,000 whites, the rest being slaves and free people of colour. There are excellent markets for butcher-meat, fish, fruits, and kitchen vegetables. On a plain, at the top of the declivity on which the town is situated, is a fine extensive barracks, called Up-Park-Camp; and not far from it, in a conspicuous situation, is a handsome residence for the admiral on the station, called the Admiral's Pen.

MONTEGO-BAY and FALMOUTH—the former situated on the north, the latter on the east end of the island—are both sea-ports of great traffic.

There are innumerable streams and rivers in Jamaica; but only one—Black River—is navigable inland, and which admits the passage of flat-bottomed boats and canoes for about thirty miles.

BRITISH LEEWARD CARRIBEAN ISLANDS.

II. ST CHRISTOPHER'S,

usually abbreviated into *St Kitt's*, is one of the Leeward Islands, and was discovered by Columbus in 1493, who bestowed on it his own Christian name. It was never occupied, however, by the Spaniards, or any others, until an Englishman, Thomas Warner, with fourteen associates, took possession of it in 1623. It is therefore the oldest of the British West Indian settlements, preceding that of Barbadoes by a year. A French ship having been driven in on the coast by stress of weather in 1625, the crew joined the British in an attack on the native Charaibs, whom they totally expelled. They then divided the island betwixt them, which they shared till the year 1629, when they were both driven out by the Spaniards, who, after having laid every thing waste in mere wantonness, departed for Brazil. The English and French then returned, but lived in continual warfare, alternately expelling each other, until, at the peace of Utrecht (1713), it was wholly ceded to the English, and the French possessions sold for the benefit of the British government. In 1733, L.80,000 of the marriage-portion of the Princess Anne (with the Prince of Orange) were derived from the sale of these possessions. In 1782, it was again captured by the French, but finally restored to Britain in the following year. It is about forty-two miles in circumference, and is divided into nine parishes. The capital of the island is Basseterre. The other towns or hamlets are very insignificant. St Christopher's lies in 17° 15' north latitude, and 63° 17' west longitude.

III. NEVIS.

This beautiful little island, consisting only of a single mountain, which rises like a cone out of the sea, green, unbroken, and verdant to the summit, was discovered by Columbus in 1493, at the same time with St Kitt's and other adjoining islands, which lie quite close and in sight of each other. It was first taken possession of in 1628 by a small colony of English sent by Warner from St Kitt's; yet so rapidly did the settlers increase, that in 1640 the population is said to have amounted to 4000 whites and 12,000 blacks. In 1689, half of the population were swept away by a dreadful mortality; nor has it ever again reached the same census. It seems unaccountable, indeed, how it could ever have maintained such a number of human beings, as it is only about 20 miles in circumference. Small as it is, however, it is divided into five parishes. The principal town and seat of government is Charles Town; and there are besides other two shipping places, Indian Castle and New Castle. Its sole produce is sugar. The entire population in 1823 was estimated by Humboldt at 11,000, of whom 9500 were slaves; but in 1825, the slaves were returned at 9288.

IV. ANTIGUA.

This island, the largest of the British Leeward

* The Spanish-American name for *hog-hunters*; so called from the great number of wild swine which abounded in the woods of the West India islands, and South American continent.

* "The caves in which the Maroons concealed their ammunition and provisions, and secured their women and children, were inaccessible to the whites. One place, called the *Cock-pits*, could be reached only by a path 150 feet in almost perpendicular height. Strange as it may appear, this obstacle was surmounted by the Maroons without difficulty. Habituated to employ their naked feet with singular effect in climbing up trees and precipices, they had acquired a dexterity in the practice, which, to British troops, was astonishing, and wholly inimitable."—*Edwards*, vol. i. Appendix, No. 2.

Islands, is situated about 60 miles east from St Christopher's, and was discovered at the same time with the latter by Columbus in 1493. It is 21 miles in length, and 50 in circumference. The most remarkable peculiarity of this island is, that, notwithstanding its considerable size, as compared with some of the others, it is the only one of them that has not a single spring or rivulet of fresh water in it. It was doubtless from this cause that it was found uninhabited by Columbus, and also that it was long left unoccupied by European adventurers after its discovery. Nature, however, presents few obstacles which the avarice or industry of man will not surmount: the lands were found to be fertile, and large cisterns were contrived to retain the water which falls in the rainy season. The water thus preserved has always been found light, pure, and wholesome. The first settlers were a few English families sent from St Kitt's, in 1632, by Warner, who appointed his son governor. The number of inhabitants, however, did not much increase until 1663, when Lord Willoughby, who had obtained a formal grant of the island from Charles the Second, sent out a large body of settlers at his own expense. In 1666, this colony was almost entirely destroyed by a French armament from Martinico, who, with a body of Charaibs, ravaged the island with fire and sword; but it was restored to the English in 1668, by the treaty of Breda. Up to this time, tobacco was the only vegetable cultivated; but, in 1674, sugar-planting was introduced with great success from Barbadoes, by a Colonel Codrington, and the colony thereafter rapidly rose into importance. In 1706, a Mr Parks was appointed governor of this and the adjoining islands, a man whose horrible character and tragical death have few parallels in history. He was by birth a Virginian of low descent, but having succeeded in marrying a lady of fortune in America, he absconded with her money to England. Here he succeeded in getting into Parliament, but was soon expelled for gross bribery. He then entered the army under the Duke of Marlborough, in whose good graces he rose so rapidly, that Queen Anne presented him with a purse of 1000 guineas, and her own picture set in diamonds; and, in 1706, conferred on him the government of the Leeward Islands, of which Antigua was then, as now, the seat of the executive. After his arrival there, he gave unrestrained licence to his brutal passions. Murder, violation, and robbery, he committed openly without shame or scruple; until the whole country rose as one man against him, attacked his house, seized his person, and literally tore him into a thousand pieces! Yet so flagrant and monstrous were his many crimes, that no proceedings were instituted against the colonists, for this act of insubordination, by the home government, who even seemed to approve of it, by promoting two of the principal actors to high official situations. Besides the occurrence of a remarkable drought of seven months, in the year 1789, whereby the whole crops were destroyed, and 3000 head of cattle perished from thirst, there is no other historical fact respecting this island deserving notice.

Antigua is divided into six parishes and eleven districts. St John's, the capital of the island, situated on the north-west, and English Harbour on the south, are the two principal towns. Both are well fortified; and, at the latter, are established a royal naval yard and arsenal, and conveniences for careening ships. Antigua was the first island which ameliorated the negro slave laws, by affording the accused the benefit of trial by jury. The inhabitants are chiefly Methodists.

V. MONTSERRAT.

This is one of the smallest of our British West India settlements, being only nine miles in length, and about as many in breadth. It was discovered in 1493, at the same time with St Christopher's, Nevis, and the other adjoining islands, by Columbus, who denominated it after a mountain in Spain (near Barcelona), to which it bears a resemblance. Like Nevis and Antigua, from each of which it is distant only about twenty miles, it was first peopled by a few English (or rather Irish) settlers, from St Christopher's, by Warner, in 1632. There is little or nothing worth noticing in the civil history of Montserrat, beyond the circumstance of its having been invaded and laid waste by a French armament in 1712. It is extremely healthy, fruitful, and beautiful, with alternate hills and vales, the former covered with wood, and the latter watered by fine streams. Almost the only staple articles cultivated are sugar and cotton.

VI. & VII. BARBUDA AND ANGUILLA.

These are the only others of the British *Leeward* Carribean islands (all included under one branch of government, as will be afterwards noticed) that remain to be mentioned. We have classed them together (although locally far separated), on account of the somewhat singular fact, that because they do not contribute to the annual importations of Great Britain, they have hitherto been left entirely unnoticed, both by government returns of our West Indian possessions, and by our various British geographers, as if unworthy even of a nominal enumeration! We owe the following slight descriptive particulars concerning them, therefore, chiefly to the notes of private visitors.

BARBUDA is situated about twenty miles north-east of St Christopher's, and ten north of Antigua. It is only about twenty miles long and twelve broad. This island was also one of Columbus's discoveries, although there is no other historical notice concerning it down to the time of Queen Anne, when we find it given in a perpetual grant to General Codrington and his posterity, by whom the greater part of it is still owned, and who have all along distinguished themselves for their philanthropic kindness to their negroes, and providing them with the bene[illegible] of Christian enlightenment. The population of the island amounts to about 2000.

ANGUILLA is the most northerly of the *Leeward* Carribee Islands, and lies about 100 miles north of Barbuda, and the same distance N.N.W. of St Christopher's, in the latitude of 18° north, and in the longitude of 64° west from Greenwich. It is thirty miles long, and only three broad, and received its name (signifying in Latin an *eel*) from the peculiar winding shape it presents, being also, for the same cause, sometimes denominated "Snake-Island." It was first discovered by the English in 1650, who found it tenanted only by alligators, and other noxious animals; but finding the soil fruitful, a colony was left on it, who soon multiplied in an amazing manner. It is curious, however, that, for nearly half a century, it was placed under no regular government, civil or ecclesiastical, and the settlers therefore became a prey to every rapacious invader of whatever nation. "Their chief suffering (says one writer) was from a party of wild Irish, who landed here after the revolution, and treated them worse than any of the French pirates who had attacked them before." The new and old settlers, however, afterwards united and harmonised together perfectly well, as is evident from the fact, that they, in 1745, although then only about 100 strong, repulsed a body of 1000 French who came to attack them, and obliged them to retire with the loss of 150 men. In 1796, the latter retaliated in a manner worthy of the atrocities of the Revolution. Two ships of war were sent with 400 picked troops, by Victor Hughes, of "red-hot memory," with directions to burn every settlement, and exterminate the whole inhabitants (British) in the island. These emissaries set about their work in good earnest, and committed the most barbarous atrocities on the defenceless inhabitants, but were happily interrupted by the arrival of Captain Barton, in the Lapwing man-of-war, who brought the French ships to action, sinking the one and taking the other. Since that time the island has remained in undisturbed possession of the British, but has never regained its previous prosperity.

The interior aspect of these two islands is quite different from that of any of our other West Indian settlements, being in many respects indeed quite *English*. The sole occupation of the inhabitants is farming, rearing stock, and cultivating provisions, for which a ready market is found in the neighbouring islands. There are no groups of masts in the bays and harbours; and instead of the laborious bustle, smoke, and noise incidental to the sugar and coffee plantations, there are to be seen only numerous little rural dwellings, surrounded by waving crops of grain, and verdant fields covered with sheep and cattle.

VIII. VIRGIN ISLANDS.

This name was given by the discoverer Columbus (in 1493) to a group of about forty small islands lying to the northward of the *Leeward Carribee Islands*, and between them and Puerto (or Porto) Rico. They extend about twenty-four leagues from east to west, and about sixteen from north to south. They are divided between the British, Danes, and Spaniards, but much the larger and more valuable number belong to the former. The names of these are Tortola, Virgin Gorda (or Penniston, and sometimes corrupted into *Spanish Town*), Joavan Dykes, Guana Isle, Beef and Thatch Islands, Anegada, Nichar, Prickly Pear, Camanas, Ginger, Cooper's, Salt Island, St Peter's Island, and several others of little or no value. Those belonging to the Danes and Spaniards will be noticed in their proper places.

The first possessors of the British Virgin Islands were a party of Dutch buccaneers, who fixed themselves at Tortola about the year 1648, and built a fort for their protection. In 1666, they were expelled by a stronger party of the same profession, who took possession in the name of England; and the English monarch (Charles the Second), availing himself of this circumstance, shortly thereafter annexed it to the Leeward Island government, in a commission granted to Sir William Stapleton. Up to 1773, the government of these islands was entrusted to a deputy-governor, with a council, who exercised in a summary manner both the legislative and executive authority; but, in the latter year, a local legislature, similar to that of the other islands, was conferred on them, with courts of justice, in consideration of the inhabitants *voluntarily* offering to pay an annual impost of 4½ per cent. to the crown upon all the natural productions of the islands. The Dutch had made but little progress in cultivating these islands when expelled; and the merit of agrarian improvement was reserved for a few English settlers from the little island of Anguilla, who removed thither in the year 1694. Their chief and almost their only articles of production are cotton and sugar; and the number of acres under cultivation is about 12,000. The entire population in 1812 was about 11,000; but, as will be seen by the tables subjoined to this article, a great decrease in this respect has taken place since in these, as in all our other West Indian islands.

IX. DOMINICA.

Although classed by geographers among the British *Leeward* Carribean Islands, Dominica may be described as *locally* and legislatively distinct both from them and the British *Windward* Carribean settlements; having a governor and legislature of its own, and being separated from the former by the large French island of Guadaloupe on the north, and from the latter by the French island of Martinico on the south. From its central situation, indeed, as well as its importance otherwise, it seems the best calculated of all the possessions of Great Britain, in that part of the world, for securing to her the dominion of the Charaibean Sea. This fact was entirely overlooked by the British Ministry during the whole course of the American war, when all the faculties and means of Great Britain were directed towards the security of our West Indian settlements, and preventing co-operation between the French and the insurgent colonists; no more than 100 soldiers, officers and privates, being assigned to garrison the island. From this criminal negligence it suffered severely during that contest, and was repeatedly captured by the French. In 1778, an armament of several thousand soldiers arrived from Martinico, who soon made themselves master of the island, after a gallant defence by the British militia, who did not exceed 120 in number. The conduct of the officer left in command of the island (Marquis Duchilleau), towards the English inhabitants, was most disgraceful. He placed them under martial law, forbidding them, on pain of death, to assemble together more than two in a place, or stir out of doors after nine o'clock at night; and several of the principal inhabitants were shot by sentinels placed for the purpose, for disobeying the latter order. Upon the pretence that the English were forming designs to retake the island, he set fire to the capital, Roseau, by which upwards of 500 houses were destroyed, with merchandise to the value of L.200,000 sterling. These continued barbarities ended in the ruin of the whole English inhabitants, who were suffering all the horrors of starvation, when, in 1783, the island was restored to the British government, under which it has since remained. In 1795, the French made an unsuccessful attempt to retake it, the whole troops that landed being either killed or taken prisoners. In 1805, Dominica was again attacked by the French, who burned Roseau, levied L.7000 sterling from the inhabitants; and, after committing many atrocities, departed on the fifth day after landing. Since that time, the island has been undisturbed, unless from insurrectionary movements amongst the runaway negroes, who, about the year 1813, made nightly incursions from the mountains, and threatened the destruction of the whole colony. This dangerous confederacy was at last broken up in 1814 by the death of their chief, named Jacko, who was shot by a party of rangers, after a desperate resistance.

Dominica is 29 miles in length and 16 in breadth; it contains about 190,000 acres of land, and is divided into ten parishes. The *nominal* capital, Roseau, is in the interior; but the great mart of trade is Prince Rupert's Bay, on the south-west side of the island. It is situated on a point of land which forms two bays—Woodbridge's Bay to the north, and Charlotteville Bay to the south. The principal productions are sugar, coffee, indigo, and ginger; it is watered by upwards of thirty fine rivers, besides a great number of rivulets. In the woods are innumerable swarms of bees, which lodge in the trees, and produce great quantities of wax and honey, both of which are equal in goodness to any in Europe. It is precisely the same species of bee as in Europe, and must have been transported thither; the native bee of the West Indies being a smaller species, without stings, and different in its habits from the European.

Several of the mountains in Dominica contain living volcanoes, which frequently discharge vast quantities of burning sulphur; and there are many springs of hot water, some of which are said to be warm enough to coagulate an egg. Mr T. Attwood, in his history of this island, gives a description of a miraculous insect peculiar to it, which he calls a *vegetable fly*. "It is of the appearance and size of a small cockchafer, and buries itself in the ground, where it dies; and from its body springs up a small plant, which resembles a young coffee-tree, only that its leaves are smaller. The plant is often overlooked, from the supposition people have of its being no other than a coffee-plant; but on examining it properly, the difference is easily distinguished—the head, body, and feet of the insect appearing at the root as perfect as when alive." This is a most extraordinary relation certainly; but not more so than the Rev. Nicholas Collins's description, in the American Philosophical Transactions, of a certain zoophyton in the Ohio county, which, he declares, is both vegetable and animal; for, having crawled about the woods in its animal state till it grows weary of that mode of existence, it fixes itself in the ground, and *becomes a stately plant, with a stem issuing from its mouth!*

There are still a few of the descendants of the ancient Charaibs residing in Dominica. They are of a clear copper-colour, with long, black, sleek hair; their persons short, stout, and well made. They live chiefly by fishing in the rivers and the sea, or by fowling in the woods, in both of which pursuits they use their bows and arrows with great dexterity. They kill the smallest bird at a great distance with an arrow, and transfix a fish at a considerable depth in the sea.

BRITISH WINDWARD CARRIBEAN ISLANDS.

X. ST LUCIA.

This is the most northerly of the group of *Windward* Charaibean Islands belonging to Britain, lying about twenty miles south of Martinico. It was first discovered by Columbus, but in which of his voyages is not exactly known, and it remained totally uninhabited by Europeans until the year 1639, when Lord Willoughby arrived with a party of English to colonise it, and succeeded in obtaining a peaceful surrender of the island from the native Charaibs. Few of our West India settlements have undergone so many alternations in ownership as this island. In 1640 (the year after its settlement), the natives rose upon the English, every one of whom they slew, with the exception of a few who escaped to Montserrat. For ten years afterwards, the Charaibs remained the sole possessors of the island; but in 1650, a colony of Frenchmen settled in it. These also, as well as various subsequent settlers, were killed or expelled by the Charaibs. In 1664, the English purchased the island from the latter, and a colony of 1400 men were settled on it; but of these only about ninety remained two years afterwards, the rest being destroyed either by sickness or by the natives. For nearly a century after this period, St Lucia was an almost incessant scene of contest and bloodshed between the English and French, by whom it was alternately taken and retaken, notwithstanding repeated treaties declaring it neutral. By the treaty of Paris in 1763, it was allotted to France, but was retaken by the British during the American war in 1779. It was again restored to France at the peace of 1783, retaken by the British in 1794, evacuated in 1795, reoccupied in 1796, restored to France by the treaty of Amiens in 1801, recaptured by the British in 1803, and has ever since remained under the British crown. These alternations of fortune naturally deteriorated the prosperity of the island, but it is nevertheless one of the most valuable of the group to which it belongs. It is twenty-seven miles long and twelve broad, and contains 203,000 acres, 35,000 of which are cultivated. It must still be fresh in the recollection of our readers, that one of the last victims to the unhealthiness of this island, was the late lamented General Stuart of Garth, who went out as governor in the year 1830, and died a few weeks after his arrival. The cause of this insalubrity is to be attributed entirely to the hitherto uncultivated state of the island, owing to its unsettled condition. The soil is excellent; and there is little doubt of its soon becoming one of the most important of our colonies in that hemisphere, under judicious management. A somewhat fanciful writer on the West Indies* gives the following uninviting account of the capital:—"CASTRIES is one of the dirtiest-looking holes I ever witnessed; my short stay did not permit me to see, and therefore I cannot describe, the houses of note therein contained. I landed on the wharf; and those along the Carenage presented the general appearance of West Indian buildings. My first ride was to the garrison, an excursion which, under the favour of heaven, I will never repeat. It is a jaunt only fit for such as love to risk their bones, and even their important necks."

XI. BARBADOES.

This is the most easterly of all the Charaibean Islands, and was the first settlement which the British made in the West Indies, in 1625. It was found without inhabitants in that year by the crew of the Olive Blossom, of London, who took possession of it by fixing up a cross where James's Town is now built, so called after the first monarch of England of that name. In 1627, Charles the First granted the Earl of Carlisle the whole island, upon his agreeing to pay his rival Marlborough L.300 a-year out of its revenues, thus excluding the rights of Sir William Courteen, an eminent London merchant, under whose patronage the first expedition had been undertaken in the year 1624. About this era it had become fashionable in England for men of high rank and distinction to engage in sea adventures, proclaiming themselves the patrons of colonisation and foreign commerce; and James Hay, Earl of Carlisle, distinguished himself amongst the rest. Courteen afterwards obtained a recognisation of his rights from Charles the First, but these were again set aside at the suit of the Earl of Carlisle, under that system of favouritism which proved the ultimate destruction of the unhappy monarch. Thus, by an act of power, which its repugnancy and absurdity alone rendered illegal, the Earl of Carlisle again found himself lord paramount of Barbadoes; and in order completely to ruin all the interests in the colony but his own, he proceeded to distribute grants to such persons as chose to receive them on his own terms. A society of London merchants accepted 10,000 acres, on conditions which promised great advantage to the proprietor, and these were allowed the privilege of sending out a governor of their own, who superseded Courteen's settlement, and the interests of the latter were cast aside. After this the emigrations from England, during the civil commotions, were so numerous, that, in 1650, it was computed there were upwards of 20,000 British in Barbadoes. "These adventurers," says Lord Clarendon, "planted without any body's leave, and without being opposed or contradicted by any body," and the colony being thus left to its own efforts, flourished without example. After the restoration of Charles the Second, the claims of Lord Willoughby, the Earl of Carlisle, and the crown, again came into competition, and formed the subject of litigation for many years, in which the conduct of Clarendon was thought so reprehensible as to form one of the articles of his impeachment before the House of Commons in the year 1667. Throughout the whole civil war, the island remained faithful to the exiled family; and to punish such stubborn defenders of a ruined cause, an armament was sent out in 1651, by the Parliament, to reduce it to subjection, who inflicted such barbarities on the inhabitants and their property, that they have never since regained their previous prosperity. This is proved by the fact, that, in 1670, there were computed to be 50,000 white and 100,000 black inhabitants, while at present there are estimated only about 90,000 inhabitants altogether.

Barbadoes is divided into five districts and eleven parishes, and contains four towns—Bridge Town, Ostins or Charles Town, St James's, and Speight's Town. Bridge Town is the capital and seat of government.

XII. GRENADA AND ITS DEPENDENCIES.

Grenada is situated between 12° 20′ and 11° 58′ N. latitude; and 61° 21′ and 61° 35′ W. longitude. It is about 20 miles in length from north to south. The face of the country is mountainous, but not inaccessible in any part, and it abounds in springs and rivulets. It was discovered by Columbus in his third voyage, in 1498, being then inhabited by the native Charaibs, by whom it was possessed unmolested until the year 1650, when it was taken possession of by the French from Martinico. By a succession of calamities and revolutions, the narration of which would interest few readers, the prosperity of this island was so much impaired, that, in the year 1700, there were found on the whole island only one hundred and fifty-three persons. From this time forth, however, its prosperity every year increased. In the wars which ensued between Britain and France, it was alternately taken and retaken by each, until, by the general peace of 1783, it was finally ceded to Britain. The name of the capital is Fort Royal, situated in a spacious bay on the west side of the island.

The Grenadines are a chain of small islands, running towards St Vincent on the north, the chief of these being Carriacou and Redonda.

XIII. ST VINCENT AND ITS DEPENDENCIES.

This is a beautiful island, about twenty-four miles long and twenty broad, lying fifty-five miles west of Barbadoes. It was discovered by Columbus, but never taken possession of. It was then inhabited by the native Carribs. From 1672 to 1748, contentions prevailed between France and England respecting the sovereignty of this island; but, in the latter year, it was mutually declared neutral. It remained thus till 1763, when it was assigned to the British. In 1779, it was captured by the French, but restored to Britain at the general pacification in 1783. St Vincent is extremely fertile, and produces sugar of the best quality. In 1812, an awful volcanic explosion took place. The matter thrown out not only covered the whole island more or less, but also many ships at a great distance at sea: it even reached Barbadoes, where quantities of the lighter particles were deposited; and the noise was heard at a distance of 300 miles. In consequence of this calamity, the British parliament voted L.25,000 to the sufferers.

St Vincent has attached to it eight small islands, which it is unnecessary to enumerate.

XIV. TOBAGO.

This is the most southerly of the West India islands, being 120 miles south of Barbadoes, and lying next to Trinidad. It is 32 miles long and 10 broad. It is equal in richness and variety of produce to any of the other islands. In 1748 it was declared neutral, but in 1763 was ceded to the English. It was taken by the French in 1781; confirmed to them in 1783; but retaken by the English in 1793. The principal town is Scarborough. The island contains 204,000 acres, of which only about a 6fth part is cultivated. The military and political history of this island is exactly similar to that of St Lucia, to which we refer our readers.

XV. TRINIDAD.

This island, which measures ninety miles long by fifty broad, lies near the coast of South America. It produces sugar, cotton, maise, fine tobacco, indigo, and fruit, but is said to be unhealthy. It was ceded to the British at the peace of Amiens. The capital is Port d'Espagne.

XVI. THE BAHAMAS OR LUCAYOS ISLANDS.

These are the most northerly of all the West Indian islands, stretching towards the coast of Florida, and forming with it the channel called the Strait of Florida. They were the first land discovered by Columbus in 1492, and amount in number to fully 500. The island which gives the name to the whole is the most northern, as well as the most important of the group. A settlement was established by the British in 1629, in the island called New Providence, and which continued until 1782 to be the seat of government. These islands were long infested by the buccaneers, and they were only expelled by the gradual erection of forts. Since that time the islands have been gradually improving. The chief article cultivated in these islands is cotton, neither sugar nor coffee having succeeded. All sorts of provisions grow in great abundance, and cattle and sheep thrive well.

XVII. BERMUDAS OR SUMMER ISLANDS.

These are a cluster of small islands lying almost in the form of a shepherd's crook, in long. 66° W., lat. 32° 20′ N., and about mid-way between the Bahama Islands and the Banks of Newfoundland. There are upwards of 400 of them, but few of them habitable; and even these so insignificant, that they are generally left out of the list of our colonies by geographers; we notice them here only from their being uniformly enumerated in the government returns.

BRITISH SOUTH AMERICAN SETTLEMENTS.

These settlements, although not properly belonging to the West Indies, naturally come to be noticed here. They are called by geographers British Guiana, extend over an immense space of the great South American continent, and include all the maritime tract between the river Corentin and Cape Nassau, in north latitude 6° 40′. The whole coast (being part of what navigators call the Spanish Main) is so flat, that it is scarcely visible till the shore is touched. The tops of the trees only are discernible; and even they seem to be growing out of the sea; nothing is to be seen but water, and the same monotonous appearance is presented far into the interior. These settlements are properly three in number—Berbice, Demerara, and Essequibo; they are, however, now one united colony, and denominated British Guiana.

BERBICE.

Berbice is situated on the banks of the river of that name, which discharges itself into the Atlantic in 6° 20′ north lat., and 57° 11′ west long. The plantations are situated on both sides of the river, and extend nearly 100 miles from its mouth. The sea-coast extends about 50 miles; and since it fell into the hands of the British, a huge embankment has been raised against the sea along the whole line, on which is a carriage road sixty feet broad, with six-feet parapets on each side, for the convenience of travelling. This colony was captured from the Dutch in 1803, and confirmed to Great Britain at the general peace in 1814. The two principal towns in this colony are Old Amsterdam, and Fort Nassau, or New Amsterdam. The latter may be considered as the seaport, being situated on a point of land on the eastern shore of the Berbice, about a mile up from the sea, the houses extending about a mile and a half along the banks of the river. It has been almost entirely built by the British. Old Amsterdam is also situated on the Berbice, about 60 (and, as some say, 100) miles from its mouth—the river itself being navigable to ships of burden for 200 miles. There runs across the mouth of it, however, a bar of sand, over which, even at high tide, there is scarcely sixteen feet of water. This greatly deteriorates the trade of the river, and the prosperity of the colony; as large ships, rather than incur the danger of crossing the bar, prefer anchoring off the port of Demerara. The principal productions of the colony are sugar, coffee, tobacco, and cotton.

DEMERARA AND ESSEQUIBO.

This tract is of much greater extent than that of Berbice, being, as near as can be ascertained, about 650 miles in length and 150 in breadth. The principal rivers are the Essequibo, the Demerara, and the Pomeroon. The former is one of the largest of the immense rivers which roll down from the South American mountains into the Atlantic. It is composed of three main streams which join together about 70 miles from the sea—Essequibo, the Massarouni, and Cayouni, all of which are great navigable rivers, and are composed of innumerable tributaries. The Demerara is a mere streamlet compared with the Essequibo, although navigable 100 miles into the interior. At its mouth it is a mile and a half broad, and sheltered from every wind; but, unfortunately, as with the Berbice, there is a bar of sand across the mouth, which at low tides is only covered with nine feet of water, and in spring-tides with eighteen. The scenery along the banks of the Demerara is peculiarly beautiful, from the fine regular ranges of plantations on each side; the sugar-estates and coffee-plantations all active and bustling; while crowds of boats passing up and down the river give life and animation to the scene. Every plantation has a wharf or landing-place of its own on the river; and being surrounded with canals or sluices for draining the land, admitting flat-bottomed boats, &c., each is in a manner insulated from the other.

The capital of Demerara is George Town, which is defended by a fort, and situated near the mouth of the river. There are several other towns, or rather villages, which it is needless to enumerate or describe; besides the fort of Zelandia, in the Essequibo, about 40 miles from the sea, and the fort of New Middle-Burgh, situated at the confluence of the Massarouni and Essequibo. This town has considerably increased in extent since the colony has come into possession of Great Britain—it contains a population of 12,000 souls.

* "Four Years' Residence in the West Indies. By F. W. N. Bailey. 1830."

Demerara was colonised by the Dutch in 1626, but it made comparatively little progress until after 1796, when it was captured by the British. Along with Essequibo, it was most inconsiderately restored to the Dutch in 1801, after several millions of money had been expended on it by the British planters and merchants. They were retaken in 1803, and finally secured to Britain at the peace of 1814.

A comparatively small portion of British Guiana is yet cultivated, and an immense field for colonial industry still lies open. The soil, which produces all, and more, than the productions of the West India islands, is far deeper, richer, and does not, as in them, *wear out.* No hurricanes visit this coast, so that the planters are never subjected to sudden damage in their crops, nor the merchants in their shipping. The seasons are more certain than in the West Indies, the genial trade-winds blowing almost incessantly during the whole year. In short, there is a probability that British Guiana may, at no distant period, become of much greater consequence than all the British West India islands put together. The chief inconveniences are a want of good water, which is generally brackish, and the myriads of insects with which this region is infested. The latter, indeed, comprehend every variety incidental to all known tropical climes. Of the eternal buzzing, biting, stinging, creeping, and crawling of these animals, it is impossible to convey any adequate idea to a European, unless the following lively remarks of an *Edinburgh Reviewer*, on the subject of Demerara entomology, may succeed in doing so:—"The *bete rouge* lays the foundation of a tremendous ulcer. In a moment you are covered with ticks. Flies get entry into your mouth, into your eyes, into your nose; you eat flies, drink flies, and breathe flies. Lizards, cockroaches, and snakes, get into the bed; ants eat up the books; scorpions sting you on the foot. Every thing bites, stings, or bruises; every second of your life you are wounded by some piece of animal life nobody has ever seen before, except Swammerdam and Merian. An insect with eleven legs is swimming in your tea-cup, a nondescript with nine wings is struggling in the small beer, or a caterpillar with several dozen eyes in its belly is hastening over the bread and butter. All nature is alive, and seems to be gathering all her entomological hosts to eat you up as you are standing, out of your coat, waistcoat, and breeches. Such are tropics. All this reconciles us to our dews, fogs, vapours, and drizzle—to our apothecaries rushing about with gargles and tinctures—to our old British constitutional cough, sore throats, and swelled faces." In addition to this humorous detail of animal pests, it may be mentioned, that the woods are crowded with snakes, some of them 30 and 40 feet long, and very dangerous.

The ornithology of Demerara comprises all that is rich and rare in formation and plumage. Nature has exhausted her fancy in the combination and contrast of hues in the same individual, from the tiny humming-bird, not larger than a humble-bee, sucking its subsistence from the bosom of the flowers, to the huge pelican and scarlet curlew, standing with their drooping wings in solemn rumination amongst the river mud. Our limits forbid us dwelling on this enticing subject.

The colonial population consists of three classes—whites, mulattoes, and negroes. The slaves were shockingly treated by their Dutch masters, but live in comparative happiness under the English, being well treated in every respect.

FOREIGN POSSESSIONS.

FRENCH.

Previously to the negro insurrection in 1792, St Domingo appertained to the French, and was by far the most valuable colony in the West Indies. Their only possessions now are Guadaloupe and Martinico (or Martinique), and the insignificant islands of Marie Galante and Deseada. These are all situated in the windward Carribean group. Guadaloupe and Martinico are islands of considerable importance and value. In 1827, the population returns were as follows:—Guadaloupe—Whites, 17,257; free-coloured persons, 16,705; negroes, 101,554; total, 135,516. Martinique—Whites, 9937; free-coloured persons, 10,786; negroes, 81,182; total, 101,905.

SPANISH.

A few years ago, the colonial possessions of Spain extended from the frontiers of the United States almost to Cape Horn. Now she has not a foot of land on the whole American continent; and of the islands, is possessed of only two worth mentioning—Cuba and Porto Rico, whose situation has been before mentioned. These, however, are of great value and importance, especially the former, which is by far the largest and finest of the West India islands; only about one hundredth part, however, is supposed to be under cultivation. The capital is Havannah, on the north coast, with a harbour capable of containing the largest fleet in safety. The entrance into it is so long and narrow, that only one vessel can pass at a time. The other principal towns are St Jago (formerly the capital of the island), Puerto del Principe, St Salvador (on the east side), Trinidad (on the south), with Santa Cruz, Baracoa, and Cadiz (all on the north or north-east of the island). There are supposed to exist veins of gold in the island, from the dust being found in the sands of the rivers; and there are also some valuable mines of copper.

DUTCH.

The Dutch possessions in the West Indies are Curacoa and St Eustatius, Saba and part of St Martin—all in the Carribean group. The two former are naturally barren. Curacoa, from its proximity to South America, was formerly a place of great contraband traffic; but since the independence of that continent, it has ceased in a great measure to be an *entrepôt.* It is 30 miles long and 11 broad, and produces sugar and tobacco. Like some of its sister isles, it is entirely dependent on the rains for a supply of water. It was held by the Spaniards until the year 1632, when it was taken by the Dutch, in whose hands it has since remained. The population is estimated at about 30,000.

St Eustatius consists but of one mountain, which is 29 miles in circumference, and cultivated to the very summit. The productions are sugar and tobacco, and the population may be about 15,000. It was first colonised by the Dutch in 1635, and continued for many years a subject of contention between them and the French, by whom it was alternately possessed, until 1781, when it was captured by Admiral Rodney. The booty which fell into the hands of the English on this occasion was estimated at L.4,000,000 sterling. It was restored to the Dutch by the peace of 1795; and after being again captured by the English, was finally secured to the Dutch by the peace of 1814.

Saba and St Martin are too inconsiderable to need further mention.

DANISH.

The Danish settlements, all belonging to the Carribean group, are three in number—St Croix (or Santa Cruz), St Thomas, and St John, of which the former alone is of any importance. It is about eighty-one miles square, and contains about 30,000 inhabitants. The soil is fertile, and well cultivated, producing sugar, rum, and tobacco. St Thomas is about six leagues in circumference, and St John about the same. They are both quite inconsiderable.

SWEDISH.

The only colony belonging to the Swedes is the small island of St Bartholomew, in the leeward Carribean group, and about fifteen miles in circumference. It has only one town and one harbour—Gustavia, and Le Carenage. The population is about 6000.

INDEPENDENT ISLAND.

ST DOMINGO.

To give a proper historical account of this, formerly the finest of all the West India Islands, would require almost a full sheet of our INFORMATION for the purpose; and a mutilated sketch would only serve to confuse our readers' ideas on the subject. We will, probably, soon recur to this interesting topic in the JOURNAL, but are here necessitated to confine ourselves to the following slender particulars:—

St Domingo lies between Porto Rico on the east, and Cuba and Jamaica on the west. It is about 400 miles in length, and 30 in average breadth. It was discovered by Columbus in 1492, who gave it the name of Hispaniola, or Little Spain. It was found possessed by native Carribs, who denominated it Hayti, or "the Mountainous Land." Columbus left a small colony, but these were soon expelled by the natives, on account of their cruelty and rapacity. The French next took possession of it about the year 1650, and, along with the Spaniards, divided the island betwixt them, after subjugating the natives. No particular event took place after this until the French revolution, when, taking advantage of the contest between the royalist and republican settlers, the natives and slaves rose in a body, massacred the whites, and established their independence; Christophe, formerly a slave, was elected chief, and after governing with great wisdom until 1811, was crowned king. In this dignity he formed a court of princes of the blood, dukes, counts, barons, chevaliers, military orders, &c., with all the ceremonials observed in the French court, and reigned undisputed till 1820; but his measures having become too despotic, his subjects rose in revolt, and, after an unavailing contest, seeing his affairs desperate, he shot himself. A republic was then established, and still continues the form of government, consisting of a senate and chamber of representatives, with a chief magistrate, or president, selected for life.

St Domingo has never recovered the devastations of the revolution, and all sorts of commercial productions have declined in an extraordinary degree. Sugar, for example, has fallen off from 141,000,000 lbs. to almost nothing; coffee from 77,000,000 lbs. to 30,000,000; cotton from 7,000,000 lbs. to 600,000 lbs.; indigo from 700,000 lbs. to nothing, &c. Such is the account, at least, presented by recent travellers, who speak of the population as being sunk in sloth and ignorance.

The capital of St Domingo is Port au Prince, on the west side of the island, within a large and beautiful bay. The population of the whole island may be estimated at 800,000, the whole of which are blacks, with the exception of a few white traders and casual residents.

Having now given a brief historical sketch of the West India islands, we now return to give a more minute account of the government, climate, productions, &c. of the British possessions.

GOVERNMENT OF THE BRITISH WEST INDIES.

The government of all the originally British West India islands is exactly alike, consisting of a governor and council, and a house of assembly, the members of which are elected by all the colonists possessed of a freehold to the amount of ten pounds. The governor is also commander-in-chief. Several islands are sometimes included in one government, who send their representatives to the island which is the seat of legislature for the time being. Thus, in the Leeward Islands, St Christopher's, Nevis, Montserrat, and one or two other small islands, send their representatives to Antigua, which is the seat of government for them all; or, in other words, the residence of the governor. The superior and inferior courts of judicature resemble, of course, those in England, the laws being the same; unless as they may be affected by the special colonial enactments passed from time to time. Assize courts are frequently held, to expedite the course of justice. There are, likewise, parish courts, wherein justices of the peace decide summarily in small debt cases. There are offices where all deeds, wills, sales, and patents, are recorded. All persons intending to leave the island are obliged to give notice at the office of enrolment three weeks before they can be entitled to a pass, or to find security for what debts they may leave unpaid in the island; and, for further precaution, masters of vessels are taken bound, under heavy penalties, not to carry off any person without such pass. The procedure of the assembly follows as near as may be the formula of the British legislature, and all their bills have the force of laws as soon as the governor's assent is obtained. The power of rejection, however, is vested in the crown, but, *until rejected*, the laws are valid. The governor can also refuse his assent to all such laws, and can dissolve and call together the assembly at pleasure. His salary is paid partly by the crown, and partly from the island revenues.

Those colonies not originally British are governed in a more arbitrary manner by a governor only, though possessing their former laws, whether French, Dutch, or Spanish.

CLIMATE.

The year may be divided into four seasons:—The first commencing with the mild vernal rains in April or May, which usually last six weeks; the second includes June, July, August—hot and dry; the third includes September, October, and November, which are the hurricane and rainy months; and the fourth, December, January, February, and March, which are the most serene and cool months.

The climate of the West Indies is pretty nearly alike in all the islands. The average of the thermometer in the towns may be set down at 80° during the summer months (from July to November). It often attains to above 90°, but in the mountains it has been known to be so low as 44°, so that a fire at noon is there necessary a great part of the year. The temperature is kept cool by the alternations of the sea and land breezes, the former blowing only during the day, the latter only during the night. Of the latter, which always blows from the centre of the island (be it ever so small), the only scientific account ever given is that of Dr Franklin, which is as follows:—"As soon as the sea-breeze dies away (in the afternoon) the air of the plains, being rarified, ascends towards the tops of the mountains, and is there condensed by the cold, which making it specifically heavier than it was before, it descends back to the plains on both sides of the ridge." It is a singular dispensation of Providence, that in Barbadoes and the smaller windward Charaibean islands, which are without these landward breezes, the sea-breeze (or trade-wind) blows both night and day.

The most delightful time of day in Jamaica is at day-dawn, before the sun has yet begun to pour his effulgence over the hemisphere of the Carribees, and before the land-breeze has died away. The sea-breeze, or "doctor," as it is gratefully designated by the inhabitants of Jamaica, which invariably blows from the south-east, or some other point ranging from south to east, generally sets in about nine o'clock A. M., at first only gently rippling the surface of the ocean, and increasing gradually, until it often assumes the strength of a temporary hurricane. Its coming is hailed by the panting, and literally melting inhabitants, with a degree of thankfulness and a sensation of relief, which can only be known by those whose lot it has been to inhale the oppressive and suffocating atmosphere of these climes.

Were it not for this regular alternation of trade-winds and inland-breezes, the islands of these seas would, to Europeans at least, be perfectly uninhabitable. Let such of our readers, therefore, whose destiny has never led them beyond the cool shores of Britain, conceive, if they can, the sufferings of their brethren in the tropics, when it happens that the 'doctor' absents himself for a whole fortnight at a time.

In the afternoon, the sea-breeze dies away, as it comes—gradually; after which, for a few hours, earth and sea are again locked in a stillness of repose—a syncope of motion, which, to a new comer, has something almost ominous; and as his imagination is generally saturated before his arrival with descriptions of those fearful visitations, the earthquakes—which are there so frequent, though seldom occasioning much damage—he instinctively listens, in that period of profound stillness, for the first rumbling growl preceding the volcanic explosion. Earthquakes, however, have for many years been becoming rarer and rarer in the West Indies—a fact which seems to confirm the hypothesis that these islands having, at one time or other, had their origin in volcanic eruptions, are gradually cooling, and that these fearful visitations will soon altogether cease. There is scarcely a house, however, of many years' standing, in the walls of which several huge cracks are not to be seen—a circumstance which called forth a witticism from a late visitor, who observed, that although the value of West India property was daily falling, the *rents* of the houses were yearly increasing.

The most dreadful scourge of these islands are the hurricanes, which have devastated them all repeatedly from time to time. Between the years 1780–87, a succession of hurricanes desolated Jamaica to such an extent, that, combined with the scarcity of provisions produced by the American war, no less than 15,000 negroes perished from famine. The more mountainous islands also suffer severely from the violent rains, which pour down, as they actually appear to do, in bucketfuls, sometimes sweeping the entire soil, and all growing thereon, from whole plantations, and leaving nothing but the bare rock! Since the gradual clearing of the islands from wood, thunder is much less frequent now than formerly, and seldom does any damage. It is, however, terrifically loud.

PRODUCTIONS.

Having exhibited in the annexed tables the staple articles of commerce produced by the various islands, we think it unnecessary to recapitulate them here, and shall, instead, shortly enumerate the productions, animal and vegetable, which form the principal articles of colonial consumpt—a subject less generally familiar to our readers.

The natural productions of all the West India islands are so uniformly alike, that a description of those in one colony may be regarded as a general enumeration of those peculiar to all. A late writer in our Journal, who was himself a residenter in Jamaica for a considerable time, thus enumerates the more common varieties of animal and vegetable food, both in the seaports and the interior:—"There are few places in the world where people in general *live* better, I believe, than in Jamaica—from the highest to the lowest—the governor to the plantation negro. Food of all kinds is in abundance—flesh, fish, fowl, fruit, and kitchen vegetables. To be sure, the assortment varies in different districts, but all are equally well supplied with some kinds or other. If fresh beef and mutton abound most in the towns, the mountains have a still better supply of pigs, poultry, kid, and game. The beef is seldom good, owing to the universal practice of drawing the oxen in teams for several years; besides, the heat of the climate obliges its consumption, or at least cooking, within four-and-twenty hours after being killed. The mutton is coarse, and, from the appearance of the sheep, one wonders that it is not a great deal coarser. The young kids are much used, and highly prized, and, when properly roasted, look very tempting and tender, but still there is a rankness of flavour about the flesh which bespeaks the future goat, and which I never could reconcile myself to. The pigs, especially those fed on the sugar estates, are the most delicate and delicious, I should think, in the universe. What the acorn-fed porkers of Westphalia may be when young, I know not, but they must be fine indeed to excel their West Indian brethren, educated on the juicy cane roots and plantain stems. The veal I never tasted. As for the fish, there are few places supplied more abundantly, or in greater variety. It would occupy, indeed, a whole page of letterpress to enumerate them; therefore I shall name none. Many of them are large and rich, but their flesh is in general soft and pulpy, nor is there any one of them at all to be compared to our own salmon. One small kind, called the *snapper*, with various other sorts, are to be seen swimming about near the shore of the clear pellucid harbour, and under the numerous quays, in thousands. In the inland streams, the mountain mullet, a fine rich trout, is the prevalent fish. Speaking of fish, I must not forget the shell-fish; but I refer to them only for the purpose of noticing two species—the oyster and the black crab. The former literally *grow upon trees*; that is to say, they adhere to the pendant branches of the willows that grow on the margin of the water, and in this state are brought into market, where they are sold at so much per stick. But, assuredly, unless informed, I should never have guessed them to have been oysters. Their shells generally resemble those of the mussel rather than the pandore. They are very sweet and wholesome, nevertheless. The black crab (which resembles exactly our Scotch *parton*, but smaller, and darker in the colour) is generally considered a great delicacy in Jamaica. The habits of this animal are as great a puzzle to the West Indians as those of the salmon are to the naturalists of Scotland. They are found in all parts of the interior, and it is believed they migrate every year from one side of the island to the other; at least they have often been met with, in hundreds together, slowly traversing the country. At these times it is dangerous to meddle with them, as, should they fix upon a man, mule, or horse, nothing but wrenching their claws off their bodies could make them quit their hold. It is a curious characteristic of this animal, that, during these migrations, nothing can make them swerve from their path. Be the obstacle which comes in their way stone, tree, or precipice, they go direct over it by means of their adhesive claws. Whilst sojourning on the seashore, they burrow in holes like rabbits. The domestic fowls are the common hen, the guinea-hen, the peacock, the turkey, the duck, and, I think, the goose. The first of these are chiefly disposed of to vessels leaving port; but the guinea-hen, although seemingly a more delicate bird, is easier kept, and stands the voyage much better. The turkey thrives uncommonly well in Jamaica. The game, or wild-fowl, is exceedingly limited in variety. The guinea-fowl and the quail are plentiful; but owing to the rank vegetation that covers the country, any thing like regular hunting is impossible. There is likewise abundance of snipes, and also numerous varieties of the pigeon tribe.

Of the fruits in Jamaica I need scarcely speak. They comprise almost every species known in the western tropics. The vine and pomegranate cluster every veranda where the owner takes the trouble to plant them. A large delicious pine-apple may be bought in the market for a fippeny (3d. sterling). The juicy water-melon, which retains its delightful coolness even when exposed, unsheltered, to the burning sun, is abundant, and grows to a very large size. Oranges are in the utmost profusion, and better I never tasted than what I met with sometimes. The tamarinds are literally allowed to rot on the trees. The mangoes are so common that they are little regarded, unless by the negroes, scores of whom are every year carried off from eating them ere they are fully ripe. Besides the fruits I have mentioned, there are the shaddock, the star-apple, the pappaw, the bread-fruit introduced by Captain Bligh from the South Sea Islands in 1793, and a host of others. Wild strawberries are found in the higher parts of the mountains. The English apple, also, grows in Jamaica, but is very dwarfish; nor must I omit to mention the pears, which are not eaten, as with us, as a dessert, but to meals, with pepper and salt! They bear no affinity, however, to the British pear, but have a large stone in the heart of them, and the fruit is of a fat tasteless nature, which few strangers relish. I have eaten the ripe figs from the tree, too; but to my taste they are nothing to be compared in their green to their preserved state. The cocoa-nut tree takes, I believe, fully a dozen years ere it begins to bear. While the nut is green, and before the white kernel, or rather coating, begins to form on the inside of the shell, the cavity is quite filled with a watery liquid of a sweet rich taste, which is reckoned very nourishing. I have taken an English pint of this liquor from one nut, and drunk it too. There is a great similarity of appearance between the palm and the cocoa-nut trees; and although the former is the statelier plant, the branches of the latter excel it in freshness of colour—bright green.

There is no scarcity of kitchen vegetables in Jamaica. The potatoes endeavoured to be raised there are, as in all tropical climes, very bad—small, watery, and waxy. The want of them, however, is amply made up by the yam in the mountains; and in the seaports there is at all times a plentiful importation of potatoes from Ireland, Britain, and America. There are green peas all the year round, and a numerous variety of small delicate beans. A plant called calaloo grows wild, which is much used in the interior, and resembles exactly our spinach in taste, colour, and medicinal properties. Perhaps I should also include the plantain among the vegetables for table use, as it is used instead of loaf-bread at all meals by the planters in the interior. There is a root, too, called the cassa, which in its green state is rank poison, but, when dried in the sun and pounded, makes a white and pleasant cake. One of the greatest treats of the vegetable species which I met with among the mountains, was, 'the garden marrow,' which, when sliced down and fried, bears the nearest possible resemblance to a rich, well-cooked pancake."

INSECTS, REPTILES, BIRDS.

One of the most annoying pests of the West Indies is the myriads of ants that every where swarm as well within as without doors. There are innumerable varieties of them—some black, some brown, some large, and some very small. But, like all the other creations of Providence, these little animals, which, by some superficial writers have been called the "plague of the West Indies," prove of the most beneficial consequence to the health of the island. They are carnivorous, and prevent the accumulation of putrid animal matter. Their scent is remarkably acute, and a dead fly, wasp, or even musquito, will not lie on the floor for two minutes, before a procession of ants will be seen issuing from some distant corner of the apartment, who drag off their prize bodily to their store-house, to be consumed at their leisure.

Perhaps the greatest annoyance experienced by new settlers in these islands is from the bites of the musquitoes, although these animals are not nearly so formidable there, in size or sting, as on the South American continent. In the latter they are so dreadful a plague, that people obliged to sleep out of doors can only find protection from the smoke of rank and green weeds thrown upon a fire to windward of them. In the islands, however, they are bad enough, in all conscience, and a new settler may almost be recognised from the blotched and swelled appearance of his face, hands, and ankles—in short, every part of his person exposed to their venomous probosces. They resemble exactly our British midge, and are in fact of the same family of insects. After a short residence, they cease to be any annoyance to Europeans, who become callous to their stings, and whom, indeed, they cease to fix upon after getting quit of their rich European blood. They do not at all trouble the negroes, whose oily skins are impervious to their stings: they are most tormenting during the night, and, to guard against their attacks, gauze curtains are hung round the bed of every respectable inhabitant in town or country. The process of getting into bed without admitting any of these tiny persecutors, is one requiring great dexterity, and not a little scientific manœuvring, as will be seen by a most humorous description, given by Captain Basil Hall in the third series of his entertaining "Fragments;" and which, although applying to the eastern hemisphere, is equally applicable to the west.

Another of the pests of the West Indies is the *chigre*, a small invisible insect, which enters the skin, and, unless extracted speedily, breeds the most disgusting sores. They abound chiefly on the coffee plantations. After getting into the flesh, they will hatch a colony of young chigres in a few hours. They will not live together, but every chigre sets up a separate ulcer, and has its own private portion of pus. Their presence is known by a sharp itching of the part.

The cockroach is a large and disgusting animal, but harmless. It resembles our cricket in appearance, and abounds in thousands.

One of the most singular of the animal phenomena peculiar to the West Indies, are the fire-flies. The light emitted from their bodies is phosphorescent, and only glows during the night. "I was in the habit," says a late writer in our Journal, on Jamaica, "almost nightly, of enclosing a dozen or more of fire-flies under an inverted glass tumbler on my bed-room table, the light from whose bodies enabled me to read without difficulty. They are about the size of a bee, and perfectly harmless. Their coming forth in more than usual numbers is the certain harbinger of impending rain; and I have frequently, whilst travelling, met them in such myriads, that, be the night ever so dark, the pathway was as plain and visible almost as at noonday. The light they emit resembles exactly the lustre of the diamond, and I have been told that it is no uncommon thing for the Creole coquettes to insert a few of them, confined in pieces of thin gauze, amongst their hair, and in various parts of their dress, just as our belles at home avail themselves of the ingenuity of the paste-jeweller."

There are few poisonous reptiles in the West India islands besides the scorpion, which is very numerous. It lodges principally about old walls, and the trunks of felled and decayed trees; its bite always produces fever, and often causes death. There are many varieties of serpents, but they are almost all harmless. The kind most common in Jamaica is the yellow snake, which is frequently found of seven and eight feet in length. It often comes into the houses; and one of them is reckoned an excellent prize by the negroes, from the great quantity of oil it yields.

One of the most common of the reptile tribe is the lizard, exactly resembling the alligator in shape. These animals are to be seen frisking about in thousands throughout all the interior, especially about the public roads. Some of them are two feet long; and many of the inhabitants consider them a great delicacy when stewed. Their flesh is quite white, and resembles that of a chicken or rabbit.

Amongst the most destructive of the animals which infest the West Indies, is the rat, which is very large in size. The history of this animal is somewhat peculiar. It was introduced into several of the West India islands about fifty years ago, by Sir Charles Price, for the purpose of extirpating the native rat. This it soon did most effectually, but at the same time overran the island itself, proving by a thousand degrees a greater pest than their predecessors. They annually do great damage to the cane-grounds. One of the first animals which attract the attention of a stranger in the West Indies, is the large carrion crow, called by the negroes the "John-crow." It is a large, heavy, sluggish bird, about the size of a British turkey, the head exactly resembling that of the latter. It is black in colour, and in the interior is seen floating at an immense height above every hamlet. Its sense of smell is so keen that it will discern the effluvia from the body of the smallest dead animal at several miles' distance, and has been known to scent the dead bodies in wrecks when the vessels themselves were out of sight of land. They are found so beneficial to the health of the island in thus consuming all putrid animal substances, that a fine of a doubloon (L.5 currency) is exacted for the killing of every one of them. When sickness prevails in a house, these birds perch upon the roof even in the midst of towns, where they will remain for many days, as if waiting for their loathsome banquet—in the same manner as sharks are said to attend sick ships at sea.

SLAVES AND THE SLAVE-TRADE.

So much has been said of late on the subject of slaves and slavery, that we consider it necessary to give only a brief detail of the origin and history of that abominable system, which is now happily in the process of being extinguished for ever. It unquestionably received its first great impulse during the adventurous reign of Elizabeth, and increased thenceforward to a height which is horrible to reflect upon. Even so late as the year 1764, Jamaica alone required an annual supply of upwards of 10,000, although the colonists had long before that begun to manifest a decided dislike to this continued influx of the wretched Africans. We find that, from the middle of last century, indeed, repeated remonstrances were made to the home government by all the colonies against the encouragement given to this traffic; but in vain. In 1774, at a public meeting in Jamaica, resolutions were passed to the effect that the "trade to Africa for slaves was neither consistent with *sound policy, the laws of nature*, nor morality." In the same year the local legislature passed laws restricting the trade; but the merchants in Bristol, Liverpool, London, and the other mercantile ports in England (whom alone the traffic was enriching), raised such an outcry, that the ministry refused to ratify the colonial law. In spite of this want of sympathy in Britain, both for the feelings of the colonists, and the sufferings of the poor Africans, we find the former afterwards doing all in their power to discourage the traffic, and passing laws from time to time for ameliorating the condition of their slaves. A better feeling soon began to spring up in Britain, and, in 1772, the first great blow was given to the system of slavery, by the decision of Lord Mansfield, that "*no man can be a slave after touching the soil of Britain.*" From this time forward, the advocates of the abolition of the slave-trade became every day more numerous and enthusiastic, amongst whom, Mr Granville Sharp and Mr Clarkson were the most indefatigable. The same principles spread also rapidly through other countries, and societies were formed to promote the Christian object. By the commencement of 1788, these exertions had produced so much effect, that the table of the British House of Commons began to be crowded with petitions on the subject, and among their supporters was almost all the array of talent (including Fox, Burke, Whitbread, Pelham, &c.) which then distinguished that assembly. Mr Pitt also became deeply interested in the subject, although, from his official situation, his repeated motions for inquiry, &c., were all so cautiously worded, that he obtained little credit for his good feeling. On the 29th May 1789, the late Mr Wilberforce, who seems, until then, to have taken little *public* interest in the matter, introduced the subject to the house in a speech of three and a half hours long, and concluded by proposing the entire abolition of the slave-trade in a series of twelve resolutions. These were supported by Mr Pitt, Mr Fox, Mr Grenville, &c. The house went into committee, which sat and adjourned from time to time, until the year 1791, when the bill founded on the resolutions was thrown out by an immense majority (amongst the foremost of whom is to be found, curiously enough, the name of Lord John Russell). At the same time, a prospective and indefinite motion for the *gradual* abolition of slavery, proposed by the late Lord Melville (then Mr Dundas), was carried by a small majority. From this time forward, an almost continual struggle was carried on between the two parties, until the year 1805, when Mr Wilberforce again succeeded in carrying his resolutions, that the slave-trade be abolished within a limited period; but the bill founded on them was thrown out by the House of Lords. The death of Mr Pitt in 1806, though it deprived the cause of one of its warmest supporters, brought in a ministry unanimously favourable to it; and, in the same year, a bill was accordingly passed, abolishing for ever the inhuman traffic of importing slaves from Africa, and negociations were at the same time opened with foreign countries for co-operating in suppressing it.

The carrying of this great measure satisfied the friends of emancipation for some time; but, of course, in the eyes of humanity, the act could only be regarded as a preliminary step to the entire extinction of slavery itself. It is needless here to review the various efforts made in Parliament of late years with this view, as the nation may be said to have been perfectly unanimous in the praiseworthy cause, the only difference of opinion being as to *how* and *when* such a measure ought to come into effect. Suffice it to say, that, on the 31st May 1833, a series of resolutions were proposed to the House of Commons by Mr Stanley, secretary for the colonies, of the following purport:—"1. That immediate and effectual measures be taken for the entire abolition of slavery throughout the colonies, under such provisions for regulating the condition of the negroes, as may combine their welfare with the interests of the proprietors.—2. That it is expedient that all children born after the passing of any act, or who shall be under the age of six years, at the time of passing any act of Parliament for this purpose, be declared free; subject, nevertheless, to such temporary restrictions as may be deemed necessary for their support and maintenance.—3. That all persons now slaves be entitled to be registered as apprenticed labourers, and to acquire thereby all rights and privileges of freemen; subject to the restriction of labouring, under conditions, and for a time to be fixed by Parliament, for their present owners.—4. That to provide against the risk of loss which his majesty's colonial possessions might sustain by the abolition of slavery, his majesty be enabled to advance, by way of loan, to be raised from time to time, a sum not exceeding in the whole L.15,000,000, to be repaid in such manner, and at such rate of interest, as shall be prescribed by Parliament.—5. That his majesty be enabled to defray any such expense he may incur in establishing an efficient stipendiary magistracy in the colonies, and in aiding the local legislatures in providing for the religious and moral education of the negro population to be emancipated."

These resolutions, with various alterations and additions during the discussions which followed—the most important of which was the substitution of a *gift of L.20,000,000* for the previously proposed loan of L.15,000,000—were ultimately carried, and a bill founded on them finally passed both houses, and received the royal assent on the 28th of July. It is peculiarly gratifying to know that the accomplishment of this great object seems to have met with cordial co-operation from most of the colonial legislatures, the chief objection being to the apprenticeship clause—several of the islands preferring *immediate emancipation* to the prospective term. Recent accounts have brought the pleasing intelligence of the passing of the emancipation act by the Assembly of Jamaica on the 12th December 1833; and as the other colonies will doubtless follow the example of the principal island, we shall here give an abridgement of the leading provisions of the act:—

"From the 1st August 1834, the slaves, aged six and upwards, are to become apprenticed labourers, without any formal indentures.—The slaves are divided into three classes: Prædial labourers, employed on their masters' lands: Prædial labourers, employed on other lands: Non-prædial labourers.—The apprenticeships to cease in August 1840, and the hours of labour not to exceed forty-five hours in the week. Non-prædial apprenticeships to cease in 1838.—Masters to be liable for the maintenance of discharged labourers above fifty, or those that are disabled.—Apprentices may purchase their discharge, without consent of the master, by paying the appraised value.—The value to be appraised by three justices of peace, who are to order sums advanced on the security of the negro, to be paid out of the purchase-money.—No apprentice to be removed from the island, nor to another estate, if the removal separates him from his wife or child.—An employer's right to an apprentice's labour may be transferred by bargain or sale, but families not to be separated.—The employer bound to supply the apprentice with food, clothes, and medicine.—Children under twelve, now born, to be indentured, and remain apprentices till twenty-one.—Special justices to be appointed for the execution of the act, who shall take cognisance of offences committed by negroes.—There are long regulations as to punishment, which we cannot abridge; but it is enacted that females are not to be flogged.—Sunday markets to be abolished, and prædial labourers to have Saturday free."

Respecting the present condition of the slaves, so much has been written and spoken on the subject of late, that we believe our readers will not thank us to enter on it here. It is satisfactory to know, that, while their moral and intellectual condition is so wretched, they are blessed with physical comforts far superior to the labouring classes of perhaps any country in Europe. To those who wish a faithful picture of the domestic condition of the negroes, we recommend a perusal of Mrs Carmichael's work on the West Indies—and we do this from *personal knowledge* of its strict accuracy and truth.

TRADE.

The present state of commerce in the West Indies will be best seen by the annexed tables; but it is necessary to say a few words in explanation of the great deterioration it has been undergoing for many years, and the consequent falling off in the value of property.

Previous to the American war, and when the trade between the American and West Indian colonies was unrestricted, the latter may be said to have attained the meridian of their prosperity; but when that great mart for reciprocal commerce was shut up, they rapidly declined. Even after the war was settled, all direct intercourse between the two was interdicted; and the planters have ever since been compelled to supply themselves with lumber, staves, flour, and others of their most indispensable articles, by a distant voyage from our British American colonies. This most unnatural system of policy is the main cause of the present depressed state of the West Indies. "All circumstances," says Mr Edwards, "necessarily and naturally lead to a commercial intercourse between our islands and the United States. It is true we may ruin our sugar colonies and ourselves also in the attempt to prevent it, but it is an experiment which God and nature have marked out as impossible to succeed. *The present restraining system is forbidding men to help each other; men who, by their necessities, their climate, and their productions, are standing in perpetual need of mutual assistance, and able to supply it.*" Besides this, the interests of the colonists have been most unjustly sacrificed in many ways to those of the British merchants—as, for instance, in forbidding them to clay (refine) their own sugar, by which a loss is yearly sustained by them of upwards of L.80,000; and this, too, solely for the benefit of a small body—the sugar refiners. Add to all this, that most oppressive duties are imposed on all articles imported into the islands, not coming directly from Britain or a British colony. The revenue thus derived amounted in 1828 to L.75,000, and the charges of collection to about L.65,000.

Under the present system of policy, indeed, it is notorious that these fine islands are every day sinking to ruin. The planters are getting unavoidably deeper and deeper in debt to the merchants (who are their bankers), into whose hands their estates are gradually passing, and these, too, must of course be ruined by having their funds sunk in properties yielding no return. It is to be hoped that the late liberal act of emancipation is only the preliminary to a more liberal system of commercial policy.

VALUE OF EXPORTS AND IMPORTS.

Total official value of imports from the West India colonies into the United Kingdom, and exports to the same from the same, for the year 1829:—

	Imports.	Exports.
Antigua	£255,500	£146,657
Barbadoes	489,214	369,836
Dominica	141,811	27,478
Grenada	359,813	93,015
Jamaica	3,741,179	2,781,483
Montserrat	40,958	8,302
Nevis	78,278	25,228
St Kitt's	192,280	97,234
St Lucia	157,533	51,505
St Vincent	414,548	99,891
Tobago	158,385	51,368
Tortola & Virgin Islands	33,243	5,606
Trinidad	604,001	361,077
Bahamas	17,915	51,524
Bermudas	4,901	24,817
Demerara	1,702,409	509,236
Berbice	325,051	51,587
Honduras	190,795	792,278
Total	£9,067,914	£5,521,169

PRODUCTIONS.

Account of the quantities of the three great articles of sugar, coffee, and rum, imported from the British West Indies into the United Kingdom in the year 1830:—

Colonies.	Sugar. Cwts.	qrs.	lbs.	Coffee. lbs.	Rum. Proof gal.

							836,537

* This alludes to the settlement of Belise, which is not exactly a colony, but an establishment of logwood and mahogany cutters, permitted, under certain restrictions, by the Spanish government.

MONEY.

What is called West India currency is an imaginary money, and has a different value in different colonies. The following are the values of L.100 sterling, and of a dollar, in the currencies of the different islands:—

	Sterling.	Currency.	Dollar.	Currency.
Jamaica	L.100 =	L.140	1 =	6s. 8d.
Barbadoes	100 =	135	1 =	6s. 3d.
Windward Islands (except Barbadoes)	100 =	175	1 =	8s. 3d.
Leeward Islands	100 =	200	1 =	9s.

EDINBURGH: Published by W. and R. CHAMBERS, 19, Waterloo Place; also by ORR and SMITH, Paternoster Row, London; and YOUNG and CUNNINGHAM, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight.
From the Steam Press of W. and R. Chambers.

CHAMBERS'S
INFORMATION FOR THE PEOPLE.

CONDUCTED BY WILLIAM AND ROBERT CHAMBERS, EDITORS OF THE "EDINBURGH JOURNAL" AND "HISTORICAL NEWSPAPER."

No. 27. PRICE 1½d.

THE AMERICAN WAR OF INDEPENDENCE.

THE American War of Independence is an event not nearly so familiar to the present generation of the British people, as, from its importance, it ought to be. It is one of those transactions which are sufficiently remote to be beyond the personal knowledge of the passing generation, and yet not remote enough to have become a subject for either popular or classical history. Hence, that America did render herself independent of Great Britain, is the sum of knowledge which four out of five persons in this country are found to possess upon the subject. The causes of the war, its transactions, and its close, so happy for America, and so disastrous for Great Britain, are circumstances of which few persons have more than a dream-like notion—though nothing can be more certain than that this war has exercised an influence upon the fortunes and destinies of every modern nation, and even, perhaps, of every civilised man now existing. In our article on British History, the objects and circumstances of the contest were adverted to, but, necessarily, in too brief a manner to convey a full idea of their significance: we shall now endeavour to make our readers acquainted a little more extensively with the affair, by presenting to them a narrative slightly abridged from an American work, the title of which is quoted below;* only premising, that some allowance must be made for a little colouring in favour of the American cause, which was perhaps unavoidable in such a production. The narrative has so many qualities suitable to our purpose, such as simplicity of arrangement, and a certain amusing quaintness of style, that we can easily overlook this fault, as we doubt not the most of our readers will do also.

STATE AND NUMBER OF THE COLONIES.

The colonies which achieved their independence on this occasion were thirteen in number, extending along the eastern shore of North America between the St Lawrence and the Mississippi. Massachusetts, including what is now Maine, New Hampshire, Connecticut, and Rhode Island, were together known, as they are now, by the general name of New England. What is now Vermont was then claimed by New York. The other nine colonies were Virginia, New York, Pennsylvania, Delaware, New Jersey, Maryland, North and South Carolina, and Georgia. The number of inhabitants in all was not much less than three millions. As the colonists, or their ancestors, came, most of them, from England, spoke the English language, and lived, like every other part of the great British empire, under the English laws, it may seem singular, at first, that any thing should have taken place to unite the whole American people in a common cause of rebellion, as the English called it—or of civil war, as they called it themselves. We shall see, however, in the sequel, that, considering the course of policy pursued by the British government, it could not well happen otherwise than it did.

Many of the provinces, or colonies, were settled between the years 1607 and 1666. At first, the British government did not pay much attention to them; but as they increased in wealth and population, they became objects of deeper interest, and the king and parliament passed many laws respecting them. These laws, at a very early date, were framed more for the benefit of England than the colonies. But previous to the year 1760, they were generally submitted to. About that period, the American affairs began to be managed in a more arbitrary manner.

TAXES IMPOSED ON THE COLONIES.

The English thought, as the Americans had become a great people under their protection, in some measure, it would be just, or at least expedient, to derive some profit from them. They began to make laws, therefore, in parliament, about the time we have just mentioned, to regulate the American trade. They required the colonists to carry to the English every thing their rich lands might produce beyond their own wants; that is, if they exported any thing, it must be sent to the English. The country abounded with fine pastures, as it does now. A great many sheep were kept by the farmers, and they were glad to dispose of large quantities of wool. All this they were obliged, by the acts or laws of parliament, to sell to the English alone. They were required, also, to buy of the English whatever foreign cloths or other manufactures they had occasion for. The colonists were not much displeased with these regulations, however. The English merchants, richer than themselves, not only supplied them with their manufactures at moderate prices, but lent them large sums of money, which the Americans used in improving the appearance and increasing the wealth of the country.

On the whole, it is likely that things might have gone on quietly for a long time, had not the British begun to lay duties on the American import trade, which was felt as a grievous interference of the mother country. In the year 1764, this taxing system was re[illegible] as possible, by the most rigorous restrictive measures.

From this time, the Americans, some of them at least, began to question the propriety and necessity of obeying a government three thousand miles over the ocean. They very generally determined, at all events, to purchase as few as possible of the English manufactures, and to make as many and as good as possible for themselves. In Boston, especially, a rich and large town, even then containing more than 10,000 inhabitants, the people were exceedingly dissatisfied with the new laws. They had bought, and used, and sold again, vast quantities of English goods; but they determined, now, either to do without them, or manufacture similar articles for themselves.

They used no more English gloves, for example; the practice of wearing mourning was given up. In fact, there was near 50,000 dollars' worth less of British merchandise sold in this single city, during the year 1764, than during the year previous. Other towns and other colonies soon followed this example. The people every where left off the use of English luxuries, and the merchants, finding themselves generally in debt to the English, and having little gold and silver, as we have seen, to pay them, or to purchase more goods with, gave up the trade almost entirely.

STAMP ACT.

However much the colonies were dissatisfied with all these heavy duties, and vexatious arrangements of commerce, they had not yet disputed the right of the English parliament to make them. They did not consider them as taxes, but as mere regulations. About this time, however, the British ministers proposed in parliament (March 10, 1764), a law for charging "certain stamp duties (taxes on various kinds of papers required to be *stamped*) in the colonies and plantations."

"A large debt had been contracted," said they, "in the course of a war, carried on chiefly to accommodate the Americans, by driving off the French, taking possession of Canada, and killing the Indians on the western frontiers. Troops must still be kept in America, the British government must protect the people, and why should they not pay a part of those taxes which the English pay in the mother country, especially as the money will be used, as it always has been, for their benefit? The tax will be small; and as for gold and silver, no doubt enough will be found. The Americans are well known to be a rich people."

But the Americans thought differently about these things, and began to speak and write as they thought, without much ceremony. "The French war," they said, "was undertaken by the English for their own good, and ought to be at their own cost. As for the future, if they (the Americans) were powerful and rich, as the English pretended, they could certainly protect themselves against the Indians, and the French were conquered already. They were willing, at all events, to furnish the troops that might be wanted for their own defence." But the Americans did not care so much what the tax was for, or what, or how much it was, as they did that it was a new thing; and as the American people had no right to send representatives to the English parliament, where the taxes were voted, they thought it as unjust as it was new.

The stamp act was not passed in parliament until March 1765. Before that time, and while the law was under consideration, all the colonies protested against it, and most of them sent agents to London to reason with the English ministers; but in vain. The act passed in the House of Commons, by a vote of 250 members against 50. Dr Franklin, then in London, wrote the same evening, to an American gentleman, as follows:—"The sun of liberty is set; the Americans must light the lamps of industry and economy." The gentleman answered, "Be assured we shall light torches of quite another kind." The people of Virginia and Massachusetts were among the first to oppose the stamp act. But the same feeling was soon spread over the whole country. The newspapers were still published on paper not stamped, and these were filled with warm discussions upon this subject. The lawyers also agreed to use no stamped paper; a great many public officers gave up their commissions, and vast numbers of the people, calling themselves sons of liberty, agreed to oppose the stamp act, and to assist each other, at all hazards.

DISTURBANCES ABOUT THE STAMP ACT.

These disorders broke out again when the first English ships reached America with their cargoes of stamped papers. The law was to go into force on the first day of November. On the 5th of October, the ships appeared in sight of Philadelphia, at Gloucester Point. All the vessels in that harbour hoisted their colours half-mast high, as a sign of mourning; the bells were muffled, and tolled for the rest of the day; and several thousand citizens soon collected at the State-house. They sent a message to John Hughes, the principal stamp officer, requesting him to resign the office; and after a day or two, finding the mob rather troublesome about his house, he concluded to do so.

Some of the stamped paper reached Boston on the 10th of September, and, by the governor's order, was lodged in the castle, to be defended, if necessary, by the artillery. But on the first day of November, at day-break, all the bells of the town sounded a funeral knell. Two very large effigies were found hanging on an elm-tree, which after this was called "the tree of liberty." The streets were filled with crowds of people. At three in the afternoon, the images were carried about the town, then hanged on a gallows, and cut to pieces. Mr Oliver, who had promised before to have nothing to do with the stamps, was carried to the "tree of liberty," and compelled to promise over again. Almost every body went armed.

Similar scenes were enacted at New York; and by the middle of November 1765, not a sheet of the stamped paper was to be seen. It was all either burned or sent back to England. The Massachusetts people, before this time, had proposed a general meeting, or congress, consisting of representatives from all the colonies. This meeting took place on the 7th of October, at New York, and there petitions were drawn up to be sent to the king and parliament of England. Their object was to effect a repeal of the stamp law. These petitions also complained of the late law of parliament, obliging those Americans, who were to be tried for resisting the stamp laws, to be carried to England for trial.

STAMP ACT REPEALED.

On the 22d of February 1766, the stamp act was

* The Story of the American Revolution, illustrated by Tales, Sketches, and Anecdotes. By Lambert Lilly. Philadelphia, 1831.

repealed by parliament. The king had just appointed new ministers more favourable to America than the old ones. They had heard of the disturbances in the colonies, and began to be alarmed lest something worse might happen. Vast numbers of petitions for the repeal had been offered by English merchants and manufacturers, who were suffering very much from the high spirit and resentment of the colonies. A great number of workmen had nothing to do. The goods lay in the warehouses unsold, and England could no longer get rice, indigo, tobacco, oil, furs, potash, and a great many needful things, as she used to do, from the colonies.

But the repeal took place, and every body was satisfied. The American merchants in London were delighted, and the tidings were received in America with the same joy. The legislatures, or assemblies, of Massachusetts and Virginia, went so far, even, as to vote thanks to Mr Pitt, and other English gentlemen who had done a great deal to obtain the repeal. They resolved to erect a statue of the king, in Virginia. But this feeling lasted but a short space. At the time of voting the repeal, parliament had also voted "that they had a right to tax America in all cases," as they pleased. The colonists soon began to be displeased with this. They had disliked the stamp law, not so much because they were too poor to pay a small tax or duty, but because they thought it unjust, and were afraid, if they paid it, that other and larger ones would be imposed upon them.

NEW DUTIES IMPOSED.

Notwithstanding these forebodings, things might have gone on quietly for a long time, or the discontent might have been altogether allayed, and the colonies continued faithful to Britain, had not parliament, in July 1767, imposed new taxes, to be paid on all tea, glass, and paints, imported from England into America. The Americans now broke out into loud complaints; but it was at Boston that these assumed the most formidable appearance. The Bostonians had such a character in England for being troublesome, that General Gage was about this time, 1768, ordered to station a regiment or two of troops among them. A frigate and four other armed English vessels were kept upon the coast to aid the revenue-men. Meanwhile, as the governor had not yet called together the Assembly, they took the matter into their own hands. Hearing that troops were coming, they agreed to provide themselves with arms, and to invite all the towns in Massachusetts to send delegates to meet at Boston. Deputies met accordingly, from 96 out of 97 towns, in September. They could make no good terms, however, with the governor. The day before they left the city, the troops arrived in the harbour. It being apprehended that the people would not suffer them to land, the fleet, fourteen ships in all, sailed slowly into the harbour, and arranged themselves, with their guns pointed, and crews ready for action, so as to command the whole town. The two regiments landed at one o'clock, and marched into town with great parade. The selectmen were desired to provide quarters or barracks for them, but refused to do so. The governor then ordered them to make use of the State-house; and a large guard was placed in front of that building, now called the City Hall, with cannon at the door.

TUMULTS IN BOSTON.

Feelings of the deepest enmity to England now grew every day stronger, and the people generally agreed to give up the use of English goods entirely. In the spring of 1770, tumults broke out in Boston betwixt the citizens and the soldiery, and continued at intervals throughout the year. The British ministry now saw they had gone too far, yet they hesitated in making reparation. In March 1771, parliament repealed the taxes on glass, paint, and other articles, but retained a duty of threepence a pound on tea. This was a great mistake, and did no good. If parliament had repealed all, and said no more about taxes, the Americans might still have been satisfied; as it was, they began to buy the goods of the English merchants again, tea alone excepted; this they would have nothing to do with. So matters went on during the year 1771. The officers of the revenue were every where despised. In Boston, one of them undertook to seize upon a vessel for some violation of law. He was seized upon himself by the people, for what they thought a violation of law, stripped, carted through the city, besmeared with tar, and plastered over with a coat of feathers.

In 1772, the English government, intending to put down the rebellious spirit of the Americans, made several new laws, which served only to make them more angry; and they now began to think of doing something for themselves in earnest. Committees were chosen in every part of the country, to attend to public affairs, and to write to each other.

In 1773, large ships, loaded with immense cargoes of tea, were sent out to America by the East India Company. But the colonists managed so well in Philadelphia and New York, that not a man could be found to receive the English tea, or have any thing to do with it. A few chests, which one Captain Chamber had brought to Philadelphia, were let down very quietly to the bottom of the river, by some people who went slyly on board the ship. In Charleston, it was landed, and lodged in cellars so damp that it was soon spoiled. The people of Boston took a keen interest in this business. The English factors there, when the tea was first known to be coming, were called upon to give up all concern with it. They made no answer, but withdrew as fast as convenient into the fortress. Captain Hall soon arrived in port with one hundred chests of tea. The people collected in great fury, ordered him to keep it on board, as he valued his life, and placed a guard and a strict watch close by the vessel upon Griffin's wharf. Two other vessels having arrived, they were obliged to anchor by the side of Hall's ship. A town meeting, meanwhile, was summoned; and the people agreed to call upon the governor, and request him to have the ships sent off. But the governor would do no such thing. A great uproar began. A person in the gallery of the hall, dressed like an Indian, shouted the cry of war. The meeting was dissolved in the twinkling of an eye. The multitude rushed to Griffin's wharf. Here were seventeen sea-captains, carpenters, and others, disguised as Indians. It was night, and these persons went on board the three vessels, and, in less than two hours, 340 chests were staved and emptied into the sea. This done, they went quietly home, and the crowd dispersed, well satisfied.

BOSTON PORT BILL.

Early in 1774, an account of these disturbances having reached England, the English government determined, by way of punishing the people of Boston, to destroy the trade of that town, by forbidding all manner of goods to be landed there. Accordingly, the Boston port bill was passed in parliament, March 14, and the news was received in Boston, May 10. Like the other laws, this also did more hurt than good. In a few days after the last bill passed, other laws were made still more severe. They were opposed in England, to be sure, by some; but a large part, both of the parliament and people, supposed, if the Americans were punished and frightened pretty well, as they expressed themselves, they would by and bye be more submissive to the mother country. The consequence was, that not only the people of Boston, but the whole people of America, north, south, east, and west, were more indignant than ever. Town meetings were held, days of fasting appointed, and news of the port bill spread over the whole country. An agreement to stop all trade with England, called the "league and covenant," was signed by immense numbers.

HOSTILITIES COMMENCED.

On the first of June 1774, the port bill was put in force. At mid-day, all business ceased in the custom-house, and no vessel was suffered to enter the harbour. This harsh procedure was the signal for civil war. The people provided themselves with arms, formed companies, and learned, as fast as possible, the business of soldiers; and, being most of them used to hunting, they were good marksmen, especially with the rifle, a most destructive weapon. The country now assumed the attitude of defiance; and, in September, the first American congress, or a collection of deputies from all the provinces, met at Philadelphia. These were the most respectable men of the whole country, and every thing they did and said had a great effect. Among other things, they approved of the conduct of the Boston people; they made an agreement to buy and use no more English goods, and wrote letters to the people of England and America. To the king they complained of the injuries done them, and prayed for redress. They also said, that, if the laws were as they should be, and as they were at the peace of 1763, the Americans would be perfectly satisfied. They did not wish to rebel, or provoke a war, if they could help it; but they would not be trampled under foot. Strangely enough, no particular attention was paid to all this in England. The ministers and the king thought that the Americans should be frightened, or forced out of their rebellious feelings. In 1775, therefore, parliament voted to raise more troops and more seamen. They encouraged the king, George the Third, to go on as he had done; insisted upon maintaining the laws which the Americans complained of; and passed a new law, forbidding them to fish, as they always had done, on the Banks of Newfoundland. On the 2d of February, a vote passed, declaring the Massachusetts people to be rebels; and, as the Americans refused to trade with England, they were forbidden to trade with any other country. But all this only made matters worse than ever.

BATTLE OF LEXINGTON.

The first battle of the American revolution was fought upon the 19th of April 1775, at Lexington and Concord. Stores had been collected at the last-named place, eighteen miles from Boston, for the American army, and General Gage determined to destroy them. Wishing to do it without fighting, he sent out 800 grenadiers and light infantry from Boston, at eleven o'clock in the evening of the 18th, as silently as possible.

It was heard of, however, in the country. By two o'clock in the morning, 130 of the Lexington militia had assembled on the green, at the meeting-house, to oppose them. They were dismissed, but collected again between four and five, at the beat of drum. By and bye, the 800 British troops came marching up the road, Major Pitcairn at their head. "Disperse, you rebels!" cried the major, addressing the militia; "throw down your arms, and disperse!" They did not disperse, however. He now rode forward, discharged a pistol, brandished his sword, and ordered his soldiers to fire. They did so, and three or four of the Americans were killed. The soldiers shouted, fired again, and then proceeded toward Concord. At this place they disabled two large cannon, threw 500 pounds of ball into wells, and staved about 60 barrels of flour. They fired upon the Concord militia, and two men were killed; a skirmish followed, and the English retreated, as fast as possible, to Lexington. The people were coming upon them, by this time, from all parts of the country. The British were fired upon, on all sides, from the sheds, houses, and fences.

At Lexington, where they halted to rest, they were joined by 900 more troops, sent out from Boston under Lord Percy. These brought two cannon with them, and the country people were kept back. They still fired upon the troops, however; and being generally good marksmen, made terrible havock. The regulars, as the English troops were called, reached Charlestown at sunset, and returned the next day into Boston. Sixty-five of their number had been killed, one hundred and eighty wounded, and twenty-eight made prisoners. Of the provincials, fifty were killed, and thirty-eight wounded and missing. There were never more than three or four hundred of the latter fighting at one time, and these fought as they pleased, without order. The regulars were obliged to keep in the main road; but the militia, knowing every inch of the country, flanked them, and fired upon them at all the corners. The news of this first battle produced a tremendous excitement throughout the country. The dead were buried with great ceremony and pomp. Great bodies of militia marched towards Boston. Agreements were entered into by thousands of people to defend the Bostonians to the last gasp. The English forts, arsenals, magazines, and public money, were seized upon by the people; and more money was coined, and more troops were raised.

At this period, the Americans were far from being well trained as soldiers, yet they were brave, and the British committed a serious error in despising them. The English nation was at that time, as it is still, the richest on the globe. They had beaten the French and Spaniards a few years before; they had large armies and navies; and they therefore believed the poor American colonists could no more resist them than so many children. The people of Great Britain, in the present day, deplore the folly which their predecessors committed in thus rushing headlong into a war with the Americans, for, but for this act of folly, the colonies might still have belonged to the mother country.

EXPEDITION TO TICONDEROGA.

In Connecticut it was resolved to undertake an expedition to Tinconderoga, a very strong place on lake Champlain, near Canada. As this place was full of stores, and stood upon the great route by which every thing and every body passed between Canada and the provinces, it was important to conquer it. The Connecticut assembly voted 1800 dollars for the purpose; and powder, ball, and whatever would be needed for a siege, was provided.

The troops assembled with as little display as possible, at Castletown, on the banks of Wood Creek, on the great road to Ticonderoga. Some of these troops were from Connecticut, some from the Boston army, and some were people from the Green Mountains, in Vermont. These latter were called Green Mountain Boys, and were famous for skill in the use of the rifle.

The leaders of the expedition against Ticonderoga were Colonel Ethan Allen and Colonel Easton. They were joined at Castletown by Colonel Arnold, from the Boston army. They marched on quietly, and arrived in the night on the bank of the lake, opposite Ticonderoga. They crossed over and landed on the other side, close by the fortress. They entered it under the covered way, by daybreak, with a tremendous shout. The soldiers of the garrison were roused, ran out half-dressed, and began firing. A hot scuffle, with gun-breeches and bayonets, hand to hand, ensued. The commander of the fort came at last. Colonel Allen ordered him to surrender. "To whom?" said the officer, in great astonishment. "To the American Congress!" said Allen, in a voice of thunder. The commander saw it was in vain to resist, and so he gave up the fort. Here were found 124 fine brass cannon, and a large quantity of ammunition. A hundred cannon more were taken by the Americans at Crown Point, another fort on the same lake, defended by a small garrison.

BATTLE OF BUNKER'S HILL.

Meanwhile, the English were skirmishing with the provincials at Boston. There were some islands in the harbour, where the English found forage for their horses and cattle. The Americans undertook to carry off these cattle from Noddle's Island and Hog Island, and succeeded, after some fighting. They scoured Pettick's Island and Deer Island soon after in the same way. The English were thus put to a good deal of trouble to get food, and were finally so much pressed by the American army, that General Gage found himself obliged to make a new effort against them. The provincials had sent 1000 men, under Colonel Prescott, to fortify Bunker's Hill, in Charlestown. Instead of doing so, however, by some mistake he fortified Breed's Hill, which is nearer the city. The Americans took possession of it in the evening, and worked so well, that, before morning, they had thrown up a redoubt about eight rods square, and so silently, that the British knew nothing of it till day-break. The latter, when they discovered the redoubt, began firing upon the people in the fort; but the Americans worked on, till they raised a breast-work, reaching from the east side of the redoubt to the bottom of the hill. As Breed's Hill commands the city, the British saw they must either be driven off, or drive off the provincials. They therefore opened a tremendous fire from the batteries and armed vessels that floated on all the waters about Boston. Showers of bombs and balls were fired. A terrible battery was raised upon Copp's Hill, opposite Breed's; but all in vain. The Americans worked on, paying little regard to the batteries, and they had finished a trench, or ditch, before noon, which reached to the bottom of the hill.

It was now the 17th of June, and on this day was fought the famous battle of Bunker's Hill. The British were determined to make a great effort. The provincials lay ready for them on the hill. General Putnam, of Connecticut, commanded the whole force. They had muskets, but few of them bayonets or rifles. They were sharpshooters, however, and were brave men as ever breathed.

About noon of a terribly hot day, the whole British camp seemed to be in motion. A vast multitude of sloops and boats started from the Boston shore, covering the water far and wide. The soldiers landed at Moreton's Point, in Charlestown, protected by their batteries behind them. The Americans took this opportunity to protect themselves still more, by pulling up some post and rail fences, which they set before them in two rows, and filled the space between with fresh hay, which they gathered from the hill. The British began to march. The militia left to defend Charlestown retreated. The British entered it, and set fire to the buildings. In a few moments 500 wooden buildings were in flames. The wind blew high, and the fire streamed up, and roared in the most terrible manner.

Thousands of people were gazing at the scene, from the Boston steeples, and waiting with great anxiety for the fate of the battle. There were multitudes, also, on all the high roofs and hills round about. Never was there such a bustle and stir. The English marched slowly towards the redoubt, halting now and then for the cannon to come up and fire. They came, at last, within musket-shot; and the redoubt, which had been as still as the grave, till this moment, blazed all at once with a tremendous volley.

The British were soon thinned off, and compelled to retreat. Many fled for their lives, and threw themselves into the boats. The green field of battle was covered with dead bodies. The officers ran hither and thither, to rally the troops, and after some time persuaded them to march forward again; but the Americans waited for them quietly, and received them once more with a flood of balls. The British now fled down the hill to the shore; and General Howe was alone upon the field; all his officers being killed and wounded around him. General Clinton, who had been watching the battle from Copp's Hill, now came to his aid with new troops. They made a third effort, with more spirit than before. Clinton led on the whole body; the cannon still firing from the ships and batteries, and the flames and smoke of the burning town sweeping over them like the blast of a furnace. The powder of the Americans was now exhausted, and they were compelled to draw off. They retired to Prospect Hill, fighting with their muskets as if they were clubs, and there began throwing up new works. The British were entrenched on Bunker's Hill, and neither army seemed willing to attack the other. Of 3000 British troops, 1054 were killed or wounded. A large part of these were officers. The sharpshooters had taken the poor fellows down like so many gray squirrels. The Americans lost five pieces of cannon. Their killed, of about 1500 engaged in the battle, amounted to 134; their wounded, to 314.

The Battle of Bunker's Hill, as it was called, though fought on Breed's Hill, had no decisive effect; yet it roused the country, showed the Americans that they were able to contend with the regulars, and taught the British that the provincials were not exactly the cowards they had taken them for. The capture of Breed's Hill did them more hurt than good. They were obliged to defend it now, and they had not too many men before to defend the town. Their soldiers were also worn out with fatigue, and were much depressed by the hot weather.

The Americans began now to fortify the town of Roxbury. Their works went up very fast, notwithstanding the continual fire of the British cannon. They had plenty of food, too, while the British were near starving. The latter could get nothing on the Boston islands, or along the Massachusetts coast, but by hard fighting, and very little by that. They were at last obliged to let most of the Bostonians pass out of the town, for they had not provisions enough to keep them alive.

AMERICAN ARMY ORGANISED.

Congress met again at Philadelphia, May 7, 1775. They were men sent from all the colonies but Georgia; and though they had no precise right, by any law, to act for the whole country, yet the whole country were ready to obey them. They chose George Washington, of Virginia, commander-in-chief of the American army, and appointed many other officers to act under him. Among these were Gates, Lee, Schuyler, and Montgomery, of New York; Pomeroy, Heath, and Thomas, of Massachusetts; Greene, of Rhode Island; Putnam, Wooster, and Spencer, of Connecticut; Ward and Sullivan, of New Hampshire. These were some of the bravest and best men of the country.

General Washington went directly to the army at Cambridge. He arrived there on the 3d of July. Though he used no parade, wearing only a small sword at his side, epaulettes on his shoulders, and a black cockade on his hat, he was easily known by his fine figure and noble countenance. He was treated every where with the greatest respect. Having reviewed the army, he found only 14,500 men in a condition for service; these had to defend a line of twelve miles. They were now arranged and trained as well and as fast as possible, no man understanding this business better than General Gates, who was an old soldier, as well as Washington. They had not 10,000 pounds of powder, at this time, in the army, being only nine charges to a man. Had the enemy known this, and attacked them, they must have fled like a flock of deer. Great efforts were made, however, and several tons soon arrived from New Jersey. More also was procured from the coast of Africa, in exchange for New England rum. This was managed so shrewdly, that every ounce in the British forts there was bought up for the American army. The Massachusetts rulers passed a law, also, that no powder should be fired at any beast, bird, or mark; they wished it all to be saved for the war.

Congress took measures for the coining of money, and the raising of troops in all quarters. The people obeyed the directions of congress with alacrity. Every man, from sixteen years of age to fifty, was a member of some militia company; and one-fourth part of the whole, called minute-men, were to keep themselves ready for action, at a moment's notice. Among other military bodies, a company was formed of eighty old Germans, who had most of them fought a long time before in Europe. They were called the Old Men's Company. Instead of cockades, they wore black crape, to signify their sorrow at taking up arms at such an age. The captain was near a hundred years old, and had been in seventeen battles. He had been a soldier forty years. The drummer was ninety-four, and the youngest in the corps was about seventy.

TREATIES WITH THE INDIANS.

About this time, congress took the necessary steps to keep peace with the Indian tribes. But they never employed them to fight against the English, though the English hired them to fight against the Americans. One objection that the Americans had to employing them was, that the Indian way of fighting was entirely too barbarous and cruel to be suffered among civilised people. Another was, that they could not be depended on. They were greedy for wager, [illegible] so deceitful that they could not be safely trust[illegible] A story told of a serjeant, who travelled through the woods of New Hampshire, on his way to the American army will show the character of the Indians:—

He had twelve men with him. Their route was far from any settlement, and they were obliged every night to encamp in the woods. The serjeant had seen a good deal of the Indians, and understood them well. Early in the afternoon, one day, as they were marching on, over bogs, swamps, and brooks, under the great maple trees, a body of Indians, more than their own number, rushed out upon a hill in front of them. They appeared to be pleased at meeting with the serjeant and his men. They considered them, they said, as their best friends. For themselves, they had taken up the hatchet for the Americans, and would scalp and strip those rascally English for them, like so many wild cats. "How do you do, pro?" (meaning brother), said one; and "How do you do, pro?" said another; and so they went about, shaking hands with the serjeant and his twelve men.

They went off at last; and the serjeant, having marched on a mile or two, halted his men, and addressed them. "My brave fellows," said he, "we must use all possible caution, or, before morning, we shall all of us be dead men. You are amazed; but, depend upon me, these Indians have tried to put our suspicion to sleep. You will see more of them by and bye." They concluded, finally, to adopt the following scheme for defence. They encamped for the night near a stream of water, which protected them from behind. A large oak was felled, and a brilliant fire kindled. Each man cut a log of wood about the size of his body, rolled it nicely up in his blanket, placed his hat on the end of it, and laid it before the fire, that the enemy might take it for a man. Thirteen logs were fitted out in this way, representing the serjeant and his twelve men. They then placed themselves, with loaded guns, behind the fallen tree. By this time it was dark, but the fire was kept burning till midnight. The serjeant knew that if the savages ever came, they would come now.

A tall Indian was seen, at length, through the glimmering of the fire, which was getting low. He moved cautiously towards them, skulking as an Indian always does. He seemed to suspect, at first, that a guard might be watching; but, seeing none, he came forward more boldly, rested on his toes, and was seen to move his finger, as he counted the thirteen men, sleeping, as he supposed, by the fire. He counted them again, and retired. Another Indian came up, and did the same. Then the whole party, sixteen in number, came up, and glared silently at the logs, till they seemed to be satisfied they were fast asleep. Presently they took aim, fired their whole number of guns upon the logs, yelled the horrid war-whoop, and rushed forward to murder and scalp their supposed victims. The serjeant and his men were ready for them. They fired upon them; and not one of the Indians was left to tell the story of that night. The serjeant reached the army in safety.

Treaties having been made with the Indians, congress recommended that the 20th day of July 1775 should be observed, in all the provinces, as a day of fasting and prayer; and it was so. The people were every where disposed to implore Heaven to prevent war, and to soften the hearts of their enemies. In Philadelphia, congress attended church in a body. As they were just entering the house of worship, they received news from Georgia, that this province had at last concluded to join in the common cause, with the other twelve. Until this time, the people there had said and done but little, but they determined now to make amends for lost time.

DECLARATION OF RIGHTS.

A declaration of rights was soon after written by congress, and sent over every part of the country. It gave a history of the whole difficulty, from first to last, between England and America, and ended with an account of the burning of Charlestown, the seizure of the provincial vessels by the British, and the hiring of the savages to fight against the Americans.

"We are compelled," said they, "to submit to tyranny, or to take up arms. We have counted the cost of this war, and have determined to be free, as our fathers have been before us, and as we trust our children shall be after us. We declare, before God, that we will defend each other, and the liberty of the whole country, to the last moment of life [illegible] was signed by John Hancock, president, and Charles Thompson, secretary, of congress. The ministers read it from their pulpits in all parts of the nation. It was read in Cambridge, to a vast multitude, and General Putnam assembled his troops on Prospect Hill to hear it. This was followed by a prayer from a clergyman. All the troops cried, three times, "Amen;" the artillery fired a general salute, and the colours were seen flying, with the usual mottoes; on one side, "An appeal to Heaven," and on the other, "He who has brought us over will defend us."

A petition was next drawn up to the English king, and addresses were written to the people of England, Ireland, and Canada. Congress were resolved to leave nothing unsaid, or undone, that offered any chance of restoring peace. The Canadians were persuaded to remain neutral, taking no part on either side. The British general, Carleton, used efforts to make them enlist as soldiers. They were offered two hundred acres of land in any part of America they should choose, at the end of the war. Each married man was to have fifty acres more for his wife, and fifty for each of his children; with a guinea (about five dollars) as a bounty, at the time of enlisting. A few only were persuaded in this way; a good many Indians, however, were hired. They collected at Montreal, in great numbers, in July 1775. Among the rest were six famous tribes, called the Six Nations. They swore, in the presence of Carleton, to fight for the English king; and thus, soon after, the Indian war began.

AFFAIR AT NORFOLK.

It may seem strange, that, during the disturbances in the various colonies, little or nothing should have been done by the English governors to put down the rebellion. The truth is, they had no troops, and not much money, at their disposal; and before they could be supplied, the spirit of independence had gone too far to be repressed. In Virginia, Governor Dunmore, being compelled to leave Williamsburgh, and fearing that it would not be safe for him to remain upon the land, went on board a royal armed vessel. Having collected a fleet, he resolved to harass the Virginians as much as possible, if he could not govern them. He was joined by all the tories, that is, the Americans who favoured the English. He laid waste the coast at various places in the most shocking manner, murdering and burning like a pirate. He burnt Hampton, on the bay of Hampton, among the rest, and undertook to establish his camp there. But the Virginians soon drove him back upon the water. He then declared all the negro slaves to be free, and invited them to join him. A few of them succeeded in doing so. He landed again at Norfolk, where the tories were numerous; and a battle was fought, a few miles from that city, at a place called Great Bridge, with a regiment of Virginia militia and minute-men. The governor had only 200 regulars about him; the rest was a mere mob of black, white, and grey.

The first attack was made by the British on the American entrenchment. The battle lasted some time with a good deal of spirit. At last the British captain was killed, and the troops fell back upon the bridge. The governor did not like fighting; so, during the battle, he contented himself with looking on at a distance. The negroes loved fighting as little as the governor. They found it by no means pleasant to have their flesh cut to pieces with bullets; so, after a few shots, they ran away as fast as they could. The governor also thought it best to retreat, and, accordingly, he and his men went on board of their vessels.

This affair did not serve to sweeten Governor Dunmore's temper, nor did it put him in a better humour to find that his friends the tories at Norfolk had been handled roughly by the people there, after his retreat with his negro allies. He now returned into the bay with a ship of war, and sent a message ashore, declaring, that unless the people furnished him provisions, he should batter the town down about their ears. They refused to supply him; so he gave them notice, in the morning, to remove the women and children; and then, with his own sloop of war, the frigate Liverpool, and two corvettes, he blazed away upon the place, till scarcely one stone was left upon another. The provincials, to disappoint him of his provisions, burnt the whole country round about. Nothing was left for the governor, and so he went away.

PROCEEDINGS IN THE SOUTHERN STATES.

In South Carolina, Governor Campbell arrived at Charlestown from England, about the same time with the news of the Lexington battle. The people were on their guard, and he tried in vain to get the better of them, by inviting the tories to assist him; but the tories were afraid to do so. He began to be frightened a little himself, being a man of less courage than Governor Dunmore; so he said little or nothing for some time. To unmask him, the American leaders sent privately to him one Adam Macdonald, captain in a militia regiment. He called himself Dick Williams, and offered his services to the governor. The latter was delighted, and told him all his plans. Having heard them attentively, Adam went away, and told the whole to the persons who employed him. They immediately sent a committee, Macdonald among the number, to wait upon his excellency, and request him to show his royal commission, if he had any, as governor. He declined this proposal. There were some hints then thrown out about putting him in confinement. These came to his ears, and he retreated, with very little ceremony or delay, to an English corvette, anchored in the harbour. The assembly requested him to return; but he refused. Nothing more was seen of him, or his government, in Charlestown. The tories were numerous in other sections of the province, however, and he mustered them together in great force. The people were alarmed. The militia were ordered out, and the two parties were on the eve of an engagement. But at length the tories were dispersed, and they gave no more trouble at that time.

The provincials in South Carolina continued to be very active. They captured Fort Johnson, on James's Island, in Charlestown harbour, and placed batteries on Point Huddrel. The English ships were at last driven off. The next thing with the people was, to send an expedition after an English vessel laden with powder, which was anchored on the bank, called the Bar of St Augustine, a town on the coast of East Florida. She was taken, and 15,000 pounds of powder were carried to Charlestown.

In North Carolina, the provincial congress raised 1000 regular militia, and 3000 minute-men. The English governor, Martin, disliked the appearance of things, and endeavoured to muster a force of the Irish and Scotch part of the inhabitants. He also fortified his own house, at Newbern, with artillery. The people seized upon his cannon, and he fled to a fort upon Cape Fear River. The provincials marched after him, led on by Colonel Ashe. He retreated on board a vessel, as the other governors had done. Colonel Ashe burned the fort to ashes the same night. The assembly declared the governor a traitor. He answered them in a very long letter, which they ordered to be burnt by the common hangman. A large quantity of ball and powder was found in his cellar and gardens at Newbern.

In Pennsylvania, the people prepared actively for war. A single mill, near Philadelphia, manufactured five hundred pounds of powder a-week. Governor Tryon, after endeavouring a long time to manage the province, followed the example of the other governors.

In other parts of the country, the enemy was not asleep. One Captain Wallace, commanding an English squadron of small vessels off Rhode Island, was doing all the damage in his power, by ravaging the coast, and making prize of the merchant vessels. His chief object seemed to be, to supply himself and his force with provisions. With this view, he made a furious attack upon the town of Bristol, and fired, from morning till night, upon their houses and churches. He bored them through and through, till, finally, the people supplied him and his squadron with fresh meat, and he sailed away.

About this time, a body of American troops were sent from Massachusetts to Rhode Island, under General Lee. He was a man of great courage, and warm temper. He obliged all the inhabitants, whom he went to defend, to take the most terrible oaths, to do precisely what congress should command, and, at all events, to break off all intercourse with the tools of tyranny "vulgarly called," as the oath said, "the fleets and armies of the king." Congress were not much pleased with this manœuvre. It was well meant, without doubt, but it was very rough, and of no real use.

On the 18th of October 1775, Falmouth, now Portland, in Maine, was bombarded by Captain Moet, of the ship Canceaux, of 16 guns. The whole town was consumed. He had formerly received some affront in the place, and revenged himself in this way. He sent the people word at night that he should destroy the town in the morning; they removed their furniture, and he went to work early the next day with his cannon. The town had been twice sacked by the Indians, but never suffered so severely before.

EXPEDITION TO CANADA.

The most important affair of this year was an expedition to Canada. The provincials had done so well upon lake Champlain, that the scheme of another expedition in the same quarter was much approved of. Congress hoped, that, if Canada was invaded at once, many of the inhabitants would join the Americans. Three thousand men, commanded by Generals Montgomery, Wooster, and Schuyler, were fitted out. Boats were built for them on the lake, at Crown Point, and the sum of 50,000 dollars was collected to pay the expenses. Governor Carleton, of Canada, entrenched himself with a strong force at the entrance of the river Sorel, which leads out of the lake, and which the Americans would be obliged to pass. The latter took possession of an island in the lake, at the mouth of the river, and from that place planned an attack on Fort St John, where the governor was. This fort stood on the left bank of the Sorel, and commanded the passage to Canada. The Americans moved on without cannon to a swamp within a mile and a half of the fort. They defeated a body of Indians who attacked them in crossing a small river, waited for reinforcements, and laid siege to the fort.

Farther north, on the Sorel, was a small fort called Chambly. The English had no idea of the provincials passing St John to fall upon Chambly; but they did so, took the garrison prisoners, obtained 124 barrels of powder for the siege of St John, and sent the colours they had captured to Congress. Other detachments scoured the country between the Sorel and the St Lawrence; the Canadians supplying them every where with arms and provisions.

Just at this time Colonel Allen and Major Brown undertook an expedition against the city of Montreal, which stands on an island in the St Lawrence. Allen found boats ready for him at Longueville, and crossed the river in the night, below Montreal. Here Brown was to have joined him with his troops, but missed his way, and Allen was left, with a small force, in the neighbourhood of the city. It was just sunrise. The murmur of the city was heard at a few miles' distance, and by and bye the roll of the English drums came upon the ear. The Americans now saw that they were discovered. Before long, a column of British infantry came marching down the bank of the river. There was an almost breathless silence in Allen's small band as they came up. Even Allen himself stood fast, and gazed at them. "To the boats! to the boats!" cried a dozen of his soldiers; "there's a thousand of them." "Silence! every man of ye!" roared Allen, brandishing a huge horse-pistol. "The first man that turns his back upon the red coats, shall smell gunpowder." They were satisfied with this arrangement, on the whole, examined their rifles, and stood ready for the onset. "Stand your ground, boys!" shouted Allen. A party of British soldiers was moving towards them from the main body, at double quick time. "Let them come!" cried a tall, fine looking hunter at his side; "let them come!" He brought his rifle to his eye, as he spoke. "Fire!" shouted the British officer, and instantly the hunter dropped dead at the feet of Allen. His hardy followers shrunk back. They were sprinkled with the blood of the poor hunter. "Fire! fire!" shouted Allen, with a voice of thunder. They fired, and a hot skirmish commenced. Several of the English fell, and several of the Americans; others fled. Some defended themselves behind rocks and trees. Allen was at last left alone, surrounded, and compelled to surrender. He brushed a few tears away for the fate of his friend the young hunter, and marched on with the English. He was kept a prisoner more than two years, and then was exchanged for some English officer, whom the Americans had taken. The irons put upon him were so fastened about him, and so heavy, that, for a long time, he could lie down only on his back. A chest was his seat by day, and his bed by night. He was sent to England, to be tried as a prisoner of state, not as a fair and open enemy, but as a rebel. At this time, all the Americans were called rebels, and the English used to speak of hanging great numbers of them when the war was over.

We left the Americans besieging Fort St John, on the left bank of the river Sorel. They continued the siege, while the expeditions were going on against Fort Chambly, and against Montreal, as we have described them. After the capture of Allen, however, Governor Carleton, who had gone to Montreal, collected about 800 Canadians, Indians, and English regulars, and started off from that place, intending to raise the siege of St John, and compel the Americans to abandon it. But the Americans were always on the watch. They thought it probable that the governor would set out about this time, and were ready for him. He embarked his 800 men in a large number of boats, and undertook to cross the St Lawrence, precisely where Allen had crossed it, at Longueville. But Colonel Warner, with 300 Green Mountain sharp-shooters, and a few cannon, lay among the bushes on the river bank, as the governor's boats came over. The Americans waited quietly till they were fairly within reach, and then poured out upon them a tremendous volley of grape-shot. The governor's party retreated in great haste, with some loss of lives; and nothing more was seen of them. News of this defeat soon came to Major Preston, the British commander of the besieged fort of St John. He began to think it a desperate case with him, and so concluded to surrender to the American general, Montgomery. This he did on the 3d November 1775. He had held out like a brave man, the siege having lasted six weeks. The Americans found in this fort seventeen brass cannon, twenty-two iron ones, and a large quantity of balls and bombs. The powder had been used to the last kernel, and the provisions to the last morsel. The capture was an important one. St John, standing on the Sorel, which leads from lake Champlain to the St Lawrence, commanded the passage to and from Canada, and was therefore called the key of Canada.

The next movement of the Americans was to take possession of the mouth of the Sorel, where it empties into the St Lawrence. The point of land which is formed by the meeting of the two rivers, was fortified with batteries, which swept the river in such a manner, that no English vessel could pass, without being bored through and through. As the St Lawrence is wide here, the Americans provided a fleet of boats and floating batteries, to guard the other side, and thus completely stopped the passage up and down that river. Just at this time, Governor Carleton had left Montreal, which stands farther up the St Lawrence from the sea, with a fleet of English ships under his command, and without having heard of these fortifications. What added to the difficulty of his situation, was, that, the very day after he left Montreal, another body of Americans, under Montgomery himself, appeared under the walls of that city, and called upon the people to surrender. This detachment had marched across the country from Fort St John. The land is flat and marshy, and their journey had been slow and difficult. It gave them great satisfaction to have reached Montreal just as the governor had gone off with his force. The city, having no defence, was compelled to surrender. General Montgomery treated the people so well, that they supplied him with some clothes for his troops. These were very much needed. It was now the middle of November, and they were weary of a long, cold march. Some of the soldiers, during this severe journey, would have gone back to their snug homes in Vermont and the other provinces; but General Montgomery divided the clothes among them, and encouraged them to proceed.

Governor Carleton was now unpleasantly situated on the river, with Montreal, in the possession of Montgomery, above him, and the fortifications at the mouth of the Sorel below. If he could have been taken, all Canada would have been easily conquered; but he contrived, one dark night, to pass through among the floating batteries, in a small boat, with the oars muffled. Thus he escaped safely to a town on the northern bank, called Trois Rivieres; and from that place he went to Quebec.

The English fleet, which the governor had left behind, surrendered to the Americans in a day or two, with a large number of soldiers and officers aboard. General Montgomery left garrisons in Montreal, and Forts Chambly and St John, on the Sorel, to keep the Indians in awe, and marched on to Quebec, with a small force of three hundred men.

ARNOLD'S EXPEDITION TO QUEBEC.

While these things were going forward, General Washington, in his camp at Cambridge, had conceived the plan of sending an expedition against Quebec, by way of a rough wild route, known only to the backwoodsmen and hunters. This was through the district of Maine. He selected Colonel Arnold to command the expedition—a rash but brave man, who had assisted, as we have seen, in the capture of Ticonderoga and Crown Point. Fourteen companies were put under his command; three of riflemen, and one of artillery, under Captain Lamb, being among the number. In all, there were about eleven hundred men. A few others joined them of their own accord; and among these volunteers was Aaron Bur, afterwards vice-president. He was then twenty years of age.

Maine is crossed, from north to south, as a map will show, by the river Kennebec, rising in the mountains between Maine and Canada, and emptying into the Atlantic Ocean, not far from Casco Bay, near a town now called Bath. On the other side of the same mountains, and close, therefore, by the small upper streams of the Kennebec, another river rises, called the Chaudiere. This empties into the St Lawrence, nearly opposite Quebec. In crossing these mountains, between the sources of the two rivers, on the two sides, it is necessary to pass very steep and wild places, over marshes and torrents. No human being dwelt there then, and nobody lives there to this day. Such was the route Arnold and his brave soldiers were to travel. He left Boston in September 1775, and arrived at Newburyport, near the mouth of the Merrimac. The vessels that waited for him here conveyed him and his men to the mouth of the Kennebec. With a fresh south wind they sailed up the river fifty miles, to a town called Gardiner. Here were two hundred batteaux ready for them. These were long, light, flat boats, much used by the Canadians, hunters and others, in shoal waters. Having laden these with his arms and provisions, Arnold proceeded up the river to Fort Wester, on the right bank. Here he divided his corps into three detachments. The riflemen, under Captain Morgan, moved on forward, as a vanguard, to explore the country; to sound the fords, that is, ascertain where the river might be crossed easily; and to look out for the portages. These are places where the river ceases to be navigable, on account of shoals, falls, or rocks. The lading of the boats must therefore be carried forward upon the banks by hand, or by beasts of burden. The batteaux are then carried on also, till the river becomes deeper and smoother.

Arnold's second detachment marched the next day after the first, and the third detachment the day after that. The current of the river was rapid, the bottom rocky, and often interrupted by falls. Every hour, the water entered some of the batteaux, and damaged the provisions and arms. At every portage—and these occurred very often—the boats were to be unladen, and carried on the shoulders of the troops. In places where the river was rapid, yet free of rocks, the batteaux were hauled up slowly by soldiers on the banks, who dragged them along with ropes. The army, however, advanced, and at length they had wild mountains to cross, steep precipices to climb, vast shady forests to pass under, and quagmires to wade through. They had also deep vallies to traverse, where the pine-trees were tossing over their heads in the stormy wind, and where the river was rushing and foaming over the rocks with a noise like the ocean. They were sometimes a whole day in travelling four or five miles, with their baggage laced on their backs, and axes in their hands to hew a road through the wilderness. Some of the men died at last with weariness; many others fell sick; and all of them were at length sorely pressed for food. Many a young soldier, as he lay down at night, hungry and tired, on his pillow of green boughs, thought of the warm bright fireside where a mother was weeping for him. But these thoughts were vain. They rose in the morning, and pressed on patiently, brave men as they were.

By the time they had reached the source of Dead River, a branch of the Kennebec, their provisions were almost exhausted. The soldiers were living, or rather starving, now, upon the poor lean dogs they had taken with them, and even this food was a luxury. At this place, Colonel Enos received orders from Arnold to send back the sick to Boston. He took the opportunity to return himself, with his whole detachment. He was afterwards tried for this desertion, by a court-martial, and acquitted, for the reason that the men must otherwise have starved. But Colonel Arnold continued to march on. For thirty-two days, not a single human dwelling was met with. The army arrived at last upon the mountains, between the Kennebec and the Chaudiere. The little food still left was divided equally, and then the troops were directed to look out as they could for their own living. They discovered, finally, with inconceivable joy, the sources of the Chaudiere, and the first log-houses of the Canadians. These people received them well, and assisted them. Arnold addressed a proclamation to the Canadians, waited for his rear-guard to overtake him, pressed on, and arrived, November 9, at Point Levy, nearly opposite Quebec. The people of the city were as much amazed at the sight of him and his men as if they had been so many goblins. The English colonel, Maclean, had heard of their coming, however, by a letter, which Arnold had given to an Indian on the Kennebec, to carry to General Schuyler. The Indian gave it to Maclean, and the latter removed all his batteaux from the Point Levy side of the river to the other bank. The wind blew a gale, too; and so the city had time to prepare for defence.

All the people of Quebec were immediately armed, and brought within the walls—soldiers or not soldiers, English, French, Scotch, and Irish, regulars and marines. The wind moderated, and Arnold undertook to pass the river on the night of November 13. The same day, Montgomery had taken Montreal. One hundred and fifty men remained to make ladders for scaling the city walls. The rest succeeded in crossing the river. The banks being very steep here, Arnold and his men marched down upon the edge of the river towards Quebec, and climbed the Heights of Abraham, close by the city, and almost overlooking it. Here he waited for his 150 ladder men, and hoped that the city would surrender. They were prepared for him, however; and Maclean not only refused to receive the message requiring him to surrender, but fired upon the bearer of it. Arnold had no cannon, and only six charges of powder to each man. Hearing, therefore, that Maclean was about to sally out upon him, he retired twenty miles up the river, to Point au Trembie. He [illegible] on his march, the ship in which Governor Carleton was sailing down to Quebec, and heard, when he reached the point, that he had left it but a few hours before.

General Montgomery arrived here, and joined Arnold on the 1st December 1775, after a weary march from Montreal. The weather was excessively cold, and the roads were blocked up with snow. His force was about three hundred men; and never were people more delighted to see each other than were these three hundred and the little band of brave fellows who had followed Arnold. Montgomery had brought clothing for the latter, and they stood in great need of it indeed.

ASSAULT OF QUEBEC.

The soldiers now marched in company, and arrived in sight of Quebec on the 5th. A summons was sent to Carleton to surrender, but he ordered his troops to fire upon the bearer. Montgomery then planted a battery of six cannon within 700 paces of the walls. They were laid upon banks of snow and ice; the pieces were small, and the fire had little effect. The snow had now fallen in huge drifts, and the weather was excessively cold. A council of war was called. An immediate assault on the city was resolved upon. Two detachments, under Montgomery and Arnold, were to attack the walls of the lower part of the town. This taken, the rest would probably submit without fighting. On the last day of the year 1775, between four and five in the morning, in the midst of a heavy snow-storm, the American columns advanced. An Irish captain, going his rounds upon the walls of the town, observed the guns fired by the Americans as a signal, and at once caused the drums to beat, and roused the garrison to arms. Montgomery, with his detachment, passing along under Cape Diamond, came to a small battery of cannon. The guard threw down their arms and fled. The Americans had nearly taken possession of it, but the road was impeded with immense masses of snow. Montgomery with his own hands opened a path for his troops. Two hundred of them came up at last, and rushed on. Just then, a cannonier, who had fled on seeing the Americans halt, returned to his post at the little battery, and, taking a match, which happened to be still burning, fired a cannon charged with grape-shot. The Americans were within forty paces. Montgomery dropped dead upon the spot, and his troops soon fled.

Arnold had made an assault, meanwhile, at another point; but he soon received a musket-ball in the leg, which splintered the bone; and he was carried off to the hospital, almost by force, as he was unwilling to quit the field. Captain Morgan, with two companies of riflemen, now advanced upon the battery. His sharpshooters killed many of the English through the embrasures. The guard fled. Morgan rushed forward, and some prisoners were taken. But here the courage of his troops failed them. Morgan alone stood firm. As the morning dawned, he rallied his riflemen with a voice of thunder, and they rushed forward. A detachment sallied out upon them, at this moment, from the walls; and the English captain summoned them to lay down their arms. Morgan aimed a musket at him, and shot him dead. The English retreated; a hot skirmish ensued. Some ladders were planted against the walls, but a terrible fire was poured down upon the men who attempted to ascend them. A detachment of the British now assaulted the Americans on another side, and they were compelled at last to surrender.

Arnold, with his remaining force, retreated three miles from the city, and entrenched himself. His subsequent operations we shall notice by and bye. Governor Carleton kept within the walls of Quebec, satisfied with waiting till reinforcements should reach him from England, in the spring. So ended the famous assault upon Quebec.

PROCEEDINGS AT BOSTON IN 1776.

Having given some account of the most important events of the year 1775, the first of the war, we come now to 1776. In the winter and spring of this year, Boston was still surrounded by the American army under Washington. The British in the town, meanwhile, were reduced to great extremity. For fuel, they used the timber houses, which they pulled down for the purpose. They were in want of food, and some armed ships were ordered to Georgia, to buy up rice; but the people of that province opposed them with so much success, that of eleven vessels, only two got off with their cargoes.

The Old South Church, in Washington Street, was entirely destroyed inside, and used as a riding-room for a regiment of dragoons. The pulpit and pews were taken out, and the floor covered with earth. The framework of one pew, carving, silk-furniture, and all, was taken out, and used for a pig-sty. The North Church, so called, was entirely demolished.

All this time, notwithstanding there was much suffering in the town, the English officers and the loyalists contrived to pass the time, when they were not fighting the Americans, in dancing, and other amusements. They had a small theatre, and, in the evening of February 8th, were acting a farce, called "The Blockade of Boston." One figure, meant to ridicule Washington, was rigged out in the most uncouth style, with a large wig and a long rusty sword. Another character was an American serjeant in his country dress, with an old gun on his shoulder, eight feet long. At the moment this figure appeared, one of the British serjeants came running on the stage, and cried out, "the Yankees are attacking our works on Bunker's Hill." The audience took it for part of the play, but General Howe knew it was no joke, and called out, "Officers, to your alarm-posts!" There was some shrieking and fainting among the ladies, of course.

The American army, at this time about Boston, was but little better provided for than the English. Many fell sick with fatigue and exposure. They had provisions enough from the country to be sure, while the English troops were said to be living wholly on salt meat, and the Boston loyalists upon horse-flesh. But the whole number, in January, was reduced to less than ten thousand; and these, having enlisted for a few months only, were every day going home. At one time there were hardly men enough to man the lines. As for powder, they had but four rounds to a man, and but four small brass cannon, and a few old iron pieces, full of holes, with the woodwork broken off. They were fitted into logs, like the barrel of a gun into the stock, and lifted up and down, and wheeled about in this way, but to some good purpose. The British kept up a continual cannonade in return; firing about two thousand shot and bombshells, it is said, in the course of a few months. But the whole of this firing killed only twelve Americans.

We have mentioned the miserable condition of the American army in the early part of the year 1776; but they soon after received five brass cannon, small arms of all kinds, cargoes of provisions, &c. These were all captured from the British off the coast by American privateers. Privateers are armed vessels fitted out by private individuals.

PROCEEDINGS IN BRITAIN.

In England, the year 1776 opened with new resolutions, on the part of the ministry, and the majority of parliament, to continue the war. The party called the whigs were violently opposed to it; but the tories, the ministry, and king, regarded the Americans as rebels, and resolved to spare no pains to punish them severely. They found it difficult to enlist soldiers in England, for the war was unpopular with the lower classes. Recruiting officers were sent about, the royal standard was raised in all the cities, and large bounties and wages were promised; but to little purpose. In Scotland, some thousands were raised; and a bargain was made with some of the small states of Germany, for about seventeen thousand German troops. These were called Hessians, because a part of them came from Hesse.

BOSTON EVACUATED.

In the meantime, the American army at Boston began to form plans for seizing upon the town, for taking the British garrison prisoners, and for destroying their fleet in the harbour; but they kept quietly in their quarters till March 1776, the British now and then sallying out on the American lines. At this time the red ground of the American flag was changed, and in place of it thirteen blue and white stripes were inserted, as an emblem of the thirteen colonies that were united in the struggle for liberty. These stripes are still retained in the national flag.

There was something of the same feeling in congress as in the army. Stimulated by the conduct of the king and parliament, they resolved, from this time, to follow up the war at all hazards. Hearing that an attack would be made upon New York, they urged General Washington to press, as closely as possible, the siege of Boston, so that the British might not be able to spare troops to send against New York. He wished to attack the town at once, but most of his generals opposed this plan, and he concluded to fortify the Heights of Dorchester, which command the entire city on the south side. Heavy batteries were opened from the American works in Cambridge, Roxbury, and Lechmere Point. The bombs fell into the town every hour, and houses were constantly set on fire by them. All this was to employ the British upon that side, while the Americans, on the night of the 4th of March, secretly marched over Dorchester Neck. The frost rendered the roads good; and such was the silence of the march, and the tremendous roar kept up by the batteries, that two thousand troops passed over, with three hundred loaded carts, and nothing was known of it till morning. Had the British suspected this manœuvre, they would have taken measures to prevent it. By four o'clock in the morning, two fortifications were raised upon the two heights. A terrible cannonade now opened from the British forts, and the shipping, upon the American fortifications on Dorchester Heights. But few men, however, were killed; and the Americans worked on in high spirits, taking no notice of the cannon-balls, as they came, ploughing the ground about them.

General Howe saw that he must either leave the town, or dislodge the Americans from the heights. He resolved upon the latter; but a long storm, and a very high sea, prevented his troops from crossing over. He finally concluded to give up the town, and transport his whole force to Halifax, in Nova Scotia. Knowing that his shipping might be prevented from passing out of the harbour by the American fortifications, he prepared a great mass of stuff for setting fire to the town, and then proposed to Washington and the selectmen, that if his troops were suffered to pass safely, the town should be left standing. This was agreed to. He had 150 carrying vessels, called transports, in the harbour; and he embarked on board these, with all his force, on the 17th of March, taking with him 1500 of the American loyalists.

CANADIAN CAMPAIGN OF 1776.

From this time the war on both sides assumed a more determined character. A strong English force was sent to relieve Carleton, in Canada. Arnold's whole force before Quebec now amounted only to 3000 men. Many of these were sick with the small-pox. General Thomas died of the disease. The river was clear of ice, April 1776, and English reinforcements were expected every day by the governor. An attack was made upon Quebec, but it failed of success; and Arnold was now obliged to break up his camp and retreat, leaving his baggage behind. Governor Carleton pursued, till the Americans reached the mouth of the river Sorel.

About the last of May, English forces arrived at Quebec, amounting to 13,000 men, commanded by Burgoyne, Phillips, and a German general, called Reidesel. Arnold, meanwhile, was skirmishing with the Canadians and Indians about Montreal and the Sorel. In a short time he went down the St Lawrence to Trois Rivieres, where there was a large body of English. He expected to surprise them in the night, but was misled by his guide; and when he arrived, late in the morning, the enemy was drawn up in battle array. A skirmish began, and the Americans were defeated. They fled over a wild, swampy country of woods, leaving many prisoners behind them; and having crossed the St Lawrence, at last arrived at fort St John, on the Sorel. The English pursued them to this place. Arnold's force was too small to resist a siege. He therefore set fire to the magazine and barracks, and retreated farther south to Crown Point. The English, having lost their batteaux, could pursue him no farther, and soon after returned to Quebec.

The Americans, under Arnold, had suffered exceedingly in the retreat. They sometimes waded in the water to the waist, and dragged the loaded batteaux up the rapids by main strength. Two regiments, at one time, had not a single man in health; another had only six, and a fourth only forty. On the first of July, they reached Crown Point; and thus ended the courageous but unfortunate expedition to Canada.

During the summer of 1776, Crown Point was taken by the British, and the Americans, now commanded by General Gates, withdrew to Ticonderoga. A fleet was built on the lake, at Skeensborough, consisting of a sloop, three schooners, and six gondolas, which are large flat vessels. They carried, in the whole, more than 100 guns, and more than 400 men. Arnold commanded the fleet.

By the month of October, the British had collected a much larger naval force; and as nothing could be done, by way of invading the provinces from Canada, till lake Champlain should be cleared of the Americans, they sailed up the lake, and engaged them. The two fleets fought till night. Arnold then very skilfully made his escape, and, in the morning, not an American vessel was to be seen. The British fleet followed on, however, and found them again off Crown Point. Some of the American vessels escaped to Ticonderoga. Seven of them remained. They were attacked, and the action continued some hours. Arnold was determined that his vessels should not be taken. He contrived, therefore, to run them on shore, and there they were blown up. He did not leave his own vessel till she was wrapped in flames. Lake Champlain was now in the power of the British; but Gates and Arnold had prevented them, strong as their force was, from invading the provinces farther south. It was now too late in the season to attempt it.

DEFENCE OF FORT MOULTRIE.

Boston, which had been entered by the American army on the 17th of March, was no longer disturbed by the enemy. The British, finding that the provinces of North Carolina and Virginia were too strong for them, determined to make an attack upon the city of Charlestown, in South Carolina.

Admiral Parker and General Clinton reached Charlestown harbour on June 28, and, with eleven large vessels of war, commenced a tremendous attack upon Fort Moultrie. This stood upon Sullivan's Island, six miles from the city, and was built of a kind of wood called palmetto, so spongy and soft that the balls were buried in it, and no splinters were thrown off. The fort was defended by sixty pieces of cannon. Ship after ship poured in their tremendous broadsides. The whole harbour seemed to be but a sheet of flame. The Americans aimed well, and every shot had its effect. Some of the English vessels were soon stranded. The Thunder, after firing more than sixty bombs, was disabled. The Bristol was almost destroyed, and a great number of men were killed. The fire of the fort suddenly stopped. Their powder was exhausted. The enemy thought themselves sure of the victory, and the ships moved nearer, with their flags flying, and their drums beating. But the Americans were soon supplied from the shore, and the battle lasted, hotter than ever, till seven in the evening. The English drew off in the night, and the enterprise was abandoned. This defence of Fort Moultrie was one of the most gallant actions of the war. The British plan now was to direct the whole English force upon the province of New York, and to make it, with the city of New York, the centre of all their operations in America. From this point they could march south upon the southern provinces; here they could receive stores from England by water, and provisions from Staten and Long Islands; and here they could ascend the Hudson, and meet Burgoyne, in his route south from Canada.

DECLARATION OF INDEPENDENCE.

The revolution had now reached a point from which it could not turn backward. The feelings of a great part of the people were alienated from England, and a deep hostility was planted in their bosoms. They had originally asked for justice, and that was denied. Oppression followed, and that they resisted. Then came the British armies, with fire and sword, to consume their dwellings, and shed their blood.

A high-spirited people were not likely to look on these things but with resentment. Their love and respect for England were originally very strong. These, indeed, lasted up to the period of which we are now speaking. But now all thoughts of reconciliation were abandoned. The people no longer asked for redress; they cast off their allegiance to the king, and determined to be free; the "spirit of '76," which is often alluded to, was the earnest voice of a nation, resolving that they would risk every thing for independence.

In June 1776, congress had chosen five of their members to consider the great question, whether the provinces should declare themselves a *free and independent nation*. These were Jefferson, Adams, Franklin, Sherman, and Livingston. They reported in favour of so doing; and congress agreed with them. Independence was solemnly declared on the fourth day of July. The declaration was written by Jefferson, and signed by John Hancock, president. It was then signed by every other member of congress. The people received and read it with great joy. Independence was proclaimed, with great parade, at Philadelphia, on the 8th. Cannon were fired, the bells rung, bonfires were kindled, and the people seemed to be mad with joy. On the 11th, the declaration was read to each brigade of the American army, then assembled at New York, and received with prodigious peals of applause. The same evening, the statue of George the Third, erected in 1770, was dragged through the streets by the "sons of liberty," and the lead it was made of was melted into musket-balls. An immense multitude at Baltimore received the declaration in the same manner, the air ringing with shouts and the roar of cannon. The king's effigy was made the sport of the populace, and burnt in the public square. In Boston, the declaration was read from the gallery of the State-house to an immense crowd, gathered from all quarters. Men, women, and children, assembled to hear it, and every moment the air resounded with the shouts of the multitude. The troops were drawn up, splendidly dressed and armed, in King Street, which from that time was called State Street. The bells rang, the people shouted, the cannon thundered and blazed, and the striped banners waved from the steeples, till the whole air [illegible]d to be alive. In the evening, all the ensigns [illegible] English lions, sceptres and crowns, whet[illegible] painted, were torn in pieces, and burnt [illegible]t.

Such was [illegible]laration of independence, and such the manner [illegible]ich it was received by the Americans. They had now declared themselves to the world as a free people; but ere their freedom could be established, they had yet to pass through a long, bloody, and desolating war.

AMERICANS RETREAT FROM NEW YORK.

General Washington now occupied New York and Long Island, which lies a few miles from the city, with seventeen thousand troops. On the 22d of August, the English landed, in great force, on the island, and a very hot battle was fought among the hills and woods. A whole regiment of fine young men from Maryland were killed, some cannon were lost, and the Americans retreated to the northern part of the island. Here the stormy weather kept the enemy from attacking the camp again. But, fearing an assault every moment, the Americans concluded to pass over to the island of New York, and join the rest of the army. This was done in the night of August 29. They kindled up circles of bright fires in their camp, to deceive the enemy, and started off in their boats at eleven o'clock in the evening. The fleet of boats moved off from the shore like an army of ghosts. Not a word was said—no drums beat—no bugles rang—no colours waved in the breeze. A fair wind favoured the troops; they crossed the water like birds. In the morning, at eight, when the fog cleared up, which had covered them in the passage, and the sun shone out bright and warm upon the green shores, the wooded hill-tops of the islands, and the smooth surface of the bay, the American army had vanished. The camp was deserted, the fires had gone down, and nothing was seen but a few distant boats which had come back for the cannon.

Previous to the retreat of the Americans, several skirmishes were fought between the two armies. Two forts, one belonging to the English, and the other to the Americans, were within half gun-shot of each other, and were only separated by a small creek. It was at last agreed between the British and American officers, that the sentinels should not fire upon each other as they went their rounds. So they became very civil. "Give us a quid of your tobacco, my good friend," cried the English guard to the American sentinel. "Oh, certainly," said the latter. He drew his twisted roll from his pocket, and tossed it across the creek to the Englishman, who gnawed off a quid, and threw it back again.

The British army now pressed the Americans with great activity; the latter were driven back from point to point. They left the city of New York at last, and the British entered it. A few days after, a terrible fire raged in the place, and consumed more than a thousand houses. The British supposed the inhabitants had set it on fire, and were so angry as to throw some of them into the flames.

DISTRESSES OF THE AMERICAN ARMY.

Washington now retreated into the back country. The British secured the Province of New York with their troops, and covered all the shores with their vessels. Several strong forts were taken, together with their garrisons. Nothing could be done to oppose them. The Americans were now much discouraged.

General Washington, with his army, marched into New Jersey, and attempted to harass the British army there, under Cornwallis. But they were too strong, and Washington was obliged to retreat night and day; over mountain and valley, he fled before them. The time the militia had enlisted for was short, and many of them went home. Whole companies deserted, and the army was so small in December, that Washington knew every man by his name. They were so nearly naked and ragged, too, and looked so miserable, that their own countrymen would not join them. Large numbers went over to the enemy; but Washington remained firm and undismayed. While other minds were shaken with doubt and fear, he remained steadfast and resolved, looking deeply into the future; and placing his trust in Heaven, he seemed to penetrate the clouds that shed their gloom upon the land, and to see beyond them a brighter and a happier day.

He always appeared before his soldiers with a smile, and fought or fasted with them, as necessity required. He inspired all around him with courage, and wrote many letters to congress, entreating them to make great exertions to send him assistance. Accordingly, they endeavoured to rouse the country, by representing to the people the necessity of an immediate increase of the army.

This appeal was not without its effect. Philadelphia, in a very short time, furnished Washington with a regiment of 1500 men, who were resolved to support him to the last. They had been accustomed to the gay company and high living of the city; but they shouldered the musket, slept with a mere blanket around them, on the frozen ground, or in sheds and barns; and suffered every thing with the poorest of the army.

The British now withdrew into winter-quarters. They occupied the villages for many miles, up and down, on the eastern side of the Delaware, with their army. Washington was below them, on the other side. But they were tired of pursuing him; and they believed that his army would soon dwindle away, and the whole country be conquered. They scarcely took the trouble to set guards at night; but Washington watched them like a lynx. On the night of December 25th, he crossed the Delaware, again, with a large part of his army. The night was dark, stormy, and cold. The river was crowded with broken ice, rushing together, and sweeping down upon its swift current. But, notwithstanding these difficulties and dangers, the river was passed by the American troops, and they marched on to Trenton. They entered that place at eight in the morning. A large body of Hessians were stationed there. They were completely surprised; but they fought bravely for a short time. Five hundred cavalry made their escape; but some fine cannon, and more than a thousand prisoners, were taken by the Americans. Cornwallis, who lay a few miles off, thought so little of the American "ragamuffins," at this time, that he mistook the noise of the cannon at Trenton for thunder.

The British army were amazed at this unexpected event. They moved and marched about, but to no purpose. Washington started off for the mountains of New Jersey. The British were close upon his rear. They encamped so near him one evening, that they thought it impossible for him to escape. They put off attacking him, however, till the next morning.

The Americans kindled up their fires, as usual, and marched off at one o'clock, without noise. They reached Princeton at daybreak, and fell upon the British there so suddenly and so fiercely, that sixty of them were killed, and three hundred taken prisoners. Their commanding officer had had some fears of an attack, and had written to the commander of the British army, a day or two before, for a reinforcement. "Don't be alarmed," was the answer; "with a corporal and six men you may scour the whole country; don't be alarmed." They found themselves mistaken, however, as we have seen.

Washington now formed a camp at Morristown. Militia came to him from all parts. The spirits of the people were raised. They had imagined that nothing could conquer the Germans, and were afraid of them as of wild beasts. Indeed, these soldiers had acted like wild beasts. They had ravaged the country like so many highwaymen, plundering, burning, and murdering. But the people found now that they were men, and that they could be killed and captured, as large and fierce as they looked, with their immense swords like scythes, their tall caps, and shaggy whiskers. The British themselves treated their prisoners with cruelty. Hundreds were confined in the New York prisons. They were often insulted as rebels. A party of them was once brought before General Howe to be tried. An English gentleman pleaded their youth in their favour. "It won't do," said the general; "hang up the rascals! hang them up!" They were only carted through the streets, however, seated on coffins; halters were tied about their necks, and the British soldiers hooted at them.

BRITISH EMPLOY THE INDIANS.

While these things were going on, late in the year 1776, at New York, Sir Peter Parker secured the coasts of Rhode Island with a large squadron, and overran the whole province. Meanwhile, a man of the name of Stuart was sent by the British among the

Indians in the high wild lands back of Virginia, and the other southern colonies. The Cherokees were persuaded by him to make war; and they rushed in upon the settlements of the whites, burning the villages, and scalping men, women, and children. But a large American force soon marched into their own country. Their wigwams were burnt to the ground, and their corn-fields trampled under foot. They were frightened at last, and begged for peace.

It once happened, during the expedition against the Indians, that, the Americans having marched a long way among the hills, Major Pickens was sent ahead with twenty-five men, as a scouting party, to examine the country. One morning, as he and his party waded through the tall grass on the bank of a stream called Little River, more than two hundred Indians came rushing out on a ridge of land just above them. Never was such a horrid noise heard as the Indian war-whoop. The woods sounded with it far and wide. The Indians were dressed in the most frightful manner, with their faces painted, long feathers on their heads, guns swinging in their left hands, and tomahawks raised in their right. "Let us scalp them," cried the Indian leader to his men; "they are too few to shoot." But Major Pickens was prepared for their onset. His men were sharpshooters, and each man had his rifle. He ordered them not to fire until he did, to take sure aim; and, having fired, to bury themselves in the grass, and load their rifles. The Indian chief soon came up within twenty-five yards of the little band, yelling and shaking his tomahawk. Pickens stretched out his rifle, took a deliberate aim, and shot him dead. The twenty-five brave riflemen now fired. The Indians fell on all sides. They yelled more than ever, with fury and terror, dropped their tomahawks, and fell back among the trees. Even there the rifles were too sure for them. Not an Indian could show himself over a log or a rock, but a bullet instantly whistled through him. One of them was seen running his gun through the roots of a fallen tree. A rifleman aimed at him as coolly as if he had been a wooden mark, hit him precisely in the nose, and laid him flat on his back. Another Indian lifted the dead body, and was running off with it—for the Indians never leave the dead—when another rifleman fired, and killed him. Dozens of them were picked off in this way, and the rest fled.

A few such skirmishes as these made the Indians soon tired of fighting the Americans, to which they had been instigated by the British. The next year, when an attempt was made to set them upon the white inhabitants along the frontiers, they replied to the British emissaries, that "the hatchet was buried so deep that they could not find it."

ACTIONS IN 1777.

In the spring of 1777, General Howe amused himself by sending out detachments from his camp to ravage various parts of the country. On the 26th of April, Governor Tryon embarked at New York with a detachment, sailed through the Sound, and landed at Fairfield, Connecticut. They marched through the country in battle array, and reached Danbury in twenty hours.

As they came, the few militia who were there fled at full speed. The British began to burn and demolish every thing except the houses of the loyalists. Eighteen houses were consumed, and 800 barrels of pork and beef, 2000 barrels of flour, and 1700 tents, were carried off or destroyed. But the militia now began to muster from the country round about.

At Ridgefield, General Arnold blocked up the road in front of the British, who were now returning. He had with him about 500 men. These brave fellows, who had marched fifteen or twenty miles in the rain, kept up a brisk fire upon the enemy, as they came on, and stood their ground, till the British formed a lodgment upon a hill at their left hand. They were then obliged to give way. The British rushed on, and a whole platoon fired at General Arnold, who was not more than thirty yards distant. His horse was killed. A soldier advanced to run him through with his bayonet; Arnold shot him dead with his pistol, and escaped. The British lost more than two hundred men, but made good their retreat to the Sound. Congress presented General Arnold with a fine war-horse, richly dressed, for his gallantry.

By way of retaliation, on the 24th of May, Colonel Meigs, an American, crossed the Sound with 170 men in whale-boats, and fell upon the enemy at Sagg Harbour, on Long Island. They burned twelve vessels, destroyed a large quantity of forage, killed six men, and brought off ninety prisoners, without losing one of their own men. They returned to Guilford, having been the distance of ninety miles in twenty-five hours from the time of their departure. Congress ordered an elegant sword to be presented to Colonel Meigs.

Washington, in the meantime, with an army of fifteen thousand men, was so strongly entrenched among the hills, that Howe dared not attack him. The summer was therefore spent in marching to and fro in New Jersey, without effecting much. But in July, the British mustered a force of sixteen thousand men at New York, which they soon after left, with a large fleet. An attack was expected every where upon the coast; but no one knew whither they were bound. Having been off at sea with high winds for a long time, they entered Chesapeake Bay at last, and landed at Turkey Point.

They left that place, September 3, and, marching towards Philadelphia, came up with Washington's army at a place called Chad's Ford, on the river Brandywine. On the 11th they had a warm skirmish, and the Americans were driven back. Congress removed to Yorktown, Virginia; and Howe entered Philadelphia, in great triumph, September 26.

The Americans were defeated again at Germantown on the 4th of October. The battle began early in the morning, when nothing could be seen farther than thirty yards. During the whole action, which lasted nearly three hours, the firing on both sides was directed by the flash of each other's guns. The smoke of the cannon and musketry, mingled with the thick fog, rested over the armies in clouds.

Washington retired into winter quarters, at Valley Forge, sixteen miles from Philadelphia. His army might have been tracked, by the blood of their feet, in marching, without shoes or stockings, over the hard frozen ground. Thousands of them had no blankets, and were obliged to spend the night in trying to get warm, instead of sleeping. They erected log-huts for lodgings. For a fortnight, they nearly starved. They were sometimes without bread and without meat. A person passing by the huts of these poor fellows in the evening, might have seen them, through the crevices, stretching their cold hands over the fire, and a soldier occasionally coming in or going out, with nothing but a blanket on his shoulders. "No pay, no clothes, no provisions, no rum," said they to each other. But they loved Washington and their country too well to desert them in these trying times.

Having seen Washington's army in their winter quarters at Valley Forge, we shall now follow the northern army, under Gates, and the English under Burgoyne, through the campaign of 1777. The latter intended to break his way from Canada, up the river Sorel, through lakes Champlain and George, and the river Hudson, to New York. He had under his command one of the finest armies ever seen.

The Americans were driven before him, from Champlain almost to Albany. Burgoyne pressed after them, but his route lay through the woods, and the Americans cut large trees on both sides of the road, so that they fell across it, and blocked it up entirely. The country was so covered with marshes, and crossed by creeks, that the British were obliged to build no less than forty bridges; one of them was a log bridge, extending two miles across a swamp. July 30, Burgoyne reached Fort Edward, on the river Hudson. He had with his army a large number of Indian warriors, and they ravaged the country in the most horrible manner. One of them murdered a beautiful American girl, Miss M'Rea. She was the daughter of a loyalist, and was to be married to a young English officer. The latter sent two Indians to guide her across the wood from the fort to his own station. They quarrelled on the way, which should have special charge of her. They became very angry, and one of them, to terminate the dispute, sunk his tomahawk in her head, and ended her life.

SURRENDER OF GENERAL BURGOYNE, AND AID PROCURED FROM FRANCE.

The spirit of the whole country was greatly excited by these things, and an army of thirteen thousand men was collected under General Gates, to oppose Burgoyne. Meanwhile, a British force, under General St Leger, had crossed Lake Ontario, from the St Lawrence, and laid siege to fort Schuyler, on the southern side. General Herkimer marched northward with eight hundred militia, to relieve it. He fell into an ambuscade, however, in the woods, and was killed. In his last moments, though mortally wounded, he was seen sitting on a stump, still encouraging his men. They stood firm, and several of the British Indians fell at their first fire. The rest were so enraged that they turned upon the loyalists and the British, and murdered several of them. The battle was heard at the fort, and two hundred and fifty of the Americans came out to reinforce the detachment. The British were wholly routed. The Indians fled, howling like wild beasts, and left their kettles, blankets, tomahawks, and deer-skins behind.

About the middle of August, Burgoyne sent five hundred Hessians and one hundred Indians, under Colonel Baum, to take possession of a collection of American provisions, at Bennington, Vermont; but General Stark was there, luckily, with eight hundred New Hampshire and Vermont militia. Colonel Baum, finding this force greater than his own, threw up temporary breastworks for defence, and sent to Burgoyne for reinforcements. Several skirmishes now followed, in which the Americans had the advantage. Animated by success, they at length ventured to make a general attack upon the breastworks of the enemy. They were without cannon, and destitute even of bayonets. The Hessians, too, fought very bravely for two hours. But they were now opposed by still braver men. The Americans rushed into the very flash of their cannon and musketry. They could not be resisted. Multitudes of the enemy fell before their keen and well-directed fire. Baum himself was killed, and most of his detachment either lost their lives or were taken prisoners.

The Americans, not expecting another enemy, had dispersed themselves after the battle. Suddenly, a reinforcement of several hundred British troops, under Colonel Breyman, arrived at Bennington. The Americans were now near losing all they had gained. But it happened that a regiment, under Colonel Warner, reached the place soon after. These, with the militia, immediately made an attack upon the enemy. They fought till sunset, when the British retreated, and, under cover of the night, the greater part effected their escape.

In these two engagements, four hundred of the enemy were killed and wounded, six hundred were taken prisoners, and two hundred and fifty dragoon swords, eight loads of baggage, and twenty horses, fell into the hands of the Americans.

By the middle of September, the American army under Gates was within three miles of the great army of Burgoyne, on the Hudson. The latter was now severely pressed for provisions, and undertook to march on towards Albany. The Americans met him at Stillwater, on the 19th; a fierce battle was fought, and the British could advance no farther. They pitched their camp on the plains of Saratoga, three miles above the village, within cannon-shot of the American lines. General Clinton was at this time attempting to force a passage up the Hudson, from New York, to reinforce Burgoyne. Spies and scouts were constantly on the alert, and hot skirmishes now took place every day between the two armies at Saratoga. September 23, a cannonade was kept up, with a tremendous roar and blaze, for three hours. The field was strewn with the killed. An English captain, with forty-eight men, had the command of four fine cannon. He fought till thirty-six of his men were killed. His horses being shot down at last, the cannon were left to the Americans.

Some of the American soldiers, during these skirmishes, often placed themselves in the boughs of high trees, the country being wild and woody, and played with their rifles upon the rear and flank of the enemy. The British officers were picked off like birds. Burgoyne himself once narrowly escaped. His aid-de-camp General Philips was delivering a message to him, when he received a rifle ball in his arm. His saddle was furnished with very rich lace, and the sharp-shooter had taken him for Burgoyne.

October 7, the whole British line was driven back by a tremendous charge. The German lines stood firm to the last, and Colonel Brooks was ordered to attack them. He galloped towards them at the head of his regiment, waving his sword; and Colonel Arnold rushed on with him. Arnold was wounded, and carried off. Brooks kept on, and the Germans were driven back. Colonel Cilley, of New Hampshire, captured a cannon with his own hands, and was seen astride upon it, in the heat of the battle, shouting to his soldiers. In this battle, Burgoyne had a bullet pass through his hat, and another through the edge of his vest.

On the 18th of October 1777, the whole British army under Burgoyne surrendered to General Gates. There were nearly ten thousand men, including Indians; forty cannon, seven thousand muskets, and a vast quantity of tents and cartridges. The whole country was filled with rejoicing. The thanks of congress were voted to Gates and his army. One of the main effects of the victory was, that the French now concluded to fight with the Americans against England. Treaties between the two nations were signed, February 6, 1778, and a fast-sailing schooner from France reached Casco Bay in Maine, in about a month, with the news. It occasioned prodigious joy in congress, in the army at Valley Forge, and over the whole country. A French fleet arrived on the coast early in July. General Clinton knew they were coming, and therefore thought it necessary to remove to New York. He left Philadelphia on the 18th of June, and marched through New Jersey towards the latter place.

As soon as Washington heard that Clinton had left Philadelphia, he broke up his quarters at Valley Forge, and followed hard after him. A hot battle was fought on the 28th near Monmouth court-house. It did not cease till the evening. Washington slept upon his cloak under a tree, expecting more fighting in the morning; but the British marched off in the night. Sixty of their soldiers were found dead on the battle-field without wounds. Fatigue and the excessive heat had killed them.

BRITISH MINISTRY CONDESCEND TO TREAT.

The intelligence of Burgoyne's surrender occasioned dismay among the British ministers. They now introduced a conciliatory bill into parliament, exactly like one which the celebrated Mr Burke had some time before failed in passing. It appointed commissioners to go to America, and offer to give up all power of taxation over the colonies, and every thing, indeed, but the authority of the king, provided they would return to their allegiance. These commissioners, however, although they did all they could to produce an impression in America, found every effort counteracted by congress. They offered more than had been asked by the Americans at the beginning of the war; but the Americans had since then been much exasperated by the barbarities of the British army—had declared their independence—and, having good prospects of successfully resisting Britain, were not inclined to go back in their career. The commissioners therefore returned without doing any good.

No other great battles were fought during the campaign of 1778. The armies only molested each other by sending out small detachments. Little also was done on either side during the year 1779. The

British main army, under General Clinton, was at New York; and the Americans, under Washington, were among the Highlands, above that city, on the river Hudson. In the spring, a British force was sent to ravage the coast of Virginia. They destroyed every thing in their way—villages, shipping, and stores. The Virginians sent to the British general to ask, "what sort of war this was." He replied, that "all rebels must be so treated." A month or two afterwards, Governor Tryon was sent to commit similar havoc in Connecticut. Colonel Whiting had mustered the militia at Fairfield. Tryon came to that place, and commanded him to surrender. He gave him an hour for consideration; but, before that time had elapsed, his soldiers set the town on fire, and a great part of it was laid in ashes. At New Haven, all possible damage was done. The harbour was covered over with feathers, poured out from the beds of the people. Desks, trunks, closets, and chests, were broken open; the women were robbed of their buckles, rings, bonnets, and aprons. East Haven was afterwards burnt, and Norwalk shared a similar fate.

TREACHERY OF GENERAL ARNOLD.

General Lincoln commanded in the southern provinces during 1779, the British holding possession of Savannah. He besieged them there with the help of the French fleet, but was driven off. Prevost, the British general, himself, met with the same bad luck in besieging Charlestown, South Caroline. The people resisted him nobly, with some assistance from Lincoln, and the siege was abandoned. But Prevost ravaged the country, burning and plundering without mercy.

During the year 1780, nothing of great consequence was done in the northern provinces. The two armies lay near each other, the British being in New York, and the Americans on the Hudson; but no battles were fought.

The most important event of this year was the treason of Arnold, one of the American generals. He commanded a very strong fort at West Point, sixty miles from New York, on the North River. He undertook to deliver it into the possession of the British. Major Andre, a young British officer, went on shore in the night from a British ship in the river, to arrange the business with Arnold. The two officers met privately at some distance from the fort. Arnold agreed, for a certain sum of money, and other considerations, to surrender the fort, with the garrison, cannon, and ammunition, into the hands of the British commander. In settling the details of this business, Andre was detained till the next day; and then the boatmen refused to carry him back. He had to return by land, and to pass by the American camp, on his way to New York. He was furnished with a horse, and exchanged his uniform for a common coat. He thought himself already out of danger, when, as he trotted quietly on through the woods, he was stopped by three Americans, who were scouting between the outposts of the two armies. "Who goes there?" cried the first, seizing his bridle. Andre was frightened, and asked the scout where he belonged. "Below," answered he, meaning New York. "So do I," said Andre, deceived; "I'm a British officer, in great haste; don't stop me." "Are you, indeed?" said the scouts; "then we'll see about that!" They found his spy-papers in his boots. He offered them his gold watch, horse, and purse, if they would release him; but they told him they knew their business too well. He was carried to the camp, and, though a brave and accomplished young man, yet he was condemned and hanged, according to the usages of war, as a spy. Even the Americans shed many tears for this unfortunate officer.

CAMPAIGN OF 1781.

Congress continued to make great efforts to supply the army, though the paper money they had issued was worth so little that a soldier would give forty of their dollars for a breakfast, and a colonel's pay would hardly find oats for his horse. The merchants of Philadelphia raised a large sum of better money, however, and sent it to the army. The ladies of that city furnished a large quantity of clothing. But the British, all this time, were overrunning the two Carolinas. They had taken Charlestown, on the 11th of May 1780, after a long siege, and a brave defence by General Lincoln.

Generals Marion and Sumpter gave the British great trouble during this campaign. Small parties of the mountain militia joined them, and they swept down upon the enemy, wherever they could find them in small parties. The farmers' wives furnished them pewter spoons and platters, to make into bullets; and they forged swords of scythes and the saws of sawmills. In October, sixteen hundred of these mountaineers mustered together to attack a British force under Major Ferguson, who had encamped not far from the mountains. For weeks they had no salt, bread, or spirits; they slept upon boughs of trees, without blankets, drank only from the running streams, and lived upon wild game, or ears of corn, and pumpkins, roasted by their great log-fires in the woods.

With the year 1781, on which we now enter, the war drew rapidly toward a close. It was carried on almost entirely in the southern provinces. General Greene was appointed to command the American forces in that quarter. At the time of his arrival, they were a miserable half-starved militia, of three thousand men. They marked the frozen ground with the blood of their bare feet, and lived half the time upon frogs, taken from the swamps, wild game, rice, and wretchedly lean cattle. But they were soon reinforced; and small parties, under Sumpter, Marion, Morgan, and others, often annoyed the forces of Cornwallis. Colonel Washington laid siege to a strong blockhouse near Camden, defended by a British colonel, and a hundred loyalists. He had no cannon, and few men; but he carved out a few pine logs in the shape of cannon, mounted them on wheels, and summoned the loyalists to surrender. They were frightened at the appearance of his big cannon, and surrendered. Not a shot was fired upon either side.

On the 17th of January, Colonel Morgan, with eight hundred militia, was attacked at a place called the Cowpens, in South Carolina, by Tarleton, a famous British officer, with eleven hundred men and two cannon. The enemy rushed on with a tremendous shout. The front line of militia were driven back. Tarleton pursued them, at full gallop, with his troopers, and fell upon the second line; they too were giving way. At this moment Colonel Washington charged Tarleton with forty-five militiamen, mounted, and armed as troopers. The whole line now rallied under Colonel Howard, and advanced with fixed bayonets. The British fled. Their cannon were left behind; three hundred British soldiers were killed and wounded, and five hundred were taken prisoners; eight hundred muskets, seventy negroes, and one hundred dragoon horses, also fell into the hands of the Americans.

General Greene was now driven back by Cornwallis into North Carolina. The latter pursued him through the province, over mountains and swamps, and arrived at the river Dan just as Greene had crossed it. Cornwallis now found it necessary to turn about; and so he marched back, and Greene soon followed him with new forces.

Sumpter joined him at Orangeburg, having received orders to do so during his hasty retreat before the enemy. It seems Greene could find no man in his army who would carry the message to Sumpter. A country girl, named Emily Geiger, at last offered her services, and was sent. She was taken by the British, and confined for the purpose of being searched. She, however, ate up the letter which she carried, piece by piece. They released her, to go home, as they supposed, but she took a roundabout way, reached Sumpter's camp safely, and delivered her message in her own words.

CONCLUSION OF THE WAR.

The Americans were defeated near Guilford court-house on the 15th March. But Cornwallis retreated soon after. He had suffered great loss, and his army was small. A militia colonel cried out in this battle, as the British were marching up, "they will surround us." He was frightened himself, and frightened his soldiers so much, that they gave way, while the enemy were one hundred and forty yards distant. Colonel Washington, at the head of his troopers, nearly captured Cornwallis in this battle. He was just rushing upon the British general, when his cap fell from his head. As he leaped to the ground for it, the leading American officer behind him was shot through the body, and rendered unable to manage his horse. The animal wheeled round, and galloped off with his rider; and the troop, supposing it was Washington's order, wheeled about also, and rode off at full speed.

Fort Watson, between Camden and Charlestown, surrendered in April, with 114 men, to General Marion. The fort was built on a mound of earth thirty feet high; but Marion, with his mountaineers, had raised a work which overlooked it in such a manner, that not a man in the fort could show his head over the parapets, or scarcely point his musket through a hole in the walls, but the riflemen above would shoot him. Greene was again defeated at Camden on the 25th of April, by nine hundred English, under Lord Rawdon.

But in a month or two the British lost six forts, and that of Augusta was among them. Here there were three hundred men as a garrison, who almost buried themselves under ground, while the Americans were building up batteries within thirty yards, which swept the fort through and through. Greene and all his officers, and all his men, fought nobly the whole season. "I will recover the province," said the general, "or die in the attempt." It is remarkable, that although his force was much inferior to that of Cornwallis, and though he was frequently defeated, yet, by his admirable manœuvres, the result of the campaign was entirely favourable to the Americans, and injurious to the British.

Greene attacked the enemy at Eutaw Springs, 8th of September, and completely defeated them, killing and capturing eleven hundred of their best soldiers. In pursuing the enemy, one Manning found himself surrounded by them. He seized upon a small British officer, and, being himself a stout man, placed him on his shoulders, and retreated, the English not daring to fire at him, The little officer was horribly frightened, but Manning took good care of him.

The war was closed by the capture of Cornwallis at Yorktown, on York river, Virginia. He had left Carolina, and now expected to overrun Virginia. But in September, the Americans and French, under Washington, surrounded him from all quarters on the land; while the French fleet, riding in Chesapeake Bay, blocked up the mouths of the rivers, and kept the English fleet from coming in.

It was impossible for Clinton, with all his forces at New York, to reinforce Cornwallis. Washington had kept him in fear all summer, and made him believe, till the last moment, that he was to be besieged in New York. It was not till August 24, that Washington left his camp on the Hudson, and marched through New Jersey and Pennsylvania, to the head of the Chesapeake. The French Admiral De Grasse, who had just arrived, carried the American forces down the bay to Yorktown.

The army passed through Philadelphia, on this march, in the most splendid style. The line was more than two miles long. The streets were crowded with spectators; and the windows, to the highest stories, were filled with ladies, waving their handkerchiefs, as the gallant troops passed by. It was a magnificent spectacle. There was Washington, with all his generals; the French Count Rochambeau, with all his; General Knox, with one hundred fine cannon; and the whole army, pressing on with proud steps and a noble confidence. The music was beautiful; every body thought they would conquer; and, just at this time, news came that the French fleet had arrived in the Chesapeake. The city rang with the shouts of the immense multitude.

By the 7th of October, Cornwallis was completely besieged; and surrendered on the 19th. His army, of about seven thousand men, marched out, at two o'clock, and passed between the American line on one side, and the French on the other, stretched out for more than a mile. They were dressed in their most splendid uniforms, with fine music, and colours flying. The English marched, carrying their colours bound up, with a slow and solemn step. The English general rode up to Washington, at the head of the line, and excused the absence of Cornwallis, who pretended to be sick. Washington pointed him politely to General Lincoln, and the latter directed him to a large field, where the whole British army laid down their arms, and were led away prisoners. No man distinguished himself more, during this siege, than Lafayette, a noble young Frenchman. He had before fought bravely for the American cause.

After this capture, the English gave up all hopes of success. No fighting of any consequence took place after this upon the land.

The British troops were wholly withdrawn from the United States of America in the following season. Britain had for some time been greatly embarrassed by the hopeless contest she carried on in America. All the European powers that were jealous of her—France, Spain, Holland—had taken advantage of her difficulties to commence war against her, and her expenditure of men and money was so great, while her success was so small, that the people began to be very clamorous. The unfortunate king, his ministry and parliament, were at last obliged to give in. A treaty of peace, in which the independence of the United States of America was acknowledged, was settled by the British and American ambassadors at Paris, in November 1782. The 3d of November 1783 was fixed upon by congress for the final disbanding of the American army. On the day previous, Washington issued his farewell orders, and bade an affectionate adieu to the soldiers who had fought with him in the great struggle, which was now over.

Soon after taking leave of the army, General Washington was called to the still more painful hour of separation from his officers, greatly endeared to him by a long series of common sufferings and dangers. The officers, having previously assembled in New York for the purpose, General Washington now joined them, and, calling for a glass of wine, thus addressed them: "With a heart full of love and gratitude, I now take my leave of you. I most devoutly wish that your latter days may be as prosperous and happy as your former ones have been glorious and honourable." Having thus affectionately addressed them, he took each by the hand, and bade him farewell. Followed by them to the side of the Hudson, he entered a barge, and, while tears flowed down his cheeks, he turned towards the companions of his glory, and bade them a silent adieu. This great man had no ambitious views for himself. After heading the movement which had achieved the independence of his country, he retired contentedly to his country seat in Virginia, leaving the people to form themselves into an independent republic.

CONCLUSION.

Thus ended the American War of Independence: the imprudence of the British punished by the dismemberment of their empire and an addition of a hundred millions to their debt—the constancy and sufferings of the Americans rewarded by the triumphant accomplishment of all their wishes. The example of America, it is well known, operated powerfully in bringing on the ensuing revolution in France, by which the whole aspect of society in Europe has been affected; and the model which she continues to hold up, of a complete system of ultra-popular institutions, exercises at the present hour an influence of which it would be difficult to rate the amount, or calculate the issue.

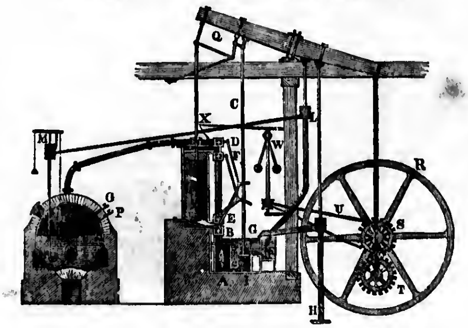
THE STEAM-ENGINE AND LOCOMOTIVE MACHINES.

REPRESENTATION OF WATT'S STEAM-ENGINE.



The steam, which is under the piston, is allowed to escape into the condenser A by the cock B, which is opened by the rod C, while at the same time the steam is admitted by the cock D into the upper part of the cylinder; when the piston has descended, the cocks E and F act in a similar manner in letting out the steam from above, and admitting it under the piston. The jet is supplied by the water of the cistern G, which is pumped up at H from a reservoir; it is drawn out, together with the air that is extracted from it, by the air-pump I, which throws it into the cistern K, from whence the pump L raises it to the cistern M; and it enters the boiler through a valve, which opens whenever the float N descends below its proper place. The pipes O and P serve also to ascertain the quantity of water in the boiler. The piston-rod is confined to a motion nearly rectilinear by the frame Q; the fly-wheel R is turned by the sun and planet wheel S T; and the strap U turns the centrifugal regulator W, which governs the supply of steam by the valve or stop-cock X.

INTRODUCTORY.

The Steam Engine is a compound machine, which exerts a moving force, and is the *first moving power* to communicate motion to other machines, mills, or engines, by which various useful operations in the arts and manufactures are performed. The mechanical force of the steam-engine is obtained from the expansion of water, which is converted into an elastic vapour, called steam, by the agency of heat, and, from the subsequent contraction or condensation of that steam, again into water, by means of cold.

In treating of the steam-engine as a first moving power, or machine, it must be separated from the secondary machines, to which it communicates power and action. A first moving power must in all cases be *itself* endowed with that mechanical energy or force which will give motion to some secondary machine, so as it may overcome the resistance occasioned by the operation which is to be performed by it. It must be distinctly observed, that the engine, or first mover, does not actually *produce* the power with which it operates, but is adapted to collect and concentrate the force which arises from some natural cause, so as to derive motion from that cause; and it must be provided with parts, to diminish such motion or force, and transmit it, in a suitable manner and direction, to the purposes required of the secondary machine with which it is to be connected, and which it is destined to move.

A familiar example of a secondary machine, and its first mover, may be instanced in a common hand-pump, which is erected over a well to raise water for domestic purposes. The man who works the handle of the pump by the force of his arms, is the first mover, because, by his muscular force, he communicates the power and motion necessary to impel the pump, which is only the secondary machine, though it performs the required operation of raising the water. Were a steam-engine to be applied for this purpose, it would be substituted for the man; and, instead of his muscular strength, the steam of boiling water would be applied in the steam-engine in such a manner as to produce motion in its parts, and those moving parts would be adapted to communicate their motion to the handle of the pump, to elevate and depress it alternately, and raise the water.

In the like manner, the steam-engine may be applied, as the propelling power, to turn a grindstone, turning-lathe, malt-mill, flour and meal-mill, cotton and flax mills, or in fact any other piece of machinery which used to be driven by the power of water, wind, or animal force.

"The steam-engine," says Mr Farey, "is an invention highly creditable to human genius and industry; for it exhibits the most valuable application of philosophical principles to the arts of life, and has produced greater and more general changes in the practice of mechanics, than have ever been effected by any one invention recorded in history. The axe, the saw, and other simple tools used by carpenters and smiths, as well as the spade, the plough, and the application of horses and oxen to draw burdens, were invented in such early ages, that they were considered the production of the demi-gods; but, for a long time after the simple implements and machines were invented, men were obliged to perform all labour by their own personal strength. The most degrading labour of hewing wood and drawing water fell to the lot of slaves; whilst thrashing and grinding corn, as well as spinning and weaving, were the constant employment of the female sex. The next advance towards our present state of improvement was the employment of horses and oxen. According to Diodorus Siculus, Minerva was worshipped under the name of Boormia, for having first taught the yoking of oxen to a plough, and horses to the levers of mills for grinding corn." It will thus be seen that animal power was first employed in performing all kinds of work.

The next inventions which were thought of were the application of the natural elements to aid man in his labours. Water and wind were employed as the moving powers of mills, and other machines. In addressing the female sex on this subject, Antipater of Thessalonica thus speaks of the power of water:—"Women, you have hitherto been employed to grind corn; for the future, let your arms rest. It is no longer for you that the birds announce by their songs the dawn of the morning. Ceres has ordered the river nymphs to move the heavy millstones, and to perform your labour." But this important invention had one very great drawback, that of the want of waterfalls, except in remote, and often inconvenient situations; and the agency of wind as a first mover is still more uncertain and unequal in its effects: so that some more efficient power was still wanting that might be more immediately within the command of man; and it was not till the admirable invention of the steam-engine in the eighteenth century, that this very effective and convenient power was discovered; and such has been the progress in the improvement of this grand invention, that, in less than a century from its first discovery, it has reached a high degree of perfection, and has been universally adopted in all the purposes of art and manufacture. "In one place we find the miner employing it to drain water from the deepest chasms of the earth; whilst, in another, it sets the wind's uncertainty at defiance, and conveys our packets across the ocean with a precision that would formerly have been deemed chimerical.

Amongst the last uses to which the steam-engine has been applied, is to that of printing, and in this instance its results are perhaps more remarkable and useful than any other of its applications; for, by this means, printed sheets of paper can be multiplied to an extent, and with such facility, that no other means hitherto thought of could perform.

If we look back for a century, and reflect on the extent of our mercantile and maritime intercourse with other nations, we will at once be able to judge of the importance of this noble invention, and the extraordinarily rapid progress of its improvement. The amazing increase of productive industry, the widely-extended magnitude of our commerce, and our pre-eminence as a nation, have all been effected by the aid of this new power; and, but for this important discovery, there is every human probability that Britain, instead of increasing in wealth and prosperity during the last century, would have been sinking in her importance and welfare; because the mines of coal, iron, copper, lead, and tin, which have in all ages formed so considerable a portion of British wealth, were, at the beginning of last century, nearly exhausted and worked out to the greatest depths to which it was practicable to draw off the water by aqueducts and the simple machinery which was then known and used; and, without the aid of the steam-engine, it is more than probable that fuel, timber, and all the useful metals, would have long ago become so scarce in Britain, that they would have been inadequate to the necessities of so dense a population. But the steam-engine has enabled us to penetrate into the rich and nearly inexhaustible treasures with which our island abounds, and consequently secured to us for ages that pre-eminence for which we have long been famed. To Britons, therefore, this inestimable and native invention must ever be regarded with just pride and veneration; and we feel confident that there are few individuals in this great country, who will not enjoy deep satisfaction by tracing the history and progress of the steam-engine.

For more than fifty years after the invention of the fire-engine, as it was first called, its operation was almost entirely applied to the raising of water—such as draining of coal and metallic mines, and supplying towns with water; and, in several instances, the water which it raised was applied to driving water-wheels, in place of natural waterfalls. It is within the last forty-five years that the steam-engine has been brought to its present high state of perfection, and, in place of animal force, and the natural powers of water and wind, has now been applied to every species of machine which was driven by their agency. So high, indeed, is the state of perfection arrived at, that self-acting machines have been invented, which are driven by the engine, without the agency of human labour at all. Every day brings forth some new and remarkable invention, and it is impossible to say to what length the power of steam may not be carried.

It has been successfully employed in propelling vessels, and even carriages; and the latter have been moved at such a velocity as to be nearly equal in speed to the winds themselves.

A noble author, in discoursing on the modern steam-engine, says it is "stupendous alike for its force and its flexibility; for the prodigious power which it can exert; and the ease, precision, and ductility with which its force can be varied, distributed, and applied. The trunk of an elephant, that can pick up a pin, or rend an oak, is nothing to it. It can engrave a seal, and crush masses of obdurate metal before it; draw out, without breaking, a thread as fine as a gossamer, and propel a ship like a bubble in the water. It can embroider muslin, and forge anchors; cut steel into ribands, and impel loaded vessels against the fury of the winds and waves. It would be difficult to estimate the value of the benefits which these inventions have conferred upon the country—there is no branch of industry that has not been indebted to them; and in all the most material, they have not only widened most magnificently the field of its exertions, but multiplied a hundred-fold the amount of its productions. It is our improved steam-engine that has fought the battles of Europe, and exalted and sustained, through the late tremendous contest, the political greatness of our nation. It is the same great power which enables us to pay the interest of our debt, and to maintain the struggle in which we are still engaged, with the skill and capital of countries less oppressed with taxation. But these are poor and narrow views of its importance; it has increased indefinitely the mass of human comforts and enjoyments, and rendered cheap and accessible all over the world the materials of wealth and prosperity; it has armed the feeble hand of man, in short, with a power to which no limits can be assigned; completed the dominion of mind over the most refractory qualities of matter, and laid a sure foundation for all those future miracles of mechanic power which are to aid and reward the labours of after generations. It chiefly is to the genius of one man (Mr Watt), that all this perfection is owing; and certainly no man ever before bestowed such a gift on his kind. The blessing is not only universal, but unbounded; and the fabled inventors of the plough and the loom, who were deified by the gratitude of their rude cotemporaries, conferred less important benefits on mankind than the inventors of our present steam-engine."

One of the most remarkable properties of the steam-engine is the immense power which can be brought into action within so limited a space. Several of these are of *one hundred and twenty horse power*, which is equal to the strength of upwards of *one thousand men* acting together. One of these engines is capable of raising water from a depth of *twelve hundred feet*, and will draw within the space of twenty-four hours a much greater quantity of water than could be accomplished by nearly four thousand men during the same space of time, with all the power these are masters of, and these working successively to relieve each other when tired; and then all would be bustle, confusion, and irregularity, while this gigantic machine continues its unvarying and steady motion, exerting its mighty power within the least possible limits, and aided only by two men to supply it with fuel. In short, it does what could not be performed by human agency by any other means, as it would not be possible to get such numerous bands of men to give their united force at one time.

It will be here necessary to inform those of our readers who are unacquainted with mechanical powers, what is the strength at which man is estimated. After much comparison, it has been found that the power of an ordinary man is equal to the raising of a weight *of three thousand seven hundred and fifty* pounds avoirdupois, or *sixty* cubic feet of water, one foot high per minute; which force he is capable of continuing for the space of several hours in a day.

The mechanical powers, especially that of a steam-engine, are now, however, always estimated by the horse power, which is *thirty-three thousand* pounds, or *five hundred and twenty-eight* cubic feet of water raised one foot high per minute; so that a horse-power is equal to eight and an eighth part of a man; consequently, *one hundred and fourteen* horse-power is equal to the force of *one thousand men*.

But it must be evident that no horse, however powerful, can exert this maximum of his strength for any length of time. The average strength of effective horses is reckoned at *twenty-two thousand* pounds, or equal to *three hundred and fifty-two* cubic feet of water raised one foot per minute.

There is hardly a department of mechanical manufacture in which the steam-engine is not now employed—namely, to the pumping of water, grinding of corn, sawing timber, grinding cutlery, rasping logwood, expressing oil from seeds, rolling lead or copper into sheets or pipes, drawing wire, twisting ropes or cables, fulling and scouring woollen cloth, grinding coffee, pepper, and other spices; and also in the various details of making steam-engines themselves; in short, there is scarcely a purpose to which they may not be employed with advantage. They are now manufactured of all sizes, from one man's power to that of one hundred and twenty horse-power.

There is perhaps no department to which the engine is applied where it performs such varied and complicated work as in the manufacture of cotton. The bales of raw cotton are brought to the mill-door in carts; the power of the steam-engine is immediately applied to them, and they are thereby lodged safely within a warehouse for the raw material; the engine next drives the machinery which spins the delicate fibres of cotton into threads; through the medium of power-looms, it weaves these threads into cloth; it then assists in the operation of bleaching, dyeing, and printing ornamental patterns in colours upon it, and afterwards glazes, presses, and packs up the printed cloth into bales, stows these in a warehouse to be ready for the market; and, lastly, when these are to be disposed of, it removes them from the warehouse, and again places them on the carts, to be sent to their final destination.

This gigantic power has relieved man of many of his most severe employments, and there is no knowing to what length it may not yet be carried. The celebrated astronomer Biot, while engaged in his operations for determining the figure of the earth, spent some time in Great Britain, and visited the principal mercantile towns and manufactories in the kingdom. He was greatly struck with the extensive use of the steam-engine; and in giving an account of his voyages and observations to the French Academy of Sciences in 1816, he makes the following remarks:—"I next visited the most industrious counties of industrious England: I saw there the powers of nature employed in the service of man under every supposable shape, and man himself reserved for those operations which mind alone can direct or perform."

Before the use of the steam-engine, all mills and manufactories were driven either by wind or water, although the former power was seldom used for manufactories. The consequence was, manufactories behoved to be placed in country situations where there were natural falls of water. This proved in many instances very inconvenient, from the difficulty of not only finding hands to work these, but also extremely expensive in erecting houses for their accommodation; besides, if these falls were remote from towns or seaports, the transporting of the raw material and bringing back the manufactured goods, entailed a heavy expense, and thereby greatly circumscribed the profits. Another evil was, that, as all waterfalls are naturally limited in their power, any increase of machinery, or augmentation of the establishment in times of prosperity, became impracticable. But since the invention of the steam-engine, all these evils can be avoided; and the consequence is, that the great bulk of our manufactories are carried on in populous towns, where fuel is easily come at, and where work-people can be easily procured, and as easily lodged, and the great expense of carriage is rendered unnecessary. And then the steam-power has this advantage, that it can be increased to any extent at pleasure, by additional engines, or replacing small ones by those of greater power. In most country situations where the proprietors have been successful, or those situated not far from markets, steam-engines have been added where additional power was required, and also for obviating defects that all waterfalls are liable to; such as giving additional power in dry seasons, as also in frosts and floods, where the water cannot act, or only in a partial manner.

We cannot better illustrate the wonderful effects of the steam-engine as a moving power, than when applied to a cotton-mill. An immense building is erected, and so adapted as to receive all the spinning-frames which it is intended to contain without any loss of space; that is, the number of horse-power of the engine to be applied is determined upon, and it is now distinctly known how many spindles, or frames with a given number of spindles, can be driven by a horse-power. The immense quantity of light and easy work which can be produced in this way is really astonishing. For the sake of simplicity of numbers, we shall suppose that a cotton-mill has been erected, the machinery of which is to be propelled by a steam-engine of *one hundred* horse-power, which is equal to the combined strength of *eight hundred and eighty men*; and this power gives rapid motion to *fifty thousand spindles*, on which the cotton threads are spun, each spindle producing a separate thread. Besides, the engine drives a great quantity of preparing machinery, which, by a succession of operations, fits the fibres of the cotton for being ultimately spun into threads by the spindles. This consists in shaking and beating machines, for removing the dust and dirt; it is then put through large carding machines, consisting of a variety of cylinders covered with leather, which is thickly studded with wire teeth; these being opposed to each other, lay all the fibres in a parallel direction, in bands of a certain breadth, called slivers, which are again twisted into thick loose threads, called roves, and finally spun into threads on the spindles. Now, to attend on the operations of a mill of this extent, *seven hundred and fifty* persons are all that are necessary, a great proportion of which are women and children, whose physical powers, taken in conjunction with that of the steam-engine, can produce as much thread as *two hundred thousand* people could do without machinery! that is, every individual employed performs the work of *two hundred and sixty-six* individuals! Each spindle in a mill will produce from *two thousand one hundred* to *two thousand five hundred* yards of thread in a day of twelve hours, upwards of a mile and a quarter in length; so that a mill of the size we have just been describing, will produce the astonishing quantity of *sixty-two thousand five hundred* miles of thread every twelve hours; which is more than sufficient to reach twice and a half round the globe. Equally wonderful results are effected by flax spinning-mills; and, also, in the production of spinning woollen yarns, from which the finest cloths, shawls, and stockings, are manufactured.

It would be impossible to give any estimate of the number of steam-engines which are employed in Great Britain, with the extent of their horse-power, as there is hardly a week passes without one or more new ones being erected for various useful purposes; but we may mention, that, in London alone, there are upwards of *three hundred*, whose united power has been estimated, in round numbers, at upwards of *fifty thousand* men or *six thousand* horse-power, in *continual* operation. In Manchester, nearly the same quantity of horse-power is employed in the different manufactures. In Leeds, it has been estimated at about *two thousand four hundred* horse-power. In Glasgow, there are about *one hundred* engines; besides those in all the other great manufacturing districts, which, if united, would be nearly equal to the entire physical strength of Britain.

The revolutions which have been wrought in our mercantile enterprise, within the last forty-five years, by means of the improved state of the steam-engine, exceed all calculation; it has relieved mankind of the more fatiguing and animal part of labour; and has increased the animal power of the nation, without requiring a greater quantity of animal food, which must inevitably have greatly raised the price of the necessary aliment of man, in a country where hardly sufficient corn can be raised to supply its population; and, in short, it has as effectually changed the system of industry for the useful arts, by which society is upheld, as the invention of gunpowder, and the consequent use of fire-arms, did the mode of warfare three centuries ago.

To the steam-engine, and the use of coal as a fuel, may be attributed in a great degree the height to which Great Britain has arrived as a mercantile nation. Before the invention of this moving power, we were undoubtedly pre-eminent among states for our physical energies and bold national enterprise, but to trace these is more the province of history than of science.

HISTORICAL ACCOUNT OF THE STEAM-ENGINE, AND ITS PROGRESSIVE IMPROVEMENT.

The steam-engine, as it now exists in its various improved forms, did not attain its present excellence till after repeated efforts had been exhausted upon it by men of genius; and even yet it is doubtless susceptible of improvements which the imagination cannot adequately contemplate. The fundamental principle of the steam-engine, namely, the power which steam has of pushing upwards any body it comes against when confined in a close vessel, must have been known in remote times; but the practical utility of this principle was only gained after a means had been invented of causing the said body to descend immediately to its original position; and so, by alternate ascending and descending, a uniform motion was gained. To show how this extraordinary principle of action in steam was gradually developed, is now our purpose.

At what precise period the expansive power of steam was first observed, is not known. The Egyptians, Greeks, and Romans, were well acquainted with the eolipile, an instrument used for the illustration of natural phenomena. This was perhaps one of the earliest attempts at natural philosophy. The eolipile is a hollow ball of metal, with a long pipe attached to it; which ball, filled with water, and exposed to the fire, sends out, as the water heats, at intervals, blasts of cold wind through the pipe. This instrument is particularly described by Vitruvius, who flourished about thirty years before the birth of Christ. He, however, seems to have had no idea of the use of steam as a moving power. The earliest account we have of the eolipile being applied to useful purposes, is by L'Orme, in his Treatise on Architecture, published at Paris in 1567, wherein he proposes to place this instrument over a fire, to assist in impelling smoke up a chimney. But this instrument has never been rendered applicable as a mechanical power.

In the year 1663, the Marquis of Worcester published a work, entitled "A Century of Names and Scantlings of Inventions," wherein he describes a mode of applying the pressure of steam to the raising of water to considerable heights. This he termed "a fire water-work;" and he also describes another machine, or engine, which he calls "a water-commanding engine," for which he obtained a patent, thereby securing to himself the profits arising from the invention.

In the sixty-eighth Scantling he describes the fire water-work as "an admirable and most forcible way to drive up water by fire, not by drawing or sucking it upwards, for that must be, as the philosopher calleth it, *infra spharam activitatis*, which is but at such a distance, but this way hath no bounder if the vessel be strong enough; for I have taken a piece of a whole cannon, whereof the end was burst, and filled it three-quarters full of water, stopping and screwing up the broken end, as also the touch-hole, and making a constant fire under it; within twenty-four hours it burst and made a great crack; so that, having a way to make my vessels so that they are strengthened by the force within them, and the one to fill after the other, I have seen the water to run like a constant fountain-stream forty feet high. One vessel of water rarified by fire driveth up forty of cold water; and a man that tends the work is but to turn two cocks, that, one vessel of water being consumed, another begins to force and refill with cold water, and so successively, the fire being tended and kept constant, which the self-same person may likewise abundantly perform in the interim between the necessity of turning the said cocks."

In 1683, Sir Samuel Morland proposed to Louis the Fourteenth of France a new method of raising water by steam, which was closely allied to the invention of the Marquis of Worcester. In the Harleian Collection of Manuscripts in the British Museum, this fact is recorded; and, in adverting to the power of steam, his principles are explained in the following terms:—"Water being converted into vapour by the force of fire, these vapours shortly require a greater space (about two thousand times) than the water before occupied, and, sooner than be constantly confined, would split a piece of cannon. But being duly regulated according to the rules of statics, and by science reduced to measure, weight, and balance, then they bear their load peaceably (like good horses), and thus become of great use to mankind, particularly for raising water."

Although Morland had evidently a pretty distinct idea of the expansive force of steam, yet his researches regarding that moving power led to few practical and useful results.

In the year 1695, Dr Papin conceived an idea of employing the expansion and contraction of steam to form a partial vacuum under a piston for raising water, and making the pressure of the atmosphere on the upper side of the piston the moving power. It is, however, curious, that neither this gentleman nor Savary, a rival in the same cause, were ever able to turn this excellent idea into any real use; but there can be little doubt that the real discoverers of the atmospheric engine took advantage of, and benefited by, the suggestion.

Captain Thomas Savery, in July 1698, obtained letters-patent for the direct application of the steam-engine to raising water. In the same year he exhibited to the Royal Society a model of his engine, and the experiments made, gave universal satisfaction to that learned body, which are the first on record obtained for this purpose. That gentleman, in 1699, published a pamphlet, entitled "The Miner's Friend," which came to a second edition, with additions, in 1702. A peculiarity of this engine was, that it had two steam-vessels at first, which he afterwards simplified by having only one. Where the water had not to be raised above a height of forty feet, this engine seemed pretty effective; but for greater depths, a more powerful engine was wanted.

In the year 1698, Dr Dennis Papin, professor of mathematics at Marbourg, whose new ideas we before noticed, in 1695, performed many experiments with the object of raising water by the power of fire, but tended to no useful purpose. After the publication of Savery's engine in 1705, Papin made several improvements on his own ideas; but no doubt, for these he was indebted to what had been achieved by Savery. After all, Papin did no more than repeat the experiments of the Marquis of Worcester. He proposed an absurd plan of introducing red-hot irons into the cylinder; which idea had but one redeeming quality, namely, that of having been instrumental in giving the idea that the water raised by the engine might be applied to driving a water-wheel; and thus suggesting the possibility of its application to the propelling of machinery.

M. Amontons, in 1699, published a description of a machine designed to be moved by the expansive force of heated air, which was afterwards to be condensed by the contact of cold water; but this was never of any real use.

The next invention that attracted any attention was that of Thomas Newcomen, a smith of Dartmouth. This person, in conjunction with Captain Savery, and John Cawley, a plumber of Dartmouth, obtained a patent for an improvement on the engine of Savery, the novelty of which consisted entirely in condensing the steam below an air-tight piston, in a cylindrical vessel having an open top. It seems probable that this idea was founded on the invention of Papin, and that Newcomen was at this time in correspondence with Dr Hook, who is known to have been well acquainted with the engine of Papin. Its mode of effecting the object was, however, totally different, as it consisted in letting in steam below a piston, which was at first condensed by applying cold water to the outside of the cylinder; but it was soon discovered that an injection of cold water thrown into the interior was a far more effective method. This, however, is said to have been discovered by accident, and not from the effect of reasoning on its consequences. The piston was kept tight by a quantity of water on the top of it; and while they were working the engine from outside condensation, they were surprised to notice the engine make several very quick strokes, and discovered that it was owing to a hole in the piston letting down water condensing the steam: and thus the useful application of the jet was discovered by accident.

Till this time, the valves were opened and shut by the hand of a person in attendance on the engine, when a boy of the name of Humphrey Potter, in order to obtain some respite from this incessant application, set his wits to work, and contrived, by attaching strings and catches to the working beams, effectually to open and shut them in a more regular manner than he could do by his personal labour. This led the way to still more effectual improvements, and advanced it still nearer to a self-regulated machine. It was about the year 1712 that it reached this state, and was employed in various places. At this time it was called the atmospheric engine.

The credit, therefore, which seems due to Newcomen is, for the admission of steam below an air-tight piston attached to the impelled point of a lever properly counterpoised—its quick condensation by a jet of cold water, which is essential to gain effect—and the mode of clearing the cylinder of air and water after the stroke—are all an addition to the principles and mechanism in use before that time, and all of which are entirely the improvements of Newcomen and those who acted in concert with him.

Little seems to have been effected in improving the engine for some years afterwards, till one Henry Beighton, an engineer of Newcastle-upon-Tyne, in 1721, inserted a curious table of calculations of the powers of steam-engines, in the almanack conducted by him, entitled the "Lady's Diary." To this ingenious person we are also indebted for improvements in the arrangement of the parts of the atmospheric engine, as well as the method of fixing, and the mechanism for opening and shutting the valves. To him also we are indebted for a discovery of the fact of steam heating a large proportion of water in condensing.

Leupold, a German, in 1720, collected mechanical inventions, and first suggested the rude idea of a high-pressure engine with a piston. This engine was also curious on account of its having a force passage-cock for the admission and emission of steam.

The engines now in use were principally those made with the improvements of Beighton; and for some years no material alteration was made on them; they were generally adopted in the coal works and copper mines.

In the year 1736, Jonathan Hulls, December 21, obtained a patent for the application of steam as a propelling power in navigation, which seems to have been the first idea of what may be strictly termed a steamboat; from the application of which mankind now reap so many advantages. He published a description of this boat, illustrated by a plate, in 1737, under the following title:—"A Description and Draught of a new invented Machine for carrying Vessels or Ships out of or into any Harbour, Port, or River, against wind or tide, or in a calm." This very rare pamphlet is to be found in the British Museum, as well as in the hands of several engineers; and proves, beyond a doubt, that the application of steam to navigation was suggested many years before it was used. The pamphlet of Mr Hulls is evidently the production of a strong and well-cultivated mind, and his views, like those of many other ingenious men, merited a better fate then they met with at the time.

In the year 1739, Bernard Belidor wrote an excellent sketch of the history of the steam-engine; and from his inquiries he infers, that of the three European nations most advanced in science, each gave birth to a man of science to participate in the glory of the important discovery of the steam-engine (these he conceives to be Papin in Germany, Savery in England, and Amontons in France); that each of these individuals was at one and the same time engaged in investigating the means of employing the action of *fire* for moving machines; but he admits the first intelligible suggestion of the idea to have been by the Marquis of Worcester. This historical sketch is closed by Belidor, with the assertion that all the fire-engines which had been constructed out of Great Britain had been executed by English artisans.

We come now to the year 1741, when John Payne made the first direct experiment for determining the density of steam; and from a series of experiments performed by him, he came to the conclusion, that one cubic inch of water will form *four thousand* inches of steam. Mr Payne afterwards made an ingenious but unsuccessful attempt to introduce a new mode of generating steam, which was done by a cast iron vessel of the figure of a frustrum of a cone, four feet diameter at bottom, to which was attached a semi-globular end of copper, whose diameter was about five feet and a half, with a small vessel inserted inside, which he called a *dispenser*, with pipes round the side fixed to it, while the bottom rested on a central pin, on which it constantly revolved, so that it might spread the water it received from above through an iron pipe. The end of this pipe passed up through the head, and was enclosed very tightly; at same time it was easily moved with a circular motion, so that the water might be showered round on the sides of the red-hot cone in a very exact manner. This vessel being kept at a dark-red heat, expanded 6.5 cubic feet of water and steam in an hour. By experiments which he afterwards made at Wednesbury and Newcastle-on-Tyne, 112 lbs. of pit coal will, by this mode, expand twelve cubic feet of water into steam. But all this tended to no useful purpose; and although similar experiments have been lately revived, yet they have proved abortive; and we have described his experiments rather that they may be avoided than followed.

Up to this period, a person was required to be in constant attendance to open and shut the cocks of Savery's engine; but the defect was at length remedied by a Frenchman of the name of Gensanne, who invented a self-acting apparatus, in the year 1744; and another method was afterwards communicated to the Royal Society by De Moura, a Portuguese, whose description was accompanied with a model. The peculiarity of his invention was a float within the receiver, composed of a light ball of copper, which was fastened to the end of an arm made to rise and fall by the float, while the other end of the arm was fastened to an axis; so that, when the float moved up and down, the axis was turned round either the one way or the other.

In the year 1751, Francis Blake read a paper before the Royal Society, on the best proportion for the cylinders of steam-engines, which is well worthy attention, not only from its value as a theoretical inquiry respecting the proportions of engines, but also on account of the result he obtained. He justly remarks, that it is evident from mechanical principles, that as the contents of the cylinder remain the same, the quantity of water discharged at each lift will in all cases be equal; and this equality is obtained by only adjusting the distance of the centre of the piston from the fulcrum of the beam. It is also obvious that the excess of the column of atmosphere above that of water, is equal to a weight on the piston driving it to a depth of about five feet within the cylinder; by the present construction acceleratedly, till friction and resistance from the uncondensed steam which remains in the cylinder, even after the injection, and is increased in elasticity, while its bounds are diminished, shall equal the force which gives it speed, and that thereafter the piston may be retarded the rest of the way. Independent of friction, and notwithstanding this diminution of force by the remainder of the steam within the cavity of the cylinder, we can demonstrate the ratio of the velocities, and the times of descent of the pistons, in cylinders of equal altitudes, to be precisely the same as if the resistance were nothing; from which we can without difficulty arrive at some conclusion in this matter by a little calculation.

In the year 1757, Keane Fitzgerald, taking into consideration the means of saving fuel in places where it was expensive, thought of agitating the water in the boiler by means of a stream of air, on the plan of Dr Hales; but he did not seem acquainted with the difference of forming steam and accelerating evaporation. Dr Hales, however, having applied to him regarding the working of ventilators for mines by steam-engines, and a rotatory motion being indispensable, Fitzgerald invented one which rendered the steam-engine applicable to the purpose, which was by means of a *fly-wheel*.

William Emerson, in 1758, published a short and distinct account of the atmospheric engine, and the method of computing its power, as far as statical equilibrium between the power and the resistance is concerned.

James Bradley next attempted to improve the construction of the boiler of the steam-engine, by forming it of wood and stone, and inserting a cast iron fire-place and chimney in the internal part of the boiler, so as it might be surrounded on all sides by the water of the boiler. He imagined by this method the heat of the fuel would be rendered more effective. He obtained a patent for this invention in 1759; but it was constructed on an erroneous doctrine, and never came into general use.

To the celebrated Dr Joseph Black of Edinburgh we owe the first investigation of the combination of heat with bodies in the solid, liquid, and gaseous state; the heat so combining with them, he proved, was insensible to the thermometer, and hence he gave it the name of *latent heat*, which he first taught publicly in 1762. He found that the quantity of heat required to convert boiling-hot water into steam exceeded five times the quantity which made water boil. He also showed that different bodies required different quantities of heat to produce the same change of temperature, and denoted this property by the phrase *capacity for heat*, for which the term specific heat is now used.

The next considerable improver of the steam-engine was John Smeaton, who, although not possessed of an inventive genius, had, nevertheless, the faculty of selecting the best methods known in his time, and, by making experiments on these, turning them to advantage. In 1765, he constructed a portable atmospheric engine, for the purpose of trying different methods of acting. After this, he superintended the erection of several large atmospheric engines; and from his nice mechanical knowledge, and accuracy of experimenting, gradually brought them to such a state of perfection, that there has been nothing of the same kind more elegantly constructed even in modern times.

The most important of Smeaton's inquiries are those which belong to the load upon the piston, whereby he discovered that engines were calculated to carry a load from one pound to more than ten to the square inch, and that those which were lightly loaded were expected to go with greater velocity. On these principles, it was supposed that an engine carrying five pounds to the inch must necessarily go at a rate double to that of one carrying ten pounds to the inch, the area of the cylinders being equal, so that the power might be equal. He demonstrated, however, that in engines, as in other machines, the maximum of their power cannot be exceeded, even by the greatest efforts of human ingenuity.

Although John Blackey attracted some notice at the time he lived, yet his inventions soon turned out worthless, and merit no attention.

We come now to speak of James Watt, a man who did more for improving the steam-engine, than all who either preceded or who have followed him. This great genius was born in 1736, and died in the year 1819. He appears to have commenced his mechanical researches on the steam-engine in the year 1764. These consisted in a series of experiments on the elastic force and bulk of steam. He continued his experiments with remarkable success, and they terminated in the discovery of what has been emphatically called Watt's Steam-Engine, the finest present ever made by science to the arts. Watt found the atmospheric engine involved in a dilemma, on account of the prodigious waste of steam essential to its very principle. For, after the piston had been impelled upwards by the elastic force of the vapour, before a vacuum could be formed below it, it was necessary to introduce a jet of cold water to condense the steam, and thus the force of the atmosphere acting above the piston would cause it to descend again to the bottom of the cylinder. But, in doing this, the cylinder was necessarily cooled to about 100°, and, in the subsequent ascent of the piston, an immense waste of steam ensued; for the elastic vapour, on being admitted under the piston, was condensed by the cold cylinder, and also by the water of condensation, so that both required to be heated up to 212°, the boiling point of water, before the ascent could be completed. Now, the question arose, Did the force gained by the increased perfection of the vacuum more than compensate for the waste of fuel in producing the vacuum? This was found not to be the case; and, consequently, the cylinder not being cooled to so low a temperature, the piston worked in a very imperfect vacuum, and with a diminished force. The great problem then forced itself upon the attention of Watt, *to condense the steam without cooling the cylinder*.

It was not long before the happy conception of *cooling in a separate vessel* flashed upon his mind. This was the first step in that brilliant career of discovery which has immortalised his name; and he himself informs us, that, at the moment the notion of "separate condensation" struck him, all the other details of his improved engine followed rapidly, so that in the course of a day his invention was complete, and he proceeded to submit it to experiment. It would be tedious, perhaps unnecessary, minutely to point out the successive stages of the discovery, and the ingenuity and skill with which he overcame and obviated every difficulty which arose in his progress: we shall therefore give an account of his engine as it is represented in the frontispiece; for although improvements have been made since his day, they are trifling compared with the vast stride to perfection which the steam-engine took under his plastic hands.

The boiler, which is the grand magazine of steam for the use of the engine, is situated upon the extreme left in the woodcut on the first page. It is indispensably necessary for the working of the machine, that there should always be a sufficient supply of steam, and that it shall always be of the proper quality, that is, that it shall always be of a proper pressure, or that it shall always possess a certain degree of elasticity. To accomplish these ends, various remarkably ingenious contrivances have been resorted to. To ascertain the level of the water in the boiler, two guage pipes O and P were used in the earlier steam-engines, and which are still in many cases continued. The pipe O, it will be observed, has its lower aperture a little *above* the proper depth at which the water should be, and the other pipe P has it a little lower. Cocks are attached to their upper ends, which can be opened and shut at pleasure. If the lower ends of both the pipes be immersed in the water, the steam, which exercises a great degree of pressure upon the surface of the water within the boiler, forces it up through both O and P; and if this be found to be the case, which is easily done by opening the stop-cocks, then there is too much water in the boiler, and some must either be let off, or the supply must be stopped for a time. If, however, steam should issue from both the orifices instead of water, then there is too little water, and an additional supply must be poured into the boiler. Lastly, if water flow from P, and steam from O, then the water in the boiler is at its proper level. This ingenious contrivance was the invention of Savery. But there is another method which merits our attention, both from its efficacy and from its universality of use. A weight N, half immersed in the water of the boiler, is supported by a wire, which, passing steam-tight through an orifice at the top, is attached to a flexible string or chain, and works upon a wheel fixed on the top of the tube, with which the reservoir M is connected. At the extremity of the chain, a counterpoise weight is seen suspended in the air, and this weight is just sufficient to balance the floating weight in the boiler, when the weight is *half immersed* in water. By this contrivance the boiler is made to feed itself with water. In the bottom of the cistern M there is a valve which opens upwards and communicates with a feed-pipe, which descends into the boiler below the level of the water in it. The stem of the valve is connected with a lever, instead of a wheel, which turns upon a point. When the water is at its proper level, the valve is closed. The moment the water in the boiler decreases in quantity, the float-weight sinks, and the descent of the end of the lever to which it is attached, raises the other end with which the valve is connected, and this admits the water down through the feed-pipe into the boiler. So nicely is this part of the machine adjusted, that instead of a sudden rush of water, and then a sudden cessation of its flow, it is made to descend in a small continued stream, just sufficient to supply the consumption arising from evaporation.

In connection with the boiler there is a valve, called a safety-valve, which secures it from accidents that might result from the steam becoming too strong. This valve, which works in a tube passing into the boiler, opens upwards. It is loaded with a weight equal to the strength which the steam is intended to have above the atmospheric pressure; for, even in condensing engines, the steam has a pressure above that of the atmosphere. When the pressure exceeds what is wanted, the valve is forced upwards, and the elastic vapour rushes out, and thus the boiler is prevented from bursting. There is another safety-valve, similar to the one we have described, but it opens *downwards* instead of *upwards*: this is to prevent injury to the boiler when the steam within it is suddenly condensed, and thus forming a vacuum. Were not the air admitted by means of a valve of this kind, on the occasion of a vacuum being formed, which frequently happens, the sides of the boiler would be crushed together by the atmospheric pressure. Connected with the boiler there is another piece of apparatus, called the *self-acting damper*. By a contrivance similar to that by which the boiler is supplied with water, this damper is made to regulate the production of steam, by rising and falling in a flue connected with the fire-place. When the steam is low, the damper rises, and a full draught is obtained, which increases the intensity of the fire. When the steam is too strong, the damper is made to fall, and the fire is thus checked. The steam is also regulated by an instrument called a *steam-guage*; and, taking every thing into account, there are so many contrivances for the prevention of accidents connected with the steam generator, that it seems far more wonderful that they ever do happen, than that they do not happen.

It will be observed, that, from the top of the boiler, a large pipe proceeds to the right, and passes into the body of the machinery, over the top of the cylinder. The cylinder is represented by that upright vessel below the letter X. It is closed at the top, and the piston-rod (to which the piston is attached, and moves within the cylinder steam-tight), being very accurately turned, runs in a steam-tight collar, furnished with a stuffing box, and constantly kept air and steam tight by a constant supply of tallow or wax. There is an outer cylinder called the *jacket*. The space between the outer and inner cylinder is constantly filled with steam. The supply of steam to press the piston up and down is regulated by means of valves, situated at the top and bottom of the cylinder. Engineers have exercised much ingenuity upon the method of working the valves, and many elegant contrivances have been suggested, but those of Watt still remain almost in universal use. In order to comprehend the action of the several systems of valves, the reader is to understand, that, when the piston is pressed up to the top of the cylinder, as it appears in the woodcut, the steam from below it is to be withdrawn, and steam above it communicated. The cylinder is deprived of its steam in the following manner: A (situated at the bottom of the cut) is the condenser which communicates with the cylinder by means of a pipe, which is provided with a valve B, and a rod C. I represents the air-pump, which draws off the water, air, or other fluids collected in the condenser. The rod of the air-pump piston, it will be perceived, is connected with the working-beam, and is here wrought by the engine itself. When the cylinder, piston, and the air-pump piston, have arrived at the top of their stroke, let the lower exhausting-valve B, and the upper steam-valve D, be opened, and the two other valves E and F closed; then the steam rushes through the valve B into the condenser A, and a vacuum is produced below the piston: at the same instant, the steam, rushing through the steam-valve D upon the top of the piston, supplies the place of air which was formerly employed in pressing the piston down to the bottom of the cylinder: on its arrival there, let the valves formerly opened be closed, and the lower steam-valve E, and the upper exhausting-valve F, be opened; then the steam which fills the cylinder above the piston, now passes off through F into the condenser, leaving a vacuum as before: at the same time, steam from the boiler is admitted through the lower steam-valve F below the piston, so that it presses the piston to the top of the cylinder, and thus the nice process of ascending and descending goes on.

The opening and shutting of the valves was formerly effected by means of the air-pump. Thus: the valves which are to open and shut together are connected, as will be observed from the woodcut, by means of jointed rods. From these rods there shoots off a lever, which reaches to the rod of the air-pump, and these levers are moved by pins attached to the air-pump, in such a situation as to move the lever, and produce the desired effect exactly at the proper moment of time. But this method of working the valves is now superseded by another. The stems of the valves are perpendicular, and move in steam-tight sockets in the top of the valve-boxes. The stem of the upper steam-valve D is a tube, through which the steam of the upper exhausting-valve F passes, and in which it moves steam-tight, both of these stems moving steam-tight through the top of the valve-box. The other valves are similarly circumstanced. The motion which works the valves in pairs is not communicated by the rod of the air-pump, but is received from the axis of the fly-wheel. This axis works an apparatus called an *eccentric*, the principle of which it is impossible to explain sufficiently in this place; but we refer the reader to an able work on the subject, where it is lucidly shown, namely, Lardner on the Steam-Engine, p. 101.

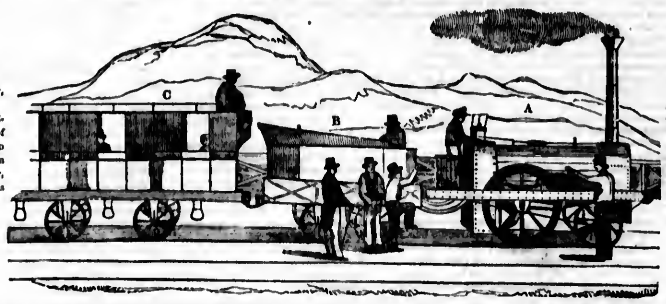
Into the condenser A, which is a close cylindrical vessel surrounded with cold water, there is inserted a tube, the inner end of which is pierced with holes like the *rose* of a watering-pot; it is provided with a cock, which is situated in the cold cistern on the outside, and through which, when open, the water passing rises in a jet in the inside of the condenser, and there condenses the steam at the moment when it has been admitted by the opening of the valves above described. The water thus admitted, and that which has been formed by the condensation of the steam, as well as any vapour which may exist, are all withdrawn by the air-pump. The latter is connected with the condenser at the bottom by means of a pipe supplied with a valve which opens into the pump. The air-pump piston, we have already observed, moves air-tight. It is provided with a valve at the top, which opens outwards or upwards. Now, the manner in which it works will be seen at a glance. Supposing the piston at the bottom of the pump, as it rises, no air can pass *down* through it, for the valve opens only *outwards*, and consequently a vacuum is left below it. Hence, the water and vapour collected in the condenser push open the valve which connects the condenser and the air-pump at the bottom of these two vessels, and enter the air-pump. They cannot return from the latter into the condenser again, because the valve opens only *outwards*. On the descent of the pump-piston, the fluids which occupy the lower part of the pump force open the piston-valve, and make their escape; neither can they return into the pump, because the piston-valve opens *outwards* also. The hot water which is thus drawn out is collected in the cistern K, from whence it is raised by the pump L, and, being conducted by a pipe to the cistern M, is made to supply the boiler in the manner already described.

To prevent the water in the cistern, where the condenser and air-pump are placed, becoming too hot, and impairing the condensation, there is a pump H, called the cold-water pump, also wrought by the engine. This raises a continual supply of cold water, which flows through a pipe in a constant stream into the cistern. There are thus four pistons attached to the great beam, and worked by the piston of the steam cylinder.

One of Watt's most beautiful contrivances connected with the steam-engine, was that of parallel motion. The apparatus Q is represented on the arm of the beam, which works the piston and air-pump in the frontispiece. It is impossible to explain it mathematically in this place. It consists of a system of rods, provided with joints, &c., which connect the rods of the piston and air-pump. The long arm proceeding from the square frame is, at the one end, firmly attached to a fixed beam, and, at the other, is connected with the square frame Q; as the rods rise and fall, the joints move, and keep them in a nearly rectilinear motion. Another striking appendage to the steam-engine, for the purpose of keeping it going at an equable rate, is the *regulator* or *governor*. This apparatus had been formerly in use for the purpose of rendering uniform the action of the stones in corn-mills, but Mr Watt was the first to make the beautiful application of it, which we now see in the steam-engine. In the woodcut, W represents the regulator. At the top of the perpendicular shaft are two arms, with balls at the extremity. This shaft is turned by a belt which communicates with a wheel, turned round by the engine. From the top of the regulator there shoots off a rod, terminating in a valve, called the throttle-valve, which regulates the supply of steam from the boiler—thus: If the engine be going very rapidly, the balls are rapidly whirled round, and by their natural tendency* to fly from the centre, they spread outwards, and, in so doing, they draw downwards the rod with which they are connected, whilst this alteration in the position of the rod closes the valve, and prevents the admission of steam, thus checking the velocity of the machine. As the motion slackens, the balls fall, and the valve is again opened. It would be difficult to point out in mechanics any apparatus more beautiful, or which answers the purpose better, than this. The large metal wheel R is termed the fly-wheel, and the small-teethed wheels S and T are called the sun and planet wheels. It is evident that the motion most generally useful is that of *continued rotation*. In the first instance, Watt proposed effecting this by means of a *crank*, but he was anticipated by another individual, who took out a patent before him, until the expiry of which he was compelled to employ the sun and planet wheel, as represented in the cut. The wheel T is affixed to the end of the rod attached to the working beam, and called a *connector*. The teeth of this wheel work in those of another wheel S, namely, that to which rotation is to be impacted. This is effected by the wheel T revolving round it, like a planet round the sun, accordingly as the end of the beam rises and sinks. It goes up on *one* side of the sun-wheel, and descends on the other, thus impelling it round. This contrivance has certain advantages, but it is inferior to the common crank, which is now used. The effect of the *fly-wheel* R is to equalise the

* Centrifugal force. See Information, article *Astronomy*.

THE LOCOMOTIVE ENGINE AND ITS APPENDAGES.



A, the engine, with boiler, &c.

B, the tender, which follows immediately in rear of the engine. It is an open light vehicle, containing a supply of fuel and water, with the engineer and his attendant.

C, A train of carriages attached behind the tender: they are from twenty to twenty-five in number on the Manchester and Liverpool Railway, varying according to the number of passengers and goods to be conveyed.

motion communicated by the action of the beam on the sun and planet wheels, or rather the crank, as that is the contrivance now in general use. That action is just sufficient to sustain in the fly-wheel an uniform velocity, and the tendency of this wheel to retain the velocity which it receives, according to the law of mechanics, renders its rotation sufficiently uniform for all practical purposes. It is evident, however, that without the regulator already described, it would be impossible to preserve uniform motion by means of the fly-wheel.

For regulating the circulation of steam, Watt suggested a method, which is called the D valve, from the resemblance which the horizontal section of the valve bears to the letter D. This method is very generally used, although it is frequently modified according to the size of the engine. Without entering into a minute description of this apparatus, it is sufficient to observe that it consists of a series of valves and plugs, which, by their opening and shutting, introduce at the proper moment the steam above or below the piston.

There have been innumerable improvements on the steam-engine since the time of Watt, almost all of which have his for their basis. In short, there are hardly two engines constructed, even by the same individual, but what are varied in some of their parts, so as to render them more effective. Many of these have turned out well, while others have failed to perform the operations expected of them.

In the steam-engines hitherto considered, the creation of a vacuum by means of condensation has been found the prominent feature. There is a class of engines called *high-pressure* engines, where this does not take place. The condensing apparatus—namely, the cold-water cistern, condenser, air-pump, cold-water pump, &c.—are dispensed with, and nothing is retained except the boiler, cylinder, piston, and valves; consequently, such an engine is small, light, and cheap, and thus well adapted for locomotive purposes. Non-condensing engines are generally termed *high-pressure engines*. These are moved by steam, generated under a considerable degree of pressure, and it is the excess of this pressure above that of atmospheric pressure from which they derive their motion. From thirty to forty pounds on a circular inch is the excess above atmospheric pressure which is generally employed in Britain.

The working parts of the high-pressure engine consist of a cylinder, having passages provided with cocks or valves for steam to enter into it, either at the top or at the bottom, and also the means of letting out the steam to the atmosphere, either at the top or at the bottom. The cylinder has an air-tight piston, to be moved from one end to the other by the pressure of the steam, with a rod fixed to it, called the piston-rod, which slides through an air-tight box at the top of the cylinder, to give motion to a crank, or some other piece of machinery.

Now, with steam in the boiler having a force of thirty pounds to the circular inch, if the piston be at the bottom of the cylinder, and the passage from the boiler to the bottom and that to the atmosphere at the top be both open, and the rest shut, the steam will exert a pressure of nearly thirty pounds on each inch of the area of the piston, and cause it to ascend. A little before it arrives at the top, the cocks must be shut; and the moment it has reached the top, the other two cocks are opened. The steam from the boiler will then press the piston downwards, and the steam which has before been allowed to enter will flow out into the open air. The passages are again closed a little before the completion of the stroke; and in this manner the movement is continued. The close of the cocks before the termination of the stroke, prevents either concussion against the end of the cylinder, or strain on the crank shaft; and the elasticity of the steam destroys the momentum of the piston, and recoils it back without loss of force. Non-condensing or high-pressure engines are of two kinds, namely, first, those which act by the generative force of steam, and, second, those whose motion depends on the generative and expansive force of steam.

RAILROADS AND LOCOMOTIVE ENGINES.

Of all the varied uses to which steam-power has been applied, that of locomotion is unquestionably the most important; promoting the greatest facility of intercourse between the most distant parts of the country, and, therefore, cannot fail to conduce, in an eminent degree, to its improvement and prosperity; binding, as it were, "its different parts more firmly together," increasing its strength, and adding consistency and unity of action, and extending its beneficial influence to the great moral interests of the nation.

The first species of locomotion to which steam-power was applied, was that of the moving of vessels on water. Setting aside the invention of Jonathan Hulls, in 1736, which led to no practical use, the individual who had the distinguished honour of first applying steam-power to propel vessels on the water was Mr James Taylor, tutor in the family of Miller of Dalswinton, Dumfriesshire, an account of whose life is to be found in the 58th number of Chambers's Journal. Mr Taylor's successful experiments about the year 1788, led others to take up his plans, which, in a few years, as every one knows, were acted upon with great advantage both in Britain and America. Within the last twenty years, steam-vessels have increased so numerously, that now there is hardly a navigable river in Europe or America which have not their regular packets; and we see the power successfully employed on the ocean itself, and triumphing over the resistance of the winds and waves, which hitherto had baffled the most successful efforts of human genius to overcome.

In situations where the country was intersected by inlets of the sea, great rivers, or lakes, these often formed most vexatious barriers to the regularity of trade; and, as far as regarded rivers, to force vessels against their streams, was found impracticable; so that navigation in them could only be extended as far as the rise of the tide. Now, since the application of this power, all these disadvantages have become unrivalled chains of communication to commerce; and what was before looked upon as a great evil, has now been rendered a blessing.

Such are the advantages which have been realised, within a very few years, by the use of steam to the purposes of navigation. And now a new application of that power has been recently successfully applied in impelling carriages on land. This has long been a favourite project with mechanists, and the many difficulties which were to be overcome in this process have to a certain extent yielded to the perseverance and skill of ingenious men. Mr Watt, to whom we are indebted for some of the most important improvements, as we have seen, in the steam-engine, entertained notions of the future practicability of this application of steam-power so early as the year 1769; for in his original patent he expressly mentions the practicability of applying it to domestic improvement. This idea appeared to have been suggested to him by Professor Robinson, but Watt never seems to have constructed a carriage to be impelled by steam. It has been said that he privately experimented on this subject, but being unable to overcome certain difficulties, he did not make public his attempts.

From the beginning of the present century, there have been various unsuccessful attempts made to move carriages on roads by the application of steam-power. The great obstacles which have hitherto presented themselves in the construction of carriages to be propelled by steam, appear to be the necessary weight of the engines, and the resistance presented by the inequalities of even the best roads; and in moving up an inclined plane, there is an addition to the other sources of resistance to drag the entire weight of the carriage and its load upwards. This oftentimes requires addition of double, nay, even quadruple power. Indeed, the most level road which can possibly be made, will always present the disadvantage of yielding to the great weight necessarily dependent on carriages and their propelling engines. To overcome, therefore, these difficulties, it becomes necessary to construct very large engines, the very weight of which increased the difficulties, in a certain measure, which they are intended to obviate, as every additional load to the carriage creates an additional resistance, arising from inertia and friction, and such other obstacles, exactly in proportion to the increase of the weight added. Hence, there are two opposite evils to contend with: First, if we endeavour to bring our apparatus within the dimensions of ordinary carriages suited to the quality of the roads, the impelling power of the machine is so diminished that it is incapable of overcoming the resistance; secondly, if we give the machine such powers as will suit it to overcome these obstacles, then it becomes too unwieldy for any practical purpose. The only rational hope we can entertain of overcoming these difficulties is by the invention of some much improved method whereby our roads can be rendered still more perfect, as also by the generation and application of steam, which will admit of a diminution in the bulk and weight of the carriage. Notwithstanding various tolerably successful attempts, by Gurney and others, to run steam-carriages on common roads, no instance has yet occurred within our knowledge of the permanent establishment of such conveyances. The case has been very different with respect to railway carriages. The leading object of a railroad is to remove all inequalities which occur on roads constructed of the ordinary materials. This purpose is effected either by means of rails of wood or iron laid horizontally along the ground. The former material is now, however, almost totally laid aside, from its want of durability. These tracks are now laid in lengths of iron from four to sixteen feet, united firmly together by joints at their extremities, and resting at every yard on a heavy block of stone firmly bedded into the ground. Each of these lengths is termed a rail; and the rails upon the most improved construction are those made of wrought iron, by the Bedlington Iron Company, for which they took a patent some years ago. The two tracks together form what is termed a single line of railway. But where there is much traffic, single railways are attended with insurmountable obstacles; and in such cases it becomes necessary to lay down another line parallel with the first, and at a distance of three or four feet from it. This is called a double line of railway, the obvious object of which is, that carriages moving in different directions may pass each other without coming in contact. There are communications at intervals, by which any carriage overtaking another, and which is moving at a greater velocity, may be allowed to pass, by means of an adjacent line or track constructed for this purpose.

Although railways appear exceedingly simple in principle, they are, nevertheless, extremely difficult in execution; and they are attended with much expense in their construction, which cannot be effectually done unless by those who have acquired a highly improved knowledge of the sciences and arts.

It must strike every one as being remarkable, that it was not until the middle of the sixteenth century that this simple invention was thought of, and was then adopted in a very rude manner among the coal-works in the vicinity of Newcastle-upon-Tyne. These first efforts were found of such utility, that, since then, they have been gradually improved and adopted in numerous situations throughout Great Britain, which has tended in an eminent degree to increase the means of conveyance, and greatly added to the powers of traction.

Upon an ordinary turnpike-road, the average weight which a horse can draw for any length of time is fifteen hundredweight; but on an improved railroad, an ordinary horse will drag with ease a load of ten tons, in addition to the weight of all the carriages which contain that quantity of goods, being upwards of *thirteen* times the quantity a horse can draw on a common road, and, in consequence, saving to the owner the keep of twelve horses. This mighty change in things in a country where the population is so dense that we cannot grow corn sufficient for our consumption, must be regarded as an incalculable blessing in a national point of view. On this head an able writer observes, "At a crisis like the present, when the country is labouring under the pressure of a redundant and starving population, the substitution of an inanimate for an animate power, by which an increase of food equivalent to the consumption of sixteen million of mouths, which is equal to the addition of a territory double in extent to that of Ireland, possessing all its natural resources and fertility, without the drawback of an unmanageable population, is a project which bears on its surface not the interests of a handful of individuals, a class of society, or branch of trade, but of the whole nation."

The number of horses employed in the kingdom is estimated at two millions, and each horse consumes as much food as will support eight men. If, therefore, a saving of one-fourth of the above is sufficient for the maintenance of four millions of people, it would effectually provide for the whole paupers in Britain.

Mr Gordon says—"Now, the suppression of the stage-horses upon our principal thoroughfares, and of the dray-horses in the great commercial towns, may be calculated to economise a saving of food equivalent to the supply of the above number of human beings.

It is, perhaps, not superfluous to remark, that the amount of food, equal to the supply of the said four millions, is not the produce of an extended agriculture and proportionate outlay, but is just *that part* of the annual produce of the country, subtracted from the whole, which is at present required for the mere purpose *of transportation*—*i. e.* to feed the animals used for draught—and is consequently a dead loss as unproductive capital.

In addition to the evil arising from such a consumption of unproductive food, is also to be considered the very great loss consequent upon the heavy capital sunk in *horse* purchase. Were this viewed, as properly it ought, as money withheld from other purposes of trade, and which might be more advantageously invested, our capitalists and men of science would not oppose the substitution of inanimate for animate power in the way they have done. Neither, did the landed interest maturely weigh the varied benefits it will produce in agriculture, would they view it in the light of an invasion upon their respective interests. They do not give a *quid* without receiving a *quo* every way as valuable. The reduction of farm consumption—the bugbear of the project—will be met and compensated by a steady and proportionate demand from other quarters; whilst in the United Kingdom, the 8,100,000 acres of land now required to feed the horses, together with the capital sunk in their purchase, will, when both applied to other and general purposes, amply compensate for the exchange.

In order more readily to show one effect, let the horses be considered only 1000; a smaller number may not make the argument so difficult. Let us reduce *this* number,* and the farmer may then turn his oat-ground into wheat-ground; and instead of so much land being employed to furnish food for a thousand horses, the same land, when turned into tillage fit to sow wheat upon, will produce sufficient bread-corn to feed two thousand poor families.

Again, if instead of 20,000 horses we kept 30,000 fat oxen, butchers' meat will be always cheap to the operative classes, whilst the quantity of tallow will of course make candles cheap; and so many hides lower the price of leather, and of shoes and all other articles made of leather; or the same quantity of land may then keep thirty thousand cows, the milk of which will make both butter and cheese cheaper to the poor, as well as the labouring manufacturer; all which articles are very considerable, and of material moment in the prices of our manufacturers, as they in a great measure work their trade to rise and fall in price according to the cheapness of their materials and the necessaries of life. The same may be said in favour of more sheep and woollen cloths.

We have said a horse consumes, on an average, as much as eight human beings. The country is burdened with poor (in want of food); so much so, that an evil is resorted to, to ease the burden; and the strongest and ablest of our peasantry are encouraged to emigrate. Our political strength is thus wasted, while the prospect that eventually these very men may meet us in battle array, is avoided in our search for present ease. Whilst, therefore, we have a remedy really good and practicable before us unresorted to, we may in truth say that we depopulate our country for a 'bestial herd.'

But it would be taking but a limited view of this part of our subject did we confine ourselves to the above observations, important though they are: there are great *financial* results to be considered likewise. The experience of the last thirty years has shown that we have hitherto legislated in vain for Ireland. A starving population cannot be cured either by education on the one hand, or by coercion on the other. Laws, however judicious in themselves, or beneficently administered, must fail to accomplish their purpose amongst a redundant impoverished people. It is bread they want; and this deficit has been the *fructifying* source hitherto of the disordered structure both of her political and moral condition. But let us, by the introduction of inanimate power, supply this want, and we do not, like Mr Canning, create a Transatlantic kingdom, but we resuscitate one at home, leagued to us by blood, by union, and neighbourhood. Let us *make them food*, and they will make themselves educated, and industrious, and happy, and prosperous. The yoke removed which has hitherto bowed the neck of the finest race in the world, Ireland will rise up, though late in time, in the energies of a renewed people, to add a vast fund of financial support, instead of the heavy burden she has hitherto been, to England. And if the last of the Union to attain her meridian of greatness and prosperity, she will likewise be the last to hand down the greatness and prosperity of the British empire to future times.

* It is worthy of remark, that when private carriages became common in this country, an act was passed to prevent the too great adoption of these vehicles, *lest the horses should consume the food of the poor.*

Nor will Scotland find less advantage from a change which will enable her to command a distant market for her home commodities, and which, at the same time, will bring all her imports cheaper to her doors. The produce of her mines will become more valuable, and property acquire a worth which hitherto it has not attained—the increase of finance returns will of course be proportionate.

In various departments of the revenue, the saving of expenditure by the substitution of inanimate for animate power will also be immense. In the post-office alone, for instance, it will amount to upwards of half a million; whilst, from the cheapness of food which the substitution will produce, the navy and army estimates will be most essentially reduced."*

We cannot better elucidate the benefits to be derived from a general use of locomotive engines, however, than by the evidence of Colonel Torrens before a Committee of the House of Commons.

"Have you considered the effect which will be produced upon British agriculture, by substituting, on common roads, steam-carriages for carriages drawn by horses?—I have.

What do you conceive that effect would be?—I think it would produce very beneficial effects upon agriculture.

State your reasons for believing that agriculture will be benefited by substituting inanimate for animal power, consuming the produce of the soil?—I conceive that agriculture is prosperous in proportion as the quantity of produce brought to market exceeds the quantity expended in bringing it there. If steam-carriages be employed instead of carriages drawn by horses, it will be because that mode of conveyance is found the cheapest. Cheapening the carriage of the produce of the soil must necessarily diminish the quantity of produce expended in bringing a given quantity to market, and will therefore increase the net surplus, which net surplus constitutes the encouragement to agriculture. For example, if it requires the expenditure of two hundred quarters of corn to raise four hundred, and the expenditure of one hundred more on carriage, to bring the four hundred to market, then the net surplus will be one hundred. If, by the substitution of steam-carriages, you can bring the same quantity to market, with an expenditure of fifty quarters, then your net surplus is increased from one hundred to one hundred and fifty quarters; and, consequently, either the farmer's profit or the landlord's rent increased in a corresponding proportion. There are many tracts of land which cannot now be cultivated, because the quantity of produce expended in cultivation and in carriage exceeds the quantity which that expenditure would bring to market. But if you diminish the quantity expended in bringing a given quantity to market, then you may obtain a net surplus produce from such inferior soils, and, consequently, allow cultivation to be extended over tracts which could not otherwise be tilled.

On the same principle, lowering the expense of carriage would enable you to apply additional quantities of labour and capital to all the soils already under cultivation. But it is not necessary to go into any illustrative examples to explain this, it being a well-known principle, that every improvement which allows us to cultivate land of a quality which could not previously be cultivated, also enables us to cultivate, in a higher manner, lands already under tillage.

If horses were displaced from common roads, would not the demand for oats, beans, and for pasture, be diminished, and land thereby be thrown out of cultivation, and labour out of employment?—If steam-carriages were very suddenly brought into use, and horses thereby displaced, I think the effect stated in the question would be produced for a time; but, practically, steam-carriages can be introduced only very gradually, and the beneficial effect upon the profits of trade, by bringing agricultural produce more cheaply to market, will tend to increase profits, to encourage industry, and to enlarge the demand for labour; so that, by this gradual process, there will probably be no period during which any land can actually be thrown out of cultivation, the increasing population requiring all the food which horses would cease to consume. With respect to the demand for labour, that demand consists of the quantity of food and raw materials which can be cheaply obtained; and as, by the supposition, the displacing of horses will leave at liberty more food, and more material, the demand for labour will ultimately be greatly increased, instead of being diminished. It has been supposed, I know not how accurately, that there are employed on the common roads in Great Britain one million of horses, and a horse, it is calculated, consumes the food of eight men. If steam-carriages could ultimately be brought to such perfection as entirely to supersede draught-horses on the common roads, there would be food and demand for eight millions of persons. But when we take further into consideration, that lowering the expense of carriage would enable us to extend cultivation over soils which cannot now be profitably tilled, and would have the further effect of enabling us to apply, with a profit, additional portions of labour and capital to the soils already under tillage, I think it not unfair to conclude, that were elementary power on the common roads completely to supersede draught horses, the population, wealth, and power of Great Britain, would at least be doubled.

* Gordon on Elementary Locomotion.

There are soils which are stated to be so poor, that oats alone can be raised upon them; would not the substitution of steam for horse-power have the effect of throwing out of employment the labour required for the cultivation of such lands?—If there are soils of such a peculiar quality that oats is the only marketable product which they will yield, the persons employed in cultivating those lands would certainly be thrown out of that particular occupation; but the extension of tillage over other lands not of this peculiar quality would create a demand for labour which would much more than absorb the persons thrown out from the culture of oats upon that land which would grow nothing else. But I doubt of there being any land which it is profitable to cultivate which would not raise some other agricultural produce than oats, either for man or cattle, for which the increasing population would create a demand.

The general impression on the minds of the committee is, that steam-carriages will, at least for the present, rather be substituted for horses used in conveying travellers than for the conveyance of bulky articles. Do you think that the substitution of steam in this manner will be injurious to agriculture and to the demand for labour, without any adequate compensating advantages?—Upon the case supposed, namely, that steam-carriages should be employed in conveying passengers only, and the whole change to be effected in a sudden manner, I think that there would in the first instance be a diminished demand for agricultural produce, but the following process would take place: As the demand for agricultural produce was diminished, the price of such produce would fall, food would become cheaper, and the cheapening of food would benefit partly the labouring class and partly the capitalists, the one obtaining higher real wages, and the other higher profits; this increase in real wages and in profits would effect a great encouragement to manufacturing industry, and would necessarily lead to an increase in the manufacturing population, and to the amount of capital employed in manufactures. The consequence would be, that after some degree of pressure upon agriculture, the increased number of human beings would create the same demand for agricultural produce, which the employment of horses [illegible]rly created. So that, even upon the extreme [illegible] at improbable supposition that steam-carri[illegible]'d never be employed in conveying agricultu[illegible] to market at a cheaper rate, still the be[illegible] country would be very great, inasmuch as we should have a vastly increased industrious population, and England would become much more extensively than she is at present the great workshop of the world. In point of fact, superseding horses by mechanical power would have precisely the same effect in increasing the population and wealth of England, as would be produced were we to increase the extent of the country by adding thereto a new and fertile territory, equal in extent to all the land which now breeds and feeds all the horses employed upon common roads. Such addition to the extent of fertile territory in England, suddenly effected, would in the first instance lower the value of agricultural produce, and be injurious to the proprietors of the old portion of the territory; but no person would therefore contend, that if we could enlarge the island of Great Britain, by additional tracts of fertile land, the public interests would be injured by such enlargement: this would be monstrously absurd. It is not less absurd to object to the increase of food available for human beings, by substituting mechanical power for horses.

In addition to the advantages you have already anticipated from the introduction of steam-conveyance, would not the increased speed and cheapness of intercourse occasion vast public benefits, in which agricultural capitalists and labourers must greatly partake?—Certainly.

As it is impossible to conceive that steam should be generally substituted for horses, and be confined only to the conveyance of travellers; and as it would necessarily be employed as vans and coaches are at present, for the speedy conveyance of light goods as well as travellers (by the hypothesis, steam-carriages being cheaper than horse-draft, or it would not be used), would not such cheapening of the conveyance of such goods have a considerable effect upon the demand for them, and thereby for labour and food?—On the principles that have been already stated with respect to agriculture, the cost of bringing all things to market is composed of the cost of production and the cost of carriage. Reducing the cost of carriage is precisely the same thing in its effects as reducing the immediate cost of production; consequently, the conveyance of light goods by steam-power must cheapen all such goods to the consumers. This will necessarily enable them to consume a greater quantity of such goods; and the consumption of the greater quantity will enlarge the demand for labour, call a larger manufacturing population into existence, and thereby react on agriculture by increasing the demand for food. This cheaper mode of internal carriage will not only lower the price of light and refined manufactures to the home consumer, but will lower their price also to the foreign consumer. This will increase the advantages which we at present possess in the foreign market, and tend to increase our foreign commerce. So that here again there will be an increased demand for manufactures and for a manufacturing population, and here again will be another beneficial reaction upon the soil. So that the more we contemplate the various effects produced upon the industry of the country by a cheaper mode of conveyance, the more we must be convinced that wealth and population will be increased, and that agriculture, instead of being injured, must necessarily partake in the increased prosperity of the country. In addition to what I have already stated, the saving of expense and of time in conveying passengers and goods, and the rapidity of communication, will produce effects, the amount of which it would be almost impossible to calculate."

But it is not in the saving of horse-power alone which railroads must be looked upon as a blessing, for by means of them we acquire a great alacrity of communication. This advantage was not thought of until the opening of the Darlington and Stockton railway, in September 1825, which gave a fresh impetus to the construction of carriages adapted for more speedy conveyance on railways, and no doubt led to the great communication between Liverpool and Manchester, as it afforded a striking demonstration of the possibility of still farther improvement in point of speed.

Ever since the opening of the Darlington and Stockton railway, coaches have been regularly plying on it between these two towns, each of which is drawn by a single horse, and contains six inside and from fifteen to twenty outside passengers, with their luggage, as well as many parcels. The speed at which they go is ten miles an hour, which must be admitted as extraordinary, when we consider that such an enormous load is drawn by one horse; and so small an exertion appears necessary, that the horse goes with as much apparent ease as if he were dragging only an ordinary-sized gig. These coaches have no springs of any kind, and yet their motion is so gentle, that it is hardly perceptible, and a passenger may read a book or newspaper with as much ease as if he were sitting in a room. Now, it is well known that few persons, without practice, can read in an ordinary carriage or mail-coach. A railway has recently been constructed from Edinburgh to Dalkeith and Musselburgh, with coaches similar to those at Darlington, by which passengers are conveyed to these places, which are six miles distant from Edinburgh, for the very small fare of sixpence: nay, no more than sixpence is required for a seat from Edinburgh to Dalhousie Maine, a distance of eight miles. So easily do these coaches go when once set in motion, that it is not easy to stop them, and it requires a particular apparatus for the purpose, which is termed a brake.

The Edinburgh railway is only a single one; and it sometimes happens that two coaches meet at places where there are no passings, when neither of them can get out of the way of the other. The coachman of that carriage next the nearest passing lane, dismounts, unyokes his horse, and re-attaches it to the other side of the coach (as they are alike on both sides), and drags it back, allows the other coach to pass, and, replacing his horse, again proceeds on his journey. It must be obvious of what immense advantage these conveyances are to the public of a crowded metropolis; affording them healthful exercise at the cheapest possible rate. From January 1, 1833, to December 31 of the same year, so many as 189,294 have been conveyed in these coaches, and many thousands, who never were six miles from Edinburgh during their lives, have had their ideas, to a limited degree, enlarged, and their health improved, by these excursions. It has been found that the number of passengers has been rapidly increasing ever since the opening of the railway, every month exhibiting increased numbers. It is anticipated that more than double will be conveyed during the current year, as, even in the month of January, the number which has gone by this railway is something more than double the number which was conveyed the same month of last year.

Such, then, are the advantages of an ordinary railway over ordinary roads, and such is the saving of horse-power, and, at the same time, a very great increase of speed. Carriages, like all other heavy bodies while in motion, begin to develope in a remarkable manner, demonstrating that grand principle in mechanics, that a state of locomotion is in reality as natural to bodies as a state of rest, and only require an impetus; which, when in action, is maintained in them with as little exertion of force as if they were in reality standing still. Hence it will be seen how fallacious that doctrine maintained by the ancients, that rest was more congenial to the natural state of bodies than motion. There can be little doubt, if all obstacles could be removed which impede the progress of machines, that, if a carriage were once set in motion, it would continue to roll on for ever, if adhesion and gravitation could be overcome.*

"It is well understood that when two smooth surfaces subjected to pressure are in contact, a certain force is requisite to cause them to slide upon each other; and this resistance to motion in surfaces is called *adhesion*. This property was not unknown at the period alluded to; but no data existed by which its extent could be defined; and, in the absence of this, every failure of purpose, which, in reality, arose from some defect in the engine itself, was attributed to a want of adhesion. The knowledge possessed even at the present day on the subject is exceedingly indefinite, having been all derived from practical results formed upon very variable premises. Experience from actual observation has taught us that a certain power of adhesion does exist, and that *generally* it is sufficient to produce the progressive motion; but this experience at the same time proves that different substances, and indeed like substances under different circumstances, possess the property in different degrees. If, for example, we take wrought iron wheels upon wrought iron rails, we find the surface of the rails presenting a greater or less adhesion to the wheels in proportion as the rails are more or less affected by the weather: when the surfaces are the most free from extraneous matter, the adhesion is the greatest; when moistened by wet, or covered with dust or mud, the adhesion is then the least. Taking, however, like substances under like circumstances, it appears that the greater the pressure upon the surfaces, the greater is the force required to give them opposite motion. Now, as the adhesion is the resistance to that opposite motion or sliding force, it necessarily follows that the two properties must be coequal; and hence it becomes evident, that the adhesive property bears some proportion to the weight or pressure applied."*

We now come to a description of railway improvements of a much higher kind than those carriages which are moved by horse-power, namely, those which are propelled by means of locomotive steam-engines.

In the year 1802, a patent was registered and taken out by Messrs Trevithic and Vivian, for a locomotive engine adapted to a railway. It was not, however, till 1804, that an engine was perfected by them, so as to act in this manner. It was first tried upon the Merthyr Tydvil railroad, and was capable of drawing as many carriages as could convey ten tons of bar iron, at the rate of five miles an hour. But what perplexed mechanists was, that the want of adhesion of the carriage-wheels to the rails was imagined to present an insuperable obstacle to the use of the engine in drawing heavy loads. This error led to the invention of many complex devices, to obviate this imaginary inconvenience.

"Mr Blenkinsop, of Middleton colliery, invented a rack reaching the whole distance of the rail, along which toothed wheels, worked by the engine, travelled, and thus produced a progressive motion of the machine. Messrs W. and E. Chapman adopted a chain stretched along the centre of the railway, which chain was grasped by a grooved wheel and roller at each stroke of the engine, and necessarily forced it onwards. Mr Brunton invented two moveable iron legs, each jointed, and terminating in a claw; these were placed behind the engine, and being acted upon by the piston, fixed themselves alternately in the ground, and drove the engine forward at every stroke. Notwithstanding the ingenuity of these and several other expedients, each had some equivalent disadvantage, either of increased friction, or diminution of power, that prevented its general adoption.

In the meantime, the superiority of steam-power was so obvious, that fixed engines were erected upon several railways, and the use of these has continued in a greater or less degree up to the present day. The means by which they effect the moving action, is either by a rope attached to the ascending train, and returned again to the bottom of the plane by each descending train, or by means of what is termed in mechanics an endless chain.

At length, about the year 1815, Mr Blackett, of Wylam, near Newcastle-on-Tyne, effectually proved, by repeated experiments, that the adhesive power of the wheels was at all times sufficient to produce a progressive motion in an engine, with a train of loaded carriages, upon a railway either level or with a very slight inclination upward.

Some time previous to the above date, and about the same period as the introduction of fixed engines, another considerable improvement was effected in the manufacture of the rails. They had hitherto been constructed of cast iron; and the exceeding brittleness of that material rendered them liable to frequent damage, both from the weights placed upon them, and the sharp frosts of the winter season. This had repeatedly occasioned the total stoppage of a whole line of road, and it was desirable that such a loss of time and money should be remedied. Wrought iron was known to possess an advantage over cast iron in this respect; but it was conceived that the softness in its texture, which constituted this advantage, would produce a commensurate, if not greater, evil in the rapid wear and occasional bending of the rails. Experience, however, proved not only that wrought iron was capable of a sufficient firmness—particularly when the rolling body was of the same material—to prevent an injurious decay from friction; but that it also presented a much greater resistance to the oxydising or rusting influence of the atmosphere than cast iron. This led to a very general substitution of the former; although at the present time the latter has many advocates among scientific men.

This, then, was the state of railways a dozen years ago; but let it be remembered that all these were isolated and private undertakings, confined to the mining districts; and that, therefore, very few persons had an opportunity of witnessing their operations. To the many, this subject was as yet a dark shadow in the womb of futurity. But from out the midst of this darkness a new era was ushered to the wondering world.

To the year 1825 was reserved the privileged distinction of applying the principle of railways to the practical purposes of general conveyance; and, on the 27th of September in that year, the first public railway, sanctioned by an act of Parliament, was opened between Stockton and Darlington. This may be considered as having been the infant essay of the more matured and stupendous undertaking, the Manchester and Liverpool railway.

The vast and continually growing increase in the population and trade of both Manchester and Liverpool, had long rendered desirable a readier communication than already existed between the two places. The propriety of supplying this defect, by establishing a railway, was first discussed in 1822; and, two years subsequently, a company was formed for carrying the project into effect. A bill, to obtain the requisite sanction of the legislature, was brought into Parliament in the session of 1825; but, after encountering a strenuous opposition on the part of individuals who had 'vested rights to protect,' it was thrown out in committee by a majority of one. At the commencement of the following session, another attempt was made, and proved successful; the second bill being eventually carried in the Commons, on the 6th of April 1826, by a majority of 47 out of 129; and in the Lords, on the 1st of May, without a division.

The projectors having gained this essential preliminary step, lost no time in commencing actual operations. Directors were chosen at a general meeting of proprietors held on the 29th May; and the draining of Chat Moss, in June, formed a beginning to this great undertaking. This was followed by the first shaft of a tunnel, to carry the railway under the streets of Liverpool to the water-side, being opened in the following September, just twelve months after the completion of the Stockton and Darlington road. In January 1827, the excavations and embankments along the whole line were in progress; and in the spring of that year, a loan of L.100,000 was obtained from the Exchequer Loan Commissioners, for carrying on the work with greater vigour. Early in the year 1828, the directors obtained the sanction of Parliament to some improved alterations in the line of road; and during that year, the Newton-bridge was completed; the piles to support the foundation of the Sankey viaduct were driven; and the last joining of the tunnel was effected. In the spring of 1829, another act was applied for to empower the company to raise additional capital by an additional number of small shares, and to carry the railway directly into Manchester over the river Irwell. As soon as this was gained, extraordinary exertions were made, and double sets of workmen employed to carry on the work during both day and night. In the course of this year, the Rainhill and several other bridges were completed; the bridge over the Irwell was commenced; and the company's premium of L.500, in addition to the purchase-money, for the most improved locomotive engine, was awarded to the Rocket, which was constructed by Mr Stephenson, a celebrated engineer, after a competed trial. On the first day of 1830, the much-dreaded and justly-doubted obstacles presented by Chat Moss were practically surmounted by the completion of one line of railway, and the crossing of a carriage and company drawn by the successful engine.

At length, on the 15th of September 1830—four years and a quarter from its commencement—this magnificent triumph of art was publicly opened. The interesting ceremony was honoured with the presence of a splendid assemblage of spectators: several of his Majesty's Ministers, some of the most distinguished characters of the age, the principal public men in the county, and a very considerable proportion of the residents both of Manchester and Liverpool, paid the deserved compliment of hailing the 'illustrious stranger.' A dark cloud was, however, destined to overshadow this brilliant scene; and while the 15th of September is commemorated as the anniversary of a new epoch in the world's affairs, the saddening reflection will recur, that on that day, too, England lost one of the brightest gems from her coronal of talent. The reader will not need to be reminded of the melancholy fate of Mr Huskisson.

On the following day, the Northumbrian engine performed the first journey for hire; and on the 17th, six carriages commenced running regularly upon the road.

We shall now attempt to give a description of this admirable engine, in the course of which the reader will be referred to the wood-cut entitled "The Locomotive Engine and its Appendages." The engine is supported on four wheels, the main part of the weight being thrown on one pair, which are turned by the engine. The boiler consists of a cylinder six

* See Information, article *Mechanics*.

* See an interesting pamphlet, entitled the Railway Companion, by a Tourist, page 111, which contains a minute and distinct account of the Manchester and Liverpool railway, well worthy of perusal.

feet long, with flattened ends; from one end, as will be observed, rises the chimney, and to the other there is attached a square box, the bottom of which is furnished with the grate where the fuel is placed. This box is three feet in length and depth, and two feet in width. It consists of two casings of iron, one within the other, having a space of three inches in breadth between them. The casing surrounding the box communicates with the boiler by means of two pipes, one from the top, and another from the bottom. When water is admitted into the boiler, it flows through the lower pipe into the casing which surrounds the fire-box or furnace, and of course fills the casing to the same level as that which it has in the boiler. When the engine is working, the boiler is kept about half full of water, and the casing surrounding the furnace is completely filled. The steam generated escapes by the upper pipe into the boiler, from whence there is another leading to the piston, and operating in the same way as in the high-pressure engine already described. Through the lower part of the boiler pass a series of small copper tubes, which at one extremity communicate with the fire-box, and at the other with the chimney, forming a passage through which the heated air escapes to the chimney. The chief part of the water in the casing being lower in its position than the water in the boiler, from its tendency to ascend when heated, passes back into the boiler; so that the water in both vessels is thus kept nearly at the same temperature. The air passing through the burning fuel, and which fills the fire-box, is carried by the draft through the tubes placed in the lower part of the boiler; thus communicating heat to the water which is there contained. It finally passes into the chimney, and rises by the draft, the power of which is increased by the waste steam, after it has worked the piston, being conducted into it by means of a pipe; and thus producing, on account of its levity, a strong current in the chimney. There are two cylinders, each of which works a wheel in the simplest manner possible. A lever connects the piston-rod with one of the spokes of the wheel, which, as the piston ascends and descends, is driven round in the same way as a common crank. The spokes which these cylinders work are placed at right angles on the wheels; the wheels being fixed on a common axle, with which they turn. For the facts contained in the above description, we are indebted to Dr Lardner's work on the steam-engine. We may mention, that the great object to be effected in the boilers of these engines is, to keep a small quantity of water at an excessive temperature, by means of a small quantity of fuel kept in the most active state of combustion.

In a railway intended for general conveyance, where the traffic each way may be considered equalised, it is highly essential to gain, as nearly as possible, a level line; as every inequality—even such as would not be discernible in a common road—forms a material obstruction to locomotive force. It is equally important that the line should be straight, or at least free from sudden curves; for, as the carriages are supported upon the rails by a flange, it necessarily follows that, where the curves are abrupt, the increased friction of the wheel against the side of the rail must very powerfully retard its progress. Both these points have been happily attained in the Liverpool and Manchester railway; the greatest ascent along the whole line—if we except the tunnels, and one ascending and one descending plane near Rainhill—being only in the proportion of one in about nine hundred, and the roundest curve not exceeding a deviation of more than one in two hundred from a straight line.

During the progress of the road, the species of impulsive power to be employed upon it became a matter of weighty and tedious consideration. Upon a level railway, the power is necessarily confined to horses, locomotive engines, and fixed engines. In discussing which of these should be adopted in the present instance, the horse was at once discarded as ineligible. The opinion of scientific men appeared so equally divided upon the remaining two, that it was considered requisite to institute a strict inquiry into the relative merits of each. This terminated in the adoption of the locomotive engine: to this undertaking, therefore, may be attributed the merit of having established the superior claims of this kind of railway power to general patronage. In the course of investigation, it was computed that the *original cost* would be rather greater, and the *annual charge* rather less, in fixed than in locomotive engines: it must at the same time be remembered, that a system of the former kind must be at once completed, while the latter can always be proportioned to the quantity of traffic.

After this question had been decided, it next became a matter of discussion as to what kind of impulsive power should be used on the two excepted points of the road. The inclined plane in the great tunnel commences at the opening towards Manchester, and descends under Liverpool in a straight line of 1980 yards, at the ratio of one in forty-eight. The whole descent, therefore, is 123 feet. The smaller tunnel ascends toward Liverpool in the same ratio. Here a fixed engine with an endless chain is used; but it was evident that the same mode could not be resorted to in the centre of the line without great disadvantage. The two inclined planes at Rainhill are each a mile and a half in length, and the ratio of their inclination is one in ninety-six—a rise that certainly requires additional power. In rejecting a fixed engine at this point, the question then to be decided was, whether the adhesion was sufficient to enable the locomotive engine to perform the task; and if so, whether it should be accomplished by increasing the power or decreasing the speed. This led to a series of experiments, the result of which was, that the difference between the adhesion on the level and such an inclination was too trifling to bring into calculation, provided the same speed were continued; but that to increase the power of the same engine for that purpose would require it to be worked to a great disadvantage on the level. It was finally agreed that an extra locomotive engine should be kept on the spot, to be attached, whenever occasion required, to the ascending train."*

In a great commercial country like Britain, where every branch of natural and artificial produce is carried to its utmost limits through all parts of the country, it must be obvious that an immense capital is annually sunk in the mere transport of marketable produce from one part of the country to another, which bears heavily upon the seller, and may in fact be reckoned an outlay for which there is no return. This kind of expense is also daily felt by the consumer. Hence it must be obvious that any method which can be adopted to accelerate the transport of these, and materially lessen the expense of carriage, must be a great public benefit.

Expeditious conveyance is no less material to mankind, and may be considered as an equivalent to capital; so that no expense is spared in the mercantile world to attain this object. Society are ready to purchase increased speed at almost any expense; and we have lately seen, that, to gain a speed of nine miles an hour, for what was formerly eight, an expense of a third of the original outlay has been paid; and that, for a mile more, or ten in the hour, even double the cost has not been grudged.

"To the merchant, time gained is equal to money; for time occupied in travelling is just so much profitable employment lost. Time occupied in the transport of goods is equivalent to so much interest of capital spent: for a thousand pounds invested in merchandise is unproductive so many days as the transport is tedious. That part of the capital of an individual which is employed in the carrying of his goods to and from market, is as much abstracted from his means of producing more of the article in which he exerts his ingenuity and labour, whether it be in agriculture or manufacture.

Easy communication lessens the time occupied in the transport, and a saving of time lessens the distance, or our notion of distance. This effects a saving of money; and a saving of money permits of a greater employment of capital. Whatever reduces the price of transportation reduces the price of the commodity transported. Whatever reduces the traveller's time reduces his claim for compensation, and (competition being always at work) he is content with a smaller profit upon his merchandise. If a scarcity of any article occurs at one point of the kingdom, the monopolist there cannot continue his increased price for any duration of time. Commerce may, in this respect, be resembled to water, for, if not obstructed, it will always circulate till it finds its level. An opening or channel being furnished, an equalised supply will make its way wherever required.

Thus we see that the strength, wealth, and happiness of a nation, depend very much upon facility of communication. The ill-defended spot in the empire is alive to the reality, that subsidies having bad roads or a tedious navigation to pass may arrive too late to present an effectual resistance to a plundering enemy. The hard-working emigrant of a remote settlement, distant from a market, feels the difficulty and loss he sustains in bringing produce to the spot where merchants and dealers meet for the purposes of exchange. A spot uncommunicated with may be visited by the horrors of famine, and no channel exist for conveying thither the food required. A grievous pestilence may sweep off an isolated people before the aid of the physician can arrive to arrest its progress."†

The practical good resulting from this increased speed of travelling, and the consequent saving of time and reduction of fares, will be seen from the constant increased number of passengers conveyed by the railway between Manchester and Liverpool:—

The number for the half-year ending on the 30th June 1831 was	188,726
And the half-year ending in Dec. same year	256,321
Being an increase of . . .	67,595

Which is more than 35 per cent. increase of travelling for the first six months of the year, and upwards of 135 per cent. increase on the travellers between Manchester and Liverpool during the corresponding months of the year previously to the finishing of the railway.

The original cost of this railway was, for Parliamentary and legal expenses, together with the survey of the country through which it passes, L.48,294; the purchase of land, L.95,305; excavations and embankments along the line of road, L.199,763; the formation, walling, and fencing of the road, L.47,520; and the rails, blocks of stone, and sleepers, L.88,432; the erection of buildings, including police stations, warehouses, and offices, L.66,697; building bridges, L.108,565; carrying the way through Chat Moss, L.27,719; the great tunnel, L.44,768; and the small coach tunnel, L.2485; engines, waggons, and carriages, L.52,637; making a total amount for this stupendous undertaking of L.820,000, of which the late Duke of Sutherland was a subscriber to the amount of one hundred thousand pounds.

We shall now proceed to give a short account of the construction of this great work. The railway is formed with a double way of lines lying parallel to each other, and four feet eight inches apart. One of these ways is used for going and the other for returning, to prevent any dangerous consequences which might occur from the concussion of two rapidly-moving bodies.

'The line has occasional sidings, to allow a free passage in case of any obstruction arising from the stoppage of a preceding train. Branch-railways communicate with some of the intermediate towns lying north and south of the road; each of them having two oblique curvilinear openings inflecting respectively toward the two extremes of the journey, to render the transition of the carriages from or to the main line less sudden.

The structure is a raised edge-rail of rolled iron, two inches broad, and one inch thick, in lengths of twenty-five feet each. These are firmly fitted together, and placed upon cast iron chairs or pedestals, and the whole supported at intervals of three feet by stone blocks, twenty inches square and twelve inches deep. Into each of the blocks two holes are drilled, and filled up with oak plugs; and to these the pedestals bearing the rail are spiked down. On the embankments, and other places where the foundation may be expected to subside, additional firmness is secured by the introduction of oak sleepers. The whole length of the road is thirty-two miles, and posts are placed every quarter of a mile to mark the distances.

The company keep a police establishment, who have station-houses at intervals of about a mile along the road. These stations form also depôts for passengers and goods from or to any of the intervening places. The duties assigned to these men are to guard the road—to prevent or give notice of any obstruction—and to render assistance in the event of any accident occurring; and to do this effectually, they keep up a continual line of communication. They are guided by a code of regulations issued by the board of management. Their directions to the engineer are given by signal. When a train approaches within a certain distance of a station, the policeman presents himself, and signifies a clear road by assuming an erect posture with his arm outstretched; should he take the position of 'stand at ease,' the engineer is aware that some obstruction exists. When a passenger is waiting at the station, a red flag is hoisted by day, and a swinging light exhibited at night. In travelling in the dark, the last carriage of every train carries 'astern'—to use a nautical expression—a revolving lamp, one side of which is red and the other blue. As long as the train is in motion, the red light presents itself to whatever follows, but at the instant of stopping, the blue light is turned outward; the engineer of the next train instantly sees this change, and is enabled, by checking the velocity of his engine, to avoid a collision that would be tremendous. The fire of the engine is sufficient to give warning to the policeman or to any object upon the road of the approach of a train.

Each engine is immediately followed by a tender or light open vehicle containing a supply of fuel and water, with the engineer and his attendant; and to this is attached a train of from five to twenty carriages, according to the number of passengers or goods to be conveyed.

The passage-carriages are divided into three classes, and are made to resemble four coach bodies joined together upon one frame. Those of the first class contain seats for eighteen passengers, three abreast, each seat being separated by arms, and numbered. Those of the second class carry twenty-four passengers, four abreast, and have the seats likewise separated and numbered. The third class are open carriages, containing seats for twenty-four passengers. Each train of carriages is attended by one or more guards, who have seats on the outside. To enable private carriages to travel along the railway, flat frames are provided, upon which the carriage is raised, and its wheels firmly secured upon the platform by moveable grooves.

The cattle-carriages are covered and fenced round with a light grating. Some of them, for the conveyance of pigs, are quite open; and it is no small difficulty for the poor Irishman, who may be thus travelling, to keep his live stock from rebellion.

The luggage-waggons for the conveyance of goods are square open carts, each of which is furnished with a tarpauling to protect the bales of merchandise from the weather. The waggons for conveying coals are likewise open carts, made wider at the top than the bottom.'*

No. 29. PRICE 1½d.

THE DUTIES OF LIFE.

The temporal duties enjoined on rational beings may be thus classed:—1. Duties which one owes to himself.—2. Duties which arise from domestic relations.—3. Duties which arise in the communities of which each one is peculiarly a member.—4. Duties which arise from the political relations of society.—5. Duties which arise between individuals who are of different nations.—We propose, in the meantime, to treat of those duties which a rational being may be said to owe to himself.

LIFE AS A WHOLE.

Life is a succession of parts; infancy, youth, manhood, maturity, decline, old age, and death. What man becomes, depends in part on his genealogy; as his infancy is, so will be his youth; as his youth is, so will be his manhood; as his manhood is, so will be his maturity; as maturity is, so will be decline; as decline is, so will be old age. If youth be passed in idleness, ignorance, folly, and crime, how can one hold his way in the world, side by side with the intelligent, the worthy, and the virtuous? If manhood has been passed in low pursuits, in rooting in the heart evil propensities, in wasting natural vigour, what awaits one in old age but poverty, pity, and contempt? If infancy be devoted to the reasonable expansion of the physical and intellectual powers—if knowledge of human duty be acquired, and be rightly used, will not manhood be worthy, maturity respectable, decline honoured, and old age venerable? Life, then, must be taken as one event, made up of many successive ones. On these unquestionable truths we found all that is worthy of any notice in the following pages.

PURPOSES OF LIFE.

We believe that human life, rightly understood and rightly used, is a beneficent gift; and that it can be so understood and used. It is irreconcilable to reason that man was sent into this world only to suffer and to mourn; it is from his own ignorance, folly, or error, that he does so. He is capable of informing himself; the means of doing this are within his power. If he were truly informed, he would not have to weep over his follies and errors. It is not pretended that every one can escape at once from a benighted condition, and break into the region of reason and good sense. But it is most clear, from what is well known to have happened in the world, that each generation may improve upon its preceding one; and that each individual, in every successive period of time, may better know the true path, from perceiving how others have gone before him. There can be no miracle in this. It will, at best, be a slow progress: and the wisdom arrived at in one age, must command the respect of succeeding ones, and receive from them the melioration which they can contribute. We understand nothing of what is called the perfectibility of human nature; but we understand this, that if human nature can be made to know wherein its greatest good consists, it may be presumed that this good will be sought and obtained. Man was created on this principle, he acts on this principle, although he is seen so frequently to make the most deplorable and distressing mistakes. If it be not admitted that mankind will always strive to obtain whatsoever seems to them good, and strive to avoid whatsoever seems to them evil, their moral teaching is in vain. If this principle be admitted, the sole inquiry is, what is good, and what is evil.

INFANCY.

Every human being comes into the world with physical and intellectual qualities, propensities, and aptitudes, which distinguish him as much from all other beings, as he differs from them in figure and appearance. As society is a consequence of the Creator's will, as the proper divisions of labour are a necessary consequence of society, it is not irrational to suppose that individuals are born with adaptation to labour in some departments, and not in others. In the early stages of life, these qualities are sometimes developed, whether they happen to be understood or not. But almost immediately after gaining some hold on life, all human beings become subject to the incidents which tend to strengthen original qualities, or to obscure or stop their progress, and even to suppress them, and engraft on the original stock those which are entirely different. It would be unjust to make infancy responsible for the evils and errors which arise in this manner; but certainly those who have the guidance of infancy are responsible, and will be held to be so. Children have a right to complain, and society has a right to complain, if duties to children be neglected; and, it is needless to remark, there is another, and inevitable accountability of a far more serious character. We shall have occasion to remark on the very sober duties of those, who, according to the order of natural and necessary law, are entrusted with forming and giving effect to natural qualities. This matter properly belongs to another place.

YOUTH.

We come now to a period when accountability begins, in all the relations which were placed in the divisions of duties. If it be asked at what age this is to be fixed, we answer, that the good sense of judicial law recognises that a child may be a witness in solemn judicial proceedings when inquiries addressed to him are so answered as to make it certain that he understands the nature and the obligation of an oath. This may be at the age of ten or twelve years. But the perception of right and wrong, and the sense of duty, begin at an earlier age. There certainly are children of the age of eight years who have a very clear sense of moral propriety; and very many who between that age and twelve can discern and reason on right and wrong, and arrive at a very sound judgment. We shall presume that all into whose hands this sheet may fall, will be fully capable of comprehending its purpose, and of judging of its fitness to be useful to them. We must assume, then, that we are speaking to those who are willing to be instructed in serious things, and that they will not reject instruction from any source, however unpretending it may be, if it come to them in a manner which they can reconcile with their own reason, and with their own duty to themselves. Young persons think that they can see for themselves, and that they need not to be told what others have seen. But let us reduce this to common sense. Suppose a person to be under the necessity of going from the place in which he has lived, and which is familiar to him, to a far distant place. Let it be supposed that the road he must travel is crossed by many roads, and that he is frequently to find himself at points where several roads are seen, either one of which, so far as he can discern, may be the right one. Will it be of use to him to have been told, before he departs, which of these many roads to take? Will it help him onward to his destination, when he is bewildered and unable to decide for himself, to find some one who can assure him of the right course? Life is a journey. Every step we take in it brings us to something new, something unexpected, and perhaps entirely different from that which was looked for. Those who have gone through it before us, have left us their instructions in what manner it is to be undertaken and accomplished. They tell us of their own troubles and difficulties; they warn us how to avoid the like in our own journey. Which is wisest, to listen to them, and weigh the worth of their warning, or to push on heedlessly, and take the consequences?

HEALTH.

We suppose that every child of the ages last spoken of, can form some opinion of the value of health. Most of them have suffered, more or less, by that time. They are now old enough to consider the purposes for which life has been given to them. They then feel that the purpose is to be pleased, and gratified; to want, and to have; and that restraint is disagreeable. But let them remember that life is a whole; that though all of them will not, yet some of them will, attain to its longest duration, and that it is wholly uncertain to whom that lot will fall. Long life may depend, and often does depend, on what children do, or omit, at an early age. Among the first gratifications which are looked for at this period, is the indulgence of the appetite for food. Here comes in a rigid law of the Creator. It cannot be broken without consequent suffering, nor repeatedly broken without impairing, and perhaps destroying, the material frame which has been described as so fearfully and wonderfully made. To require of that delicate machinery, on which the action of life depends, that which it is not qualified to do, and which it cannot do; to force it to do that which is offensive to it; and to make this requisition habitually, is a sin against natural law. Its punishments are well known. The restless sleep, the heavy head, the many sensations of uneasiness, the positive pain, the disgusting remedies, are the punishments which follow. They are not all. Nature loses its charms, companions their interest, duties become irksome, the mind hates its labour, penalties are incurred, parents or teachers are regarded with displeasure. These are the fruits of momentary gratification of the appetites. On the other hand, there is a law of nature that food shall be grateful. It is required to supply the daily waste, to continue life. If there were not a craving want, we should take food as a mere necessary duty. It is kindly made to be a pleasure, and, like every other pleasure, it is to be used, and not abused. Thus, by ignorant or wilful pursuit of pleasure, we violate a law which brings with its just punishment not only the loss of the like pleasure for a time to come, but also pain and suffering from indispensable remedies. When children are sick, they are subjects of tenderness and pity; but in most instances they rather deserve to be punished, for they have broken a law wilfully, since they have disregarded their own experience. As to kinds of food, nature is not unreasonably nice about this: that which it complains of is quantity.

CLEANLINESS.

This is not a mere matter of decency. It is one of the positive commands arising from the constituted order of things. Be it remembered, that every thing that lives, vegetable or animal, is wasting while life continues; and that all which is sent forth through the millions of openings by the skin, has run its round, and is lifeless; and that more than half of all the food taken comes forth in this manner. If perspiration, sensible and insensible, be permitted to rest on the skin, and stop the way of that which is coming, nature is offended, and will show that she is so. Such neglect is one of the causes of disease. This fact was probably well known to eastern nations, since it was part of their religious duty to cleanse the skin. These nations were ignorant of the modern comfort of wearing a garment next the skin which can be frequently changed. The absence of this comfort was one of the causes of those dreadful diseases of which we read, and which are now unknown among Christian nations. There are classes of labourers and mechanics, whose health would be preserved, and their lives prolonged, if they knew how much depended on periodical cleansing. It may be said that there is a connection between cleanliness and moral feeling. Perhaps it may be going too far to say, that those who habitually disregard cleanliness, and prefer to be dirty, have no moral perception; but it may be truly said, that those who are morally sensitive are the more so from respecting this virtue. There is a close affinity between moral depravity and physical degradation. The vicious poor are always shockingly filthy: the depraved rich are visited by worse penalties: they may have clean garments; but what can wash away the impurities which vice has made part of themselves? It is not for one's-self only that the virtue of cleanliness commends itself. Every one comes within the observation of others. However uncleanly one may be himself, he is not the less offended at the like neglect in those whom he observes. Now, it is every one's duty to himself to recommend himself to others, so far as he innocently and reasonably can, and to obtain their respect. Clean and costly garments may fall very short of doing this, if it be seen that they are a covering for the neglect of this important law. If there be a lovely object to the human eye, it is a clean, clear-faced, healthy, innocent, neatly clad, happy child. There are few children who may not, if they will, be neatly dressed, for this does not depend on that of which the dress is made. There are fewer who may not have a clean skin, and healthy look, if they are properly fed, and sleep in pure air. There are none who may not have a clean skin, for we speak to those who are old enough to judge for themselves. And let it be added, for their inducement, that, in obeying the command to be clean, they are performing a moral duty; in neglecting it, they are inflicting an evil on themselves in two ways; first, in diminishing their own comfort; second, in losing the esteem of others.

AIR.

Among the generally unknown causes of loss of health is the respiration of impure air. The congregation of many persons in one apartment, especially when artificial light, in great quantity, is permitted, is a cause of more maladies than is commonly supposed. Three causes, in such case, combine to destroy the fitness of the air for respiration—the animal heat of the assembly, the lights, and the breathing of the same air again and again. There must be such assemblies. The remedy is proper ventilation. The smoke of lamps has frequently occasioned death. No lamp is properly trimmed if it emit any thing more than a pure bright flame. It is a common practice to keep sleeping apartments shut up. If there be several persons in a small room which has been shut up for several hours, it would be shocking to know how often they must breathe again and again the same air, and how unfit it is to be breathed after it has once visited the lungs. Add to this the impurity of the air, which is continually in contact with the furniture prepared and constantly used for sleeping, in an unaired apartment. It is not mere nicety, or fastidious delicacy, which requires that the pure air should be admitted where the human lungs are in action, but it is a law as old as the creation of man, and cannot be disregarded. A skilful observer might select among many, from the appearance of the countenance, those who have just left an apartment in which they have been respiring for hours a spoiled atmosphere. No doubt that this cause, long continued, so affects the whole mass of blood as to bring on many diseases. If pure air be peculiarly necessary to any class of persons, it is so to children. We believe a more useful suggestion could not be made on the subject of health to the whole community, than to invite them to respect this law of nature, that there cannot be perfect health where the air is impure, and that this applies especially to apartments appropriated to sleep. Visiting friends are often put into sleeping apartments which have not been opened for days and weeks; this is far enough from kind treatment, however innocently it be done.

TIME.

Every person connects himself in his usual thoughts of himself, with all the lapse of time in which he can remember, and with all the lapse of time through which he expects to live. This he calls his life. He does not live in time that is past, nor in time that is to come. He actually lives only in the present moment. Yet he feels that he lives in the past, and will live in the time to come, because the past, the present, and the future, are so connected, that he cannot separate them. It is, then, a law prescribed to us, from which no one can free himself, that he shall suffer in the passing moment for the wrongs done in time gone by, and for the evils of which he dreads the approach. As this is certainly so, how little does he regard the operation of inflexible law, who provides for himself a load of self-reproach, for any gratification which he can procure, by error or by crime!

Let us lay out of the case those errors and crimes which have been alluded to, and consider negligences and follies. Man was meant for action, and his actions were intended to enable him to secure good to himself. Good to himself depends on the performance of his duties to himself. Duty to himself requires that he should improve his faculties, and should avail himself of all the opportunities given to him for that purpose. The hours, then, which are permitted to slide by without any improvement, are lost. In so losing them, he breaks the law of the Creator. Apply this to the vocations in which one is to cultivate his mind in any business, mechanical, scientific, or learned. When one sees himself surpassed by others, and left far in the rear; when he is called on to measure himself against another; and when he sees that comparisons are made between him and others, greatly to his disadvantage, he may feel, and most men do feel, that they are thus depreciated because the precious time which was allotted to improvement has been passed in trifling amusements, or in idle pursuits. To some minds the suffering from such causes is extremely acute. They have no one to blame but themselves. The bitter remembrance which they have of the past, as connected with the present and the future, is the punishment for breaking a positive law. They may console themselves, perhaps, with the firm resolution, that they will repair the wrong done in the past time by diligence in the time to come; but they find that time brings with it its own demands. They are fortunate, indeed, if they can do in one space that which belongs to it, and that also which belonged to another, and in another season of life.

One cannot innocently say his time is his own, and that he may dispose of it as he pleases. His time is his life. It is given to him in trust. Like other trustees, he will be held to an account, in which there is no possibility of concealment, and where nothing will depend on proof. It may be supposed that it will be said to him, there was confided to your use a term of time; you knew, or could know, the laws prescribed to you in performing your trust; are you come from that trust to render an account of it, burdened with reproach from your own conscience, and with marks of guilt, which you cannot hide? or, are you come, without any advancement in the knowledge of your duties, and with no other account than that your days rolled by in childish pursuits, or idle amusement, *no wiser* when you were severed from the world than when you left the cradle of infancy? or, are you come with the exalted acquirements which you might have, and with that innocence and purity which you would have, if you had read the laws of the created world, and those which have been revealed, and placed before your eyes? Where have you read in these laws, that no duties to yourself, and to your associates, nor to the *Lawgiver*, were enjoined upon you? Have you not been told, by every breath you draw, by every movement of your frame, by every thought of your immortal mind, by every just pleasure, that you have had, by every pang that you have suffered, and by all that you have been made capable of perceiving and learning, that there were laws prescribed to you in your trust, and that an account of your stewardship would be exacted from a judge who cannot be deceived?

SELF-LOVE.

It is an invariable law of nature, that every human being shall do those acts which he thinks will secure good to him, and that he shall avoid those acts which will occasion evil to him. Why, then, should not every one do any and every act in his power by which his own will may be gratified, and avoid doing any and every act which is disagreeable to him? The only answer that can be given to this question is, that man is a free agent, entrusted with the power, and charged with the duty, of ascertaining for himself what is good and what is evil, and that this power and duty extend to those with whom he dwells in society, and also to his Creator.

Children always conform to the natural impulse of self-love, until they learn from the discipline which is applied to them, that they cannot have their own will without subjecting themselves to a suffering, the dread of which controls the natural impulse. They learn, after a time, that the greater good lies in giving up what they will to do, and doing what is required of them, rather than to meet the certain consequences. We think that the whole science of morals will be found in the principles contained in the truth above stated.

Self-love is just as strong throughout life as it is in childhood. It is that quality of our nature to which all excellence may be referred; but it is also that to which all unworthiness may be referred. As the dread of punishment, or an unwillingness to displease those whose kindness a child desires, will restrain him, or put him into action, so, in more advanced life, the dread of suffering a certain or probable evil, and the certainty of losing the good will of others, will restrain, or impel to act. With those whose minds have been properly disciplined, and who have learned to comprehend their relation to the Creator, there is a far higher motive, which is founded in a submission to the Creator's laws. As one goes on in life, he may or may not acquire more and more clear and just perceptions of what will be the greatest good to himself, and how he can obtain it. It is a self-evident proposition, that if a person could certainly know what it would be best for him to do, or not to do, in relation to all things and persons, and under all circumstances, and if he should conform to this knowledge, he would best obey the impulse of self-love, and most exactly conform to the laws prescribed for his good.

It cannot be too often impressed upon the youthful mind, that *life is to be taken as a whole*: for if this extended view be not taken, it must frequently happen that it will seem right in certain circumstances; and when the view is limited to these circumstances, that certain acts may be done, or avoided as the great good. Yet, if the consequences could be foreseen, they would disclose that this seeming good would turn out to be a positive evil. It often seems good to the young to avoid the performance of labours which are assigned to them, and to spend in amusement the time which should be devoted to fit them for duties which will be incident to future condition. This misapprehension of good is to be lamented; but with some, this is not all. Their own self-love prompts them to engage in a course of folly, so that not only do they fail to obtain that which is real good, but they find, under the mask of pleasure, that which proves to them to be the most grievous suffering.

The same truth runs, in an endless variety of forms, into manhood, and through all the stages of life. We are impelled by self-love not only to provide for the craving wants of our nature, but to seek pleasure, riches, power, distinction, and luxuries. These propensities are given for wise and beneficent purposes. It is the misapplication of them, as seen in the world, which constitutes human misery. He is called brave and honourable who defends himself, even at the risk of life, against those who would do to him that injustice and wrong which would make the gift of life of no value. But the brave, who invade the rights of others, and subject them, by violence, to losses and to sufferings, without cause, misapply this principle of action. To get riches by honest industry, or the reasonable exercise of one's talents, is a commendable use of self-love. To get riches by unfair and dishonest means, to hoard them up, and to brood over them in secret, is a pitiful misuse of this commendable impulse. To have power over one's fellow-men, and to use it faithfully, and for their benefit, is a relation which one may honestly and commendably desire, as a reasonable exercise of self-love. To seek such power by deceitful representations, and to obtain it by violence and fraud, and to use it for purposes of supposed self-benefit, and to the injury and oppression of others, is another form of self-love. But there are few, if any cases, in the history of mankind, in which self-love has appeared, in the latter form, without eventually overwhelming the agent with disappointment and sorrow. It is true that for a time such an one may seem to flourish in his schemes, and command the applauses of those who look up to him in his apparently fortunate elevation; but, in the very nature of things, if his heart could be sounded, there is no one whom he looks down upon, who is not more at ease than himself. His day of humiliation may be at hand, in the course of events which he cannot control; and if not, he learns, when it is too late to correct his error, that he has misapplied the impulse of self-love. This misapplication is to be seen in many cases of daily occurrence, and in things of little, as well as in those of comparatively great, importance. The principle is every where the same.

We shall be answered, perhaps, that all this is incident to human nature. There is no help, it is said, for these evils. Every boy who has learned Latin repeats the maxim, *humanum est errare* (it is human to err). A more mischievous maxim was never invented. If men understood, as most certainly they may do, that they need not err, and that it is best for them they should not, they would rather adopt as a maxim that none but the wilfully ignorant, and the wilfully foolish, *err*. Such a state of things is yet afar off. It may seem to be foolish, indeed, to assert that any society should ever come to be so well informed as to make a proper use of self-love. Let us not despair. We may improve very slowly; yet, if every one does even the little that he can, in showing, by precept and example, what things a rational and accountable being should desire, and what he should avoid and reject, certainly the time may come when self-love will never be so misapplied as to be necessarily followed by penitence and sorrow.

Will it be denied that there is a certain best course of action for every human being, in every possible condition in which he may find himself? Or, that no small proportion of human suffering arises from not having discerned that it was best, in past circumstances, to have acted differently, or not to have acted at all? Or, that whether one did or did not act, in the supposed case, that his motive was to secure to himself the greatest good of which that case was supposed to allow? If these things cannot be denied, then the great end of life is so to regulate self-love as that it may secure the greatest good. Let us suppose that every person in society knew what it would be best for him to do or not to do, so that his physical, intellectual, and moral condition, should be as good as he could make it. His self-love would never be directed to any end which would impair his bodily powers, or keep his mind in ignorance, or misinformed, or make him a subject of reproach or contempt in his own view, or in that of others. This, it will be said, is an impossible state of things. So it was said that it would be impossible to root out the use of *ardent spirits*. This great change is not wholly accomplished; but does any one doubt that great advance has been made towards its entire abolition? Let us go on, then, in the work of improvement. Let every one try to show the proper uses of self-love. The day may come when every one will admit that all the sufferings which may visit the human family are of their own making, those only excepted which arise from the general laws of the Creator. As to those, they may be greatly mitigated by intelligent moral agency. When these come, they can and will be endured with piety and resignation, if the sufferer can console himself with the certainty that he has done no wrong thing, nor neglected any proper one, to which the cause of his sufferings may be referred.

LABOUR.

It is commonly considered that labour is the *curse* declared to mankind, as a consequence of the transgression of the *first man*. It is foreign to our purpose to enter into any discussion as to the true meaning of this historical or allegorical account; the Christian revelation may not be dependent on a literal understanding of it. However this may be regarded under the influence of further reasonable research, we must take man as he is; and so considering him, labour is not an *evil*, but a *pleasure*. Is it a curse to man, as he now *is*, to be enabled *by labour* to comprehend the existence of the Deity, and the beauty and utility of his works? to adorn the earth and bring its productive power into action? to apply the material substances of the earth to reasonable use, convenience, and ornament? to expand and improve the human mind? to cultivate and strengthen the moral power? Certainly these are the effects of labour; and labour so applied constitutes man's highest happiness.

There are two kinds of labour:—1. Mere bodily labour; 2. Labour of the mind. These two are sometimes necessarily combined. The mind and the body demand some sort of employment. No one whose mind is free from natural defect can prevent its action. It will think of something, good or evil, profitable or foolish. Every one who attends to the operations of his own mind must be convinced that this is so. The body and limbs cannot be kept in any one position for any considerable space of time, unless they have been in action, and demand repose. If it were painful to us to direct the action of the mind to useful labour, and if it were distressing or inconvenient to us to exercise our muscles for purposes which we believe to be proper, then it might be that labour is a curse; but many, nay all, who require of the mind to perform its duties to any useful purpose, and especially those who have disciplined the mind to an accustomed service, find that the absence of employment is an affliction. We cannot see how this should be otherwise, if we rightly comprehend man's relation to the universe, of which he constitutes a necessary part.

As to bodily action, it is seen that children in their sports go through a series of exertions, often exceedingly violent too, from mere pleasure. Men frequently exercise the body much more severely in matters of amusement than they have any occasion to do in necessary labour. This action seems to be a dictate of nature. In many cases of indisposition, bodily motion is the prescribed remedy, and is commonly a successful one. There are sound reasons why this should be so. There is an universal action of the material system to which man belongs, and a continual waste and demand for supply. Excepting only in the involuntary movements in man's structure, which are not confided to his care, he is required to aid nature in her operations. If he would put himself in the best condition to receive, and derive pleasure from his daily food, he must keep himself in action. Those who have the least pleasure in using what was given to be used, as the means of pleasure to the senses, are those who keep the body inactive. This is true of those who labour with the mind only; more strikingly true of those whom affluence excuses from labour of body and mind. They seek happiness in indolence and in luxury. They find it not, because they violate a law of nature. No product of the vineyard, the field, or the sea, however aided by inventive art, will furnish a welcome repast to one who sits in listless idleness, on a downy cushion, from breakfast time till dinner. The day-labourer who sits down to his coarse meal has a pleasure to which the luxurious idler is a stranger. The one receives a rational benefit from the kind and just bounty of nature; the other seeks it where nature has decreed that it shall not be found.

The labour of muscular action is not only in itself a pleasure, but it is the means prescribed to us for the acquirement of subsistence; for the gradual improvement of society; for applying natural and artificial products to our comforts, to our convenience, and to reasonable luxuries. Nor only so: this is the groundwork of all the beautiful and imitative arts; of the discovery and application of the chemical power of matter; of the wonderful contrivances by which man securely moves on the face of the ocean; by which he cultivates his acquaintance with the stars, and raises his thoughts to the Author of all being. Let us not, then, regard labour as a curse, but a blessing, and rank it among the many causes for thankfulness. It is obvious that muscular action would have been given to us in vain, if it were not directed by intelligence. There must, then, be labour of the mind. This is no where said to be a curse. If there be any thing for which we should be specially thankful, certainly it is that we are blessed with the power of mental exertion. This labour is in itself a source of happiness; and in its fruits has made, out of savage men, a rational and improving social being. The most restless and comfortless of all creatures is he who has no occupation for his mind. If one would invent the most miserable condition for a human being, other than mere physical suffering of the most excruciating kind that can be without extinguishing life, it would be to deprive him of all employment of body and of mind.

Can there be a doubt that in man's present condition the ability to labour is his exalted privilege? And is he not accountable for this privilege? Is not reason given to direct him in the use of it? It is well known to those who have compared the condition of mankind in different ages, how much the labour of body and mind has been able to accomplish. Even within the last half century, the most surprising changes for the better have taken place, from the right use of this productive power. On this depends the condition of the human family. From the joint labours of all who wish well to their fellow-men, there will be obtained, eventually, the knowledge of the best manner of using the products of the earth, the best mode of ruling men in their social relations, the just homage due to the Creator, and the true purpose for which human life has been given.

To some descriptions of persons labour is irksome. They are obliged, in their vocations, to use certain muscles, and those only. They repeat the same act throughout the day. Their labour becomes tedious, because it requires little or no action of the mind. To this numerous class we venture to offer a relief which is within the easy reach of many of them. It is well known that the nature of habit is such, that the hands will do what they have been accustomed to do, without any obvious attention, and the mind is left to do what it will. The mind might be employed, while the hands are busy, in pursuing some connected train of thought. Muscular action, so far from being an interruption to the action of the mind, may be made to assist it. Persons who think intently are often seen to have some habitual movement; and we have heard several persons acknowledge that their best ideas had come to them when they were engaged in some simple occasional duty, such as the folding of paper, or the cutting of the leaves of a book. The stir of body seems to produce a corresponding stir of mind. The relief which we suggest is, that sedentary labourers should provide themselves with subjects for reflection, and exact of their minds to attend to these subjects. By such simple means, the memory may be strengthened, the stock of knowledge may be greatly increased, and the mind surprisingly invigorated. One might begin this exercise by attempting to remember, with the utmost precision, every act done during the preceding day, and so go back from day to day. Better still would it be, if the purpose were to see wherein one had not done as well as he might, and as he may wish he had done. This exercise may be applied, also, to the contemplation of subjects suggested by reading; and this contemplation will raise questions which will lead to the examination of books. There may be hundreds of poets, philosophers, and moralists, at the work-benches in this country, who have no thought, of themselves, that they are such. It is in the power of any person who can read and understand the English language, to strengthen his memory, give himself an interesting employment, and furnish himself with a rich fund of the truest philosophy, in this manner. He may commit to memory six lines, each successive day, of Pope's Essay on Man, and on each day repeat all he had learned on preceding days. On the 21fith day he would be able to repeat the whole essay. This might be done without losing one moment of time, and without making the slightest error in one's work. When accomplished, it would be an intellectual treasure for which any man might be thankful, and of which he might be justly proud. The first efforts may be discouraging, but perseverance will insure success. Every one who is accustomed to thinking can attest that most new subjects are at first confused and undefined; but they gradually disclose themselves, and fall into shape and order, just as material substances, used on the work-bench and the anvil, take that form, smoothness, and polish, by successive operations, which the workman requires.

HABIT.

This quality of our nature has engaged the attention of many philosophic minds. It has been considered an *ultimate fact*, as it is called; that is, one of those qualities which, like respiration, digestion, and many others are found to exist; and beyond which fact no investigation can be made. Its laws, rather than its nature, have been the subject of remark. It may be, that habit is to be referred to the law of action, which appears to pervade all material and intellectual being. Life is divided into parts; in one we are awake, and active; in the other, wrapped in sleep, and quiet. Each successive day is a sort of new existence, in which we are to repeat many of the acts of the preceding day. We repeat these acts, because nature demands the repetition of them. Also, almost every one is engaged in some vocation, on which he relies to supply his wants, and gratify his wishes; and most persons have in view certain pleasures, which are innocent, or otherwise. It seems to us that habit arises from this demand for action, and from the manner in which this demand is supplied. Action relates to our selves, to other persons, and to things around us which minister to our wants; supplying its demands, associates us with these persons and things. The want, whatever it may be, arises, and forthwith all things connected with satisfying it, force themselves into notice, and these become a part of our very existence. It is a well-known fact that the appetite for food will associate itself with a particular hour of the day, and with persons, places, and objects of gratification; so that one becomes hungry rather according to the hour than the natural want.

It may perhaps be an ultimate fact, behind which we cannot go, that those acts are most easily and well done which are oftenest done. One who uses a flail, an axe, a scythe, a sword, or a pen, can use either the better the oftener they are used, until he arrives at a point of excellence at which his power of improvement stops. This may perhaps be accounted for by supposing that the first effort which the mind makes to direct muscular action, is the most difficult one. After repeated efforts, the mind seems to understand better and better how to direct, and the muscles how to obey, till at length a very slight effort of the mind seems to be all that is required, and even an effort so inconsiderable and rapid as not to be the subject of notice. On this truth seems to depend the astonishing facility of action to which (among many other instances) jugglers and musicians attain. This is called *habit*, which word is derived from a Latin word which signifies custom or use. There are customs or habits of the mind as well as of the muscles. Persons who accustom themselves to extemporaneous speaking, acquire a surprising ease and readiness in the complicated action of conceiving, uttering, and expressing, by sounds, by looks, and gestures, whatsoever they would impress upon an audience. The mind has its own habits also, in the quiet of contemplation, and in exercising its various powers. It has its own associations, too, with external objects, of which many curious instances are stated in philosophical works.

The moral deduction which we make from these general principles is this, that there is a continual craving to do some act, to obtain some object; or a continually recurring necessity to do some act to prevent an evil, or inconvenience. The frequency of this call upon us to do something, whether it be for eventual good or evil, leads to the practice, custom, or habit of doing; and in some cases, the impulse to act becomes so powerful, that reason, self-respect, the laws of society, and even those of the Law-giver of the universe (if these are heeded), present no sufficient barrier to the impulse. It is to this all-important truth, in the nature of man, that we earnestly invite the attention of the young. The capacity to create habits is the consequence of the power given to us to promote our own welfare, individually, socially, and as accountable beings. This capacity was designed to fasten us down to that course of action which will accomplish these ends of our existence. Like every thing else with which we are entrusted, it may be rightly and profitably used, or may be misused, and perverted to our certain ruin. Habit is the kindest friend or the cruelest foe to human welfare. When it assumes the latter character, it approaches us in the most deceitful and seductive forms. It comes wearing attractive smiles—it delights—it fascinates—it substitutes its own irresistible will for our own—it triumphantly points to the gulf to which it bears us. The fly caught in the spider's web is a faint illustration of the power of habit. He knows, from the first moment, his destiny. The gambler, the drunkard, and the felon, when and how do they learn that they have been caught in the web of habit!

INTEMPERANCE.

This word has attained a meaning more limited than its proper one. It is applied commonly to persons who take habitually ardent spirits; but it is equally applicable to all transgressions of the law of moderation. All acts which may be lawfully done for one's own good, when carried to excess, are acts of intemperance; and all such acts are sooner or later followed by some sort of suffering, according to their nature and degree. Excessive labour of body or mind are as much acts of intemperance as to make one's self dull and stupid by taking food, or irrational and giddy by taking spirits. But there is a wide difference in the degree of immorality in the kinds of excess. An intemperance in study, which brings untimely death in some instances, is not condemned as an immoral transgression (though it certainly is such), for the motive which leads to this intemperance is an honourable one. The loss of health and character, from abusing the privilege of taking nourishment, is universally condemned, because the motive, and the acts done in obedience to its impulse, are irrational and disgraceful.

There are two kinds of intemperance against which the young should be warned. The one is drinking, not for nourishment, but for pleasure; the other is, using tobacco. It has been already demonstrated that nature requires a certain quantity of proper food to maintain a healthy and happy condition of body and mind; also, that excess of any kind will be followed by suffering. This is just as certain as that a full vessel must throw off just as much as is added to its contents. It is very natural that young persons should assemble for the sake of society; being assembled, they must have some employment for the muscles of the body, and the craving of the mind. We have shown that such propensities spring from natural constitution, and that they must be satisfied. There must be a community of purpose in the meeting. That may be found in any muscular action in which all can join, and which has some definite object, as athletic games; or it may be found in some intellectual employment which is common to all present. Unhappily, the most frequent bond in such meetings is *to drink*, for in this all can join. Connected by this common attraction, the mind is called into action; but for what purposes? Those who frequent places of public entertainment can answer this question. Some who are sent to public seminaries can also answer it; and some can answer it who know that they are maintained *there* by pinching economy *at home*. Some others could answer it, who never had a serious thought why such places were established, nor for what uses they were intended.

We refer again to the demonstration heretofore made, that the law of nature, which cannot be broken with impunity, inexorably admits so much, and no more. Let us, then, look in upon a gay company of young persons, around a table, and half concealed by tobacco smoke. What sort of air are they breathing? what sort of substances are they casting into their physical system, already bursting with excess? what sort of thoughts have they in their minds? and what sort of words are flowing from their lips? We *could*, but will not, answer these questions for them. Let us pass by this revel, and go to the next morning. We might then propound some other questions. Are not their heads heavy, hot, and throbbing? Are not their eyes thick and burning? Are not their tongues white and parched? Do not the nerves tremble? Is not the mind muddy and confused? In what condition are they to perform duties to themselves, to those they serve, to instructors, to affectionate parents? *Is not this dear-bought pleasure?* How long can nature bear to be *pleased* in this manner? This matter does not stop here. The same scene is repeated again and again. *Soon habit asserts its awful dominion*; and then the scene *must* be repeated. The craving cannot be resisted. From social drinking, the step is an easy one to solitary drinking. *There is no resting-place for habit; every thing in this system of being must keep on, or end.*

It is believed that the sort of criminal excesses to which we allude are not from the promptings of nature. We venture to assert that they are entirely artificial in the beginning. It seems irrational that any one should like to take more of any thing than nature requires; and more so that one should naturally desire to take burning liquids to the degree of intoxication, or perhaps to take them at all. It is believed there is no such natural propensity; but that such liquids, when first taken, afford less pleasure than pure water. The taste for these articles is created by association, by imitation, by fellowship; and, above all, because there is a kind of tradition that it is *manly* to drink. Songs in praise of the juice of the grape, and of meaner liquors, have some effect in the delusion of drinking. There is a fascination in combined poetry and melody. Such combinations are well known to have the most powerful influence in national associations. They inspire a feeling which bears men on to victory or death. The songs of Bacchus do the same. They conquer the strength of those who sing, and of those who listen to them, and sometimes lay their admirers, not in the bed of honour, but of contempt.

If one could get the ear of such a misguided youth, he would not do much by reasoning with him. He might do something by getting him to reason for himself. It would be necessary to bring to his view some facts from which he could reason. He must be made to know what a wonderful contrivance the digestive power is, and by *whom* it was contrived. That its purpose is to take the inanimate substances, which nature provides for it, and convert them into living, sensitive being, and, possibly, into thinking power, and immortal spirit. He must be reminded how easily every human contrivance may be deranged, and the more so, and irreparably, in proportion to the minuteness and delicacy of construction. But as one might fail to make a thoughtless boy comprehend the nature of the principle of life which resides in his own bosom, because he cannot see it, some illustration must be made. Unhappily there is none which can be effective to this end. The nearest that occurs is this. Let us suppose, then, one knows the use and the value of the human eye in its physical, intellectual, and moral relations; that he knows he must take care of it, and frequently bathe it in cold water, as well to cleanse it as to refresh and brace it, so that it may still be an eye to him, when decline and old age shall come. Let us further suppose, that, instead of so using and so preserving this delicate organ, he should, when he first rises in the morning, let fall into it a drop of burning spirit, and at eleven o'clock another, and so on, at the proper hours, until he sleeps again: How long would the power of vision remain to him, and how soon will this organ of delight become a source of insufferable pain? It must be much the same with the digestive organs as to the abuse of them.

If one could, in some such way, bring home to the perception of an erring youth the grievous wrong which he is inflicting on himself, he might be prepared to reason on his own case, and might be asked some such questions as these: Is it of any consequence to you to be free from suffering and sorrow? As you must inevitably keep company with yourself as long as you live, is it of consequence to you to make of yourself a pleasant and agreeable companion, and not one who will be continually complaining and upbraiding? Is health of any value to you? Can you use your limbs, and the faculties of your mind, as you would like to do, without it? Can you have health if your habit is to throw into that delicate part of your system whereon the action of life depends, substances which excite it to an unnatural exertion, or deprive it of all power of exertion? Does not every part of your system sympathise with the injustice which you do to your digestive organs? Will not your brain, and consequently your mind, suffer by this violence? Do you expect to attain middle age, and old age? Will not the seeds you are now sowing come up in that space of time? Will they come up in the form of enfeebled muscles, chronic aches, self-reproaching thoughts, the loss of the capacity to enjoy the bounties and beauties of creation? Will they grow up to overshadow your moral sense, and shut out the delights of intellectual power? Was life given to you for the few years in which you can sing, drink, and "enjoy yourself," or that you may enjoy life in every stage of it, as a rational being, and by rendering your homage to nature in obeying her laws, and your gratitude to Him who ordained these laws for your happiness? Do you not look forward yourself to be at some time a parent? Have your own parents ever so conducted themselves towards you, that you have a right to punish and afflict them? Are you willing that your parents should see you and know you as you know yourself? If you should be a parent, are you willing that your children should be told with whom, and in what manner, you "enjoy yourself?" Would you tell them how you spent your youthful days and nights, and recommend to them to take yourself as an example?

TRUTH AND FALSEHOOD.

These two subjects relate to two parties: 1. That one who speaks truth or falsehood; 2. That one to whom it is spoken. We propose to consider this matter only in relation to the first party, and as to him in two views. 1. Whether there be any, and what law, which requires that the truth should be spoken; and, 2. What good or evil one may do to himself by lying.

1. One reason why truth should be spoken is, that the knowledge which any one person can have from the use of his own senses, in many things which it most materially concerns him to know, is very limited. He must therefore often depend for his knowledge on what others say to him; and when the thing spoken of is exclusively known to the party speaking, the other must rely entirely on what he says. If, therefore, it be considered how great a part of the most serious concerns in life proceed on declarations made by one person to another, we may readily conceive, that, if these could not be relied on, the affairs of mankind would be greatly embarrassed, and confidence in each other would be destroyed. As this matter of speaking the truth is one which concerns all persons, so all persons agree in holding liars in contempt. Even the very lowest persons consider themselves to be disgraced when charged with the guilt of lying. They can endure charges which would subject them to public punishment, with more composure than they can endure this. A lie is always understood to be resorted to, to secure some advantage or prevent some evil to the person who resorts to it; or to occasion some disadvantage or injury to the person to whom, or of whom, the lie is told; sometimes both these purposes concur. The object in view is always an immoral one, and the means used are always regarded as disgraceful. It is at once obvious that wilful falsehood is forbidden by natural law, which is intended to regulate our social relations, and is expressly forbidden by divine law, which condemns all acts of fraud and deceit, and commands us to do to others as we would have them to do to us.

2. It is a rare occurrence that any one who descends to falsehood succeeds in the object which he may have in view. He is commonly detected, and, if not, is suspected, which may operate quite as much to his disadvantage. If he should escape detection and suspicion, he lives in constant fear of both. He has a very troublesome secret to keep. If he should be able to do this, still he cannot hide it from himself that he is a liar; and such a person, by natural justice, is compelled to pass that sentence upon himself, which he knows that others would pass upon him if they were as well informed as he is. A liar is therefore obliged to feel like a guilty person, and an habitual liar very soon comes to look like one. If there be no higher motive than one's own interest and welfare in speaking the truth and avoiding falsehood, this is a very sufficient one. If a man is known to be a person unworthy of confidence when he speaks, he has not the benefit of being credited even when he speaks the truth; he voluntarily deprives himself of the advantages of social life; his assertions secure to him no credit; his promises are contemned; he makes himself to be alone in the very bosom of society, for every one shuns him. In the administration of justice in courts, a person is not regarded as a witness, whose common reputation is that he is not believed when he speaks. The objection to him is not that he might not tell the truth in the matter which is on trial, but that such a person ought not to be received as a witness, because he cannot be credited in any thing that he says. When such a person has been called and examined as a witness, it is usual to examine other witnesses to prove his character; and if it be proved that he is unworthy of credit, what he has sworn to is disregarded, though he may have declared the truth. This is the common fate of all such unfortunate persons in society, as well as in courts. Independently of the criminality, lying is very poor policy. If the object be to obtain a supposed good, it rarely is obtained by such means; and if it be, the price so paid must always be greater than the good is worth. If the object be to conceal a wrong done, it is rarely successful; and if not, it leaves the offender without excuse for his error, and adds another wrong. If the object be to charge an innocent person with a wrongful act, or to deprive one of his good name, or of some lawful possession, or subject him to some evil which he ought not to endure, the offence is of that cast which the law of the land holds to be *malicious*, and it deals with such offence accordingly. In short, it is very difficult to violate any law of natural justice or divine prohibition without encountering an adequate punishment; and it may be assumed that the punishment which follows lying is as certain and just as in any instance of criminality. If every tenant of every prison, and if every person who is in the custody of a goading conscience, were asked this question, *what was your first step from innocence and purity?* he would probably answer, *telling a lie!*

SINCERITY AND INSINCERITY.

These are other names for truth and falsehood. They are not commonly applied to the most serious concerns of human life, but to what are called the "imperfect obligations." Such obligations, it is well known, are not enforced by the law of the land, but are binding as duties arising as well from natural law (reasonably expounded) as from divine law. Sincerity is a duty to one's-self, because it is demanded by self-respect. As every one has an individual separate physical being, so every one has a *separate circle* within which he exists, and into which no one has a right to intrude. His thoughts, motives, opinions, and policy, are his own. What he will or will not do (so that no wrong be done to others, and no act of duty be withheld from them) is for him to decide upon. Within this circle he makes up his judgments on all persons and things. In his outward deportment he must frequently act in a manner not consistent with these judgments. As an example: one has made up, from repeated observations of a certain individual, a very clear but very unfavourable judgment of his qualities; but there is no occasion to disclose what the judgment is. The observer is obliged, or finds it convenient, to meet this individual, and to deal with him, and perhaps to interchange courtesies with him. It is undoubtedly proper to manifest the respect, in such case, which the decencies of life require, and to show the common proofs of good will. There is no insincerity in this. Though no one can possibly avoid forming judgments of others, nor avoid liking or disliking them, even including very near friends and relatives, yet there may be a positive violation of duty in publishing these judgments, or in disclosing these feelings. The divine law, "judge not that ye be not judged," does not, it is believed, interdict these judgments, because they cannot but be made; but it forbids the wanton, unnecessary, and injurious publication or manifestation of them. Those who are keen observers of their fellow-men, see in their faces, in their manners, in their modes of speaking, in their tones of voice, in the sentiments which they express, &c., causes for respect, esteem, confidence, and approbation; or they may see causes for disrespect, suspicion, strong disapprobation, and disgust. But all these things belong to the *individual circle*. It is not insincere to keep them there. On the contrary, society would be intolerable if they were not kept there; it is very hazardous to the observer to let them out unnecessarily. He may be mistaken both as to the favourable and unfavourable judgments which he forms. Further observation, new circumstances, unexpected changes, may essentially correct his judgment; and, therefore, a prudent man will keep them to himself: they are his own peculiar property, and were obtained for his own use. It sometimes happens that one must associate with, or have something to do with, persons who are exceedingly repulsive and disagreeable to him, though that person may not be so to all, if to any others; and no moral effort will be effectual to remove these impressions. The dutiful course seems to be, not to disclose these impressions even to the party who causes them, if it can be avoided. One may be quite as disagreeable and repulsive himself to other persons, though he may have no suspicion that he is so. He would not like to be told of this, nor would he be able, probably, to change the relation for the better, if he were.

The world gets over these difficulties by establishing a kind of common currency under the name of *politeness*. Those who understand it are never deceived as to its value. They know the coin in all its denominations, and how much of it is to be parted with on all occasions. They know the precise point, in human intercourse, where its value ceases, and where recourse must be had to other means. The rules of civility settle many points in these difficulties. Civility is, however, distinguishable from politeness. The latter is a coin of the world; the former is the manifestation of Christian feeling. They are often confounded, as their practical effect is much the same. They are *insincere* who lavish the currency of politeness, and who lead others to believe that far better opinions are entertained of them than really are. They are contemptibly insincere, who for their own selfish purposes, or from the weakness of desiring to render themselves agreeable, stoop to commend directly, or by insinuation, qualities in others, which they affect to see, but which they well know do not exist in them. This is called *flattery*, which word is derived from a Latin word which signifies wind, breath, puff. This is a kind of aliment, which perverted self-love finds to be exceedingly pleasant. Although it is in truth precisely what its origin indicates, there is hardly a man, woman, or child, who is not disposed to partake of it, if it be artfully disguised. But, on the other hand, all sensible persons, of whatever age or sex, who see what it is, and why offered, feel for the flatterer the contempt which he deserves. This insincerity is, and ought to be, deemed a high offence. It implies art and deceit in the flatterer, and sufficient weakness in the flattered, to be subdued to the purpose in view. The flatterer's purpose may be to secure to himself no more than a better esteem than he can have any pretence to, and it may be, through that, to secure to himself something which may be very costly to his victim.

CIVILITY.

The well-being of society would be greatly promoted if the nature and use of this Christian virtue were more generally known. We take this to be, in personal intercourse, the observance of the command, Do to others as you would that others should do to you. The most rapid glance at any community shows this: That some of its members are brought into contact, in matters of business, necessarily; others meet, incidentally, who have no particular connection; others meet for social purposes in various forms; and that there is a large proportion who know of each other very little beyond the fact that they are of the same country, and perhaps not even that. There must be a *best rule* of deportment for all these classes; and no one will deny, that if this rule were defined, and faithfully applied, there would be much more of every-day comfort and complacency in the world than there is well known to be. If we rightly understand the meaning of civility, it is the manifestation of kind feelings, and of a desire to do all things which are to be done, under the influence of such feelings, in a becoming and agreeable manner.

If every person understood the true foundation of society, the common origin of all its members, their natural and necessary sympathies, their community of interests, their necessary action upon and with each other, it might be supposed that all who are reasonable would be civil. They would be so, because they would promote their own good, because they would be doing what it is proper to do, to promote the good of others; and because they would know, that in so doing they would conform to the design of their creation. We do not include under the term *civility* the great duties of justice, acts of munificence, important personal services. These arise out of some special relation which an individual bears to one or more other individuals. It seems to be limited to the manner in which the common or accidental intercourse of the members of society in general should be carried on. This matter may be better understood by some examples. Thus, if one comes into the presence of another as a beggar, servant, labourer, mechanic, trader, merchant, farmer, lawyer, physician, clergyman, or public officer; or if it be a female, or child of either sex, there may be very various modes of receiving these different persons; yet, certainly, by every one of the laws which we are endeavouring to illustrate, these several persons are entitled to civility. Even the beggar, perhaps one should rather say the beggar in particular, if not deformed by voluntary transgression, should be received with civility—that is, gentleness, kindness, decorum, are to be observed relatively to each one. Why? because no man can afford to be deemed insensible to the calls of reasonable humanity; nor a stranger to the decencies of life; nor ignorant of what is due from him, nor to him, in any of his proper relations. *Politeness* may be quite another thing, in some of the supposed cases. One interchanges politeness with those who happen to know what politeness is—*civility with every body*. A king would be polite to the ladies of his court, to his prime minister, to the members of his council, to foreign ministers, &c., and civil to his coachman, and to the humblest of his subjects.

We may find many illustrations, and fill ever so many pages with them. Let us take one which will concern the greatest number. In this country a stage-coach and a steam-boat bring many persons into a small space, who may be utterly ignorant of each other's existence until they meet. They have a common object, that is, to be transported in the same vehicle from the point of departure to that of destination. Circumstances compel them to be very close to each other, and each one has the power of being very disagreeable to each one of the others, in a variety of well-known modes. Let us suppose that each one consults merely his own interest, including in that his own self-respect, the reasonable good-will which each man desires from all others, and the ever-present principle of doing as he would be done by. He shows that he is sensible of the presence of his fellow-men; that he thinks them of sufficient consequence to wish to have their good opinion; that he is attentive to their comfort or convenience; that he is disposed to learn something from them, or communicate something; or to join with them in disposing of the time in which one has nothing to do, but to be carried. Take the other side of the picture—he puts himself in the best place, takes out his cigar, lights it from a pocket apparatus, and goes to smoking; he sees no one, speaks to no one, and endeavours to hear no one; if spoken to, he answers in a coarse monosyllable, and in a tone which prevents all further attempt at intercourse with him. If he make his presence known to all, beyond his sullen sitting there, it is by some selfish exclamation, or contemptuous ejaculation, on what is passing within his notice. Which of these two persons is *civil*? which of them is making the most of human life? which of them is attracting good will? which of them ought to like himself the best? which of them will have the most to look back upon with pleasure? which of them is a rational, sensible, well-disposed human being? and which of them is a selfish brute?

There is one other consideration which operates on all men who have had much experience in the world. Men and things change, and take new and unexpected relations. Persons who have been long and even intimately connected, suddenly or gradually sever; persons who have known little of each other, and that little uninteresting or unfavourable, are brought in contact by some unexpected turn of affairs. Sometimes one needs favours, or at least good-will, from those he never thought to be of the least importance to him. In such and in a multitude of other circumstances, one may find the advantages of having been acquainted with the virtue of civility, which implies that one has given no unnecessary offence. There are other cases in which one is called on by duty to do things disagreeable to himself, and exceedingly so to others. But there is no good sense in performing such duty morosely, and with inhumanity. As the laws now are, one may be authorised and required to put another to death. It would not be expected that such a duty should be performed *politely*; but there is the strongest reason why it should be done *civilly*.

ANGER.

This word is derived from a Latin word, which means to choke, or strangle. In several other languages its root is found, and in all it has the signification of strangling, choking, constraining, or narrowing. In common understanding of its meaning, which is the true one, it is a violent passion of the mind, arising from some real or supposed injury; and its natural tendency is to do two things: first, to take satisfaction for the injury; second, to make the offender suffer. This passion does not appear to be wrong in itself. Like many other excitements which are common to our nature, it was given to us for useful purposes, and is only wrong when its dominion is injuriously submitted to, and unjustifiably obeyed. There is a principle of general operation among all animated beings, which reconciles the existence of anger with the wisdom and benevolence of the Deity. All animals are entrusted by nature with the preservation of their own rights, and the promotion of their own welfare. But all animals are liable to have their rights infringed, and their welfare disturbed by others. If there were no sensibility to wrongs, the cunning and the strong would make all others obedient to their will. Anger is justifiable in self-defence, and in exacting justice, and in making an offender suffer, within the limits of reason. It is only in the misdirection and irrational use of anger that men make this principle of their nature a cause of affliction to themselves. Certainly the indulgence of an irritable angry temperament is one of the sorest troubles experienced in human life.

Anger has its seat in the mind. It is a passion which literally means an excitement of the human system, by the action of some external cause perceived by the mind. It is that passion which has the most immediate and the closest connection with the material system. Every one who has experienced a violent fit of anger knows that the natural action of the heart is quickened, and that his blood courses through his veins with a feverish rapidity; he feels that his face reddens with this action of his blood, that his eyes are full and distended, that he has a sense of choking in the throat: these emotions will gradually subside as the fit goes off, and the blood will resume its accustomed flow. So far this may be only a temporary physical evil. This, however, is not all the evil. Such an excitement can never occur without affecting other parts of the system. The interior organs of the system, which minister to the digestive process, partake in the evil effects of this violent action of the blood. These also are choked and constrained in their natural and necessary action. Physicians and naturalists tell us that the frequent action of anger generates stones in the gall bladder, makes the liver schirrous (become hard), and, deranging the indispensable flow of the bile, brings on jaundice and other diseases. (Such afflictions arise from various other causes also.) It is well known that there are instances of sudden death from violent anger. This is accounted for by the sudden rushing of the blood through delicate vessels which are not strong enough to hold it. They give way, the human machine is ruined, and death follows. It is said the theories as to long life are contradictory. By some it is referred to temperance. But some persons have lived long who were not remarkable for this virtue. It is rational to suppose that a naturally good constitution will endure long, if the rules of temperance are respected, and if the system is never subjected to violent passions. It is probable that those persons live longest who are not only temperate in quantity and quality, but who are also good-natured and cheerful.

Supposing the foregoing suggestions, as to the nature of anger, to be well founded, they are to be applied by persons who are entrusted with their own rights and welfare, and whose great purpose is to obtain the greatest good from life *as a whole*. It is admitted that all persons may, and perhaps must be, sometimes angry, until all persons attain to a much higher state of moral perfection than has hitherto been known. But it seems to be of great importance to one's-self to learn in what way he can govern the propensity to anger, so as to make it what it was meant to be; that is, means to his safety and welfare, and not, as too often it is, a cause of suffering and humiliation.

The causes of anger are supposed to be these:—First, by the law of nature and of society every one has rights in what he regards as his own property; second, one has a right to hold unimpaired whatsoever he can justly acquire in reputation and character; third, he has a right to have his feelings respected by others, if he do no wrong to their feelings; fourth, he has a right to have the like rights respected in those with whom he is necessarily connected by family and social ties; fifth, he has a right to be treated with justice, and, according to established laws, by those who are entrusted with power; sixth, he has a right to have those who are bound with him, in a common subjection to such laws, treated with justice. Whenever any one is offended by the violation of any of these rights, he may be justifiably angry. But in what manner and to what end he shall express his anger, so as to do himself the greatest justifiable good, is the thing to be known.

Every one who has had a violent fit of anger upon him, knows that it was to himself (independently of the cause and object of his anger) a painful and even a very distressing sensation. No one ever looked back upon such a state of things, as to himself, with satisfaction, but generally with regret, and sometimes with remorse. He feels humbled and grieved in his own estimation of himself. He may too well remember that he used expressions and did acts which he is grieved to have resting in the memory of others, or in his own. It is probable, also, that no one ever saw another in a violent passion, without feeling that this angry person was degrading himself, and acting more like a brute than a rational being. Whatever be the cause of such anger in another, cool spectators always regard the angry person as under a temporary loss of reason, and in danger of doing some serious mischief, and are prompted to restrain him. Every one feels, in such a case, that the least that can happen to one so acted upon, and so acting, is, that he is preparing for himself hours of self-reproach and of bitterness. If no one likes to remember that he was violently angry himself, and if he is offended in seeing others so, it must be admitted that violent anger is contrary to natural law, as it most certainly is to divine law. It is an abuse of the trust confided to us to promote our own welfare.

As to the cause and object of anger, there are certain cases in which sudden and violent anger is justifiable. The law of society permits the expression of it by violence, even to the destruction of human life. Thus he, who in violation of all law, human and divine, is attempting to take the life of a fellow-being, may be justifiably slain by him who is in such peril. The same law justifies the like act in attempts to commit some grievous crime in relation to persons or property. This justification occurs only when the offence is in the course of being perpetrated. In most cases in life, where anger is felt, the causes are of far inferior grade to those which the law of the land notices. It is to those of common occurrence to which our attention is now directed.

The cause of anger is some real or supposed wrong done, which prompts us to obtain reparation, and to punish the offender. It is consistent with reason for any one, who is under the influence of anger, to be prepared to ask and answer the question, whether the wrong is real or only supposed, and whether he is himself free from the first imputation of having occasioned, by his own error, that which he regards as a wrong. If the offence is real, other questions arise of this nature: What real good shall I secure to myself by attempting to get a reparation? and in what respect shall I advance my own welfare by attempting to punish the offender? May I not, in either of these attempts, involve myself, by words or acts, in some wrong, and give my adversary the advantage of finding me an offender, in trying to vindicate myself? If I could succeed in my attempt, what will it come to? Shall I not make the wrong done to me more notorious, and subject myself to the pity and compassion of others? Is it not better to be silent and quiet, and leave the offender to time and his own conscience, than to engage myself in a controversy which is sure to be vexatious, and in which I shall run the risk of doing wrong, and in which I shall not be likely to get any good? If I succeed in humbling my adversary, I shall surely make him my enemy for ever; for, in the nature of man, he is slow to forgive the wounds inflicted on his own self-love. When this matter is over, and time has dissipated the mists which now prevent a clear view of it, and when other feelings and sentiments have arisen, shall I like myself the better for having been silent and quiet, than if I shall have attempted to command justice, and to inflict punishment? It is probable that young and ardent minds, and those who are looking back by the light of experience, will answer such questions very differently. But the experienced can tell the young, with sorrowful truth, that among the most painful sufferings of life are to be numbered those which have arisen from sudden impulses of anger, expressed in words or acts. The experienced can also tell, with like truth, that, in the common occurrences of life, angry words and acts have seldom, if ever, accomplished the purpose for which they were intended; they have neither obtained justice, nor punished the offender; but, on the contrary, they have often converted the injured party into an offender himself, and involved him in bitter recriminations, keeping up an irreconcilable aversion, and even enmity, through life. We have, so far, supposed there to be a real and justifiable cause of anger. But the case is very much stronger against the indulgence of angry feelings when the cause is only imaginary. It is in many cases imaginary, especially among young persons. They take up sudden impressions concerning the supposed conduct and words of their associates and acquaintances, when no such conduct or words have occurred; or, if any did, none with intention to wound or offend. If there be one case in which one feels himself peculiarly humbled, it is when he has manifested anger towards one who has committed no offence, or who is entirely unconscious of having done so.

It sometimes happens that an offended person can restrain himself from expressions and words when he has been seriously offended. But he cherishes a malicious sort of feeling against the offender, broods over the wrong done, and permits his imagination to inflame the sense of wrong, until he makes himself too unhappy, under this excitement, not to express it in some mode which will occasion pain or affliction to the offender. If there be any one who has fallen into such a condition, he may be asked, whether he knows of any thing in the nature of regret or remorse for his own follies and sins, which is so exceedingly burthensome as to carry about with him the feeling of aversion, ill-will, and malice, towards one who has offended? What, then, is to be done? angry words and acts are forbidden by the law of nature, by self-respect, and by convenience; the memory of an unavenged wrong is intolerable. Is there no remedy? We think there is one in every person's power. If the individual with whom one is at variance can, by calm expostulation or by mutual friends, be brought to a just perception of the case, that is the remedy. If that fails, there is another; it is of high authority: if thine eye offend thee, pluck it out. Blot such a person from the memory; never permit him to come into your thoughts. Will you pass your life in humiliating bondage to such an one? We say, *blot such an one out of your memory*. You do him no wrong by that. You do yourself a just and great good; you cut a moral cancer out of your heart.

Among the sources of affliction in human life, is the uncalled-for interference of third persons in the angry collisions of others. It may sometimes be an unavoidable duty to take a part in an angry quarrel. When this duty is to be performed, it concerns every one who is mindful of the trust confided to him of taking care of himself, not to engage in the controversy in such a manner as to become a principal party in it. As a general rule, it is the safe course to let angry persons settle their own concerns as they can. Certainly, no one who claims to be regarded as having a discreet sense of his own welfare, plunges himself into a quarrel. Yet this is a very common thing. It is often seen in schools. Parties and divisions grow up, extend, and become more and more bitter, from the most trifling causes, and are often carried out into manhood, and show their evil consequences through life. This is so, because impressions made in that season are very vivid and durable. It is a duty sometimes to take a part in controversies. It must be remembered, when one engages in such quarrel, that one is dealing with persons who are under a sort of derangement, and who are most exceedingly sensitive, and perhaps mutually vindictive. Those who interpose are bound, by the law of self-regard, to interfere with calmness and sound discretion, and so to conduct themselves, in word and deed, as to do no evil to themselves while they attempt to do all the good possible to the angry parties. On the whole, mismanaged anger is a prolific source of suffering. Yet when calmly looked back upon, in a great majority of cases, the cause was some insignificant trifle, magnified into serious importance by angry words and pitiful acts. Such is the propensity of persons to busy themselves in the quarrels of others, that there is little reason to hope that a preventative can be successfully offered to any but to those who have studied out and who reverence the will of the Deity, as disclosed in the nature of things, and in his own positive law.

SELF-RESPECT.

Every one has some sort of opinion, more or less distinct, of all persons with whom he is acquainted. This opinion may embrace intellect, disposition, virtues, vices, personal appearance, deportment, condition in life. So also every one has some opinion of himself on the same, and on many other subjects best known to himself. When one examines his own opinion of himself, he seems to do it as though he were another person. He uses the eyes of others. He turns aside, as it were, by the way, to see himself pass by. The judgment which one forms of himself is often much more unsound than that which he forms of others. The eye cannot see itself; so neither can any one see himself. He must use a mirror. There are many of these. History, books, daily example, his own experience, every person he comes in contact with, are mirrors. If he sees himself in these, and thereby corrects his own errors and follies, and gives himself reasonable and just credit for his attainments, he may come at length to be entitled to entertain a respect for himself. There is a certain best thing to be done, and a certain best manner of doing it, in all possible circumstances in which one may find himself. Nothing is entitled to be considered *best* which does not conform to natural law, the law of God, the positive law of the land, the conventional laws of society (so far as they are founded in reason and good sense), and to the decencies of life. To that best thing, and to that best manner, no one, perhaps, ever perfectly attains; but it cannot be doubted that there is some such standard. He who comes the nearest to it is he who is best entitled to entertain a respect for himself.

PRIDE.

There is a kind of pride which is often mistaken for *self-respect*. We hear of honourable and of laudable pride. We take pride to be that self-esteem in which a man holds himself. It may be founded in his estimation of the qualities of his mind, in his attainments, in his possessions, in his strength, his beauty, his parentage, and descent. It may also be founded in a consciousness of virtue, and of having faithfully done one's duty in all the relations of life. It seems to arise necessarily from comparing one's-self with other persons. If this be the right meaning of pride, it is very clear that it is not always a sentiment which entitles one to respect himself. A man would be thought to be very unwise who should openly declare that he valued himself, in comparison with other men, on account of his wealth, his beauty, or his family connexion; equally unwise, if he should declare his opinion of himself to be, that he was superior to other men in the gift of natural intellect, in the cultivation of it, or in the practice of the various virtues. The common sense of mankind, founded in natural reason, does not approve of that self-gratulation which rests on the accident of birth, of inheritance, nor even on the acquisition of fortune by one's own industry; nor does it approve of that feeling, when founded on qualities which belong to the mind, nor even in the practice of the virtues, unless when manifested in a certain manner. There must be, in the very nature of things, some persons in every community, large or small, who are superior to others in these sources of self-esteem. In every city, town, and village, in this nation, there are some persons who are in possession of some of these causes of self-esteem in some comparative degree, and other persons who have the fewest or the least of them. Those who so use their advantages as to entitle themselves to the esteem of others, and who are acknowledged to be respectable for that use, may well be entitled to respect themselves from such causes. Those who use them in such a manner as to announce the feeling of superiority over others, and habitually to offend the watchful feeling of self-love, are properly called *the proud*. It is believed that these views conform to natural law, and to the necessary constitution of human society.

VANITY.

A still greater mistake is made in substituting vanity for self-respect. The word vanity is made out of two Latin words which signify *exceeding emptiness*. It is commonly understood to mean a strong desire to be noticed, considered, and esteemed by others, but on account of things rarely worthy of a rational mind. Vain persons covet praise. They thrust themselves, and all on which they value themselves, upon the notice of others. They delight in recounting their achievements, and sometimes make the sad blunder of speaking to those who know they are mistaken. They touch adroitly on their own excellences, and provoke others to descant upon them. They have such delightful visions of self-complacency, that it seems cruel to disturb them. Such persons are very ready to become tools in the hands of more knowing persons. In general, the display of this poor passion is made by persons of very light and frivolous minds. It is seen at all ages, but strikingly in youth. To see a young person strutting or mincing along in a new garment, or in some personal ornament, and watching to see if he is noticed, and by whom, excites a feeling of pity and contempt. The same feeling arises when young persons are seen, who say in their movements, as intelligibly as though they spoke in plain English, "Do they not think me very handsome—elegantly dressed—a charming figure—most exceedingly graceful?" In some instances lookers-on do think so, and smile contemptuously at the same time. But, in general, lookers-on see no such thing as the vain imagine; they do see that which it would be shocking to those votaries of vanity to know *is* seen. They do see talents wasted, time misspent, foolish hopes, and vain desires. They do see that the purposes of life are misunderstood or perverted. Is there any remedy for these follies? None, probably, unless one would bring home to the minds of the vain, that they violate the strongest precept laid down in the code of natural law for the government of persons individually and socially. That precept commands them so to conduct themselves in all things, as to entitle themselves to self-respect, and, consequently, to the respect of others. If the vain could conceive how small a portion they make of created being, how insignificant a part they make of civilised society; how many there are in that society, whose pretensions, if asserted, would be transcendantly superior to their own, they might, perhaps, dismiss their little vanities, and devote themselves to gratifications worthy of their intended nature.

GRATITUDE AND INGRATITUDE.

If a destitute young person should attract the notice of a wealthy man, and should be by him supported, educated, and established in the world, so as to be able to live, to become independent and respectable, every one would say that this is a case for the feeling and the expression of fervent gratitude. Let us suppose that the patron of this young man frequently reminds him of his former condition, and by what means he finds himself where he is. Suppose the patron exacts a frequent acknowledgment of his bounty, and takes to himself unqualified praise for his goodness. Let us suppose that the obliged party finds his condition very irksome, and almost wishes that he had never been the subject of such burthensome favour, and is at length provoked to say so; *Is he ungrateful?* It would seem, then, that gratitude had two sides to it, as well as two parties. He who has conferred a favour has not done all which it concerns him to do; and he who receives a favour may have a difficult task to perform. A bargain is an exchange of one thing for another, and the parties are even. The conferring of favours, whether these be asked for or not, seems to stand on very different grounds. Many elements make up that compound from which gratitude is said to arise. The parties may understand the nature of the favour very differently at the time when it is conferred, and more differently afterwards. He who confers has a retentive memory; he who receives, a fading one: time engraves the favour deeper and deeper in the former, and wears it out more and more in the latter. In the former it often preserves the freshness of a new occurrence; in the latter the sense of favour often goes, and the weight of obligation alone remains. It may be that the complaints made against ungrateful persons are not always well founded, and that the expectations of those who confer favours are as little so. Some poet has written,

> He that's ungrateful has an only fault,
> All other crimes may pass for virtues in him.

The meaning of this couplet must be, that the members of society are under no obligations to confer favours, and that, if they do confer them, the party obliged is a monster if he do not—*what?* We know not what is intended, nor that there is any rule by which gratitude is to be manifested. We think that every member of society is to do what of good he can, and to whomsoever stands in need of it. He is not to stop to measure and calculate how he is to be paid for it. He may not be paid by the party benefited directly, but by some other, and in some other and unexpected way. Whosoever confers favours opens an account with the changes and chances and accidents of life. His credit side will look well in the close. If he confer a favour, he does it because he thinks he can, and ought to do it. He has the *pleasure* of doing it. If he wishes to avoid the affliction of ingratitude, he has only to avoid letting the party obliged know, unnecessarily, whence the benefit comes. When a favour is done, the party conferring it takes on himself the duty of respecting that feeling of the human heart which is founded in reasonable self-love, and which is entitled to respect—that is, *not to ask one who has had the misfortune to be bound in chains, to clank them for the gratification of him who put them on.* There are cases of extreme ingratitude. They may have been occasioned by the irritating or indiscreet conduct of the party who was entitled to a different return. They are not of common occurrence. When they do occur, uncaused, the disappointed party may hope to find a better subject in his next essay.

SLANDER.

This is a two-fold crime: 1. It is a breach of natural law, of divine law, and of the implied law of society, in relation to the party spoken of; 2. It is a breach of the same law, in relation to the party speaking. It has been commonly treated of in the first relation. It is now to be noticed in the second; and if it be shown why it is a breach in this, the other will take care of itself. We beg leave to ask a slanderer a few questions: Do you desire to be esteemed in society for your intelligence, your sense of justice, your knowledge of the decencies of life, and for the observance of them? If you happen to be ill-tempered, petulant, and disagreeable to your family connexions and associates; if you make hasty and troublesome judgments which you have to rescind or reform; if you happen to be ridiculous in your deportment, and remarkable for silly vanities; are you willing to have these things set forth in any, and every company, by any one who knows of them? Suppose there to be only some slight foundation for some one or more of these things, which, if you could have an opportunity to explain, would be entirely cleared up, are you willing to have that slight foundation made the basis of a structure of reproach, which, if true and real, ought to expel you from decent society? Suppose there to be no foundation at all for any such accusation of yourself, and yet somehow, and unaccountably, it is afloat and circulating, should you not think great injustice to be done to you? This is just what you do to others. You take away their good name, if they deserve to have one; you magnify their little faults and errors, and make them ridiculous or odious; you try them on indictments for serious offences, on which they have no opportunity to defend themselves, and of which they are ignorant. Where did you get your information? What credit were they entitled to from whom you had it? Did you understand them as they meant to be understood? Where and how did your informants learn what they communicated? Were they thoughtless or malicious slanderers like yourself? How much have you added to their slanders by way of recommending and making yourself agreeable? Have you broken any law by this conduct? We take the liberty to answer for you.

You have broken every law which an honest and honourable man, and a rational individual, should respect. 1. You have made every person whom you have spoken to, fear you and shun you. You have shown that you know not what the value of a good name is, and have forfeited your own, if you ever had any. You have shown that you are a stranger to self-respect; that you have probably every one of the faults, follies, and errors, which you impute to others; and desire to bring them down to your own level. Thus you have broken that law which commands you to do no evil to yourself. 2. You have violated that principle of natural law which commands you to do no injustice to your fellow-men. You know not what opinions you may entertain of the party you have slandered, if circumstances (as they may) should bring you into connection with him. You may find him to be, on a better knowledge of him, an amiable and worthy person. You may find all that you have said, and helped to circulate, utterly groundless. If he be one whom you occasionally meet, and even ask to partake of your hospitality, how can you meet him, and manifest towards him every sentiment of respect and esteem, when you have so spoken of him? One of two things must be true: either you *act a lie*, when you meet him in such a manner; or you *spoke a lie*, when you represented him as you did to others. 3. You have broken the law of God. To this law, perhaps, you are a stranger, and know not what wrong you have done. If so, the kindest thing that any one can do you is, to urge you to find out what it is, and to learn there the sentence of the slanderer.

It may be asked, whether one is to be entirely silent at all times, and on all occasions, as to the character and conduct of others? Certainly not. There are many occasions for speaking of others, and for speaking the *truth* of them, whatever that may be. All the members of any community are interested in knowing the true character of each other. The knowledge that this character may be known, is one of the most salutary correctives of erroneous conduct, and one of the strongest inducements to pursue that which is commendable. It is probably the case, that the members of every community are pretty well understood by all who have an interest in knowing them. We know not of any law which holds it to be immoral *to speak the truth of any one, from good motives, and for justifiable ends*. It is all-important that this principle should prevail in our country, where so much depends on public opinion. Surely one's arms are not to be folded, and his lips closed, when he sees one bent on mischief, public or private. It may be one of the highest moral duties to declare what men are, and what they are aiming at, in many supposable cases. There can be no surer guide than the *motive* and the *end*. Inquiries are sometimes made, in matters of greater or less interest, concerning others, confidentially, and where the inquirer needs to be truly informed. The party inquired of has a right to be silent, if he thinks he has good reason to be so; but if he answer, he is bound to state the truth. If he choose to speak, and wilfully conceal the truth, so that the inquirer is deceived, he subjects himself to the imputation of an intentional deceiver.

There may be also, and there frequently are, confidential discussions of character, especially concerning public men, and where perhaps there is no particular end in view. This does not seem to be wrong; such intercourse is not founded in malicious nor unworthy motives. It is even sometimes instructive and philosophical. This, perhaps, is the extreme limit. In all other imaginable cases, it is probably most consistent with one's own self-respect, and all truly respectable motives, to let other persons alone, and leave to them the care of their own characters.

PROFANITY.

Excepting the high crimes, which are punishable by the public laws, there is no one so shocking as *profanity*, nor any one which there is so little inducement to commit. Profane swearing is of two kinds: 1. That in which the Deity is called on to do the pleasure of a sinning mortal; 2. That in which the Deity is called on to witness the truth of such a being's thoughtless or wicked declarations. This common practice can be accounted for chiefly on two grounds: 1. Pitiable ignorance; 2. Abominable wickedness. On the first ground, surely the profane swearer must be ignorant of the import of the terms which he uses. If he did understand his own words, he would be struck with horror. Surely, if there be any escape for the profane from that condemnation which they imprecate on others, it must be, that mercy will be extended to them in compassion for their ignorance. On the other hand, if they are not ignorant, but do knowingly and wilfully so misuse the gift of an immortal mind, and that unquestionable proof of divine power and goodness, *the ability to speak*, they cannot be subjects of moral instruction. They should be left, like the consumers of alcohol and tobacco, to shock and to warn others.

Swearing, which formerly pervaded every rank of society, is now to be chiefly found in a very low and uninstructed class: it is, in fact, a vulgar and proscribed mode of speech. Nevertheless, it is still used occasionally by persons of no humble rank, especially by the young, though chiefly for the purpose of giving an emphasis to speech, or perhaps simply to give token of a redundancy of spirits and a high state of excitement. To those who are guilty of it for these reasons, it is only necessary to point out, that no well-informed person can be at the least loss, with the genuine words of the English language, to express all legitimate ideas and feelings, and that to use either profane or slang words, is, at the very least, the indication of a low taste and an inferior understanding. A direct, pure, manly use of our native language, is an object which all may cultivate in a greater or less degree; and we have invariably observed, through life, that the most virtuous persons are the most exempt from the use of mean and ridiculous phraseology, and monkey tricks of all kinds.

Does not one who is habitually profane, necessarily entertain a low opinion of himself? Would any respectable merchant, or mechanic, or farmer, receive into his service a youth whom he knew to be a profane swearer? Could any one who is known to be such, find admission into any school, academy, seminary, or college? Would any respectable parent admit such an one to be a companion of his children, or a visitant in his family? Would not every reasoning person say, that a youth who is so ignorant as not to know that swearing is a violation of natural and divine law, must be ignorant enough not to know that there are many other laws for the proper government of society, and consequently that he is an unsafe person to be trusted? If the profanity be the consequence of voluntary wickedness, then surely all reflecting persons would say, that he who is wicked in this respect, is indeed wicked; but then he will be wicked in others also. For, as there is one chain which runs through all the virtues, and binds them in a sympathetic union, so also is there a chain which unites all the vices. He who swears may be justly suspected of drinking; he who swears and drinks, may be justly suspected of gaming; he who swears, and drinks, and games, must keep very bad company by day and by night. He who keeps such company from such motives, must squander his own property, or steal that of somebody else to expend. He who robs another will commit forgery, and he who is so desperate as to commit these two latter crimes, will not hesitate long to put a human being out of the way of his pressing wants, if he is tempted to do it. It is probable that habitual lying and swearing are the first steps in that mournful series of crimes, and the first beginnings in the course of deplorable wretchedness, which deform and disgrace human society. Will any one maintain that these are necessary evils, and that God has so made man that they cannot be prevented? Surely these are evils wholly of human origin; and where they begin, there lies the power to extirpate them.

ENVY.

It is to be kept in view that the main object is to show that this is a good sort of existence, if man knew how to use it, and that he is the author of his own afflictions. This is remarkably illustrated in the matter of *envy*. It is probable that a large proportion of mankind, in all classes, suffer from the dominion of this passion. It can be shown that it is peculiarly the passion which man has made for himself out of emulation, which latter is the Creator's work. In this instance, man has been exceedingly ingenious and successful in making himself miserable. He has done worse: he has provided for himself, in creating envy, a fountain which sends forth not one water, but many, and each one foul and poisonous. He who has submitted himself to envy has bound himself to think, to feel, and to act, as envy prompts. It would be most shocking to know what agency this monster has had in human affairs. If any one should read history, and watch the movements of his fellow-men, merely to learn the operation of this principle of action, he would see, probably, the most operative cause of the misery which men inflict upon themselves and on each other. If one has not time to read history, and watch his fellow-men, he may perhaps learn much of what he would find in these authorities, by *reading his own heart*.

The word envy comes from two Latin words, *in* and *vidio*, and signifies looking *against*. It arises from perceiving in other persons, qualities which one's own self-love leads him to wish to have—as beauty, strength, grace, learning, eloquence, power, &c. It extends to riches, to office, to distinction, to the respect and esteem in which one is held by his fellow-men, and even to birth and ancestry. It makes one *sorry* that he has not these good things, and makes him *angry* that others have them. One easily persuades himself that great injustice is done to him, in that *he* has them not. The next step is to *hate* him who has them. Then comes the desire to deprive the supposed fortunate possessor of the benefit of them. But to admit that one has these malignant promptings, is contrary to another principle of self-love; and therefore no man tells another of his own envy, and he tries to wrap it up from his own view. As he cannot and dare not openly manifest that he is envious, he must obey the suggestions of malice in the dark. He therefore intrigues, insinuates, and becomes adroit in putting one thing for another; he secretly and by covert means undermines the object of his hatred. He whispers his doubts, suspicions, opinions, and belief. If the tenure of the hated object is too strong to be shaken, then the bad use which he makes of his advantages are sought out. The base accompaniments of his fine qualities are brought forth, and placed in the strongest light. "She is beautiful; *but* she is vain, haughty, and silly. He is rich, *but* he got his wealth by frauds, and hoards it like a miser. He is able, eloquent, and popular; *but* he is selfish and insincere, and would put a yoke on every neck in the country, if he could. He is making a great flourish in the world, *but* it is all false and hollow; he came from nothing, and will go back to nothing." It may be easily inferred that one who has surrendered himself to the dominion of envy, not only deprives himself of the profitable use of what he has or might have, but makes himself wretched in contemplating what he must know he cannot have; he is so wrought upon, that whatsoever seeds of crime he may have in his heart, are sure to start into luxuriant growth.

Can any rational being doubt that this sort of suffering and crime are entirely of man's making? Can it be doubted that he can prevent them? These are violations of natural law and divine law; and no law comes from this source which cannot be understood and obeyed. Let us take an example, and seek out the unreasonableness and immorality of envy; and to do this effectually, we must take a strong case, and in some degree a fanciful one. Let us suppose that in a seminary of females there is one who is very beautiful; her parents are very rich, and are highly respectable; and that this young lady is distinguished by her genius, and her diligence and good conduct, and is obviously in the receipt of the preceptor's unqualified approbation. Let us further suppose that there are some of her schoolfellows who envy her. Their countenances show what they feel. Every mark of favour manifested to this fortunate person is a blow on every envious heart. Discontent, distress, and malignity, take up their abodes in these hearts, and enter into thriving partnership. But the beauty, the genius, the diligence, the wealth, the parentage, the applause, are not among the dividends which these partners make; these remain where they were; and what dividends do they make? Let us suppose that the envious would do what they would; that is, annihilate the envied qualities, and make the possessor too low and contemptible to be more thought of; and let us suppose, too, that the successful adventurers succeed to what is now the first eminence; is there no one below to pull them down? They are soon down, and by like means; and thus the demolition would descend, until the seminary became too low a place for even envy to find something to live on.

Is not this a fair example of what we continually see in all grades and classes of social life? and is not this passion of envy, earthborn, mischievous, and odious? What is the remedy? Common sense and plain reason point out the remedy. Generally speaking, every member in society is just as much in his own place as he is in his own skin. No one can be in another's place. Every one has his place originally assigned to him, and his natural condition in it, by means over which he had no control, and in making which he had no agency. What he will make out of himself, and of the circumstances in which he finds himself, must depend (after the irresponsible state of infancy is passed) on his own thoughts, motives, and acts. He will find his greatest good, not in repining at the good of others (which he can never make to be his own, and which he cannot destroy without expecting retributive justice as to himself), but in making his own condition as good as he can, consistently with self-respect and peace of mind. That which is given to others, and all that they can lawfully acquire, is righteously their own. All that is given to one's-self, and all that he so acquires, is in like manner his own. If he would have no injustice done to him by those who are below him, he must do no injustice to those who are above him. We entertain no doubt that the day will come when youth will be so instructed, and men so self-disciplined, as to know that the laws of nature and the laws of society, when conformable to these, permit to every person a proper place, enjoin duties in that place, and ensure happiness from the performance of those duties. When that day comes, envy will die.

EMULATION.

This has been sometimes classed with envy, but they have nothing in common. One would feel like a culprit in being known to be envious, but would rightly take praise to himself in being emulous. This motive to action was given to man for the best possible purposes; and upon the application of it, with justifiable views, and to commendable ends, the advancement of human welfare mainly depends. We understand it to mean, the desire to obtain excellence in laudable pursuits. An envious man may be supposed to say, "Your eminence distresses me; I cannot bear to see you sitting up there; and though I have not the shadow of hope that I can ascend to your place if you were out of it, nevertheless I must pull you down if I can, and then we shall stand on the same level." An emulous man may be supposed to say, "I admit that you are where you should be. You have raised yourself by fair and just means. I have no desire to disturb you, nor to impede your further progress. You have done me no injustice; on the contrary, you have rendered me the important service of showing me how one may honourably rise.

I shall follow your example, and endeavour to place myself by your side. If I can get there, we shall have a fair, good-tempered rivalry, and we may animate and quicken each other's efforts. If you are able to keep always in advance of me, you will make me diligent, and enable me to excel others, if I cannot equal you." There seems to be nothing immoral in this. In this view, emulation is presented in its true and amiable character. Like every thing else entrusted to man's use, it may be, and often is, perverted. It frequently excites very unworthy feelings. Hence it has been confounded with envy. It is upon the principle of emulation that diligence in schools is commonly founded; and it is in schools that the perversion alluded to is frequently noticed. When several children are required to get and recite the same lesson, there must be a best and worst among them. That they are such, respectively, may depend on natural talent, and upon industry, or on both. It deserves great consideration, whether rewards and punishments are generally understood in their true philosophy. There must be emulation in schools; because there is, and ought to be, that stimulant every where in all the vocations of life. If men had not the advantage of comparing themselves with each other, and the promptings to exertion which arise from that comparison, this life would be very still and stupid. But what use is to be made of this principle in schools? is a question of exceeding interest. We express no opinion on this point, because we might not express a sound one, and might thereby do some injury, and very possibly no good in any case. Add to this, that such an inquiry does not come within our general object.

PEACE OF MIND.

It is believed that most persons pass a large portion of their lives in a state of inquietude and uneasiness. Persons who have no bodily disease are anxious and disturbed. They have some urgent want which cannot be gratified, or which cannot be so, without incurring some evil, which would be worse than the unsatisfied want. They have the dread of some probable or possible evil to come, and which is the more terrible because of the uncertainty of the manner and of the time in which it may come. Others are uneasy from remembering the past, in which some benefit was not secured, some blunder made, some wrong done to themselves, some vain gratification not obtained. There are many persons who are habitually discontented. They find every thing goes wrong. The weather is bad; their food is not as they would have it; no one does any thing in the right time, or right manner; or that is done which should not be, or that is omitted which should be done. Such persons are always groaning, sighing, or grumbling. They dislike every body, and every body dislikes them; and particularly, their abundant *advice* is disliked, and their manner of giving it. There are other persons who are of unquiet mind for more serious causes. They have recollections which distress or torment them. They are transgressors; perhaps criminally so. They have been able to conceal this, but they live in the fear of disclosure; at any rate, the fact cannot be hidden from themselves.

These are frightful instances of the agency of this companion which every man has in his own bosom. There are hours in every one's life, when he must compare the condition in which he is with that in which he thinks he might have been. To some persons, these are hours of dread and terror. It is believed that this cause of suffering is purely of human origin, and that prevention must be found where the error began. It is the law of the Deity that there shall be such suffering when the guilty mortal makes it necessary to apply that law. There are great differences in the temperament and natural dispositions of persons. It is incredible that the worst-tempered person would not make a better whole of life, by suppressing their natural propensities, and acquiring a control over themselves, and teaching themselves to look out for what may be pleasant and agreeable (passing by that which seems ill to them), instead of doing exactly the reverse.

There are cases in life in which it is said there must be anxiety and inquietude, from the very condition in which men are placed. Persons who sustain public offices, persons who are placed in important trusts, persons whose vocations are perilous, those who are pricked by the thorn of political ambition. It is probable that such persons do experience many painful and distressing emotions, and that they sometimes pay dearly for their distinction; but it is demonstrable that even such persons might have tranquillity, if they had a right frame of mind. There are persons who substitute an aching solicitude for the reasonable discretion and care, which is all that is required in the performance of duty. There are others who greatly overvalue the distinctions to which they attain or aspire; and very few of them reflect, that, when they do succeed, they must take success, especially in popular governments, with the accompaniments of having their worthy acts misunderstood and reproached, and their mistaken ones magnified and distorted, to suit the occasions of adversaries.

The remedy for this sort of suffering is within every one's power. Those who are poor, and in humble life, if not in extreme poverty, may possess peace of mind; and it is of easier acquisition by these than by those who are involved in the duties of office, and the responsibility of trust, and the embarrassment of wealth. Certainly, without this treasure, no earthly grandeur, no promise of posthumous glory, is worth having or seeking for. If the laws of nature, and the teaching of revelation were properly known, respected, and obeyed, the common causes of inquietude would hardly be known. For example, what is more common than complaints of the weather? It is too hot or cold, wet or dry. It is not nature that mistakes about the weather, but ourselves. The movements of the winds and the waters, and the temperament of both, proceed on some great and universal laws, far beyond human perception. That which is exacted of us to believe is, that it is so, and to adapt ourselves to it, by our experience and ingenuity. What sort of effect would it produce in the earth, if such things were regulated by human perception of what is best? When one has occasion to put to use a board or stick of timber, which has been in contact with the ground for a certain length of time, he disturbs and puts to flight families, communities, and whole nations of living beings. Man may be much in the same relation as to general laws (not meant for him to comprehend), in which these insects are on the removal of their covering.

As to all causes of inquietude arising from the operation of nature's laws, in which human agency has no concern, they must be right, although they occasion inconvenience to individuals. As to the acts and omissions of others which affect us, some questions are to be asked and answered before one can rightly judge of these; viz., what is the real cause of our complaint? Did not the first fault arise from some act or omission of our own? Do we judge reasonably of the supposed wrong? Do we make charitable allowance for the misapprehension which may affect the party complained of? When the inquietude arises from our own wayward and peevish disposition, from our own misconduct, negligence, or breach of laws, which we could know if we would, the remedy lies in becoming wiser and better, and more reasonable in learning how we may make of life that which it was intended to be, when we use it as we should. Let any reasonable being look back on his own life, and calmly consider the causes of his own contentions, ill-will, and sufferings, in body and mind; how many of these can he fairly lay to the blame of the Creator's laws, of nature's laws, or those of society, whether positive or implied? If to these he can charge but very few, who but himself is there to take the residue?

We have been trying to show what peace of mind is not. We have to show what it is, or rather in what it is founded. It comes from sober conviction that the Creator has made his own laws for his own universe; that he requires conformity to these laws; that he permits and enjoins the use of what is good and right; that he punishes all that is wrong and disobedient. He has trusted every mortal with his own welfare, but has associated him with others who live in the same trust, each one for his own, but yet for mutual welfare. All are to contribute their common efforts to the common good. Those who have the means are to aid others in acquiring a knowledge of the laws which are common to all. If these laws were understood and applied, how abundantly would peace of mind increase in the world! The schoolboy would get his lessons and obey his preceptor; the labouring classes would labour diligently, live temperately, and find a greater pleasure in their frugal food than the luxurious in their festivals; for the former live as nature orders, the latter as fashion dictates. The opulent and luxurious would learn that the accidents of their fortune do not exempt them from the laws of nature; that, if they have affluence beyond their reasonable and commendable wants, they are blessed with the means of purchasing a precious name; they would learn that no wealth will exempt any man from earning an appetite for his pleasures by physical motion; that, if he is tired of being rich and happy, *he must work* to accomplish some reasonable purpose. His distinction is, that he may choose the means in which he will expend *to be busy*, while others can only work in some prescribed mode *to live*.

The middle classes, and all who are not dependently poor, have as many and as valuable sources of enjoyment as those have whom they think to be better off than themselves. They can love and be loved; they can be respected and esteemed; they can have the consciousness of behaving well, where their lot has been cast; they have a far keener zest for natural and reasonable pleasure than those who misuse the bounties of accidental condition; they can have peace of mind when it is denied to those whom they deem more fortunate. If these natural laws, which seem to be so plain and obvious, were understood and respected, the labourers *in mind*, in all their varied employments, would do diligently, and in the best manner in their power, that which they have undertaken. Men of public trust would do honestly, and with a single view to their trust, that which they have undertaken. Suppose it were all so, and yet troubles and disappointments come. This may be, and yet there would be peace of mind. If every one were assured that no act, no omission of his own, makes him suffer, that he has acted faithfully and honestly, and to the best of his ability in the circumstances in which he was placed, he would be entitled to have, and by the law of immutable justice, he would have, *peace of mind*.

HAPPINESS.

There is no word in our language more commonly used, nor any one less defined or less understood. It is sometimes taken to mean pleasurable sensations derived through the senses; sometimes it means a peculiar state of mind. It may be said that a pirate who has been brought to the most perfect penitence, and who is sensible that he has forfeited his life to the demands of justice, and that he is about to be transferred from the perplexities and sufferings of this state of being to endless felicity, is *happy* that he is going to be *hanged*. Perhaps it is easier to tell what happiness is not, than what it is. The most perfect *health* is not happiness, unless one has something to do. Health and *riches* do not make one happy. These accidents of being, rather excite cravings for enjoyment. They are means, not ends. A rich man can ride but one horse, or sit but in one coach, or eat but one dinner, or wear but one suit of garments, or live but in one house, at a time. Persons in moderate circumstances can do the same.

Health, riches, *power*, and *distinction*, do not make happiness. Distinction is troublesome: it has more pains than pleasures; it is jealous, envious, and distrustful. Power does not make one happy; it demands the most busy watchfulness to keep it. If lost, its absence is often followed by painful suffering, and the possession of it is always accompanied with the fear of losing it. Riches are sometimes regarded as means of enabling one to live in elegant luxury, and even in voluptuous enjoyment. This is no way to be happy; the appetite soon become satiated; the stomach wears out; the senses are palled; diseases come; the body may be racked on a velvet couch as well as on a straw bed. Is there, then, any such thing as happiness? There must be such a thing, or the laws of nature, which provide for physical, intellectual, and moral being, are false and deceitful, and the gift of revelation is a fable. If there be such a thing as happiness, it will be found in that knowledge of and obedience to the laws of nature which make health. It will be found in obeying the propensity to action, to some continuous, useful end; that is, in pursuing reasonably some one of the many vocations in society which tend to secure one's own self-respect and peace of mind, and which tend also to the common good. But there may be disappointments, ill luck, and causes of mortification and sorrow. These, we apprehend, do not seriously disturb any well-regulated mind, when there is a consciousness that no reasonable foresight or prudence would have discerned and prevented the cause. Finally, one may feel assured, that if he so live as to be healthy, so use his time as to be reasonably busy, to some good purpose, and so couduct himself as to be justly entitled to his own approbation, and if he live in the habitual assurance that there is an omnipresent, omniscient, and merciful judge of moral, accountable, and immortal man, he will certainly be happy.

FROM THE EDITORS.

The matter of this sheet has been extracted, with a few slight alterations, from the Moral Class-Book of Mr William Sullivan, published two years ago at Boston, in the United States, and of which we have already given a few specimens in *Chambers's Edinburgh Journal*. Of the excellence of purpose, firmness and expressiveness of language, profound observation, and amiable sentiment, displayed in this book, we need hardly speak, after presenting the reader with such ample materials for forming a judgment of his own. It is impossible, however, to omit the opportunity of congratulating our brethren on both sides of the Atlantic—for we never can consider them but as one nation—on the rise, in America, of a body of moral writers, of whom Mr Sullivan is but a specimen, who seem resolved, as they are unquestionably able, to seek the improvement of their fellow-creatures in all that tends to elevate them in the scale of being. If it did not appear invidious, we would even be inclined to say that moral literature in America is at present under happier auspices in some respects than it is in our own country: a higher order of talent seems there applied to the humbler and more useful class of subjects, than amongst us. While this is to be candidly acknowledged, it affords us the greatest pleasure to find ourselves able, by the command of so many channels of publication, to diffuse the better writings of our American contemporaries in Britain, by which our more immediate countrymen are put in possession of what they could neither obtain from the writers of their own country, nor, to any great extent, in its original shape. We originally intended to reprint the Moral Class-Book piecemeal in the Journal, and had made some progress, it will be recollected, in parcelling out the introductory part, which consists chiefly of a view of the evidences for divine revelation. We found, however, that not only was this apt to induce a sense of tediousness, but it prevented the force of the author's reasoning from fully taking effect; and we subsequently formed the resolution of presenting the bulk of the volume in two numbers of the Information for the People. The present sheet contains M. Sullivan's view of the Duties which one owes to Himself: another, to be published a little later in the series, will comprehend the Duties which one owes to Others, as classified in the opening paragraph.

EDINBURGH: Published by W. and R. CHAMBERS, 19, Waterloo Place; also by ORR and SMITH, Paternoster Row, London; and YOUNG and CUNNINGHAM, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers in Scotland, England, and Ireland.—Published once a fortnight.

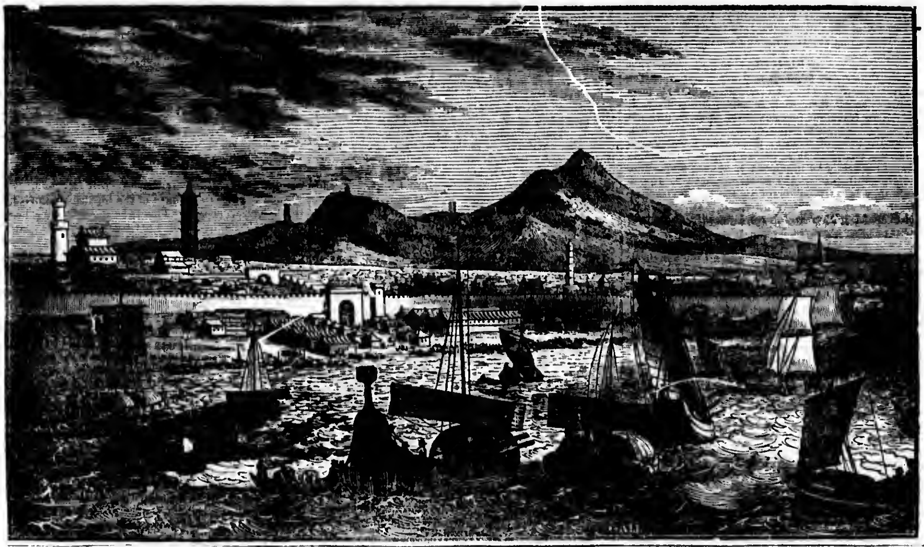
CHINA AND THE TEA TRADE.

VIEW OF CANTON.



GEOGRAPHICAL POSITION—BOUNDARIES AND DIVISIONS.

CHINA—called by the inhabitants Tchong-Koue, or the Middle Kingdom, from an idea that it is the centre or heart of the universe, around which all the other nations of the world lie scattered like minor provinces—is an immense country of Asia, extending 18° from north to south, and about the same from east to west, and lying between 20° and 47° of north latitude. It is conterminous with Asiatic Russia on the north-west; bounded on the south and east by the Pacific Ocean (that part of it being commonly called the Chinese Sea); on the west by huge mountains and sterile deserts, separating it from the great body of Asia; and on the north by the regions of Tartary, from which it is separated by the stupendous erection known by the name of the Chinese Wall, which extends 1500 miles in length. The Tartars call China Catay and Nicancarou; the Japanese, Thau; and the natives of Siam and Cochin-China, Cin (pronounced Chin or Tsin). From the latter countries lying nearest (nautically) to the Hindostan dominions, it is conjectured, with much probability, that the last-named appellation first gave rise to the European name of China. Some theorists, however, set down its derivation from the patronymic of the first imperial family Tsin, or Tai-tsin.

It is divided into fifteen provinces. Pe-tchelee, Shansee, and Shensee, are situated towards Asiatic Russia on the north and north-west; Setchuen and Yunan on the west; Quansee and Quanton on the south; Fo-Kien, Tchekian, Kiannan, and Shantong, on the east; and Honan, Houquang, Koetchou, and Kiangsee, in the central region. Of these provinces, a survey was made by some Jesuit missionaries, employed by the Chinese government, nearly a century ago, the execution of which occupied about ten years. A manuscript map, by a Chinese, constructed according to this survey, is now preserved among the archives of the Royal Library of Britain. Pe-tchelee is now the principal province in the empire, from its capital Pekin being the residence of the emperor and seat of government. Its name signifies the northern court, in contradistinction to Nankin, or the southern court, where the emperor formerly resided.

The whole area of China is estimated at one million and a half of square miles, or upwards of eight hundred and forty-three millions of acres, of which six hundred and forty millions are reckoned arable.

INTERNAL APPEARANCE AND CLIMATE.

From its immense extent, it may easily be imagined that China presents almost every variety of scenery. "In the long line of internal navigation," says Mr Barrow, "between the capital (Pekin) and Canton, of 1200 miles, with but one short interruption, the traveller will observe every variety of surface, but disposed in a very remarkable manner in great masses. For many days he will see nothing but one uniform extended plain, without the smallest variety; again, for as many days he will be hemmed in between precipitous mountains of the same naked character, and as unvaried in their appearance as the plains; and, lastly, ten or twelve days' sail among lakes, swamps, and morasses, will complete the catalogue of monotonous uniformity. There is a constant succession of large villages, towns, and cities, with high walls, lofty gates, and more lofty pagodas; large navigable rivers, communicating by artificial canals, both crowded with barges for passengers and barks for burden, as different from each other, in every river and every canal, as they are all different from any thing of the kind in the rest of the world." One general feature, however, pervades the empire—the utter nakedness of the country, as respects trees and hedges.

The climate of China embraces almost every degree of the thermometer. In Canton, it ranges from 80° to 90° during the summer, but the winter months are so cool that many of the inhabitants use fires. There can be no more certain criterion of the climate of any country than its vegetable productions, and we may therefore mention here generally, that within the bounds of China are all the varieties of tree, shrub, flower, and herb, to be found growing in every other country of the world. The temperature, however, may be generally described as rather warm than cold; but it is much affected by the direction of the winds, which may be literally said to "box the compass," with uniform regularity, during the various seasons of the year. They blow from the north and north-east in October, November, December, January, February, and March, during which months the weather is rather cold; in April and May, from east and south-east, when it is milder, but still cool; in June and July, from the south and south-west, when it is hot; and in August and September, from the west, when the temperature is oppressively sultry and hot. Speaking summarily, the coldest months are November, December, and January; the warmest, July, August, and September. Canton, although situated in the same parallel of latitude as Calcutta, is so much cooler during the winter months, that fires are generally used; nay, ice has frequently been found at Canton of the thickness of a dollar, but snow is never or rarely seen. The air is generally dry during the north, moist during the south, and clear during the west winds. The north winds are the most violent, and the south the most feeble. In the months of July, August, and September, the hurricanes, called by the inhabitants *Tay-fun*, usually occur, which, although extremely violent, and coming in sudden gusts, seldom occasion much disaster, owing to the inhabitants being prepared for them. The climate of China is on the whole highly salubrious; and many of the complaints common to the whole of Europe are there unknown. The Chinese profess to be free from stone, gout, and gravel complaints; and they are at all events seldom affected with cutaneous diseases. Much doubtless is owing to their uncommonly temperate mode of living, of which we will have occasion to say more hereafter. Epidemic fevers, however, are very frequent and fatal, arising from the crowded state of the towns and numerous swamps. The small-pox, too, was formerly very destructive, from the characteristic prejudice of the Chinese against all foreign innovations, however beneficial in the mode of treatment. Their physicians pretended to distinguish *forty* different kinds of small-pox; and when a favourable sort appeared, they endeavoured to propagate it, not by inoculation in the usual mode of incision, but by inserting into the nostril a little cotton wool dipped in the virus, or putting on the clothes of the infected! Of late years, however, the European mode of vaccination has generally been adopted, and at the present moment has perhaps entirely superseded the ancient practice. Sore eyes, and even total blindness, is very common, and is undoubtedly to be ascribed to their low crowded and smoky habitations, conjoined with their practice of bathing their face in warm water even in the hottest of the summer months.

Several parts of China have suffered much from earthquakes; but there is no appearance of volcanic eruptions throughout the country, though various substances of that description are found in some of the islands along the western and southern coasts.

HISTORY.

From the grossly fabulous and exaggerated nature of the Chinese records, an air of doubt has been thrown over all their early annals. Pretending, as they do, to trace the foundation of their empire not only as far back as the time of the deluge (of which, it is well worthy of remark, their traditions bear attestation), but even to a period long antecedent to it, it can scarcely be wondered at that a disposition should prevail to reject the whole as purely fictitious. There may be as much error in too great disbelief, however, as in too ready acceptance. The early annals of every nation are mingled up with much that is absurd, and obscured by the suggestions of ignorance and superstition. Nor are those Chinese historians, who trace the origin of their kingdom back through ninety millions of years before the Christian era, a whit more deserving of ridicule than the Romans themselves, who, with all their enlightenment, believed that the gods of their barbarous mythology took an immediate and active share in sublunary matters. The only substantial ground for wonder, in regard to China, is, that many modern writers, some even of our own country, should have given in their adhesion to the fabulous records of the native historians, and pretended to have established beyond doubt that the Chinese empire was founded more than 2000 years before the Christian era! The following may be given as an abstract of the result of their veracious theories:—They suppose that Moses, by Mount Ararat, does not mean to particularise any individual mountain, but merely the first land which showed itself upon the subsiding of the deluge, which they conjecture to be the elevated parts of Asia: That he followed the track of the large rivers of China which flow southward, as leading to a fertile and open country, and became the founder of the Chinese monarchy—identifying him with the Fo-hee or Foo-shee of their history: That, becoming offended with the impiety of his rebel offspring, he separated himself from them shortly before their presumptuous erection of the Tower of Babel; and steering his course eastward, after 200 years' peregrination, settled himself in one of the northern provinces of China (2114 years before Christ). Here, having settled his colony, and established the religion, laws, and government, which he had received from his antediluvian ancestors, he died in the 115th year of his reign, and 950th of his life (1999 years before Christ). He was succeeded by Shin-nong or Zing-nung, who reigned 140 years, and at his death (1859 years before Christ) left the crown to Whang-tee or Hoang-tee, the inventor of Chinese arithmetic and other arts, who reigned 100 years; and at his death left the crown to Shau-hau (1759 years before Christ).

But it were a mere waste of room to complete the enumeration of this genealogical succession of princes. Suffice it to say, that these theoretical historians trace it, with painful accuracy, down to the reign of Yau (1452 years before Christ), in the 67th year of whose monarchy happened the remarkable solstice mentioned in the book of Joshua, and which is actually noticed in the old Chinese annals, although without the specification of any year. From this time downward, the national records have undoubtedly some appearance of veracity, being principally contained in the *Shoo-King* (or history) written by Confucius, who lived about 500 years before the birth of Christ. Mr Barrow, to whose researches the present age is chiefly indebted for the information most deserving of belief respecting this singular nation, suggests a much more moderate and rational statement, of which the following is the substance:—He observes, that although the Chinese may be admitted to have been among the first nations of the world, after the flood, yet they do not appear to have made such progress in arts and learning as the Chaldeans or Assyrians; that is, only from the time of Confucius that they seem to have advanced in civilisation; that previous to his time, the country was divided into a number of petty kingdoms, under separate chiefs, with a recital of whose reciprocal wars and struggles for superiority the Chinese annals are chiefly filled; that their historical records are sufficiently abundant and complete during the last 2000 years, and the transactions of each reign fully detailed without interruption, down to the present time; and that, during this time, the empire of China has been less disturbed by foreign wars or intestine commotions, than any other portion of the world of which we possess any accounts.

Even from this view of the subject, very great deductions must be made. We are, however, compelled to walk according to our lights, and to offer the following summary of the Chinese dynasties from the period when their chronicles begin to assume an air of probability:—

From the reign of Yau (mentioned above) until the final succession of the present royal family of Tching, or Ta-tsin, in 1644 (A.D.), the Chinese annals enumerate twenty-two imperial dynasties. Three royal families are mentioned as having possessed the throne from 1767 till 258 before Christ—Kia, Shang, and Chew. About the latter year appeared a Chinese hero, Chi-hoang-ti, who overran the empire, extirpating all the petty chiefs and rulers, and uniting the whole of China. He also built the great Tartar or Mongolian wall, and reigned until the year 207 before Christ. This prince was the first of the present family of Ta-tsin, who of course are justly proud of their great claims to antiquity.

The empire was, however, again dismembered, after his death, under his son Ul-shi, but was reunited, ten years later, by Lieu-pang. He adopted the new name of *Hong*, and founded the dynasty of Hang. The princes of this dynasty extended their conquests considerably to the west, and took part in the affairs of Central Asia. The religion of Tao-tse prevailed during their ascendancy; and in the same period Judaism was introduced into China. In the course of time, the princes degenerated, and, under Hien-ti, China was divided into three kingdoms (220), which were again united by Wu-ti (280). Whilst the whole aspect of Europe was changed by the general migration of nations, two empires were formed in China, with the extinction of the dynasty of Tsin—one in the north (386), and the other in the south (420). After this, China was torn by internal commotions, and almost every province had a separate ruler, when, in 900, the people elected the able Shao-Quang-Yu emperor. He was the founder of the dynasty Sing, or Song, which reigned till 1279. His immediate successors resembled him, yet the country suffered considerably by the devastations of the Tartars. Under Yin-tsong (1012), the Chinese were forced to pay tribute to the Tartar Leao-tsang. Whey-tsong overthrew the empire of Leao-tsang (1101); but the Tartars possessed themselves of the whole of the north of China (Pe-cheli), 1125. Kao-tsong II. was their tributary, and reigned over the southern provinces only. Under the emperor Ning-tsong, the Chinese formed an alliance with Genghis-Khan, and the Niu-cheng submitted to this great conqueror (1181). But the Mongols themselves turned their arms against China, and Kublai-Khan subjected them, after the death of the last emperor, Ti-ping (1260). Under the Tang dynasty, arts and sciences flourished in China; several of the emperors themselves were learned men. The Chinese authors call the Mongolian dynasty of emperors *Yuen* (from 1279 till 1368), and Kublai-Khan is by them called *Shi-tsu*. This was the first time that the whole of China was subjected by foreign princes. But the conquerors conformed themselves entirely to the Chinese customs, and left the laws, manners, and religion of the country unchanged. Most of the emperors of this line were able princes. But after the death of Timur-Khan, or Tsing-Tsang (Tamerlane), 1307, and still more after that of Yeson-Timur-Khan, or Tai-ting (1318), divisions in the imperial family frequently occasioned internal wars, which weakened the strength of the Mongols. The Chinese Chu took up arms against the voluptuous Toka-mur-Khan, or Shunti, and the Mongolian grandees became divided among themselves. Toka-mur-Khan fled into Mongolia (1368), where he died (1379). His son Bisurdar fixed his residence in the ancient Mongolian capital Karakorum, and was the founder of the empire of the Kalkas, or northern Yuen. This state did not remain long united; but, after the death of Tokoz-Timur (1400), each horde, under its own khan, became independent; in consequence of which, they were, with few exceptions, constantly kept in subjection to China after this period. Chu, afterwards called Tai-tsoo IV., a private individual, but worthy of the throne, delivered his country from the foreign yoke, and founded the dynasty of Ming (1368 till 1644), which gave the empire sixteen sovereigns, most of whom were men of merit. On the frontiers of the empire, the remains of the Niudshee Tartars, now called Mantchoos, still existed. The emperor Shin-tsong II. gave them lands in the province of Leao-tong; and when an attempt was made, soon after, to expel them, they resisted successfully, under their prince Tai-tsu, and obtained possession of Leao-tong; upon which their chief assumed the title of emperor. He continued the war during the reigns of the Chinese emperors Huan-tsong and Hi-tsong, until his death. His son Ta-tsong succeeded him, and Hoai-tsong, a good but weak prince, was the successor of Hi-tsong on the throne of China. On the death of Ta-tsong, the Tartars did not appoint any one to succeed him, and discontinued the war. But in China, Li-tching excited an insurrection, during which Hong-Puan put an end to his life (1644). Li-tching's opponents called in the Mantchoos to their assistance. They got possession of Pekin, and of the whole empire, over which they still reign. Under Shum-chi, a child of six years old, the conquest of China was completed (1646–47), and the present dynasty of Tsing was finally established. He was succeeded, in 1662, by his son Kang-hi, who subdued the khan of the Mongols, took Formosa, and made several other additions to his empire. During the reign of this prince, the Christian religion was tolerated, but his son Yong-ching prohibited it in 1724. The son of the latter, Kien-Lung, continued the persecution against the Christians (1746–73). He conquered Cashgar, Yarkand, the greatest part of Songaria, the north-eastern part of Thibet and Lassa, the empires of Miao-tse and Siao-Kin-tshuen, and extended his territories to Hindostan and Bucharia. He peopled the Calmuck country, which the expulsion of the Songarians had rendered almost a desert, with the fugitive Torgots and Songarians from Russia. In 1768, he was totally defeated by the Burmese of Ava; nevertheless, the Chinese took possession of a town in Ava in 1770, and returned to their country with the loss of half their army. They were more successful against the Miao-tse (mountaineers). Towards the end of his reign, his minister, favourite, and son-in-law, Ho-Tchingtou, abused his influence over him. Kien-Lung was succeeded, in 1799, by his 15th son, Kia-King. His reign was frequently disturbed by internal commotions. The Catholics, whom he favoured, have lost most of their privileges by their inconsiderate zeal; and at Pekin, the preaching of the Christian religion has been strictly prohibited. Kia-King was succeeded, in 1820, by his second son, Tara-Kwang, whom the Russians call *Daoguan*.

Such is a brief summary of the historical annals of this singular people. Throughout their chronicles occur many periods which are completely blank, and these chasms have been filled up, as usual, with gross fables, which throw an air of doubt over the whole; but it is worthy of remark, that many of the leading facts recorded in their more veritable histories, have been confirmed by contemporary travellers and historians of other nations.

On the whole, however, it appears, that, instead of having existed as a great and united nation from a period of 3000 years before Christ, as the natives pretend, China was not formed into one state until between 200 and 300 years before Christ. Since the establishment of the Mogul dynasty, the empire has not been again divided, but has experienced two great revolutions, at the accession of the Chinese dynasty of Ming, and the re-accession of the Mantchoo Tartar dynasty (Tsing) in 1644; and has scarcely in any reign been free from revolts, wars, and domestic seditions. Instead, therefore, of having a right to be regarded as a privileged country, governed from time immemorial by the same constitution, exempt from foreign conquest and intestine commotions, the only peculiarity it possesses, distinct from the other empires which have been swept from the earth, is—that, owing perhaps to its peninsular situation, at the extremity of the habitable world, and its consequent exemptions from the destructive sweep of those conquering nations who supplanted those whom they overthrew, it has preserved its usages and manners in a great measure unaltered, amid the many internal revolutions it has undergone. Still, the fact of this, the greatest mass of population which was ever united under one government, being kept together in one bond of union for a period of time far exceeding that at which the earliest European nation may be said to commence, presents a moral phenomenon of the greatest interest, and seems altogether inexplicable by any of the usual principles which are supposed to bind society together. That it has neither been owing to the nature of the government, nor the virtue of the princes, nor the morality and peaceable disposition of the people, is certain; and we can only conjecture that the system of strict exclusion from all communication with foreign nations, and the national habit of appealing to ancient usage as the universal rule of conduct in all matters of life, have served to preserve their primitive habits and ideas in a great measure unchanged, and left unstimulated those energies invariably called into action by the free intercourse of mankind.

GOVERNMENT.

The government of China is not so much what is usually understood by an "absolute monarchy," as a specimen of what we learn from history to have been the social arrangement of a patriarchal family. The emperor, like the "head of a house" in those times, is perfectly unlimited in his power over all under him. He can dispose of the lives of his subjects at pleasure; can make or abrogate whatever laws he chooses; all offices and emoluments emanate from him alone; in short, he is equally the source of all power, honour, and mercy in the state. He can even appoint his own successor to the throne, either from his own family, or whatever class of his subjects he pleases. One of the leading principles in the Chinese constitution is to place as great a distance as possible between this universal autocrat and his subjects, and to hold him up as a demigod, a sort of *dragoman* betwixt heaven and mortals, alternately communicating the decrees of one and the petitions of the other. He is altogether exalted above the common gross sphere of humanity. He is styled the "Holy Son of Heaven, sole guardian of the earth, and father and mother of his people." In fact, he is *believed* to be of heavenly origin; and this superstitious notion appeared sufficiently obvious by the obstacles opposed to the succession of the present Mantchoo dynasty, on account of their family not being able to trace its descent through more than eight generations. The new monarch, aware of the danger of this stigma to the stability of his throne, caused his genealogy to be drawn out and published, wherein it was given out that the daughter of heaven, descending on the borders of the lake Poulkouri, at the foot of the White Mountain, and eating some red fruit, conceived and bore a son, partaking of her nature, and endowed with wisdom, strength, and beauty; that the people of that nation chose him for their sovereign, and that from him was descended the present Son of Heaven, who filled the throne of China. This explanation at once satisfied all the scruples of his celestial subjects. Offerings are made to his person and throne, and he is worshipped by prostration, not merely in his presence, but in places where he is *supposed to be present*—as our sailors lift their hats on coming upon the quarter-deck of a man-of-war. When Lord Amherst, in his ill-starred mission to Pekin in 1816, stopped at one of the stages towards that capital, a repast was found prepared by orders of the emperor, and he and his suite were ordered to prostrate themselves nine times before the *table*, as if the descendant of the red fruit of lake Poulkouri had been personally present. It is, of course, only in keeping with such superstitious notions, that the emperor should be reckoned not only the sovereign of China, but of all the world besides, the other royal personages being merely his vassals. "Heaven has not two sons, earth has not two kings, a family has not two masters, sovereign power has not two directors; only one God and one emperor." Such were the precepts of the learned Confucius 500 years before Christ, and such is the doctrine of the Chinese at this hour.

'This irresponsible autocrat bears two distinct characters: first, that of High Priest; and, secondly, that of the Sovereign of the Empire, or "Father and Mother of the People." In the first character, he is sole mediator with heaven for the sins of the nation; the sole officiator at all solemn rites and sacrifices for propitiating the favour of God. He has thus exclusive credit of all the blessings the people enjoy—such as plentiful crops, favourable weather, &c.; and although occasions of public calamity, storms, inundations, and such matters, are also laid to his charge, yet such is the infatuation of the people, that they forgive his faults in consideration of the proof thus afforded of the attention of heaven to his conduct! But care is always taken to present his character in the most amiable light possible to his subjects, who only hear of him as practising all the Utopian virtues of his station—remitting taxes and punishments, protecting virtue, punishing oppression, relieving the poor. So much for the head of the executive. What may be called the administrative government, consists of the emperor's council and the great public tribunals. The council is composed of the ministers of state, taken from the first order of mandarins, and presidents of the supreme tribunals, but is never assembled except upon occasions of extreme public importance; every thing being in general directed by an inner council, where the emperor sits in presence. There are six superior tribunals at Pekin. The first, named Lü-poo, watches over the training of mandarins, or persons to fill official situations, as well as over their conduct after being appointed to office; reports their proceedings and character to the emperor, and, in short, has them entirely under their surveillance. The second tribunal, called Ho-poo, may be designated the court of finance, where all the revenues of the empire, the royal treasures and domains, and every branch of public expenditure, is managed. The third tribunal, Lee-poo, or the court of ceremonies, superintends the observance of ancient customs and religious ceremonies; examines the public schools, and reports the progress of the sciences; receives foreign embassies (a great tax on their time); and regulates all matters of etiquette about the court. The fourth tribunal, Ping-poo, is something akin to our war-office, in having the management of all the military concerns of the empire. Fifth, Hong-poo is the police department, directing every thing relating to the detection and punishment of crimes. The sixth tribunal, Kong-poo, is the tribunal of public works, having charge of the palaces, public buildings, canals, mines, manufactories, &c. All these tribunals have under them a great number of subordinate tribunals scattered throughout the empire, subservient to their various objects of institution. Each of the six supreme tribunals has two presidents, one of whom must be a Tartar by birth, and the other a Chinese. They have, also, twenty-four assessors, who are half Chinese half Tartars.

There is, also, another tribunal, the nature of which sufficiently demonstrates of itself the grand principle upon which the Chinese government is based—namely, of making every thing depend upon the emperor. This is a board of *censors*, who send an inspector to watch over the proceedings of each of the tribunals—both the supreme and subordinate. These functionaries take no part in the proceedings of the tribunals, but merely sit and attend to all the proceedings, which they report to their principals, and these again to the emperor. These agents are, in short, his spies; and by them he indirectly governs his empire. The mandarins are changed from one situation to another every three years, to prevent their acquiring too much influence with the people, at which times they are obliged to appear regularly at court—to resign the seals of office, we suppose, and kiss *the ground*, upon entering on a new one.

The beautifully complicated machinery of government just described, might be supposed, if properly regulated, well adapted for accomplishing its object; but it is only by that very elaborateness of construction rendered the more liable to be abused. The emperor being the prime source of all power, it would be requisite for him to manage the whole machinery with his own hands, or under his own inspection at least—a task which would require him to possess as many hands, heads, and eyes, as Briareus and Argus had between them. The necessity, therefore, of relying upon the fidelity of so many thousand agents for his information and the execution of his will, is in every department of his government taken advantage of; and the whole may be generally described as a uniform system of corruption, plunder, and oppression, from the prince to the beggar. As soon as the censors (or spies) visit the provinces, they are instantly waited upon by the mandarins, who attempt to purchase their favour with rich presents, the value of which has of course been raised by the most grinding exactions from the poor inhabitants. Every mandarin entrusted with any temporary lucrative commission from the court, makes all he can of it by the most unscrupulous means, and, by bribing the higher officers about the court, is allowed to sit down in quiet with his ill-got gains. As all complaints must pass through the hands of these officers, of course no remonstrance ever reaches the throne against such oppressions. It is true, frequent examples happen of a guilty mandarin who is sometimes imprisoned, and his riches confiscated to the state; but it is well known that these examples of punishment do not originate in motives of justice. "The emperor," says M. de Guignes, one of the most intelligent of our modern travellers, "makes use of his grandees, as of a sponge, to suck up the riches of his subjects. When the sponge is full, he squeezes it, and sends it elsewhere to be filled anew." One mandarin, complained of by Lord Macartney, was dismissed by the emperor to the government of Quang-ton and Quang-see, with the following observation:—"I place you in a city where there are many European curiosities, but from which nothing is ever sent to me." The hint was not lost. Upon entering on his government, the inhabitants found it impossible to obtain an audience of him for less than a present of 15,000 or 20,000 piastres (L.4500). "I have lived a long time in China," observes M. de Guignes; "I have traversed that vast empire in all its extent. I have every where seen the strong oppress the weak, and every man who possessed any portion of wealth, employ it to harass, to burden, and to crush the people." In fact, the jealousy and suspicion which prevail between all the members of the government, from the emperor to the lowest of the magistrates, sufficiently evince how little they trust between themselves to their fine moral maxims, by the influence of which they pretend the throne is upheld, and the happiness of the people secured.

The great basis of the Chinese government is the strict inculcation of the sacred nature of filial obedience into the hearts of the young. The parent is understood to possess unlimited power over his offspring as long as they live—a maxim which has been for ages interwoven with their earliest feelings and ideas. The child stands in the same relation to the father as the father does to the sovereign. No wickedness or unnatural treatment by the father can relieve a son from his subjection. The merit of every good action performed by the son is ascribed to the father, but the son bears his own disgrace. In like manner, as already mentioned, the sovereign receives all the merit of the country's prosperity, but incurs no disgrace for its misfortunes. To be consistent, in thus placing the young and vigorous at the mercy of the old and feeble, the emperor sets an example by prostrating himself, at the commencement of every year, before the empress dowager, before receiving the prostrations of his officers and attendants. This same principle pervades all the branches of authority; the governor of a province or city being held as the father of all under his jurisdiction. The effect of this State-morality is, while it must certainly be viewed as the cause of the long stability of the government, to deteriorate the principles and feelings of the people, and destroy all genuine sentiment amongst them. From the beggar upwards to the sovereign, each individual is the slave of him immediately above himself; and, what is worse, all are aware of the hypocrisy of each other, and there are no other bonds to hold society together, save the chains of tyranny.

LAWS.

The laws of this singular nation may be described as those of the bamboo, the cord, and the scimitar. "This great nation," says Mr Barrow, "may be aptly enough compared to a great school, of which the magistrates are the masters, and the people the scholars. The bamboo is the ferula, and care is taken that the child shall not be spoiled for sparing the rod; the bamboo, however, is not used merely as an instrument for flogging the people. In the fundamental laws of the empire, it forms the scale by which all punishments are supposed to be proportioned to the crimes committed, and which are carefully dealt out by weight and measure. Punishment, as an example to deter others from the commission of crimes, would seem, indeed, to be less the object of Chinese legislation, than that of satisfying the claims of rigid justice; to wipe off a certain degree of crime by the infliction of a proportionate degree of suffering."

The laws are embraced in a code called the Leu-lee, which has generally undergone some modifications under each new dynasty, but has continued fundamentally the same from time immemorial. It is one of the duties of the mandarins to instruct the people in the provisions of these laws, and they are likewise promulgated in all the schools and public seminaries. The code of the present family, called the Ta-tsing leu-lee, consists of six great heads, to correspond to the functions of the six supreme tribunals, and embraces an epitome of the whole system of government. Our readers would not, we believe, thank us for an exposition of this institute of Asiatic jurisprudence; but the fifth division, relative to crimes and punishments, contains matter sufficiently curious and interesting. Treason—which, besides the crime of rebellion, comprehends nine other species of offence, amongst which are parricide, impiety, and desertion to a foreign power—is invariably punished with death, in the former case with the most lingering tortures. But it is not merely upon the criminal himself that the penalty for treason falls. All the male relations of such persons are indiscriminately beheaded, the females sold into slavery, and all their connexions relentlessly put to death. And it is well did the vengeance of the law always terminate here; but it too frequently happens that whole villages, nay, sometimes entire districts, are indiscriminately slaughtered for the crime of one individual! To intrude into the line of the imperial retinue while the emperor is travelling, subjects the offender to death. One of the most extraordinary decrees is, that if the emperor's physician is discovered compounding any medicine in a manner not sanctioned by established usage, he is punished with 100 blows. If any dirt is found amongst his majesty's food, the cook receives eighty blows; and if he mixes any unusual ingredient or sauce which his majesty's palate does not agree with, he receives 100 blows, and is compelled to swallow the article himself! All cases of deliberate murder are punishable by death; and death, with the most lingering tortures, is denounced against parricides. The penalty of death is also awarded against a slave who shall strike his master; a son who shall strike his father or mother; a grandson who shall strike his grandfather or grandmother; a wife who shall strike her husband's father, mother, grandfather, or grandmother. But if a father kill a son, grandson, or slave, even designedly, the punishment is no more than sixty blows of the bamboo, and a year's imprisonment. Even this lenient punishment is generally remitted for a fine, as the law presumes the cause of the act to be the disobedience of the child, which is held as a crime of the deepest dye, as affecting the principle of the whole system of government. The jealousy of the Chinese law on this important point is further illustrated by the following decree—"that a child or grandchild, who is guilty of addressing abusive language to his or her father or mother, paternal grandfather or grandmother, a *wife* who is guilty of the same to her husband's father or mother, paternal grandfather or grandmother, shall in every case *suffer death by being strangled!*"

There are five degrees of punishment for offenders:—The first is inflicted by the lesser bamboo,* and is said merely to be in the way of reproof and admonition. The correction extends from four to twenty blows. The second degree extends from twenty to forty of the larger bamboo. The third is temporary banishment to the distance of 150 miles, extending from one to three years. The fourth degree is perpetual banishment, with one hundred blows of the bamboo. The fifth and ultimate punishment is death, either by strangulation or decollation. There are also various kinds of torture to extort confession and evidence. The punishment by the bamboo, however, is, in the case of offences committed by the officers of government, commuted to fine or degradation, and, under peculiar circumstances, the benefit of commutation by fine is extended also to private individuals. In fact, there is a regular scale of charges for those not legally excluded from the degradation of flogging, of which all who are rich enough may avail themselves. The motive of this regulation is evidently to fill the coffers of the royal treasury.

REVENUES.

No correct estimate, for want of the necessary data, has ever been ascertained of the actual amount of the revenues of this immense empire, and the most different statements have been put forth on the subject by various writers and travellers. The Chinese themselves, of course, attempt to impress foreigners with a most exaggerated idea of its magnitude. A Chinese minister represented it to Lord Macartney as amounting to a sum exceeding sixty millions sterling, of which, after defraying all the civil and military expenses, about twelve millions were supposed to remain for the

* This instrument, which makes so conspicuous a figure in the Chinese code, is of two sizes: the larger is five feet eight inches long, two and three-fourth inches broad, and two inches thick, weighing two and two-third pounds; the smaller is the same length, two inches broad, one and one-fifth thick, and weighs one and five-sixths of a pound. The infliction is applied in open court immediately upon sentence being passed.

emperor's private support. Mr Barrow reckons "that fifty millions, in an economical government like this, where the officers and magistrates are so shamefully paid that they could not live without robbing the people, may be considered as an ample revenue for all the necessities of the state." Some late writers have reduced the estimate as low as twelve millions; but such a calculation is evidently absurd. Perhaps the nearest to the truth is that of the intelligent M. de Guignes, who accompanied the Dutch embassy in 1794. He drew up a minute summary of each individual tax, and branch of expenditure, and their amount, and the result was as follows:—

Revenue - - - -	L.31,555,554
Expenditure - - - -	22,222,221
Surplus	L.9,333,333

the surplus, after the emperor takes what he immediately requires, being deposited in the public treasury. If this calculation be correct, it is evident that enormous sums must thus sometimes be accumulated. Mr Barrow, it is true, says, "that the immense treasures said to have been amassed by the reigning dynasty, exist only in the imagination of the Chinese." But he seems to have forgotten what he himself states in another place, where, speaking of the various means adopted to preserve the emperor's popularity, he tells us that the sovereign sometimes remits a whole year's taxes to his people—a proceeding which could not easily be put in practice with an empty exchequer. The emperor has also private domains, the revenue of which was estimated by M. de Guignes at upwards of four millions.

The revenue is raised from a land-tax, amounting to about a tenth of its produce, one-half of which is paid in money, and the other half in kind. There is besides this a tax on salt, coals, and manufactures; and a capitation-tax upon merchants, artisans, &c., who are held lowest in the scale of society. It is a curious fact, that the regulations for collecting the duties on manufactures, and preventing smuggling, resemble exactly the British system of permits, excise-officers, licences, &c. In addition to these revenues, is the large amount raised by the duties on foreign shipping and merchandise, of which we will have further to speak when we come to treat of the trade of China.

ROYAL FAMILY—COURT-DRESS AND CEREMONIALS.

As may be imagined, the emperor is domiciliated in a style adapted to his immense wealth, high rank, and pretensions to unlimited sway. His train of courtiers, officers of state, and other attendants, when he appears in public, which is exceedingly seldom, is inconceivably numerous; and being all apparelled in gorgeous silks and satins of the brightest dyes, garnished with gold and silver, their appearance is inexpressibly magnificent. But it is only while going through this public exhibition that all this show of wealth and magnificence has any reality. When released from duty, they retire to their mean and solitary cells in the outskirts of the palace, where they devour their rice out of wooden bowls with their chop-sticks, and then lie down on their mats on the uncovered floor, to slumber away the hours till their services are again required; for to enter into conversation with his fellow-slaves, would, as being so strange a departure from the national taciturnity, subject the parties to the suspicion of conspiracy.

The emperor has three classes of wives. The first consists of one who has the rank of empress; the second, of two queens and their attendants; and the third, of six queens and their attendants. The emperor's wives and women are doomed to reside for ever within the walls of the palace, and are, after his death, imprisoned for life in a prison called the "palace of chastity."

The princes of the blood who are descended in a direct line from the reigning family, have their name and date of their birth registered in a yellow book, and have the privilege of wearing a yellow girdle; but those who are only of collateral descent, have their names enrolled in a red book, and wear a red girdle. So inimical is the spirit of the government, however, to a multitudinous nobility, that even the princes of the blood beyond the third generation, unless they have talents and learning to recommend them to some honourable employment to which rank is attached, gradually merge into the common mass. The princes have the privilege of being tried only by their peers, and may procure exemption from any corporal punishment by a fine. The persons of those who wear the yellow girdle are held so sacred, that any one insulting them incurs death. Those who hold no office, only receive a salary equal to the pay of a common soldier in the Tartar bands, and receive 100 taels (about 30 guineas sterling) at their marriage. The emperor and his children wear robes of satin of a bright yellow colour, while all the other branches of the royal family, like the mandarins, wear robes of a violet colour. The emperor, his sons, and those of the first rank, are also distinguished by figures of dragons with five claws embroidered on their vestments: princes of the second rank have dragons with four claws; those of the third rank, as well as the mandarins, have, instead of dragons, serpents with four claws. The *button of ceremony* on the head-dress of the emperor consists of three dragons of gold, placed one above the other, encircled and studded with pearls. His upper robe has four circles embroidered with dragons. His necklace, which in his case alone is composed of pearls, consists of 112 pearls, and other ornaments of rubies, sapphires, and amber. His girdle is of a bright yellow, with four circles of gold, studded with rubies, sapphires, and pearls. The oldest son of the emperor, called Hoang-tay-tse, has a similar button with his father, only with fewer pearls. His necklace is of coral, and he has a bright yellow girdle like his father, but adorned. The bonnets of the sovereign and heir-apparent have also a figure of the idol *Fo*. The other sons of the emperor are adorned in much the same fashion as the eldest, but with fewer ornaments. All these distinctions of dress in the royal household—as indeed the apparel of every class in the kingdom—are expressly regulated by law.

The public exhibitions of the royal person amid all the pomp and circumstance of his household, are limited to certain fixed festivals, such as the anniversary of his birth, beginning of the year, &c. Those on the former occasion are the most splendid, all the principal officers of the government, tributary chiefs, and Tartar princes, being in attendance. As the ceremonies observed on such occasions—like every thing else in China—never vary, the following description of one in 1793, given by Lord Macartney, may be taken as an equally faithful account of the exhibitions at the present day:—"The 17th September being the emperor's birth-day, we set out for the court at three o'clock in the morning. We reposed ourselves about two hours in a saloon, at the entrance of the palace inclosure, where fruit, tea, warm milk, and other refreshments, were brought to us. At last notice was given that the festival was about to begin, and we immediately descended into the garden, where we found all the great men and mandarins in their robes of state, drawn up before the imperial pavilion. The emperor did not show himself, but remained concealed behind a screen, from whence, I presume, he could see and enjoy the ceremonies without inconvenience or interruption. All eyes were turned to the place where his majesty was imagined to be enthroned, and seemed to express an impatience to begin the devotions of the day. Slow solemn music, muffled drums, and deep-toned bells, were heard in the distance. On a sudden the sounds ceased, and all was still. Again they were renewed, and then intermitted, with short pauses; during which, several persons passed backwards and forwards in the *proscenium*, or foreground of the tent, as if engaged in preparing some grand *coup de theatre*. At length the great band, vocal and instrumental, struck up with all their powers of harmony; and instantly the whole court fell flat upon their faces before this invisible Nebuchadnezzar. The music might be considered as a sort of birth-day ode, or state-anthem, the burthen of which was, 'Bow down your heads, all ye dwellers on the earth! Bow down your heads before the great Kien-long! the great Kien-long!' And then all the dwellers upon China-earth there present, except ourselves, bowed down their heads, and prostrated themselves upon the ground, at every renewal of the chorus. Indeed, in no religion, either ancient or modern, has the Divinity ever been addressed, I believe, with stronger exterior marks of worship and adoration than were this morning paid to the phantom of his Chinese majesty. Such is the mode of celebrating the emperor's anniversary festival, according to the court ritual. We saw nothing of him the whole day, nor did any of his ministers, I presume, approach him, for they all seemed to retire at the same moment we did."

All who are admitted to the honour of an audience of his "celestial majesty," are compelled to perform the ceremony of prostration, or *koutou*, which consists in prostrating themselves nine times on the ground, and beating it as often with their foreheads. This humiliating ceremony is exacted from foreign embassies as well as natives, as typical of the emperor's dominion over all the earth, and has been hitherto complied with by all the European plenipotentiaries who have visited the Chinese court, with the exception of the British; of which more hereafter. Of the other internal regulations of the royal household, nothing is known.

CLASSES OF POPULATION—OCCUPATIONS.

The population of China, under the emperor himself and his family, may be divided into eight distinct classes. And one of the most striking circumstances in the social system of this great despotism is, the want of that which has almost universally been reckoned indispensable to the stability of a monarchy—*a nobility*. With the exception of the princes of the blood, whose persons are in some degree held sacred, there is no rank but what is derived from the holding of some office in the state. But although those thus favoured are, by courtesy, esteemed noble, and even some families are, by the emperor's favour (such as the descendants of Confucius), allowed to retain a title of honour, they derive no power, privilege, or emolument therefrom. The sons of the highest mandarins derive no dignity or advantage from the rank of their fathers. As the possessions of a parent, too, are all equally divided amongst his sons, the riches of the greatest families diminish in proportion to the number of heirs; and if these are no way distinguished by talent, they soon sink back into the common mass of the people.

The great body of the people may be divided into the following classes:—The MANDARINS, the MILITARY, the LITERATI, the BONZES (or priests), the HUSBANDMEN, who are the most favoured class in the state, the ARTISANS and the MERCHANTS, who are the *least* respected, *especially those who traffic with foreign nations!* It is one of the most curious features of this singular government, that, being so essentially despotic in itself, both in principle and practice, it possesses one feature generally reckoned the main principle of a democracy—namely, that *the highest honours and offices in the state are alike open to all classes of the people*. The meanest origin is no bar, and the proudest rank is no recommendation, to the individual. This system no doubt soothes the public mind, and induces the people to bear with greater patience that insolence of office and stretch of power which they themselves have the prospect of exercising in turn. The result, however, is exactly in the inverse ratio to the plausibility of the system. "Where the offices of state," says Mr Barrow, "are open to the very lowest of the people, when possessed of the requisite qualifications, the candidates for employment become so numerous, that every trifling fault is laid hold of to create a vacancy; and these frequent removals and degradations fall in precisely with the system of government, which is to break down all connection between the officers and the people, and to turn the respect and veneration of the latter exclusively to the sovereign." It is found, that the more mean the original condition of a mandarin has been, the more oppressive and extortionate is his conduct to those under him, not only with the view of making his origin be forgotten in his present elevation, but, knowing the insecurity of his situation, of making the most of it while it is in his power. The people, however, submit patiently to his exactions, assured that his dismissal (of which they are certain) will open the way for one of themselves to enjoy the same opportunities of robbery and oppression.

In accordance with the national system, however, the office of mandarin, to which all ranks eagerly aspire, is almost wholly engrossed by individuals selected from the three humblest classes, the husbandmen, the artisans, and the merchants. Those who have acquired wealth, by whatever means, generally enter into some of these occupations to render them more eligible for the office, in order, that, by attaining it, they may enjoy their possessions in more security. Others purchase the office with their whole fortune, secure of finding the means of recruiting their finances during their three years' administration.

The mandarins consist of two classes, the civil and the military. The former, however, are the chief officers who govern the empire, although they are placed under such restrictions as to prevent their ever becoming dangerous to the emperor. They cannot marry in the province or city they govern, nor hold office in a province within 50 leagues of that where they were born, until they are 60 years old; with many other despotic regulations of the same nature. A mandarin has unlimited power in his district, but his conduct is watched by those above him, as it is the policy of the Chinese government to make every department responsible for the one immediately inferior to it. Notwithstanding this surveillance, however, and although their salary is barely sufficient for simple maintenance, it is regarded as a phenomenon by the Chinese to see a mandarin leave office without amassing great riches. Their means of accomplishing this we have already explained under the head of Government. Notwithstanding their infamous exactions, the people observe towards them the greatest reverence. They are saluted with the title of "Great Lord," and every one bends the knee while addressing them. The two chief classes of mandarins are divided into nine different orders, who are all minutely distinguished by particular parts of their dress. The most marked, however, is the button in the bonnet, which, among those of the first order, consists of a red ruby; others of a meaner order have a rock-crystal; and the most inferior, one of gold. The number of civil and military mandarins is calculated at between 20,000 and 30,000.

The *literati* form the most distinguished part of the Chinese nation, as it is from amongst these that the individuals necessary for discharging all the higher duties in the state are recruited. To ensure the adequate accomplishment of these learned statesmen, there is, as before stated (under head of Government), a board of censors, named *Lii-poo*, to direct their studies, and examine into the progress of their erudition; and government has fixed for every city of the first, second, and third class, the number of literati allowed to qualify themselves annually in each, by taking out a diploma, corresponding to the degree of Bachelor of Arts in Britain. There are, then, in China upwards of 24,700 individuals annually added to the qualified literati; and it is, therefore, conjectured that there are never less than 495,000 of this body. These are all exempt from taxes of every description; and as soon as they have taken out their degrees, their names are enrolled in the lists of the *Lii-poo*, who choose from amongst them the higher orders of mandarins.

It is, however, in productive labour that perhaps two-thirds of the Chinese are employed; the remaining third, amounting, after deducting the civil and military officers, students, literati, &c., to about ten millions, being engaged in trading and manufactures. It is the great maxim of the Chinese government, that agriculture is the true source of national prosperity and wealth; and they have in every age honoured and protected the cultivators of the soil. This class, indeed, may be considered much the happiest and most independent of the nation; for although they pay to the amount of a tenth annually to the emperor, they have neither priesthood nor poor to support—unless the poor of their own families, whom all classes are bound to provide for. The monarch is the universal proprietor of the soil, and the tithe exacted from it is the whole rent paid by the farmer. But though he is thus in a manner a tenant at will, he is never disturbed in his possession so long as he continues to pay his land-tax, and has the power of letting out any part, or the whole, if he pleases, to another. As there are no public funds in which to vest capital, and commercial speculations are reckoned degrading, all classes are eager to lay out their capital in land. It is for this reason that even the princes and nobility vie with each other in countenancing agriculture. Yet, notwithstanding all this encouragement, the amount of land cultivated is trifling in comparison to the extent of the empire. By a report made to Kien-long in 1745, it appeared that there were only about 6,000,000 of acres under cultivation, out of the 640,000,000 calculated to be capable of tillage. From the want of enterprise, but still more from the want of skill and suitable implements, immense tracts of lands are allowed to lie waste; and it is estimated that a fourth of the whole country consists of lakes and swamps, most of which are capable of being drained. It will easily be seen how inadequate the produce of the soil is to insure a regular supply of food to the inhabitants, in seasons of scarcity, occasioned by long droughts, which frequently occur; and when it is considered that there is no foreign supply of grain to make up for deficiencies, little wonder need be expressed at the terrific famines which often afflict the nation. To provide against these scarcities, a year's produce of the land is always kept stored up in public granaries; but this provision is never found sufficient to prevent the frequent recurrance of the most dreadful scenes of starvation.

We are somewhat puzzled what to say regarding the amount of the population of China; for although all accounts agree that it is something enormous, there is a difference of millions between the statements proceeding from what may be termed the most authentic sources known. The mandarins attendant on Lord Macartney, in the year 1793, gave out the population at 333 millions; and by a census taken in 1813, by order of the Chinese government, this enormous mass is swelled up to 367,821,647, which gives about 268 to the square mile. This calculation has been implicitly credited and commented on by various writers; and a late contributor to one of the acutest of our periodicals,* gravely philosophises upon it in anticipation of the benefits expected to accrue to Britain from the opening of the trade between it and China. But Mr Barrow, certainly the most intelligent and trustworthy writer on this subject, considers this estimate as not only improbable, but impossible. And certainly, when we compare the ostensible means of subsistence with the number of *mouths* here thrown open to swallow it, the alleged impossibility would seem sufficiently manifest. The most veracious and probable calculation, in Mr Barrow's opinion, is that taken from some statistical accounts of China, drawn up by order of Kia-king, about the years 1810-12, translated by the celebrated Chinese scholar, Dr Morrison of Calcutta, who accompanied Lord Amherst's mission in the year 1816-17. According to this census, the total population, including all ranks and conditions, great and small, amounts to between 145,000,000 and 146,000,000 *mouths* (by which designation the census is always taken); and this estimate acquires the greater probability, from its tallying pretty exactly with a census taken by Kien-long in 1743. By the latter, the number paying taxes was stated at 20½ millions, which, reckoning five persons to each family, would make in all about 142½ millions.

The more moderate calculation relied on by Mr Barrow is even greater than the following estimate, given in a British parliamentary paper, on the subject of China, drawn up and published in 1830. From this statistical table, it appears that the whole population of China proper, exclusive of Tartary and the dependant provinces, amounts to 141,470,000 souls, which, when compared with the area or surface of the country, gives an average of 103 souls for every square mile. Let this be compared with the known averages of some other countries:—

	Souls
China, per square mile	103
Hindoostan	104
Austria	110
France	164
England	222

Thus we see that this so much vaunted population does not amount to one-half of that of England, compared with the relative extent of territory of each country.

The cause of the apparently excessive population of China arises from the provinces being very unequally peopled, and the over-crowded portion of the country to which foreigners generally, if not solely, have access, and thence draw their exaggerated conclusions. There are, in fact, but four provinces, out of the fifteen into which the empire is divided, that are densely inhabited; these embrace but little more than one-fourth of the entire area, yet contain above two-thirds of the population.

PRODUCTIONS—AGRICULTURE—TEA CROP.

The staple productions of China are rice, tea, silk, cotton, sugar, salt, porcelain, tin, lead, musk, rhubarb, quicksilver, saltpetre, wines, fruits, and various manufactures.

Rice is the great staple article of food; and so much is its importance regarded, that a high festival is held at the commencement of each seed-time. The emperor performs in person, and prepares himself for the solemn occasion by three days' fast and prayer. He then goes forth in great pomp, takes the plough in his own hands, opens a furrow, and throws in the first seed of the season. The same is done in every part of the empire, on the same day, by the viceroys and governors. The grain reaped from this seed is preserved in granaries, and reserved for sacrifices. The cultivation of this grain, of which there are two crops annually, requires little or no labour; water supplies every purpose, and for the most part this element is abundant in every part of the empire. The growers display great ingenuity in their various contrivances for raising the water from the rivers, by means of wheels, levers, swinging buckets, &c. The first crop of rice is sown in March, and the second in July, the grain being ready for the sickle three months after it is sown. Exclusive of rice, there is a great deal of barley grown in some districts, besides wheat, maize, peas, and beans. Oats, which spring up spontaneously, are pulled up as a useless weed. The implements of husbandry are extremely simple. The plough is held by one hand, and consists but of a single piece of crooked timber, the lower extremity of which is armed with a hook, and the superior guided by the hand; while a perpendicular piece of wood rises from the middle of the beam, across the top of which another piece is placed lengthways, one end of which is fixed to the handle, while the other is connected with the traces. This implement does not turn up the earth to the depth of more than six inches, so that new earth is never reached; and being thus exhausted, the ground requires often to be left fallow for want of manure.

The Chinese excel in gardening more than in agriculture, and especially in the art of laying out garden grounds; and this may be considered the only one of the fine arts in which they display genius or taste. Their style indeed strongly resembles that of England. The most magnificent and extensive of the emperor's gardens are those of Yuen-min-yuen, at Pekin, and of Gehol in Tartary; the latter of which is described in glowing terms by Lord Macartney, who says it reminded him of the pleasure-grounds at Lowther Hall in Westmoreland. They are, however, on somewhat larger a scale, being ten English miles in diameter, or 60,000 acres, containing within the precincts thirty separate habitations for the emperor, each resembling a village of considerable size.

The Tcha, Tha, or Tea-tree, grows equally in the mountainous and level districts, but prefers a light and rocky soil. It is sown by putting seven or eight seeds into a hole, two or three of which only spring up, and these are afterwards transplanted into rows. They begin to yield leaves three years after being planted, but require to be renewed every five or six years, as the leaves then begin to grow hard and harsh. The appearance of the tea-shrub resembles that of the broad-leafed myrtle, with a flower like that of the wild white rose. There are different modes of cultivating the tea-crop in different provinces; but there are in fact only two distinct species of it, the green and the black. All the rest are mere combinations of these two in different proportions, or are simple varieties produced by difference of soil, culture, gathering, or curing.

The black tea is grown in the maritime province of Fo-kien, with the exception of about one-third of the bohea, which is produced in the north-east corner of Canton province, in a district called Wo-ping. Green tea is all grown in the maritime provinces of Kiaguan, Kiang-si, and Che-Kiang, but chiefly in the two former. Some of the buds of the plant in Fo-kien are picked in the early part of the spring, before they have burst, and a small portion of these is mixed with the best parcels of congou, to give them a flavour. Pekoe is also brought to Canton unmixed with other leaves.

In the beginning of April, the leaves are stripped off the plant; a new crop is then thrown out, and picked about six weeks afterwards, and a third crop about the end of May: the two first pickings are the best, and nearly equal in quality. The third crop of leaves yields tea of little strength and inferior flavour: hence the best crops are composed wholly of the choice leaves of the two first gatherings, with a small sprinkling of the buds or pekoe. The inferior crops contain a larger share of the third pickings, and none of the pekoe. The black tea in Fo-kien is cultivated largely by cottagers in small plots of ground or gardens. The leaves are picked by the family, and immediately sold to persons whose business it is to collect quantities of them, and manufacture them in parts, that is, expose them to be dried by the wind under the shade, and afterwards to be further dried in a heated warehouse. The tea merchants and the agents of the Hong merchants come to the tea districts, and purchase quantities of the dried leaves of the first, second, and third gatherings, discriminating the leaves of young and old plants of those grown in well-known favourable spots. They then complete the drying or roasting process, and employ women and children to select the hard, the best leaves, with more or less discrimination, according to the object of making very fine, middling, or common tea. The green tea is less highly dried than the black, and Mr Barrow supposes that it is from the former thus retaining much of its natural juices, that its nervous properties (generally ascribed to its being dried in copper vessels) are to be imputed. The green tea is usually pressed into chests while hot, to give it a finer flavour. The tea is made into parcels of from 100 to 600 chests each, with a distinctive name to each parcel, and conformity of quality, where the tea merchant acts honestly; hence those parcels of tea, which, under certain Chinese names, have proved, in a series of years, of excellent quality and similar characters, and which are greatly sought after at the London sales, are not the produce of any particular farm, but owe their character to the skill and good faith with which the tea merchant or the Hong merchant's agent have executed their commissions in selecting only superior parcels of leaves in the markets of Woo-y-shan. Like the black tea, the different classes are formed by selecting the better from the inferior leaves after they have been dried; the light leaves separated by a winnowing machine from the heavier, the latter of which constitute the gunpowder tea; the lighter are of inferior quality, and only used by the common people. The blooming appearance of hyson, gunpowder, &c. is said to arise from the effects of carefully roasting the leaves in iron vases placed over a fire, and by rubbing them against the sides of the vessel; in this process, with the green teas much skill is requisite, and there is a class of persons hired by some of the tea merchants to superintend their respective manufactories. The bohea tea is composed partly of the lower grades of the Vu-y-shan tea, which has been left unsold after the departure of the last ships of the season, and partly of the tea grown in the district of Canton called Wo-ping.

The tea-chests undergo severe scrutiny in Canton, previously to being purchased; and if, when finally examined at the period of their shipment, they are found superior to the quality which has been attached to them, their price is raised; if inferior, they are rejected, or their price lowered. The scientific mode of proving the finer teas is to put a small quantity into a cup; pour on it pure spring water at full boiling heat; place the saucer above the cup, filling it also with boiling water to increase the heat: after a sufficient time has elapsed for the leaves to unfold themselves, to examine the appearance, flavour, but particularly the *colour* of the infusion. The latter quality is of course only known to the initiated.

Tea is the universal beverage of China. It is drunk at all meals, and is almost the only liquor used at feasts, and while visiting each other. But it is a general rule amongst them never to drink tea immediately after a long fast, being apt to affect the nerves, and create giddiness. The tea-shrub is cultivated only in China and Japan, and is supposed to be indigenous to one or both of these countries. All attempts to introduce it into Europe have hitherto failed.

The quantity of tea annually plucked in China, it is impossible to calculate, unless we also knew the quantity consumed by the natives. About 54,000,000 of lbs. are annually exported from Canton to all parts of the globe; and it is a remarkable fact, that of this quantity Great Britain and Ireland alone consume nearly 32,000,000 lbs—being about 10,000,000 lbs more than all the nations of the civilised world put together!

MANUFACTURES.

From the inveterate adherence of the Chinese to all ancient customs and practices of every description, they have been left completely behind by almost every civilised nation in all useful mechanical arts, even those which originated with themselves. Every thing seems to have stood still in China but Time. Nothing can be more illustrative of this fact than in the case of the silk-manufacture, of which they were undoubtedly the inventors, and the knowledge of which, as their annals boast, they possessed 3000 years before Christ. The native reeler and weaver still continue to labour on by the same tardy process, and with the very same materials, as were used by their ancestors; while in England, where the manufacture was totally unknown until the fourteenth century of the Christian era, Sir Thomas Lombe, so far back as 1718, erected at Derby a machine, driven by a water-wheel, by every revolution of which wheel 73,726 yards of organzined silk-thread were thrown off, and amounting per day to 318,504,960 yards! At this day, the silks of China will not bear comparison with those of Lyons, Spitalfields, and Edinburgh; the first for light fabrics, the second for the more substantial, and the last for shawls. Again, in the article of porcelain (from the Portuguese *porcella*, a cup, they being the first who introduced it into Europe), which, until a very late period, continued to be the admiration of the world, we have been enabled, through the researches of Reaumur and other chemists, to compound earths matching that with which nature voluntarily furnishes the Chinese, and not only equal them in the fineness and durability of the ware, but infinitely excel them in elegance of manufacture. For nearly a century, the clumsy fabrics of the Chinese, with their daubs of blue paint, which formerly were the principal ornaments of the mansions of the wealthy, have been driven out of the market by the beautiful wares of Dresden and Sèvres.

The same remarks may be applied to all the other manufactures of China, the principal of which, besides

* Westminster Review, February 1834.

the two above mentioned, are those of cloth, nankeen (or cotton), linen, paper, and ink. In whatever department of art the Chinese continue to maintain a superiority over, or equality with, the rest of the world, the cause is to be found in the bounty of nature, not their own ingenuity. Thus, the beautiful yellow which distinguishes the nankeen cloth is a natural quality of the cotton grown in the province of Kiang-nan (of which Nankeen is the capital), and is to be found in no other district of China. The Chinese still pertinaciously adhere to their ancient practice of fabricating their paper from the bark of the bamboo and Koo-tchoo (by the latter of which names they term it), notwithstanding their being perfectly well aware of the superiority of that made from rags, and the infinitely greater cheapness and simplicity of the manufacture.

The Chinese ink is obtained from the soot produced by the smoke of pines and the oil in lamps, mixed with the isinglass of asses' skin and musk, to correct the odour of the oil. It is principally made in the province of Kiang-nan.

ARTS AND SCIENCES.

What we have said respecting the stationary condition of the manufactures applies equally to the arts and sciences of China. The process of printing continues the same as when originally invented by themselves about 1700 years since. The characters are first written on paper, which is glued upon boards of hard wood, and the engraver carves the characters upon the wood, hollowing out the intermediate parts. When an impression is to be taken off, the printer lays on the ink with a brush, applies the sheet of paper, which he presses down with a softer brush than the other, and with a greater or less degree of pressure, according to the quantity of ink laid on. Such is the primitive mode of printing still persevered in throughout the interior of China, although moveable types are of course necessary in printing the Royal Gazette of Pekin, which is issued daily, and other documents.

One of the most singular features of Chinese genius is developed in their attempts at painting. They display extraordinary powers of minute imitation, and will copy with the utmost exactness the number of petals, thorns, spots, &c., of a flower, and the scales of a fish; but they are utterly unable to mix and soften their tints, and copy every defect as well as excellence in the object of their imitation. They have not the slightest idea of perspective, considering the diminished and faded appearance of distant objects as the consequence of a defect of vision; and they therefore insist upon placing every object in the foreground. When one of their ministers of state beheld a portrait of his Britannic majesty, he remarked that it was a pity it should have been spoiled by the dirt on the face—meaning the shading of the nose. When they draw a picture of the emperor, they consider it would be almost impious to represent him of the ordinary human proportions, and therefore make him twice as large as any of his attendants—the head particularly. But this self-conceited people consider themselves in this, as in every other art, pre-eminent over all other nations, and reject with disdain the remonstrances of European artists.

In sculpture, as in painting, the Chinese have no conception of order, attitude, or proportion; and there can be nothing more monstrously grotesque than the figures which *adorn* their temples, bridges, and tombs. It is affirmed, indeed, by recent travellers, that there is not a statue or column in the whole empire worth notice.

The Chinese music remains in that state of primitive simplicity in which it has been observed to exist in all barbarous nations. Dr Burney says, that "all the melodies of this nation have a strong analogy to the old Scottish tunes;" that "both resemble the songs of ancient Greece;" and that "the music of all three ought to be considered as *natural* music." Their gamut, like that of the Greeks, consists of five natural tones, and two semi-tones; but they use neither lines nor spaces in noting down their music, which they do in a column confusedly, without any attempt at marking time, key, or expression. They always endeavour to play in unison, having no idea of counterpoint or parts in music. Their musical instruments are extremely rude, consisting chiefly of drums, bells, triangles, &c.; and the only kinds resembling those of Europe are a species of lyres, or harps, with strings of silk, and a small organ, or rather Pan's pipe, made of unequal reeds, stuck into a hollow cup of wood, and blown by a pipe for the mouth, which conveys the wind to all the reeds. Dr Burney tried in vain, however, to adapt a scale to this instrument. The great delight of Chinese taste, in short, is in the commingled sounds of all sorts of instruments at once. An anecdote is told of a Chinese of rank, who, being in London, was carried by a friend to one of the theatres. When the orchestra at first commenced, he appeared inexpressibly pleased, but listened with the utmost indifference to the beautiful overture that followed, asking impatiently if the musicians were not going to play again the fine air they did at first? His friend was puzzled to imagine what the air could be; until, upon the performers proceeding to re-tune their various instruments after the first act was over, the Chinese exclaimed, in rapture at the medley of sounds, "There it is—that's it now!" The affected gravity and unsocial life of the Chinese, indeed, are unfavourable to the cultivation of music. They like to see dancing, but not to practise it—like the Turks, considering it a species of labour, not of pleasure. It is told of a Turkish ambassador that when he saw, at a ball given by some nobleman in London, all the nobility and gentry of both sexes capering about on the floor, he expressed unfeigned wonder at their giving themselves so much trouble, and observed contemptuously, "We make our slaves do all these things for us!" And thus it is with the Chinese.

In almost all the mechanical arts, however, the Chinese are wonderfully expert, and in some have attained a degree of perfection unrivalled by any other nation. No people have carried the art of dyeing, or of extracting dyeing materials from animal, mineral, and vegetable substances, so far as the Chinese have done, and this without any scientific chemical knowledge. They show particular dexterity in fashioning ivory fans, baskets, nests of eight or nine moveable balls one within another; "yet it does not appear," says Mr Barrow, "that they practise any other means than that of working in water with small saws. As little can Europeans pretend to rival their large horn lanterns of several feet in diameter, perfectly transparent in every part, without an opaque spot, and without a seam; yet a small portable stove or furnace, an iron boiler, and a pair of common pincers, are all the tools required for the manufacture of those extraordinary machines. Their expertness in cutting tortoise-shell, mother-of-pearl, and all kinds of stones and gems, is extraordinary, and in all the metals they work with extreme neatness.

Respecting the state of science in China, Mr Barrow says, "Nothing has yet appeared in Europe, from an authentic source, to warrant any other conclusion than that of the utter ignorance of the Chinese in the pure, speculative, and abstract science of mathematics. Their knowledge of arithmetic and geometry is bounded by mere practical rules. Their numerical notation is marked down by symbols of the language, as that of the Greeks and Romans was by letters of the alphabet. The common operations of arithmetic are generally performed by a few balls strung on wires (called the *swan-pan*), somewhat resembling the Roman abacus, and sometimes by the joints of the fingers. The measure of quantity is usually determined by reducing all surfaces and sides to the dimensions of squares and cubes; and with those few practical operations they contrive to manage all the common purposes of life." All other recent observers concur with Mr Barrow in attesting the defective knowledge of the Chinese in the science of astronomy, for their proficiency in which they have hitherto enjoyed such high reputation. Their high pretensions in this department turn out to be founded fully as much on superstition as scientific observation. So sensible are the Chinese monarchs of this fact, that for many generations the construction of their vaunted Imperial Almanac has been entrusted to foreigners, the native astronomers only contributing the important department of fixing the lucky and unlucky days, days of festivals, &c. "The Chinese system, if system it can be called," says Mr Barrow, "resembles so closely that which remains of the Hindus, that both must have been derived from the same source. The period, or cycle of sixty years, by which their chronology is regulated—the period of 10,800 years observed by the Tao-tse which is the sum of the first three Hindu ages, with their intermediate periods—the division of the zodiac into twelve signs and also into twenty-eight constellations, or habitations of the moon, corresponding with the twenty-eight Hindu naschatras—are so many signs of a common origin; and both may perhaps have derived the remains of this science from some third nation, more ancient than either; as the little which both nations do possess appears to be the remains rather than the elements of the science." There is, nevertheless, a board of astronomers and mathematicians maintained at Pekin, which is, in fact, one of the official departments of government; and a committee is annually appointed with great ceremony to superintend the compilation of the national calendar. It is curious to see this ostentatious show of a love of learning kept up by a people who are still so ignorant as to reckon that the firmament is a body encircling the earth, the latter of which is a solid fixed square, and round which the sun revolves, as well as the moon; that all the stars are stuck into the sky at an equal distance from the earth;—who gravely decide, by the state of the planetary system, the days proper for taking medicine, marrying a wife, setting out on a journey, laying the foundation of a house, &c. Their geographical is on a par with their astronomical knowledge, as may be imagined from their supposing China to be the middle region of the globe, and terming one mountain, which is reckoned the centre of the empire, the "Navel of the Earth." The more educated are at this day well acquainted with the fallacy of such doctrines, but they are still propagated amongst the mass of the people, as it would be equally impolitic and dangerous to expose the delusions which have obtained credence amongst them from time immemorial, and the gross ignorance of their idolised sages. The fact is, that the pretended knowledge of the literati, and ostentatious patronage of learning by the government, is a mere State-trick, for the purpose of exciting the veneration of the ignorant multitude.

Of natural philosophy, or chemistry, the Chinese know literally nothing, except from a practical acquaintance with the results of certain causes. Of medicine, as a science, their whole stock of knowledge is a combination of quackery and empiricism; and it is a remarkable fact, that the healing art, which, in almost every other quarter of the known world, whether savage or civilised, justly obtains its professors the highest respect, honours, and emolument, is in China so little estimated, that all classes are allowed to practise it *ad libitum*. There are no schools for medical instruction; the theory of the human frame is wholly unknown to them; and they even reject the doctrine of the circulation of the blood. Their remedies are chiefly of a vegetable nature, and consist almost solely of ginseng (a native root), which they pretend to prepare in seventy-seven different ways, rhubarb, China-root, and tea. Their surgical knowledge is equally defective, as may be judged by the fact, that the practice of it is limited almost entirely to the honourable fraternity of barbers. Their operations consist in setting a fracture, reducing a dislocation, letting blood, by scarifying, cupping, or acupunctuation (for they entertain a sentimental horror of the lancet and scalping knife), cutting corns, cleaning the ears, tweaking the nose, beating the back, pulling the joints till they crack; in short, we may sum up our account of Chinese knowledge of the healing art, with the remark of the late Dr Gregory of Edinburgh, that "the emperor of China could not command in all his dominions such medical aid as a smart boy of sixteen, who had been apprentice for one year to a well-employed Edinburgh surgeon, would be able to afford."

LANGUAGE AND LITERATURE.

The language of the Chinese is another branch of their history, respecting which the rest of the world has been impressed with the most preposterous and exaggerated ideas. It has been represented as consisting of millions of characters—as being perfectly unattainable by foreigners, and so forth; and thus has this truly barbarous nation acquired a reputation for philological science as spurious as that which they have enjoyed for other branches of antique erudition. "It is true," as Mr Barrow says, "that their language, more than any thing else, stamps them as an original people. It has no resemblance whatever to any other language, living or dead, ancient or modern. It has neither borrowed nor lent any thing to any other nation or people, excepting to those who are unquestionably of Chinese origin. The written character is just now as distinct from any alphabetical arrangement as it was some thousands of years ago; and the spoken language has not proceeded a single step beyond the original meagre and inflexible monosyllable." All this certainly goes to prove the Chinese to be a primitive people, and so far the circumstance is a moral curiosity; but at the same time it shows their inveterate and immoveable obstinacy in adhering to a system of characters so utterly unreducible to any kind of intelligible vocabulary. The foundation of the language is purely hieroglyphic and symbolical, including all the remarkable objects of nature, such as the sun, moon, earth, fire, water, wood, stone, a horse, a cow, a dragon, &c.; the utensils most commonly in use—a knife, a spoon, a box, &c.; the primary relations of life—a father, mother, brother, son, &c.; some of the most obvious qualities of bodies, as straightness, crookedness, &c. &c. To give a detail of the history of the Chinese language, through its various modifications and arrangements, would occupy the space of volumes, and to no purpose beyond the amusement it might afford to those antiquarians who delight in the investigation of matters as frivolous as they are obsolete. Suffice it to say, that the Chinese language, which has hitherto proved such a mystery to all the rest of the world, has at length been fathomed and rendered clear by the industry of British genius. In fact, the difficulties attending the acquisition of it have proved almost altogether visionary. The industry of Dr Marshman and Dr Morrison has supplied us with grammars and dictionaries of this singular language, and placed within our reach all the supposed treasures it contained. "Europeans," says Mr Barrow, "have been deceived as to the vast number of characters in this language, which was supposed to create its difficulty. In the great Dictionary of Kaung-hee there are not more than 40,000 characters, of which about 30,000 only are in use. The Lexicon of Scapula contains about 44,000 words, Ainsworth's Dictionary 45,000, and Johnson's about the same number. The whole works of Confucius contain only about 3000 different characters. The *Leu-lee* may have, on the whole, about 100,000 characters, but not more than 1800 different ones throughout the whole work. Where, then, can there possibly be any difficulty?" The same writer also adduces numerous instances of Europeans acquiring the Chinese language in a comparatively short time.

From all that has yet been seen, the trouble of learning the Chinese language will be very inadequately compensated by the literary "treasures" of which Mr Barrow speaks. There are no doubt a profusion of poems (so called), novels, histories, and dramas, &c.; but of what character are they? From the translations which we have yet been favoured with, the poems, like some of Ossian's sublime passages, consist of unintelligible imagery; their novels of silly and pointless stories; their histories, as we have already seen, of fables; and their dramas, although for the most part true to nature, yet exhibiting nature in her most revolting forms. M. de Guignes, Mr Barrow, and other visitors of Pekin, assure us that the theatrical exhibitions are beyond every thing abominable and disgusting.

It has been with all writers a theme of wondrous animadversion, how a government so despotic as that of China should make the cultivation of letters a subject of such special anxiety. Even the intelligent Mr Barrow makes a marvel of this fact, notwithstanding that his own writings (had we no other authority) furnish a sufficient explanation of the seeming anomaly. It is true, there is a school to be found in every village of China, and that the instruction of the pupils forms one of the most anxious concerns of the government; but what is the nature or purpose of their education? To instruct them in all the erroneous doctrines of their parents—to confine their knowledge to the native productions of Chinese writers—to make, in short, Chinese politicians of them. The boasted system of education in China is not for the purpose of enlightening the people, but of keeping them in darkness. They are allowed to know nothing of other nations, and cannot therefore comprehend their own degraded and enslaved condition.

RELIGION.

There can scarcely be said to be any religion in China—at least as a system of divine worship or a regulation for the conduct of the people. There is no sabbatical institution, nor congregational worship; no external forms of devotion, petition, or thanksgiving. The emperor takes the sole charge of the spiritual concerns of the people, and is the only individual in the nation who directly addresses the Supreme Being, performing at fixed periods certain ceremonies and oblations. The equinoxes are the times when the grand sacrifices in the temple dedicated to Heaven are offered up, when every kind of business is suspended in the capital. The national, or rather Government-religion, may be described as a sort of Deism. The Tien, or Great Spirit, is invested with the attributes of omnipotence, omniscience, and ubiquity. The names by which this sovereign power is known, are *Whang-tien*, the illustrious heaven; *Chang-tee*, the supreme ruler; *Tien-tee*, heaven and earth; *Che-chung*, the first and the last; *Ken-puen*, root and branch; and other descriptive denominations. In addition to this supreme power, however, the Chinese, like all barbarous nations, invest all the elements with innumerable spirits and genii, fanciful images of which they worship both in their own houses and in temples dedicated to the purpose. These temples are under the care of the Bonzes, who live unmarried, and associate in convents like Romish monks. The idol-worship exhibited in these temples is characterised by every mark of the most debasing and besotted superstition. When a votary has applied to his idol for some time in vain to obtain a certain boon, he abandons the ungenerous spirit in indignation; sometimes demolishing his image, and kicking it through the streets, with every mark of contumely! In every possible circumstance of life, the Chinese implore the protection and aid of some idol. Should a countryman be about to raise a building, or attempt any other work in which he might lie in danger of receiving injury, he places a small stone upright, surrounds it with a few candles, burns two or three gilded papers, and then proceeds to work with perfect confidence. They also consult oracles previous to undertaking a journey, commencing a law-suit, &c.; and thus the Bonzes, who are the interpreters of the responses, are kept in constant employment. So strong, indeed, is the resemblance of the interior of a temple of Fo, the dress of the priests, and the ceremonies of devotion, to those of the church of Rome, that one of the missionaries says, "it seems as if the devil had run a race with the Jesuits to China, and having got the start of them, had contrived these things for their mortification." The foreign religions which subsist in China are the Jews, Mahomedans, and Christians, and these seem to be tolerated merely on account of the public usefulness and learning of the missionaries of these sects. The Christians, for the same reason, are the most generally respected, but have been treated, from time to time, with the most arbitrary capriciousness, being persecuted by one emperor and encouraged by another. In the year 1747, five missionaries were beheaded in Fo-kien, and two Jesuits strangled in the same year in Kiang-nan, all of which was done "according to law," which says, that the chief of any sect who seduces the people from their duties under religious pretences, shall be strangled.

REVIEW OF MANNERS, CHARACTER, AND CONDITION.

From all we have said, it will be evident that civilisation has as yet advanced little beyond the infancy of what may be called agricultural society in China. It may be readily admitted that they were amongst the first of existing nations who arrived at a certain degree of excellence; but it is not less evident that they have long remained stationary, and have even in some points retrograded. "They can only be said," observes Mr Barrow, "to be great in trifles, whilst they are really trifling in every thing that is great." The following assertion of Sir William Jones may almost be literally adopted:—"Their letters, if we may so call them, are merely the symbols of ideas; their philosophy is in so rude a state as hardly to deserve the appellation; they have no ancient monuments from which their origin may be traced, even by plausible conjecture; their sciences are wholly exotic; and their mechanical arts have nothing in them characteristic of a particular family—nothing which any set of men in a country so highly favoured might not have discovered and improved."

In their moral qualities, the Chinese are a strange compound of vanity and meanness, affected gravity and real frivolity—an utter want of all manly judgment and sense, combined with the most insidious art and cunning, the usual accompaniments of vulgar ignorance. The Tartar race are distinguished by a blunt and unstudied frankness of manner and openness of disposition; but the true Chinese betray the most debasing servility of tone and manner—plausible, sly, and artful. They have not the slightest regard to truth, and will assert and deny any thing with the most unblushing effrontery, being also entirely destitute of shame. The pain inflicted by the bamboo is the only consideration they attach to public and disgraceful corporeal punishment. They have neither sense of honour nor self-respect. "A Chinese prince, or powerful mandarin," says a recent traveller, "will commit extortion or oppression whenever he can do it with impunity, and regards it as a matter of right attached to his station. A Chinese trader will cheat and defraud whenever it is in his power, and even piques himself upon his skill in overreaching, as a proof of his talent. A Chinese peasant will pilfer and steal whatever is within his reach, whenever he can hope to escape detection; and the whole nation may be affirmed to have almost nothing in view but their own self-interest and security. Their general character, in short, in point of morals, compared with the minute enforcement of duty by the penal laws, affords an irresistible proof of the utter incompetency of legislation, without the aid of religious principle, to reach beyond the mere external conduct of individuals, or to produce any thing like real social virtue among human beings." In their feelings, the Chinese are cruel, sensual, and vindictive. Mr Barrow, M. de Guignes, and other travellers, all agree in their representations of the inhuman conduct of those in authority. One of the arbitrary laws of China is the compelling of the natives to pull the imperial barges alongst the canals; and Mr Barrow had several opportunities of witnessing the merciless exercise of this authority on the part of the military. The impressed labourers took, of course, every opportunity of deserting; and whenever there was a deficiency of hands, the despotic officials set off to the nearest hamlet, roused the natives out of bed with the whip, made them jump into the water to assist the towing operations, lashing them with long cart-whips all the while with the most ruthless barbarity. Mr Barrow also relates another specimen of Chinese indifference to human life which he witnessed in passing down the great canal betwixt Canton and Pekin. Several persons who had crowded to the brink of the canal, had posted themselves upon the high projecting stern of an old vessel, which broke down with their weight, and precipitated the whole group into the water. Although numbers of boats were plying about at the very spot, not one was observed to go to the assistance of the drowning wretches, whose shrieks and cries were totally disregarded.

Nothing is so significant of the moral condition of a people as their treatment of the female sex, and no where are the women so inhumanely used as in China. They are not permitted to stir out of doors, excepting the wives of the lower orders, who are to be seen toiling at all kinds of laborious tasks, while their indolent husbands are sitting quietly smoking their pipes. In the country they are even to be seen drawing the plough and harrow, while their lazy helpmate drives them on.

Amongst the other moral iniquities of the Chinese, is the crime of infanticide; and from the contempt in which females are generally held, parents expose their female children without the slightest remorse. It is a part of the duty of the Pekin police to go their rounds with carts, at an early hour of the morning, to pick up the bodies of the infants that have been thrown out into the streets in the course of the night, and to carry them, without inquiry, to a common pit without the city walls, where they are thrown in promiscuously. It has been calculated that there are between 20,000 and 30,000 female infants yearly sacrificed in China! What a horrible picture of national depravity does not this one fact present!

In comparison with the lower orders of the Chinese, the slaves in our West India colonies live like princes. They have scarcely an article of furniture, besides two or three jars, a few basins of coarse earthenware, a large iron pot, a frying-pan, and a portable stove. They use neither tables nor chairs, but at meals all the family sit upon their heels round a large pot, with a bowl in each of their hands. After taking the rice from the pot with a spoon, they then take their chop-sticks, which consist of two small pieces of wood, or generally of porcupines' quills, and are held between the two first fingers of the right hand. With this strange utensil they throw their food into their mouths with remarkable expedition. Boiled rice is their staple food, with the addition of millet or barley; but they likewise eat all sorts of animal and vegetable putrescent substances. The dead hogs thrown overboard the ships in the river at Canton are greedily picked up by the natives; and in the public market, dogs, cats, and rats, are exhibited for sale. It is strange, that, amongst this sober people—for sobriety is the only offset they present to their innumerable immoralities—there is almost no use made of milk.

INTERCOURSE WITH FOREIGN NATIONS—BRITISH TEA-TRADE.

The systematic discouragement which the Chinese government displays towards all intercourse with foreign nations, explains the trifling amount of commerce carried on in a country adapted better than any other in the world for its prosecution, whether we consider its geographical situation, its productions, or the genius of the people. The innumerable rivers and canals with which the country is intersected, present facilities for internal communication possessed by no other country; yet there is no regular system of trade amongst them; it consists almost solely of barter, there being no circulating medium, excepting a small copper coin, the value of which is almost too minute for calculation. It is reckoned that on the grand Pekin canal there are upwards of 10,000 boats and barges of various descriptions continually employed in the interchange of national produce. Of the commercial capabilities of China, indeed, we need only look to the immense number and crowded state of their cities. These are divided by the Chinese into three classes, according to the number of leagues which they occupy; and of the first class alone—or *imperial* cities, as they term them—the natives enumerate upwards of 4000. There is much exaggeration here no doubt, but even estimating the number of social communities at a third or even a fourth of what is set down by the Chinese, what an enormous source of consumption for all the necessaries of life is here shown! What an unbounded mart for all kinds of British manufactures would be thrown open by the removal of the government restrictions upon commerce! That the people of China are anxious for this free intercourse with other nations, has been abundantly shown; and in fact their greedy and peculatory disposition sufficiently guarantees the readiness with which they would engage in foreign traffic. But the all-powerful constraints of the government hang like a millstone round their necks. Whatever be the ignorance of the lower classes, there is no want of enlightenment in the executive, which is conscious that a free trade would inevitably lead to the breaking up of the whole despotic system of ruling. Their jealousy, indeed, is not so much to be wondered at, considering the precedent before them in the rise of the British power in the neighbouring kingdom of India—the only wonder is, that amid all the turmoils of war which have disturbed the world during so many ages, this country, so fertile in every thing which can make a country desirable, should have remained totally unmolested. That it is not from internal strength, is well known. At this moment they can hardly be said to possess either army or navy; and an army of 20,000 disciplined British soldiers would effect the conquest of China in a few weeks or months. Their sole protection has been their distance from the moving events of Europe.

It is well known that the foreign trade of China is confined exclusively to one port—that of Canton. The overland trade with Russia and India has now almost entirely ceased. So great is their jealousy of the Russians, indeed, that the latter are the only people interdicted from even visiting Canton. To enter upon a history of the origin and progress of British intercourse with China, would be to interfere with a subject already in progress, and which will probably form another topic for our INFORMATION—India and the East India Company. We need, therefore, merely observe in this place, that hitherto that Company has enjoyed exclusively the right to trade between China and Britain. This monopoly they have possessed since the year 1600, when they obtained their first charter; and although the continuance of it has proved a popular subject of animadversion for a long series of years, it seems questionable whether, without such an association, we would ever have obtained intercourse with that remote region. Their wealth and enterprise, through a long-continued series of difficulties and losses, were alone the means of establishing this branch of British commerce; nevertheless, having outlived the period of their utility, and their right to enjoy a monopoly any longer, they have very properly been denuded of their advantages over private traders.

Tea does not appear to have been known in Britain previous to 1650, and it is evident, from the following note in Mr Pepy's Diary, that many years elapsed previously to its coming into general use:—"September 25, 1661. I sent for a cup of tea (a China drink), of which I had never drunk before." And in 1664, there is mention made of the East India Company commissioning their foreign agent to purchase 2 lbs. 2 oz. of tea as a present to his majesty! From this time forward, however, the increase in the consumption of tea increased with a rapidity scarcely less wonderful than the progress of the British cotton manufacture. Such was the demand for it, that smuggling increased to an amazing extent. So much so indeed, that in 1784, Mr Pitt carried his measure for reducing the duty from 119 to 12½ per cent.; and the consequence was, that the legal imports of tea were almost immediately doubled. In 1795, however the duty was raised to 25 per cent.; and after successive augmentations, in 1797, 1800, 1803, and 1806, it was raised to 96 per cent. *ad valorem*. At this it continued till the year 1819, when it was raised to 100 per cent. upon all teas that bring above 2s. per lb. at the Company's sales, at which rate they have ever since continued. This system, as every one knows, is soon to be broken up by the act of Parliament, which throws open the trade between China and Britain after the 22d April 1834.

Canton, at which the whole of the foreign commerce is carried on by the Chinese, and, consequently, at which all the exports of tea take place, is situated on the eastern bank of the river Pekiang, a beautiful placid stream, as wide as the Thames at London. This great outlet of Chinese trade is about 400 miles in length, and Canton stands at the distance of 80 miles from its mouth. Canton consists of two descriptions of towns—that which is inclosed by walls, and the suburbs; both together, they are said to contain from seven to eight hundred thousand inhabitants. The circuit of the walls, which are of a moderate height, and furnished with a few cannon, is estimated by some at five, and by others at nine, miles. Only about a third part, however, of the space inclosed is covered with buildings; the rest is occupied with pleasure-grounds and fish-ponds. The neighbouring country is very charming, hilly towards the east, and presenting in that quarter a beautiful prospect. The houses are generally low; and towering above them may be seen temples and pagodas. The populous streets are long and narrow. At night the gates are closed, and bars thrown across the entrance to the streets. From this inclosed city, as well as from every other town in China, all foreigners are rigorously excluded; and these, provided they have permission, must take up their abode in the suburbs, which contain a very miscellaneous population, though not therefore inferior in point of accommodation or appearance. But the most curious particular regarding Canton is the existence of a floating town on the river, consisting of perhaps forty or fifty thousand barks, junks, and vessels of various kinds, arranged close to each other in regular rows, with passages between them to allow other vessels to pass. This floating town extends several miles in length. For what reason we know not, the owners of these vessels and their families are not allowed to come ashore, and so they spend the whole of their lives on the water.

Foreigners are not permitted to go ashore and reside at pleasure at Canton. Their only land establishments consist of *Hongs* or Factories, which extend in a line along the banks of the river, from which they are distant about 100 yards. They are built on a broad quay, with a spacious promenade in front. The hongs or factories individually consist of courts or lanes, admitting of no thoroughfare, and solely dedicated to the accommodation of the foreign residents. Large warehouses for the reception of goods are adjacent. The place of the Chinese suburbs which is most frequented by foreigners, is termed China Street, consisting entirely of shops, in which the native dealers are to be seen seated from morning till night. Their tricks in entrapping British seamen into purchasing their commodities, have long been matter of notoriety. Their signs uniformly exhibit an English name as well as a Chinese one; and having picked up an acquaintance with the most familiar of Jack's expressions, their mode of addressing their rough customers evinces at once the crafty and unscrupulous disposition of the natives.

The manner in which foreigners have heretofore conducted business at Canton is as follows:—When a ship arrives, it is necessary immediately to get a native merchant (or, as he is called, a Hong merchant) to become security for the import and export dues, as well as for the good behaviour of the crew. In this there is never found the slightest difficulty, there being, on the contrary, always a competition amongst the natives for the honour of a consignment. The import duties consist of a tax upon the different species of goods, as well as a tonnage upon the vessel. Their mode of determining the latter is curious enough. They measure the ship from the centre of the foremast to the centre of the mizenmast, for the length, and close abaft the mainmast, on the outside, for the breadth; then multiplying the length by the breadth, they divide the product by ten, and hold the quotient to be the proper result. Although destitute of a native currency, with the exception of the small copper coin before mentioned (called a cash), foreign coins are quite current in Canton, especially Spanish dollars. In fact, it is affirmed that there is no port in the world where business is conducted with such facility and dispatch. In addition to the tonnage and cargo charges, there is also levied what is called a *kumshaw*, or present to government, exigible from ships of every burden alike. It has been estimated that all these various port charges, including the expenses of victualling the ships, &c., amount to about 7000 dollars on a ship of 400 tons register.

The British trade with Canton has hitherto consisted of two branches—that of the East India Company, and that carried on by private individuals in the British ports in India; who began to be tolerated (under certain restrictions) at the renewal of the Company's charter in 1814, and whose business has increased so rapidly, as almost entirely to supersede the exports of the Company from China in every article but that of tea. This is shown by the fact, that, in 1813, the Company's exports amounted to nearly L.1,000,000, and in 1829, to only L.583,651. In fact, the expensive mode of the Company's transacting their business at Canton, leaves it doubtful whether they have derived the smallest benefit from their monopoly for many years. The expenses of their establishment, consisting of supercargoes, writers, repairs on houses, &c., have annually amounted to between L.140,000 and L.150,000.

Up to the present time, the importing of tea has been confined exclusively to the port of London, the government-tax or duty being an *ad valorem* one of 100 per cent. upon all teas sold as above 2s. per lb., and 96 per cent. on all sold at 2s. or under; but if rated at the sale price, when that is doubled by the Company, the duty also is doubled; or, in other words, the public are compelled to pay above 300 per cent. more than it would otherwise cost them!

It has been hitherto customary for the East India Company to expose their teas periodically at public sales—previously announcing the quantity to be disposed of; so that they have had the privilege of regulating the price according to their pleasure. The purchasing of the teas has all been managed by professional brokers on behalf of the tea-merchants, who, after examining the lots, mark each box with a conventional sign, expressive of its quality. By this process of sale, the public have, as it appears, been seriously injured. The persons employed in purchasing teas at the periodic sales have pursued a practice of leaguing among themselves to bid up the prices considerably above what they ought to be; and hence, by the duplication of the duty above a certain price, the public, as above stated, have hitherto paid much higher for their tea than what the article can be bought for in America, Hamburgh, and other places abroad, where the same kind of monopoly has not existed. From these complicated causes of the enhancement of the price of tea, it appears that the consumption of that article has been declining in this country from the beginning of the present century. In 1801, with a population of 10,942,646, the amount of tea consumed was 20,237,753 lbs. or 1 lb. 13 oz. to each individual. In 1811, with a population of 12,609,864, the amount of tea used was 20,702,809 lbs. In 1821, with a population of 14,391,631, the amount of tea used was 22,892,913. And in 1831, with a population of 16,537,398, the amount of tea used was 26,043,223, or one pound nine ounces to each individual. The East India Company and its advocates have long endeavoured to persuade the people of this country that no British free-trader could possibly negociate the purchase of a good cargo of tea at Canton—that their good credit, their extensive system of dealing, their knowledge of Chinese customs, &c., give them a preference with the Hong merchants over all other competitors. We take the liberty of saying that this is a pure fallacy. Witness the dealings of the Americans, the Dutch, the French, the Portuguese, and others, with the Hong merchants. "The American intercourse with China," says M'Culloch, "commenced shortly after the termination of the revolutionary war, and has since gone on rapidly increasing, so as to constitute one of the most valuable branches of the trade of the United States." Mr M'Culloch gives a table showing the extent of the exports from Canton to America from 1804 to 1826–7, by which, in the last-mentioned year, it is seen that the Americans had twenty-six ships in the tea-trade, and that the total value of exports from China was 4,363,788 dollars. "The principal articles," continues this most accurate authority, "carried by the Americans to China, are bullion, furs, Turkey opium (an article legally prohibited), English woollens and cottons, and ginseng. The commodities exported by the Americans from China are tea, nankeens, raw and wrought silk, sugar, cassia, and camphor, with minor articles." The Americans are exceedingly enterprising in this, as in every other trade in which they engage. The teas chiefly imported by the Americans are souchong, gunpowder, hyson, young hyson, and hyson skin; it therefore appears they principally use green, or a more delicate tea than the British. The price of tea per pound in the United States is in general about a half what it is in England. The Dutch are less enterprising than the Americans, yet they seem to take the lead among the continental nations at Canton. The Dutch tea-trade, like that of America, is free, and the effects of this free-trade are observable in the following table of the comparative prices of tea at London and Hamburg:—

Species of Tea	Coy's selling price, per lb, in 1828-29.		Prices at Hamburgh, per lb, in 1828-29.		Excess of Coy's prices over those of Hamburgh.		Excess of Hamburgh prices over those of the Company.	
	s.	d.	s.	d.	s.	d.	s.	d.
Bohea	1	6¼	0	8¼	0	10		
Congou	2	4	1	2½	1	1½		
Campoi	2	0	1	2	1	7		
Souchong	2	10¼	1	1¾	1	8½		
Pekoe	3	9¼	4	6¾			0	9½
Twankay	2	5¾	1	2¼	1	3½		
Hyson skin	2	4	0	11¼	1	4¾		
Hyson	4	1¾	2	8	1	5¾		
Gunpowder	6	6¼	3	5¼	3	1		

Mr M'Culloch, from whose excellent work we quote the foregoing table, presents the following forcible view of the injurious effects which have been sustained through the exclusive privileges of the East India Company:*—"Bohea is the cheapest of all sorts of tea brought from China, and is, consequently, most generally consumed by the lowest classes. From 1793 to 1811, its price, at the Company's sales, amounted to about 1s. 6d. per lb. In 1812, it was raised from 1s. 7d. to 2s. 3d., and continued at about that rate till 1825-26, when it was reduced to 2s., and has since fluctuated between 1s. 6d. and 1s. 7d. This fall has had the effect of increasing the consumption of bohea from about 2,000,000 lbs. in 1823-25, to 3,788,012 lbs. in 1828-29—a striking proof of the powerful influence of a reduction of price in augmenting consumption! But were it not for the monopoly, the price of bohea might be farther reduced from 1s. 6d. or 1s. 7d. to 8½d. or 9d.; for such is the difference between the price charged for it by the Company and its price at Hamburgh, New York, &c.! Were it reduced to this extent, it may be fairly presumed that the consumption of bohea would amount to 7,000,000 or 8,000,000 lbs. The vast increase that has taken place in the consumption of coffee since 1807, shows the prodigious influence of low prices in extending the demand for such articles. Coffee, however, is troublesome to make, and is neither so suitable for, nor so well liked by, the poorer classes as tea. Its increased consumption is in fact quite as much owing to the system followed in the tea-trade, as to the reduction of the duty affecting itself.

"Congou is the next cheapest tea disposed of by the Company. It was sold by them at 2s. 11d. per lb. in 1815-18, and they have since permitted it to fall to about 2s. 4d.—an inconsiderable decline, compared with that which has taken place during the same period in the price of pepper, and other eastern articles imported by free-traders. Congou is used by the middle classes, and forms about two-thirds of all the tea consumed in the empire. Notwithstanding the reduction of its price, it is still sold, like bohea, at an advance of about 100 per cent. over its price in Hamburgh. The rate of advance on the finer species of tea is not so great, so that the weight of the monopoly falls principally on the lower and middle classes. It should, however, be observed, that the exorbitant price of tea in this country has driven all but the very wealthiest class to the secondary qualities; and it is to this that it is owing, that, notwithstanding England is the richest country in the world, and the taste for tea is more generally diffused amongst us than amongst any other people, we consume very little of the superior qualities! Indeed, some of the finest are not to be met with in our markets; and while about a dozen kinds of tea are regularly quoted in Hamburgh, Amsterdam, and New York Price Currents, there are never more than seven, and sometimes only six, species to be met with here. Imperial—a very fine green tea, regularly imported into America and all parts of the Continent—is unknown in the English market. Singlo, once imported by the Company, has disappeared for about 40 years. Pekoe and gunpowder, the finest qualities of black and green, are little known in the English market, and, in fact, are only imported in small quantities by the officers of the Company's ships. Thus, like all other monopolies, that of the supply of tea has not only the effect of adding enormously to its price, but of substituting inferior in the room of better qualities. Were their prices the same, can there be a doubt that superior teas would be in as great demand here as in the United States?"

By the operation of the act of Parliament passed in 1833, abolishing the monopoly of the East India Company, the British tea-trade will be placed on a footing resembling that on which it stands in America and other countries; it being decreed to be "expedient that all his Majesty's subjects shall be at liberty to repair to the ports of China; and to trade in tea and all the other products of the same empire," under certain restrictions. In future, therefore, vessels may be freighted from any port in the United Kingdom to trade with China, and hence the dealers in tea will be supplied by importers on a fair principle of competition, and without having the article heightened in price by the interference of the London traders. At, or shortly after, the opening of this great trade, misarrangements may occur to the detriment of the public; but it is clear that a free-trade in tea will ultimately be conducted on the most advantageous terms for the people, not only as regards the reduction of prices, but the introduction into use, as in America, of a superior quality of teas. The new law provides that, in lieu of the duties recently payable on tea, there shall be collected and paid, from and after the 22d day of April 1834, the several duties following; that is to say—For every lb. of bohea, 1s. 6d.; for every lb. of congou, twankay, hyson skin, orange pekoe, 2s. 2d.; for every lb. of souchong, flowering pekoe, hyson, young hyson, gunpowder, imperial, and all other teas not enumerated, 3s. As this scale of duties must prove a source of endless disputation at the various places of import, from the difficulty of ascertaining one quality of tea from another by tasting or by examination, there can be little doubt but a fixed duty will be imposed instead.

* M'Culloch's Commercial Dictionary, a work containing the most ample, and, we believe, the most accurate details on the subject of the tea-trade; and which we recommend to the perusal of all who are interested in the traffic with China.

Edinburgh: Published by W. and R. Chambers, 19, Waterloo Place; also by Orr and Smith, Paternoster Row, London; and Young and Cunningham, Dublin. Sold by John Macleod, Glasgow, and all other Booksellers.

CHEMISTRY.

Chemistry is the science which defines the laws or principles which regulate the combinations of elementary particles of matter, and relates to those operations wherein the nature of bodies is changed, or by which they acquire new properties. The term Chemistry is of doubtful derivation; but it seems to have been applied at an early period to various methods of melting or preparing metals, and was identified with the visionary science of alchemy, which professed to be the art of transmuting copper and other base metals into gold and silver. It is only within the last sixty or seventy years that chemistry has risen to the rank of a science; but during that period it has advanced towards perfection with a rapidity unparalleled in the history of philosophy. The applications of chemistry are universal. There is no science so immediately conducive to human comfort. To whatever art or manufacture we turn our attention, we find that it has either been created by chemistry, or indebted to it for some of its greatest improvements. In the present sheet, it is our object to present a simple and intelligible view of the principles of this exceedingly important science, with a description of the various elemental bodies, and their more immediate combinations. We shall commence with the laws of matter: the first of which to be noticed, is

ATTRACTION.

The term attraction, in its general signification, denotes that power or force by which the masses or the particles of matter are made to approach each other, and either to come only into contact or to enter into intimate union. Attraction is every where diffused, and it is impossible to conceive of the universe subsisting without it. It is the tie which connects the most remote parts of it together; and were it dissolved, the spacious fabric of the universe could no more exist as it does at present; the particles of which the countless worlds or globes are composed, would literally exhale into space like dew-drops before the rising sun, and nothing of the beautiful creation would exist but an infinity of invisible atoms which renounced the society of each other. There are various kinds of attraction. That of gravitation, which causes the weight of bodies, and which is exerted at apparent and frequently immense distances, and between masses of matter of the most stupendous magnitude. Of this species of attraction we have already given an account in the number of this work which was devoted to Astronomy. The attractions dependent upon magnetism and electricity also operate at sensible distances, and so far coincide with gravity. There is also capillary attraction, which, however, we need not advert to.

But, besides these, there is a species of attraction which is exerted between particles of matter, and which takes place in general at insensible distances. That all bodies are composed of minute atoms, the aggregate of which constitutes masses of matter, is a fact too obvious to stand in need of illustration. These particles adhere to each other with various degrees of force, and can be separated by methods which it is the province of the chemist in a more particular manner to investigate. The species of attraction by which particles are made to unite, is of two kinds. When it is exerted between particles of a similar nature, it is called the attraction of aggregation or cohesion; and when it is exerted between particles of a dissimilar nature, it is called chemical attraction or affinity, or the attraction of composition. The distinction between these two kinds of attraction may be thus shown:—If a solution of common potashes be mixed with oil, a union immediately takes place between the particles of the two bodies, the result of which is a new substance possessing properties entirely different from either of the constituents in a separate state. This change is effected by means of chemical attraction, which takes place only between particles of matter of a different nature. The new body which has been formed is the useful article soap; and if the watery vapour be driven away from it by the application of heat, it assumes a solid consistency, as in the form in which it is commonly used for domestic purposes. Now, it is familiar to every one that the particles of the soap adhere to each other with a certain degree of tenacity, and the application of force is necessary before one part of the wedge can be separated from another. This results from the attraction of cohesion.

The restoration of cohesion to a body after it has been deprived of it, is exhibited in a great variety of instances. For example, if a large quantity of sugar which has been dissolved in water be allowed to stand and cool, the attraction of cohesion will take effect between the particles, and the sugar will again resume the solid form. Here, however, a remarkable circumstance has occurred. Whatever the state of the sugar may have been originally, it invariably, in resuming its solidity, assumes a particular form, one of great regularity and beauty. It was formerly opaque, it is now transparent; originally a shapeless mass, it is now a prism of six sides, surpassing in lustre and symmetry the products of the lapidary's wheel. This solid spontaneous production is called a crystal; and the process by which it is produced is entitled

Crystallisation.—Bodies, whether solid, fluid, or vaporous, are susceptible of assuming the crystalline form, and the substances which do so are numberless. The shapes which the crystals take, and the facility with which they assume them, are various. Instances of crystallisation, such as sea-salt, Epsom salts, saltpetre, are familiar to every one. Water, it is well known, when cooled to a certain degree, assumes the form of ice, which is crystalline. There are two modes of producing artificial crystals. First, by dissolving the substance of which we wish them to be formed in water, and allowing the *solution* (as the dissolved substance is termed) to cool; or by melting it by fire without water, and allowing it to cool slowly. The same body does not invariably exhibit the same form of crystals; there may be several forms of crystals belonging to one body, but in one or other of these it is sure to crystallise, and not according to any other form. It is also to be observed, that very different kinds of matter may crystallise after the same model.

Whether or not all the attractions subsisting between bodies be referable to one general cause, modified by circumstances, is still a question amongst philosophers; and such it must remain, until some great discovery be made in chemistry similar to the theory of gravity, which, although minutely described by Plutarch, was only explained and applied to astronomy by Sir Isaac Newton. The attraction of gravitation is foreign to our subject; that of cohesion has been already sufficiently explained; those dependent upon magnetism and electricity will come to be treated of in a number of this work which we intend to devote to these subjects. Therefore, there only remains chemical attraction to be adverted to.

CHEMICAL ATTRACTION OR AFFINITY.

We have already shown, that the attraction which has received this name is that which unites the atoms of two or more distinct substances, so as to form one perfect homogeneous compound. This process is, in chemical language, termed *Combination*. It is quite distinct from aggregation, which is the union of particles of a similar kind, forming a mass which has the general properties of the particles of which it is composed, whatever may be its structure and form. It is also to be distinguished from *Mixture*, in which the particles, although they may be intimately blended, are not, as it were, amalgamated with each other so as to lose their own individual natures, and become endowed with entirely new properties. The difference between the two will be clearly seen from the following example:—If into a crystal bottle we pour a quantity of oil and a quantity of water, and shake them well together, the two substances can never be made to unite permanently together. Although they appear to be so for a short while after the experiment is made, yet, if the vessel be allowed to stand for a sufficient length of time, the particles of water, being heavier than those of oil, will descend to the bottom, whilst those of the oil will settle upon the top. Here, then, it is evident that there has been no chemical attraction exerted between the particles of the two bodies, because no chemical change has taken place. In a word, there has been a mechanical mixture without any chemical combination. But if with the water in this experiment we mix a quantity of potash, so as to form a pretty strong solution, the results will be very different. The particles of the two bodies will intimately combine with each other, and a compound will be formed, having properties entirely different from either the oil or the potash. The substance obtained in this experiment, as we have already noticed, is soap. The general name for the substance formed by chemical combinations such as these, is a *Compound*; the substances of which it is composed are called its component or constituent parts or principles. The separation of these is termed *Decomposition*; and when decomposition is performed for the purpose of ascertaining the composition of a body, it is named *Chemical Analysis*. The reunion of the constituent parts is denominated *Chemical Synthesis*. Integrant particles of a body differ from the constituent particles thus:—The latter are the most minute parts into which a compound body can be resolved by decomposition, and are hence of a different nature, both with regard to each other and the substance itself which their mutual union gives rise to. The integrant particles are the most minute parts into which any body can be resolved *without* decomposition.

THE LAWS OF CHEMICAL COMBINATION AND DECOMPOSITION.

There are various laws connected with, and phenomena attendant upon, chemical attraction. Besides those already mentioned, which are, that it takes place only between bodies of a different nature, that the qualities which characterise bodies when separate are changed or annihilated by their combination, and that it takes place only between the atoms or most minute particles of bodies, there are the following:—Chemical attraction can take place between two, three, or even a greater number of bodies. A change of temperature always takes place at the moment of combination. The force of chemical affinity between the constituents of a body is estimated by that which is requisite for their separation. But the most important and perhaps most familiar law is, that the degree of attraction varies very considerably in different bodies. That bodies have a stronger tendency to unite more closely with some substances than with others—that, to employ the language of mental philosophy, the particles of matter exercise various degrees of likings and dislikings, is a fact upon which the whole science of chemistry depends. It is evident that, from the strength of affinity varying in different bodies, all chemical compositions and decompositions are effected. The preference of uniting with another substance which any given body is found to exercise, is metaphorically termed elective attraction, or affinity. It is of two kinds, each of which derives its appellation from the number and the powers of the principles which may be brought into contact with each other. When a simple substance is presented to a compound one, and unites with one of the constituents of the latter, so as to separate it from that with which it is combined, and by this means producing a decomposition, it is said to be effected by *simple elective attraction*. Some substances, however, will not be thus easily decomposed; and it is found necessary to introduce two or more principles, in order to effect the end in view. When two principles, therefore, are presented to a compound body, and when the principles unite each with one of those of the compound substances, two new substances are formed; and all instances of decomposition in this manner are said to be effected by *double elective attraction*. It is to be observed, that all changes effected in this manner are permanent, and that the new compound thus formed cannot be decomposed, until a substance having a more powerful attraction for one of their constituents than they have for each other, is brought into contact with them.

To the prince of philosophers, Sir Isaac Newton, we are indebted for the first attempt at a rational explanation of chemical combination. He was of opinion that the minute atoms of certain bodies attract each other with an unknown but enormous force, which begins to exert itself only when the particles are at very small distances from each other, and that, accordingly, this force exerts itself, and the bodies unite when they are brought within the requisite distance. These views slowly made their way into the science; but towards the middle of the eighteenth century, they seem to have been almost universally adopted. The term chemical affinity was substituted for that of attraction, and the strength of the affinity existing in bodies came to be measured according to the order in which they were decomposed. It is unnecessary to mention the various tables of affinity which were published previously to that of Bergman, who in 1775 gave to the world a copious table of affinities, and appears to have fixed the opinions of chemists in general to his own views of the subject. According to this philosopher, the affinity of each of the bodies, say *a*, *b*, *c*, *d*, for *x*, differs in intensity in such a manner, that the degree of affinity in each may be expressed by numbers. He supposed affinity to be elective, in consequence of which, if *a* have a greater affinity for *x* than *b*, if *a* be presented to the compound *b x*, a decomposition will ensue, *b* will be set at liberty, and the compound *a x* will be formed.

These views of Bergman were admitted until the beginning of this century, when Berthollet published his Chemical Statics. He believed atomic attraction to be similar to that which exists amongst the planetary bodies; but he supposed that the strength of affinity depended a good deal upon the state of the particles, as well as upon other circumstances. The force of attraction, therefore, according to this theory, must increase with the mass of the attracting body; and hence, affinity cannot be elective in the literal sense of that word. But if Berthollet overturned Bergman's notions regarding elective attraction, he did not place a better theory in its stead as explanatory of phenomena; for he was compelled to affirm, in consistency with his views, that bodies united in all proportions—an absurd hypothesis, which is refuted by

THE ATOMIC THEORY.

This theory was not discovered all at once and immediately acknowledged by chemists; it was gradually brought to light by the repeated experiments of successive philosophers, whose labours, however, it will be impossible to exhibit a view of in this place. To Mr Dalton, an honoured name, we are indebted for the first developement and demonstration of the fact that bodies unite in definite proportions; and of which we shall now attempt to present the reader with as clear and simple a view as possible. Whilst engaged in determining the composition of the two gases called severally carburetted hydrogen and olefiant gas, Mr Dalton discovered that for complete combustion they require *different* but *determinate* quantities of oxygen gas. A volume[a] of carburetted hydrogen requires two volumes, whilst a volume of olefiant gas requires three volumes of oxygen gas.

The conclusions at which Mr Dalton arrived are, that bodies consist of *atoms* incapable of further diminution or division; that in chemical combinations it is these ultimate particles which unite; and that, in the case above mentioned of the combustion of the two inflammable gases, carburetted hydrogen is a compound of one atom of hydrogen and one atom of carbon; whilst olefiant gas is a compound of one atom of hydrogen and *two* atoms of carbon. The atoms he considered as spheres, and represented them by such symbols as a circle with a dot in the centre, a circle with a vertical diameter, and the like. In this manner the composition of a number of the best known bodies was represented by him, and the ratios of the weights of the atoms of the simple bodies inferred. For instance, he concluded from his experiments that carburetted hydrogen is composed of, hydrogen one, and carbon five; while olefiant gas is composed of, hydrogen one, and carbon ten. Now, as the former gas consists of one atom of hydrogen and one atom of carbon, then the weights of these atoms are to each other in the relation of one to five. If the weight of the atom of hydrogen, therefore, be represented by one, that of carbon will be five. In this manner, the ratios of the weight of the atoms of all the simple bodies may be ascertained by a careful analysis of the compounds formed by the union of the simple bodies.

We shall recur to the gases again, but in the meantime will illustrate the doctrine of definite proportions by some familiar examples of the fact. The combinations of mercury or quicksilver with some other bodies, afford a striking proof of the truth of the theory. If this brilliant white fluid metal be agitated for some time in the open air, the surface becomes covered with a black, insipid, insoluble powder. This arises from the metal having combined with oxygen, one of the gases of which the atmosphere is composed, and hence is termed an oxide. It consists of two hundred parts of mercury and eight of oxygen. If, however, the metal be subjected to a considerable degree of heat, it will be converted into a red shining mass, which is also a compound of the metal with oxygen; but in the latter case, sixteen parts of oxygen have united with the two hundred parts of the metal. The combinations of mercury with sulphur are also striking on this point. Innumerable instances of the same kind might be adduced, but these are sufficient to prove the remarkable truth, that when different substances combine by chemical attraction, the proportions of the ingredients are always uniform; that for every atom present of one substance, there is exactly one, or two, or three, &c. of the other. Thus, if there be ten atoms of one substance, there are exactly ten or twenty, &c. of the other, but never an intermediate number, as thirteen or twenty-three to ten; for then a particle of the compound would consist of one atom of the first, and of one and three-tenths, or two and three-tenths, &c. of the second substance, which is absurd, as atoms are considered indivisible. If, for instance, any quantity of sulphur, intermediate between the two combinations of that substance with mercury, be added, it will not combine with it, but remain as a foreign ingredient in the sulphuret of mercury, as the compound is termed. All bodies, however, do not unite in several proportions, thus giving rise to several distinct compounds from two elements; there are many elementary bodies which will only unite with each other in one proportion, so that any two of such substances can only form one compound.

EQUIVALENT RATIOS.

The result of these investigations has been the formation of scales exhibiting the equivalent ratios of chemical bodies, and which are expressed by numbers. It is evident that some body must be fixed upon and expressed by unity. Hydrogen gas, being the lightest known body in nature, and combining in the smallest proportion by weight with the other simple substances, has been taken as a standard of comparison for the combining proportions, or *equivalent numbers* of all other bodies; and which, in all likelihood, are simple multiples of its number. Oxygen has also, by some chemists, been taken as the standard of comparison, and represented by ten. Water is a compound of eight parts by weight of oxygen, with one part by weight of hydrogen; which two gaseous bodies we shall afterwards describe. Whenever hydrogen and oxygen gases are burnt in any proportion whatsoever, they invariably form water; and they cannot be made to combine directly in any other proportion. From this, Dalton concluded that water is a compound of one atom of hydrogen and one atom of oxygen. But the weight of the latter gas being eight times that of the former, then it followed that the atom of oxygen was just eight times heavier than the atom of hydrogen. Hence, if the latter be represented by one, then will the former be represented by eight, according to those who take hydrogen as the standard. Those who take oxygen as the standard, and represent it by 10, make the equivalent for hydrogen 1.25; the result is of course the same for the proportion of 1.25 to 10, being exactly the same as that of 1 to 8.

These observations relative to water lead us to speak of the doctrine of volumes, so generally embraced by chemists upon the Continent. The union of gases is always effected in simple proportions of their volumes; and a volume of one gas combines with an equal volume, or twice or three times the volume of another gas, and in no intermediate proportion.

ELEMENTAL BODIES.

With regard to the elements of matter, chemists have agreed amongst themselves to consider all those bodies as simple which have not yet been decomposed. It is not implied that they are absolutely so, for the probability is, that the metals, as well as other substances, are compounds, and may yet be resolved into simpler constituents, when other agents shall be detected in nature, or other Davys shall arise to apply those which now exist, in a manner of which we are as yet in ignorance. It is also probable that the atoms of simple substances sometimes appear united in groups of two, three, or more atoms. On these suppositions we could explain some problematical phenomena, which otherwise cannot be accounted for.

There are at present fifty-four substances which are accounted simple, from their not having yet been decomposed. For the convenience of study, they have been artificially divided into two classes, according to the manner in which they arrange themselves at the poles of the voltaic pile. The first comprises those elements which are attracted by the positive pole, and have been called *electro-negative* bodies. The second consists of those which are attracted by the negative pole, and have been termed *electro-positive* bodies; of course, the electrical energies of these substances are merely comparative; for in a compound of two bodies of the same class—say the electro-positive—one will be less electro-positive than the other, and will consequently pass to the positive pole during decomposition. In order to understand what has been stated above regarding positive and negative electricity, it will be necessary to describe a voltaic pile, or rather battery, as by that apparatus the powerful fluid is now made to develope itself. A voltaic or galvanic battery is a wooden trough, divided into a number of compartments, in which are placed, at intervals, plates of copper and zinc soldered together. The trough is filled with fluid containing an acid, and from each end a wire proceeds, the extremities of which are brought into contact with the substance which is to be experimented upon. One of these wires conducts the negative and the other the positive electricity; and hence the extremities derive their respective names of negative and positive poles, round which, the constituents of the substance, undergoing decomposition, arrange themselves, the electro-negative bodies at the positive, and the electro-positive at the negative poles.

Tables have been formed representing the order in which substances are decomposed; but this order is not invariable, for the electrical state of bodies, which is influenced by the temperature, considerably affects their decomposition. From the small number of elementary substances, which, as already mentioned, amount to fifty-four, is all the beautiful variety of terrestrial matter composed!

HEAT OR CALORIC.

In our investigations of the phenomena of the material universe, we perceive two kinds of motion, which result from the two principles *Attraction* and *Repulsion*. Of the former we have already spoken, and it only remains to say a few words upon the latter. Repulsion, like attraction, takes place both at sensible and at insensible distances. The former is exemplified by the flying off of the same light bodies which have been first attracted, after they have been some time in contact with a piece of excited resin or glass, and also by the recession from each other of the two similar ends of two magnetised needles. Repulsion at insensible distances, which is chiefly excited by heat, or, as it is called in chemical language, caloric, is exhibited in a great variety of phenomena connected with the principle. Whether heat be a material substance pervading matter, or only a peculiar state or condition of matter, is still a doubtful point in philosophy, there being ranked on both sides of the question some of the greatest names of ancient and modern times. But the settling of this question is of comparatively little importance: the effects produced upon the material universe by the agency of heat are palpable to every one, and admit of no dispute. It is the great counteracting principle to attraction; for when a continued addition of heat is made to any body, the distances which exist between the constituent atoms is increased, and the bulk of the body is enlarged. Matter is capable of existing in three different states; namely, the solid, fluid, and aëriform. If the principle of heat did not exist, we can only conceive of matter existing in one state, which would of course be that of solidity. It is the application of heat which first softens a hard or solid body, and then causes it to assume the fluid and aëriform states. Thus, ice, when heated, becomes water, and water, when heated to a greater degree, becomes steam. If heat again be abstracted from the steam, it assumes the fluid state, and, if further cooled, it takes the solid form of ice. Thus there is kept up amongst material substances a continual struggle between the attraction of aggregation and the repulsive power of heat, which, combined with the various effects produced by heat upon different substances, gives rise to the beautiful variety of solids, fluids, and airs, exhibited in external nature.

EXPANSIVE POWER OF HEAT.

Heat exists every where, and can be obtained from every thing. All bodies, whether solid, fluid, or aëriform, can be made to evolve heat when subjected to certain processes; so that there is not in nature such a thing as absolute cold. Even ice contains a quantity of heat; for by chemical means it can be made colder than we find it in its natural state; and chemists are from time to time discovering processes by which a greater degree of cold can be obtained than any previously known. Heat being thus an agent universally present in matter, it becomes a question of some moment, what are the effects which it produces in matter? The first and most remarkable of its properties is that of *dilating* or expanding bodies. This fact must be so familiar to every one as scarcely to require illustration. It must have been frequently observed, that the iron rim or hoop of a coach or cart wheel is heated to a considerable degree before it is put upon the wheel. The reason of this is obvious: when hot, the circle is a good deal larger than when cold, and thus slips easily upon the wheel; as it cools, the circle decreases, and thus firmly binds the woodwork together. In the expansion of fluids, we have a familiar example in the measurer of heat itself, the *thermometer*. The mercury in the glass tube rises and falls, that is, expands or contracts according to the quantity of heat which is imparted to it. The expansion of aëriform substances is illustrated by a bladder being partly filled with cold air, and held before the fire. The air will swell out, or expand with the heat, and become in some instances so tense as to burst the bladder. The general law, therefore, is, that the expansion and contraction of matter are, with a few exceptions, dependent upon the increase and diminution of heat. The quantity or condition of heat that is discoverable by the simple measurer of heat above alluded to, or by the organs of sensation, is called *Temperature*. We are unacquainted with the extremes of temperature, relative either to heat or cold. It has been compared to a chain, the extremities of which are concealed

[a] Volume, in chemistry, is a term employed to denote any quantity in bulk of a substance. It is usually applied to the gases. Thus, one volume of hydrogen gas is, say, a cubic foot, yard, or any other quantity, then two volumes is of course just double the cubic foot, yard, or whatever other quantity was previously mentioned.

from view, whilst only a few of the middle links are exposed to observation. Although the universal result of an increase of temperature is an increase of bulk to the body thus subjected to heat, yet all bodies are not alike expanded by the application of the same quantity of heat. The same increase of temperature causes a liquid to expand more than a solid, and an aëriform body more than either. It of course follows as a general law, that different bodies at equal temperatures do not contain the same quantities of caloric. This quality of matter is called the capacity of bodies for heat, and the quantity of heat which is necessary to raise any particular body to a certain temperature, is called its *specific* caloric.

LATENT HEAT.

When a body changes from the solid to the fluid state, there is a quantity of heat absorbed, which has no effect in raising the temperature. This has been called *latent* heat, a discovery effected by Dr Black, and which we shall shortly explain. For a demonstration of this doctrine, we may have recourse to water. If ice at a temperature below 32° be exposed to a warmer atmosphere, it receives caloric, and gradually rises to that point of the thermometrical scale. But as soon as it reaches it, the rise of temperature ceases, the ice begins to melt, and during the whole period of its liquifaction, its temperature, as also that of the water flowing from it, remains stationary at 32°. It is evident, that, as caloric has continued to be communicated, a quantity of it has disappeared, and become absorbed during the fusion. The same phenomenon takes place when a liquid is converted into vapour; and the inference drawn from it is, that when a body passes from one state into another, a quantity of heat or caloric is lost, becomes latent, or passes into the body without raising its temperature. Dr Black was of opinion that this latent heat became chemically combined with the solid, and was the cause of fluidity. Dr Irvine, his pupil, took a different view of the subject. He supposed that the absorption of heat into the latent state is not the cause of liquifaction and vaporisation, but the effect. The absorption he attributed to what is called change of capacity for heat, or that quality of matter which causes one kind to be more or less heated than another, by the addition of the same quantity of heat. He concluded, as a general law, that the capacity of all solids for heat is increased by fusion, and that of all fluids by evaporisation. It is impossible to enter further into this interesting subject in this place; but, before quitting it, we may mention an exception to the law of expansion by heat in the case of water. It is well known that water freezes at 32°, but it does not increase in density below 39½°. It is then at its maximum, and above or below that point its density diminishes. Hence ice is specifically lighter. The earth alumina, which will be afterwards described, also possesses the remarkable property of being contracted by heat.

EQUAL DIFFUSIVE POWER OF HEAT.

We shall now shortly advert to some other phenomena connected with caloric. It has an invariable tendency to establish or maintain an equilibrium; that is, to *diffuse* itself equally over the material world. Thus, a bar of hot iron, when brought into contact with the colder atmosphere, gives forth its heat, until it becomes of the same temperature as the surrounding air. The facility with which bodies absorb or part with their caloric, depends upon the nature of the body; and the property is called the capability of bodies to *conduct* heat. Thus, if a piece of wood and a piece of iron be put into the fire, the iron soon becomes too hot to be touched, whilst the wood may be laid hold of with impunity by one extremity whilst the other is burning. The metal is a good conductor, therefore, and the wood a bad one. Solids are better conductors than fluids; and, generally speaking, the greater the specific gravity of the body, the greater is its conducting power. This observation, however, is not universally true. Besides their power of conducting heat, as it were from particle to particle in themselves, bodies have the power of *radiating* heat. Thus, the iron bar just alluded to threw off to the surrounding atmosphere heat in the form of radii or rays. Some bodies have greater power of radiating heat than others; and those that radiate quickest, cool in the shortest time. Hence, by the rapidity of cooling, the radiating power of bodies can be made manifest by experiment. For instance, if two vessels, both of tin plate, but one of them having its outside coated with lamp-black, be filled with boiling water, and two thermometers introduced, it will be found that the water in the blackened vessel cools a great deal more rapidly than that in the other. Upon this principle of the different radiating powers of bodies, a number of domestic utensils are formed; for example, teapots of shining metal, which retain the fluid which they contain hot for a length of time. Good conductors are bad radiators, and present bad receiving surfaces. Bodies have also the power of reflecting heat, in the same way as we see them reflect light. Metals are the best reflectors of caloric, and the worst radiators; and it is generally the case, that the reflecting power of bodies is strong in proportion as the radiating energy is weak. It is therefore necessary, that, for the reflection of heat, the reflecting surface must not only be hard and well polished, but it must also be of a material which is a bad conductor and absorber. Such are the principal phenomena connected with heat. We shall now shortly advert to a physical agent closely allied to it, namely,

LIGHT.

The nature of light, like that of heat, is still unknown to us. There are two theories respecting it: the first is, that light is a real substance emanating from the sun, and from all luminous bodies, from which it is projected in right lines with great velocity; the second is, that the sensation of light is produced by the vibration of a subtile fluid filling space—and is hence called the undulatory theory. An examination of these theories, however, does not belong to this place. The connection between light and heat is so obvious, that it is scarcely possible to examine the one independently of the other. If a mass of iron be put into a fire for some time, no change is produced except the expansion of the metal and the elevation of its temperature. Gradually, however, as the heat is communicated, a remarkable occurrence will be observed. The iron becomes ignited or red-hot; in other words, it emits light, and renders objects visible. The original sources of light are, first, the celestial bodies, as the sun and stars; and, secondly, terrestrial bodies, as a common fire or candle. Light passes freely through the atmosphere, and, striking upon objects, is reflected or thrown back by them; and thus they become visible. By means of a wedge of glass called a prism, light can be separated into seven colours, which are violet, indigo, blue, green, yellow, orange, and red. But it is only with the chemical agency of light that we have to do. Its influence in this way is conspicuous in a variety of natural and artificial processes. In vegetation it is indispensable, as without it plants are deficient of their due elementary constitution. They are weakly, inodorous, and of an unwholesome colour. Vegetables which grow in the dark have a blanched appearance. The power of light to dispel vegetable colours is manifest in bleaching, where a dingy web becomes pure and white by exposure to the sun's rays. Its energy is still more decisively seen in the influence which it exerts in promoting chemical combination and decomposition, and the latter effect has been made use of as a measure of its power. Light enters into a kind of transitory union with certain substances, rendering them visible in the dark. Bodies which possess this property are called phosphorescent; such are the shells of fish, the bones of land animals, marble, limestone, and the like. The glow-worm is a remarkable instance of phosphorescence in living animals.

COMBUSTION.

Combustion may be called the disengagement of heat and light, whilst certain substances are entering into chemical combination. It is entirely distinct from *ignition*, which results simply from an elevation of temperature, without being accompanied by any change in the chemical constitution of the body thus rendered incandescent. It is unnecessary to enter upon the various theories which have from time to time been brought forward to account for this every-day phenomenon. It is now generally admitted, that whenever the chemical forces which determine either composition or decomposition are energetically exercised, the phenomena of combustion or incandescence with a change of properties, are displayed. A question naturally arises, whence come the heat and light evolved during the process? To this interrogatory no satisfactory response has ever yet been given. They are sometimes referred to the condensation which usually takes place during chemical combination; but there are instances where light and heat are produced during the expansion of bodies, as in the case of the explosion of gunpowder. The fact is, that the whole is still a mystery; but no doubt, we think, can exist, that the generation of these imponderable substances, if substances they be, is intimately connected with the disengagement of the electric fluid. We must wait in patience for a solution of the problem, until the genius of man has discovered more delicate instruments of philosophical investigation than any with which we are as yet acquainted.

AIR AND WATER.

We prefer commencing our description of individual substances with the two above named, not only because they are familiarly known to us, but because they are composed of the three gaseous or aëriform bodies which hold the most conspicuous place in the material world. The air or atmosphere is an invisible fluid encircling the globe all round, and which rises above it to the height of about fifty miles. Its various uses in the economy of nature are so striking, and so conspicuous at every step of scientific investigation, that in ancient times it was looked upon as one of the primary elements of matter. By the practical philosophers of modern days, however, it has been discovered that it is a compound composed of two gases or airs, namely, oxygen, which signifies a generator of acidity or sourness, and azote, which literally implies no life, because it destroys animal life. Water was also looked upon by the ancients as a simple substance, but modern investigation has proved it also to be a compound. Its constituents are oxygen and hydrogen, which latter word signifies to create or form water. Atmospherical air consists of oxygen one-fifth, and azote four-fifths (estimated by volume under the same pressure), with a small proportion of what is called carbonic acid gas, and also watery vapour. Water consists of one volume of oxygen and two of hydrogen, and can easily be made by an electric spark being passed through a jar containing these two gases, mixed in the above proportions. We shall speak more in detail when we come to describe the elemental substances individually.

ACIDS.

Acids are a most important class of chemical compounds, and have the following characteristic properties:—The greater number of them have a sour taste, and most of them are very corrosive. They change vegetable blues to red, are soluble in water, and unite with the alkalis, earths, and metallic oxides, forming what are called salts; an order of bodies of the highest importance in the arts, manufactures, &c. Some acids are destitute of a sour taste, but their affinity for the three classes of bodies above-named is always characteristic. Acids are all compound bodies, and some of them have more than one basis or radical. There are a number of acidifying principles, but oxygen (which shall be immediately described) is the most extensive one. The acid is distinguished by the name of its base, and its degree of oxydation; that is, the quantity of oxygen it contains by the termination of that name in *ous* or *ic*, or the prefix *hypo* (under). The highest degree of oxygenation is marked by the termination *ic*, as nitric acid, and the salt which is formed from it is made to terminate in *ate*; the next by that of *ous*, as nitrous acid, and the salt which is formed from it is made to terminate in *ite*; and the lowest by *hypo*, as the *hypo*nitrous acid. Sometimes oxygen combines in a greater quantity with the acidifiable radicals, in which case the product is said to be superoxygenated. All acids are not susceptible of these various degrees of oxygenation, some being limited to only one. There are a considerable number of acids, and the number is continually increasing by the discovery of new ones; but of the most important there are few, and these we shall notice as we come to treat of their bases.

SALTS.

This term has been usually employed to denote a compound in definite proportions of acid matter with an alkali, earth, or metallic oxide. When the proportions of the constituents are so adjusted that the resulting substance does not affect the colour of infusion of litmus or red cabbage, it is then called a neutral salt, because the peculiar powers of both bodies are suspended and concealed; they are rendered neutral or inactive. When bodies combine in such a way as to satisfy their mutual affinities, they are said to *saturate* each other. When the predominance of acid is evinced by the red of these infusions, the salt is said to be acidulous, and the prefix *super*, or *bi*, is used to indicate this excess of acid. If, on the contrary, the acid matter appears to be in defect, or short of the quantity necessary for neutralising the alkalinity of the base, the salt is then said to be with excess of base, and the prefix *sub* is attached to its name. These compounds are denominated salts, because they generally have a saltish taste.

METALS, OXIDES, EARTHS, AND ALKALIS.

We arrange these classes of substances together, because, although they are to a certain extent distinct, yet they have all a very remarkable relationship, as we shall shortly see.

Many of the metals, such as iron, lead, &c., are familiarly known to every one, but there are a great many others which are very rarely to be met with. The following are some of the characters which distinguish metals from other bodies: They are hard, heavy, and opaque; insoluble in water; they possess a peculiar lustre; admit of being so highly polished as to reflect light; are capable of being melted by heat, and of recovering their solidity by cooling; most of them may be extended by hammering, and some of them into the thinnest films. They are of various colours, and require different degrees of heat to fuse or melt them. They occur in the earth in what are called *veins*, and are seldom found in the pure metallic state, but generally in combination with some other substance, in which state they are called *ores*. The metals, which are all simple bodies, will be individually described afterwards.

When metals are subjected to heat until they become melted, they combine with the oxygen of the atmosphere, and form what are called *oxides*. Oxides are destitute of those properties which distinguish the metal from which they are formed. Instead of being bright, shining, elastic, and ductile substances, they are generally a dry, earthy-looking powder. Other substances besides metals, however, are capable of being converted into oxides; and it must be kept distinctly in view, that in every case there is not so much oxygen imparted as will produce *acidification*. Oxygen frequently combines in various proportions with a substance rendering it an oxide, but without advancing it to the state of an acid. In order to distinguish each compound thus formed, the language of chemistry is very systematic. The first is called a *prot*oxide; the second, a *deut*oxide; and the third, a *per*oxide.

The term *Earths* was formerly, and is still, but in a modified sense, applied to several substances which compose all the various rocks, stones, gems, mountains, and soils covering the surface of the globe. They are tasteless, inodorous, dry, uninflammable, sparingly soluble, difficultly fusible, and of moderate specific gravity. Their number is ten, and their names are, silex, alumina, magnesia, lime, barytes, strontites, zircon, glucine, yttria, and thorine. The four first have long been known to mankind; the remainder have been discovered in our own times. These bodies will be more particularly described when we come to treat of their metallic bases. *Alkalis* may be defined—those bodies which combine with acids so as to impair or neutralise their activity, and produce what are called salts. They are distinguished by properties the reverse of acids, and the two classes are generally looked upon as antagonist substances. Besides the power of neutralising acids, there are four alkalis, namely, potash, soda, ammonia, and lithia, which possess the following properties in a high degree: They change vegetable blue to green, red to purple, and yellow to a reddish brown; they have an acrid and urinous taste; they are powerful corrosives of animal matter, with which they combine so as to produce neutrality; they also unite with oils and fats, forming the well-known substance soap; they combine with water and alkohol in any proportion. Four of the earths, namely, lime, baryta, strontia, and magnesia, possess alkaline properties to a considerable extent, and are hence called alkaline earths. These bodies differ from the pure alkalis, inasmuch as they become insoluble in water when neutralised by carbonic acid. Moreover, alkalis possess the power of changing vegetable colours *after* being saturated with carbonic acid, and by this criterion they are distinguished from the alkaline earths.

Twenty-five years ago, few substances seemed more likely to retain a permanent place in chemical arrangements than the solid and refractory earths which compose the crust of the globe; and also the alkalis so widely diffused in nature, and so useful in the arts and manufactures. It was long observed that the properties of earths very nearly resemble those of the compounds of oxygen and metals called metallic oxides; but it remained for the brilliant genius of Sir Humphry Davy to show that both the earths and alkalis are metallic oxides.* It thus appears, then, that the globe is one vast mass of various kinds of metals, disguised by various substances, but chiefly by oxygen. We have here a complete view of the method by which nature has elaborated the endless diversity of material substances around us. Oxides, we see, are produced by the combination of a certain quantity of oxygen with a metal or other substance. Earths and alkalis are simply metallic oxides; whilst a farther impregnation of these substances with oxygen produces an acid; and, lastly, the union of acids with alkalis, &c. gives rise to that very numerous and important class of substances called salts.

It will now be necessary to describe the fifty-four elementary substances of which all the various compounds of nature and art are formed. There is nothing either very wonderful or mysterious in the fact, that, from this small number of fundamental constituents, the infinite variety of objects should be produced; because, as we have seen, any given two of them, if made to unite in different proportions, can be made to produce the most opposite substances. These, again, united with each other, give rise to new compounds, which are susceptible of being combined, and so on through an almost infinite rotation of chemical union. Of the elemental substances at present known, five seem capable of combining with all the others. They are the most electro-negative of all known bodies. Hence, when they are disengaged from the compounds which contain them, by the agency of galvanism they always arrange themselves round the positive pole. When combined with a certain portion of the other simple bodies, they form *acids*; and when, with the rest, they constitute *bases* or *alkaline bodies*, are capable of uniting with and neutralising the acids, as we have formerly observed. To these five bodies the name of *supporters of combustion* has been given. The eighteen bodies, which, when combined with the supporters, become acids, have been distinguished by the name of *acidifiable bases*. The thirty-one bodies, which, when united with the supporters, become alkalis, have been called *alkalifiable bases*.† Here, then, are three sets of simple bodies; and as this classification of them is not only convenient, but justifiable on philosophical principles, we shall adopt it. The *simple* supporters of combustion are as follow:—Oxygen, chlorine, bromine, iodine, and fluorine. They are all most important in chemistry, as well as in the economy of nature; but the first is in every respect entitled to precedency.

OXYGEN.

Oxygen gas is a permanently elastic fluid; that is, one which no compressing force, or degree of cold, hitherto applied, has ever been able to reduce to a liquid or solid form. It forms, as we have already observed, one of the constituents of the atmosphere, is colourless, destitute of taste and smell, and possessed of all the properties of atmospherical air. Its specific gravity is 1.1111, that of common air being reckoned unity.‡ Combustible bodies burn in it with more brilliancy, and more light and heat is evolved, than when combustion takes place in the atmosphere. Animals breathe it without inconvenience for a much longer time than they can do the same bulk of common air; and it is indispensable to animal, perhaps vegetable, life. Oxygen has the power of combining with every other simple body; the multifarious compounds which it thus forms, such as oxides, acids, and bases, or alkalis, we have already adverted to. In the act of respiration, oxygen, in the nice economy of the human body, is made to unite with it, and becomes a portion of the human frame; perhaps it is nearly allied to the principle of animal life. Vegetables also inhale and exhale it at certain seasons, so as admirably to supply what is absorbed by animals. It is the intensely rapid chemical union of oxygen with the combustible body, which gives rise to the light and heat in our common fires, candles, &c. It may be readily procured from a variety of substances, as, for instance, from saltpetre or the black oxide of manganese. These may be introduced into a gun-barrel, with the touch-hole plugged up. From the orifice of the barrel let a tube be conducted into an inverted glass jar, filled with water. When the other extremity of the apparatus is subjected to heat, the oxygen gas is expelled from the manganese, and, entering the glass jar, displaces the water, and fills the vessel. This is a cheap and easy method of obtaining this remarkable aëriform body.

CHLORINE.

This is a gaseous body of a yellowish-green colour, a strong suffocating smell, and of a pretty strong astringent taste. Reckoning air as unity, its specific gravity is 2.5. If breathed undiluted, it destroys animal life; however, it not only supports combustion, but possesses the remarkable quality of setting fire to many of the metals, even at the common temperature of the air, when beaten out into thin leaves, and introduced into it. The combinations of metals with chlorine are called *Chlorides*. Chlorine possesses the property of destroying all vegetable colours, and of rendering vegetable bodies exposed to its action white. This property has occasioned the introduction of chlorine into bleaching; for if unbleached linens be exposed to its action, the matter which gives them their grey colour is destroyed, and the substance assumes its natural whiteness. Chlorine, however, must be used cautiously, for if applied in its pure and not sufficiently diluted state, it destroys the fibre of the cloth. Chlorine combines with oxygen in four different proportions: two of them contain so much oxygen as to form acids; these are, chloric acid and perchloric acid; but as the other two do not manifest any acid properties, they are to be considered as oxides, and are called protoxide of chlorine and peroxide of chlorine. Besides uniting with oxygen, chlorine combines with hydrogen, and forms the well-known acid called

Muriatic Acid.—If chlorine and hydrogen be mixed together in equal volumes, and exposed to common daylight in a glass flask, they will in a little time combine, and even explode in combining, if exposed to sun-light or the light of a candle; two volumes of muriatic gas result. Its specific gravity is 1.2844; in its pure state this gas is transparent, colourless, and elastic; under very strong pressure it condenses into a liquid. Water absorbs this gas with avidity. One cubic inch at 69° absorbs 417,822 cubic inches of the gas; heat is produced, and, when cold, the bulk of the water is increased to 1.3433 cubic inches. This is liquid muriatic acid. With these proportions of constituents, its specific gravity is 1.1958; one hundred grains of it consist of 40.39 of real acid, and 59.61 of water. It is a colourless liquid, and, when exposed to the air, it smokes, because the gas exhaled condenses the moisture of the atmosphere. It extinguishes both flame and life, and is not inflammable. It is of a pungent, suffocating, and somewhat aromatic smell. It powerfully reddens vegetable blues. The best method of obtaining it is by pouring sulphuric acid upon an equal weight of sea-salt, and collecting the gas which is given off over mercury. An immense number of salts are formed from the combination of muriatic acid with oxides; such as common sea-salt, which is a muriate of soda. These are very extensively used, both in the arts and medicine. Chlorine combines with azote, and forms what is called

Chloride of Nitrogen.—This is an oily liquid, and the most powerfully explosive compound known. In this respect it is one of the most dangerous substances of nature; it consists of four volumes of chlorine combined with one of azote. Chlorine combines with carbon, but the compounds are unimportant.

BROMINE.

The term bromine is from a Greek word, signifying "a strong disagreeable odour." This substance was discovered only so lately as the year 1826; it resembles chlorine in many of its habitudes. It is of a brownish-red colour, very disagreeable smell, sharp strong taste, powerfully corrosive of organic bodies, and, when taken internally, a violent poison. Its specific gravity is 2.96; it destroys vegetable colours almost as powerfully as chlorine. Like chlorine, it sets fire to certain metals when brought into contact with it; it is not combustible, and it extinguishes combustion; it becomes solid at a little below zero; but if combined with water; so as to form a hydrate, it affords fine red crystals at 32°. An acid is formed by the combination of bromine with oxygen, and is called bromic acid; another with hydrogen is called hydrobromic acid. Chlorine also combines with it, and forms a chloride. There are numerous other combinations of bromine, but the compounds are unimportant.

IODINE.

This substance was first discovered in 1811 by a saltpetre manufacturer of Paris. It is derivable from sea plants, and in some of its properties much resembles chlorine, which is also a marine production. If common sea-weed be powdered dry, and treated with sulphuric acid whilst subjected to heat, a violet-coloured vapour is expelled, which, if collected in a vessel, condenses into scaly dark-grey crystals, somewhat of a metallic lustre. These are iodine, so called from the violet colour of its vapour; iodine being a Greek word, and signifying "violet coloured." Its specific gravity is 3.0844. Its smell is disagreeable, its taste acrid and hot, and it possesses poisonous properties. It is a powerful stimulant, and has of late been much employed as a medicine. It destroys vegetable colours, but not so completely as chlorine. It melts when heated to 224½°, and volatilises at 351½°. It forms a beautiful blue colour when mingled with water holding starch in solution; it is itself slightly soluble in water, but more so in alcohol and ether. Iodine combines with oxygen in three proportions, forming iodic acid, iodous acid, and oxide of iodine, with chlorine, forming chloriodic acid, with bromine in two proportions, forming bromides, and also with azote and hydrogen. But a particular account of these substances does not require to be given in this place.

FLUORINE.

The existence of this substance, strange to say, is conjectural; yet its separate identity is supported by the strongest analogies. It exists, or rather is supposed to exist, in fluor or Derbyshire spar, and is thus provisionally called fluorine. If some of this mineral in powder be distilled with strong sulphuric acid, from a leaden retort (a vessel somewhat of the shape of common Rupert drops) into a leaden receiver kept cold with ice, an intensely active fluid is produced. "It has," says Davy, "the appearance of sulphuric acid, but it is much more volatile. When applied to the skin, it instantly disorganises it, and produces very painful wounds. When it is dropped into water, a hissing noise is produced, with much heat, and an acid fluid is formed." This substance has been called *hydrofluoric acid*, because it is conjectured to have fluorine as a base, combined with hydrogen, to form an acid upon the principle which we have formerly described. Other views have been adopted with respect to this substance, but the above is the one now generally admitted.

Such are the properties of the supporters of combustion. Their atomic weights, according to Dr Thomson, are as follow:—Oxygen, 1; fluorine, 2.25; chlorine, 4.5; bromine, 10; iodine, 15.75. There exist, therefore, as we have seen, *oxygen*, *chlorine*, *bromine*, *iodine*, and *fluorine* acids, and the same number of sets of *bases*. Let us now direct our attention to the *simple acidifiable bases*, which are the following eighteen substances:—

HYDROGEN.

Hydrogen gas is a permanently elastic fluid, transparent and colourless, and, when *pure*, destitute of taste or smell. It can scarcely be said to exist in an isolated state, but it forms one of the constituents of water, from which it can be disengaged by various simple processes. It is the lightest body with which we are acquainted, and is employed in combination with other gases to inflate balloons. A bladder filled with this gas will ascend in the atmosphere, in the same manner as a piece of cork or wood plunged by force to the bottom of a vessel of water. Hydrogen will not support combustion, but is itself remarkably combustible. When one volume of oxygen is mixed with two of hydrogen, it burns with a loud explosion, by an electric spark, or the contact of a red-hot wire. The product of this experiment is water. It is said that a few cautious draughts of this gas may be taken, but it cannot be inspired for any length of time without occasioning death. Frogs live in it for a long time, so that these animals must take a tenacious hold of animal life. By far the most important compound of hydrogen with any other substance is that with oxygen, forming the indispensable fluid which covers nearly two-thirds of our globe, water. This substance in scientific language should be entitled an oxide of hydrogen. It unites with the other supporters of combustion; but the compounds, except muriatic acid, already mentioned, are not of any great importance.

AZOTE OR NITROGEN.

This gas is permanently elastic, transparent, colourless, and inodorous. It is a very little lighter than oxygen. When breathed, it destroys animal life; and a burning body, if immersed in a jar containing it, is instantly extinguished. It is not combustible; it enters extensively into combination; it is an abundant element in animal matter; and its existence in such large quantity is a chief distinction between the constitution of animal and vegetable life. Its existence in the atmosphere we have already adverted to. Whether it is chemically united with oxygen in that compound, or only mixed with it, is unestablished. That it has the property of combining with all the supporters of combustion, there can be little doubt; but the subject has not yet been thoroughly investigated. With oxygen it unites in no fewer than five proportions; by far the most important chemical compound is

Nitric Acid, or *Aquafortis*.—This virulent substance is a compound of one volume azotic, and two and a half volumes of oxygen gas. Common nitric acid is of an orange colour, on account of its containing a little muriatic acid, as also a little sulphuric acid and water. Light has likewise an effect upon it. The specific gravity of the strongest procurable nitric acid is 1.55.

* See Chambers's Journal, No. 26.

† Article Chemistry, in the Encyclopædia Britannica, seventh edition, one of the best treatises extant, and written by the able chemist Dr Thomson.

‡ Specific gravity is explained in a note at the end of the sheet.

and then it contains one-seventh of its weight of water; that of commerce is about 1.423, and contains two-fifths of its weight of water. Nitric acid has very remarkable effects upon water with regard to the production of heat. If diluted with half its weight of water, heat is evolved; but if the water be in the state of snow, intense cold is the result. Hence, this compound is employed to produce great degrees of cold. If nitric acid very concentrated be thrown upon phosphorus, charcoal, or oil of turpentine, it inflames them. It is very extensively used in the arts, and forms a numerous and important class of salts, having the generic name of *Nitrates*, such as nitrate of silver, nitrate of potash, &c. Some of these we shall notice afterwards. *Nitrous acid* is a compound of the same kind, but with a lesser quantity of oxygen. Amongst the other compounds of azote and oxygen, that entitled the *protoxide of azote*, or, as it was formerly called, *nitrous oxide*, is the most remarkable. Davy discovered that we may breathe it for a short while without any effect being produced, except an exhilaration of the mind similar to that which takes place during the earlier stages of intoxication. Combustibles burn in it more brilliantly than in common air. It is probable that this gas may yet be found available in medicine. There is also a *deutoxide of azote* and a *hyponitrous acid*, but these do not require minute detail. Azote combines likewise with chlorine and bromine; but the next most important compound is that which it forms with hydrogen, and which is familiarly known to us by the name of

Ammonia, or *Hartshorn*.—It is obtained in the state of gas, by means of the salt called *sal ammoniac*, which is a compound of muriatic acid and ammonia. This substance is to be introduced into a retort, along with quicklime, and then subjected to heat. Ammonia is driven off in the form of gas, and is to be collected in glass jars standing over mercury. Ammoniacal gas is colourless, has a strong pungent smell, an acrid caustic taste, and cannot be drawn into the lungs. Its specific gravity is 0.59027. Water absorbs 780 times its volume of this gas, and in this state it is employed for chemical purposes. When the gas is mixed with chlorine, a sudden combustion and detonation takes place. The chlorine unites with the hydrogen of the ammonia, and forms muriatic acid, whilst the azote is disengaged in the state of gas. The muriatic acid formed, combines with a portion of ammonia, and forms sal ammoniac. Ammonia is an alkali, and possesses the properties distinguishing this class of substances in a very decided manner. It of course neutralises acids, and the salts which it forms are numerous, and of considerable importance.

CARBON OR CHARCOAL.
